H4b: When presented with a bilingual product description, consumers who are not under time pressure and who are in a high-justification condition will resort to central information processing.

Under conditions of deeper processing, prejudice or ethnocentrism do not affect evaluations.

H5: When asked to evaluate a product in deeper processing condition, subjects who are highly prejudiced, will evaluate the product in the same way as those who have less prejudice regardless of the language on the package.

H6: When asked to evaluate a product in a deeper processing condition, subjects who are highly ethnocentric, will evaluate the product no differently than those who have less ethnocentrism regardless of the language on the package.

Earlier research leads one to expect prejudice scores for women to be lower than those for men, we also expect women to evaluate products in a bilingual package more favorably than men.

H7: Women will exhibit less prejudice than men.

H8: Women will not significantly differ in their evaluation of a product in an English-only package versus the same product in a bilingual package, while men will have a lower evaluation of a product in a bilingual package versus the same product in an English-only package.

Methodology: In this study, we used a 2 (English-only or bilingual language description) X 2 (central or peripheral information processing) X 2 (high or low prejudice/ethnocentrism score) experimental design. Analysis of data collected from 240 undergraduate students at a major public university shows support for all hypotheses except H8 (Women will have no difference in product evaluations while men will). This finding is adequately explained with support from prior research.

This is the first study to examine the effect of ethnocentrism and prejudice on the evaluation of a product in a bilingual package. The findings suggest that managers should think carefully before deciding to use Spanish on their packages because our study suggests that typical consumers rate a product in a bilingual package less favorably than a product in an English-only package.

## EXTENDED ABSTRACT

The Exploratory Behavior (EB) concept was introduced in the early 1980's (Raju, 1980; Raju and Venkatsen, 1980) to designate behavior aimed at modifying environmental stimulation. This concept originated in the psychology field with studies of individuals' internal need for stimulation. This literature suggests that individuals have a preferred (or optimal) stimulation level (OSL). When stimulation (complexity and/or arousal) falls below this level, individuals become bored and try to increase it to the desired level. Applied to marketing, when in this situation, consumers tend to seek more diversity in their information search activities and buying decisions. In contrast, when stimulation surpasses the optimal level, individuals try to reduce it to a more comfortable level (Hoyer and Ridgway, 1984; Price and Ridgway, 1983; Raju, 1980; Raju and Venkatsen, 1980).

EB and OSL have been researched in numerous marketing contexts. However, the extant literature has some gaps that this paper seeks to address. First, we develop a nomological model that uses individual-level OSL-related antecedents to perceptions of risk. Raju's exploratory tendency scale (1980), one of the most popular operationalizations of EB, has been tested mostly in single countries (e.g., USA: Ganesh, Arnold, and Reynolds 2000; Goodwin and Etgar 1980; Mehrabian and Russel 1974; Raju 1980). Relatively few have examined EB and OSL cross-culturally or in non-US settings (for exceptions, see Faison, 1980; Murray and Manrai, 1993). This study develops a model for EB and tests it with data from two countries, namely Portugal and the UK. In sum, to the best of our knowledge, our study is the first test of the nomological model, with two countries

In our paper a review of the concept of Exploratory Behavior, Optimum Stimulation Level and Perceived risk is provided. The following hypotheses are proposed regarding the nomological relationships between these constructs:

H1: OSL is related positively to EB.
H2: EB is related negatively to consumers' perceived risk.
H3: OSL is related negatively to consumers' perceived risk.

Based on these hypotheses, a nomological model of the relationships of EB and related concepts is proposed. An empirical study was conducted in two nations representing differing cultures to validate the proposed model. Two high-involvement products were used (cars and laptops) as previous research on perceived risk shows that it is related to high-value, high-involvement purchases.

Results from the cross-cultural empirical study mostly substantiate the hypotheses based on the proposed model. Regarding EB antecedents, H1, suggesting that OSL is positively related to EB, was confirmed. This suggests that the level of homeostatic arousal predicts the disposition to engage in information- and acquisition-related exploratory consumer-related behaviors, such as seeking information, talking/reading about new products, and experiencing or buying them. In what concerns EB outcomes, the negative impact of EB on perceived risk (H2) was also confirmed for both EB facets, for both products, in both countries. OSL was hypothesized to negatively affect perceived risk (H3). However, results differed across OSL operationalizations.

These results emphasize the usefulness of the EB construct, capturing the disposition for engaging in exploratory, varied, and novel consumption- and information seeking-related activities in different cultures.

# Cross-cultural Differences in Delight

Ana Valenzuela, Baruch College, USA
Barbara Mellers, University of California, Berkeley, USA
Judy Strebel, San Francisco State University, USA

## EXTENDED ABSTRACT

This paper examines cross cultural differences in delight. Delight is a combination of affect (pleasure or happiness) and surprise (contrast with expectations). In consumer and business marketing, pleasant surprises occur when customers experience new products, new features of familiar products, service upgrades, sales promotions or free gifts. Past research shows that surprising positive events are more pleasurable than expected positive events, and surprising negative events are more painful. Surprise amplifies emotional experiences by causing arousal and activation that heightens valence. However, are such magical effects universal? Are Chinese customers and American consumers delighted by the same events? If so, does delight have the same effects on behavior? Cross cultural researchers have found numerous differences in the emotional reactions of Westerners and East Asians. For example, the frequency and intensity of positive emotions is stronger in Western cultures than in Asian cultures (Scollon, Diener, Oishi, & Biswas-Diener 2004; Heine, Lehman, Markus and Kitayama 1999). Asians also tend to report lower levels of well-being.

What are the reasons behind this disparity in emotional experiences? First, groups differ in cultural norms. It is more desirable to express and experience positive feelings in Western cultures (Kitayama, Markus and Kurokawa 2000). Asian cultures are more accepting of negative feelings (Diener and Suh 1999). Second, groups differ in their need for positive self regard. A review by Heine, Lehman, Markus and Kitayama (1999) suggests that Japanese are more critical of themselves than Westerners. Greater self criticism could lead to lower levels of well being. Third, groups differ in their outlook of the future. Chang, Asakawa and Sanna (2001) compared optimism and pessimism by asking Japanese and European Americans to predict the probability of life events. European Americans showed no differences in their predictions of their own future and that of others. However, Japanese participants believed they were less likely than others to experience positive events; [ADD "that is,"] they exhibited a pessimistic bias.

On the other hand, probably the more relevant difference between Westerners and East Asians is in reasoning styles. Nisbett, Peng, Choi and Norenzayan (2001) argued that East Asians reason holistically and make little use of categories, while Westerners focus their attention on objects and the categories to which they belong. East Asians rely heavily on dialectical reasoning, while Westerners are more likely to use analytical reasoning based on formal rules and logic. The holistic reasoning style of Asian cultures is guided by the assumption that everything in the universe is connected (Choi, Dalal and Kim-Prieto 1999). Holistic reasoning styles are also associated with a greater acceptance of contradiction. Confronted with apparent contradictions, a dialectical person will try to reconcile opposing propositions, seek a middle way or transcend the points of disagreement. Analytical thinking styles tend to confront the contradiction head on and reject the less plausible proposition (Peng and Nisbett 1999). Perhaps because they create more holistic and complex causal theories, East Asians are less likely than Westerners to experience surprise and more likely to experience hindsight (Choi and Nisbett 2000).

Then, if surprising positive events are more pleasurable than expected positive events and East Asians are less likely to experience surprise, they may report less pleasure than Westerners when confronted with a positive unexpected event. We argue that these cross-cultural differences are due, in part, to differences in the extent of exhibited hindsight bias, which, in turn, affects experienced surprise. Finally, we expect that positive feelings about an unexpected gift may transfer to related stimulus such as a store, brand or product. Accordingly, we designed three studies to test the effect of cultural orientation on affective reactions to an unanticipated gift and on attitudes towards a related product/service:

In Experiment 1, we found support for the hypothesis that Westerners derive greater pleasure than East Asians from an unannounced gift ($2 gift certificate at a University Café) relative to no gift. Moreover, Westerners are happier than East Asians with an unannounced gift (University car sticker valued at $2) relative to an equivalent announced gift. Culture was a moderator of expectations on reported pleasure. Westerners were more delighted than East Asians by unexpected positive events.

Experiment 2 investigated cross-cultural differences in surprise and hindsight as potential causes of affective differences. We found that Westerners reported less hindsight and more surprise than East Asians with an unexpected gift. Surprise mediated immediate pleasure. Surprise and hindsight were negatively correlated. Presumably, East Asians believed that they could better anticipate unexpected events, and, as a consequence, felt less surprised about it. In Experiment 2, the gift was a University car sticker that was allegedly provided by the University Bookstore as a token of appreciation for completing a customer satisfaction survey. Reported pleasure associated with the car sticker transferred to attitudes about the bookstore. In other words, reported pleasure was correlated with attitudes: Not only did Westerners feel happier than East Asians about the unexpected gift but also had more positive attitudes towards the bookstore when the gift was unexpected.

Experiment 3 builds on research showing that East Asians and Westerners differ in their concept of luck. Specifically, East Asians are more likely than Westerners to believe in luck as a way to deal with uncertainty. Experiment 3 demonstrates that East Asians derive greater pleasure than Westerners from an unexpected gift associated with good luck, and that their positive affect transfers to their evaluations of the overall experience. In other words, the addition of an element of luck allows East Asians to experience the emotional amplification resulting from the unexpectedness of the gift.

Our findings have implications for the design of international marketing strategies. Marketers often use pleasant surprises to influence consumers' brand evaluations and, thus, purchase decisions. In fact, the marketing literature emphasizes the role of consumer delight as a source of competitive advantage (Oliver et al. 1997). However, the use of "delighting" marketing activities across countries has to accommodate these identified differences in consumer reactions to "unexpectedness".

# Cultural Differences in Brand Extension Evaluations: The Moderating Role of Functional and Prestige Brand Concepts

Alokparna Basu Monga, University of Texas-San Antonio, USA
Deborah Roedder John, University of Minnesota, USA

## EXTENDED ABSTRACT

Brand extension research has identified a number of factors that influence how consumers respond to extensions, including the nature of the extension, type of parent brand, and consumer motivation levels. Recently, culture has been added to the list, with researchers examining whether consumers from different cultures respond to brand extensions in the same way (Bottomley and Holden 2001; Monga and John 2007; Ng and Houston 2006). One of the most interesting findings from this stream of research is that consumers from Eastern cultures perceive higher brand extension fit and evaluate brand extensions more favorably than consumers from Western cultures (Monga and John 2007). Styles of thinking, analytic versus holistic, have been implicated in this research (see Nisbett, Peng, Choi and Noranzayan 2001). Consumers from Eastern cultures, who tend to be holistic thinkers, are more readily able to see stronger relationships between the parent brand and the extension than consumers from Western cultures, who tend to be analytic thinkers.

In this article, we extend this research by investigating how consumers from different cultures respond to brand extensions as a function of parent brand concepts. Brand concepts are brand-unique meanings that exist in the minds of consumers (Park et al. 1991). Function-oriented brands (e.g., Timex) possess unique aspects related to product performance, whereas prestige-oriented brands (e.g., Rolex) are viewed as expressive of self-concepts or images. Research has shown that prestige brand concepts (e.g., luxury and status) are more abstract than functional brand concepts (e.g., durability and reliability), allowing prestige brands to accommodate a wider range of products that share few physical features (Park et al. 1991). A prestige brand like Rolex can be successful launching dissimilar extensions (e.g., scarves and neckties), unlike a functional brand like Timex, which is more successful when launching extensions that share similar attributes in similar product categories (e.g., stopwatches and oven timers) (Park et al. 1991).

We propose that cultural differences in brand extension evaluation will be smaller for prestige-oriented brands than function-oriented brands. Prestige brands have salient and accessible associations that can be used to connect the brand to seemingly unrelated types of brand extensions by consumers from both cultures. Functional brands, in contrast, may have salient and accessible associations, but they are less likely to provide a basis for linking the brand to potential brand extensions in very different product categories. Since consumers from Eastern cultures are more adept at finding relationships between the brand and the extension, a larger cultural difference will emerge for function-oriented brand extensions.

We test this prediction in a series of two studies. In study 1, we compare brand extension responses of American (Western) versus Indian (Eastern) consumers for prestige and functional parent brands. Using hypothetical brands, we find that cultural differences in extension evaluations were much smaller in the case of prestige brands, compared to functional brands. In study 2, we replicate this result by priming analytic and holistic styles of thinking within a culture. This approach, used extensively in cross-cultural research, allows us to rule out alternative explanations based on the myriad of factors that vary between Eastern and Western culture. We find that the effects of priming styles of thinking mirror those found across cultures in study 1. We also test brand name strategy (direct brand name versus endorsed brand name) as a proposed moderator of these effects. Consistent with prior research, we find that an endorsed brand name strategy enhances evaluations of a dissimilar extension of a functional brand among analytic thinkers. However, as expected, no such effects were found for holistic thinkers.

# Food Shopping in Urban China in 1996 and 2006: Homogenization and Stratification

Ann Veeck, Western Michigan University, USA
Hongyan Yu, Jilin University, China
Alvin C. Burns, Louisiana State University, USA

## EXTENDED ABSTRACT

Over ten years ago we first collected data related to the wide-sweeping changes in food consumption behavior that had occurred in urban areas of China in the post-reform years (Veeck 2000; Veeck and Burns 2005). Since that time, in response to state reform policies and market mechanisms, changes related to the food provisioning of families have been, if anything, even more rapid. These myriad changes lead to a number of questions related to how this transformation of the marketplace is being experienced by consumers.

Since food shopping and other food-related tasks are highly social experiences (Lupton 1996; Valentine 1999), as well as serving individual, task-driven needs, a primary question involves how new shopping patterns alter and absorb roles and identities. Are these changes in food provisioning behavior reflecting, or even contributing to, a breakdown of social systems and the rise of individualization that is frequently associated with modernity (Beck 1992; Giddens 1991)?

As urban dwellers become farther removed from the sources of their food, they are relying on increasingly distant and complex chains of production, distribution, and processing to deliver their food. Some researchers have associated the shroud of mystery that accompanies modern food systems with an environment of distrust (Fischler 1980; Mennell, Murcott, and Van Otterloo 1992). This leads to the question of how Chinese urban consumers evaluate new food options and ensure the safety of food that they serve to themselves and family members.

Another important question involves the extent to which emerging social distinctions are being defined and altered through food-related tasks. A growing disparity in China in occupational mobility, access to resources, and, simply, life opportunities has been well-documented (e.g. Bian 2002). Given the primacy of food-related activities in defining relationships and establishing roles and identities, the food retail environment in Chinese cities is an important place to examine the ongoing stratification of society.

The data from this research are based on two sets of food shopping observations and interviews, conducted in 1996 and 2006 in urban areas of China. In both studies, we asked each of the participants to allow us to accompany them as they conducted a routine food shopping trip, starting and ending at their homes. Following the shopping trips, we conducted an interview with the participants in their homes and surveyed their cooking and dining areas. For both sets of observation/interviews we took hundreds of photographs of the food shopping trips and the homes. We audiotaped our observations from the marketplace, as well as each interview. The notes and interviews were later translated and transcribed.

The most striking difference we found in our food shopping trip observations between 1996 and 2006 was in how much more diverse in 2006 the behavior of our participants was, including choice of retail venue, time spent shopping, amount of food purchased, and money spent. In 1996, every one of our observations of shopping expeditions involved a trip by foot to a neighborhood food market featuring multiple food stalls. In 2006, we observed shopping trips to diverse food venues, including four morning markets, one outdoor food market, five enclosed food markets, four supermarkets, and one small family-owned grocery store. The diversity

in the 2006 shopping options is a testament to both the variety of options now available for purchasing groceries and the wide-ranging life styles that are accommodated by these options.

In this period of economic and societal change in Chinese cities, consumption activities are a particularly important tool for developing and reaffirming important relationships. We found the social dynamics of traditional food markets in which the shoppers frequently encountered and spoke to neighbors and engaged in relatively protracted transactions with the vendors to be quite different than the relative anonymity of the modern supermarkets in China. However, the most important relationships affirmed through food transactions—that is, the nurturing of family members—remained equally salient to respondents between 1996 and 2006.

Through this research, we also wished to explore another outcome that has been associated with modernity in contemporary society in the West: the notion of a "risk society," (Beck, 1992; Giddens 1991) in which advanced technologies lead to a public that is increasingly aware of and consciously avoids risk. In fact, we found that, while consumers are not necessarily more concerned with the safety of the food supply than they were a decade ago, the source of their fears had altered due to the changes. In particular, newer forms of food handling, such as modern agricultural techniques and manufacturing are generating concern related to safety. At the same time, other newly-available food options, such as purchasing trusted brands and organic foods, serve as a tool used by some consumers to feel more secure about the food they serve their families.

The increasing heterogeneity of food purchasing behavior resulting from the stratification of society suggests the potential for feelings of alienation related to the inequality of consumption opportunities. Our research found that consumers are more likely to rejoice in the wide availability of new choices than feel resentful of the growing inequities (Davis 2005). Still, it bears watching to see if disenchantment grows as social stratification expands.

In this transitory period of food retail expansion, the repertoire of choice available to each Chinese consumer should be monitored. This may well be a "golden period" in the food supply, in which, in the intersection between traditional food suppliers and modern food retailers and manufacturers, consumers are experiencing the best of both worlds. The changes that occur in the food retail environment in the next few years may determine if the retail landscape continues to provide a variety of options for most urban consumers, or if the options recede to the homogenization often associated with supermarkets in the West (Clarke et al. 2002). Furthermore, it will be important to monitor to what extent the opportunity of choice in food consumption is available to all urban residents.

# Guiltless Gluttony: The Asymmetric Effect of Size Labels On Size Perceptions and Consumption

Aradhna Krishna, University of Michigan, USA
Nilufer Z. Aydinoglu, Koc University, Turkey
Brian Wansink, Cornell University, USA

## EXTENDED ABSTRACT

Obesity is now seen as one of the leading public challenges of our time. General consensus holds that the increase in food portions is one factor contributing to the obesity epidemic in the U.S. Standard portions, as defined by the federal government are considerably smaller than portions typically consumed by the public. This discrepancy makes it difficult for people to relate the amounts they eat to recommended amounts and contributes to people's uncertainty about the appropriate amount to eat. In this context of large portion sizes and uncertainty about appropriate portion sizes, we propose that size labels that manufacturers choose to use on their food products can have a major impact on consumers' purchase and consumption behavior.

The basic conceptual question we ask in this research is "how do people integrate different cues to form size judgments?" In the context of food and drink categories, judgments of size estimations can be made using multiple inputs coming from the stimulus: *visual* cues from the stimulus itself, *semantic* cues in the form of size labels (and other written information), and *sensory* cues from post-consumption judgments. Furthermore, information coming from these multiple sources can be inconsistent. For example, a product can be (intentionally) mislabeled by the marketer as a "large" when it is actually "small" within the context of similar products in the category, and vice versa. We explore to what extent people rely on the visual size versus the size label in forming size estimations, which will then affect their actual consumption.

We build on the Heuristic-Systematic Model (HSM) from the information processing paradigm as a framework to explain this information integration. The model suggests two different modes of information processing: *systematic* processing (with a more comprehensive and analytic orientation) and *heuristic* processing (with a more limited, less effortful orientation). We propose and demonstrate that size labels can be used as a semantic heuristic in making size judgments for everyday food and drink consumption, since people may find it difficult to estimate absolute sizes of products from visual product stimuli.

A series of three laboratory experiments and a field study show that size labels influence not only size perception but also actual and perceived consumption; and that their effect is most pronounced under conditions of limited cognitive resources and increased concern for accuracy.

Study 1 uses a 2 ("size label": inconsistent, consistent) x 2 (actual "serving size": six, eight pretzels) mixed-subjects design to test the effect of size labels on size perceptions, with sixty one participants. Snack plates with mini-pretzels are used as the stimuli. Each participant is presented with two snack plates sequentially with size labels attached and is asked to indicate pre- and post-consumption size estimations for both plates. ANOVA tests with pre-consumption and post-consumption perceived size as the two dependent variables show a significant interaction between serving size and size label (consistent vs. inconsistent), and planned contrasts are in expected directions. Accordingly, we demonstrate the biasing influence of size labels over visual stimuli in this study.

Studies 2 and 3 establish the conditions of *when* the biasing effect of size labels are most pronounced. Study 2 tests for cognitive load and uses a 2 ("size label": small, large) x 2 ("actual size": small, large) x 2 ("cognitive load": load, no load) between-subjects design, with one hundred and sixty participants. Mini-sandwich bowls, which also include nutrition information, are used as the stimuli in this experiment. We establish that under load, participants are subject to the biasing effect of size labels, while in the absence of load, they can correct for the bias. As a second moderator, Study 3 tests for concern for accuracy, operationalized through measuring nutrition consciousness. It uses a 2 ("size label": small, large) x 2 ("actual size information given": 30 gr., 50 gr.) x 2 ("nutrition consciousness": high, low) between-subjects design, with two hundred participants. We find that when consumers care less about their nutrition and energy intake estimation accuracy, they are more likely to rely on size labels as a simplifying heuristic.

Finally Study 4 explores the effects of size labeling on actual and perceived consumption in the field. Packed portions of eggs are used as the stimuli for this experiment during a breakfast of thirty three Rotary Club members as participants. We find that the mere use of different size labels for the same product affects the amount people consume (without knowing). This indicates that actual behavior can also be influenced by the use of labeling. Further, consumers may not even be aware of the effect of the size label on their consumption behavior.

The studies together also suggest an asymmetry in the biasing effect of size labels. Since obesity-prone consumers are inclined to consume large quantities, they are more open and willing to accept a larger item being labeled small, and not feel guilty of increased consumption. However, when the reverse happens, when a smaller item is labeled large, consumer skepticism takes a hold, and they are suspicious that the marketer is trying to signal better value for a smaller product. As such, the size label has a smaller effect on size perceptions in the latter case. We call this asymmetric effect "guiltless gluttony".

In sum, since size labels can (mis)lead food perceptions of consumers, marketers need to be careful in their adoption of new labels; mislabeling (unwittingly using a size label that connotes a different size perception from what the actual product is perceived to be) could result in serious negative consequences for the firm if recognized by public policy officials, consumers or the media. For the wellbeing of consumers, it is critical to use size labels ethically. Since consumers are increasingly faced with the dangers of obesity, a more educated view of size labels and serving sizes is critical for each consumer. Public policy officials need to be vigilant about marketers mislabeling products to unfairly influence consumer purchase behavior.

# Conspicuous Consumption: A Preliminary Report of Scale Development and Validation

Etta Y. I. Chen, National Chengchi University, Taiwan
Nai-Chi Yeh, National Chengchi University, Taiwan
Chih Ping Wang, National Chengchi University, Taiwan

## EXTENDED ABSTRACT

Since conspicuous consumption was proposed by Thorstein Veblen in 1899, it has been extensively discussed in the field of economics. As the *Veblen effect* indicates, the demand for consumer goods is increased when its price is higher than that of others (Leibenstein 1950). In Veblen's time, what motivated conspicuous consumption was the desire to gain prestige from others via accumulation of wealth or luxury goods.

However, conspicuous consumption behavior today has become more sophisticated and subtle (Trigg 2001). The meaning of conspicuous consumption has changed with the evolution of societies and consumption value. Thus, the main components of conspicuous consumption vary today. As consumers employ product symbolism for their social interaction (Belk 1985, Holbrook and Grayson 1986, Kleine, Kleine and Kernan 1993, Laverie, Kleine and Kleine 2002, Richins 1994, Solomon 1983), conspicuous consumption does not only mean the ostentation of wealth, but also the ostentation of something symbolic to specific reference groups in order to gain their recognition or prestige.

In the field of consumer behavior, conspicuous consumption is a relatively less explored construct. The only existing scale (Marcoux, Filiatrault, and Cheron 1997) was ad hoc designed for certain research context and limits its generalizability. Besides, as the content of conspicuous consumption changes over time, the need for an appropriate definition and measurement of this special consumer behavior in today's society has emerged. Hence, the objective of the present study was two-fold. First, through a literature review, the content of conspicuous consumption was clarified. Second, based upon the new definition and major dimensions, we developed a scale for measuring behavioral tendencies of conspicuous consumption following the rigorous procedures suggested by Hinkin (1998).

Drawing from the literature review in economics, sociology, and marketing (Page 1992, Mason 1981, Mason 1982, Mason 1998, Shipman 2004, Solomon 1983, Trigg 2001), we defined conspicuous consumption as "the extent of one's behavioral tendency of displaying one's social status, wealth, taste or self-image to one's important reference groups through consumption of publicly visible products." Using a deductive approach, we integrated past theory and research to derive four key dimensions underlying conspicuous consumption, which are conspicuity for aspirant group, conspicuity for uniqueness, conspicuity for conformity, and conspicuity for status.

Followed standard psychometrical procedures for scale development (Hinkin 1998), there are five phases in the scale development and validation.

*Item generation.* Initially, all potential items were written referring relative literatures to reflect the conceptual definitions of the four dimensions. After we ensured that all items were articulated in consistent terms, written in concise statements, and dropped redundant items, 75 positively worded items were remained in the item pool.

*Content validity and questionnaire administration.* This phase was assessed by nine Ph.D. students, who served as expert judges. The result of this analysis showed an overall SAI of .84, which indicated a high level of correct matching. After items with a high degree of inconsistency were deleted, a total of 41 items with content validation were retained. For convergent validity, the previous conspicuous consumption scale (Marcoux et al., 1997) and the interpersonal influence scale (Bearden, Netemeyer, and Teel 1989) were measured. Besides, the self-esteem scale (Rosenber, Schooler, and Schoenbach 1989) was used to examine discriminate validity. Further, we also measured consumer's actual conspicuous brand consumption behavior to verify criterion related validity. Meanwhile, an additional independent survey conducted to identify the conspicuity of the brands. In the administration stage, all data were collected from 317 undergraduate students. This sample size reached an acceptable item-to-response ratio of 1:7 (Hinkin, 1998). Then, we randomly assigned all samples into two groups for exploratory factor analysis (EFA) (N=158) and confirmatory factor analysis (CFA) (N=159).

*Exploratory factor analysis.* The principle factor method and oblique rotation were adopted, without specifying the number of factors in the first run. The results indicated that the first four extracted factors fell into the domain of our dimensions. Next, four factors were specified in the second EFA estimation, and 30 items remained, of which all factor loadings were over .4.

*Confirmatory factor analysis.* CFA processed with the LISREL 8.51 program, we deleted items with modification indices exceeding 3.85. The final 15 items had a good model fit (GFI=.91, RMSEA=.06).

*Reliability and construct validity.* Scale validation, regarding the response bias, the correlation between our scale and the social desirability scale was insignificantly low, which eliminated this concern. The Cronbach's Alpha, CFA indexes, and MTMM results indicated the good reliability and validity of this scale. First of all, the Cronbach's Alphas of the four dimensions were all above .7, which indicated high reliability. Second, the convergent and discriminant validity was verified by the high correlations between our scale and Marcoux scale. The low correlation between our scale and the self-esteem scale provided the evidence of good discriminant validity.

As for the criterion related validity, evidence of a nomological network was investigated. The significant correlation between our scale and the interpersonal influence scale indicated the first evidence of good criterion-related validity. Second, we also conducted hierarchical regression, using both the new scale and the existing Marcoux scale to compete for their predictability of consumers' conspicuous brand purchase. The result showed that our scale had a significant 3% additional explanatory power after the Marcoux scale had entered the model before our scale. In contrast, there was no significant R-square increase for the Marcoux scale if our scale entered the regression first. This result provided further evidence of the criterion related validity of our scale.

This article developed four key dimensions and the measurement scale to capture the definition of conspicuous consumption. According to these four dimensions, society value sets up the standard of what represents status symbols; fashion leaders in aspirant groups drive the trendy style and the public mimics, from the peer leaders to the peer followers. This notion is quite different from the conspicuous consumption in Veblen's time, only limited to the wealth ostentation via luxury goods. In the

society which encourages materialism, this preliminary finding of conspicuous consumption indeed provides a new perspective for future research.

# Assessing the Consumer Perceived Value Scale

Gianfranco Walsh, University of Koblenz-Landau, Germany
Thomas Kilian, University of Koblenz-Landau, Germany
Holger Buxel, University of Applied Science Muenster, Germany

## EXTENDED ABSTRACT

### Abstract

In recent years perceived value has attracted significant attention among marketing scholars. Recently, Sweeney and Soutar (2001) identified four dimensions of consumer perceived value (CPV) and developed scales to measure these dimensions. Their CPV scale, based on previous research in Australia, was administered to consumers in Germany. We assess the cross-cultural validity of the measure of consumer perceived value (Study 1). After validating the CPV scale, an abbreviated version of the CPV scale (with 12 items) is proposed and assessed that has equally good dimensional properties as the original version. In Study 2, using a second sample, we validate and apply the abbreviated version of the CPV scale.

### Introduction

Given the increased competition in the service industry, many retailers and other service firms focus on delivering value to customers as a means of competitive advantage. The literature suggests that consumer perceived value is associated with customer satisfaction, loyalty, and trust (e.g., Lee et al., 2002; Parasuraman and Grewal, 2000; Yang and Peterson, 2004) and is hence relevant to researchers in consumer behavior and services marketing. This study tests the universality of a concept known as perceived value within Germany for both private-label (PLB) and manufacturer-brands (MB). In recent years perceived value has attracted significant attention among marketing scholars. Sweeney and Soutar (2001) identified four interrelated dimensions of consumer perceived value (CPV): Quality, Emotional, Price, and Social. They validated the scale using exploratory and confirmatory factor analysis (CFA). Sweeney and Soutar's (2001) CPV scale, based on previous research in Australia, was administered to consumers in Germany. In this article, we assess the cross-cultural validity of the measure of consumer perceived value (Study 1). After validating the CPV scale in a German context (and in four non-durable product contexts cereals, chocolate bars, and sweet corn), an abbreviated version of the CPV scale (with 12 items) is proposed and assessed that has equally good dimensional properties as the original version. Sweeney and Soutar (2001, p. 216) argue that they have developed "a parsimonious and practical four-dimensional scale". However, it is likely that researchers and practitioners interested in measuring consumer perceived value would disagree and may be deterred by the scale's length.

### Method

Based on a sample of 323, we tested a 17-item, four-factor structure using CFA. The factor structure was tested with the German data, both for PLB and MB sub samples. Inspection of model fit revealed good global fit as well as high coefficients of determination for all the items. Then we considered internal and external criteria to develop the 12-item CPV short scale. Internal criteria relate to internal consistency and dimensionality, external criteria are concerned with criterion-related validity, and judgmental criteria involve assessments of content validity and ease of use.

The 12-item, four-factor structure was tested using CFA and resulted in a good overall fit for both sub samples.

In Study 2, using a second sample (n=319), we validated and applied the abbreviated version of the CPV scale. The reliability of the CPV short scale was assessed with Cronbach's Alpha and CFA. Alphas ranged from .82 to .93 for the PLB and from .71 to .89 for the MB sub sample, and the CFA resulted in a reasonably good overall fit for both four-dimensional models. To assess the practical utility of the CPV short scale, CPV-based segments were identified, employing a two-step clustering procedure, which resulted in choosing a four-cluster solution as the most appropriate representation of the data. The clusters were labeled 'Private Label Brand-oriented' (n=112), 'Functionalists' (n=107), 'Social Utility Seekers' (n=58), 'Manufacturer Brand-oriented' (n=42).

### Discussion and Implications

This study had three objectives relating to; testing the CPV scale's reliability and validity in Germany for PLB and MB, applying it to measure CPV in different product categories and assess a short form of the scale. The findings presented in this research provide further support for the internal validity of the CPV short scale as a viable scale for measuring CPV. The most important finding is that there is an indication of generality of most scale items. Given this finding, there is reason to believe that the CPV scale has elements of construct validity and has potential use across international populations. The results have implications for research and practitioners on how to deal with CPV in retailing and other customer services.

In terms of future research implications, it seems that additional countries need to be considered to permit a triangularization of internal and external results. Indeed, Steenkamp and Geyskens (2006) argue that consumer value may vary across countries. Furthermore, the CPV scale was developed specifically for durable goods purchased in the offline shopping environment. In this study CPV was examined in four product contexts (non-durable product contexts) for both PLB and MB, suggesting that future research should include more and other product contexts as well as services. Thus we urge researchers to continue to consider these important issues. However, additional research is needed to more firmly establish the CPV scale's generalizability.

Sweeney and Soutar (2001, p. 218) argue that consumer perceived value "should be viewed as a part of a continuous process in the maintenance of a relationship between manufacturer and retailer with a given customer". Insofar, our findings are likely to have managerial implications, especially for retailers and other service firms targeting the German market. Interestingly, in Germany, the 'Social' dimension is more reliable in the context of private label brands than manufacturer brands. This dimension refers to the utility German consumers derive from the product's ability to enhance social self-concepts, such as status. Perhaps consumers buying PLB are more eager to get social approval for their product choice, whereas consumers buying MB are more confident about their choice. Also, knowledge of distinct CPV segments is useful for retailers in constructing marketing communication strategy and designing appealing store environments.

# When Uncertainty Brings Pleasure: The Role of Outcome Imageability and Mental Imagery

Cheng Qiu, The University of Hong Kong, Hong Kong
Yih Hwai Lee, National University of Singapore, Singapore

## EXTENDED ABSTRACT

Neither consumers nor marketers appear to like uncertainty. Previous research shows that uncertainty during the purchase process may reduce customer loyalty, undermine consumer confidence, and delay purchase decisions. As such, consumers may seek information to reduce uncertainty while marketers may benefit from strategies that reduce such consumer uncertainty. Continuing these research efforts, yet contrasting past approaches, we examine uncertainty from positive outcomes and specify conditions where consumers can gain more pleasure from uncertainty than from certainty.

Consider an example of a "sure-win" lucky draw where consumers are assured of winning a prize. Upon drawing a prize, the marketer may immediately tell the consumers what the prize is, or alternatively, reveal the particular prize at a later time so that the consumers are uncertain about the prize for some period of time. Comparing between these approaches, which would elicit greater pleasure? Which would better sustain the pleasure consumers derive from the positive event, and why? Our research addresses these questions involving situations where individuals know the eventual outcome is positive yet they do not know which particular outcome would occur.

We suggest that such positive uncertainty may (a) elicit greater immediate positive feelings than certainty, because it evokes greater arousal which intensifies affective reactions, and (b) increase the duration of positive feelings beyond a mere pleasant surprise. Moreover, the durability of positive feelings hinges on the outcome imageability of the uncertain events. This is because the duration of positive feelings is proposed to increase with the level of imagery processing consumers engage in regarding the possible outcomes. Such imagery processing (e.g., visualizing the possible prizes and the situations of using these prizes) would be favorably enhanced when the uncertain events possess cues that are high in imageability in terms of both amount and specificity of imagery. When this happens, the ensuing imagery elaboration would feed and sustain the positive feelings that consumers experience. In contrast, consumers facing a certain positive outcome may imagine less about the outcome, causing their positive feelings to dissipate more rapidly.

As both extent and content of elaboration are two broad dimensions of imagery elaboration, we suggest that the outcome imageability of uncertain events is positively linked to the number of potential outcomes. However, this association should be bounded because a large number of alternative outcomes are unlikely to aid imageability due to the lack of a specified set of identifiable alternatives from which concrete mental imagery can be generated. Therefore, outcome imageability should be higher when the number of potential outcomes is moderate rather than small or large. Experiment 1 tested this conjecture.

*Experiment 1*. This experiment employed a 3 (outcome imageability: limited-possible-outcomes vs. moderate-possible-outcomes vs. infinite-possible-outcomes) x 2 (measurement of feelings: T1—immediately following the event vs. T2—five minutes later) mixed-factorial design. Participants played a computer-simulated lucky draw game and were notified of winning a prize worth $12. Next, participants in the limited-possible-outcomes condition were informed they would receive one of two possible

functional prizes and read the prize descriptions. Participants in the moderate-possible-outcomes condition were informed they would receive a consumer electronics product—a category cue that was pretested to elicit higher levels of imagery processing. Participants in the infinite-possible-outcomes condition received no further details about the prize. Thereafter, participants indicated their feelings (T1). Five minutes later, their feelings were measured again (T2). As predicted, only participants facing a moderate number of possible outcomes (high outcome imageability) remained as happy after a period of time, whereas participants facing limited or infinite possible outcomes (low outcome imageability) experienced a significant drop of positive feelings from T1 to T2.

*Experiment 2*. This experiment had a 2 (uncertainty: present vs. absent) x 2 (outcome imageability: low-imagery product vs. high-imagery product) x 2 (instruction to imagine: present vs. absent) x 2 (measurement of feelings: T1—immediately following the event vs. T2—10 minutes later) mixed-factorial design. To obtain further support for our hypotheses, we compared the levels of positive feelings immediately following an uncertain event with those following a certain event; we adopted a different manipulation of outcome imageability by varying the imagery-evoking nature of prizes; we administered process-baseline conditions where participants received instructions to imagine about the prizes; we collected thought protocols to test the mediating role of imagery elaboration as the mechanism underlying the pleasurable uncertainty effect. Consistent with our prediction, participants in the uncertain condition experienced greater positive feelings at T1 than those in the certain condition. Moreover, only participants who were told they might receive one of two possible high-imagery (sensory-stimulating) prizes remained as happy after 10 minutes, whereas those in the certain condition (regardless of the nature of prize) and those in the uncertain, low-imagery (functional) prizes condition experienced a significant drop of positive feelings from T1 to T2. As expected, we found no differences between the instruction and no-instruction conditions, suggesting the nature of prizes may have constrained the extent of imagery elaboration. Participants who were instructed to imagine about the prizes also wrote down their thoughts about the prizes. Their responses were coded as either an imagery thought or a non-imagery thought, upon which we created an imagery elaboration index (the number of imagery thought divided by the number of total thought). Confirming our prediction, the imagery elaboration index fully mediated the effect of uncertainty and outcome imageability on the durability of positive feelings, whereas the number of total thought did not.

Aside from the immediate pleasurable effect of future positive uncertain outcomes, the temporal aspect of the pleasurable uncertainty effect may bear richer theoretical implications. In this respect, our main contribution lies in identifying the role of outcome imageability of the uncertain events and the ensuing imagery elaboration as the mechanism responsible for the durability of the pleasurable effect. Future research may further consider the contextual effects that pleasure under uncertainty brings, which may also be of interests to practitioners where the creation of positive uncertainty is not only an end (delighted consumers) but a means to an end (favorable responses to subsequent marketing stimuli) as well.

# Situation-Based Shifts in Consumer Benefit Salience: The Joint Role of Affect and Cognition

Sonja Wendel, Erasmus University Rotterdam, The Netherlands
Benedict G.C. Dellaert, Erasmus University Rotterdam, The Netherlands

## EXTENDED ABSTRACT

Advanced information and communication technologies now allow firms to provide consumers with anytime, anywhere access to many of their communications and services (e.g., product information, after-sales services). This type of highly flexible interaction with consumers places new requirements on firms, because they need to design their interfaces and services to meet variations in consumer demands across a wide variety of usage situations (Seybold 2001). In particular, the benefits that consumers require in products and channels may vary strongly across usage situations (Gutman 1982; Wendel and Dellaert 2005). Although previous research emphasizes that situational differences are particularly important in understanding consumer behavior (Belk 1974; Lutz and Kakkar 1975), few studies have addressed the question of how these benefits are made salient in consumers' minds. It has been suggested that benefit salience is rooted in a selection process, whereby some benefits are cognitively more accessible in memory to the consumer in a particular usage situation because of their strong associations with past experiences (Ratneshwar et al. 1997). This cognitive structure implies that consumers process decision information in a selective manner, depending on the thoughts activated in a specific situation. The role of affective states in explaining variation in consumer benefit salience also has been suggested as an important area for research (Lutz and Kakkar 1975), although it remains a relatively unexplored research domain. The objective of this paper is to combine these two perspectives and jointly investigate the affective and cognitive routes by which situational differences in benefit salience may arise.

Specifically, we address the process by which benefits become salient in consumers' minds across usage situations and explore two routes (cognitive and affective) by which the situation jointly influences benefit salience, in terms of both benefit importance and the number of salient benefits. We argue for a direct effect of usage situation on consumers' benefit salience (cognitive route) and an indirect effect of usage situation (via affective states) on benefit salience (affective route).

We test the proposed hypotheses empirically by asking respondents to imagine themselves in a usage situation, in which they have a choice of web sites to look for food product information. The Internet particularly emphasizes the importance of anytime, anywhere access for many consumer–firm relationships, which raises the question of how firms can meet these varying needs across individual consumers. We collected data through an online survey run with two university panels. The sample consists of 276 subjects, 22.5% of whom are men. We adopt a 2 x 2 between-subject experimental design to vary the situation and assign respondents randomly to one of four conditions that represent the different hypothetical usage situations. We focus on time and social factors as two situational characteristics for manipulation (Belk 1975). To create the two time and two social conditions, we alter the time that respondents had available to search for a recipe on the Internet and the social context in which respondents had to search, respectively. To measure pleasure and arousal, we use seven-point bipolar adjectival scales (Mehrabian and Russell 1974). In total, we define 13 benefits: understandability, relevance, reliability, adequacy, scope, usefulness, usability, speed, hyperlinks, entertainment, navigation, interactivity, and decisional control. These benefits represent the main themes in current management information system and marketing literature (e.g., Mathwick and Rigdon 2004).[1] To measure benefit salience, we asked respondents to indicate on a seven-point Likert-type scale how important they found each benefit to be in the particular experimental usage situation. We assessed the number of benefits made salient by determining how often respondents indicated a score of six or higher for each benefit (composite score) and adding those scores.

Next, we purified our scales by conducting two confirmatory factor analyses on pleasure and arousal as well as on the 13 benefits. We then performed two analyses by making use of a three-stage least squares approach to test the proposed model. First, we analyzed the effect of positive affect and situation on the number of salient benefits. Second, we tested the influence of positive affect and situation on benefit salience (relative shift). As anticipated, positive affect (i.e., pleasure) significantly increases the number of salient benefits. We also test for the effect of situation on positive affect and find significant positive results regarding the effect of social pressure on pleasure and arousal. Yet, we do not observe an effect for time constraint on pleasure and arousal. The results of the analysis of the situation on the number of salient benefits shows no effect for time constraint. Surprisingly, social pressure has a significant negative effect on the number of salient benefits, even when we control for the effects of affective state. The results further show that positive affect has the strongest influence on the benefit entertainment. To examine whether the differences between entertainment and the remaining benefits are significant, we perform several Wald tests and find significant differences between entertainment and all other benefits except interactivity. Moreover, the effect of situation on benefit salience illustrates that social pressure has a significant negative effect on adequacy, scope, usefulness, speed, entertainment, navigation, and decisional control and time constraint has a significant negative effect on entertainment. Given our interest in the relative shift of individual respondents' benefit salience, we conducted a Wald test and restricted the shift within both manipulation conditions to be constant. The Wald test results are significant and provide further evidence that the relative importance of benefits shifts across the situations.

The impact of the situation on consumers' benefit activation (salience) has received considerable support over the years; however, many of these studies are not very specific about the processes involved. We offer a first attempt to empirically untangle this "black box" and further understanding of the influence of the situation on consumer decision making. We examine two mechanisms that underlie the link between situation and benefit salience. We find support for both routes, which highlights the importance of accounting for cognitive and affective effects simultaneously in understanding the effect of situation on consumers' benefit salience.

# The Affective-Cognitive Model of Stimulus-Based Affect: Individual Differences in Response to the Vividness of Product Descriptions

David J. Moore, University of Michigan, USA
Leah J. Bovell, Georgia State University, USA

## EXTENDED ABSTRACT

This study expanded the theoretical issues addressed in the Affective-Cognitive model proposed by Shiv and Fedorikhin (2002). That model demonstrated that when an individual is confronted with a hedonic choice like an enticing piece of chocolate cake, the lower order cognitions (e.g., thoughts or memories of previous pleasant consumption pleasures) activate the release of lower order affective reactions to the appetizing stimulus. Shiv and Fedorikhin (2002) demonstrated that choices may be driven by lower order affect when the decision maker is mentally preoccupied and has little time to make the decision. The current study expands the perspective of previous research by focusing on three important factors: (a) The manner in which the stimulus product is described for the message recipient. Here we manipulated a vivid presentation (an emotionally evocative description versus a pallid description highlighting the details of the nutritional value of the ingredients. (b) We focused on the affective and appetitive reactions that are activated through the lower order route such as craving and desire (Gendall et al. 1997; Cepeda-Benito et al. 2000; Belk, Ger, and Askegaard 2003). (c) We also looked at the manner in which individual differences in affect intensity (Larsen and Diener 1987; Moore et al. 1995) influence consumers response to vivid product descriptions.

## Theoretical Rationale for Hypotheses

First, vivid descriptions of delicious food products can prime the appetitive and emotive pathways of the brain and thereby activate intensely strong lower order affect and cognitions. Thus, it can be predicted that the influence of vividness on the stimulation of desire will be mediated by the activation of favorable memories of previous experiences of pleasure associated with consuming the product (Anderson and Bower 1980; Kisielius and Sternthal 1984; Bone and Ellen 1990). This pattern of mediation will also be observed for other dependent measures like attitude toward the product as well as purchase intention.

Second, consumers who score high on the affect intensity measure will experience stronger lower order affect and cognition. Since sensory arousabilty is a dimension of affect intensity (Larsen 1995; Moore and Homer 2000), it should be expected that when individuals are presented with product descriptions that are designed to stimulate vivid imageries of the pleasures of food consumption, those who are high on the affect intensity scale will experience stronger emotional arousal. Presumably, the evocative product consumption descriptions will activate a network of memories of the aroma of pleasurable experiences that will stimulate lower order cognitions. These lower order cognitions, according to Shiv and Fedorikhin (2002), should activate the release of lower order affective reactions (e.g., cravings and desires for the food). In other words, affect intensity should moderate the impact of vividness on emotional responses such as desire and craving and attitudinal judgments.

## Subjects and Design of the Experiment

Subjects (N=197 undergraduates) participated in a 2(Product Description: Vivid vs. Pallid) x 2(Affect Intensity: High vs Low) between subjects design. The test product was Cinnabon™ rolls.

## Findings

The results showed that: (1) the associative network of memories of prior experiences of delightful consumption experiences including the memory of the aroma associated with the product, mediates the influence of vividness on outcome measures such as craving and desire, hedonic attitudes, and purchase intention. (2) Desire and craving for the consumption experience are very powerful emotional reactions and may therefore mediate the effect of vividness on purchase intention. (3) While individual differences in affect intensity revealed very interesting insights about appetitive desires and attitudes, the predicted interactions with vividness was only evident with respect to hedonic attitudes (Voss, Spangenberg and Grohman 2003). (4) Nevertheless, with respect to lower order cognitions produced through the exposure to vivid product descriptions, this study found an interesting relation with affect intensity. Hedonic rationalizations–thoughts people use to justify yielding to an eating temptation–served as the mediating mechanism through which affect intensity influenced craving and desire. On the other hand, cognitive deliberations–thoughts that focus on the consequences of indulging–failed to resonate with high affect intensity consumers and hence did not mediate its influence on craving and desire. It is interesting to speculate about the reasons why hedonic rationalizations and not cognitive deliberations, served as the mechanism through which affect intensity influenced craving and desire. This study did not provide us with the evidence to conclude that high affect intensity consumers are more inclined to resort to hedonic rationalizations when faced with an eating temptation. More research is needed to verify this relationship.

Future research is desperately needed to determine the reason for the relative lack of an affect intensity x vividness interaction. In this study the vivid and emotionally evocative description was designed to activate a network of memories of pleasurable indulgence in consuming a product category that is generally considered to be a 'forbidden pleasure'–Cinnabon™ rolls. To a large extent, these product descriptions served as a powerful source of sensory stimulation in a similar manner as the actual presentation of the product itself has been shown to produce lower order affect and cognition in previous research (Shiv and Fedorikhin 1999; 2002). Our findings seem to have implications for the effectiveness of print advertising. Future research should address television advertising where the richness of sound and evocative visual stimulation may produce stronger lower order affect and cognition from the viewer (Moore, Harris and Chen 1995).

It is interesting to note that Cinnabon™ is known for its seductive aroma which is an active part of the marketing strategy for that brand. In this study one of the items in the measurement of the associative network of memories asked specifically whether the 'memory of the aroma itself stimulated my cravings'. This suggests that the activation of that 'aroma' memory node may have caused the product description to function as an olfactory cue. The emotional and neurological response to an olfactory sensation is extremely swift leaving very little time for cognitive deliberation. According to Ehrlichman and Halpern (1988), this affect involves "minimal cognitive activity"-a type of affect that is "cognitively shallow" (LeDoux 1995). It is quite possible that this phenomenon may explain why hedonic rationalizations, and not cognitive delib-

erations mediated the influence of affect intensity on craving and desire.

# The Effect of Weather on Consumer Spending

Kyle B. Murray, University of Western Ontario, Canada
Adam Finn, University of Alberta, Canada
Peter Popkowski Leszczyc, University of Alberta, Canada
Fabrizio Di Muro, University of Western Ontario, Canada

## EXTENDED ABSTRACT

This paper analyzes the effect of weather on consumer spending. In particular, we propose that mood mediates the relationship between weather and consumer spending. We conduct three studies to investigate this relationship, and find that mood does indeed mediate this relationship. We utilize actual tea consumption, as well as willingness to pay for tea, as dependent variables in our studies. Tea is an appropriate product to use in order to test relationships between sales and weather because it is a neutral product. For instance, tea is the most widely consumed beverage after water, it can be found in over 80% of US households. In 2006, Americans consumed over 50 billion servings of tea, or over 2.25 billion gallons of tea.[1]

We begin by reviewing literature documenting the influence of weather on human behavior. For instance, research in finance (ie, Saunders, 1993; Trombley, 1997; see also Hirshleifer and Shumway, 2003; Goetzmann and Zhu, 2005) suggests that the weather may affect stock trades. Furthermore, ample research in psychology dicusses how weather influences peoples' behavior. Persinger and Levesque (1983) examined temperature, relative humidity, wind speed, sunshine hours, barometric pressure, geomagnetic acitivity and precipitation with respect to mood. Overall, they found that 40% of mood evaluations were accounted for by a combination of meteorological events; in particular, barometric pressure and sunshine had the greatest impact on mood. Other researchers have found that low levels of humidity (Sanders and Brizzolara, 1982), high levels of sunlight (Cunningham, 1979; Schwarz and Clore, 1983), high barometric pressure (Goldstein, 1972), and high temperature (Cunningham, 1979; Howarth and Hoffman, 1984) have all been associated with positive mood. In addition, Keller et al (2005) finds that weather's psychological influences are moderated by the season and the amount of time spent outside. Specifically, Keller et al (2005) found that pleasant weather improves mood in the spring because people have not experienced such weather during the winter months.

Although the influence of weather on behavior has been explored in fields such as finance and psychology, it has been largely ignored in the marketing literature. In fact, very little research has explored the association between weather and consumers' behavior. To date, the most direct evidence for the impact of weather on consumer behavior comes from Parsons (2001), who examines the impact that weather has on daily shopping behavior. However, he does not report sales data and, instead, focuses exclusively on the number of shoppers. More importantly, Parsons' (2001) data does not speak to the psychological mechanisms underlying the effect of weather on sales.

The effect of weather on consumer spending, as well as the influence of mood on this proposed relationship, has not yet been explored. We investigate this issue using a mixture of methods and types of data. First, we have collected daily sales data from a small retailer specializing in a single product category, along with the corresponding daily weather, over a six year time horizon, in order to examine the relationship between weather and consumer spend-

ing. Second we investigate the effect of weather on mood and consumption of the retailer's product and purchase behavior using daily panel data. Finally, we use a laboratory experiment to determine whether mood mediates the effect of (artificial) sunlight on willingness to spend on a product.

The results of the first study highlight the important effects of temperature, humidity, snow fall, and especially sunlight, in retail sales. The second study replicates the general finding of previous research, which indicates that sunlight affects mood, while simultaneously demonstrating that mood affects spending. The third study found support for the effect of sunlight on willingness to pay for a product that would be consumed sometime in the future, rather than immediately, and demonstrated the effect was fully mediated by negative affect.

Overall, the results of the studies reported in this paper provide strong evidence that weather can impact consumer spending. In particular, the observed effect of mood mediating the effect of sunlight–whether real or artificial-on consumer spending is of obvious relevance for the literature on the influence of store illumination on consumer shopping behavior. In this literature, the dominant theoretical model, the Mehrabian-Russell (1974) (M-R) model of approach-avoidance behavior, posits that the combined effects of pleasure, arousal and dominance influences people's behaviors in certain environments. Regarding lighting, the M-R (1974) model theorizes that brighter lighting increases arousal, and that the combination of pleasantness and arousal will positively influence consumers' shopping behaviors. Existing field research (ie, Summers and Hebert 2001; Areni and Kim 1994) has supported the M-R (1974) model of approach-avoidance behavior. Thus, the observed effect of lighting on consumer behavior is assumed to be mediated by arousal and pleasure. However, our results run counter to the M-R (1974) model. In particular, our results suggest it is not so much arousal nor pleasure, as the mitigation of negative affect, which explains the positive effect of high levels of illumination on shopping behaviors. Furthermore, our evidence is stronger than that of Summers and Hebert (2001), and Areni and Kim (1994), because we show that the positive influence of high illumination, caused by the mitigation of negative affect, actually influences consumer spending, while in Summers and Hebert (2001) and Areni and Kim (1994) work, the authors do not measure consumer spending.

# Mood Influence on the Valuation of Multiple Gains and Losses

Dorothea Schaffner, University of St. Gallen, Switzerland
Pragya Mathur, New York University, USA
Durairaj Maheswaran, New York University, USA
Andreas Herrmann, University of St. Gallen, Switzerland

## EXTENDED ABSTRACT

The present research studies subjective valuation focusing on people's preferences for integrating or segregating multiple gains and losses. For example, we investigate whether a gain of $200 in a lump sum is perceived as preferable to two segregated gains of $90 and $110. Preferences for integration or segregation are of interest because they reflect basic valuation processes. Inspired by Kahneman and Tversky's prospect theory (1979) a considerable body of literature investigates preference formation when people evaluate multiple gains or losses and comprehensively describes the preference patterns that result from hedonic evaluation processes (Linville and Fischer 1991; Thaler 1985; Thaler and Johnson 1990): People typically prefer segregated gains and integrated losses (Thaler, 1985). However, the prospect theory is relatively silent about the information processes that are employed for valuation and does not differentiate among determinants of value (Payne and Bettman 2004; Rottenstreich and Shu 2004). And although a growing body of research is devoted to the influence of mood on information processing, rather less attention has been paid to these influences in the context of the valuation of multiple gains and losses.

This research seeks to enhance the understanding of the influence of mood on preferences for segregated versus integrated gains and losses. Moreover, the heuristic-systematic model (Chaiken 1980; Chaiken 1989; Chen and Chaiken 1999) is employed to shed light on the information processing strategies that underlie preference formation in the context of valuation.

Extensive literature confirms that mood states influence information processing strategies and subsequent judgment and decision making (e.g. Bless et al. 1996; Martin et al. 1993; Schwarz and Bless 1991; Wegener et al. 1995). Principally, this research differentiates between informational goals (Bless et al. 1990; Bless et al. 1996) and mood-management goals (i.e. the desire to maintain positive or to repair negative mood states) (Wegener and Petty 1994; Wegener et al. 1995). While informational needs are found to induce systematic information processing, mood-management goals are suggested to trigger heuristic processing. In this sense, people face a complex dilemma between informational needs and mood management motives (Wegener et al. 1995). However, evidence on how the dilemma is solved and on the conditions that lead to the different effects of mood remains inconclusive.

Because of these inconsistencies in previous research the present research proposes the *hedonic valuation hypothesis* to predict the influence of mood on information processing and preferences for segregated versus integrated gains and losses. The hedonic valuation hypothesis attempts to reconcile mood-management theories (e.g. Raghunathan & Corfman, 2004; Wegener et al., 1995) defining the conditions determining mood-management goals.

The hedonic valuation hypothesis posits that a valuation by sadness and a valuation by happiness are both guided by mood-management goals. However, we propose that the mood-management goal is only elicited if the valence of the initial mood (i.e. negative) is incongruent with the valence of an event (i.e. a gain).

Sadness is associated with pessimism and depression and signals that something is amiss and induces the goal to seek for pleasurable stimuli to repair the negative affective state when evaluating a gain (Parrott & Sabini, 1990; Raghunathan & Trope, 2002). Therefore, when evaluating a gain, sad people are predicted to seek the more pleasurable outcome of segregated gains, processing information in a heuristic way.

Because gains do not threaten the positive mood of happy participants they do not sense a need to manage their mood. Therefore, happy people elaborate the information on gains by employing a more systematic way of information processing (Wegener et al., 1995), resulting in a lower preference for segregation. Recent research corroborates with that notion, suggesting that positive moods cause people to me more creative (Martin et al., 1993), to be more efficient in problem solving (Isen et al. 1987), and to bring more information to mind than negative moods (Mackie and Worth 1991).

The reversed logic applies for losses. The hedonic valuation hypothesis proposes that because losses threaten a positive mood, happy participants process the according information in a heuristic way (Wegener et al., 1995) and choose the less upsetting option, an integration of losses.

Sadness, in contrast, is related to depression and greater pessimism, leading to a preference for passivity (Raghunathan & Corfman, 2004). The hedonic valuation hypothesis proposes the preference for passivity causes sad people to process information on losses with neither acknowledging the heuristic cue, nor processing the information in a systematic way, resulting in a low preference for integration or segregation.

To test these predictions an experiment comprising 90 subjects was conducted. Confirming predictions based on the hedonic valuation hypothesis, results convey that mood-management determines information processing and preferences only if the valence of the mood (e.g. negative mood such as sadness) is incongruent with the valence of the event (e.g. a positive event such as a gain). This incongruence elicits a heuristic information processing and a preference for segregated gains and integrated losses, respectively. The interaction of a positive mood and a positive event – on the one hand – induces systematic processing, resulting in a relatively low preference for a segregation of gains. On the other hand, the interaction between a negative mood and a negative event leads to no specific mode of information processing, resulting in a relatively low preference for integrated losses.

This study extends past research by defining the conditions (incongruence between valence of mood a stimulus) that elicit mood management goals. Additionally, the present research adds to the existing knowledge on the conditions of mood influence on information processing. In the context of the valuation of gains and losses mood-management motives (Raghunathan & Corfman, 2004; Wegener & Petty, 1994; Wegener et al., 1995) seem to be more influential than the informational function (Bless et al., 1996) that mood conveys. Further, the present research helps to enhance the understanding of the psychology of valuation and the value function of the prospect theory (Kahneman & Tversky, 1979), showing that valuation depends for a large part on feelings.

# The Effect of Primed Reference Points on the Shape of Attribute-Value Functions, Attribute Importance, and Choice

Koert van Ittersum, Georgia Institute of Technology, USA
Joost M.E. Pennings, Maastricht University, The Netherlands

## EXTENDED ABSTRACT

### Introduction

One of the challenges of effective product positioning is to increase the importance of those attributes on which the product performs better than the competition and to decrease the importance of those attributes on which the product performs less than the competition. It is therefore imperative for marketers to comprehend the importance of attributes in judgment and choice (Van Ittersum et al. 2007; Wansink and Van Ittersum 2004). The importance of attributes in judgment and choice is driven by decision-makers' attribute-value functions. Attribute-value functions reflect the idiosyncratic valuation of an attribute at different attribute levels, relative to decision makers' reference points (Tversky and Kahneman 1991). Decision makers' reference dependence, loss aversion, and diminishing sensitivity determine the shape of value functions. As decision makers rely on their attribute-value functions in judgment and choice, the shape of value functions influences the importance of attributes in judgment, and choice (Van Ittersum and Pennings 2007; Van Ittersum et al. 2004). This research examines if, when, and how priming (internal and external) reference points influences the shape of attribute-value functions and as a result the importance of attributes in judgment, and choice.

Priming decision makers' *internal reference points*, reference points stored in decision makers' memory, prior to a judgment task is hypothesized to stimulate them to incorporate their internal reference points when constructing their attribute-value functions, triggering decision makers' reference dependence and feelings of loss aversion (Vaughan 1928). Accordingly, we hypothesize to find more *concave*, *convex*, and *S-shaped* (versus linear) value functions for *primed* decision makers prior to the judgment and choice task than for *unprimed* decision makers. With decision makers relying on their attribute-value functions in judgment, we further hypothesize that the primed reference points influence the importance of attributes in judgment, and choice.

Next, we propose that priming *external reference points*, reference points provided by external stimuli in a judgment and choice task, such that decision makers experience gains (losses) stimulates the construction of concave (convex) value functions. With decision makers relying on their attribute-value functions in judgment tasks, and convex functions being steeper than concave functions, the importance of an attribute among decision makers with primed external reference points representing a loss-prime is higher than the importance of an attribute among decision makers with primed external reference points representing a gain-prime. The choice likelihood of a product performing more favorable on an attribute with an external reference point representing a loss-prime is higher than that of a product performing more favorable on the same attribute with an external reference point representing a gain-prime.

These effects of priming are proposed to be moderated by the extent to which decision makers' attribute-value functions are well-defined, and will be stronger for decision makers with undefined value functions (Carlson and Bond 2006).

### An Empirical Study

To examine our hypotheses, we took a within-subject design approach by priming 201 participants' internal and external refer-ence points in two lab studies. In Study 1, the effects of priming internal reference points were examined for computers (attributes: price, working-memory size (Mb)). In Study 2, the effects of priming external reference points were investigated for cars (attributes: price, fuel efficiency (mpg)).

To establish the *shape of participants' attribute-value functions*, participants rated each product on ten levels of each of the two attributes. To estimate the shape of the value functions, the EXP-IPT technique is applied (Pennings and Smidts 2003). This technique fits the attribute-level valuations for each participant to both the negative exponential function (concavity/convexity) and the log of the inverse power transformation function (S-shape). Based on a pairwise comparison of the Mean Squared Error, the value functions were classified as either concave/convex or S-shaped.

To determine the *importance of attributes in judgment* in both studies, a full factorial judgment task ($2^4$ profiles) was employed. The importance of attributes was calculated by establishing the maximum difference in valuations for an attribute across all attribute levels related to product profiles and dividing it by the sum of the maximum differences of all attributes in the stimulus set. To study the effects of priming on *choice*, participants were asked to make a choice: Study 1 computer 1 ($500, 256 Mb), or computer 2 ($2,000, 1,024 Mb); Study 2: car 1 ($2,500, 9.5 mpg), or car 2 ($8,500, 30.5 mpg). To differentiate between participants with well-defined and undefined value functions, we use participants' knowledge about the product as a proxy for their experience with the relevant attributes and attribute levels (Hoeffler and Ariely 1999) (1=I do not know a lot about [*product*], 9=I know a lot about [*product*]).

To *prime internal reference points*, we stimulated half of the participants to write down the price and the size of the working memory of the computer they work most on prior to the different judgment tasks.

To examine the effects of priming external reference points, participants were randomly assigned to either the $-loss/mpg-gain or the $-gain/mpg-loss prime condition. In the $-loss/mpg-gain ($-gain/mpg-loss prime) condition, participants were informed that "the majority of college students purchase cars with an average price of $2,500 ($8,500) that drives an average of 9.5 mpg (30.5 mpg)."

### Conclusions

We find that priming *internal* reference points influences the shapes of attribute-value functions for decision makers with undefined value functions. Priming their internal reference points stimulates reference dependence and feelings of loss aversion in the value-function construction process. Consequently, more decision makers with concave, S-shaped, and convex attribute-value functions are found among the primed decision makers than among unprimed decision makers. When decision makers' internal reference points are not primed, they are more likely to construe linear attribute-value functions, particularly decision makers with undefined value functions. The effects of priming on the shape of attribute-value functions for decision makers with undefined value functions changes the importance of attributes, and choice.

Priming *external* reference points as gains (losses) also influences the shape of attribute-value functions, but only among decision makers with undefined value functions. Priming external

reference points as gains (losses) increases the likelihood that decision makers exhibit concave (convex) value functions. This effect of primed external reference points has a corresponding effect on the importance of attributes in judgment, and choice.

# Driving the Extra Mile: The Interplay between Psychophysics and Loss Aversion in Determining Consumer Search Intensity

Ritesh Saini, George Mason University, USA

## EXTENDED ABSTRACT

This research adds to the existing literature about digressions from optimal consumer search rules. Previously it has been demonstrated that consumers are (irrationally) influenced by relative-savings and not just absolute-savings in their decisions to extend searching for a better deal (Thaler 1980, Kahneman & Tversky 1981). This relative-thinking behavior has it's foundations in the Weber-Fechner law of psychophysics. But most of the studies demonstrating relative-savings behavior have focused on purchase situations devoid of historical reference prices. In real markets consumer's price perceptions, and the consequent search intensity, is likely to be influenced not just by relative-savings but also by how these prices compare to the historically-pegged reference prices in the consumer's mind. In this paper we demonstrate that search intensity is also influenced by whether prices are in a gain- or a loss-state relative to their internal reference prices. When prices are higher than the reference price, consumers are more likely to engage in extended search for a lower price, relative to when prices are lower, even when the absolute saving is the same. This is true for both riskless and risky search situations. This effect is strongest when prices under consideration are in the vicinity of the internal reference price. These findings are contrary to the "absolute-savings" predictions of economic theory and the "relative-savings" predictions of psychophysics. Also, while people have a good metacognitive understanding of the "absolute-savings" and "relative-savings" behavior, their understanding of the impact of loss aversion on search behavior is limited.

All the studies in this paper use a modified version of Thaler's (1980) classic search-willingness problem in which the consumer has an option of purchasing an item at a store or making a 10 minute trip to buy it at another store for $5 less. In the current paper the purchase item is always a tank-full of gasoline and the consumer can either purchase it at a default gas station on her way home, or drive an extra 10 minutes to purchase it from another station at a lower price. Being a frequently purchased item, most participants in these studies had a well defined reference price for gas (around $2.50/gallon). In Study 1, participants in one condition were told that the gas price is $1.79 (gain domain) while in the other condition, gas price was $3.29 (loss domain) at the default gas station. Participants in both conditions were asked (on a 7-point scale) about their willingness to drive to a discounted station and save 20¢/ gallon. Absolute-savings theory predicts no difference in either condition. Relative-savings theory predicts greater propensity to seek a 20¢ discount when the price is lower. However loss aversion predicts greater search intensity in the loss domain when the current prices are higher than the historical reference price. Participants were found to display greater search intensity in the $3.29 condition.

In both conditions in Study 1, the prices were in relative vicinity of the reference price. Given the marginally decaying shape of money's value function, loss aversion is likely to be strongest in this zone. At more distant points, where the value function is flatter, we hypothesize that loss aversion will have a diminished impact.

Study 2 explored price points more distant from the consumer's historical reference price. Besides just $1.79 and $3.29 (both proximal points), participants' propensity to seek a 20¢/gallon saving was also measured at more distant points: $0.79 and $8.29.

Similar to Study 1 results, loss aversion explained greater search propensity for $3.29 condition relative to the $1.79 condition. However, for price points more distant from the reference price, loss aversion's influence is diminished and relative-savings behavior drives search intensity. Consequently, search propensity for a 20¢/gallon saving was found to be greater when gas price was $0.79 than when it was $8.29.

Study 3 explored the consumers' metacognitive knowledge about this behavior. Participants were told about the setup of Study 2 and asked to predict the extent of search intensity in each of the four conditions. Most participants predicted behavior in accordance to the relative-savings theory for all four prices. Very few participants (< 5 %) predicted loss-averse behavior.

Study 4 looked at the prospect of risky search. Here extending search did not guarantee a better deal. Instead there was uncertainty associated with greater search. This meant that extending search was a risky decision. A 2X2 between-subjects design manipulated the (a) gain-loss domain and the (b) risky-riskless search context. As per the gain loss asymmetry, it was hypothesized that people will display greater risk tolerance, by extending search, in the loss domain ($3.29/ gallon) than in the gain domain ($1.79/ gallon), and this effect would be enhanced in the risky search condition. The results were along predicted lines.

# The Endowment Effect and Its Reversal: Examining Possession Loss Aversion and Focus of Attention

Mauricio Palmeira, Indiana University, USA

## EXTENDED ABSTRACT

The endowment effect (Thaler 1980), a well-known phenomenon in decision research, refers to people's tendency to demand much more to give up an object than they would be willing to offer to acquire it. This asymmetry in valuations of an object based on whether it is under one's endowment or not has been explained as a consequence of loss aversion (Kahneman and Tversky 1979). The basic idea of loss aversion is that losses have a greater hedonic impact than gains, so the pain of giving up an item is greater than the joy of acquiring it.

Recently, Brenner, Rottenstreich, Sood and Bilgin (2007) proposed a new psychological mechanism, termed possession loss aversion (PLA). PLA posits that the value of items leaving one's possession is exaggerated relative to the value of items entering one's possession. In other words, the value of an endowed item is exaggerated regardless of its valence, such that attractive items are perceived as more attractive, and unattractive items are perceived as more unattractive. As a consequence, PLA predicts the endowment effect for attractive items, but its reversal for unattractive items. Consistent with PLA, in a series of experiments, Brenner et al.'s results showed a tendency to keep attractive items, but to trade unattractive items.

There is another line of research that brings important insights to choices between unattractive items. Dhar and Simonson (1992) investigated the effects of having an option as the focus of attention in a comparison task. They showed that when two attractive options are being compared, simply making one of the options the focus of attention increases its preference. Conversely, Dhar, Nowlis and Sherman (1999) showed that when two unattractive options are compared, making an alternative the focus of attention decreases its preference. If one can argue that the endowed item receives greater attention than the non-endowed item, this focus of attention principle should predict the endowment effect for choice between attractive items and its reversal for choice between unattractive items, just like PLA.

In fact, this exactly what Carmon and Ariely (2000) showed. They argued that buyers and sellers focus on what each stands to forgo in an exchange, such that sellers are more sensitive to aspect of the item, whereas buyers are more sensitive to the expenditure. Although, they used pricing tasks, it seems reasonable to expect that this attention asymmetry would also occur in choice tasks, such that more attention would be paid to the endowed item (i.e. the item that one would forgo in a transaction).

Given that PLA and an attention-based mechanism predict the same pattern for choice tasks, more research is needed for a better understanding of this effect. In order to contrast the two theories, I turn to pricing tasks. Following one of the scenarios used by Brenner et al. (2007), consider two jobs that only differ in one aspect, such that one involves working on some weekends and the other does not. How much would one demand to switch to the job with the weekends requirement? How much would one offer to switch from the job with the weekends requirement? From a PLA standpoint, a negative item seems more unattractive when it is under one's possession, so people should tend to offer more to part with a negative item than they should demand to acquire it, as the

hedonic impact of items that leave one's possession are greater than the hedonic impact of items entering ones' possession.

At first, a prediction based on an attention-based principle might not be clear, as in one condition a person forgoes both money and the item, while in the other condition, the person receives both. In this case, for each person, there seems to be no difference in the amount of attention paid to the item and the expenditure. I propose that pricing of the negative items can be viewed in an alternative and perhaps more natural way. Reexamining the jobs scenario (and any other scenario involving pricing of an unattractive item), I argue that a person that is paying to part with the weekend requirement is actually buying his/her weekend time. Similarly, a person setting a price to accept the working on weekends requirement can be said to be selling his/her weekend time. In this sense, this scenario becomes a clear buying and selling situation and as such, buyers are expected to focus on the money and sellers on the item (weekend time). Considering weekend free time, instead of working on weekend requirement as the item being bought or sold, following an attention-based mechanism we should expect selling prices to be higher than buying prices.

Two experiments showed consistent support for an attention-based mechanism over PLA. In experiment 1, using the job scenarios described above, participants were willing to accept a 10.4% reduction in their salaries to part with the weekend requirement. On the other hand, participants required a 23.9% raise to accept the weekend requirement (z=4.23, p<.01). In experiment 2, participants were asked to consider a task consisting of a few hours of a tedious work as a punishment for losing a library book. Participants that could pay not to do the work were less sensitive to the amount of work ($18.9 vs. $36.7) than participants that would get paid to do the work replacing a friend ($30.0 vs. $98.9), F (1, 69)=10.0, p<.01. These results validate the proposed view of selling and buying time, as sellers were more sensitive than buyers to changes in the item (amount of work).

In conclusion, the present research suggests that the reversal of the endowment effect for unattractive items observed in choice tasks may be the result of heightened attention to the endowed item, which in turn decreases its attractiveness and not due to a psychophysical property inherent to how people make evaluations as suggested by PLA.

# Bipolar Scales Mask Loss Aversion

A. Peter McGraw, University of Colorado, Boulder, USA
Jeff T. Larsen, Texas Tech University, USA
Daniel Kahneman, Princeton University, USA
David Schkade, University of California, San Diego, USA

## EXTENDED ABSTRACT

Loss aversion (Kahneman & Tversky 1979), which is well established in choice scenarios, is commonly assumed to be due to the anticipation that losses will have a greater effect on feelings than equivalent gains (Ariely, Huber, & Wertenbroch 2005; Kahneman & Tversky 1984; Kermer, Driven-Linn, Wilson, & Gilbert 2006; Zhang & Fishbach 2005). But loss aversion has proved difficult to detect in judgments of feelings (Mellers, Schwartz, Ho, & Ritov 1997; Rozin & Royzman 2001). We argue that loss aversion is disguised in judgments of feelings because bipolar scales, which are typically used to measure evaluative judgments (e.g., attitudes, emotions, and moods), inhibit its detection. When a scale is bipolar, people rate opposite-valence outcomes separately on the positive and negative portions of the scale, so that positive and negative outcomes are not compared directly (see Marsh & Parducci 1978). We present response modes that encourage comparative processing across valence, as occurs in choices, and show that losses loom larger than gains in judged feelings. Loss aversion is better detected in judged feelings when the response mode implicitly encourages comparisons of negative outcomes to positive outcomes, and loss aversion is best detected when people explicitly compare the intensity of their feelings about an outcome to their feelings about opposite-valence outcomes in a manner similar to a choice process. Furthermore, when feelings are measured with a comparative response mode, the loss aversion detected in feelings accurately predicts loss aversion in choices.

In Study 1, we asked participants to imagine that they would play a gamble that had a 50% chance to win $200 and a 50% chance to lose $200. Participants judged how they would feel about winning the gamble and how they would feel about losing the gamble. Judgments were made on either a bipolar scale, a unipolar scale of intensity, which ignores valence and measures only the magnitude of feelings, or a relative intensity scale, which requires the explicit comparisons of feelings about opposite-valence events (e.g., Which outcome would have a greater effect on your feelings?). While loss aversion was not present in bipolar scale ratings, evidence for loss aversion was present in responses on the unipolar intensity scale, which implicitly encourages comparisons of the gamble outcome. The greatest evidence for loss aversion in judgments occurred for the relative intensity condition which involves a judgmental process that mirrors a choice process.

In Study 2, we replicated the differences in the detection of loss aversion for judgments on a bipolar scale versus relative-intensity scale for an equal probability gamble to win or lose $50. We also showed that (loss averse) judgments on the relative intensity scale predicted respondents' unwillingness to play the gamble. Bipolar scale judgments did not predict risk averse preferences, which incidentally, were the same in both response mode conditions.

Studies 3 and 4 extend our findings to non-monetary outcomes and address criticisms that loss aversion in judged feelings is an affective forecasting error (Kermer et al. 2006). We show that bipolar scales mask loss aversion and comparative judgment tasks reveal loss aversion for judged feelings about pleasant and unpleasant images from Lang et al.'s (1999) International Affective Picture System. Participants were shown sixteen images and were asked to judge the intensity of the affective reactions to the pictures on a bipolar scale and a unipolar intensity scale with a short break in between each measure (Study 3). Even when the scales were used within-subjects, participants judged the unpleasant pictures to be more intense and the pleasant pictures to be less intense on the unipolar (comparative) scale than on the bipolar scale. When the procedure was replicated with the same pictures for a bipolar scale and relative intensity scale, the findings were consistent with the conclusion that loss aversion in actual feelings was present in the comparative judgment task (Study 4). When pleasant and unpleasant pictures were assigned the same level of intensity on the bipolar scale, those same pictures were judged to be unequal on the relative intensity scale, with unpleasant pictures overwhelmingly more likely to be judged as more intense.

In summary, we show that bipolar scales tend to mask evidence for loss aversion in feelings because the scale discourages comparative judgments of intensity across valence. Respondents seem to use different sized category values for positives and negatives. Judged feelings show evidence of loss aversion to the degree people judge the intensity of a negative outcome relative to that of a positive outcome. Opposite-valence judgments that are more comparative resemble choice processes, which improve the detection of loss aversion in judgment. Moreover, the loss averse judgments in the comparative judgment task predict loss aversion in choices, whereas judgments on the bipolar scale do not. Finally, we show that loss aversion is evident in actual reactions to emotional stimuli, linking loss aversion to a more general phenomenon of negativity bias (see Cacioppo & Berntson 1994; Baumeister, Bratslavsky, Finkenauer, & Vohs 2001; Rozin & Royzman 2001).

# The Hungry Ghost Dinner and Auction: Real-World Auction, Other-World Meanings

Siok Kuan Tambyah, National University of Singapore, Singapore

## EXTENDED ABSTRACT

The Hungry Ghost Festival is celebrated in indigenous and diasporic Chinese communities around the world during the seventh month of the Lunar Calendar. The festival has several mythologies relating to its origins and religious significance. Traditional festivities have evolved over the years and have incorporated urban folklore and other cultural practices. In particular, for the Chinese community in Singapore, an integral event that has taken prominent place is the Hungry Ghost Dinner Auction (HGDA). The HGDAs are laden with socio-cultural meanings and exhibit immense economic potential and impact. With an estimated 200 events taking place over the entire month at about an average of S$30,000 spending per event, it is a multi-million dollar industry.

Given the recent interest in auction theory due to the proliferation of Internet auction sites, this paper seeks to enhance the understanding of the bidding behavior and the social interactions of bidders in a live auction setting, and the extent to which social and cultural goals influence the bidding behavior of auction participants. In particular, this paper asks the following research questions: (1) What motivates participants and bidders to attend and be involved in the HGDA? (2) What is the psychology of bidding when the final prices paid are exorbitantly higher than the economic value of the goods?

I first review the literature on motivations for attending auctions and the psychology on bidding. There are many reasons (economic, social, psychological and otherwise) for participation in auctions. In the literature on auctions, the phenomenon of overbidding has been frequently observed. In common value auctions, people may bid past their limits because they are using personal and social information to evaluate an item's value. The psychology of overbidding can be attributed to various factors such as the winner's curse, escalation of commitment and auction fever (or competitive arousal). The time-compression of decision making and the adrenaline-charged atmosphere combine to make live public auctions a crucible for highly emotional and fiercely competitive manifestations of bidding behavior.

The principal researcher and the research team visited over forty locations where the Hungry Ghost events were held over the duration of the lunar seventh month. These auctions represented diversity in terms of the scale of operations with tables ranging from twenty to two hundred (an equivalent of two hundred to two thousand guests). Ethnographic techniques were used for data collection. Organizers and participants were interviewed before and during the dinner and auction. The research team also observed the proceedings and took detailed fieldnotes which were further supplemented with photographs and videos. The textual and visual data were reviewed, organized and analyzed within each auction and across auctions. The research context is described with an emphasis on the auction mechanism and auction items. The funds raised in the current HGDA are used to organize the following year's HGDA, and successful bidders have up to a year to pay for the items.

Reasons like those suggested by Greenleaf (2004) such as getting a good bargain and paying prices lower than those at fixed price retailers do not exist in the HGDA as other social and emotional reasons for participating in the HGDA take precedence. The consensual and cooperative nature of the exchange is apparent in the case of the HGDA. Dinner guests and auction participants are first and foremost constrained by social obligations to attend the event. Showing up at the event means "showing face" to the important people in one's business and social community and an opportunity to return the favors of business associates. The HGDA participants who bid for such items are often able to enhance their standing in the community through the social visibility and prestige that such participation brings.

HGDA bidders appear to be paying exorbitantly high prices for the various categories of auction items. Although most of the HGDA items have some value outside the auction, these values are dramatically enhanced within the context of the HGDA. For example, a DVD player which retails for S$300 can fetch a final bid of S$600. A stack of twenty oranges that costs no more than S$10 from a neighborhood grocer is considered an auspicious item worth hundreds of dollars in bids when it is decorated with elaborate trimmings and prayed over by a priest

The construction of value takes place in a web of complex social relations as bidders are extensively influenced by others in the cultural context of the HGDAs. The effect of social facilitation is strongest because of the live auction setting and the social prestige factor involved. Bidders are happy to put in high bid amounts because they feel they are giving back to the community and fostering good business relationships. In addition to social facilitation, the participants believed that their decisions and actions have important cosmic influence. They are pleasing the gods, and helping to take care of the "good brothers" (i.e., the hungry ghosts). For participants and bidders at the HGDA, the auctions are more than a process of assigning values to material goods. For them, the symbolic value they derived is the social recognition they are accorded as being part of the real-world community and the satisfaction of performing the duty of compassion for the other-world community of hungry ghosts.

# Triggers of Extraordinary Experiences Within A Sub-cultural Consumption Event

Jeffrey Allen, University of Central Florida, USA
Carolyn Massiah, University of Central Florida, USA
Robert Cascio, University of Central Florida, USA
Zachary Johnson, University of Central Florida, USA

## EXTENDED ABSTRACT

Extraordinary experiences (EE'S) are extremely happy (Maslow 1961; 1970), highly enjoyable (Csikszentmihalyi 1990; 1997), and fully absorbing (Quarrick 1988) mental states of being that exceed consumers' day-to-day levels of emotional intensity. There has been growing recognition (McAlexander and Schouten 1998; Schouten and McAlexander 1995) that extraordinary experiences are influential in the formation and maintenance of consumption communities (e.g., Kozinets 2001; McAlexander and Schouten 1998; McAlexander, Schouten, and Koenig 2002; Muniz and O'Guinn 2001; Muniz and Schau 2005; Oliver 1999).

Extraordinary experiences involve absorbing, flow, and peak experiences. Privette (1983) demonstrates that peak and flow experiences have overlapping characteristics–included in these characteristics is absorption, which she describes as critical to full involvement and is "perhaps equally pertinent to enjoyment and peak experiences." (Privette 1983, p. 1363). In this study, we are not looking to differentiate between the three constructs–rather, we are looking at the common links between the three that tap into the construct of extraordinary experiences. The common characteristics between these constructs of interest to this study are happiness, enjoyment, fun, pleasure, involvement, and absorption (Privette 1983; Privette and Sherry 1986). To date, there is virtually no research on what facilitates extraordinary experiences in a consumption-related context. An understanding of what triggers extraordinary experiences would provide insight into consumption communities that goes beyond our current knowledge. The current study works to uncover triggers of extraordinary experiences.

Last year an estimated 200,000 plus bikers attended Biketober Fest (Daytona Beach Chamber of Commerce 2006) to celebrate the brotherhood of bikers. It is a male-dominated event that, as the name implies, revolves around motorcycles, specifically the Harley-Davidson brand. Many bikers return each year for the social activities which include: barbeques and pig-roasts, band concerts, wet t-shirt and bikini contests, women's mud and coleslaw wrestling, tattoo and "beer-belly" competitions, motorcycle races, and custom bike shows, among others. But more than offer hedonic activities, Biketober Fest was chosen for study because of its potential for extraordinary experiencing (Schouten and McAlexander 1995), representing one of the largest motorcycle rallies worldwide. These factors make this event an ideal context for this study.

Using a random street intercept on the most commonly-traveled thoroughfare, a representative sample of the biker population was obtained. Structural equations methodology (Joreskog and Sorbom 2003) was employed to test the hypotheses. Both exploratory factor analysis (EFA) and confirmatory factory analysis (CFA) were both completed with results as expected. The model's fit to the data is respectable [$c^2(193)$=255.50, p=.002; RMSEA=.035; GFI=.92; AGFI=.90; NFI=.92; NNFI=.97; CFI=.98].

Consistent with prior work on triggers of peak and flow occurrences (Csikszentmihalyi 1975; Laski 1961; Maslow 1971), the pursuit of cutting-edge knowledge facilitates EE's. Consumption events such as Biketober Fest enable attendees to discover the latest advances in bikes and custom bike-building first hand. Pursuing motorcycle knowledge also had a positive influence on biker camaraderie, the strongest relationship in the model. With so many bikers in attendance, the common interest that brings them together leads to social interaction where thoughts and ideas about bikes are exchanged.

Biker camaraderie had a direct positive influence on Biketober Fest participants' EE's. This finding is inline with other research (Csikszentmihalyi 1975; Lanier et al. 1996; Yeagle et al. 1989) suggesting that sociable interaction with others may help to facilitate EE's. The appreciation of others both during and after an extraordinary experience may also help to explain why comradeship and a sense of brotherhood are so strong within the biker subculture. To be acquainted with someone before striking up a conversation is not necessary. The strength of the subculture gives members the ostensible right to treat every other biker as a friend or brother.

Previous work (Laski 1961; Maslow 1971; Quarrick 1989) recognizes that sex or even the possibility of sex (Lanier et al. 1996) can trigger EE's. In this study, women's sexual openness had a direct influence on the EE's of Biketober Fest participants. Additionally, women's overt sexuality had a positive effect on bikers' sub-cultural values. It is reasonable that women's sexual openness reinforces a dominant set of values including male domination and sexual freedom (Schouten and McAlexander 1995). Maslow (1971) noted that individuals who experience peaks frequently perceive it as a kind of perfection, or close to it. Events like Biketober Fest may likely be perceived as approaching a kind of sub-cultural perfection that is consistent with bikers' preferred state of being (see also Csikszentmihalyi 1990; 1997) where men dominate and women are subservient.

Based on the rationale that common interests spark comradeship, women's sexuality was initially thought to have a positive influence on biker camaraderie. On the alternative, reciprocal relations were evaluated in favor of a model whereby the effects of sexuality and camaraderie are symmetrical. Some flashing we observed during data collection was clearly instigated by male bikers who encouraged women to bare their breasts. Sexuality, however, did not directly impact bikers' subcultural values when tested for significance. To further clarify relations between the constructs, several researchers adopted the role of participant-observer to document flashing incidents. While on two occasions women openly displayed their breasts with little provocation, multiple observers agreed that in most instances there was interplay between the bikers and women involved.

One remarkable characteristic of EE's is the self-centering that the individual experiences. The EE's of Biketober Fest participants had a direct positive influence on their belief strength in subcultural values. According to Schouten and McAlexander (1995), to be members of a consumption subculture they must believe in a common set of values. The finding that bikers' EE's at the event reinforced dominant values of freedoms and machismo provides quantitative support for their ethnographic findings on the biker subculture. Although previous research suggests a positive directional relationship resulting from these triggers (Privette 1983, McAlexander Schouten and Koenig 2002, Maslow 1970), we acknowledge the possibility exists that these are consequences of extraordinary experiences as well.

From a managerial perspective, consumption events designed to facilitate EE's can enhance brand loyalty and consumption frequency (Csikszentmihali 1975; Laski 1962; Maslow 1971). Pleasurable events designed to keep consumers apprised of advances in products/brands or provide piquant sexuality can trigger experiences that are extraordinary. Alexander, Schouten, and Koenig (2002) show that brandfests can enhance brand communities, lead to more positive relationships between consumer and product/brand/company/other consumers, and increase feelings of integration into the brand community. Absorbed in the activities, Biketober Fest participants enjoyed themselves and felt free to do what comes naturally. For bikers, many of these activities contain strong sexual overtones. We should note here that, although sex appeals are used to promote a variety of products/brands, but for some consumption communities (e.g., Marti Gras goers and Spring Breakers), sexuality this overt would probably be too intense.

Through events that facilitate EE's, a reciprocal set of benefits between consumers and the organization accrues over time. Alexander, Schouten, and Koenig (2002) show that Jeep has benefited in community-building efforts through high repurchase rates of participants. Harley-Davidson's involvement with the biker subculture provides a good example. Harley maintains a strong presence at Biketober Fest and similar biker events by staging and funding many activities and seminars. In contrast to a mundane daily existence, the emotional responses EE's generate are extremely desirable (Csikszentmihalyi 1990; 1997; Maslow's 1968) so consumers want to repeat them. The finding that respondents in the sample had attended the event an average of seven times lends support. In turn, the organization's product/brand is associated with the extremely positive emotions that consumers experience. More than purchase, consumers are likely to purvey their knowledge of the product/brand to close family members, friends, and other constituents.

# Procedural Priming and Consumer Judgments: Effects on the Impact of Positively and Negatively Valenced Information

Hao Shen, Hong Kong University of Science and Technology, Hong Kong
Robert S. Wyer, Jr., Hong Kong University of Science and Technology, Hong Kong

## EXTENDED ABSTRACT

When consumers search for information about a target product, they actively employ a search strategy that permits them to gather information efficiently and to construe its implications (Janiszewski, 1998). For example, they might first consider attributes that have favorable implications before other attributes that might disconfirm these implications. Alternatively, they might focus on unfavorable attributes and only later consider information that would qualify them. When consumers are unable or unmotivated to process all of the information they receive, the procedure they use to search the information is likely to influence their impression of its referent (Diehl and Zauberman 2005).

The present research examined the influence of a procedure's accessibility in memory on consumers' information search and their impression of the object. We expected that stimulating individuals to apply a particular strategy in searching for information in the course of performing one task would increase their likelihood of applying this strategy when processing information in a second, unrelated situation they encounter subsequently. The effect of applying this strategy in the second situation will be more evident when the motivation and ability to search for information is low than when it is high.

The information that consumers identify and use as a basis for evaluating a product may be influenced by both the concepts that happen to be accessible in memory and the type of search procedure they employ. In some instances, however, the effects of the two types of knowledge can be opposite in direction. It is therefore important to distinguish between the two types of knowledge and when their effects are likely to predominate.

In the first study, we manipulated both the search strategy that participants employed and the time they were given to apply it. Some participants were exposed to five products and are told to decide whether they would choose each product by circling either "yes" or "no". Others were told to indicate whether they would reject each product by circling one of these alternatives. Then, in an ostensibly unrelated shopping questionnaire, they were asked to form impressions of a computer described by 10 attributes. They were told that they would have either 15 seconds or as much time they liked to form their impressions.

Participants were expected to identify favorable attributes before considering unfavorable ones in the course of deciding whether to choose products in the priming task, but to identify unfavorable attributes before favorable ones in the course of deciding whether to reject them (Shafir 1993). Furthermore, these search strategies were expected to generalize to the product evaluation task they performed subsequently. When they did not have an opportunity to consider all of the attributes presented, therefore, participants were expected to evaluate the product more favorably in the first condition than in the second. When they had as much time as they wanted, however, this difference was expected to be minimal. The results of experiment 1 were consistent with these predictions.

Experiment 2 confirmed this conclusion using a different priming procedure. Participants rank ordered a set of product attributes either from most attractive to least attractive or from least attractive to most attractive. After that, they evaluate two products each described by 10 attributes. They had either 15 seconds or as much time they liked to form the impression.

Rank ordering attributes from most to least attractive was expected to activate a procedure of searching for positive attributes (Schwarz and Wyer 1985). Correspondingly, ranking attributes from least to most attractive should lead to greater weighting of negative attributes. These attentional biases were expected to generalize to the task that participants performed subsequently. This effect was expected to be evident only when participants did not have time to read all of the attributes. The results of experiment 2 confirmed this expectation.

In the third study, both concept and procedure accessibility were manipulated. In *procedural* priming conditions, participants were exposed to prices of the rooms available in 10 hotels in each of three cities. They were asked to rank the prices in each city either from highest to lowest or from lowest to highest. In *conceptual* priming conditions, participants only saw five prices of hotel rooms in each city. In some conditions, however, these were the five highest prices in the list that was presented under procedural priming conditions, and in other cases, they were the five lowest prices in the list.

Then, participants were asked to read over the prices of rooms in hotels of one city and try to form an impression of the average price of hotel rooms in that city. Participants in high information load conditions were asked to form an impression on the basis of 24 prices, whereas those in low information load conditions formed an impression on the basis of only six prices.

We expected that participants in procedural priming conditions would judge the average price of hotels in the second task to be more expensive if they had ranked prices in the first task from highest to lowest than if they had ranked them from lowest to highest. As in experiment 2, however, the effect should only occur when participants found it difficult to process all of the price information they were given. In contrast, we expected that participants in conceptual priming conditions would evaluate the hotels in the second task as less expensive when they had been exposed to high prices in the first task than when they had been exposed to low prices, and that this would be true regardless of the amount of information they were asked to consider (Adaval and Monroe 2002). The results of the third study confirmed these expectations.

The fourth study manipulated both procedure and concept in a different way. Similar to experiment 3, participants still ranked order prices from highest to lowest or from lowest to highest. However, although some participants ranked low prices, others ranked high prices. Again, participants evaluated the hotels in the second task as more expensive if they had ranked prices from highest to lowest. However, they evaluated the hotels as *less* expensive if the set of prices they had ranked were high than if they were low.

In combination, our studies demonstrated the effect of procedural knowledge on information search and impression formation. More importantly, the third and fourth studies provided one of the first demonstrations of the different effects of procedural priming and conceptual priming in a single research paradigm.

# Left-Right, Left-Right: The Effects of *Digit-Direction* On Eye Movement Bias and Price Encoding Strategy

Keith S. Coulter, Clark University, USA

## EXTENDED ABSTRACT

A number of studies in the behavioral pricing literature have examined the "greater-than-expected" demand associated with 9-ending prices (e.g., Schindler and Kirby 1997; Schindler and Kibarian 1996). Researchers have argued that this greater-than-expected demand is due to the use of a truncation (i.e., "rounding-down") price encoding strategy, which involves representing a price in memory in terms of its left-most digits only. The left-most digits are more likely to be remembered than the right-most digits because they are encountered first as prices are read from left-to-right, and because they represent the more valuable parts of the price information.

We argue that the rounding down of prices may depend not only upon the left-to-right processing of numeric digits, but also upon the "directionality" of digits. Directionality refers to the left or right-facing orientation of particular numbers-that is, consumers perceive these numbers as "pointing" or "facing" in a particular direction. We show that the digits 1, 2, 3, 4, 7, and 9 are perceived as "left-facing," 5 and 6 are perceived as "right-facing," and 0 and 8 are perceived as "neutral."

We further demonstrate that the perception of digit directionality may create eye-movement bias, which can lead consumers to direct their attention to the left or to the right of the specific digits employed. Eye movement bias is established through the use of a classic visual (optical) illusion (i.e., the Mueller-Lyer illusion). The M-L illusion consists of two lines which are equal in length-one of the lines has outward-facing "tails" on its ends, the other has inward-facing tails. The line with the outward (inward) facing tails is perceived as longer (shorter) than the one with the inward (outward) facing tails, because the eye tends to be pulled in the direction of the extraneous stimuli (i.e., tails), resulting in an over-(under-)estimation of length.

Research has demonstrated that the extraneous stimuli (tails) in the M-L illusion need not be inwardly or outwardly sloped lines; the effect is possible as long as the configuration of elements making up the characters exhibit non-symmetrical left-right variation (Coren 1986). Thus, in Experiment 1 we utilize combinations of left and right-oriented digits to correspond to the extraneous stimuli. A left-facing digit on the left and a right-facing digit on the right (e.g., $7-5) are substituted for the two outward facing extraneous stimuli, whereas a right-facing digit on the left paired with a left facing digit on the right (e.g., $5-7) are substituted for the inward facing stimuli. We find that the perceived physical distance between outward-facing prices is greater than the perceived physical distance between inward-facing prices. Our results lead us to conclude that digit direction creates eye movement bias, which influences physical distance estimations.

In the case of multi-digit prices, we expected that the eye movement bias resulting from digit directionality should influence the degree to which *contiguous* digits are attended to and encoded, thereby impacting price rounding behavior. We argue that bias toward (or to the right of) a particular digit should increase the likelihood that the digit is processed and encoded, whereas bias away from (or to the left of) a particular digit should decrease the likelihood that the digit is processed and encoded. As the likelihood of processing a particular digit increases, the likelihood of rounding that digit to the nearest whole number decreases. Results from a second Experiment confirm our expectations. The important practical implication of our findings is that digit direction can result in greater-than-expected demand for an item at a particular price.

We suggest that future research efforts should be directed toward investigating the effects of digit directionality on other price combinations; future research efforts might also employ eye-tracking devices to more directly confirm the theoretical eye-movement bias→attention→price truncation linkage.

# The Effect of Communication Norms on Interpretations of Meaningless Information

Alison Jing Xu, Hong Kong University of Science and Technology, Hong Kong
Robert S. Wyer, Jr., Hong Kong University of Science and Technology, Hong Kong

## EXTENDED ABSTRACT

Literally meaningless product attributes, such as "Yucca schidigera extract" in cleansing gel, are objectively uninformative and, therefore, should have no impact on product evaluations. In fact, however, consumers often assume that such attribute descriptions are both informative and relevant to the product being described (Carpenter, Glazer, and Nakamoto 1994). The present research examined the effects of these descriptions and their contingency on both (a) the source of the ad containing the descriptions and (b) consumers' knowledge about the type of product being advertised.

Print advertisements are often conveyed in magazines that target different readerships. For example, *You* is a popular magazine that aims to provide information about shopping, food and traveling that is of use to general readers. However, *Beauty Expert* is a professional magazine whose mission is to provide medical consultation to beauty specialist and beauty saloons. Consumers will hold a different normative expectation for the product information that is communicated by each source. Because *You* targets consumers at large, it is expected to communicate information that can be easily understood by ordinary consumers. Because magazines such as *Beauty Experts* target specialists, however, consumers may expect them to convey more complex product information that experts will find valuable.

When consumers read an ad from a professional magazine that contains literally meaningless information, they may perceive it as confirming their normative expectation that the magazine conveys complex and detailed product information. They may therefore attribute their inability to comprehend it to their lack of knowledge about the product category and may infer that it actually provides valuable and positive information about the product. If they encounter the same ad in a popular magazine, however, they may perceive the meaningless information as deviant from the norm. Then, they may attribute their inability to comprehend the information to the advertiser's intentions to be persuasive. As a result, they may discredit the information and evaluate the product negatively.

These differences, however, may only occur among consumers with relatively high knowledge about the product category, who can judge whether the meaningless information conforms to the norm or deviates from it. Unknowledgeable consumers may attribute their failure to understand the objectively meaningless information to their lack of familiarity with the type of product being advertised and may assume that it is meaningful regardless of the source. To this extent, this information may have a generally positive influence on their judgments. Furthermore, these consumers may also use the source as a heuristic. That is, they may evaluate the product more favorably when it is advertised in a professional magazine than when it is advertised in a popular magazine, and this may be true regardless of whether the ad contains literally meaningless information or not. To formalize these predictions:

H1a: When an ad is contained in a professional magazine, consumers will interpret literally meaningless information in the ad to be meaningful and will evaluate the product more favorably than they would if the ad did not contain this information.

H1b: When an ad is contained in a popular magazine, consumers will interpret literally meaningless information in the ad to be meaningless and will evaluate the product less favorably than they would if the information were not contained in the ad.

H2: These effects will be more evident when consumers are knowledgeable about the type of product being advertised than when they are not.

Two experiments evaluated these hypotheses. First, a pretest was conducted to select product categories about which participants had different amounts of knowledge. Males reported higher knowledge about *beer*, drank beer more often, and knew more real brands of beer than females did. Correspondingly, females reported having greater knowledge about *cleansing gel*, used cleansing gel more frequently and knew more real brands than males did. By using these categories in the main experiments and pooling over genders, the effects of participants' knowledge were determined independently of the type of product being judged.

*Experiment 1* verified the assumption that consumers hold different normative expectations for the messages communicated by different sources. We assumed that both knowledgeable and unknowledgeable consumers would expect a popular magazine to convey information that general consumers will understand, but would expect a professional magazine to communicate complex product information that only experts might appreciate. This was the case. Participants generally thought that the ad with meaningless information fit the professional magazine better whereas the ad without meaningless information fit the popular magazine better. In addition, knowledgeable participants interpreted the meaningless information to be meaningful when the ad was taken from a professional magazine, but as meaningless when the ad was taken from a popular magazine. In contrast, unknowledgeable consumers interpreted meaningless information similarly regardless of the source of communication.

*Experiment 2* determined the effects of these factors on product evaluations. Our hypotheses were again confirmed. When a product ad was ostensibly advertised in a professional magazine, adding literally meaningless information into the ad *increased* participants' evaluation of the product. In this case, consumers apparently interpreted the information as meaningful and favorable. When the ad was ostensibly conveyed in a popular magazine, however, adding literally meaningless information *decreased* consumers' evaluation of the product because consumers discredited both the meaningless information and the meaningful information. Moreover, these effects only occurred when participants had relatively high knowledge about the product category under consideration. Unknowledgeable consumers, however, generally liked products better when they were advertised in a professional magazine than when they were advertised in a popular one, regardless of the type of information conveyed.

In the first two experiments, the difference in consumers' objective knowledge about the product category and their subjective knowledge about it were confounded. *Experiment 3* avoided this confound by manipulating consumers' perceptions of their knowledge about the product category experimentally, indepen-

dently of their actual knowledge. The effects of subjective knowledge on reactions to meaningless information, and its contingency on the source of the ad, paralleled those observed in Experiment 2, indicating that subjective knowledge and not actual knowledge was responsible for these effects.

# Sunk Cost Effects in Consumer Decisions: Role of Anticipated Regret

Junsik Kwak, Dongseo University, Korea
Jongwon Park, Korea University Business School, Korea

## EXTENDED ABSTRACT

One should base one's decision on the incremental costs and benefits of undertaking any action. Thus, a prior cost or investment that already occurred in the past should not influence a current decision. Yet, it often exerts a strong influence. This "sunk cost" effect has been previously demonstrated in numerous settings (e.g., Arkes and Ayton 1999; Conlon and Wolf 1980; Garland 1990; Heath 1995; Moon 2001; Soman and Cheema 2001; Staw and Hoang 1995). The effect has been also demonstrated when the sunk cost is related to time as well as to money (e.g., Soman 2000). The present research attempted to extend the literature by examining various alternative mediating processes that might be responsible for the effect and identifying boundary conditions for the effect that have not been previously investigated.

Several explanations of the sunk cost effect have been proposed by various researchers (see Arkes and Blumer 1985 for a review). There are at least, five processes that are potentially responsible for the effect: *perceived cost of future action, perceived benefit of future action, anticipated regret from inaction, perceived wastefulness,* and *perceived justifiability*. The present research examined these alternative mediators in two ways. First, self-report measures of mediators were obtained and their mediation role was tested in covariate analyses. Second, a regulatory focus (promotion focus versus prevention focus) and regulatory fit, both of which were likely to influence the level of anticipated regret from inaction, were experimentally manipulated and their impact on the sunk cost effect was then examined.

Three experiments were conducted to examine the sunk cost effect in situations in which people who either had purchased an outdoor concert ticket (sunk cost conditions) or just obtained it for free (no sunk cost conditions) had to decide whether or not to attend the concert in an adversary situation (e.g., in a very cold weather). In addition to this sunk cost variable, Experiment 2 manipulated participants' regulatory focus, and Experiment 3 manipulated the regulatory fit between the regulatory focus (promotion focus versus prevention focus) and the frame of an ad message for the concert (fit versus non-fit).

Results from the experiments consistently showed a significant sunk cost effect. That is, participants in the sunk cost conditions were more likely to attend the concert, compared to those in the no-sunk cost conditions. This effect was true regardless of whether the dependent measure was a dichotomous variable (i.e., Y/N decision) or a continuous variable (i.e., intention ratings).

In addition, results from the experiments provided consistent support for the mediation role of anticipated regret from inaction. First, in all three experiments self-report ratings of anticipated regret from inaction were obtained and their mediation role was analyzed. Results indicated that the ratings were significantly higher in the sunk cost conditions than in the no-sunk cost conditions. Furthermore, controlling the ratings as a covariate eliminated the effect that the sunk cost manipulation had on decisions. This suggests that the anticipated regret was responsible for the sunk cost effect. Second, Experiment 2, which manipulated individuals' regulatory focus, showed that the sunk cost effect was significantly moderated by the regulatory focus. That is, the effect was restricted to conditions in which participants were promotion focused. This provides additional support for the mediation role of anticipated regret from inaction.

Experiment 3, which manipulated the regulatory fit between participants' regulatory focus and the message frame of an ad, showed that the sunk cost effect on decisions was more pronounced when there was a regulatory fit between the ad message and individuals' regulatory focus than when there was a non-fit. This effect was likely to be due to the increased level of anticipated regret in the former conditions, compared to the latter conditions. This suggests that the moderation effect of the regulatory focus found in Experiment 2 may not be simply due to the promotion nature of individuals. It may be rather due to the matches between the type of decision target (e.g., promotion vs. prevention-focused ad message) and the individuals' regulatory focus.

Finally, these and other results suggest that decision makers' anticipated regret from inaction is the reason for the sunk cost effect to occur. Theoretical and managerial implications of findings are discussed.

# The Perceived Value of Time in a Transaction

Yu-Tse Lin, Asia University, Taiwan
Lien-Ti Bei, National Chengchi University, Taiwan

## EXTENDED ABSTRACT

Prospect Theory (Kahneman and Tversky 1979) focuses on people's perceptions of monetary gains or losses. This theory has been applied to various marketing areas, such as reference pricing, purchasing choices, gift giving, and insurance purchases (Thaler 1985; Erdem, Mayhew and Sun 2001; Lemon and Nowlis 2002). Considering that searching and purchasing a product or service "costs" consumers' time (i.e., require time to accomplish) (Becker 1965; Zeithaml 1988; Okada and Hoch 2004; Leclerc, Schmitt, and Dube 1995), Prospect theory should be able to explain consumers' perceived values of time. Prior research has applied this theory to consumers' perceptions of wait-time (Leclerc et al. 1995; soman 2001). However, previous studies in this area all used scenarios and asked for the participants to recall their feeling of waiting. The current research argues that unlike money, judging the value of time is not a routine activity to consumers; the perceived value of time or the feeling of waiting is hard to retrieve accurately from memory. Therefore, an actual waiting scenario is created to test whether Prospect Theory is possible to explain consumers' perceived values of time during a transaction. In addition, consumers' perceptions may be different when they are in a hurry than when they are not in a rush. Past research indicated people are more concerned about time when they experience pressure from lack of adequate time (Schriber and Guteck 1987; Edwards, Baglioni, and Cooper 1990). Time pressure, then, is a covariate in the current research.

The value function of Prospect Theory has three major features. First, the value function is defined over perceived gains and losses relative to some natural reference point. Second, the value function is described as a concave line for gains and a convex line for losses. Third, the loss function is steeper than the gain function. As stated above, if one treats time spent on a purchase as a cost, then these three features of Prospect Theory may also be applied to consumers' perceptions of time in three ways. First, consumers feel happier, when the actual time they spend during a transaction is less than their expected time; whereas consumers are annoyed or frustrated when the actual time of a transaction is more than the expected time. Second, the marginal perceived value of saving time decreases as the magnitude of the time difference increases, while the marginal perceived loss of waiting decreases as the magnitude of the time difference increases. For instance, Ms. A, who wastes an extra 30 minutes while banking because a clerk suddenly left for lunch, should feel less unhappy than Mr. B, who waits 30 minutes due to two clerks leaving for lunch one after the other. The 30 minutes of extra waiting for Mr. B is separated into two sections since two clerks left, making it more annoying than Ms. A's experience, even though they both waited an identical 30-minutes. Third, the perception of a negative value (i.e., waiting a longer time) is larger than the positive value (i.e., waiting a shorter time) over the same time period. For example, Ms. C saves 15 minutes and Mr. D wastes 15 minutes: Mr. D's aggravation due to the experience of losing 15 minutes is likely to be greater than Ms. C's pleasure associated with gaining 15 minutes.

This experiment employed a computer program to simulate the wait-time in a bank. Participants were randomly assigned into one of four computerized experimental conditions: opened counters once, opened counters twice, closed counters once, and closed counter twice. The experiment consisted of a 2 (opened or closed counters) × 2 (once or twice) between-subject design. The depen-dent variable is the consumer's perceived value of time. The computer program simulated the waiting conditions in a bank as well as assigned numbers to indicate turn of service. After several virtual customers were served, participants built up an expectation for their wait-time which would be their internal reference point for further saving or losing time later. During the waiting process, one or two counters opened or closed to speed up or slow down the service. The feeling of gaining or losing time was then created.

A 2-way ANCOVA is employed on the data set of 93 respondents to examine the relationship between the gains or losses of time and the perceived value of time, with time pressure as the covariate. The results indicate that the three features of Prospect Theory are also applicable to consumers' perceived values of time. First, consumers' perceived value of time is defined as their perceived time gains and losses relative to their expected wait-time as the reference point. Second, consumers' perceived value of time is a concave line for gains and a convex line for losses. Third, the valance of consumers' perceived time loss is stronger than a perceived time gain. Furthermore, consumers' perceived values of time increase as the level of time pressure increases in both gain and loss conditions. In other words, when consumers are in a hurry, they are more sensitive to the time and the function of time is valued more highly than if time is not a factor or concern.

# The Mental Accounting of Gift Card versus Cash Gift Funds

Rebecca White, University of Chicago, USA

## EXTENDED ABSTRACT

While the popularity of gift cards has dramatically increased in recent years, there has been little investigation into how monetary gifts in the form of a gift card may lead consumers to spend and conceive of gift funds differently than if the gift were offered as cash. From a logical, economic point of view, consumers should treat gift funds equivalently, regardless of format (e.g., cash, gift card). However, research on the topic of mental accounting has demonstrated that equal funds are not always regarded, allocated, and consumed equivalently (e.g., Kahneman and Tversky 1984; Thaler 1985, 1999). The theory of mental accounting provides a broad description of cognitive processes through which people perceive, categorize, evaluate and engage in financial activities. Through the process of either literally or figuratively categorizing funds into budget categories, wealth accounts, and income sources, consumers typically treat assets within mental accounts as of non-fungible, or imperfectly transferable.

One relatively overlooked source of mental accounting effects involves the format in which funds are presented. When money is offered in a gift card format, the process of perceiving and evaluating how these funds should be used may qualitatively differ, and consequently the consumption of these funds may be influenced. The simple presentation of gift funds as a gift card versus cash may influence the primary income mental accounting of the funds themselves, which could in turn influence how the gift money is spent. However, consumption of funds may also be influenced by the payment mechanism through which the funds must be spent (e.g., Soman 2001). Gift card funds are typically more limited in their exchangeability compared to cash gifts, which may lead one use gift card funds differently than equivalent cash solely due to the practical restrictions of gift card funds. The current research was designed to address whether the presentation format of funds–specifically as a gift card versus cash gift–influences the manner in which these funds are regarded and consumed, as well as whether any fund format effects are primarily due to the influence of income mental accounting or to payment mechanism restrictions.

In the first experiment, the influence of gift fund format upon intended spending was examined. Participants were asked to imagine a scenario in which they received and spent either a cash gift, a gift card, or a gift card with a cash-back feature, all of equivalent monetary value. The participants were asked to report whether they would spend funds above and beyond the gift amount received in the scenario. When gift funds were presented as a gift card rather than as cash, individuals' likelihood to consume all of the gift funds was increased. When given a gift card, the participants were not only more likely to spend the gift funds, but also to spend additional funds from their current assets. When concerns about lack of fungibility and possible waste of unspent funds were removed by the cash-back gift card condition, participants were nevertheless significantly more likely to consume gift card funds than cash gift funds. Therefore, any increase in consumption resulting from the gift card format does not solely appear to be due to the effect of payment mechanism, or related concern about waste or inability to use the gift money. Rather, it seems that the simple presentation of funds on a gift card led to increased spending of those funds.

In the second study, the magnitude of this spending increase as a result of gift card format was examined. Participants were asked to imagine receiving a cash gift or an equivalently valued gift card, and were then asked to indicate whether they would intend to purchase a series of items on a shopping trip. When gift funds were presented in gift card rather than cash format, participants' reported amount of intended spending nearly doubled, and was significantly larger than the amount of the gift itself. In contrast, those asked to imagine receiving a cash gift reported an intention to spend nearly the exact amount of funds that they received as a gift, on average.

The third experiment was designed to determine whether differences exist in people's conceptualization of gift funds based upon their initial presentation format. Participants were asked to imagine spending a cash gift or a gift card, and asked to endorse their primary interpretation of their purchase out of a set of 3 monetary interpretation options (e.g., "I feel like I just spent $53.00 on a DVD set.") or a more symbolic option ("I feel like I have basically received a free DVD set as a gift."). Those in the gift card condition were significantly more likely to endorse the symbolic option than any of the monetary interpretations. Therefore, gift card funds may not always be categorized in monetary terms, and may often be viewed as possessing symbolic rather than monetary value (e.g., as a free DVD set).

Experiment 4 was designed to replicate and extend the previous results to a real-world examination of the impact of the format of gift funds. Participants in this study were asked to report their use of and thoughts about either a gift card or a cash gift they received over a recent holiday season. Compared to cash gift use, those who reported about gift cards spent significantly more than the gift amount at the time of purchase, gave a more positive rating of the gift that they received, and were more likely to spend the funds on hedonic rather than utilitarian purchases. Taken together, these experiments suggest that the presentation of a gift card rather than cash influences how gift money will be conceived, allocated within a person's mental accounts, and subsequently spent. As gift cards are claiming an increasing role in consumers' gift purchases and gift consumption, there are both theoretical and practical grounds for further investigation into how the presentation of gift card funds may influence consumer behavior.

# The Tri-Mediation Model of Persuasion: Incorporating Negative Advertising Appeals

Keith S. Coulter, Clark University, USA

## EXTENDED ABSTRACT

An on-going concern of advertising practitioners is the persuasive impact of their marketing communications. One of the most widely employed measures of persuasive impact is change in brand attitude (Ab). Consequently research attention continues to focus on describing the specific types of cognitive and affective responses to advertising that lead to brand attitude formation. The traditional "Dual Mediation" model (DMM), which has been well supported within the ad effects literature (e.g., Brown and Stayman 1992), models the effects of various constructs (i.e., ad cognitions, brand cognitions, and attitude toward the ad) on brand evaluations. However a weakness of the DMM is that it appears unable to model the effects of negative comparative advertising.

In this paper, we utilize a political advertising setting to re-define the traditional Dual Mediation Specification in order to model the effects of negative appeals. Because cognitive responses to a political advertisement can be directed toward either the sponsor or the opponent, and because these cognitions may act independently in terms of their influence on brand (sponsor) attitudes, we refine the brand cognitions construct to include both sponsor (i.e., CbSpon) and competitor or opponent (i.e., CbOp) components. Our modified version of the DMM results in three levels of mediation, and hence is referred to as the Tri-Mediation Model of persuasion, or "TMM."

We utilize an experimental setting to examine the impact of political ad type (positive, negative comparison, and negative attack) and argument strength (strong, weak) on the various paths and constructs in the TMM. Student subjects (n=359) were randomly assigned to one of the six conditions, viewed a target ad, and then filled out a written questionnaire.

We utilized structural equation modeling to analyze data. We find that *negative* thoughts about the ad sponsor's opponent or competitor can indeed have a *positive* effect upon attitude toward the sponsor. Our multiple-group analysis results indicate that if the message is strong, direct attack ads may be superior to either direct comparison ads or positive ads in generating favorable attitudes toward the sponsor. The reason for their effectiveness appears to lie in their ability to trigger the generation of a proportionately larger number of (negative) cognitions regarding the sponsor's opponent. These outweigh the relatively greater number of positive thoughts generated in regard to the sponsor, and the relatively greater salience of those thoughts in forming a sponsor evaluation in the case of positive or negative comparison ads.

Multiple group analyses further reveal that if the advertising message is weak, then direct comparison ads appear to be superior to either positive ads or direct attack ads in generating positive attitudes toward the sponsor.

Because our Tri-Mediation Model of Persuasion effectively incorporates thoughts about the advertising sponsor's competitor into overall sponsor evaluations, we are able, in effect, to utilize a *non*-relative measure of advertising effectiveness to assess the *relative* nature of a negative political ad. We demonstrate that a peripheral cue (attitude toward the ad) can have an impact on the central route to persuasion by fostering message acceptance not only in regard to the sponsor, but also in regard to the competitor (opponent).

# Permission to be Prejudiced: Legitimacy Credits in the Evaluation of Advertisements with Black and White Models

Beomjoon Choi,  California State University, Sacramento, USA
Christian S. Crandall, University of Kansas, USA

## EXTENDED ABSTRACT

Blacks are nearly 13% of the population in the U.S and they have substantial buying power. Consequently, advertisers have a real interest in attracting this market segment, and cannot fail to include Black models in their advertising messages. But given the relatively low frequency of Black models featured in commercials (Wilkes & Valencia, 1989; Williams, Qualls, & Grier, 1989), it appears that advertisers may be hesitant to use Black models. It is likely that advertisers may have real concerns about how White consumers may react to non-White models in their ads. This is especially a concern for high-value goods other than cars, in whose ads Blacks are highly unlikely to appear (Bailey, 2006). Why are there so few Black models in commercials, given that the research literature suggests that race has not been found to have an impact on viewers' responses (e.g., Whittler, 1989)? Although the research seems to indicate that Whites do not evaluate ads featuring Blacks differently from those featuring Whites, it may be that practitioners have found that ads featuring Black models are less effective in attracting consumers to buy their products—a result they have refrained from publishing, if not acting upon. In this article, we use a more subtle technique for demonstrating racial bias than has been typically used by marketing researchers for the assessment of models in advertising.

Most of the early research shows that White consumers do not respond negatively to advertisements or promotional materials featuring Blacks (Bush, Gwinner, & Soloman, 1974; Schilinger & Plummer, 1972; Solomon, Bush, & Hair, 1976; Bush, Hair, & Solomon, 1979; Tolley & Goett, 1972). In a long series of studies in marketing and social psychology, many studies have found little bias against Black by White participants, and often a bias in favor of Black targets (e.g., Devine, Plant, Amodio, Harmon-Jones & Vance, 2002; Whittler & DiMeo, 1991). But one must ask where the source of this apparent indifference lies. Is it because there is little or no prejudice affecting these decisions, or is it because White responses to ads with a Black model are carefully controlled, with prejudice and discrimination suppressed?

We suggest that evaluations of Black models in ads are determined by a complex mix of positive and negative feelings characterized by ambivalence. Crandall and Eshleman (2003) have proposed the Justification-Suppression Model (JSM) of the expression of prejudice. They argue that racial prejudice is usually suppressed, resulting in lower overt expressions of prejudice than is genuinely felt. However, because affect has motivational properties, people will seek a way to express prejudice, and justifications will allow overt discrimination. A justification is any process that can allow the expression of prejudice, without suffering sanctions, whether external or internal. There are many different kinds of justification, and they appear in many guises. One particular justification of prejudice expression is "legitimacy credits." Legitimacy credits are the memory of previous non-prejudiced behavior, which can be called upon to offset a subsequent release of prejudice. Legitimacy credits can be acquired by engaging in any overtly non-prejudiced behavior—by behaving positively toward a group, by having friends from the group, by smiling at group members on the bus, by buying a piece of art from a group member, or even by evaluating the group positively on a rating scale.

In the present study, we investigate how the acquisition of legitimacy credits affects the evaluation of the ads featuring Black and White models, by providing people a chance to gain legitimacy with a positive evaluation of a high quality ad featuring a Black model. Then, we measured people's evaluation of the subsequent mediocre ad with another Black model. In the pilot study, we use a between-subjects design, and seek evaluations of high or low qualities ads featuring Black or White models. Because the single-ad between-subjects method offers no acquisition of legitimacy credits, we expect no bias against Black model ads. Results show, when evaluating the ads, participants were highly responsive to the overall quality of the ad, but they were unresponsive to the race of the model. When employing this straightforward method, it might appear that this population of students lack prejudice, and do not discriminate on the basis of race. In Experiment 1, we introduce an opportunity to gain legitimacy. White participants first evaluate a high quality ad with a Black (legitimacy credits) or White (no credits) model. In Experiment 1, participants then evaluate a mediocre ad featuring either a Black or White model, anticipating that in the no credits conditions, participants will not show an anti-Black bias in evaluation, whereas the participants who first evaluated an ad with a Black model will, on a subsequent evaluation, show an anti-Black bias in evaluation. As expected, when people were provided an opportunity to positively rate a high quality advertisement featuring a Black model, they evaluated the target advertisement with a Black model more negatively than that with a White counterpart. Participants in the Suppression condition did not downgrade an ad with a Black model compared to an ad with a White model, but participants in the Legitimacy condition did— leading to a fairly strong preference for the White ad by White participants.

The present study investigated the impact of model's race on evaluation of advertisements and the underlying psychological mechanism. A favorable rating for one advertisement featuring a Black model may be sufficient justification to allow subjects to express their prejudice toward the target advertisement with a Black model. This study suggests that consumers' underlying psychological mechanisms to exposures of advertisements featuring Blacks, are subtle, complex, and multiply-determined. Whites will only release their attitudes into expression with there is some kind of justification for doing that. Any person looking for signs of racial prejudice must not simply go forward and ask—one cannot possibly trust a simple answer to a simple question in this context. As long as people are not permitted by the situation to release their attitudes without guilt or shame, they are not likely to express their genuine prejudice.

# The Role of Product Category Familiarity in Self-Referent Advertising

Claudiu Dimofte, Georgetown University, USA
Richard Yalch, University of Washington, USA

## EXTENDED ABSTRACT

Advertisers frequently encourage consumers to process ad information in relationship to specific aspects of their selves, such as traits and experiences (Burnkrant and Unnava 1995). The self-related elaboration of incoming stimulus information is presumed to result in more positive evaluations and superior message recall (Debevec and Romeo 1992). The present research proposes that consumer familiarity with a category is a limiting condition for self-referencing effects and suggests that memory intrusions is the mechanism by which this limit occurs. We attempt to explain how consumer knowledge and the temporal perspective of the self-referencing process (operationalized as the episodic and temporal dimensions of the self, respectively) jointly contribute to consumers' response to self-referent messages.

Retrospective self-referencing invites consumers to reminisce about past personal brand experiences, whereas anticipatory self-referencing encourages consumer-originated imagination exercises that promote favorable self-brand associations. Krishnamurthy and Sujan (1999) contend that both retrospective and anticipatory cases involve a self-referencing mechanism that is indissolubly linked to a memory matching effort on the consumers' part, particularly of the episodic memory variety.

A simple way of contrasting episodic and semantic memory is in terms of their elementary functions: episodic memory is concerned with *remembering,* whereas semantic memory is concerned with *knowing* (Tulving 1993). Similarly, consumers familiar with a product category are thought to have systematically acquired significant amounts of related knowledge that directly impacts their information processing patterns (Mitchell and Dacin 1996). Conversely, individuals less familiar with the product category have yet to develop this domain knowledge and are significantly impaired in terms of their depth of information processing (Alba and Hutchinson 1987). We therefore propose that:

H1: In self-referent advertising, consumers of low familiarity with the product category will predominantly exhibit episodic processing and consumers of high familiarity with the product category will mainly exhibit semantic processing.

H2: In self-referent advertising, amount of ad detail, consumer familiarity with the product category, and the temporal orientation of the ad will interact, such that: for consumers of low familiarity with the product category, attitudes toward ad and brand will be more (less) favorable under anticipatory self-referencing than under retrospective self-referencing in the high-detail (low-detail) ad; no difference is expected for consumers of high familiarity with product category.

*Study 1.* A first experiment employed a 2 (temporal orientation: retrospective and anticipatory self-referencing advertisement) X 2 (amount of ad detail: low and high) X 2 (familiarity: low and high, measured) random assignment design. Participants attended to a print ad that encouraged them to remember/imagine details of their own Florida vacation. Data provided substantial evidence toward the conceptually proposed role of consumer familiarity with the product category in self-referent advertising. First, it was shown that individuals more familiar with the product category tend to

have a detailed schema of their self-product interactions, leading to semantic processing of ad stimuli. Conversely, people less familiar with the category only rely on their occasional, specific instances of self-product interactions and therefore resort to episodic matching when processing. Overall, little support was found for hypothesis 2's prediction of a three-way interaction involving ad detail. Once the moderating role of consumer familiarity is accounted for, the effects of Krishnamurthy and Sujan (1999) are not evident.

*The Memory Intrusions Account.* Cognitive psychologists accept that both accurate and inaccurate source attributions can occur from heuristic processes that evaluate a mental experience. Pezdek et al. (1997) proposed that the success of planting false childhood memories will vary along the event plausibility dimension. This schema-based account argues that the likelihood of individuals' taking ownership of a suggested false childhood event increases whenever subjects possess relevant mental schemata for such events. Garry et al. (1996) showed that when adults imagined childhood events, these events were later judged as more likely to have occurred than events that were not imagined. The authors termed this effect "imagination inflation" and discovered that most people (in particular children) exhibit it. Imagination inflation after exposure to self-referent imagery would therefore be expected to occur more for individuals lacking the schema relevant to the imagined activity (low-familiarity processors) than for people who possess such generic knowledge.

H3: In response to self-referent advertising, consumer familiarity with the product category and the temporal orientation of the ad will interact such that under retrospective self-referencing more memory intrusions will occur for consumers familiar with the product category than for those unfamiliar with it, while under anticipatory self-referencing the intrusions pattern will reverse.

H4: In response to self-referent advertising, consumers' attitudes will follow the pattern described by the memory intrusions, such that under retrospective self-referencing, attitudes toward the ad and brand will be more favorable for consumers familiar with the product category than for those unfamiliar with it, whereas under anticipatory self-referencing the attitudes pattern will reverse.

*Study 2.* A second experiment employed a 2 (temporal orientation: retrospective and anticipatory self-referencing advertisement) X 2 (familiarity: low and high, measured) random assignment design. Participants were instructed to express their certainty that specific events had happened to them during the previous 15 years (Life Events Inventory 1), including taking a Delta Airlines commercial flight. Subsequently, they attended to a print ad that encouraged them to either remember or imagine details of their own Delta flight. Dependent measures were collected at the end. Three weeks later, an identical LEI was collected. Intrusions were counted as LEI2-LEI1. A two-way ANOVA found the significant interaction proposed in H3 on the number of memory intrusions. ANOVAs also found the significant interactions proposed in H4 on the attitude toward the ad and brand measures. Finally, mediation analyses showed that the effect of familiarity on self-referent attitudinal response was mediated by memory intrusions.

*Discussion.* A general practical implication for marketers addresses the need to match consumer product category familiarity with the specific type of self-referencing employed. This research also predicts that retrospective stimuli such as the "Remember the Magic" series of Disney ads are likely to be effective for consumers with frequent past visits to theme parks (not necessarily Disney-owned), while less so for occasional visitors. Conversely, Ford's "Imagine Yourself in a Mercury" promotional campaign will likely work better for first-time buyers, while less so for more seasoned consumers.

# The Impact of Narrative Immersion and Perceived Self-Character Similarity on Evaluations of Product Placements

Namita Bhatnagar, University of Manitoba, Canada
Fang Wan, University of Manitoba, Canada

## EXTENDED ABSTRACT

Where the place for companies to make product-related claims traditionally resided in spaces clearly allocated for promotional purposes (e.g., between programs), today, unambiguous delineations between programming and promotions are harder to come by. The use of product placements—where brands pay to make seemingly innocuous cameo appearances within media content and keep this sponsorship hidden (Balasubramanian 1994)—has gained in popularity over the past two decades. It is no longer unusual to encounter brands sharing space with characters within media narratives—e.g., *General Motors* vehicles that appear in the movie *Transformers*, the *Bulgari* jewelry brand embedded in author Fay Weldon's book *The Bulgari Connection*, and *Saab* cars within the television sitcom *Seinfeld*.

This rise in incidence of product placements—fueled by the need for revenues by production/publication houses and to break through the clutter of customary promotional practices by companies—has not gone hand-in-hand with an adequate understanding of their impact. Researchers have called for rigorous examinations beyond explicit brand memory and attitudinal effects of placements (Law and Braun-LaTour 2003). While contextual issues such as fit with the storyline, placement modality (e.g., visual/auditory, foreground/background) and audience-character attachments (Russell and Stern 2006) have been investigated, more needs to be done to understand how narratives that house placements are consumed as well as consequences for the narratives themselves. Further, academic scrutiny in the field of communications (e.g., Babin and Carder 1996) and marketing (e.g., Law and Braun 2002, Russell 2002) has primarily been limited to the context of TV and films. While these remain the biggest categories for placement expenditures, brand integrations frequently occur in media as diverse as music, radio shows, the Internet, videogames, books, magazines and newspapers. Outside of films and television, the highest proportion of brand integrations occur in magazines (PQ Media) that remain virtually unexamined within product placement research.

In this paper, we bring together research on narrative processing, persuasion, cognitive load and product placements to examine the role of narrative immersion and perceived self-character similarity on brand evaluations, narrative evaluations and persuasion knowledge in the context of brands embedded within magazine articles.

Though a long tradition of inquiry into audience-character relationships exists, this has only recently been applied to consumer processing of narratives within which placements occur. Further, persuasion research has primarily examined the persuasiveness of rhetorical product advocacy messages (e.g., ads). Consumers routinely encounter information in narrative form (by way of newspapers, magazines, TV and the like), yet the persuasive impact of narratives is not thoroughly understood (Green and Brock 2000). The idea of narrative transportation is the notion of losing oneself within a story (Gerrig, 1994). Research into narrative transportation has shown that mental immersion is persuasive (Green and Brock, 2000). Escalas (2004) found corroborating evidence within the context of advertisements that exhort audiences to "star" in positive hypothetical scenarios of product use. By bringing about mental transportation, the ads were able to lower consumers' critical thinking and heighten affective responses. This in turn led to more favorable evaluations of ads and brands. In salesperson research, Campbell and Kirmani (2000) find that cognitively busy consumers with less access to persuasion motives evaluate salespeople more positively. Along similar lines, we hypothesize that asking respondents to take the perspective of dissimilar characters should prove to be cognitively effortful. Thus, consumers should have fewer mental resources available to question the provenance of branded inclusions. Audiences that do not use their persuasion knowledge would therefore evaluate brands and the media content within which they appear more favorably. While putting ourselves into the shoes of people we consider as different may be a mental challenge, we have well-developed scripts and schemas related to our own lives and those of people we see as similar. Thus, identifying with experiences of similar characters should not be cognitively burdensome, and audiences should possess the cognitive capability for scrutinizing vicarious experiences and brand claims contained therein. Suspicions of ulterior persuasive motives should then temper brand as well as narrative evaluations.

We examined the joint effects of similarity and immersion on brand/story evaluations in a series of four laboratory experiments. Regardless of how similarity is manipulated across the first three studies, results consistently establish that the impact of perceived self-character similarity is moderated by the extent of immersion into the narrative. Participants, deeply immersed into the story, evaluated both the narrative and brand embedded within it more favorably when self-character similarity was low rather than high. A lack of immersion however led to stronger evaluations when experiences of a similar versus dissimilar character were described. In addition, persuasion knowledge was found to be greater when similar characters were used. In study 4 we employ implicit and explicit brand memory tasks to understand these results. As predicted, participants immersed into the story of a dissimilar protagonist performed better on (target and filler) brand memory tasks compared to a similar protagonist. We thus find initial support for a cognitive resource account of results obtained.

These results have important theoretical and practical implications. We contribute to literature on narrative processing and marketing communications by examining the impacts of character similarity and immersion on placement efficacy in print (magazine) media. Most prior research has been limited to understanding placement effects within television and film contexts and little research on been done on brand integrations within magazine media—a key venue with high placement expenditures. One limitation of this, and previous, research is that companies rarely use product placements in isolation and placements seldom appear within a single medium. For example, the portfolio of promotions used to launch BMW's *Z3 Roadster* spanned appearances within the movie *GoldenEye*, cross-promotions of the car with the movie, and public relations appearances by actors. Further, brands integrated within Rachel Ray's cookbooks also appear on her television show *Day to Day with Rachel Ray* and her magazine *Every Day with Rachel Ray*. We propose to examine the joint effects of different forms of marketing communications across media in future research.

# Anti-consumption: Now on Sale

Ahir Gopaldas, York University, Canada

## EXTENDED ABSTRACT

This research uses theories of market mythology (Levy 1981; Holt 2004; Holt and Thompson 2004; Thompson 2004) to illuminate how and why an anti-consumption lifestyle (voluntary simplicity) is being refashioned into a contemporary consumption phenomenon (simple living). Voluntary simplicity is defined as a lifestyle of minimal, ethical, and ecological consumption (Gregg 1936; Leonard-Barton 1981; Elgin 2000; Craig-Lees and Hill 2002; Shaw and Newholm 2002; Zavestoski 2002; Etzioni 2004; Grigsby 2004; Bekin, Carrigan, and Szmigin 2005; Huneke 2005; McDonald et al. 2006; Miller and Gregan-Paxton 2006). An integrative literature review highlights the antecedents (access to wealth and education), manifestations (reduction of consumption relative to societal norms), and consequences (sense of control and self-sufficiency), and the long historical legacy of the lifestyle.

Simple living is conceptualized as a market mythology consisting of select strands of the voluntary simplicity ideology detached from the practice and diluted for the mass market. The simple living market mythology is delineated in three steps. First, a meta-analysis of historic essays and recent ethnographies is conducted to identify the major themes in voluntary simplicity discourse. Second, a popular lifestyle magazine, a recent blockbuster movie, and informant narratives are analyzed for major themes in the simple living discourse. Third, the voluntary simplicity and simple living themes are compared and contrasted.

While eight myths are identified in the voluntary simplicity discourse, only six of those are retained in the simple living discourse: the myth of less, the myth of consumer goods and consumption activities as pathology, the ecological and ethical mythology, the myth of work-life balance and the demythologizing of money, the myth of individual agency, and the myth of community loss and gain. The two missing myths are also of considerable theoretical interest: the myth of modern cities and technology and the myth of exemplary citizenship. First, while many simple-living advocates have promoted rural living (e.g. Thoreau) and opposed modern technology (e.g. the Amish), the contemporary market mythology does not appear to take a firm stance on either subject. Rather, individuals are encouraged to find simplicity in their own context, wherever that may be geographically, and discourse about technology is rare and vague. Second, exemplary citizenship for the public eye is a theme that runs through some historical texts; for example, Gandhi famously declared, "My life is my message." However, the emphasis on living simply as a personal statement or identity project is absent in contemporary iterations of the mythology. The universality of decentered subjects and their consumer identity projects in postmodernity (Firat and Venkatesh 1995) might yield one explanation: since all consumers (simplifiers and non-simplifiers alike) are presumably engaged in continuous identity work, the significant differences between the subcultures may lie in the *how*, not the *whether*.

Market mythologies, like that of simple living, can be put to work in advertising and entertainment. The simple living magazine analyzed for this research focuses on 'simple' cooking, decorating, housekeeping, fashion, and personal grooming. A major retail chain advertisement for personal electronics claims to clear the clutter of consumer choices by making the choice for the consumer in each product category. The paradox that the ad uses simple living discourse (i.e. clearing the clutter) toward persuading consumers to buy more electronics is presented without any irony. Hirschman (2000) finds that movies that address mythic tensions have considerably greater commercial success. The movie analyzed for this research is devised around the tensions between materialism and simplicity. While simultaneously looking for a slower-paced, values-driven job in journalism, a highly-educated, middle-class, woman is accidentally thrust into a high-profile, high-stress, round-the-clock, consumption-focused career in fashion. The pathology of consumption, the search for work-life balance, and the eventual triumph of individual agency are core mythic themes of the film.

# A Qualitative Study of Mother-Adolescent Daughter-Vicarious Role Model Consumption Interactions

Yossi Gavish, University of Haifa, Israel
Aviv Shoham, University of Haifa, Israel
Ayalla Ruvio, University of Haifa, Israel

## EXTENDED ABSTRACT

### Conceptualization

The traditional paradigm in marketing views parents as role models for their children in the consumption domain (Clark et. al 2001). This paradigm is based on the perspective that experienced parents serve as a primary source of information for their children. However, in today's Western cultures, an ever-increasing emphasis on a youthfulness ideal may cause a shift in role modeling, making children potential role models for their parents. Struggling to feel, look, and behave youthfully, parents might perceive their children as experts/role models.

Women engage in youthfulness-oriented activities and annually spend $3000 more than men to stay young (Weiss 2002). Additionally, maturing women seek reaffirmation of their self-concept of youthfulness as a normal, healthy, positive, and acceptable image of aging (Barak and Stern 1985). They recalibrate their inner age scale to make youth the most important and tend to adopt consumption patterns fitting a younger cognitive rather than chronological age. Integrating a youth ideal with lower cognitive ages may lead mothers to view their daughters (especially adolescents) as role models in certain consumption situations. Consequently, the mother-daughter dyad may serve as a preferred unit of analysis (Moore et al. 1988). Additionally, vicarious role models, such as celebrities, can impact both mothers and their adolescent daughters' consumption behaviors.

This paper develops and qualitatively evaluates an integrative perspective on consumption interactions of mothers, adolescent daughters, and vicarious role models. These interactions are studied using three theoretical frameworks (consumer socialization, intergenerational influence, and role models) and focusing on the influence of adolescent daughters on their mothers' self-consumption.

The first framework, consumer socialization, suggests that parents serve as socialization agents to their children through consumer learning (Moschis and Churchill 1978; Caruana and Vassallo 2003). Though consumer socialization provides insights on how children acquire motivations, attitudes, and behaviors about the marketplace (Carlson et al. 1994), it has focused mainly on a uni-flow of socialization from parents to their children.

The second framework, intergenerational influences (IGI), refers to the within-family transmission of information, beliefs, and resources across generations (Moore et al. 2001). Although studies under this framework have emphasized mostly information transmission from older to younger generations, it can also explain adolescent daughters' influence on their mother's consumption, adding a dimension to socialization theory.

The third framework, role modeling, deals with the impact of role models on individuals' consumption behavior (Bush and Martin 2000; Clark et al. 2001). Any person individuals have direct or indirect contact with, who can potentially influence their behaviors can be a role model (Bandura 1977). Given Western cultures' increasing emphasis on youthfulness (Thompson and Hirchman 1995), adolescent daughters and their mothers might use similar consumption role models (e.g., celebrities) for expressive products, which are consumed to fit one's personality and lifestyle and to make favorable social impressions (Shah and Mittal 1997). Thus, the approach developed here extends beyond the mothers–adolescent daughters relationships.

Children's influence on family consumption decision-making, children's socialization, IGI, and role models have been researched before. In combination, these frameworks could explain if, when, and how adolescent daughters impact their mother's behaviors for products that are relevant to and used by the mothers. To the best of the authors' knowledge, this combined approach has not been studied before. The frameworks are described first. Then, the results of a qualitative study, conducted to assess the consumption interactions are presented and discussed.

### Method

The study was qualitative and exploratory and included in-depth interviews with dyads of mothers and their adolescent daughters. The mothers and their adolescent daughters were interviewed separately in order to avoid bias in their answers. Three issues were examined: if and when adolescent daughters serve as role models for their mothers; if and when mothers serve as role models for their adolescent daughters; and whether the youthfulness ideal of Western cultures exists and influences the consumption behavior of mothers and their adolescent daughters. Ten dyads of mothers-adolescent daughters were used as the study's sample.

While a convenience sample was used, the dyads included mothers and daughters at different ages (daughters: 15.5-18; mothers: 39-51), from different social strata (low to high), and in different geographical locations (two cities in Northern/Central Israel).

### Major Findings

Three issues were examined: whether adolescent daughters serve as role models for their mothers; whether mothers serve as role models for their adolescent daughters; and whether the emphasis of youthfulness in Western cultures exists and influences the consumption behavior of mothers *and* their adolescent daughters.

The interviews partially answered these questions. Regarding adolescent daughters' use as role models and fashion markers for their mothers, most mothers referred to this issue and confirmed that their adolescent daughters' fashion opinion was very important. This is compatible with Zolo (1995), who suggested that teenagers serve as trendsetters for their parents. The second question, drawing on the consumer socialization literature, asked if and when mothers serve as role models for their adolescent daughters. This question was answered positively. Most interviewed dyads shop for fashion items together *and* in the same stores. Moreover, many adolescent daughters occasionally borrow their mothers' fashion items.

Regarding the issue of cognitive versus chronological ages, the interviews suggest that there is a gap between mothers' cognitive and chronological ages in support of cognitive age theory and the youthfulness ideal of Western cultures. Notably, such a gap

mostly failed to materialize for adolescent daughters. Hence, consumption similarity appears to be driven more by the gap for mothers than the gap for daughters.

Finally, external role models such as celebrities did not have a great influence on mothers or their adolescent daughters. Thus, the cognitive ages' gap, which is narrower than the cognitive ages' gap, did not lead to the use of shared role models. While a convenience sample was used, the dyads included mothers and daughters at different ages (daughters: 15.5-18; mothers: 39-51), from different social strata (low to high), and in different geographical locations (two cities in Northern/Central Israel).

# Intergenerational Influence in Consumer Deal Proneness

Robert M. Schindler, Rutgers University-Camden, USA
Vishal Lala, Pace University, USA
Colleen Grussenmeyer-Corcoran, U.S. Vision, Inc., USA

## EXTENDED ABSTRACT

Given the importance of promotional deals as a marketing technique, there has been considerable interest in deal-prone consumers–consumers who show an enduring propensity to respond to such deals. While the demographic characteristics (e.g., education, income) and behavioral characteristics (e.g., brand loyalty) of deal-prone consumers have been studied (Bawa and Shoemaker 1987a, 1987b, 1989; Schindler 1998), little attention has been given to the factors that cause an individual to develop into a deal-prone consumer. In this paper, we examine the role played by parents in influencing their children's deal proneness.

Children acquire habits, skills, knowledge, and attitudes relevant to functioning in the marketplace by the process of consumer socialization (Ward 1974). The socializing factors include parents, peers, institutions (e.g., school), mass media (e.g., television, radio), and the web (John 1999; Meyer and Anderson 2000). Of these factors, the "intergenerational influence" of parents has been identified as a particularly important force (Heckler, Childers, and Arunachalam 1989; Moore, Wilkie, and Lutz 2002). Indeed, researchers have found intergenerational influence to play a role in children's brand preferences (Moore et al. 2002), skepticism towards advertising (Obermiller and Spangenberg 2000), innovativeness (Cotte and Wood 2004), values and orientations such as value consciousness and convenience orientation (Mandrik, Fern, and Bao 2005), preference for shopping goods (Heckler et al. 1989), and online shopping preferences (Lueg et al. 2006). However, there is considerable variation in the extent of this influence. Previous research on intergenerational influence indicates that at least four characteristics of deal-prone behaviors make deal proneness particularly well suited for transmission from parent to child. (1) Deal-response behaviors, such as coupon clipping and buying products on sale, are particularly visible and salient behaviors that offer a child ample opportunity to learn by observing (Childers and Rao 1992; Moore and Lutz 1988). (2) Deal-response behaviors are concrete as compared to attitudes, which tend to be more abstract (Hoge, Petrillo, and Smith 1982; Mandrik et al. 2005). (3) Deal-response behaviors may be viewed as routine activities performed with little thought (Heckler et al. 1989). (4) The high frequency with which deal-response behaviors occur provides a child with numerous opportunities to learn by observation. Since children are likely to learn specific deal-response behaviors, such as using coupons, rather than a global trait of deal-proneness, parent-child similarity should also exist for interest in particular types of promotional deals, such as using coupons or buying items on sale.

In Study 1, 265 student participants responded to a questionnaire containing a set of items measuring their deal proneness, their attitude towards their parents' shopping habits, their exposure to parental shopping behavior, their perceptions of the deal proneness of their family members, and some basic demographic characteristics. Results indicated that the respondents who reported their parents as being deal-prone had higher deal-proneness scores than the respondents who did not report their parents as being deal-prone. This effect is robust in that it does not interact with the respondent's gender, age, or whether or not he or she lives at home. Further exploration of this result showed that children with parental shopping exposure during teenage years had higher deal proneness scores than those who did not report exposure during their teenage years.

Whereas Study 1 relied on adult children's perception of their parents' deal proneness, Study 2 involved asking parents to directly report their own deal proneness. A deal-proneness measure was obtained from each member of 83 parent-child dyads. Analysis of these measures revealed a significant parent-child correlation, which indicated a similarity in level of deal proneness. We also observed a substantial similarity in the pattern of deal-type preferences between parents and their adult children. To determine the statistical significance of the parent-child similarity in deal-type preference, we used the logic of a permutation test. We created 10,000 random parent-child dyads to produce a sampling distribution of mean deal-type preference correlation coefficients. The position in this sampling distribution of the mean deal-type correlation coefficient of the real parent-child dyads indicated that our observed parent-child similarity in pattern of deal-type preferences is far greater than would be expected by chance alone.

Further analysis of Study 2 results showed that parent-child deal-proneness correlations for children with teenage parental shopping exposure were positive and significant, but parent-child correlations for children without teenage parental shopping exposure were not significant. Finally, we unexpectedly found parent-child deal-proneness similarity when parent and child were of opposite genders but not when they were of the same gender.

The findings of these two studies provide several lines of evidence that support the role of parental influence in the development of deal proneness in young consumers. The first line of evidence is that young adults and their parents show similarity in the extent of their deal proneness. This was demonstrated using a perceptual measure of parental deal proneness in Study 1 as well as using, in Study 2, the more rigorous method of administering a multi-item deal-proneness measure separately to each member of the parent-child dyad.

A second line of evidence is that young adults and their parents show similarity in their preferences among particular types of promotional deals. It should be noted that this is indeed a second line of evidence. It could have very well been the case that young adults and their parents show similarity in a general predisposition toward promotional deals without showing any similarity in their preferences for, say, cents-off coupons over advertised discounts.

A third line of evidence supporting the role of parental influence in deal proneness is the demonstration that several parent-related factors that would plausibly affect the degree of parental influence do in fact moderate the extent of parent-child deal-proneness similarity. Studies 1 and 2 were consistent in showing the importance of a child's exposure to parental shopping during the child's teenage years and the importance of a child's attitude toward the parents' shopping habits. Study 2 provided evidence for a relation between parent-child gender similarity and the degree of deal-proneness similarity, albeit in the direction opposite that which was anticipated. In all, these two studies provide considerable evidence that parental influence plays an important role in the development of consumer deal proneness.

# Not Me or Not Them?: The Role of Culture in Discrepant Effects of Health Communication on Self and Others

Sukki Yoon, Bryant University, USA
Ashok K. Lalwani, University of Texas at San Antonio, USA
Patrick Vargas, University of Illinois at Urbana-Champaign, USA

## EXTENDED ABSTRACT

Consumers these days seem increasingly health conscious (e.g., Niknian, Lefebvre, & Carleton, 1991). This belief is well reflected in various marketing communications in both the commercial (e.g., Burger King's low-carb menu) and social (e.g., the "Truth" anti-smoking campaign) domains. Ironically, although today's consumers are perhaps more health conscious than they used to be, they may not be notably healthier than their previous generation. Indeed, some indicators point to the opposite: according to a recent report from National Center for Health Statistics [NCHS], nearly a third of U.S. adults (31%) were obese in 2002, more than double the 15% in 1980. Quite interestingly, however, Americans consider this a serious national problem, but less an individual problem, as a recent survey reports that 90% of American adults think that most Americans are overweight, but 70% think that "the people they know" are overweight, and only 39% think that they themselves are overweight (Pew Research Center, 2006).

This distorted view of self (vs. others) is not surprising, as numerous studies have demonstrated that people tend to maintain an enhanced evaluation of the self (e.g., Gilovich, 1983). What is noteworthy is that this self-other gap may be culturally universal, yet the direction of the discrepancy appears to be culture-specific, sometimes very different between collectivists and Caucasians. That is, unlike Western Caucasians, Eastern collectivists' self-views are sometimes negatively biased (e.g., Heine 2005; for opposing views see Sedikides, Gaertner, & Vevea, 2005). This article explores this self-other gap on the health consciousness dimension, a variable that has not been investigated elsewhere in a cross-cultural context.

A stream of research has addressed the health disparity among diverse racial groups by investigating the inequalities in various health indices such as mortality, smoking, alcohol use, obesity, blood pressure, cholesterol, and physical inactivity. In those studies subgroups were typically defined based on socio-economic status (SES), combining a variety of demographic data (e.g., race and county of residence). These SES studies did help health care providers practically (e.g., identifying who is in most need of care), yet did not offer a clear explanation for the phenomenon. An interesting report by Murray et al. (2006) provided compelling evidence for which subgroup is better (worse) off than other groups in terms of a range of health indices. Analyzing twenty-year longitudinal data from the Bureau of the Census and the NCHS data, Murray et al. (2006) concluded that Asian Americans have a lower risk of major fatal diseases (e.g., cancer and cardiovascular diseases) and higher life expectancy than the other seven comparison groups.

The first question arises: Asian Americans appear healthier than other Americans, but do their perceptions accurately match reality? We propose that the self-health consciousness bias (i.e., the tendency for people to believe that they are more health conscious than others) observed among Americans predominantly mirrors American individualism, so the same bias should not emerge among relatively collectivistic Asian populations. We further extend this argument to a broader context by looking at different cultural indices and demonstrate that collectivists in general tend to believe that they are less health conscious than others, whereas Caucasians perceive themselves to be more health conscious than others. Consistent with this proposition, we ask the second question that is of practical interest for social marketers: do Caucasians and collectivists perceive health communications as more or less persuasive to themselves (vs. others)?

H1: Collectivists will perceive themselves to be less health conscious than others, whereas Caucasians will perceive themselves to be more health conscious than others.

H2: Collectivists would perceive health campaign messages to be less influential on themselves than others, whereas Caucasians would perceive the same messages to be more influential on themselves than others.

Study 1A presented the data in line with our hypothesized framework and showed that Caucasian Americans significantly perceive themselves to be more health conscious than others, whereas if anything, the opposite is true for Asian Americans.

Study 1B showed that Koreans believe their families and friends to be more health conscious than themselves, and thus are more likely to take actions recommended in anti-smoking advertising. However, Americans reported the opposite: their families and friends are less health conscious than they themselves are, and thus less likely to take the recommended actions.

Study 2A used three different operationalizations of culture. Americans (vs. Koreans), Caucasian Americans (vs. Asian Americans), and those with a highly individualistic (vs. collectivistic) outlook perceived themselves to be more health conscious than their family and close friends and the general public (i.e., the "not me" effect), whereas the opposite was the case for participants from Koreans, Asian Americans, and those scoring low on individualism (i.e., the "not them" effect).

Study 2B conceptually replicated the findings from Study 1B in a different health campaign (i.e., low-fat milk consumption). Koreans perceive others as more responsive to health campaigns, whereas Americans perceive others as less responsive to the message. Furthermore, as was the case between self and others, the same pattern of the perceptual gap emerged between close others and distant others. That is, when compared to close others, among Koreans, in-group members (i.e., family and friends) are perceived to be more likely to accept the health-related messages than out-group members (i.e., the general public), but among Americans, this pattern was reversed. This effect was apparent not only in behavioral intention as in Study 1B, but also in two additional measures used in Study 2B: cognitive and affective attitudes.

In sum, Studies 1A, 1B, and 2A showed that collectivists reported being less health conscious than close and distant others, whereas individualists reported the opposite (H1). Studies 1B and 2B replicated these findings in a health communication context, demonstrating that collectivists believed the positive effects of health messages to be greater on close and distant others than themselves, whereas individualists believed the positive effects would accrue to them more than to close and distant others (H2). The results were replicated across all three measures of persuasion.

These findings add to a growing body of knowledge that demonstrates systematic and contradictory self-other perceptions among collectivists and individualists.

# When the Loss of Free Will Can Be Costly: A Novel Approach to an Anti-Smoking Campaign

Aditi Grover, University of Southern California, USA
Michael Kamins, University of Southern California, USA

## EXTENDED ABSTRACT

In the United States, people who smoke cigarettes are on the rise. Of all smokers , adolescents and young adults constitute the highest percentage (United States Department of Health and Human Services 2000). Because smoking poses a threat to every organ of the body, these rising numbers are a cause of serious concern.

These rising numbers of young smoker reflects, in part, the successful marketing strategies of tobacco firms of years past and it demands more creative anti-smoking messages to counter such success. Several studies in the literature currently show that messages which define social disapproval as an outcome of smoking are more effective in deterring the young from smoking than messages that blame the tobacco industry 'making' people smoke and suffer (e.g., Pechmann and Ratneshwar 1994). However such research findings are not undisputed (Pechmann and Riebling 2006). For example, certain studies have found support for the effectiveness of messages that implicate the tobacco industry for smoking-related suffering. Discrepancies as such motivate the need for more research in antismoking messages.

In this manuscript, we build on the existing research stream which finds support for the effectiveness of social-disapproval messages. We introduce a concept - novel to marketing – the construct of *free will* defined as the ability to make conscious choice(s) for oneself, and opine that social disapproval messages that integrate loss of free will as a consequence of smoking are likely to induce more favorable ad attitudes and impactful messages. While drawing on the psychological theory of reactance (Brehm 1966), we predict that associating an act (e.g., smoking) as a threat to one's freedom (that is, free will) is likely to produce negative emotions in an individual and motivate him/her to ward off the threat (the act or smoking).

Furthermore, we expect that a fundamental need to retain one's free will is inextricably associated with one's ability to build/maintain a self-image that is approved by society. Therefore messages that make salient loss of "free will" in addition to social disapproval as an outcome of smoking are likely to be more convincing than messages that make salient social disapproval alone. We hypothesize:

> H1: Nonsmokers exposed to messages that emphasize social disapproval and loss of free will are likely to report more favorable attitude toward the ad and lower short term intention to smoke than those exposed to messages emphasizing social disapproval alone.

One of two sources can be blamed for the loss of free will: the self (internal attribution) or tobacco companies (external attribution). Past studies show that internal attributions help individuals reaffirm the belief in themselves and in their ability to predict and to control future events. On the other hand, external attributions 'hand-over' power to predict and to control future events to an external entity. We therefore expect messages with external attributions to induce negative and self-destructive emotions of fear because people are likely to feel helpless when an external entity (rather than the self) is in control of their life decisions. We, therefore, expect that when nonsmokers believe that the self (*vs.* the tobacco industry) is responsible for negative outcomes of smoking, then they are likely to report lower intentions to smoke. We also hypothesize:

> H2: Nonsmokers exposed to messages which emphasize social-free will from an internal responsibility perspective are likely to report more favorable attitude toward the ad and a lower short term intention to smoke than those exposed to messages that suggest an external responsibility.

We created three experimental conditions to test our hypotheses: a social anti-smoking advertisement and two conditions which emphasized the loss of the smoker's free-will either assigning the blame to the smoker or the tobacco industry. One hundred and thirty one graduate students from a major university in the United States volunteered to participate in this experiment. Results suggest that emphasizing simply a social perspective in terms of an anti-smoking campaign may not be sufficient to gain maximum advertising impact. While attributing blame for loss of free will led to a more impactful anti-smoking advertisement relative to the social ad alone (supporting hypothesis 1), there was only a directional difference in the hypothesized direction between the blame conditions (not supporting hypothesis 2). Discussion of these findings leads to ideas for future research.

# Reward or Punish: Willingness to Pay for Ethically-Produced Goods

Remi Trudel, University of Western Ontario, Canada
June Cotte, University of Western Ontario, Canada

## EXTENDED ABSTRACT

There are two substantively and theoretically important questions regarding consumers' response to CSR. First, do consumer attitudes influence their willingness to reward good corporate behavior, or punish irresponsible corporate behavior? Second, do these attitudes ultimately influence the amount they are willing to pay? With two experimental studies we demonstrate a strong relationship between ethical behaviour and willingness to pay: the ethicality of a firm's behavior is an important consideration for consumers and influences how much consumers are willing to pay for the firm's products. Consumers are willing to pay *more* for ethically-produced goods, and more importantly, they demonstrate a positive-negative asymmetry, whereby consumers will pay substantially *less* for unethically-produced goods.

Most marketing research has focused on the relationships between corporate associations or expectations and consumer response (Brown and Dacin 1997; Sen and Bhattacharya 2001; Creyer and Ross 1997). Most of this research, though, has focused exclusively on the relationship between favorable corporate actions and consumer behavior. That is, the work answers the question of how consumers react to *positive* CSR activities. One of the most generally accepted and far reaching phenomenon in psychology is the asymmetry between positive and negative–bad versus good (for comprehensive reviews see Baumeister, Bratslavsky, Finkenauer, and Vohs, 2001; Rozin and Royzman, 2001). That is, negative and positive information is treated differently. Our research examines the differences in the relationship between willingness to pay and positive (versus negative) ethical product information.

Experiments 1 and 2 test the prediction that consumers are willing to pay more for ethical products and pay proportionately less for unethical products. The research design involved three between-subjects conditions where participants evaluated written scenarios of a coffee company followed by a questionnaire. Coffee was chosen because the subjects are very familiar with the product, and the price range tested is well within their financial means, making the choice as realistic as possible.

The results show that not only are consumers were willing to pay *more* for ethically-produced goods, but more importantly, a positive-negative asymmetry exists whereby consumers will pay substantially *less* for unethically-produced goods. The results indicate that when given information about the social behaviors of a firm, consumers are willing to reward a firm for its behavior, albeit only marginally more than in an unsure or no-information condition. However, consistent with previous research in other domains on positive-negative asymmetries, participants were willing to pay proportionately less for an unethically-produced good confirming that negative information (unethical product information) has greater impact than positive information (ethical product information). The substantive mean differences between conditions, and the standardized coefficients of the regression results, would suggest that the functional relationship between ethical behavior and WTP is steeper in the unethical direction than the ethical direction. Therefore, the negative effects of unethical behavior have a substantially greater impact on WTP than the positive effects of ethical behavior. Thus our positive-negative asymmetry account extends previous research in psychology and economics to show that this asymmetry persists into the domain of social marketing. These are encouraging results form a social welfare perspective, as they suggest that firms should behave in a socially responsible manner.

# The Influence of the Online Decision Environment Characteristics on Consumer Selective Information Processing and Choice

Ying Jiang, University of Ontario Institute of Technology, Canada
Girish Punj, University of Connecticut, USA

## EXTENDED ABSTRACT

The uniqueness of the online shopping environment and the rapid growth of the online retail sales make it important to understand consumer information processing and decision making in an online setting. Specifically, this research examines (1) how online decision environment characteristics influence the extent consumers selectively process attributes and alternatives and (2) whether selective information processing mediates the effect of decision environment characteristics on consumer choice.

The adaptive decision making view posits that due to limited cognitive capacity, consumers often use a variety of information processing and decision making strategies contingent on the decision environment to construct their preferences (Bettman, Luce, and Payne 1998). Thus, consumers' information search process can be highly selective. They only select certain attributes and alternatives to process and neglect others. *Selective* information processing refers to consumers spending unequal amounts of time or effort acquiring information for each alternative or attribute (e.g., Bettman, Johnson, and Payne 1991; Lurie 2004). Research shows that task complexity and selective attention influence consumers' decision about which information to select for processing (e.g., Bettman, Luce, and Payne 1998; Lurie 2004). Task complexity can be determined by attribute type (digital vs. non-digital), attribute correlation (positive vs. negative), and alternative organization (random vs. sorted); consumer selective attention can be affected by attribute perceptual salience (salient vs. non-salient) and alternative organization (random vs. sorted by the non-salient attribute).

As non-digital attributes require much more time and effort for consumers to process (Biswas and Biswas 2004; Lal and Sarvary 1999), when attributes are positively correlated, consumers can opt to use simplifying heuristics and process fewer attributes. Thus, the extent of selective information processing of attributes is greater for products with more non-digital (vs. digital) attributes and positive attribute correlation. However, when attributes are negatively correlated, using simplifying heuristics reduces decision accuracy. Thus, the extent of selectivity information processing of attributes is small regardless of attribute type when attributes are negatively correlated.

It is generally accepted that sorting alternatives by attribute helps consumers to screen alternatives. However, we hypothesize that the extent of selective information processing of alternatives is greater only when alternatives are sorted and attributes are positively (vs. negatively) correlated. When attributes are negatively correlated, screening alternatives by one attribute tends to reduce decision accuracy.

As consumers tend to pay more attention to the perceptually salient objects in the environment (Janiszewski 1998), they are likely to focus more attention on the perceptually salient attribute. Thus, they are likely to use the perceptually salient attribute to screen the alternatives. As a result, they may examine and choose alternatives with better values on the perceptually salient attribute. However, alternative organization may also increase the perceptual salience of the sorting attribute and consumers' screening behavior (Areni, Duhan, and Kiecker 1999). Thus, we predict when alternatives are listed in random order, attribute perceptual salience influences consumers' selective information processing of alternatives and choice; however, when alternatives are sorted by the *non-salient* attribute, attribute perceptual salience has no effect on consumers' selective information processing of alternatives and choice. As the adaptive decision making theory posits that consumers process information contingent on the decision environment and the process of information processing can create a new preference structure, we argue that consumer selective information processing of alternatives mediates the interaction effect between attribute perceptual salience and alternative organization on consumer choice.

Finally, based on the cost-benefit theory of consumer information search, we expect that the extent of selective information processing of attributes is negatively correlated with the extent of selective information processing of alternatives.

We tested these hypotheses in two experiments. We constructed an experimental web site in which attribute type, attribute correlation, alternative organization, and attribute perceptual salience were manipulated. Participants were asked to search for information on the experimental web site and make choices after the information search.

Results from the two experiments supported our hypotheses. Specifically, In Study 1, we find that consumers tend to selectively process attributes when there are more non-digital (vs. digital) attributes and attributes are positively correlated, and selectively process alternatives when alternatives are sorted (vs. random) and attributes are positively correlated. Further, the results also indicate that the extent of the two types of selective information processing is negatively correlated. In Study 2, we find that that consumers tend to examine and choose alternatives with better values on the perceptually salient attribute when alternatives are listed in random order. However, sorting alternatives by the perceptually non-salient attribute attenuates such an effect. Further, the results show that consumers' selective information processing of alternatives mediates the interaction effect between attribute perceptual salience and alternative organization on consumer choice.

This research adds to the literature of online consumer information processing and decision making by specifying the online decision environment in which consumers are more likely to selectively process attributes/alternatives. We further show that the impact of the online decision environment characteristics on consumer choice is mediated by how consumers selectively process information.

# The Impact of Online Information on the Purchase of Certified Used Cars

Vandana Ramachandran, University of Maryland, USA
Siva Viswanathan, University of Maryland, USA
Sanjay Gosain Capital Group Inc., USA

## EXTENDED ABSTRACT

Several markets are characterized by significant information asymmetries between buyers and sellers, with sellers possessing superior information to buyers about the true quality of their offerings. Sellers of low quality products therefore have an incentive to misrepresent the quality of their offerings. Lacking adequate information to distinguish higher quality from lower quality products, buyers are unwilling to pay a premium for higher quality products. To prevent the ensuing market collapse, these markets have resorted to quality-signaling mechanisms such as certification to help reduce the frictions associated with such information asymmetries. As is well known, when the quality signal issued by sellers of the product or service is costly, in a rational equilibrium, prospective buyers could use these signals to discriminate between products of differing quality. While such quality signaling mechanisms are valuable to both buyers and sellers in such markets, their value to consumers, and the competitive advantage they provide to sellers, depends crucially on the nature and extent of the information asymmetries in these markets. Signaling mechanisms are more valuable and result in higher returns when buyers face greater difficulty in acquiring information about underlying product attributes. This is especially true in the market for used goods.

Over the last few years the growth of the Internet has dramatically increased the availability of information to prospective buyers across a number of markets. Consumers now, have access to a wide range of information regarding products and services, as well as alternatives, to make purchase decisions. Such information can potentially help bridge the information gap between buyers and sellers, and significantly reduce the information asymmetries in these markets. The abundance of information available through various online sources brings to the fore questions regarding the salience and the value of conventional quality signaling mechanisms.

We study one specific used goods market- the market for used cars. Given the complexity of the offerings and the difficulty in determining quality, certification, in particular, plays a very important role in reducing the frictions inherent in the market for used cars. While certification has traditionally been valuable to buyers as well as sellers of used cars, the growth of the Internet, and the emergence of auto-retailing websites in particular, has dramatically increased the amount of information available to consumers seeking to purchase used cars. The changing landscape of used vehicle markets makes it an ideal setting to understand the impact of online information on consumers' choice of certification, and price paid–issues that would be of considerable interest to academicians as well as practitioners.

An interesting feature of the used car market is that, unlike markets where quality signals such as certification are provided by independent third parties, certification for used cars is largely provided by the dealers themselves. This is likely to increase the salience of online information for consumers who may no longer need to rely on certification as a source of vehicle information. We draw upon a unique and extensive dataset of over 12,000 consumers who obtained vehicle and transaction related information from online information sources in their used vehicle purchase process to examine the impact of their information acquisition on their choice of certified used cars, as well as the price paid. We use a matched sample of certified and non-certified purchases to estimate the impact of online information on certification and price, while addressing issues regarding treatment effects, error covariance and endogeneity within a three stage least squares estimation framework. Additionally, we control for several factors including vehicle characteristics, buyer demographics, experience and psychographics, unobserved vehicle quality, additional warranties, and seller type and location.

We find that while consumers pay a premium for certified vehicles compared to their uncertified counterparts, online information has different impacts on the price paid for certified versus non-certified purchases. In particular four different categories of online information are found to be valuable to consumers seeking to purchase used cars–reliability information, information about used-car features, transaction-related information, and information about alternatives. Interestingly, we find that the two product-related information categories–reliability and features-related information–decrease the demand for certification. In addition, these information categories increase the price paid by consumers for non-certified cars. In contrast, the two price-related information categories–transaction and alternatives-related information–increase the demand for certified used cars; and decrease the price paid for non-certified cars. Thus, we find that reliability and features-related information serve as a *substitute* to certification, while transaction and alternatives-related information serve as a *complement* to traditional certification of used cars.

This study makes several important contributions. It is among the first to characterize the various categories of online information sought by consumers seeking to purchase used cars. More importantly, our study is among the first to disentangle and examine the implications of these different types of information for the quality signaling mechanisms adopted by sellers of used cars. We show that the availability of different types of online information has a significant impact on consumers' choice of certified used cars and price paid. A key implication then is that, as long as the cost of providing different categories of information is low, online infomediaries can have a significant impact on buyer as well as seller behaviors in the traditional market for used cars. In particular, traditional dealers selling non-certified used cars benefit when consumers obtain more transaction and alternatives-related information. On the other hand, sellers of certified used cars benefit more when consumers have increased access to reliability and features-related information. Consequently, these findings also have significant implications for dealers' partnerships with different types of online information intermediaries.

# The Multiple Source Effect of Online Consumer Reviews on Brand Evaluations: Test of the Risk Diversification Hypothesis

Do-Hyung Park, Korea Advanced Institute of Science and Technology, Korea
Se-Bum Park, Korea Advanced Institute of Science and Technology, Korea

## EXTENDED ABSTRACT

Consumers are often exposed to persuasion attempts by multiple message sources. Advertisers, for example, provide an army of product endorsers to consumers in advertising containing multiple testimonials in favor of a product. With the proliferation of information on the Internet, the persuasive advantage of multiple message sources draws much attention from academics and practitioners because subjective experiences, evaluations, and opinions of a multitude of consumers can reach far beyond the local community to affect other consumers around the world (Dellarocas 2003; Mayzlin 2006).

Particularly, online consumer reviews (OCRs)–defined as any positive or negative statements made by potential, actual, or former customers about their experiences, evaluations, and opinions on products and services–are considered a major informational source for consumer judgments and a critical decision variable for online merchants (Chatterjee 2001). Recent studies demonstrate that the online reviews have a significant impact on sales of online merchants (Chevalier and Mayzlin 2006; Reinstein and Snyder 2005; Mayzlin 2006). Consistent with these findings, online merchants such as amazon.com, barnesandnoble.com, and circuitcity.com encourage their customers to post and read product reviews.

Although the multiple source effect of OCRs is not directly addressed, a spate of research has demonstrated that the use of multiple sources in persuasive communication is one of the most powerful strategies for increasing message advocacy (Moore and Reardon 1987; Calder, Insko, and Yandell 1974; Harkins and Petty 1981a, 1981b, 1987). One popular explanation for these observations has been that exposure to multiple message sources gives rise to greater conformity pressure as a result of normative influence (Krech, Crutchfield, and Ballachey 1962), or social majority impact (Latané 1981). In contrast to this view, Harkins and Petty (1981a, 1981b, 1987) demonstrate that greater message elaboration prompted by different arguments from divergent and independent message sources contributes to enhanced persuasion. Simply put, this message elaboration hypothesis suggests that a message recipient engages in more effortful scrutiny of information each time a new message source provides a different argument whereas the recipient puts less effort into processing an argument if it comes from the same message source already encountered.

A series of Harkins and Petty's studies has laid a strong theoretical foundation for understanding the underlying mechanism of the multiple source effect of OCRs on brand evaluations. This research argues, however, that the message elaboration account alone may not provide a sufficient explanation for the multiple source effect of OCRs because unlike in most message persuasion contexts consumers are often faced with significant purchase-related risks such as product performance uncertainty or privacy and security risks in transacting with online merchants (Friedman, Kahn, and Howe 2000). In this circumstance, WOM referrals like OCRs are perceived as one of the most effective information sources for reducing perceived risks (Murray 1991). The perceived diversity of review sources of OCRs may contribute to reduce perceived risks through the process of risk diversification. In many situations, consumers utilize diversification processes in order to reduce monetary and non-monetary risks. Sensible investors, for example, diversify their investment portfolio into a number of investment options in their expectation that profitable options will at least compensate for possible losses sustained from options that are not profitable (Bodie and Merton 1999). Consumers also seek a variety of product assortments to hedge their future preference uncertainties (Kahn 1995; Simonson 1990). Similarly, we postulate that consumers are likely to search for multiple arguments from more divergent sources of OCRs in order to construct a representative information portfolio that reduces their online purchase risks. In the current research, two experiments are conducted to test this risk diversification hypothesis.

Experiment 1 found that a more diverse pool of review sources and a larger number of positive OCRs enhanced brand evaluations because participants engaged in more message elaboration (Harkins and Petty 1981a, 1981b, 1987). Furthermore, the findings provided some intriguing evidence that such persuasive advantage might also have emerged because more diverse review sources were capable of reducing participants' online purchase risks, which was also true in the presence of the greater number of positive reviews. Experiment 1 thus raised a possibility that the multiple source effect of OCRs could enhance participants' brand evaluations not only through greater message elaboration but also through the process of risk diversification.

Experiment 2 supported our risk diversification view that greater perceived diversity of review sources contributed to enhanced brand evaluations under high risk contexts. Considering that exposure to OCRs in the low brand reputation condition prompted more effortful processing of reviews regardless of the review structure than the high brand reputation counterpart, the data provided strong support for the risk diversification hypothesis that more divergent review sources enhanced brand evaluations by reducing significant online purchase risks than a less diverse set of review sources. When no significant perceived risks were involved, however, increasing the number of OCRs contributed to brand evaluations as much as increasing the diversity of review sources of OCRs.

Contributions made from the present research are twofold. First, we have successfully replicated Harkins and Petty's (1981a, 1981b, 1987) message elaboration hypothesis on the multiple source effect within the context of OCRs. With the risk diversification hypothesis, we have further identified the perceived diversity of review sources as another important factor that determines the persuasive advantage of OCRs. In order for OCRs to have the alleged impact on brand evaluations, message elaboration and risk diversification processes must operate simultaneously, particularly when significant purchase-related risks are involved. Second, the current research is also of managerial significance to online merchants that are considering OCRs a strategic marketing tool. Prior research has shown that online merchants strive to increase the total number of OCRs in favor of products they sell or their website (Chevalier and Mayzlin 2006). This research implies, however, that it is also of equal importance that online merchants induce more diverse OCRs from multiple sources with dissimilar backgrounds.

# Time versus Money: Differential Use of Heuristics

Ashwani Monga, University of Texas at San Antonio, USA
Ritesh Saini, George Mason University, USA

## EXTENDED ABSTRACT

Economists usually treat time in a manner similar to their treatment of money—as just another scarce resource which people spend to achieve certain ends (Becker 1965). However, time and money are often treated differently by consumers. For instance, choices are risk-seeking for losses of money but relatively risk-averse for losses of waiting time (Leclerc, Schmitt, and Dube 1995). Relatedly, while studying time as a medium of exchange, Okada and Hoch (2004) find that when individuals pay in time rather than money, they display greater willingness to pay for riskier options. In the context of sunk costs, the consideration of past investments has been found to be relatively weaker for time (Soman 2001). Finally, extending prior work by Soman (1998), Zauberman and Lynch (2005) show that time costs are discounted more than money costs because of a difference in how slack (i.e., perceived surplus) changes from the present to the future; change in slack is greater for time than in money. To sum up, prior research reveals that when information such as magnitude of risk, prior investments, or time delay is processed by individuals in the context of time versus money, there are quantitative differences in how this information is utilized to arrive at judgments and decisions. We contribute to this stream of research by demonstrating that a qualitatively different form of decision making—making decisions based on quick and easy heuristics—gains prominence when one works with time rather than money. We show that this is largely driven by the fact that temporal (vs. monetary) information is harder to process.

The two heuristics we examine—compromise and anchoring—have been very well documented in the consumer research literature, and we focus on them to test our proposed theory. The compromise effect is a type of menu dependence (Huber, Payne, and Puto 1982; Simonson 1989) in which preferences are irrationally influenced by the menu of options in the choice set. This effect runs counter to the following notion of similarity: Given two options B and C, the inclusion of an option A, which is more similar to B than to C, ought to reduce the preference for B (relative to C) because some of those who earlier chose B can now choose A. Simonson (1989) demonstrates that including A can *increase* the preference for B. Because B is now in the middle of the {A, B, C} menu, it represents an easy-to-justify compromise. The other heuristic we examine, anchoring (Tverksy and Kahneman 1974), is the tendency to rely heavily, or anchor, on one piece of information in order to arrive at a decision. For instance, the willingness to pay for a product can be influenced by an arbitrary anchor such as the last two digits of one's Social Security number (Simonson and Drolet 2004). In a series of experiments, we examine whether such heuristics are used more in time than in money.

Experiment 1 shows that when a compromise option is made available, people rely substantially more on the heuristic of choosing the middle option, the compromise, when people expect to spend time rather than money. Experiment 2 shows a similar effect for the anchoring heuristic. When an anchor provides an easy way to make a decision, those in the time condition are more likely to rely on this anchor than those in the money condition. Experiment 3 replicates the results of the anchoring heuristic and provides direct evidence for the process that heuristics are used more in time because, compared to monetary expenditures, temporal expenditures are harder to account for. Consistent with this proposition, when participants in both time and money conditions are primed to account for their expenditures, they no longer differ in their use of heuristics. The associated response times offer additional process evidence.

Our findings add to literature on the use of heuristics in decision making. The reliance on heuristics has been found to vary with factors such as level of involvement (Chaiken 1980), constraints on processing capacity (Ratneshwar and Chaiken 1991), and type of emotion (Tiedens and Linton 2001). We believe that the factor we explore—currency—is significant because a considerable portion of people's spending decisions relate to time and, therefore, they might be driven more by heuristics.

Implications also arise for practice. Consumers sometimes have the choice to expend either money or time. When trying to sell a house, one could either pay a real-estate agent or spend one's own time looking for the highest bidder. If people spend time instead of money, and use different decision processes, it has implications for both consumers (i.e., home buyers) and businesses (i.e., real-estate firms). To sum up, people often make spending decisions. Our results suggest that the nature of the currency is important in determining how those decisions are made.

# Achieving the Compromise Effect with Missing Attribute Information: Introducing Shadow Options

Kunter Gunasti, Penn State University, USA
William T. Ross, Jr., Penn State University, USA

## EXTENDED ABSTRACT

*Consider the following real life purchase situation:*

*You go to an auto parts store to purchase a set of four snow tires. The dealer shows you two options. Brand X costs $90 per tire and has a tag on it that indicates that it has a traction rating of 5.1 out of 7. Brand Y costs $125 per tire and the traction rating on its tag is 6.3 out of 7. The tags indicate that the traction ratings are provided by the same well respected auto magazine. Just as you are about ready to choose Brand Y because of its better traction rating, the dealer tells you that the store also carries Brand W that costs only $60 per tire, but that the magazine has not provided a traction rating for it. You consider the idea of buying that tire for a minute. You decide that you are not going to buy it without knowing the traction rating, but even so the total cost is only $240 for a set of 4 tires compared to $500 for a set of the Brand Y. Maybe it is not worth paying so much after all. You ask yourself: what is the difference between a 5.1 vs. 6.3 rating anyhow? As you think more about it, paying $360 for a set of Brand X tires seems like a better choice and you change your initial decision of buying Brand Y.*

In the scenario above, introducing a third option, even though this option was missing a crucial piece of information, changed the initial choice in the binary set and increased the choice probability of the middle option in the new choice set. If the marketer had not mentioned the third option, the final decision would have been different. Some reflection suggests that consumers face numerous similar scenarios during their purchases. For instance, the local wine store where the authors live, like many other internet and bricks and mortar wine merchants, regularly reports wine evaluation scores from the *Wine Spectator,* a respected and apparently unbiased wine magazine. These scores are reported for some wines and not for others for two reasons, first because *Wine Spectator* cannot possibly rate every wine, and second because the wine merchants may choose not to report the scores.

Brands gain share when they become center options in a choice set (Simonson 1989). This phenomenon, known as the *compromise effect,* has been shown in past literature when a third option (W or Z) was added to a binary choice set (X, Y). In the vast majority of cases there was a large and significant increase in the choice of the option (X or Y) adjacent to the newly added option as the existing option takes the middle or compromise position in the new X, *Y*, Z or W, *X*, Y set. In these studies, all options were described with two attributes each, and all attribute information was provided. The new option (W or Z) was relatively better than X and Y on one attribute and relatively inferior to X and Y on the other attribute.

In this manuscript, we investigate whether the introduction of a third option with a missing attribute also leads to a compromise effect. As one of its attributes is unknown, this new option can have any value for that attribute. Thus, it may actually be much *better or worse* than X or Y on either dimensions and away from the trade-off line (as defined in Sheng et al. 2005). Due to its missing attribute and its unknown location in the choice set, this alternative will generally achieve a low choice probability. Hence we refer to it as the *shadow option*. It is important to note that a *shadow option* is a distinct concept from that of a *phantom decoy* used in earlier literature (Simonson 1989). More specifically, shadow options have missing attribute information but they may still be chosen by the decision maker, whereas phantom decoys have complete attribute information but they are not available for choice.

In three empirical studies, we investigate the robustness of the compromise effect achieved by the addition of a shadow option to a binary choice set. In the first study, we show that the compromise effect holds for a newly added option when only one attribute is available (one attribute is missing) as well as when both attributes are available (no attributes are missing). There is an important distinction between the two cases, because in the case of missing attribute information the newly added alternative may actually be better or worse than the existing ones, whereas in the case of complete information the new option will be superior to both existing options on one attribute and inferior on the other.

In the second study, we demonstrate that the shadow option (W or Z) alters choice probabilities in favor of the adjacent option whether it is next to X or to Y (i.e. *W*XY or X*Y*Z). In either case, the choice of the new compromise option is increased. Also in this study, the missing attribute types are reversed, and different types of products are included. It is demonstrated that the effect is independent of attribute or product type. In the third study, we examine three important issues. First we investigate whether the effect occurs due to attribute polarization (extreme attribute values of the shadow option). Second, asking some participants to make explicit inferences about the missing attributes, we also identify where they locate the third (shadow) option in their mental maps relative to the other two options and therefore, we are able to show that the observed effect is in fact a compromise effect rather than another violation of independence of irrelevant alternatives (IIA). Finally, we explore how being prompted to make explicit inferences about missing attribute information affects the choice of compromise option. Parallel to past studies which suggest that choice justification increases the compromise effect, we find an increase in the effect when consumers are prompted to make explicit inferences about the missing attributes.

Our findings have important theoretical implications for defining and understanding the mechanism that underlies the compromise effect. We discuss various practical implications for marketers and sales strategies for manipulating consumer choices.

# Would Perceived Unfairness Lead to Regret?

Felix Tang, The Chinese University of Hong Kong, China
Jianmin Jia, The Chinese University of Hong Kong, China

## EXTENDED ABSTRACT

Realizing one has involved in an unfair transaction (e.g., unfair pricing practice) can be shocking and regretful; such feelings could drive consumer to refrain from future transaction with such company. Much of the extant literature on regret are based on regret theory (Bell 1982; Loomes and Sugden 1982), which views regret as a result from the comparison of the chosen outcome against the outcome of a forgone or imagined alternative. The focus is placed on the outcome discrepancy; how such discrepancy arises is assumed to have no impact on regret whatsoever (see Pieters and Zeelenberg 2005 for an exception). However, fairness of a situation may signal the goodness or appropriateness of a decision, leading to regret, even when such cognition comes into light after the fact.

The article's main hypothesis echoes the theme of the ACR 2007 conference in "building bridges", positing that perceived unfairness may lead to regret, independent of outcome and outcome discrepancy. Both fairness and regret involve a comparison standard. While regret arises from comparison with an imagined or forgone outcome, fairness arises from comparison with a socially comparable outcome obtained by similar others. This article not only examined both constructs simultaneously but also linked them together. This unfairness-regret hypothesis is evidential in consumers' regret on their decision to have purchased from businesses with unfair practices (e.g., unfair pricing, racial discrimination, child labor) (Feinberg, Krishna, and Zhang 2002; Smith 1990; Streitfeld 2000). These observations are consistent with Bell's (1982) proposition that regret may arise when individuals realize, after the fact, to have made the wrong decision. Other hypotheses examined how outcome discrepancy leads to satisfaction and repurchase intention and what roles do fairness and regret play in affecting them. A model is proposed to examine the relationship among outcome discrepancy, perceived fairness, experienced regret, satisfaction, and repurchase intention in a consumer decision making situation involving interpersonal comparison standard.

In an experiment, each participant read a scenario describing the shopping of internet connection service. Since valence of outcome may independently influence regret, the actual amount paid was controlled across all conditions. Outcome discrepancy was manipulated by whether the price paid by a friend for the same Internet service provider was higher (favorable condition), the same (equal condition), or lower (unfavorable condition). To control for an expectation of the possibility of price discrepancy, participants in all conditions were made aware of such possibility. All other relevant variables, such as price expectation and service quality, were also controlled.

A structural equation model was built to test the proposed model and the model fitted the data well. The results suggested that when information on outcome of other consumers (e.g., price paid or performance received) is available, consumers consider outcomes of others as reference points to compare with their outcomes in forming perception of fairness and experiencing regret. Realizing one has purchased from or participated in a transaction with a business that, after the fact, deemed to be unfair does lead one to regret from participating in such a transaction. This unfairness-regret relationship is outcome dependent and outcome discrepancy dependent. In addition, it questions the assumption that regret is experienced only when a foregone outcome is better than that of the chosen option.

The data also suggested that the influences of social comparison on satisfaction and repurchase intention are fully mediated by fairness and regret. Satisfaction is mainly driven by perceived fairness; repurchase intention is mainly driven by experienced regret. Furthermore, the data suggested that discrepancy between one's outcome and a comparable other's outcome has a significant direct influence on consumer's repurchase intention. Although this effect was not hypothesized, it was not a total surprise. Sometimes we obtain a better treatment than some comparable others (e.g., our friends, family, coworkers), even we might not judge such outcome to be fair nor express satisfaction with such outcome immediately, it is logical and reasonable for us to go back the next time, perhaps alone, as we have learned that such decision would lead to good outcome.

The article contributes to marketing literature in several ways. First, we examine the simultaneous influence of fairness and regret on satisfaction and repurchase intention. We found that price discrepancy influences satisfaction; and such relationship was fully mediated by perceived fairness and regret. Besides, a direct influence from fairness to regret was also found and regret had a direct influence on repurchase intention, after controlling for satisfaction.

Second, it proposes and finds evidence to support the unfairness-regret hypothesis. That is, regardless of the outcome, lower perceived fairness leads to higher regret. This hypothesis is important because it questions the assumption that regret is experienced only when a foregone outcome is better than that of the chosen option. The effect cannot be explained by counterfactual thinking as it is captured by the social comparison variable. This article demonstrated that fairness of a situation has a direct influence on regret, which in turns directly affects repurchase intention. This article highlights that the consumer cares about not only getting a good deal, but also getting it in a fair way.

Third, it explicitly calls for attention to examine regret in interpersonal contexts. Most of the literature on regret focused on individual decision making. This article explicitly examined how social influence affects regret and invoked social comparison theory in guiding our hypotheses formulation. Results from the experiment demonstrated that the influence of regret is inflated when fairness was ignored, suggesting a limitation of existing models of regret that did not incorporate social comparison.

# Big Raccoons and Small Giraffes: Anchoring in Sequential Judgments

Daniel Mochon, Massachusetts Institute of Technology, USA
Shane Frederick, Massachusetts Institute of Technology, USA

## EXTENDED ABSTRACT

Ever since Tversky and Kahneman (1974) showed that irrelevant anchors can affect judgments, researchers have investigated the boundary conditions of this effect. Most research since then has focused on the original paradigm, where people are asked to make an explicit comparison between the object being judged and some (arguably) irrelevant anchor (Jacowitz and Kahneman, 1995; Strack and Mussweiler, 1997). More recently, researchers have also looked at situations where the anchor is self generated as an approximate, but incorrect benchmark for the requested judgment (Epley and Gilovich, 2001). Although both of these procedures have produced consistent anchoring effects, the range of circumstances under which numbers in the environment affect people's estimates is still unknown. Some studies have argued that simply writing down a number 35 times (Wilson, Houston, Etling, and Brekke, 1996), or even being exposed to it subliminally (Mussweiler and Englich, 2005) can cause anchoring, while others have argued that such effects are weak and hard to replicate (Brewer and Chapman, 2002).

In this research, we explore the extent of anchoring in a common situation–when respondents render multiple judgments sequentially, as they do in many surveys. Suppose, for example, respondents were asked to estimate the weight of an average adult giraffe. Will the giraffe then be judged as being lighter or heavier if they also first estimated the weight of an adult raccoon? Suppose further that another group estimated the weight of both a raccoon and a wolf before judging the weight of a giraffe. Would this matter? What would be the direction of the effect? This particular form of anchoring has not been well explored in the literature. Moreover, the effect of more than one anchor is rarely examined, even though in most situations people commonly make multiple judgments.

In the first study, we tested whether judgments to previous questions can anchor subsequent ones. We presented participants with questions of objective quantities (such as the weight of an average adult giraffe), and manipulated the number of estimates preceding the target question. In one condition, the target question appeared alone. In a second, it was preceded by an estimate of a related but lesser entity (e.g., the weight of an average adult raccoon). In a third condition, it was preceded by a question asking for the estimate of a medium entity (e.g., the weight of an average adult wolf). In the fourth condition estimates of both the smaller and medium entities preceded the target judgment. We found across various domains that previous questions function as anchors of subsequent ones. The judgments of the target questions were assimilated towards the previous judgments. We also found that the effect was larger when the target judgments were preceded by both the small and medium judgment than when preceded by either the small or medium judgments alone, suggesting that multiple prior judgments can amplify the effect.

In study 2, we tested whether target judgments are anchored on preceding judgments unrelated to the target domain. For example, prior to the giraffe judgment, respondents were asked to estimate the number of states east of the Mississippi, and the average lifespan of a Japanese woman (which yield similar estimates as the weights of a raccoon and wolf respectively). We found that simply producing smaller numbers in preceding responses does not cause anchoring. We also tested whether the effect was produced by conceptual priming apart from produced responses. For example, prior to the giraffe judgment, respondents were shown pictures of a raccoon and a wolf, and were asked to identify them. Our results showed that it is also not sufficient to merely group the giraffe with the smaller animals. It appears instead that both conditions are necessary–preceding judgments must be made and those judgments must have conceptual similarity to the target domain. This restricts the set of circumstances in which we should expect anchoring in surveys, although the remaining subset is still pretty large.

These findings have important implications for the anchoring literature as well as for survey research in general. They add to the growing literature showing that anchoring effects are much more prevalent than previously thought. Even though there was no explicit comparison with the previous judgments, the target judgments were assimilated towards them. The results also demonstrate that anchoring effects extend beyond the immediately preceding judgment to even earlier ones. This finding poses a challenge for the existing theories that try to explain the anchoring effect. More generally, these studies suggest the existence of an important consideration in survey design that is often overlooked.

# If I Want You to Like Me, Should I Be Like You or Unlike You? The Effect of Prior Positive Interaction with a Group on Conformity and Distinctiveness in Consumer Decision-Making

Veronika Papyrina, San Francisco State University, USA

## EXTENDED ABSTRACT

The extant research points to contradictory findings regarding social influence in consumer decision-making. On the one hand, there is empirical evidence which suggests that consumers conform to other members of their groups. For example, Venkatesan (1966) presented participants with three identical men's suits and asked them to choose the best suit individually or in the presence of three confederates who uniformly pointed to the target suit. Consistent with the notion of conformity, participants followed the responses of confederates and selected the target suit more often in the group rather than in the individual condition. On the other hand, several more recent studies demonstrated the opposite effect, namely, that individuals seek distinctiveness in the presence of others. For example, Ariely and Levav (2000) examined the sequential choices of people in a small group setting and showed that every next person in a group tried to select something different from what other individuals before him or her had chosen.

The goal of the present research is to reconcile these conflicting results. To this end, I propose that whether a person will conform to or seek distinctiveness from others in a particular consumption situation is contingent on the absence or presence of one's prior positive interaction with the group. I also suggest that this effect will occur in a public context, that is, when an individual's choice is visible to other group members.

Theoretical arguments for the above relationship build on the idea that people are driven by two fundamental and equally strong motives–the desire to belong with others and the desire to be unique. The main proposition, which is based on the Optimal Distinctiveness Theory (Brewer 1991), is that these two motives compete with each other in a such way that satisfaction of the former activates the latter, and vice versa. More specifically, I suggest that when individuals do not have an experience of prior positive interaction with the group, they will be more likely to conform. The rationale for this proposition is that on such occasions the need to belong is not yet satisfied, and individuals will be motivated to gain approval by and to create a common identity with the group by choosing the same brands and/or products as other group members. And alternatively, I expect that when individuals already have a history of positive relationships with the group, they will be more likely to seek distinctiveness from other members because in this situation the need to be unique will take precedence over the need to belong.

The results of experiment yielded support for the interaction effect of prior positive interaction with the group and visibility of one's consumption decision to others on conformity and distinctiveness. Specifically, I found that individuals were more likely to follow the preferences of other group members when they believed that others would become aware of their consumption decisions yet they did not have a history of positive relationships with the group. As predicted, the pattern of results was reversed after people experienced positive interaction with other members of their group. In this situation, individuals were more likely to make choices which allowed them to stand out of the group rather than choices which signified conformity to others. Consistent with expectations, no evidence was found for the relationship between prior positive interaction with the group and either conformity or distinctiveness in the context of private consumption decisions.

# A Psychophysiological Perspective of the Stress-buffering and Persuasive Impact of Positive Communication Style

Zhenfeng Ma, University of Ontario Institute of Technology, Canada
Laurette Dubé, McGill University, Canada

## EXTENDED ABSTRACT

Consumers' search for health information is often prompted by their personal encounter with health threat. At the time when consumers resort to health information, they are often under considerable stress. Thus, health communicators must strive to alleviate stress while at the same time maximize persuasive impact. In this study we look at the stress-buffering and persuasive impact of positive communication style, via the use of positive peripheral pictures, on consumers facing health threat. Different from prior studies, we used a psychoneuroendcrine (PNE) model of stress, which views stress as an integrated process that involves affective, autonomic and endocrine changes. The PNE approach allows us not only to examine the role of positive communication style in alleviating both psychological and physiological stress reactivity but also to uncover the psychophysiological mechanisms underlying the persuasive effect of positive communication style.

Studies from positive psychology suggest that for individuals under stress, positive stimuli have the potential to alleviate psychological and physiological stress reactivity. Based on the PNE model of stress, we hypothesize that for consumers who have undergone a health threat, health communication presented in a positive style by using positive peripheral pictures will reduce psychological distress, and autonomic and endocrine reactivity than health communication presented in a neutral manner (H1).

Research evidence suggests that people under stress concurrently engage in two modes of coping, that is, approach and avoidance. Approach coping represents a cognitive and emotional orientation toward threat or threat-related information, whereas avoidance coping represents an orientation away from threat or related information. Research has shown that positive stimuli and its ensuing positive affect can broaden one's thoughts and actions repertoire and facilitate cognitive processing of potentially threatening information. We thus hypothesize that for consumers facing health threat, positive communication style will lead to better persuasive outcome than neutral communication style (H2). We further hypothesize that the impact of positive communication style on consumers under stress will be mediated by changes in affective and physiological responses. Specifically, when communication is presented in a neutral style, the unmitigated psychophysiological responses will have negative impacts on persuasion. However, when the same information is presented in a positive style via positive peripheral pictures, the negative impact of psychophysiological reactivity will be attenuated (H3).

Hypotheses were tested through a 2 (stress condition: stress vs. no stress) x 2 (communication style: positive vs. neutral) between-subject design. Eighty healthy women from the local community participated in the study. Participants first preformed a mental imagery task, which was used to manipulate stress, and then a web-browsing task, which was used to manipulate communication style. In both tasks, autonomic responses were continuously measured. Mood and endocrine responses were measured three times: before the imagery task, between the imagery and the web-browsing tasks, and after the web-browsing task. Finally, the persuasive impact of health communication was measured using a self-administered questionnaire.

Stress was manipulated using a guided mental imagery task which pertains to health-related scenarios: osteoporosis prevention (the no-stress condition) and a mammogram screening procedure (the stress condition). In the stress condition, participants were led to imagine, with the aid of computed-mediated instructions and audio-visual cues, detecting a suspicious lump in the breast, going through a mammogram screening procedure and finally reaching the point of waiting for screening results. In the no-stress condition, participants imagined several low-risk scenarios such as paying a routine visit to the physical therapist and engaging in mild exercise.

Communication style was manipulated through a consumer health information website, which offers information and recommendations on various healthy lifestyle behaviors. The positive communication style was operationalized by embedding non-content-related background color pictures of natural scenery on the periphery of the webpage. These pictures had been pre-tested to elicit positive affect relative to neutral stimuli. In the neutral communication style condition, the same information was presented without using peripheral pictures. Except for the presence/absence of pictures, the information and recommendations in both conditions were identical in all other aspects.

Psychological responses were measured using the short form of the Profile of Mood States (POMS-SF). Following standard scoring procedure we calculated an index of negative mood and an index of positive mood. Autonomic responses were measured using a computer-based physiological data acquisition system. Two measures of autonomic response were derived: skin conductance level (SCL) and heart rate variability (HRV). Endocrine response was indexed by salivary cortisol. Persuasive impact was measured in terms of attitude toward the health communication.

The analysis shows that compared with health information communicated in a neutral style, information presented in a positive style alleviated psychological, autonomic and endocrine stress reactivity. Thus H1 was supported. Moreover, for stressed consumers the positive communication style also induced superior acceptance of the persuasive messages, thereby supporting H2. A further look at the PNE mechanisms suggests that for stressed consumers, the positive communication style increased the persuasive impact relative to the neutral style by changing the nature of the effect of PNE responses on persuasion. Specifically, for stressed consumers the PNE reactivity had negative effects on persuasion when the information is presented in a neutral style, but a positive impact on persuasion when the same information is presented in a positive style. These findings supported H3.

Although the stress-buffering influence of positive stimuli is not new to researchers, it is the first time that we observed such an influence in a communication context. Perhaps more importantly, our findings shed light on the underlying psychophysiological mechanisms of the persuasive impact of positive peripheral cues. Our findings show that affective, autonomic and endocrine changes during exposure to communication each uniquely mediated the persuasive impact of positive communication style. These findings suggest that an exclusive focus on psychological aspect of stress experience, as is typical of current literature, may have neglected important mechanisms underlying attitudinal change under stress.

# The Evolution of New Product Rumors in Online Consumer Communities: Social Identity or Social Impact?

Scott A. Thompson, Arizona State University, USA
James C. Ward, Arizona State University,, USA

## EXTENDED ABSTRACT

Prior studies of consumer word of mouth behavior have focused on released products. This research indicates that word of mouth serves as a complement to other sources of information such as advertising and expert reviews. However, consumers also engage in word of mouth about unconfirmed, unannounced, and unreleased products. Such rumors develop and spread in the absence of the kind of outside information present in the contexts previously studied in the word of mouth literature.

Research on rumors in the social psychology literature has found that the emergence and diffusion of rumors depends on the social context and the groups involved. These results suggest that new product rumors may spread and change depending on the social context in which they exist and the interests of those spreading the rumors. Therefore, two theories of group formation and intergroup communication are considered.

Social Identity Theory is the perspective adopted by the brand community literature. Social Identity Theory contends that intergroup dynamics are naturally competitive due to attempts by group members to maintain and enhance their relevant social identities through intergroup comparisons. As a result, consumer groups formed around competing products will tend to develop and spread rumors that reflect positively on their favored product and negatively on competing products. Over time, this will lead to a polarized environment with rival consumer groups either discussing completely different rumored products or discussing the same product but in different terms. This polarization should be most pronounced among the most frequent participants since they will hold the strongest social identities.

On the other hand, if social identities are not as influential as the brand community literature suggests, Dynamic Social Impact Theory may be more instrumental in understanding the diffusion of new product rumors. Dynamic Social Impact Theory lacks the competitive intergroup dynamic suggested by Social Identity Theory. Instead, it suggests that the spread of new product rumors between groups will follow an iterative and assimilative process. Therefore, new product rumors should diffuse between consumer groups formed around competing products. As a result, new product rumors discussed in rival groups will become more similar over time. Furthermore, this convergence should occur more rapidly among frequent participants in each group since they are subject to the highest levels of social impact.

To test these competing theories, actual word of mouth communications regarding a rumored product were gathered from three online forums. Two forums were dedicated to the products of two competing companies: Intel and AMD. In addition, messages were gathered from a third neutral "General Hardware" forum. The messages cover the period from when the first rumor about the product appeared until the non-disclosure agreement prohibiting the release of information about the product expired. The final dataset spans a period from March 2004 to July 13, 2006 and contains 409,576 messages posted from 18,121 unique user accounts.

The message data was analyzed using Centering Resonance Analysis (CRA) which uses a form of network analysis grounded in centering theory. The centering theory approach employed by CRA makes it well suited to studying new product rumors. Such rumors are comprised of evolving networks of associations centering on a focal subject. Over time, these associations change as the rumor spreads between individuals and groups. CRA identifies these networks of associations and provides a method to measure both the relationships and the degree to which networks vary between texts. Therefore, CRA provides a means to assess whether rumors are growing more or less similar and more or less focal within and across the three forums.

The results show that new product rumors become more similar between the rival consumer forums over time. Furthermore, the pattern of results holds even for members who are dedicated to one forum and refrain from participating in the rival forum. In addition, there is a lag in the convergence process with similarity between contemporaneous messages being greatest for later time periods in the two rival forums. This lag is consistent with a diffusion process.

This pattern of findings supports the predictions made by Dynamic Social Impact Theory. The results show that members of competing groups are willing to spread rumors about competing products. Furthermore, they are willing to spread rumors which are similar to those from opposing groups. Finally, even members dedicated to one group are willing to adopt and spread such rumors.

Overall, these results call into question the assumption that dedicated, identified users will refrain from spreading rumors about rival products. Our results strongly suggest that, at least in some circumstances, they are willing to do so. We should emphasize that these results do not indicate that social identities were not present. On the contrary, some participants showed clear evidence of the ingroup bias associated with social identity when selecting *where* to post. However, these same members did not act to protect their social identification when deciding *what* to post. This may be a result of either conflicting identities among group members or an indication that the frequent participants in the opposing consumer community are considering purchasing the rival product. Future research should explore these potential explanations.

# A Life Course Perspective of Family Meals Via the Life Grid Method

Robert Harrison, University of Nebraska, Lincoln, USA
Ann Veeck, Western Michigan University, USA
James Gentry, University of Nebraska, Lincoln, USA

## EXTENDED ABSTRACT

As much as any consumption behavior, the ritual of the family meal serves to define roles and identities, establish social relationships of inclusion and exclusion, and convey meanings of taste and style. Over the course of a lifetime, meal patterns are altered to conform to changing relationships, economics, nutritional ideology, geographical locations, technologies, health concerns, styles, and many other influences. As a result, systematically investigating how the meanings and processes of meals change in response to individual, generational, and historical influences can increase our understanding of changes in family consumption behavior over a lifetime. This research examines the dynamics of family meals by pairing life course theory with the life grid method of obtaining oral histories to capture the historical and social forces of change.

The primary framework currently used to look at generational differences in household consumption behaviors, such as meal patterns, is the family life cycle. However, the family life cycle is a model of trajectories in which consumption patterns are assumed to be somewhat steady state in nature. As such, it ignores the transitions between stages and the likely possibility that those transitions are experienced differently today than they were in earlier times. Variation in the life courses of different generations creates cohort effects that influence consumption profoundly. As Scott et al. (2006, p. 23) note, errors of presentism (i.e., assumptions and agendas of the present are projected upon the buyers of the past) exist. Methods that study changing consumption patterns in historical context are needed to counteract errors of presentism.

This research uses the life grid method to examine changes and continuities in family meals over a life time. Combining components of the structured and unstructured interview (Fontana and Frey 1994), the life grid method involves asking respondents questions about events that have occurred in their lifetimes, including historical events (such as the 1929 Depression and World War II) and internal events (such as changes in jobs, residences, and family). These lifetime events are then used as cues when questioning the respondent about patterns in individual or family behavior. Through the collection of mutually reinforcing memories, the life grid method enhances recall of less memorable details in individuals' lives (Berney and Blane 2003).

We conducted interviews with 15 participants, aged 80 and over, living in four different senior resident centers, about how their meals have changed over the course of their lifetimes. In the course of the interviews, the interviewer worked with each participant to construct a "life grid," by working chronologically though time to record the residences, jobs, and family changes of the participant. After the life grid was completed and the participant's life history was outlined on paper, the interviewer could pair the life grid with historical events to cue the participant to particular times in his or her life and make inquiries about meals.

To analyze the interviews, we used the themes of life course theory (Bengston and Allen 2003). We found that multiple temporal contexts of development, including individual changes, generational changes, and historical changes interacted to affect family meals. Major historical time events like the Great Depression and World War II had a profound impact on the family eating patterns of our participants, with social class mitigating the extent to which families had to adjust their eating behavior according to these events. In addition, participants recalled how transformational developments and technological innovations, including changing food retail structures and new home appliances (e.g. refrigerators and microwaves), had changed both the composition and patterns of their meals.

Normative expectations or aspirations related to family structure also affected the family meals of our participants. Through analysis of the interviews, we learned how individuals' roles and responsibilities changed in response to micro- and macro-environmental elements, as they aged, acquired spouses and children, changed jobs and locations and experienced historical events. In their current stages of lives, our participants continued to develop new roles and relationships, as they developed "family" bonds with other residents of their resident centers.

A "diachronic perspective on development" was also elucidated through the interviews, with the focus on entire lives rather than enclosed periods of time. We learned how our respondents were able to adjust, sometimes quickly and sometimes gradually, to sudden or incremental changes in their life paths. While the respondents shared the commonality that they were all currently living in a residential center, they displayed much heterogeneity, according to past and current influences, in terms of their adjustments to eating meals in a community environment.

Altogether, we found collecting oral histories from the elderly via the use of the life grid method to be helpful in analyzing changes in family meals over the past eight decades. In particular, it offers interesting glimpses of the development of the family in response to socio-cultural and historical developments. In addition to food-related behaviors, a number of lifelong consumption activities and products would be interesting to study through structured analysis of the effects of influential events, including home purchases, vacations, celebratory activities, investments, educational services, arts activities, and many others.

# Cognitive Load, Need for Closure, and Socially Desirable Responding: Cognitively Constrained versus Motivated Response Biases in Cross-Cultural Consumer Research

Ashok K. Lalwani, University of Texas at San Antonio, USA
Chi-Yue Chiu, University of Illinois at Urbana-Champaign, USA

## EXTENDED ABSTRACT

With globalization, survey researchers have increasingly studied cross-cultural differences in various consumer behaviors, including determinants of decisions under uncertainty (Fong and Wyer 2003), effects of emotional appeals on persuasion (Aaker and Williams 1998), country of origin effects on product perception (Gürhan-Canli and Maheswaran 2000), and salespeople's ethical sensitivity to stakeholder interests (Blodgett, Lu, Rose, and Vitell 2001). Given the plethora of cross-cultural studies conducted in recent years, it is important to understand how socially desirable responding (SDR) differentially influences participant responses across cultures. Prior research distinguishes between two types of socially desirable responding–*self-deceptive enhancement* (SDE) and *impression management* (IM). SDE is a spontaneous tendency to present an internalized, unrealistically positive view of the self, whereas IM is the deliberate, strategic presentation of a socially approved image of the self (Paulhus 1991).

Recent research suggests that consumers with an individualist cultural orientation differ from those with a collectivist orientation not only in the degree of SDR, but also in the relative prevalence of different SDR styles. Specifically, because individualists are especially motivated to view themselves as independent, self-reliant, and unique, they have a propensity to engage in SDE (Heine and Lehman 1999; Lalwani et al. 2006). Such responses help to establish a view of oneself as capable of being successfully self-reliant, skillful, and competent. Conversely, because collectivists are driven to seek social approval and avoid social disapproval, they are especially likely to provide normatively desirable and socially appropriate responses and, hence, to engage in IM (Heine and Lehman 1999). Consistent with these ideas, considerable evidence supports a positive association between individualism and SDE and between collectivism and IM. In contrast, no relationship has been observed between individualism and IM and between collectivism and SDE (Lalwani et al. 2006). The presence of culture-specific SDR styles renders direct comparison of cross-cultural survey data difficult and less meaningful.

An understanding of how motivational and cognitive factors in the survey context influence cultural differences in SDR styles is important for survey researchers. In a survey setting, participants are expected to give responses that reflect their true perceptions and beliefs. However, some cognitive and motivational demands in the survey setting may increase the respondents' reliance on culture-specific SDR styles as a way to cope with the demands. Therefore, one major research challenge is to identify the cognitive and motivational demands that accentuate cultural differences in SDR styles, so that with knowledge gained from addressing this issue, survey researchers can anticipate how the survey settings could elicit different levels of culture-specific SDR styles. Two such demands examined in the current investigation are cognitive busyness and need for closure.

Because SDE is a spontaneous and automatic process, we hypothesized that cognitive load would not influence individualists' tendency to engage in SDE. In contrast, depletion of cognitive resources would interfere with the execution of an effortful process (Gilbert and Osborne 1989) like IM. Hence, the tendency to engage in IM will be significantly reduced when the introduction of additional cognitive load renders collectivists cognitively busy.

Since individualists do not engage in IM to begin with (see Lalwani et al. 2006), a cognitive load manipulation would not have a discernible effect on individualists' tendency to engage in IM. In short, cognitive load is expected to reduce IM (but not SDE) among collectivists only: cultural differences in IM are hypothesized to be *less* pronounced when consumers are cognitively busy (vs. non-busy). Thus, making consumers cognitively busy would *reduce* the influence of cultural orientation on IM.

Need for closure (NFC) is a personal desire for firm answers that provide epistemic closure (Kruglanski and Webster 1996). An important source of epistemic closure is cultural consensus; individuals feel epistemically secure when their beliefs are widely accepted in their reference groups or cultural groups (Fu et al. 2007; Kruglanski et al. 2006). Considerable evidence suggests that high (vs. low) NFC individuals have a greater tendency to follow cultural norms (Chiu et al. 2000; Fu et al. 2007). Since NFC increases adherence to normative cultural practices, we hypothesized that cultural differences in SDR styles would be more pronounced among high versus low NFC consumers. Specifically, the association between individualism and SDE and that between collectivism and IM should be stronger among high (vs. low) NFC consumers. Six studies supported these hypotheses.

The findings have important theoretical and methodological implications. By examining the moderating role of cognitive load and NFC in the culture-SDR relationship, the paper sheds light on the cognitive and motivational processes that underlie culture-characteristic SDR styles. The studies also advance our understanding of the distinct impact of cognitive load and NFC—two variables that have been believed to act similarly by several researchers (e.g., De Dreu, Koole, & Oldersma 1999; Kardes, Cronley, Kellaris, & Posavac 2004; Webster & Kruglanski 1994). Methodologically, the findings may aid researchers in modifying the cognitive and motivational environment in survey settings to reduce cultural responses biased by distinct SDR styles.

# Construction of Country-Specific, Yet Internationally Comparable Short Form Marketing Scales

Martijn G. de Jong, Erasmus University, The Netherlands
Jan-Benedict E.M. Steenkamp, University of North Carolina at Chapel Hill, USA
Bernard Veldkamp, University of Twente, The Netherlands

## EXTENDED ABSTRACT

Using scientific methods of measurement, analysis, and interpretation are the foundation of marketing's claim to be a science. In the last decades, measurement of consumer behavior and marketing constructs has improved tremendously. Our discipline has also started to systematically catalogue our measurement knowledge in influential handbooks of marketing scales. The popularity of these books is due to marketing science's strong desire to use measurement instruments that are rigorously validated in previous research, rather than ad-hoc constructed scales. However, at least two important issues remain.

First, existing scales are often too long for administration in non-student samples and applied studies. Long scales are well-known to lead to higher costs of data collection, respondent fatigue and frustration, and respondent attrition. Consequently, researchers have started to develop short-forms of existing scales. Moreover, existing common practice to select high-loading items for a short-form does not allow the researcher to measure particular ranges of the latent construct with varying precision, even if academic or managerial insight dictates otherwise.

Second, while it makes much sense to start scale development in the largest, most advanced economy of the world, it is increasingly recognized that marketing theories and measurement are affected by socioeconomic, institutional and cultural contexts. Unfortunately, international marketing research presents important measurement challenges. Scale length becomes an even more pertinent issues as data collection costs multiply by the number of countries. The educational attainment of non-U.S. respondents is often lower, making respondent fatigue and attrition even more problematic. Moreover, it is not obvious that U.S.-developed measurement items are equally informative in other countries. The scales may contain items that are not informative about the underlying construct in particular countries, while relevant items tapping into local cultural expressions of the construct in question may be missing. Although researchers have acknowledged the problems with standardized scales (also known as "imposed etic scales"), the question is how to compare country scores if the set of items differs across countries. What is needed is a method that evaluates the information content of items for each country, allows for shorter scales and country-specific items, and yields sample-independent item characteristics that can be used by other researchers in new samples, while still enabling substantive cross-national comparisons across countries.

For this purpose, we propose a new model that yields fully country-specific, yet cross-nationally comparable short form marketing scales. The procedure is based on a combination of two powerful psychometric tools: hierarchical item response theory (IRT) and optimal test design methods (OTD). Hierarchical IRT has recently been introduced in the marketing literature, while OTD has not been used to date. IRT-based item parameters are sample invariant, and hence, can be used to score respondents in new samples on the same underlying scale. This allows comparison of new findings with previous findings, whether obtained in the same country or in other countries where the model has been applied before. This is another step towards generating a rigorous bank of marketing data and findings that is characteristic of science. The procedure is flexible in the sense that the researcher can specify various constraints on item content, scale length, and measurement precision. Researchers can either impose that the scale length varies across countries, or impose a fixed length across countries at the expense of cross-nationally varying reliability. Moreover, precision can vary along the trait continuum, dependent on a researcher-specified distribution.

Our procedure can be used to construct a short-form marketing scale in a single country or in multiple countries. Since our procedure allows inclusion of country-specific (or "emic") items in standardized (or "etic") scales, it presents an important step toward resolving the emic-etic dilemma that has plagued international marketing research for decades.

In the empirical section, we demonstrated the procedure on the susceptibility to normative influence construct. There is a resurgent interest in social influences on consumer decision making. When making product choices, consumers are frequently influenced by preferences of others, such as family members, friends, neighbors, and so on. The dominant measure for consumers' susceptibility to normative influences (SNI) is the unidimensional, 8-item scale developed by Bearden and colleagues. It measures the predisposition to being influenced by others when making purchase decisions. This scale has been used successfully to study social influences on various aspects of consumer behavior such as attitudes toward brands and advertising, consumer confidence, protective self-presentation efforts, purchase of new products, consumer boycotts. Our dataset contained 28 countries across 4 continents. We developed cross-national SNI scales for each country. The results indicated that different items were selected in different countries, and that scale length indeed varied across nations. In other words, an item is differentially useful to measure latent constructs and some countries require more items than others to obtain a certain acceptable precision for the latent construct.

# A Test of the Validity of Hofstede's Cultural Framework

Jeffrey Blodgett, North Carolina A&T State University, USA
Aysen Bakir, Illinois State University, USA
Gregory Rose, University of Washington, Tacoma, USA

## EXTENDED ABSTRACT

This paper examines the validity of Hofstede's (1980) cultural framework when applied at the individual unit of analysis. Although other researchers (e.g., Triandis, 1995, Schwartz, 1999; House et al., 2004) have also made substantial contributions to our understanding of culture, it is Hofstede's framework that has provided the theoretical foundation upon which much cross-cultural research has been based. Indeed, it is widely acknowledged that, "Hofstede has inspired a great improvement in the discipline by specifying a theoretical model which serves to coordinate research efforts" (Redding, 1994).

Hofstede's cultural framework has been applied in a wide variety of contexts, across most (if not all) of the behavioral science disciplines. In marketing, Hofstede's cultural framework has been applied in studies of advertising (Alden, Hoyer, and Lee, 1993; Gregory and Munch, 1997; Zandpour et al., 1994), global brand strategies (Roth, 1995), and ethical decision making (Blodgett et al., 2001), and is discussed in numerous textbooks (e.g., Keegan and Green, 2003). Clearly, Hofstede's cultural framework has provided the catalyst for many studies throughout the social sciences, and has helped shape marketing thought.

Given the pervasive influence of Hofstede's work across the academic community, it would be reasonable to assume that the validity of the cultural framework has been fully established. However, despite the many studies that have employed Hofstede's framework, it has not been subjected to rigorous tests of reliability and validity (as per Churchill, 1979 and Schwab, 1980). Indeed, several studies raise concerns about the empirical validity of Hofstede's framework (Kagitcibasi, 1994; Soondergaard, 1994; Bakir et al., 2000).

In order to examine the empirical validity of Hofstede's cultural framework an exploratory study was conducted. Subjects were asked to review Hofstede's original 32-item cultural instrument and to indicate which dimension (power distance, individualism/collectivism, uncertainty avoidance, masculinity/femininity) each particular item was intended to reflect. The percentage of subjects who "correctly" classified a particular item was then calculated in order to provide a measure of "face validity." Subjects were also asked to respond to each item (as in a typical questionnaire), thus indicating their underlying values. This data was then used to compute the reliabilities of the four dimensions; and was factor analyzed to determine whether the various items loaded in a manner that is consistent with Hofstede's framework, thus providing evidence as to discriminant and convergent validity.

The sample (n=157) was drawn from two different populations. One group of respondents consisted of 97 MBA students, all of whom have full-time work experience. Another group consisted of 60 faculty members from the behavioral sciences (marketing, management, psychology, sociology, and communications). Given that faculty in the behavioral sciences typically are well trained in construct development their inclusion provides a strong test of the reliability and validity of Hofstede's framework.

Overall, the 32 items were correctly matched by the subjects to their underlying dimensions only 41.3% of the time, on average (see Table 1). The individualism/collectivism items were correctly classified, on average, 43.1% of the time; the uncertainty avoidance and masculinity/ femininity items were successfully identified 30.4% and 26.0% of the time; and the power distance items were correctly classified by subjects 63.1% of the time. Overall, these rates indicate that most of the items lack face validity.

Cronbach's alpha was then computed for each of the four dimensions. Higher levels of alpha indicate that the various items behave in a consistent manner, and reflect the extent to which the items are measuring the same, underlying construct. Unfortunately, none of the four cultural dimensions appears to be sufficiently reliable. Although individualism/collectivism and masculinity/femininity display moderate levels of reliability (.666 and .651), the reliabilities for uncertainty avoidance (.351) and power distance (.301) do not approach minimally acceptable standards (see Nunnally, 1978).

In order to assess the convergent and discriminant validity of Hofstede's instrument principle components factor analyses were performed. If each of the four dimensions is indeed distinct one would expect to find four factors, with similar items loading together to form a coherent structure. Several different analyses were performed, one with the number of factors constrained to equal four. A coherent factor structure did not emerge. Instead, the results indicated that the cultural framework, when applied at the individual unit of analysis, is lacking in both convergent and discriminant validity.

There is no doubt that the concept of culture is legitimate. The authors commend Hofstede for his pioneering work in this area, and for bringing the concept of culture to the forefront of the various behavioral science disciplines. The issue for marketers, however, is how to best capture this construct and its various dimensions. This study presents evidence that Hofstede's cultural instrument lacks sufficient validity when applied at the individual unit of analysis. This critique is not meant to be overly critical of Hofstede's framework. Instead, it is hoped that these findings will eventually lead to a valid measure that captures the richness of the various cultural dimensions and can be deployed at an individual level. Given the diversity of the world marketplace, it is essential that marketers have a robust measure of culture so that our understanding of consumer behavior can keep pace with a rapidly changing environment, and that the academic discipline can make a meaningful contribution to both theory and practice. With that goal in mind, the authors plan on conducting future studies to assess the reliability and validity of other cultural measures, such as those by Schwartz (1999), Triandis (1995), Maznevski and DiStefano (1995), and the GLOBE instrument developed by House et al. (2004).

# To Have and to Hold?  Implications of Disposition Tendencies for Consumer Research

Kelly Haws, Texas A&M University, USA
Rebecca W. Naylor, University of South Carolina, USA
William O. Bearden, University of South Carolina, USA
Robin Coulter, University of Connecticut, USA

## EXTENDED ABSTRACT

Much of consumer research focuses on the acquisition of products and the various considerations and processes that determine how consumers make acquisition decisions. The three phases of consumption (i.e., acquisition, consumption, and disposition) are typically viewed as sequential, rather than cyclical. However, the impact of one's consumption decisions does not end with disposition. Rather, disposal behaviors may very well influence acquisition behaviors, and our psychological approach to the disposition of goods may not only be indicative of the way in which we form relationships with products and brands, but may also shape these relationships.

This research focuses on what we believe is the cyclical nature of the relationship between acquisition, consumption, and disposition, and specifically on the way in which disposition tendencies influence subsequent acquisition. In order to explore this relationship, we identify a continuum, anchored by consumers we call "packrats" and those we call "purgers," along which consumer disposition behaviors and attitudes differ. Coulter and Ligas (2003) defined packrats and purgers from both a behavioral and psychological perspective. Packrats are consumers who keep things and find it difficult to dispose of things. Purgers, on the other hand, continually take stock of whether items are needed and are typically willing to dispose of them if not needed. We propose that these individual tendencies can greatly impact one's decision making processes and behaviors with respect to product acquisition.

Much of the previous research on disposition has focused on defining what constitutes disposition, exploring secondary markets for the sale of goods that are being disposed, and examining the disposal of favorite or cherished possessions. Less attention has been directed to the question of how consumers decide whether to dispose of goods. We therefore focus our attention on the initial decision to dispose or not dispose and the impact that general tendencies in such disposition decisions have on the three phases of consumption. To our knowledge, apart from Coulter and Ligas' (2003) work using depth interviews to define the concepts of packrats and purgers, no other research has explored individual differences in overall disposition patterns or how these patterns might affect acquisition.

To enhance our understanding of disposition, we first develop, evaluate, and empirically test a disposition tendency measure, which we call the Disposition Tendency or DisT scale. We formally define disposition tendency as an individual's willingness to either retain or relinquish physical possessions. Through a series of four studies, we investigate consumer behaviors that are likely affected by differences in disposition tendencies and provide evidence of the proposed cyclical nature of the consumer acquisition, consumption, and disposition process. The implications of understanding consumers' tendencies to hold onto or dispose of products are vast, including direct implications for theory (e.g., how disposition tendency differences impact consumer decision making), for marketers (e.g., how retail, website, and advertisement layout can best meet consumers' preferences; the impact of increased second-hand product markets), and public policy (e.g., waste, littering, environmentalism, and landfill concerns).

In studies 1 and 2, we develop a five-item measure of disposition tendencies, known as the DisT scale. Validity and reliability of our measure are established through various psychometric tests and comparisons with related constructs. Specifically, we discriminate between DisT and a clinical construct called compulsive hoarding. In addition, we also document and discuss interesting relationships between DisT and frugality, change seeking, self-control, and materialism.

In support of our conceptual model, studies 3 and 4 document the impact of DisT on preferred purchase quantities and price sensitivity, respectively, demonstrating that differences in consumers' tendencies to retain or relinquish their possessions do in fact impact specific acquisition related behaviors and preferences. In study 3, we found support for our hypothesis that packrats prefer to purchase larger sizes. This preference is shown to be a preference for larger sizes in general, and not simply a belief that larger sizes are a better value. As such, this result is consistent with our proposition that just as packrats like to be surrounded by many possessions, they reflect this tendency in acquisition. Specifically, they prefer to purchase larger jars of peanut butter than do purgers, in effect stockpiling peanut butter, thus surrounding themselves with more physical possessions (even of a perishable food item). In study 4, we find that DisT scores had a significant effect on the bargain price consumers would pay for a basket of 13 different consumer products, such that participants with higher scores on the DisT scale (i.e., packrats) reported lower prices. These results support our hypothesis that packrats are generally willing to pay less for consumer goods and services than are their purger counterparts, and suggests that, because packrats tend to acquire more possessions, they are more likely to seek out bargains during acquisition.

Although disposition is certainly the least researched aspect of the consumption process despite numerous calls for researchers to look beyond acquisition and consumption (Holbrook 1987; Jacoby 1978; Wells 1993), we have tried to make a case that it is nonetheless, extremely important in influencing the decisions that consumers make and the considerations that marketers might have as well. Our DisT measure provides a solid foundation for future research on disposition, and our demonstrations of the cyclical nature of disposition on acquisitions provide a unique theoretical contribution that will impact future research.

# The Role of Uniqueness Motivations in Social Comparison Processes

Caglar Irmak, University of South Carolina, USA
Beth Antonuk, Loyola College, Maryland, USA
Sankar Sen, Baruch College, USA

## EXTENDED ABSTRACT

Individuals often rely on their own product evaluations to estimate those of others. The implications of such projection processes, wherein the self serves as the standard of comparison, are well explored in extant consumer behavior literature (Ames and Iyengar 2005; Davis, Hoch, and Ragsdale 1986; Hoch 1987, 1988). Less understood, and relatively less examined, is the manner in which individuals incorporate others' product preferences into their own via projection processes that consider others as the comparison referent. For example, consumers estimate the opinions of others to arrive at standards that they chose to comply with (e.g., refraining from purchasing an item they predict their friends will dislike in order to conform to the group) or ignore (e.g., selecting that same item in order to self-differentiate).

The desire to conform or differentiate varies based on an individual's need for uniqueness (NFU), defined as the self-esteem driven need to maintain a sense of at least moderate distinctiveness within one's social milieu (Snyder and Fromkin 1977). In the consumer domain, it has been demonstrated that high NFU individuals have stronger preferences for unique products relative to low NFU individuals (Ames and Iyengar 2005; Tian, Bearden, and Hunter 2001). More complex and less understood, however, is the role of NFU in people's benchmarking of self-other preferences. Prior research has yielded contradictory results regarding the effect of NFU on social projection. On the one hand, research demonstrates that NFU moderates individuals' projection of traits (Kernis 1984); on the other hand, it is perceived similarity, rather than NFU, that moderates the social projection of object preferences (Ames and Iyengar 2005).

The present research builds on theories of uniqueness (Snyder and Fromkin 1977; Tian et al. 2001), self-affirmation (Steele, 1988) and self-other asymmetry (Codol 1987; Hoorens 1995; Mussweiler 2001) to suggest that NFU-related motives are more likely to influence social comparison processes when individuals' sense of self-distinctiveness is not affirmed. Prior research suggests that the reference point for projection is one factor likely to generate such a condition. When the self is the reference point in social comparisons, individuals exhibit a greater tendency to ascribe correspondence between information regarding the self and others compared to instances in which others act as the standard of comparison (Codol 1987; Hoorens 1995; Mussweiler 2001; Srull and Gaelick 1983). This reference-point based asymmetry in social comparison processes has been attributed, in part, to the greater threat to one's sense of distinctiveness posed by comparing oneself to others than by comparing others to oneself (Codol 1987). Such threats to uniqueness are, in turn, typically countered by self-affirmatory processes (Steele 1988; Steele, Spencer and Lynch 1993). Along these lines, research on self-serving social comparisons (Goethals, Messick and Allison 1991; Klein 2001) demonstrates that social comparison estimates tend to be more susceptible to self-enhancement motives when individuals rely on information about others to arrive at judgments about the self (i.e., others as the reference point), compared to instances where information about the self is used to estimate that of others (i.e., self as the reference point).

Based on this, our basic contention is that NFU-related motives are likely to influence social comparison processes when threats to self-perceptions are generated, as is the case when others,

as opposed to the self, serve as the reference point for comparison. Thus, we predict that when the self is the reference point in social comparisons, individuals will project their own product appraisals to those of others, irrespective of their NFU level. When others serve as the reference point, however, we predict that NFU will moderate the projection of others' product appraisals to own appraisals, such that low NFU individuals will project to a greater extent than will high NFU individuals. We investigated these predictions in three studies.

Study 1 exposed participants to an advertisement for a new product and varied the order of their object appraisals. Respondents stated their attitude towards the product either before (i.e., self as the reference point) or after (i.e., others as the reference point) predicting the preferences of others. Our results show that, across NFU level, individuals projected their product evaluations to others; if individuals disliked (liked) the product they estimated a lower (higher) market share. When others were the reference point, however, low NFU individuals projected their estimates of others' product adoption onto their own preferences to a greater extent than did high NFU individuals.

Whereas study 1 asked participants to estimate others' preferences, in study 2 participants were provided with information about the estimated adoption level of the new product. Results replicated those of study 1. Further, while low NFU individuals rated the product more positively when they were provided with a high (vs. low) adoption level estimation, high NFU individuals liked the new product better when the estimated adoption level was low (vs. high).

In study 3 we provided further evidence for our self-affirmatory account of social comparison processes by manipulating and measuring respondents' perceived similarity to others. Specifically, we asked study participants to elaborate, between the tasks of stating their own attitudes and predicting others' preferences, on the ways in which they are different from others. If non-motivational processes drive social comparisons, we would expect the salience of differentness from others to result in a failure to project across NFU level and in both reference point conditions. In line with our proposed account, however, the perceived similarity manipulation impacted social comparison processes differently based on the reference point of the social comparison (i.e., self or others). Specifically, when the self was the reference point both high and low NFU individuals used the differentness made salient by the manipulation to arrive at disparate estimates of adoption level (i.e., not projecting). When others served as the reference point, however, asking respondents to state their differences from others alleviated the reference point-induced threat to self-esteem for high NFU individuals, leading them to project. On the other hand, low NFU individuals, who are threatened by differentness from others, stated their closeness to others by projecting.

In summary, we demonstrate that while both high and low NFU individuals are likely to project their preferences for new products onto others, high NFU individuals are less likely than low NFU individuals to project their estimates of others' preferences onto their own. Moreover, unlike self-anchored projection (Ames and Iyengar 2005), the bases for the moderating effect of NFU on others-anchored projection appear to be motivational; alleviating the projection-induced threat to the high NFU individuals' self-image by having them deliberate on their differentness from others

attenuates the moderating effect of NFU on the projection of product preferences.

# The Effects of Product Quality and the Perceived Structural Relation Between Functions on the Value Inference of Convergence Products

Sara Kim, University of Chicago, USA
Do-Hyung Park, Korea Advanced Institute of Science and Technology, Korea

## EXTENDED ABSTRACT

These days, strategies for new product development have moved beyond the simple addition of a new feature within an existing product category. In the era of digital convergence, a new function from another product category can also be added to a product (e.g., the addition of an electronic dictionary to a cellular phone). Demand for convergence products combining the disciplines of several application domains has accelerated for the last decade (Schirrmeister and Sangiovanni-Vincentelli 2001). Despite the attractive marketability of convergence products, few studies have focused on how consumers infer the value of products with functions from different product categories. This study examines how consumers infer the value of a new convergence product.

Previous research on new products focused on feature addition. The newly added feature usually enhanced the existing function. One stream of research on new feature addition has considered characteristics of the new feature such as novelty and relevance with an existing product category (Brown and Capenter 2000; Moreau, Lehmann and Markman 2001), while another stream of research has investigated the characteristics of existing features (Mukherjee and Hoyer 2001; Nowlis and Simonson 1996). According to diminishing sensitivity, a new feature adds more value when it is offered by a relatively inferior product than when it is offered by a relatively superior product (Nowlis and Simonson 1996). A new feature is more noticeable when existing features play an inferior role. The Nowlis and Simonson (1996) study says that they extend previous research on diminishing sensitivity because they show that this phenomenon still occurs across features. However, this study points out that a new feature is not truly 'new' if the new feature simply enhances the existing function. What if a new function from another product category is added to a product? Will the diminishing sensitivity phenomenon still occur?

In the first experiment, feature addition is examined in order to show that the diminishing sensitivity phenomenon occurs when a new feature and an existing feature perform the same function. The experimental design has been slightly modified from the previous one. Instead of using monetary terms to measure overall product value, the experiment measured the perceived overall evaluation of the product with a 7 point bipolar scale. The results of the experiment are consistent with the Nowlis and Simonson study (1996). When the new feature enhances an existing function, new feature addition has greater impact on overall product evaluation if the new feature is added to a product with inferior existing features than with superior existing features.

Experiment 2 explores how consumers infer the value of a new function added to a product from another product category. This research investigates a unique aspect of the value inference of multifunctional products: perceived structural relations between functions. The perceived structural relation is formed when consumers infer that a feature enhancing the performance of one function may enhance the performance of other function. The reason that it is 'perceived' structural relations is because this inferred structural relation between functions may simply be the perception of the consumer. When consumers perceive the existence of a relationship between a new function and an existing function, the existing function may not always be the background. In this case, consumers can infer the value of the new function based on the value of the existing function. That is, consumers will infer that the value of a new function is greater when an existing function is superior than when it is inferior. Experiment 2 shows that the impact of the new function will be greater when the existing function is superior than when it is inferior when individuals infer the value of a new function based on a high perceived structural relation with an existing function. However, the new function will contribute to the perceived value of a product more when the existing function is inferior than when it is superior if the new function has a low perceived structural relation with the existing function. This result is consistent with previous studies on diminishing sensitivity.

According to the results of Experiment 2, subjects infer that the performance of the DMB function will be better if it is added to a 5 mega pixel camera phone than if it is added to a 1.3 mega pixel camera phone. They think that an increase in the number of pixels enhances the DMB function (the new function) as well as the camera function (the existing function). Therefore, the addition of the DMB function has a greater impact on the overall product evaluation when it is added to a 5 mega pixel camera phone than when it is added to a 1.3 mega pixel camera phone. However, when the electronic dictionary function is added to a camera phone (the low-perceived-structural-relation condition), subjects perceive the value of the electronic function is greater when it is added to a 1.3 mega pixel camera phone than when it is added to a 5 mega pixel camera phone.

This study contributes to the literature on inferential processes in terms of a new kind of inferential process which is based on the perceived structural relation. This study also contributes to the research on new products since it considers digital convergence products to extend the previous studies on feature addition.

# Let it Rock: The Effects of Brand Name Placement in Songs on Attitudes toward the Artist and the Brand

Bruno Kocher, University of Lausanne, Switzerland
Macro Lalos, University of Lausanne, Switzerland

## EXTENDED ABSTRACT

This paper focuses on a specific type of product placement, namely brand placement in song lyrics and particularly on its impact over consumers' attitudes toward the brand and the artist. Three significant factors were identified in the literature and manipulated through two experiments: Congruence of the artist-brand dyad, strength and valence. Whereas the impact of congruence on product placement has been proven (Russell, 2002), the last two elements are novel and explicitly stated as important for future research (Balasubramanian, Karrh and Patwardhan, 2006).

## Congruence

Russell (2002) develops the notion of congruence as a major factor determining audiences' reactions toward product placement. Incongruent information triggers cognitive elaboration and auditors' attention, thus improving the memory of the placement. Whereas congruence enhances realism, incongruent information elicits suspicions about the reasons for the brand appearing in the show; thus triggering unfavourable effects on evaluation. Russell (2002) conceptualizes congruence as the combination of modality (visual / audio) and plot connection (lower / higher). In this research, congruence was conceptualized as the fit or match between the brand and the artist. The first study probes the proposed model in an incongruent artist-brand dyad, and the second study investigates the congruent artist-brand dyad.

## Valence

In general, academic literature suggests that putting forward product advantages rather than disadvantages enhances the attitude toward it, and vice versa when communication for the product is negative (Balasubramanian, 1994). Notwithstanding that several variables are considered to moderate the effects of negative communication on attitudes toward brands (Ahluwalia, Bumkrant, and Unnava, 2000; Till and Shimp, 1998), recent studies proved that, under certain circumstances, negative communication related to products can yield positive cues (Money, Shimp and Sakano, 2006). In addition, in line with Campbell's (1995) attention-getting tactics research, placing positive brand arguments in songs may be perceived as manipulated communication by audiences.

Building on the previous arguments, the hypotheses laid out in this paper suggest that individuals will have more positive attitudes toward artists and brands when the communication valence is negative, compared to less favourable attitudes when the communication valence is positive.

## Strength

The influence of the communication modality will be moderated by the strength of the relationship between the artist and the brand. In the context of product placement in movies or sitcoms, strength is operationalized by fore versus background placement or by visual only versus visual and verbal placements (Russell and Stern, 2006). As this study concerns music songs, strength was implemented by repeating a brand name as to reinforce the association with the artist. Balasubramanian et al. (2006) specifically underlined the importance of "repetition" as an operationalization mode that could have a significant influence on product placement effectiveness. Therefore, the effect of repetition is seen as a cata-

lyser of communication on attitudes, and depends on whether the product is communicated positively or negatively.

## Studies

Two scenario based studies (coherent/incoherent brand-artist dyad) were designed and implemented to test the hypotheses. Eight scenarios were crafted (four scenarios per study); each of them combined the effect of communication valence (positive/negative) and strength (repeated/not repeated). One artist was chosen and remained constant across all eight scenarios. Two brands were chosen to create an incoherent artist-brand dyad (used in study one) and a coherent artist-brand dyad (used in study two). These were chosen while executing several pretests after which the appropriate stimuli were obtained. To avoid likeability, an equally liked / disliked artist and two neutrally liked brands were selected.

The studies were carried-out among a sample of undergraduate students. These were given two booklets presented as unrelated studies belonging to two different researchers. The first booklet was presented as a study on general attitudes concerning celebrities and brands; the second booklet was presented as a study on new trends in the music industry. Respondents were asked to imagine a situation in which they were invited by a music company to listen to new songs from a given artist, in order to assess the new album. It was stipulated in each scenario that the artist mentioned in his lyrics (either in a positive or negative valence) once only or several times (strength) a brand (either incongruent in study one or congruent in study two). Finally, respondents were asked about their attitudes toward the artist and the brand using a five item 7 point Likert scale (Aggarwal, 2004). Several manipulation checks were executed to ascertain the reliability of the manipulations.

Two (incongruent/congruent) 2 X 2 (valence: positive vs. negative; strength: none repeated vs. repeated) between-participant ANCOVAs were performed to measure the effect of treatments over attitudes toward the artist and the brand. The most significant results are:

## Incongruent artist-brand dyad-attitudes toward the artist:

The two-way interaction between valence and strength was significant. A planned contrast revealed that if a brand is communicated negatively and for repeated times, the average attitude toward the artist is more positive compared to the attitude when the brand was communicated positively and for repeated times. In contrast, when a brand is communicated negatively but not repeatedly, no significant difference was reported compared to a brand communicated positively but not repeatedly.

## Incongruent artist-brand dyad-attitudes toward the brand:

The between-participant effect of valence was significant. Participants reported more favorable attitudes toward the brand after the artist mentioned the brand negatively instead of positively. However, the two-way interaction between valence and strength was non significant.

## Congruent artist-brand dyad-attitudes toward the artist:

The between-participant effect of valence was significant. Participants reported more favorable attitudes toward the artist after he mentioned the brand negatively instead of positively. However,

the two-way interaction between valence and strength was non significant.

**Congruent artist-brand dyad-attitudes toward the brand:**

The two-way interaction between valence and strength was significant. A planned contrast revealed that if a brand is communicated negatively and for repeated times, respondents have more positive attitudes toward the brand compared to attitudes when it is communicated positively and for repeated times. No significant difference was observed over the attitude toward the brand when this was not repeated, irrespective of the positive or negative communication modality.

Implications for marketers are considerable, since misused valence can discount individuals' attitudes over brands and artists. Finally, the research proposed several findings which could be worth considering in better law framing, due to the ethical implications that hybrid messages contain.

# A Friend and/or A Foe?: Exploring Activeness of Objects in Consumption

Olga Kravets, Bilkent University, Turkey
Berna Tari, Bilkent University, Turkey

## EXTENDED ABSTRACT

The issue of consumer-object relation has received considerable attention in consumer research. Taking Belk's (1988) notion of the extended self as the conceptual foundation, a significant body of work has examined the role of things in self-actualization, constructing social identities and coping with identity change in transition periods (e.g., Price et al 2000; Schouten 1991), as well as feelings of possessiveness, and moral effects of possessions on personality and person's well-being (e.g., Hill 1991; Richins 1994). Another active stream of consumer research explores how consumption objects mediate social relations and the ways consumers use goods to make and maintain social distinctions (e.g., Kates 2002). While this research has generated valuable, rich insights into various facets of person-object relations in consumption contexts, as a generalization, much of this research focuses on symbolic aspect of goods and consumer-object relations; hence objects are often conceived as passive relation-partners, albeit endowed by people with meanings. However, our exploratory study reveals that some people see and interact with various objects as active entities that could enhance or interfere with their everyday life. It is this activeness of objects, how it transpires in and impacts consumption that we seek to explore.

In this research, we draw extensively on the existent research into consumers' relation to things and to animal companions (ibid.; Hirschman 1994; Holbrook et al 2001). In addition, we engage a selection of concepts, debates and ideas on the activeness of things from the world of art, literature and popular science. Thus, we consider the 1920s soviet constructivists' concept of a *socialist thing*–an active partner and co-worker, whose activeness arises primarily from its functionality. The core of the notion is the belief that "thing has an agency that is potentially beneficial to the human subject, which is itself rendered more active and "evolved" through interaction with this thing" (Kiaer 2004, 263). We also draw on works of fiction from the same period in the Soviet history, where such agency of things was celebrated as well as questioned (e.g., Olesha 1923). That literature anticipated the emergence in the 1950s of a controversial idea of *resistentialism*, which rests on the belief that inanimate objects have a natural hostility toward humans; thus, it is things rather than people who increasingly control daily living (Jennings 1948). Finally, our research is informed by more recent academic works that consider activeness of objects, premised on objects' utility among other things. Particularly, emphasizing the importance of the materiality of things and their sensual qualities, Miller (1998) contends that objects are active insofar as they are constituents of social relations. Latour (1992; 1994), to oversimplify greatly, argues against the artificially made distinction between inanimate objects and human subjects, and advocates thinking of things as non-human actors, that carry huge amount of social work.

The notion of things' activeness emerged in the course of in-depth interviews conducted as part of an exploratory study into car ownership practices. As the significance of this notion became apparent, we broadened the scope of the inquiry to include objects other than cars to enhance our understanding of this phenomenon. Such research conduct is consistent with the methodological logic of grounded-theory approach (Goulding 2002). We interviewed 23 consumers about their experiences with active objects in their lives. We followed the guidelines of McCracken's (1988) "long interview," allowing our interviewees to lead the way raising the issues of interest to them as regards the suggested topic. The analysis was iterative; we focused on discerning broader patterns and common themes across the interviews, moving back and forth between the themes and the literature to develop an understanding of the themes (Goulding 2002).

Two thematic constellations of relating to active object emerged in the study, each comprising of a number of practices. The first, objects as companions, refers to seeing and treating a particular object as a partner, which helps a person to cope with the daily challenges. The theme is realized through humanizing tendency, which in turn is enacted in practices naming objects, assigning gender, celebrating their birthdays and constructing their life-histories. Informants report a range of positive experiences resulting from object companionship from emotional support ('makes me smile') to improving the quality of person's life (both through objects' functioning and its aesthetics). The second theme –object as a consumer– relates to the idea that objects place demands on people in terms of skills, knowledge, manner of use but it also relates to people' perception that some objects have needs and desires, feelings and interests. Such view is evident in the practices of buying 'presents' for a pet-object and servicing an object as a way of pleasing it. The positive experiences with the objects companionship depends on the functional performance of the object, and adequacy of the demands it puts on people relative to its performance and centrality of the object in people's everyday life. Overall, the two tentative thematic constellations are deeply intertwined, they become evident and acquire their significance in specific contexts, and importantly they speak of the activeness of things, which appears to emerge in relations, in people's mundane practices and daily experiences with objects.

Conceiving the paper as polemic, we conclude by pointing out three issues that arise from considering the activeness of things. The first has to do with how, if at all, the perceived activeness of an object reflects on consumption patterns. The second concerns the general question of the use of consumption objects and consumption as work, against the background of consumer researchers' focus on acquisition and prevalent interest in symbolic aspects of consumption. The third is the question about the nature of relationships between people and objects, activeness of which arises and depends on both their utility and their aesthetic value. Theoretically, we hope to contribute to an understanding of object-relations that arise from objects' functionality. Practically, by focusing on practices, including both people's doings with things and social work of things, we hope to contribute to the research on sustainable consumption, for, given that sustainability is not just a matter of technical fixes but of social and cultural practices (Shove 2003), a more nuanced understanding of *curating* practices, for example, could help in devising effective strategies to increase the longevity of objects in use, thereby promote sustainable consumption.

# Tinsel, Trimmings, and Tensions: Consumer Negotiations of a Focal Christmas Artifact

Cele C. Otnes, University of Illinois at Urbana-Champaign, USA
Elizabeth Crosby, University of Illinois at Urbana-Champaign, USA
Robert Kreuzbauer, University of Illinois at Urbana-Champaign, USA
Jennifer Ho, University of Illinois at Urbana-Champaign, USA

## EXTENDED ABSTRACT

Ritualistic consumption is defined as the use of goods, services and experiences in expressive, dramatic, symbolic, formal and intense ways, in contexts often repeated over time (Rook, 1985). Scholars consistently demonstrate that consumers find rituals to be financially, socially, and emotionally significant (Belk 1989; Otnes and Lowrey 2004; Sherry 1983; Wallendorf and Arnould 1991). Participating in consumption rituals often involves coordination and planning among nuclear and extended families, and such planning can require weeks, months or even a year or longer. However, little is known about how family members negotiate as they co-create the aesthetic aspects of ritualistic experiences.

This paper explores how family members negotiate as they co-create a key ritual artifact of the Christmas holiday—the Christmas tree. Our interviews with consumers clearly indicate that many consider the tree a key—if not *the* key—ritual artifact during the holiday season. The tree acts as a ritual hub, with important and sensory-laden sub-rituals emanating from it. Since the relationships between members are fluid and constantly renegotiated, co-creation of Christmas tree traditions is fluid within a household as well. Given the integral role of the tree at Christmas, we explore these questions: 1) what tensions pervade consumers' co-creation of the Christmas tree?; and 2) what negotiation strategies do consumers employ when trying to resolve these tensions?

As part of a larger study on consumers' Christmas experiences, we conducted depth interviews with 26 consumers from December 2006 to February 2007. We employed snowball sampling, recruiting informants from among acquaintance networks. Informants ranged in age from 22 to 64, and resided in either the Midwest or the Northeast United States. Interviews ranged from 45 to 75 minutes, were audiotaped and transcribed, and yielded 334 double-spaced pages of text.

In analyzing the text, we sought out emergent themes while engaging in dialectical tacking (Strauss and Corbin, 1998), immersing ourselves in the interdisciplinary literature on Christmas and ritual celebrations to seek out consistencies and/or inconsistencies with our text. In our initial readings we narrowed the findings such that patterns of association and assumption emerged and became clear (McCracken, 1988). Although we did not initially intend to focus on how consumers negotiate the Christmas tree, the quantity and quality of text devoted to the artifact spurred us to narrow our focus. We then narrowed it even more to unpacking the specific tensions that emerge as consumers select, decorate, and display the tree.

We find four distinct pairs of tensions can shape consumers' co-creation of the Christmas tree: aesthetics vs. tradition, family fantasy vs. family reality, authenticity vs. convenience, and $taste_1$ vs. $taste_2$. For each tension, a set of negotiation strategies emerges, although consumers sometimes apply the same strategy to resolve different tensions.

*Aesthetics vs. Tradition.* One function of rituals is to connect consumers of one ritual occasion to other similar events across time (Gillis 1996). One way consumers do so is by retaining and reusing the same ritual artifacts every time they celebrate Christmas. But one difficulty with this behavior is that these sentimental ornaments may not meet consumers' own likely shifting standards of beauty, which are likewise embedded in an increasing valorization of aesthetics as a cultural value (Postrel, 2003). Many informants express ambivalence toward marrying sentimental and aesthetic approaches, and a few adamantly oppose doing so, even when other family members wish to. Those informants who must resolve family tensions between aesthetics and sentimentality when co-creating the Christmas tree employ three strategies: dictate, segregate (same-site), or segregate (multiple-site).

*Family Fantasy vs. Family Reality.* Many informants possess an idealized image of how they want their Christmas tree selection and decoration to proceed. However, the realities of everyday life—including time pressures and changes in their household structure as family members move through the life cycle—means much of the time, their fantasies of co-creating the Christmas tree cannot always be fulfilled. When consumers are not able to enact their ritual fantasies, they often employ three strategies that help them negotiate the tension between ritual fantasy and ritual reality: adhere to an acceptable minimal standard, reserve the sacred, and eliminate the tradition, while mourning the loss in order to resolve the tension..

*Authenticity vs. Convenience.* For many informants, the meaning of an authentic Christmas tree tradition stems from their adherence to two rules. The first—that one must have a Christmas tree, especially if young children are involved in the celebration, is described by Caplow (1982). The second involves the necessity of having a live Christmas tree rather than an artificial variant. But authenticity also requires consumers to retrieve, haul, care for, and clean up after a real tree; thus, many informants often note (with regret) that they have opted for an artificial tree. When informants try to negotiate the tensions arising from the decision to opt for authenticity over convenience, they follow two strategies that we have previously identified–adhere the minimally acceptable standard or eliminate the tradition, while mourning the loss in order to resolve the tension.

*$Taste_1$ vs. $Taste_2$.* The final tension that emerges can stem purely from different established tastes in tree fashions. Not surprisingly, the central role of the tree means some consumers develop very specific ideas as to how they want their trees to appear. Sometimes these preferences are the result of new market offerings—and innovations in trees can result in clashes of aesthetic preferences within a household. When informants try and negotiate the tensions arising from differences in taste, they follow two strategies–joke/tease or use a third party mediator.

We explore the ways in which consumers negotiate the aesthetics of the focal ritual artifact of the Christmas tree. We hope this paper encourages scholars to revisit consumers' understanding of aesthetics as these understandings are negotiated and reconceptualized within their social networks, both during ritual occasions and beyond.

# Protecting the Portals of Home

Karen V. Fernandez, University of Auckland, New Zealand

## EXTENDED ABSTRACT

We make many transitions between places, identities, and cultural environments every day—from home to work (Tian and Belk 2005), from one role to another (Ashforth, Kreiner and Fugate 2000), and from the familiar to the strange (Mehta and Belk 1991). Thresholds, the physical barriers between separate bounded states, are often crossed. Both invited and uninvited crossings of these thresholds usually occur at portals, which are points of entry within thresholds. Portals thus represent particularly dangerous places within the dangerous liminal zones of boundaries (Douglas 1966).

Home, one's primary dwelling place—representing "inside", privacy, family, leisure, familiarity, order/structure and sacred—is the antithesis of "outside", public, stranger (Belk 1997); work (Tian and Belk 2005), journey (Case 1996), disorder/anti-structure (Turner 1969) and profane (Belk, Wallendorf and Sherry 1989). Consequently, the home is the ideal context in which to examine the processes by which consumers control access to their selves and their extended (Belk 1988) selves. Two inter-related essential qualities of a home are the provision of privacy and security (Porteous 1976; Smith 1994). This need for privacy and security exists in dialectical tension with the need to invite others into the home for social and other activities (e.g. maintenance and repair). This dialectical tension between the private and public nature of the home (Korosec-Serfaty 1984) is focused on portals. Thus, it is managed by attempting to control others' access to the portals of the home.

Consumer researchers have devoted considerable study to possession attachment—consumers' relationships with psychologically appropriated material objects (Kleine and Baker 2004). Key among these studies is Belk's (1988) study of how consumers can extend themselves by experiencing their selves "through concrete sets of persons, places and things" (Tian and Belk 2005, p.297). Belk (1988) explains that consumers can incorporate a possession into self through controlling or appropriating its use, creating it, knowing it intimately, and by contaminating it. This stream of research has focused on the meaning of possessions, how they are incorporated into self, and how they subsequently serve to define and communicate self-identity, but has not explicitly examined how self-extensions are protected.

Places, spaces that have been given meaning through personal, group or cultural processes, may vary in scale, tangibility, and familiarity (Low and Altman 1992). Conceptualizing a place usually involves a defined physical (e.g. a house) and/or psychological (e.g. a haven) territory. Place attachment is the bonding between person and place that develops over time due to a series of interactions between person and place (Kleine and Baker 2004; Low and Altman 1992). When attached to a place, people often engage in territoriality. Territoriality is the attempt to influence or control actions, interactions or access (of people, things and relationships), by asserting and attempting to enforce control over a specific geographic area (Sack 1983). Territoriality can involve erecting and maintaining physical and/or psychological barriers or boundary markers. Thus, personalization of a space can be as much a territorial marker as a wall. Due to the biological basis of territoriality, environmental psychologists have mostly studied territorial demarcation and reactions to intrusion, leaving its potential to explain attachment and self-expression unfulfilled (Brown 1987).

Consequently, as suggested by Kleine and Baker (2004), the extant consumer research literature on possession attachment and extended self was enriched by the extant environmental psychology literature on place attachment and territoriality, to theoretically frame this research.

As part of a larger study, the author conducted eleven videotaped, unstructured depth interviews to explore the theme of protection of home. The videotaped interviews were transcribed and these 150 pages of single-spaced transcripts, along with the original videos, photographs and fieldnotes formed the data set. Open and axial coding (Spiggle 1994), in conjunction with the relevant consumer research and environmental psychology literature, was used to develop interpretations. The resultant interpretations clarify how consumers protect places, people and possessions within their homes by physically, symbolically and ritually protecting three important portals of the home: the front door, the hearth, and the bed.

Like the Parisians described by Rosselin (1999), all informants controlled access to their front doors with one or more marketer-derived protection devices such as locks, chains, peepholes, intercoms, and security alarms. However, some informants also resorted to more symbolic protective devices such as altars and family photographs to protect the primary entrance to their home. One home, inhabited by three members of a neo-tribe, utilized a carpet that literally (through its pattern) and symbolically (through its provenance) symbolized family/neo-tribe. Many women identify, and become identified with, home in general and the kitchen in particular. Consequently, the male role of defender of the family was expressed in the males' symbolic protection of their wives' hearths using guns, arrows, photographs of ancestors, and mementoes of a former heroic self. The bedroom door was sometimes territorially marked with signage, but even more critical was the defense of the bed, where consumers are at their most vulnerable. This portal was protected by cultural artifacts, reminders of religious blessing and even a magical Princess Bed that repelled "bad people".

This study adds to consumer researchers' understanding of extended self by drawing on territoriality research to explain how self extensions can be protected by drawing on the power of the group. Protective symbols can originate from groups large and small—from organized religion, cultural myths, ancestors, extended family or its post-modern proxy, the neo-tribe. The processes of personalization and accompanying processes of upkeep and maintenance of the home serve to inextricably link the identities of transformer and transformed. The analogy of home décor as clothing for the body of the family (Belk 1988), is extended. Clothing, while serving to convey identity, also can protect the body. Likewise, consumers' attempts to personalize the portals of their home function to mark and protect their territories, protecting those who dwell within. Finally, this study also demonstrates the value that the literature on place attachment can add to our understanding of possession attachment.

# The "Shaken Self": Product Choice as a Means of Restoring Self-View Confidence

Leilei Gao, Stanford University, USA
S. Christian Wheeler, Stanford University, USA
Baba Shiv, Stanford University, USA

## EXTENDED ABSTRACT

Consider the following scenario. Pat and Robin, both aspiring marketing academics, are equally confident about their intelligence. Pat and Robin are each asked to write a short essay titled "I am an intelligent person." Unfortunately, Pat recently suffered a fracture in his dominant hand from an accident during a ski trip. He, therefore, uses his non-dominant hand to write the essay; Robin writes the essay with her dominant hand. Later, Pat and Robin are confronted with a choice between two options—subscriptions to either the *Wall Street Journal* or *Sports Illustrated*. Assuming that the subscriptions cost the same, is it possible that Pat and Robin would display systematic shifts in preferences for the choice options as a consequence of writing their respective essays? For instance, is it possible that Pat, who wrote the essay with his non-dominant hand, would be more likely to choose *Wall Street Journal* over *Sports Illustrated*? Although intuition might suggest that the task of writing the essay with one's non-dominant (vs. dominant) hand should not affect subsequent choices, the basic thrust of this article is to suggest otherwise. Specifically, a goal of this paper is to examine the effects of the "shaken self," that is a momentary lapse in self-confidence on subsequent product choices.

Previous research suggests that self-view confidence depends on the availability of stable evidence in support of that self-view, and that a lack of such confidence motivates efforts to restore it either directly (Festinger 1954; Tiedens and Linton 2001) or indirectly (Steele 1988). The purpose of this research is to extend prior work by examining how subtle situational factors can induce lowered confidence in a particular self-view and thereby affect subsequent product choices. Specifically, we posit that seemingly inconsequential actions, such as writing an essay with one's non-dominant hand, can lower self-confidence and lead to self-bolstering product choices. Thus, in the scenario presented earlier, we posit that Pat, writing with his non-dominant hand, would begin to experience uncertainty regarding his intelligence. As a result, Pat would display a strong propensity to systematically choose products (such as the *Wall Street Journal*, the more "intelligent" of the two options) that would help him restore his confidence in his intelligence.

In developing our conceptualization, we propose that subtle situational factors that reduce self-confidence will instigate processes aimed at restoring the self-concept. We argue that this restoration can occur via multiple means, including more direct methods (e.g., purchasing products to restore the specific shaken self-dimension) and more indirect methods (e.g., affirming an unrelated self-value). Once the self-restoration has occurred, individuals make choices similar to those whose self-concept was never shaken in the first place. We tested these notions across a series of three experiments. In these experiments, we relied on a previously validated handwriting procedure (Briñol & Petty, 2003) to subtly reduce self-confidence (or not) and tested the effects across three self-dimensions (being exciting, intelligent, and health-conscious). We predicted that this subtle manipulation would lead participants to choose products affirming the shaken self-confidence dimension, unless they were first provided with a means of restoring the self-concept.

In the first experiment, we tested the core hypothesis that those who wrote about a self-dimension with their non-dominant hands would be more likely than dominant hand participants to choose products consistent with that self-dimension. Specifically, participants in this experiment were instructed to write an essay portraying themselves as being exciting. Some participants were assigned to write the essay with their dominant hands; others were assigned to write the essay with their non-dominant hands. Participants then engaged in a purportedly unrelated task choosing between exciting brands (e.g. Apple) and competent brands (e.g. IBM). Results indicated that compared to participants who wrote about their excitingness with their dominant hand, those who wrote with their non-dominant hand were more likely to choose exciting brands in the final choice task.

In the second experiment, we replicated this basic result in a different self-domain (intelligence) and demonstrated the self-view recovery function of product choice. Specifically, participants in this experiment were instructed to write about their intelligence either with their dominant hand or non-dominant hand. The final choice task was between a fountain pen and a pack of candy. As expected, non-dominant hand participants were more likely to choose the fountain pen (vs. candy) as their study reward. However, this effect was attenuated if non-dominant hand participants were given an opportunity to select self-bolstering products (e.g. a bookstore gift certificate) before the final choice task.

In the third experiment, we replicated the core effect in a third domain (health-consciousness) and showed that indirect means of self-bolstering (i.e., self-affirmation) similarly eliminates the effect of the manipulation on choice. We found that compared to participants who wrote about their healthy life habits with their dominant hand, participants who wrote with their non-dominant hand were more likely to choose a healthy snack (an apple) versus a non-healthy snack (M&M's). This effect, however, was attenuated after participants were given the opportunity to reaffirm a most important value in their life before the final choice task.

The findings from three experiments provide support to the hypotheses that subtle situational factors such as writing about one's self-views with one's non-dominant hand can lower self-confidence and increase the propensity to choose self-view bolstering products. Further, these effects on product choices will be attenuated when participants are first provided with the opportunity to bolster the self-concept either directly (through choosing products from sets of self-view bolstering products) or indirectly (through self-affirmation). These results highlight the importance of the self-concept and self-view confidence for product choice and illustrate the role of product choices in maintaining stable self-views. We discuss the implications of our findings and present several directions for future research.

# Flattery and Persuasion: A Dual Attitudes Perspective

Elaine Chan, Hong Kong University of Science and Technology, Hong Kong
Jaideep Sengupta, Hong Kong University of Science and Technology, Hong Kong

## EXTENDED ABSTRACT

Several studies have shown that the target of flattery evaluates the flatterer positively, because people have a basic desire to believe good things about themselves (e.g., Vonk 2002). Recent research, however, suggests a caveat. Namely, when people are aware of an ulterior motive (e.g., the consumer who suspects that a salesperson is offering a compliment just to close the sale), they discount the flattery and correct their otherwise favorable opinions (e.g., Campbell and Kirmani 2000; Main, Dahl and Darke 2007).

The current research offers some new insights into flattery and its consequences. In particular, we use the dual attitudes perspective (Wilson, Lindsey and Schooler 2000) to show that even when the target of flattery perceives an ulterior motive and corrects for it, the original positive reaction (the implicit attitude) co-exists with, rather than being replaced by, the discounted evaluation (the explicit attitude). The implicit attitude, which takes the form of a relatively automatic reaction, is then likely to be manifested upon subsequent exposure to the source of flattery if capacity is constrained at the point of measurement; otherwise, it is the explicit evaluation that is reported.

Second, we draw on the attitude strength literature (e.g., Krosnick and Petty 1995) to show that the implicit attitude, because of its relatively automatic activation, is more likely to persist over time and also resist negative information, compared to the explicit attitude. The implicit effects of flattery, therefore, can be particularly insidious. A third goal of our research is to establish theoretically-derived boundary conditions for the posited discrepancy between the implicit and explicit attitudes produced by flattery, in order to illuminate the processes underlying this discrepancy.

Four experiments were run to test our hypotheses. Experiment 1A used a simple one factor between-subjects design (Implicit vs. Explicit attitudes measure) to examine the basic thesis that flattery induces two distinct attitudes. Participants were asked to imagine they had received a leaflet from a new department store; the leaflet contained some store details and an invitation to visit, along with fulsome compliments on the participants' fashion sense. The key dependent measures, administered on a computer, comprised a set of items assessing store evaluations. Responses were collected under either time-constrained (5 seconds per item; implicit measure) or unconstrained conditions (unlimited time; explicit measure). The predicted difference was observed between the two attitude measures ($M_{implicit}$=5.71, $M_{explicit}$= 5.02, $F(1, 53)$=4.03, $p$<.05). Also of interest, a delayed behavioral intention measure (likelihood of visiting the store) which was collected three days after the main study, was correlated more strongly with the implicit attitude than the explicit attitude ($r_{implicit}$=.75, $r_{explicit}$=.14, $F$=4.10, $p$<.05). A follow-up study, Experiment 1B, was run to replicate these findings using within-subjects measurement. A similar procedure was used as before, except that all participants were asked to provide evaluations under *both* time-constrained (implicit attitudes) and time-unconstrained conditions (explicit attitudes). The order of these two measurements was counterbalanced, and the ordering had no influence on the results. Reassuringly, as with the between-subjects method used in Experiment 1A, results again revealed that the implicit attitude resulting from flattery ($M$=5.06) was higher than the explicit attitude ($M$=4.33; $F(1, 64)$=17.14, $p$<.001). Further, this study obtained convergent evidence regarding the greater predictive validity of implicit attitudes: a lower

difference score–and thus, greater similarity–was observed between a delayed attitudinal measure and the implicit initial attitude ($M_{diff}$=-.14) vs. the explicit initial attitude ($M_{diff}$=0.59, $F(1, 64)$=14.89, $p$<.001).

Experiment 2 used a 3 (Flattery condition: store-noncontingent vs. unrelated-noncontingent vs. store-contingent) X 2 (Measures of store attitudes: explicit vs. implicit) design to provide further insights into these findings. In this study, the flattering comments were couched as positive feedback on a personality survey undertaken by participants. Participants in the non-contingent (contingent) conditions were made to believe that the feedback was insincere (sincere)–i.e., non-contingent (contingent) on their actual responses on the survey. Further, in the two "store" conditions, the flattery emanated from the store which was evaluated later; in the "unrelated" condition, the feedback source was the marketing department of the university–this can therefore be viewed as a no-flattery condition from the store's perspective. Store evaluations were obtained under either time-constrained or unconstrained conditions. As expected, results in the store-noncontingent condition replicated our earlier findings ($M_{explicit}$=4.41; $M_{implicit}$=5.44, $F(1, 100)$=9.46, $p$<.01). However, in the unrelated-noncontingent case, since the feedback came from a different source, no difference was expected or found for implicit vs. explicit judgments of the store ($M_{explicit}$=4.31; $M_{implicit}$=4.52; $F$<1, $ns$), ruling out a simple mood-based explanation of our earlier findings. Also of interest, comparisons with this baseline condition showed that non-contingent flattery by the store exerts its effect by raising implicit attitudes ($M_{store-flattery}$=5.44, $M_{department-flattery}$=4.52, $F(1,100)$=6.56, $p$<.05), not by lowering explicit judgments ($M$'s: 4.41 vs. 4.31, $F$<1). Finally, we expected no difference between explicit and implicit attitudes when the feedback by the store was perceived to be genuine (contingent condition), since participants should no longer discount the flattery in their explicit judgments. Results supported this view ($M_{explicit}$=5.10; $M_{implicit}$=5.22; $F$<1).

Experiment 3 used a 2 (Self-esteem: self-affirmation vs. threat) x 2 (Measures: explicit vs. implicit) design to identify another boundary condition for the discrepancy between the implicit and explicit attitudes induced by flattery. In the affirmation (threat) condition, participants wrote about a positive (negative) attribute of their own, before being exposed to the same flattery manipulation and dependent variables as in Experiment 1. Since the favorable implicit attitude is caused by a desire for self-enhancement, we expected that this effect would be diminished if participants were already feeling enhanced before exposure to flattery– i.e., in the affirmation condition. In accordance, while the threat condition produced the prior pattern of discrepancy ($M_{explicit}$=4.32; $M_{implicit}$=5.14; $F(1, 101)$=5.66, $p$<.05), this was no longer observed in the self-affirmation condition ($M_{explicit}$=4.41; $M_{implicit}$=4.19; $F$<1). Finally, this study also included a measure of resistance to negative information. After initial attitude measurement, all participants were exposed to negative information about the department store; attitudes were then measured again either implicitly or explicitly. Across conditions, the difference between initial and post-attack attitudes was lower–i.e., resistance was higher–for implicit vs. explicit attitudes ($M_{implicit}$=.07; $M_{explicit}$=.61; $F$=4.09, $p$<.05).

Taken together, results from our studies provide new insights as to the dual attitudes produced by flattery, and also shed light on

the underlying mechanism by documenting informative boundary conditions for the duality. Finally, this research contributes to the dual attitude literature (and simultaneously documents the potentially insidious effects of flattery) by showing that the implicit attitude can have more far-ranging impact than the explicit attitude.

# The Roles of Product Characteristics and Framing Effects in the Effectiveness of Cause-Related Marketing

Chun-Tuan Chang, National Sun Yat-sen University, Taiwan
Yu-Kang Lee, National Sun Yat-sen University, Taiwan

## EXTENDED ABSTRACT

Cause-related marketing (CRM) has become a major corporate philanthropic trend to donate money to a charity each time a consumer makes a purchase. CRM has been widely accepted as an effective marketing tool in terms of enhancing consumer perceptions of the long-term image of the sponsoring firm (Ross, Patterson, and Stutts, 1992; Berger, Cunningham, and Kozinets, 1999; Brown and Dacin, 1997; Bronn and Vrioni, 2001; Gupta and Pirsch, 2006) and boosting short-term sales (Varadarajan and Menon, 1988; Strahilevitz and Myers, 1998; Strahilevitz, 1999). Because of the increased use of charity-linked promotions in the marketplace, recent studies have begun to examine potential factors that might affect the CRM effectiveness and how consumers respond to CRM (e.g., Strahilevitz and Myers, 1998; Strahilevitz, 1999; Webb and Mohr, 1999; Hamlin and Wilson, 2004; Subrahmanyan, 2004). The objective of present study is to investigate potential influences associated with donation framing, product price, product type, and donation magnitude on CRM effectiveness (i.e., the effectiveness of using promised donations to charity as purchase incentives) in *advertising* contexts.

The experiment tested the relative effectiveness of ad messages to promote products on CRM in a 2 (donation framing: absolute dollar value vs. relative percentage of a sale price) X 2 (product price: low vs. high) X 2 (product type: frivolous vs. practical) X 2 (donation magnitude: low vs. high) mixed design. Product type and donation framing were selected to be between-subjects variables, and product price and donation/cash discount magnitude were operationalized as within-subjects variables. Participants consisted of 240 part-time undergraduate students (103 males, 136 females, and 1 who failed to identify sex) from seven evening courses across a variety of disciplines (i.e., language-related, business, engineering, humanity, and law school) at four large universities in Taiwan. Participants were randomly assigned to one of the four experimental conditions above. In order to eliminate the effects of product-selection bias, two products were chosen for each product type (frivolous vs. practical) based on a pre-test. In each experimental condition, eight scenarios were developed with order counterbalanced, varying from two products with two price levels and two donation/cash discount magnitudes. The participants had to choose one preferred option out of two alternatives (i.e., donation vs. cash discount) in each scenario.

Analysis of variance (ANOVA) was used to test interrelationships among the researched variables. Although previous studies (Strahilevitz and Myers, 1998; Strahilevitz, 1999; Subrahmanyan, 2004) suggest that product type and donation magnitude determine the effectiveness of product-charity bundles, the present study raises concerns over possible ineffectiveness of CRM when bundled with products of certain types (i.e., frivolous products) and when offered at certain donation magnitudes in cause-related advertising. Three observations regarding the CRM effectiveness are noteworthy. First, as is predicted, the results indicate that consumers may be more likely to choose a product offering a donation over the other providing an equivalent discount with a coupon subject to donation framing method and price level. The beneficial effects of product type on CRM may only occur when donation information is framed in absolute dollar terms or

when the product has a lower price. Strahilevitz's results (1999) are held for the conditions of donation framed in absolute dollars, but not for those conditions of donation presented in relative percentage of a sale price. Furthermore, there is no support for the role of product type either in the three-way interaction with product price and donation magnitude or in the three-way interaction with donation framing and product price. This suggests that the effects of product type decrease when both product price and donation magnitude are considered and framed in the ad.

Second, effects of donation magnitude can be conditional on CRM effectiveness. Consumers appear to accept a product with a cause more easily when the magnitude is lower than when it is higher. This finding may be counter-intuitive in that one might expect doing more good may lead to more purchases. When consumers face a large trade-off between charity motive and economic self-interest, they seem to prefer something directly beneficial to them, which may explain why a discount would be a more tempting and attractive option than a donation to a charity. Nevertheless, when the donation/discount magnitude is low, an absolute dollar amount could enhance CRM effectiveness, perhaps due to the tiny and relatively painless degree of monetary sacrifice. The obvious objectives of marketers are to communicate superior deal value to consumers and accelerate their purchase decisions in a CRM context, and an interesting aspect of this strategy is that marketers stand to gain not just by changing the donation magnitude of advertising package but by introducing appropriate "framing" of their offered products such that they enhance consumers' likelihood to purchase a cause-related item. Investigating impacts of donation framing is an important marketing and public policy issue because both presentation formats of donation amount in absolute dollars and relative frequency are commonly used as good-faith attempts to express the amount being donated. However, they may not be equivalent with respect to their ability to enhance CRM effectiveness. There is a reason to believe that the percentage-of-price format can be more problematic and ambiguous than the absolute-dollar format since a percentage of a sale price requires a consumer to calculate the actual donation value in a mathematical step, thus increasing the complexity of the task and the comprehension. All these might reduce the advantages of CRM.

Third, the effects of product price and donation magnitude cannot be ignored. Effects of donation magnitude on CRM effectiveness could be contingent on product price levels. Although consumers may say that they would support charitable donation, many of them are not actually willing to share the costs and the responsibility of supporting the causes through their purchases. One explanation could be that at the lower product price, the amount stated as being contributed to charity is also low and hence perceived as a small request. A clear conclusion can be made that the appropriate CRM should rely on a harmless and tiny commitment through lower priced items with lower donation magnitudes. Either one of the two opposite conditions would eliminate CRM effectiveness.

This article has theoretical and practical contributions to CRM, consumer purchase decision-making, and marketing practice. Marketers of CRM should also decide how to present a donation amount appropriately. How the price effects of a pro-

moted product interacts with product type and donation magnitude offer further useful implications for marketers who seek to optimize the effectiveness of cause-related campaigns

# The Role of Mortality Salience in Consumer Persuasion

Javier Horcajo, Universidad Autónoma de Madrid, Spain
Ya Hui Michelle See, National University of Singapore, Singapore
Pablo Briñol, Universidad Autónoma de Madrid, Spain
Richard Petty, Ohio State University, USA

## EXTENDED ABSTRACT

One of humans' most basic instincts is the drive toward self-preservation. According to Terror Management Theory (TMT; Greenberg, Pyszczynski, and Solomon, 1986), this instinct, coupled with the knowledge of inevitable death, leads people to counter their fear of death by creating and maintaining a cultural worldview, which gives meaning and order to the world. In line with this idea, laboratory research has shown that reminders of death lead to more favorable evaluations of people who personify cultural values and to more negative evaluations of people who defy those values (e.g., see Greenberg, Solomon, and Pyszczynski, 1997; for a review).

Recent research conducted in the consumer domain has suggested that mortality salience (MS) can play an important role in polarizing consumer judgments (e.g., see Arndt, Solomon, Kasser, and Sheldon, 2004; Ferraro, Shiv, and Bettman, 2005). For example, Mandel and Heine (1999) showed that high-status products (e.g., a Lexus automobile, and a Rolex watch) are evaluated *more favorably* by consumers who were subtly reminded of their own impending mortality than by control participants. In contrast, low-status and low-status products and brands (e.g., a Chevrolet Metro automobile, and Pringles potato chips) were rated slightly less favourably by MS participants than by their control counterparts. The authors argued that MS participants were more interested in purchasing high-status products than control participants because these products make them feel more valuable within the culture.

The present research examines why MS might lead to such polarized judgments. Based on the self-validation hypothesis (Petty, Briñol, and Tormala, 2002), which states that thoughts held with greater confidence are more impactful in consumer judgments (Briñol, Petty, and Tormala 2004), we argue that MS can influence judgments by affecting the confidence with which consumers hold their thoughts. Thus, we test self-validation as a metacognitive mechanism through which MS influences judgments (see, e.g., Alba and Hutchinson, 2000; Petty, Briñol, Tormala, and Wegener, 2007; for a review in metacognition).

Specifically, we predicted that MS will increase the confidence with which people hold their cognitive responses, and the increased thought confidence, in turn, will lead to attitude polarization, a typical effect in MS research. We expected to show the typical polarization effect for MS, with the novel prediction that MS-induced polarization occurs via self-validation. This finding would be important because it would introduce an additional antecedent for self-validation effects, and suggest a mechanism for MS effects in consumer persuasion.

### Experiment 1

One hundred and thirty-two participants were first exposed to a printed vita of a job candidate containing either strong or weak attributes in support of the candidate. Attribute cogency was varied in this study to lead participants to generate mostly positive or negative thoughts toward the job candidate. After participants read the vita and wrote their cognitive responses about it, MS was experimentally manipulated. Participants were asked to write about dying in a terrorist attack (MS condition) or to write about being cold (control condition). Finally, all participants reported their attitudes toward the candidate.

In line with the self-validation hypothesis, we found that the effect of attribute cogency on attitudes toward the job candidate was greater under the MS condition rather than control condition. Thus, MS participants relied on their thoughts in forming attitudes, but control participants did not use their thoughts to judge the candidate.

### Experiment 2

Experiment 2 aimed to replicate the previous findings using a more conventional MS induction. In this experiment, one hundred and sixty participants received the same attribute cogency manipulation used in Experiment 1 in order to manipulate the direction of participants' thoughts. After listing their thoughts about the candidate, we induced MS by asking participants to describe what they thought will happen when they die, or to write about being cold (control).

We replicated the effects of Experiment 1 showing more attribute cogency effects for MS than control participants. Importantly, combining the data from Experiments 1 and 2, we established that the mortality salience effects on attitudes were mediated by thought confidence.

### Experiment 3

Experiment 3 examined whether the effects obtained so far could be generalized to important worldviews such as about one's country. Furthermore, Experiment 3 examined whether extent of elaboration, which has been found in past research to moderate self-validation effects (Petty et. al., 2002), also moderates the effects of mortality salience on attitudes.

Seventy undergraduate students from a public university in Spain were first exposed to a message written by a foreign exchange student arguing either in favor of or against Spain. After participants read the pro- or anti-Spain message and wrote their thoughts about it, they were asked to write about their own death (MS condition) or about felling anxiety toward exams (control group). Following the MS manipulation, all participants reported the confidence they had in the thoughts they wrote about that message, and also reported their attitudes toward the exchange student who wrote the essay. Finally, participants completed a self-report elaboration measure.

As predicted, the confidence induced by the MS manipulation led those participants to use their thoughts more when judging the source of the message than control participants. In line with the self-validation hypothesis, the effects of MS on attitudes were mediated by changes in thought-confidence. Importantly, this finding occurred only among participants who reported greater elaboration.

### Discussion

Across different manipulations of all the variables, we predicted and found that MS can influence attitude change by increasing the confidence with which consumers hold their own thoughts. As in past research, MS led to attitude polarization in impression formation toward a job candidate (Experiments 1 and 2) and toward the source of an essay about one's country (Experiment 3). Of most importance, we demonstrated for the first time that the effects of MS on judgment can be mediated by changes in thought confidence.

Furthermore, in accord with the self-validation hypothesis, thought confidence induced by MS influenced attitudes only among high elaboration individuals. Taken together, these findings are important because they provide an entirely unexplored mechanism for MS effects that may also apply in consumer persuasion.

# The Impact of Goal Framing on the Choose–Reject Discrepancy

Parthasarathy Krishnamurthy, University of Houston, USA
Anish Nagpal, The University of Melbourne, Australia

## EXTENDED ABSTRACT

Consumers often make decisions about options that go with a base product configuration, such as deciding whether to purchase "wireless card" connectivity when buying a computer. In this regard, researchers have examined whether the task of adding options to a base model (choosing) versus removing options from a fully loaded model (rejecting) affects the composition of the final configuration (Levin, et al. 2002; Park, Jun, and MacInnis 2000). Research suggests that choosing versus rejecting, i.e., *task framing*, is of consequence; choosing typically results in a smaller final configuration than rejecting (Huber, Neale, and Northcraft 1987; Park, et al. 2000; Yaniv and Schul 1997). We refer to this as the *choose–reject discrepancy (CRD)*.

In this research, we argue that it is possible to take advantage of the information processing differences between choosing and rejecting to modify/reverse the CRD; sometimes, choosing options will lead to larger option sets relative to rejecting. Several studies indicate that choosing is more motivating than rejecting, and that people are more willing to commit the necessary resources and time to complete a choose than a reject task. For example, researchers find that people employ a stricter decision-criterion when choosing relative to rejecting (Huber et al. 1987; Yaaniv and Schul 1997). Other researchers (Ganzach 1995; Wedell 1997) argue that decision-makers see the task of choosing as more important because they feel greater need to justify their choices compared to rejecting, "In a sense, rejection is a passive form of expressing preferences. Because one makes a positive statement in the choice task about which alternative is preferred, one may feel a greater need to justify preferences (p. 883)."

In light of the above-mentioned research, we argue that people will be more motivated and willing to commit the needed cognitive resources and time to execute the choose task compared to the reject task. This difference in processing motivation can be leveraged to reverse the choose–reject discrepancy through positive or negative goal framing; positive goal frames stress gained realized by action whereas negative goal frames emphasize gains given up by inaction.

The question of whether framing effects interact with the level of processing motivation has been examined in a variety of domains including decision-making, health communication, and marketing (Meyerowitz and Chaiken 1987; Rothman et al. 1993; Wegener, Petty, and Klein 1994). Meyerowitz and Chaiken (1987) find that decision-makers are more persuaded by negatively-framed messages because of higher motivation. Also, Chaiken (1980) and Petty and Cacioppo (1986) suggest that under low motivation, people will not scrutinize the entire message and will be persuaded by the valence of the message. Thus, positively-valenced messages should be more persuasive under low (rather than high) motivation. Along similar lines, Maheswaran and Meyers-Levy (1990) suggest that positive (negative) information is differentially compelling under low (high) motivation. Overall, this literature implies that negatively-framed information is given greater weight when the processing motivation is high and positively framed information receives greater weight when the processing motivation is low.

If positive frames are over-weighted under low, rather than high processing motivation, then they should be more effective under rejecting relative to choosing. Thus, in the context of choosing or rejecting product options, describing the benefits achieved by not rejecting options (reject–positive frame) should be more compelling than describing the benefits achieved by choosing options (choose–positive frame). Hence, the number of options in the final configuration, and the monetary value thereof, will be greater in the reject-positive condition than in the choose-positive condition. This replicates the choose–reject discrepancy. However, for negatively-framed information, the reverse should be true. Describing the benefits given up by not-choosing (choose–negative frame) should be more compelling than emphasizing the benefits given up by rejecting (reject–negative frame). This is our principal choice prediction. To investigate the above prediction, we juxtapose task framing with goal framing.

In study 1 we examine whether choosing is indeed more motivating than rejecting. One way to establish greater motivation and willingness to commit cognitive resources to the task at hand is to examine the effect of a secondary, orthogonal resource-depleting task on the decision-maker's ability to focus on the principal task of choosing versus rejecting. If the primary task is inherently motivating and people are willing to commit the necessary resources to the task at hand, increasing resource depletion via a secondary task will have a smaller impact on one's ability to maintain focus on the primary task. The results from study 1 indicated that resource depletion affects task focus only under the reject frame but not under the choose frame, which comports with the idea that processing motivation may be higher under choosing. We also observed that the task of choosing took more time than rejecting. Since choosing takes more time than rejecting, it corroborates the idea that choosing is more motivating than rejecting.

The results from study 2 support the principal choice prediction. Under positive goal framing, rejecting led to an increase in the number and value of the options in the final configuration than choosing, replicating previous results. However, under negative goal framing, choosing led to a higher number and greater value of the options, reversing the traditionally observed–choose reject discrepancy.

# When Regulatory Fit Does Not 'Feel Right': The Inhibiting Effect of Contextually Dominant Decision Strategies

Mehdi Mourali, University of Calgary, Canada
Frank Pons, Université Laval, Canada

## EXTENDED ABSTRACT

Consumers use a variety of strategies to form judgments and make decisions. For example, When choosing between two alternatives, they may select the most attractive one or reject the most unattractive one (Shafir 1993). When forming preferences among several brands, they may compare them on specific attributes or rely on overall evaluations of each brand (Mantel and Kardes 1999). The strategies that consumers use often depend on their motivational orientations, but they also interact with those orientations to influence the value of decision outcomes. Regulatory fit theory (Higgins 2000) maintains that when people use decision strategies that sustain versus disrupt their current motivational orientation, they feel right about what they are doing. This, in turn, leads them to value of the decision process more (Freitas and Higgins 2002) and feel more confident about their subsequent reactions toward the decision outcome, which can increase the extremity of these reactions and even the monetary value of a chosen option (Avnet and Higgins 2006, Cesario, Grant, and Higgins 2004, Higgins et al. 2003).

We propose that the presence of contextual fit, which results from a strong association between a particular decision context and a particular decision strategy, can inhibit the effects of regulatory fit on the valuation of both the process and the outcome. We presented evidence from two studies in support of our hypothesis. In the first study, we used a selection/elimination decision paradigm and found significant regulatory fit effects (selection is compatible with a promotion focus, whereas elimination is compatible with a prevention focus) on task enjoyment and satisfaction with choices when the task required the expression of a personal judgment. These effects, however, disappeared when the choice task had a single right answer. Past research (Heller et al. 2002, Kim and Goetz 1993), and our own pretest suggest that elimination is a naturally dominant strategy when choosing among options with a single right answer, but not among options requiring personal judgment. We reasoned that using a decision strategy that is inconsistent with the contextually-prescribed strategy may inhibit the feeling right experience usually associated with regulatory fit. When regulatory fit does not lead to feeling right, it can neither increase the process value nor the extremity of postdecisional reactions to a decision outcome.

In the second study, we used a different choice paradigm based on attribute-based versus attitude-based processing. We manipulated contextual fit by having respondents practice using a particular strategy prior to the focal choice task. We also manipulated regulatory fit (attribute-based processing matches a prevention focus, whereas attitude-based processing matches a promotion focus) and tested the moderating influence of contextual fit on the relationship between regulatory fit and the amount of money respondents were willing to pay to acquire their chosen product. We found that regulatory fit increased the monetary value of a decision outcome when the decision context did not evoke the use of a contextually-dominant strategy. In the latter case, however, monetary value was highest when the contextually-dominant strategy was adopted regardless of regulatory focus.

Our findings add to the current knowledge on regulatory fit effects by identifying an important boundary condition. However, the exact mechanisms underlying these findings are still unclear.

Lee and Aaker (2004) suggest that processing fluency may be at the basis of the feeling right experience resulting from regulatory fit. It is possible that a regulatory fitting strategy that is inconsistent with the contextually-dominant strategy loses its processing fluency and thus does not produce a feeling right experience. Clearly, future research needs to test this and other alternative explanations to gain a better understanding of the mechanisms underlying the observed effects.

# When Do Consumers Prefer More Choice? Moderating Effects of Regulatory Focus

H. Onur Bodur, Concordia University, Canada
Lissa Matyas, Concordia University, Canada

## EXTENDED ABSTRACT

While it is clear that a large assortment has many benefits for both consumers and retailers, recent research has proposed that providing consumers with vast number of alternatives to choose from may be a mixed blessing (Schwartz et al. 2002), potentially leading to a less compelling choice experience or to a less satisfactory outcome. Iyengar and Lepper (2000) report interesting results to this effect. In their field experiment, participating shoppers were 10 times more likely to buy a jar of jam when six varieties were on display as compared to 24. Wathieu et al. (2002) further argue that restricting a consumer's choice set to fewer alternatives makes it easier to make a decision and leads to greater satisfaction with the decision after the fact. The main problem consumers have with an extensive array of options in the pre-decision stage is the confusion that too many alternatives can cause.

In this paper, we present an alternative explanation for when assortment size leads to greater satisfaction with the chosen alternative. We propose that the impact of assortment size on choice is moderated by regulatory focus. Regulatory focus theory identifies two distinct motivational systems: promotions and prevention focus (Higgins 1997, 1998). Promotion focus relates to higher level concerns with accomplishment and advancement and the presence or absence of gains. Consumers with promotion focus aim to ensure hits and avoid errors of omission or misses (missing an opportunity for improvement), whereas, prevention focus relates to greater concern with safety and fulfillment of responsibilities and the presence or absence of losses. Consumers with prevention focus aim to ensure correct rejections and to avoid errors of commission (making a wrong decision). More risky, less conservative, less cautious strategies are expected in a promotion focus than in a prevention focus (Liberman et al. 2001). We argue that if the choice is approached with a promotion focus, consumers concentrate on identifying the best alternative and prefer a larger assortment as it will translate into more hits. Conversely, a prevention-focused individual concentrates on avoiding regret and stops at the choice that meets his/her requirements and, therefore, will find it easier to process a small assortment.

The purpose of this paper is twofold: (1) To investigate whether regulatory focus moderates the relationship between assortment size and consumers' evaluation of the choice task and the chosen alternative, and (2) to investigate whether the nature of the relationship between assortment size and consumers' evaluation of the choice task and the chosen alternative is nonlinear.

First, we propose that consumers' regulatory focus moderates the relationship between assortment size and consumer reactions (Crowe and Higgins, 1997; Higgins, Shah, and Friedman, 1997). Under prevention focus, comparing many options increases the difficulty of making correct rejections, whereas under promotion focus, the priority is to have as many hits as possible, so large assortments can serve this purpose better. In particular, we propose that consumers with a promotion focus have a more positive experience with the choice task and will be more satisfied with their chosen alternative when faced with a large assortment size compared to a small assortment size. However, consumers with a prevention focus have a more negative choice experience and less satisfaction with their choice when choosing from a large vs. small assortment size. Second, we investigate whether the relationship between assortment size and consumer reactions is non-linear (i.e.,

an inverted-U shape). Although consumers may enjoy large assortment size, the complexity of the choice task becomes overwhelming as assortment size increases, resulting in more negative consumer experiences.

In Study 1 (n=296), we manipulate regulatory focus and assortment size in a lab experiment and measure participants' evaluation of the choice task and the chosen alternative. Pretest 1 (n=67) conducted prior to Study 1 was used to select product categories that are equally promotion and prevention oriented to allow manipulation of regulatory focus using a thought-listing task. Three equally promotion and prevention oriented products were selected ($p>.20$). In pretest 2 (n=42), the effectiveness of the thought listing task in manipulating regulatory focus was tested. The results indicate that the manipulation was successful ($p<.05$). Overall, Study 1 results indicate a significant interaction of regulatory focus on evaluation of the chosen alternative and the choice experience ($p<.05$). In addition, we find a nonlinear relationship between assortment size and evaluation of the chosen alternative and the choice task ($p<.05$). The inverted-U relationship holds primarily for the promotion focus participants.

Study 2 was a field study involving 203 shoppers at a large North American city. Different from Study 1, Study 2 was conducted in a naturalistic shopping environment, allowed consumption of the chosen alternative, and closely tied the participation incentive to the choice task. We also measured chronic regulatory focus using the Regulatory Focus Questionnaire. Consistent with our predictions, prevention focus individuals find their chosen alternative more attractive compared to promotion focus individuals when they choose among limited assortment set. This effect is reversed when choosing from an extensive alternative set.

Overall, our findings provide partial support for our predictions, and present an interesting contrast to predictions in extant research. Understanding of the moderating role of goals on the relationship between assortment size and consumers' evaluation of the choice task and the chosen alternative demands further research and this paper takes an important step in that direction.

# Bystanders Don't Just Stand By: The Influence of Social Presence on Service Experience

Yi He, University of Hawai'i, USA
Qimei Chen, University of Hawai'i, USA
Dana L. Alden, University of Hawai'i, USA

## EXTENDED ABSTRACT

Remaining competitive in today's rapidly changing service industry requires continuous improvement of customer service. Despite the renewed importance of service satisfaction, this subject matter has been approached mostly by examining comparatively stable individual factors that influence satisfaction (e.g., expectation, Oliver 1997; product expertise, Alden, Hoa and Bhawuk 2004). The more transient and malleable situational cues (e.g., social presence) have received limited attention. Seeking to bridge these gaps, we have conducted two experiments in China and the United States to: 1) evaluate the impact of social presence during positive as well as negative service encounters, 2) test for ways that culture moderates the hypothesized social presence effects, and 3) establish a new nomological net that features social presence and its moderators as antecedents to service satisfaction and behavioral intentions.

Customer service satisfaction primarily refers to affective responses to service encounters, with an emphasis on experience- and transaction-specific encounters (Schneider and White 2004). Generally the experience of positive (negative) emotions has been found to increase (decrease) customer satisfaction (Menon and Dube 2000; Oliver 1996). Social presence has been linked to several other constructs including the experience of positive and negative emotions. Webster *et al*. (2003) found that publicizing academic success in the presence of peers enhanced college students' feelings of pride. These results suggested that including social presence as a moderating factor related primarily to emotional experiences in service consumption settings might enhance the theoretical richness of the customer satisfaction model. Finally, as the impact of social presence originates from the need for social approval and acceptance with the intention to protect social image (Costa *et al*. 2001; Goffman 1967), it has clear cultural linkages.

## Study 1

Study 1 aimed at testing the overall moderating impact of social presence on positive and negative emotional experiences in a service setting. Cultural strengthening/weakening of those effects was also tested. It was hypothesized that social presence will enhance satisfaction when the valence of emotion is positive, and reduce satisfaction when the valence of emotion is negative. We also hypothesized that social presence effects for collectivistic (individualistic) consumers will be stronger (weaker).

Two factors were manipulated using different treatment scenarios in a service setting that was very familiar to college students in both countries–a college bookstore. The scenarios featured both textual description and culture-free cartoon illustration. The first factor, service experience, was manipulated by depicting interactions between a service provider and a college-age customer in a polite or rude manner. The second factor, social presence, was manipulated using the cartoon illustrations. In the social presence condition, other customers were depicted in a manner so that it was clear they could overhear the conversation between the service provider and the customer. In the no social presence condition, no other customers were depicted. Therefore, study 1 featured a 2 (service outcomes: positive vs. negative) X 2 (social presence: social presence vs. no social presence) X 2 (cultural value-orientation: collectivist/China vs. individualist/U.S.) between-subject de-sign. Key outcome measures include: satisfaction and behavioral intentions.

The results of study 1 indicated that social presence enhanced satisfaction when the service encounters were positive (M=4.9 versus 4.1, t (93)=1.86, p<.04). However, social presence did not appear to influence service evaluation during negative service encounters. Further, the hypothesized moderating effect of cultural value-orientation was not found.

## Study 2

In study 2, we examined the interaction effects involving the type of social presence and service outcome attribution on service satisfaction and behavioral intentions. To address the "ecological fallacy" issue (Smith 2004), we revisited the effect of cultural value-orientation using an individual-level measure–self construal. Classification of self- versus other-attributed emotions is based on whether the cause of dissatisfaction lies in the self or other people (Oliver 1993). The effect of social presence on emotions is triggered by concerns about social evaluation (Schlenker and Leary 1982). It was hypothesized that that the negative effect of self- versus other-attribution will be stronger when out-group observers are present versus no observers. We also hypothesized that consumers who are low on independence, due to their increased sensitivity to contextual social factors such as social presence, should react to negative service encounters more negatively whenever others are present (regardless of the type of presence) than when they are alone. By contrast, social presence should have little or no impact on consumers who rate themselves as high on independence.

Participants were asked to read a cartoon scenario depicting a disagreement between a customer and a bookstore cashier. Self- versus other-attributed emotions were manipulated by scenarios in which either the bookstore employees or the customer was clearly responsible for the problem leading to the disagreement. For the type of social presence manipulation, cartoon figures were identi-fied using captions as either friends or strangers. As such, study 2 employed a 2 (self-attributed *versus* other-attributed negative ser-vice outcome) X 3 (in-group social presence, out-group social presence *versus* no social presence) X 2 (high- *versus* low-indepen-dence) between-subject design.

The results of study 2 indicated that compared with no social presence condition, social presence (in-group or out-group) significantly increased the negative effect of a disappointing self-attributed service encounter but reduced the negative effect of a disappointing other-attributed service encounter. Further, social presence reduced the negative effect of a service disaster on service evaluation for consumers with high independent self-concepts [satisfaction: M=3.7 versus 4.2, t(161)=1.46, p<.08; intentions: M=3.4 versus 3.8, t(161)=1.40, p <= .08] and increased its negative effect for consumers with low independent self-concepts [satisfaction: M=4.0 versus 3.3, t(145 )=1.88, p<.03; behavior intention: M=4.3 versus 3.5, t(145)=2.36, p<.01].

Overall, the present research revealed the intricate interplay of situational cues (social presence and its type), a customer factor (cultural value-orientation) and a provider communication factor (attribution) on evaluation and intentions. Social presence remains an interesting and understudied construct in consumer research that represents fertile ground for further exploration.

# Proximity to or Progress toward Receiving a Telephone Service? An Experimental Investigation of Customer Reactions to Features of Telephone Auditory Messages

Liad Weiss, Columbia University, USA
Anat Rafaeli, Israel Institute of Technology, Israel
Nira Munichor, Israel Institute of Technology, Israel

## EXTENDED ABSTRACT

Telephone waiting is an undesirable experience for most customers and can negatively impact service evaluations (Katz, Larson, & Larson, 1991), but is often unavoidable because of staffing costs (Hall, 1991) and the inability to predict service demand (Zeithaml, Parasuraman and Berry, 1990). Customer reactions to waiting can have significant business implications, calling for attention to factors that may mitigate negative reactions to queues and waiting. In telephone waiting, auditory messages through the telephone system are the primary means by which firms can facilitate waiting. Auditory messages are a sole source of information during telephone waiting and thus are a key for shaping customer reactions. Yet research on the effects of auditory messages on caller behavior is very limited.

Aiming to fill this gap, we investigated customer reactions to auditory messages, concentrating on messages that provide information about location in the queue. We assume that firms can manage queue perception and thus reactions to waiting through manipulating the information provided to customers about the queue. Specifically, information provided can help to create two types of psychological frames for people waiting in a telephone queues: A progress oriented frame, and a proximity to the service oriented one. Our prediction is that these frames can differently affect customer reactions. We compare and contrast predictions, drawn from these two frames, and argue that a sense of progress approach affords more accurate predictions of caller attitudes, whereas a sense of proximity frame offers a better approximation of caller behavior.

Our analysis introduces goal proximity as a critical variable for understanding people's reactions to queue length. The logic of proximity to a goal suggests —assuming that the duration of waiting is identical— that shorter queues will make people feel greater goal proximity than longer queues. Thus, queue length—or the number of people ahead of a customer in a queue—is predicted to influence the level of proximity a waiting customer senses.

At the same time previous research has demonstrated that actual long distance from the goal—or low goal proximity—creates frustration and dissatisfaction, whereas high goal proximity causes people to invest higher effort in persuing their goals (Kivetz, Urminsky, & Zheng, 2006). This implies that telephone queues that induce a higher (vs. lower) sense of goal proximity will induce greater satisfaction in and lead to more queue persistence of callers.

An alternative perspective for analyzing effects of telephone queues is people's sense of progress, as introduced by Munichor & Rafaeli, 2007). This perspective can lead to predictions that contradict those of goal proximity since— assuming equal duration of a wait—longer queues must also be faster. Thus, a sense of progress perspective suggests that people in a longer queue (vs. in a shorter queue of the same waiting time) will feel a greater sense of progress. Sense of progress is known from previous research to motivate people, so we can suggest that queues that induce a higher sense of progress will lead to better customer reactions in terms of satisfaction and queue persistence.

Message update frequency—or the number of times a customer hears a message while waiting—is also a salient attribute of a telephone system that has not been previously examined. We suggest that rapid updates emphasize to people whether a queue progresses quickly or slowly, and therefore moderate the relationship between progress rate in a queue and callers' sense of progress.

We examined our predictions using an experimental simulation of telephone waiting, in which we measure customers' reactions to auditory messages. The simulation provided the callers with information about their position in the queue while holding the duration of the waiting constant. Furthermore, this infrastructure allowed accurate measurement of caller satisfaction and queue persistence (as opposed to abandonment) rate. Our between subject experimental design created two queue lengths (long and short) and two update frequencies (high and low). This design enabled the examination of the two suggested psychological orientations of people in queues: Sense of progress orientation was manipulated through informing callers that the line they have joined is long (i.e. 'your position in the line is 9') and progressing them rapidly (i.e. every 18 seconds, which add up to three minutes of waiting). Sense of proximity orientation was manipulated through informing callers that the line they have joined is short (i.e., 'your position in the line is 2') and progressing them slowly (i.e., every 90 seconds, which add up to 3 minutes of waiting).

The findings support our predictions regarding the previously unexamined idea that customers' reactions to a telephone waiting are influenced by the way they perceive their progress or proximity to the end of the queue. The findings show that the same message may affect callers' satisfaction and behavior in contradictory ways that depend on the way the message is being used: callers are more (less) satisfied but are (more) less persistent in a (proximity) progress oriented queue. Our analysis suggests an explanation for this apparent contradiction. According to our analysis the two dimensions of customer reactions—behavior and satisfaction—are influenced by separate mechanisms—sense of progress influences satisfaction while sense of proximity influences persistence.

Specifically, our findings show that–in queues with equal duration—a progress (proximity) oriented queue leads customers to report high (low) satisfaction through affecting their sense of progress, while simultaneously lead them to be less (more) persistent in the queue, through affecting their sense of goal proximity. Furthermore, the queue orientation, which influences sense of progress and satisfaction in a condition of high frequency updates, does not have this influence in a condition of low frequency updates. This finding suggests on a moderating effect of update frequency on the relationship between queue orientation and caller sense of progress.

Integration of our findings with current literature concerning physical waiting environment allows us to propose the concept of *auditory waiting environment* as a key feature of the waiting situation. This concept broadens the previous literature focus on time fillers (Munichor and Rafaeli, 2007). The concept also suggests that analyses of telephone queues and waiting can embed multiple psychological dimensions that can be manipulated through telephone messages, which expands the role of recorded messages.

In an experiment that followed the one reported above, participants in the simulation experiment were contacted two days after the original experiment and were asked for their retrospective satisfaction. Their reports supported the original findings. This

support helps to affirm our suggestion that the auditory waiting environment design as a key influence on customer satisfaction.

# The Value of Human Warmth: Social Presence Cues and Computer-Mediated Communications

Ji Hee Song,University of Seoul, South Korea
Candice R. Hollenbeck, University of Georgia, USA
George M. Zinkhan, University of Georgia, USA

## EXTENDED ABSTRACT

Organizations communicate with customers through various media. Historically, communications occurred through mass mediated messages (e.g., television, newspapers) or face-to-face communication. During the last decade, emerging technologies have enabled firms to communicate with customers using individualized methods (Hoffman and Novak 1996). An important difference between traditional face-to-face communication and computer-mediated communication is that the former encompasses more psychological connections. In face-to-face interviewing, people communicate via multiple cues (e.g., eye contact, gesture, facial expression). At the same time, computer-mediated communications exhibit little emotional or social appeals.

One way to overcome the lack of human warmth in computer-mediated communication is by increasing the social presence of each party. Social presence is defined as the salience of another person in a mediated environment (Short et al. 1976). For instance, the presence of an avatar or the presence of socially rich descriptions or pictures of products in decision making (e.g., purchasing a product from an e-store) have a positive impact on purchase intention (Gefen and Straub 2004; Holzwarth et al. 2006). Relatively little research examines the impact of social presence cues in virtual communication settings (e.g., firms communicating with their customers via emails or instant messaging). According to social presence theory, when customers communicate with a firm through a computer-mediated communication channel, they receive different cues for interpretation (Short et al. 1976). To the extent that a computer-mediated channel sends signals that create a sense of face-to-face communication, customers will consider the virtual communication experience more communicative and friendly.

This leads to a question regarding consumers' perceptions of social presence cues. During computer-mediated communications, as the level of social presence cues increases, is communication effectiveness enhanced from the consumer's perspective? Social presence theory predicts that the optimal level of social presence depends on how much the situation requires social presence. In other words, the appropriateness and need for social presence differs across the types of situations/inquiries. For instance, imagine that a consumer is sending an instant message complaining about his billing error. The firm's response might not be personalized or prompt for many reasons including: 1) all available representatives are taking care of other customers, 2) the corresponding representative is not knowledgeable to resolve the issue and s/he needs to transfer the case to other reps, and 3) it takes a long time to retrieve the consumer's billing information and history. Under these situations, including more psychological connections and human warmth to the exchange will help the communication become more reciprocal and interactive regardless if the major concern is not yet resolved. On the other hand, if the firm sends a prompt response message that is personalized and associated with the former message (e.g., resolving billing error), adding social presence cues to this message will not make a significant difference in the communication outcome.

Therefore, the objectives of this paper are twofold: (1) to explore the influence of social presence cues and (2) to test the moderating role of situation in computer-mediated communications. Social presence theory is applied as a theoretical background to address the two objectives. In particular, this study focuses on a situation where consumers communicate with an e-store through an Internet chatting function.

The hypotheses are tested using a full factorial design. The experiment was a 2 (with vs. without social presence cues) X 2 (non-personalized vs. personalized message) between-subject factorial design. 120 participants were recruited from undergraduate and graduate business courses from an AACSB-accredited University. Participants were assigned to a scenario where they received a wrong product from an e-store. Participants engaged in live online chatting with a store representative to resolve the problem. After participants completed the chatting session, we collected dependent measures including: reciprocity perceptions, attitude, satisfaction, and repurchase intention.

We found three interesting results. First, the inclusion of social presence cues in computer-mediated communication enhances consumers' perceptions of reciprocity and site quality, and strengthens consumer loyalty and favorability toward the site. Second, reciprocity perception mediates the influence of social presence in terms of loyalty, attitude, and perceptions of site quality. Third, the influence of social presence cues on reciprocity perception depends on the degree of social presence required for a given situation.

One important feature that differentiates the Internet from traditional media is the potential for immediate interactions between customers and firms. Here, we find that increasing the level of social presence cues can be an effective measure for stimulating interactive and effective communications.

Here, we apply social presence theory in the context of computer-mediated communication. Previous studies have explored the influence of social presence cues on trust (Gefen and Straub 2003; Gefen and Straub 2004), system/media acceptance (Karahanna and Straub 1999), and patronage behaviors (Hassanein and Head 2005) in commercial web sites. However, the application of these findings to consumer behavior is somewhat limited. Our results provide support for social presence theory, indicating the usefulness of the theory for consumer behavior applications in the area of new media.

New media offer important opportunities for organizations to establish interactive communications with their customers. A first step toward stimulating such virtual relationships is to understand consumers' perceptions. This research provides preliminary understanding of how consumers perceive computer-mediated interactions and highlights the important role of social presence cues.

# The Influence of Art Infusion on the Perception and Evaluation of Consumer Products

Henrik Hagtvedt, University of Georgia, USA
Vanessa Patrick, University of Georgia, USA

## EXTENDED ABSTRACT

A great deal of evidence exists of the widespread use by marketing practitioners of visual art as a tool (Hoffman 2002; Martorella 1996). However, virtually no research has been conducted to provide insight and understanding regarding the strategic use of this tool to meet marketing objectives (Margolin 1992). The current research represents an initial step to systematically analyze the influence of visual art on evaluations of consumer products. With three studies, we investigate the phenomenon of *art infusion*, which we define as the influence that the presence of art has on consumer perceptions and evaluations of products with which it is associated. In this research we theorize that perceptions of luxury spill over from art, creating more favorable evaluations of these products.

## What is Art?

We adopt a consumer-focused perspective, namely that art is that which is categorized by the viewers as such (Bourdieu and Darbel 1997; Dewey 1989). This definition is particularly relevant, as it is the viewers' or consumers' perception that matters in this context, irrespective of scholarly debates about what does or does not constitute art. Evidence supporting the notion of a general schema was also found in a descriptive survey conducted by the authors. Based on these self-reports, on extant research (Hagtvedt, Hagtvedt, and Patrick 2007), and on a review of art history (e.g., Tansey and Kleiner 1996), artworks may be identified as works perceived as embodying human expression, where a perceived main feature of the work is the manner of its creation and/or execution rather than just a concept, idea, or message underlying it or conveyed by it, and where this manner is not primarily driven by any other contrived function or utility. Although there appears to be virtually no restriction on what may be successfully marketed as art in the contemporary art market, the average consumer nonetheless appears capable of distinguishing between works characterized by the creativity and skill of an artist and works characterized primarily by marketing efforts. While training presumably enhances this ability in viewers, it seems reasonable that with the emergence and development of visual art through the millennia of prehistory, perhaps tied to aesthetics as a pre-linguistic form of communication (e.g., Averill, Stanat, and More 1998; Lindgaard and Whitfield 2004), even untrained viewers are able to identify visual art as a distinct category of human expression.

## The Art Infusion Phenomenon

Several theoretical perspectives shed light on how the properties of art may spill over on products, including classical conditioning (Gorn 1982), halo effects (Balzer and Sulsky 1992), and contagion (Rozin, Millman, and Nemeroff 1986). In line with such perspectives, we propose that visual art may influence consumer evaluations of the products with which the art is associated, while the type of influence will follow from how art itself is perceived. At a general level, art is associated with a heritage of culture, it has historically represented a special kind of quest for excellence, and it has connotations of luxury and exclusivity (Hoffman 2002; Margolin 1992; Martorella 1996; Tansey and Kleiner 1996). We propose that a product infused with art will take on these connotations, causing more favorable product evaluations. This phenomenon is not tied to the content of a specific artwork, but to a general schema for art.

## Study 1

The objective of this study was to demonstrate that the presence of visual art leads to enhanced evaluation of consumer products via a content-independent spillover of luxury perceptions. A deal was contracted with a local restaurant to survey 100 of their patrons in exchange for conducting a customer satisfaction survey. One hundred people participated in the study (53% male, 47% female; $M_{age}$=43 years; average family income=$5,600 per month). The product to be evaluated was a typical set of silverware (a set of a spoon, fork, knife, teaspoon, and steak knife), exhibited in custom-made black velvet boxes with white satin lining. The top of the box had a print of either Van Gogh's Café Terrace at Night (art image) or a photograph of a café at night (non-art image). Participants were fleetingly exposed to the front face of the box before it was opened and then answered a set of questions about the silverware. Results revealed significantly higher product evaluations and perceptions of luxury for the art condition. Further, perceptions of luxury fully mediated the influence of art on product evaluation.

## Study 2

In this study, 107 participants were randomly assigned to one of three conditions: an advertisement for bathroom fittings featuring the painting Girl with a Pearl Earring by Johannes Vermeer, a photograph of Scarlett Johansson posing as the Girl with a Pearl Earring, or no image. Thus, content was matched for the two visual images. Results revealed that product evaluation and perceptions of luxury were significantly higher for the art image, and that the perceptions of luxury fully mediated the influence of art on product evaluation.

## Study 3

Seventy-six undergraduates participated in this study, using a soap dispenser as the stimulus with three experimental conditions (one of three images on the front face of the soap dispenser: artwork pre-tested to elicit positive affect vs. artwork eliciting negative affect vs. decorative non-art image, with same content as the positive artwork). The art-conditions of differing valence were incorporated to control for the alternative explanation that the content of the artwork could be driving the results rather than the general connotations of art. The non-art image was also included to demonstrate that the art, not the content of the image, was driving the results.

Results revealed that for both product evaluation and perceptions of luxury, the two artworks caused significantly higher ratings than did the non-art image, while there was no difference between the two artworks. Further, the perceptions of luxury fully mediated the influence of art on product evaluation.

# Persuasion Pleasure and Selling Stress: The Role of Non-Verbal Communication in Consumer Influence Settings

Bob M. Fennis, University of Twente, the Netherlands

## EXTENDED ABSTRACT

Compliance strategies used in interpersonal communication have received ample, but skewed attention in the literature. That is, studies have focused on what the agent presents, but have largely ignored the role of nonverbal communication in this process (e.g., Burger 1999; McFarland, Challagalla, and Shervani 2006). The present research aims to fill this void by examining the role of facial displays, bodily posture, gesticulation and other forms of nonverbal communication in consumer influence settings. In short, we hypothesize that features of the interpersonal interaction give rise to either one of two specific patterns of nonverbal behavior that may directly affect consumer compliance. In four experiments we examined the expression of these patterns of nonverbal and their effects on the persuasive outcome of the interaction between agent and target.

## Theoretical Background

There are various grounds to expect that nonverbal behavior will play a significant role in interpersonal persuasion situations, both in interaction with "the verbal channel" and by itself. More specifically, it has been argued that nonverbal channels are harder to control by the agent than the verbal channel and thus convey more 'sincere' or diagnostic information to the target with respect to the agent's motives and goals. In addition, nonverbal behavior is more accessible to the target than to the actor, which makes it difficult for the latter to regulate such behavior. Finally, nonverbal behavior is displayed quicker and appears less 'planned' than verbal behavior (Ambady, Krabbenhoft and Hogan, 2006). With regard to the *valence* of nonverbal behavior, the persuasion interaction provides the agent with information on goal attainment while the persuasion attempt unfolds. From the start of the attempt, the target will provide negative or positive feedback to the agent. The agent's anticipation of success or failure resulting from this feedback will induce concomitant emotions that subsequently affect which types of nonverbal cues may occur in these situations (cf. Ekman 1992). Negative feedback will induce nonverbal cues expressive of the stress and anxiety associated with anticipated failure ("selling stress"). Conversely, positive feedback will induce nonverbal cues expressive of the positive emotions associated with anticipated success ("persuasion pleasure"). Both types of nonverbal cues are thought to affect consumer compliance and persuasion, such that cues expressive of anticipated success will result in more persuasion than cues expressive of anticipated failure.

Moreover, there is reason to assume that the effects of nonverbal cues on compliance and persuasion will be "boosted" when they are embedded in a social influence strategy, compared to a situation of a simple request, without any persuasive script. In short, a consumer attending to a persuasion script (i.e. a compliance-gaining technique) may be distracted from thoroughly processing the "true meaning" of the nonverbal behavior and integrate it with all other information. This implies that nonverbal cues will act as heuristics under these circumstances and affect compliance through their impact on agent credibility perceptions (cf. Chaiken and Trope 1999).

## Method

In a series of four experiments, the hypotheses on the expression and effects of nonverbal cues in consumer influence settings were tested. Study 1 focused on the expression of cues associated with anticipated failure, and Study 2 examined the display of cues associated with anticipated success. In both experiments, nonverbal behavior of agents attempting to persuade a resisting (Study 1) or yielding (Study 2) target (actually a trained confederate) was observed and rated by judges in categories indicating the respective patterns of nonverbal behavior. Moreover, Study 2 assessed the mediating role of agent emotions. Study 3 and 4 shifted attention from the manifestation to the persuasive effects of both patterns of nonverbal cues. In Study 3 the role of cues associated with anticipated failure and success in conjunction with a Door-In-The-Face technique was examined in a commercial supermarket setting. In Study 4, the impact of both types of nonverbal cues was assessed in a non-profit influence setting. Moreover, a different type of social influence technique was used (a "Continuing Questions Procedure", Burger 1999). Finally, Study 4 examined the mediating role of agent credibility perceptions.

## Results and Discussion

Study 1 found evidence that a target providing an agent with negative feedback on the success of his/her persuasion attempt, induced a pattern of nonverbal behavior expressive of anticipated failure on the part of the agent: a more pronounced pattern of forced ('non-duchenne') smiles, diverting one's gaze off the target, speaking with a low and soft voice, frequent posture shifts, hiding one's face, and self-touching. In contrast, Study 2 showed that providing an agent with positive feedback induced nonverbal cues associated with anticipated success: 'authentic' (duchenne) smiles, fast and loud speech, and use of illustrators (arm gestures). In addition, agent emotions were found to mediate the impact of target feedback on agent nonverbal behavior. Study 3 demonstrated that a sales agent displaying cues associated with anticipated success induced higher consumer purchase rates than an agent displaying cues associated with anticipated failure. Moreover, the impact of nonverbal behavior on purchase rates was more pronounced when the agent employed a Door-In-The-Face influence technique, than under target-request only control conditions. In Study 4 results showed a similar effect in a non-profit context where consumers were asked to donate money to charity. Furthermore, it was found that employing a different persuasion technique (the Continuing Questions Procedure) again boosted the effects of nonverbal behavior on compliance. Finally, Study 4 revealed that perceptions of agent credibility mediated these effects.

Our findings support the notion that social influence settings may induce one of two distinct patterns of agent nonverbal behavior depending on the nature of feedback of the target. In addition, both patterns have been shown to affect persuasion in predictable ways, across various types of settings and in the context of various persuasion techniques. Finally, the present studies shed light on the processes underlying the expression and effects of nonverbal behavior in consumer influence settings.

# Effect of Delay on Perceptions of Bargaining Outcomes: Moderating Role of Persuasion Knowledge

Shweta Oza, University of Miami, USA
Joydeep Srivastava, University of Maryland, USA

## EXTENDED ABSTRACT

Bargaining and negotiation are perhaps the most fundamental of marketing processes through which buyers and sellers establish terms of exchange. Bargaining is important in consumer markets as well because the prices of many products are negotiated (e.g., automobiles, real estate). Bargaining is the norm rather than the exception in many cultures. However, consumer researchers have devoted disproportionately little attention to bargaining (c.f. Buchan, Croson, and Johnson 2004; Corfman and Lehmann 1993; Schurr and Ozanne 1985; Srivastava and Oza 2006). This anomaly has led to calls for more research on bargaining from consumer researchers (Bazerman 2001).

Recognizing that time and information are two key factors in bargaining, this paper examines the influence of time taken by an opponent to respond to an offer on perceptions of bargaining outcomes. Although the role of costly delay has been empirically examined (e.g., Rapoport et al. 1995; Srivastava et al. 2000), only a few studies examine the effect of opponent's response time on perceptions of bargaining outcomes (Galinsky et al. 2002; Srivastava and Oza 2006).

This research further examines the influence of delay or the time taken by an opponent to respond to an offer on perceptions of bargaining outcomes. Specifically, this research extends the previous work in two important ways. First, we propose a conceptualization in which inferences of opponent's reservation price lie at the core of the underlying explanation for the effect of response time on perceptions of bargaining outcomes. Although our conceptualization, based on attribution theory, is similar to Srivastava and Oza (2006), we explicitly examine the extent to which inferences of opponents' reservation price mediate the influence of response time. Additionally, to provide deeper insight into the underlying the process, we explore whether delay *per se* influences perceptions of bargaining outcomes. To the extent that bargainers infer opponent's reservation price based on the time taken to respond to an offer, it is necessary for the delay to be directly related to the bargaining situation. Second, exploring the boundary conditions for the influence of response time, we examine whether activation of persuasion knowledge moderates the influence of response time on perceptions of bargaining outcomes.

Three studies are reported in this research. Together, the studies provide insight into the underlying process by identifying and testing the boundary conditions. Identifying conditions in which the effect of response time can be attenuated suggests potential ways of making consumers less prone to falling prey to tactics such as the time taken to respond to an offer.

Study 1 demonstrates that inferences of opponent's reservation price mediate the effect of response time and that it is not delay *per se* that affect perceptions of bargaining outcomes. Replicating previous findings, bargainers were more satisfied with their outcomes when their offer was accepted after a short delay than when it was accepted immediately. However, response time influenced perceptions of bargaining outcomes only when the delay was related to the bargaining but had no influence when it was caused by an unrelated event.

Studies 2 and 3 demonstrate that activation of persuasion knowledge attenuates the influence of response time on perceptions of bargaining outcomes. When delay is recognized as a persuasive tactic, persuasion knowledge and its associated defense mechanisms reduce the potential influence of the tactic. Study 2 showed that when bargainers are primed with a description of bargaining processes and associated tactics, opponent's response time does not influence perceptions of bargaining outcomes. The implications of the priming are clear in that the results show that consumers can be educated to guard against bargaining tactics such as response time. Study 3 showed that persuasion knowledge can be activated without the external intervention of a prime. In fact, persuasion knowledge may be activated spontaneously by cues that may exist in the bargaining situation. For example, study 3 showed that persuasion knowledge was activated by altering the description of the opponent. When the opponent was described as an expert in selling, time taken to respond had no effect on perceptions of bargaining outcomes. It is noteworthy that unlike previous research that activates persuasion knowledge via ulterior motives (e.g., Campbell and Kirmani 2000; William et al. 2004), we activated persuasion knowledge by altering whether the opponent had the ability and knowledge to employ bargaining or persuasive tactics. Importantly, this research highlights the relevance and applicability of the persuasion knowledge model to a bargaining setting.

Overall, this research examines an interaction process factor, such as time taken to respond, that may emerge from within the bargaining environment to influence bargaining processes and outcomes. In addition, the findings provide insight into the boundary conditions for the influence of time taken by an opponent to respond to an offer. From a consumer welfare perspective, we identify a factor that can attenuate the influence of response time on perceptions of bargaining outcomes. Given consumers' susceptibility to response time in inferring whether they are better off or worse off in the bargaining relative to opponents (Thompson et al. 1995), knowledge of these factors may help make consumers less prone to attributions and fall prey to bargaining tactics.

# Inferences of Interpersonal Preference Similarity Based on Unrelated Product Categories

Valeria Noguti, University of Technology Sydney, Australia
Jack B. Soll, Duke University, USA

## EXTENDED ABSTRACT

In e-stores such as Amazon.com, someone contemplating any product can be directed to recommendations from users who have bought this product. Such recommendations do not necessarily refer to the product category originally contemplated. Do people think they will like products someone else bought just because this other person likes some unrelated product they themselves like? We propose that the answer to this question is yes. We present a phenomenon we call *similarity extrapolation*–the psychological transfer of similarity in preferences between self and others from a specific, yet arbitrary, domain to unrelated domains.

We propose that, in the comparison of another person's preferences with self preferences, people categorize the other in relation to the self, and this categorization serves as a basis for future inferences about the other person. This process is called categorical inference. People form impressions of new individuals based on an active categorization process (Brewer 1988). Moreover, as people often interpret information about others according to its congruency with the self (Gramzow et al. 2001), it is likely that the categorization occurs as a function of how similar to the self individuals are perceived to be. Once categorization takes place, additional attributes of individuals will be inferred (Brewer 1988) according to how individuals fit in the category. In similarity extrapolation, the fit would determine a graded structure leading to an increasing trend that relates degree of similarity in a domain and people's predicted similarity in other domains.

We explore similarity extrapolation in two studies. The first study was designed to show insensitiveness to domain, that is, that people extrapolate similarity to the same extent from one domain to extremely different domains. In this study, participants first chose one vase in each of 20 pairs. Participants were then matched with another participant (hereafter, partner) who had preferences either similar or dissimilar from theirs for the set of vases. Subsequently, participants learned their partners' choices for these 20 pairs of vases. Participants were then presented pairs of stimuli in one of four domains–either a new series of vases, sculptures, tourist activities, or comic strips–and were asked to choose the option they preferred, and the option they thought their partner chose. We had 40 participants per domain (20 in the similar and 20 in the dissimilar condition.) Thus, we had 160 participants in total. As we expected, participants picked the same option for the partner and themselves more times with a similar ($M = 14.9$, $SD = 3$) than with a dissimilar partner ($M = 11.3$, $SD = 3.2$, $p < .001$), and this difference was *significant by domain*. As we hypothesized, participants' inferred similarity with partners based on preferences for vases was independent of predicted domain.

The second study was designed to both provide evidence for categorical inference as an explanatory mechanism and demonstrate similarity extrapolation with similarity information clearly selected from sets likely to contain disconfirming information. In this study we tested similarity extrapolation from opinions for vases to opinions for tourist activities. Pairs of items were shown side-by-side on the computer screen. Preferences were measured on a six-point scale ranging from "(1) strong preference for the item on the left" to "(6) strong preference for the item on the right." For the analyses, we report dichotomized responses (choice of one of the two options.) Study 2 involved two selection conditions: *full* and *partial*. In the full condition ($N = 59$), participants evaluated three

pairs of vases and were then shown the opinions of their partners for the same three pairs of vases. The partial condition involved a second manipulation: partner's similarity, which could be either similar ($N = 20$) or dissimilar ($N = 20$). Participants first evaluated 12 pairs of vases and were then *explicitly told* they would be shown their partners' opinions for either the three pairs for which there was strongest (similar condition,) or weakest agreement between self and partner (dissimilar condition.) After learning partners' preferences, participants in all conditions were asked to estimate how many times in a set of 10 pairs of tourist activities they would choose the same item as their partner (predicted agreement question.) Participants were then shown 10 pairs of tourist activities and asked to rate each pair on the same scale used to rate vases. Participants were also asked to predict their partners' preferences (item-by-item prediction.)

Results from the partial condition demonstrate insensitiveness to information selection, that is, we observed significant similarity extrapolation in the number of times participants chose the same tourist activity for themselves and for their partners (item-by-item): similar partner ($M = 7.8$, $SD = 2.14$) versus dissimilar partner ($M = 5.2$, $SD = 2.48$, $p = .001$). Participants did not predict significantly higher overall agreement for tourist activities (predicted agreement question) in the similar partner condition ($M = 5.15$, $SD = 2.43$) than in the dissimilar partner condition ($M = 4.65$, $SD = 1.53$, $p > .1$). In the full condition we found evidence for categorical inference. A significant linear trend contrast was obtained from agreement for vases to the predicted agreement question for tourist activities (participants were divided in four groups according to the number of times participants agreed with their partners for the three pairs of vases–denoted by the subscripts from 0 to 3: $M_0 = 3.14$, $SD_0 = 1.77$; $M_1 = 3.71$, $SD_1 = 2.02$; $M_2 = 4.05$, $SD_2 = 1.96$; $M_3 = 6.46$, $SD_3 = 1.81$; $p = .001$). A significant linear trend contrast was also obtained from agreement for vases to the item-by-item agreement ($M_0 = 5.71$, $SD_0 = 2.5$; $M_1 = 5.12$, $SD_1 = 2.23$; $M_2 = 6.36$, $SD_2 = 1.71$; $M_3 = 7.31$, $SD_3 = 1.93$; $p = .043$). These linear trends suggest categorization occurred in a graded structure such that the more similarity was perceived for vases, the more similarity was inferred for tourist activities.

We conclude with implications of similarity extrapolation for agent decision making, gift-giving, brand extensions, and online recommendations of the type "People who bought this also bought that."

# "Size Counts": The Effect of Queue Length on Choice between Similar Restaurants

Ornit Raz, Massachusetts Institute of Technology, USA

Eyal Ert, Israel Institute of Technology, Israel

## EXTENDED ABSTRACT

Consider the following situation: a customer is faced with a choice between two restaurants that look similar, except that outside one, but not the other, trails a relatively long queue of customers. Which restaurant the customer should prefer? This question is of interest of many restaurants, cafes, bars, and other services that are typically located in the same area and face hard competition.

However, it seems that predicting behavior in such situations is not trivial. On the one hand, both logic and empirical evidence suggest that customers are reluctant to waiting and are likely to prefer the restaurant that is associated with a shorter queue. On the other hand, previous research on herding behavior suggests a variety of reasons that make customers follow the herd, which can imply preference for the longer queue. Unfortunately, previous research on queuing falls short in providing clear predictions for the effect of queues on behavior in such settings because it is typically focused on customers' responses in the queue. The research on queuing management does not address customers' preferences for services that are associated with different queue lengths.

The current research provides a first step towards understanding the effects of queues on customers' choice between services. Specifically, it examines prospective customers who can choose between similar restaurants that are associated with different sizes of queues. The focus of interest is the question whether the length of the queue can have an effect on the customer's choice between the restaurants.

The empirical examination is conducted by observations made across pairs of similar restaurants during prime hours to analyze the potential link between the length of the queue outside each restaurant and the number of customers who choose that restaurant (and join its queue). We manipulated the degree of customers' familiarity with the restaurants by looking at six pairs of "tourist restaurants" (i.e., restaurants that are located in tourist destinations and serves tourists who are not familiar with the restaurants), and six pairs of "local restaurants"(that the customers are usually familiar with). We hypothesized that if queues are indeed related to customers choice between restaurants, then the effect will be stronger with tourists because their low familiarity with the service. This stronger effect would be reflected by larger fluctuations between the restaurant's popularity from day to day in tourists but not in local restaurants (e.g., the restaurant that was more popular in a certain day will become less popular in another day–an effect that we call "inversion effect"). Each pair was carefully selected to ensure that the restaurants were indeed similar in terms of food type, quality of the food served, number of seats available, and pricing. In addition, the two restaurants in each pair were situated adjacent to each other. For each pair, we made six sets of observations over six consecutive days during prime hours. Two main measures were recorded: (a) the length of the queue outside each restaurant at the start of each observation, and (b) the total number of customers who joined each queue during the 20-minute observation period.

The results showed a strong positive correlation between the length of a queue and the number of customers who joined the queue, suggesting that customers preferred restaurants with larger queues. As predicted, this correlation was much stronger in tourist restaurants ($r_{length,join}$=.86, $p$<.0001) than in local restaurants ($r_{length,join}$=.72, $p$<.0001). As expected, the variance in changes of restaurants' popularity from day to day in tourist areas is significantly larger than in local areas ( F=4.63, $p$<.0001, Levine's test). In order to control for possible restaurant fixed effects (e.g., quality), we regressed the preference for a certain restaurant on the queue length in that particular day, and the average queue lengths of all other 5 days of observation. The regressions results showed that the effect of the queue length on choice was significant even when such fixed effects are controlled. Specifically, in local restaurant there seem to be a fixed effect (e.g., A}B), but the probability of choosing A decreases when the queue for A is shorter. In tourist areas, there were no evidence for such fixed effects; the only significant effect was that of the queue length on choice.

The findings of the current study have important implications for restaurants managers, mainly in tourist destinations. The results suggest that such restaurants face continual competition, with each day starting a new "game." Creating a longer queue outside a restaurant as the prime dining hours begin may have a strong influence on determining the winner in this competition.

We believe that in local areas, it will be harder for restaurants to benefit from herding behavior once their relative positions have been established. Yet, holding longer queues seems beneficial even in local areas. This effect would be probably most relevant whenever a new restaurant is opened. Then, the owners/managers may benefit from keeping supply slightly lower than demand. Informal conversations with restaurant managers reveal that some are already aware of this phenomenon and act accordingly.

The current study has also important theoretical implications. First, it is the first empirical study that examines whether herding can occur when it implies a direct and noticeable cost such as waiting longer times. Second, it provides some insights on the effect of queues on prospective customers outside the queue. The strong association between the length of queues and choice that was demonstrated here suggests that it should be interesting to study similar situations and to further study the cognitive mechanisms associated with such decisions. We think that the positive effect observed here is limited to cases where customers have an obvious choice, and where queue length may hint at service quality (e.g., restaurants, nightclubs). It is probably foolish for a post office to intentionally create longer waiting lines. Yet, at least in the case of restaurants, trying to eliminate or shorten queues is not a recipe for success. Indeed, the current study demonstrates that "size really counts."

# The Impact of Size of Self-Generated Consideration Set on Post-Choice Regret

Song Su, Tsinghua University, China
Rong Chen, Tsinghua University, China
Ping Zhao, Tsinghua University, China

## EXTENDED ABSTRACT

Regret is a negative emotion that is the result of a comparison between factual and counterfactual experience. Operationally, the basis for the measure of the level of regret is on the comparison between the outcome of the chosen option and that of a forgone alternative. The underlying assumption that regret arises from a comparison with one forgone alternative ignores the impact of other alternatives in the consideration set during the decision-making process. As many studies point out, consumers often adopt a two-stage strategy to make choices in real decision-making situations. More specifically, they first form a consideration set with some elimination rules, then they make a choice among the self-generated alternatives. In reality, consumers are often obsessed with more than two options in the consideration set when making their final decisions. Recently, researchers have suggested that it is possible to induce regret not only by the outcomes comparison, but also by the decision-making process. The majority of prior studies neglect these influences of process factors on regret. Therefore, for a better understanding of regret it may be insufficient to consider only the outcome comparison from a better-forgone brand.

Some attempts have begun to examine how the size of a prescribed consideration set influences regret. Currently, as consumer rights rise and information overload increasingly confronts consumers, the adoption of a two-step decision strategy and the formation of a self-generated consideration set before making choices are more prevalent in real consumer decision settings. We believe that the self-generated consideration set should have a more direct impact on self-focused negative emotions, such as post-choice regret. In addition, market and social trends also increase the possibility that a better-forgone alternative comes out of the consideration set.

By realizing the gap, we set two research objectives in this study. The first is to investigate whether the size of a self-generated consideration set influences post-choice regret. The second is to explore whether the size effect varies with the source of a better competing alternative, i.e., inside or outside of the consideration set.

We posit that all else being equal, the feeling of regret is higher when the size of a consideration set is larger, as the feeling of choice responsibility is larger when given a greater number of available alternatives. Given the same magnitude of outcome comparison, we argue that regret is lower when the better alternative comes from an unawareness set, as consumers intend to ascribe the inferior result to external attributes such as lacking ability or opportunity to seek sufficient information. More interestingly, we postulate that the effect of size reverses when the better option comes from an unawareness set, that is, the feeling of regret is lower when the size of consideration set is larger. In this case, consumers try to justify the decision by "at least I tried" reasoning that focuses on the decision process for regret regulation. They will perceive greater decision-making efforts involved when forming a larger size of consideration set prior to a real purchase, thus increasing the justifiability for their purchase decision. Therefore, they will associate themselves with less responsibility and self-blame for the bad outcome, thus resulting in lower post-choice regret. Whereas, when consumers make a choice with a small consideration set, they may engage in introspection for the extent of effort and prudence they paid in the decision-making process, and feel responsible for not conducting a thorough information search and including more alternatives into their consideration set. Self-attribution and more responsibility lead to higher regret. Thus, the size effect may vary with the source of better-forgone option.

Accordingly, we propose the following hypotheses:

H1. *When the size of consideration set is increased, increased regret is experienced.*

H2. *For the same outcome difference, the level of regret is lower when the better performing alternative comes from an unawareness consideration set than when the better one comes from the self-generated consideration set.*

H3. *When the better performing option comes from an unawareness set, the experience of regret attenuates as the size of consideration set is increased.*

Two experimental studies tested the hypothesis. The first study examined the effect of size on regret with a 2 (size of consideration set: two alternatives vs. five alternatives) x 2 (outcome valence of chosen brand: positive vs. negative) x 2 (information availability of better-forgone brand: known vs. unknown) between-subjects factorial design. Findings of the study demonstrate that when the size of self-generated consideration is larger, subjects' regret is higher regardless of whether the performance of the chosen brand meets its prior expectation or not, as long as information on the better-forgone brand is available. Even when information of the better-forgone brand is not available, subjects still feel regret when their expectation of the chosen brand is not met, giving support to counterfactual thinking. Furthermore, in this circumstance, the size effect of a consideration set persists.

The second study extended the first by investigating the size effect in situations where the better option comes from an unawareness set with a 2 (outcome valence of chosen brand: positive vs. negative) x2 (source of comparison information: awareness set vs. unawareness set) x2 (size of consideration set: two alternatives vs. five alternatives) between-subjects factorial design. Findings of this study demonstrate that when the better option comes from an unawareness set, subjects experience lower regret than when the better one comes from a self-generated consideration set, regardless of the whether the outcome valence of the chosen brand is positive or negative. Moreover, when subjects are dissatisfied with their chosen brand and find a better option from the unawareness set after choice, they experience less regret than when they previously form a larger consideration set. The two studies support all hypotheses.

The paper explicitly shows that for a better understanding of regret, we should consider not only the outcome comparison, but also the number of other forgone alternatives and the source of the better option. It enriches the literature by adding more evidence on how the decision process may influence regret.

# When Starbucks Meets Turkish Coffee: Cultural Imperialism and Islamism as 'Other' Discourses of Consumer Resistance

Elif Izberk-Bilgin, University of Michigan, Dearborn, USA

## EXTENDED ABSTRACT

Global brands such as Starbucks, McDonalds, and Nike present marketers tremendous opportunities for growth beyond the saturated shores of American and European markets. The prestige and quality associated with global brands often make them the foci of consumer desire in developing countries. However, their association with powerful nation states and multinational corporations can also render global brands to diverse consumer interpretations. For example, global brands are perceived as symbols of cultural imperialism, threats to national sovereignty, and even enticements of infidel. Such interpretations materialize in both subtle and overt consumer reactions ranging from individuals' refraining from a particular global brand to vandalization of businesses (*Economist* 2000).

This form of consumer behavior is theorized as consumer resistance. Past research has conceptualized consumer resistance as a reaction against a permeating consumer culture and hegemonic consumerist ideology, excessive materialism, and controversial marketing strategies (Penaloza and Price 1993, Ozanne and Murray 1995, Firat and Venkatesh 1995). It has been argued that this consumption bonanza leads to a loss of authenticity and meaning. This, in turn, is seen as the basis for a rise in defiant consumers, trying to evade the mainstream marketplace by pursuing alternative lifestyles such as voluntary simplicity or downshifting (Elgin 1981, Schor 1998). Extending that research, Holt (2002), Kozinets (2002), and Thompson and Arsel (2004) conclude that resistance is a postmodern and postmaterialist phenomenon through which consumers engage in socially and environmentally conscious, anti-materialist, and anti-corporate discourses and practices as they seek authenticity and personal sovereignty in everyday life. However, interpretations of consumer resistance as a postmodern, postmaterialistic phenomenon are not readily applicable to consumer resistance in developing countries. In developing countries, it is not affluence and malaise that shape consumer culture, but rather poverty, unemployment, devaluation of local currency, lack of opportunities for education, migration, corruption, failed state policies, and social polarization.

This research extends the existing literature by examining consumer resistance in a developing country context in light of economic, cultural, social, and political consequences of globalization. More specifically, this study analyzes resistance as a consumer reaction against not just consumer culture and marketers' practices but also globalization and the problems it bears for consumers in everyday life. Anti-globalization sentiments underlying consumers' anti-corporate reactions have been addressed by previous research through an examination of Starbuck's influence on other American coffee shops (Thompson and Arsel 2004). However, cross-cultural contexts, undoubtedly, better represent the full scope of economic, cultural, social, and political tensions that global-local encounters bear. In other words, consumer resistance emerges at full throttle when Starbucks perceivably threatens the reign of Turkish coffee in Turkey. Not surprisingly, the discourses and practices of resistance that such an encounter engenders, as identified through this research, are quite distinct from those noted in previous studies.

The data of this study has been collected over three months of fieldwork in Turkey, a developing country with a prominently Muslim population. Turkey as a transitional country, with its rapidly developing consumer society despite increasing poverty rates, offered a natural setting to observe and understand alternative motivations and practices of consumer resistance as informed by globalization in a non-Western Muslim context. The researcher is a native of Turkey; being fluent in Turkish language and well-versed in local culture has allowed the researcher to establish ethnographic credibility with the informants studied and construct a culturally informed account of resistance in this country context.

The ethnographic fieldwork involved in-depth semi-structured interviews, participant observation, and consumer diaries. Thirty depth interview respondents were identified through snow-ball sampling, a technique frequently applied in qualitative research to identify information-rich cases through social networks (Patton 2002). Informants were selected from low, middle, and high socio-economic status to capture diverse reactions to globalization and resistance to global brands. The sample included twelve Islamist[1] women and their family members to account for the recent surge in the interest in political Islam among Turkish consumers.

The analysis of interview transcripts, informant diaries, and researcher's field notes revealed resistance toward many global brands including Coca-Cola, Nestle, McDonalds, Microsoft, Marlboro, Nike, Starbucks, and Shell. In particular, this study identified discourses of cultural imperialism and Islamism as prominent motivators of consumer resistance in this field site.

The discourse of cultural imperialism this research identifies is especially noteworthy given that it challenges recent anthropological theories of 'hybridity', 'creolization', and 'glocalization'. In response to claims of imperialism and cultural homogenization, these theories contend that elements from various cultures can be selectively appropriated to structure 'hybrid' forms of meaning-making and behavior leading to heterogeneity of cultural expression (Appadurai 1990, Featherstone 1991, Hannerz 1987, Robertson 1995). However, despite anthropological claims of cultural heterogeneity, this research suggests that the discourse of cultural imperialism continues to function as a folk theory that influences consumers' narratives of resistance in Turkey as evinced in the following informant quote:

> McDonalds, Marlboro, Coca Cola, and what is that kahve [café] that all the rich kids go today, oh, Starbucks-I think all of these brands are the instruments of imperialism. These are all polluting our country and our language. Everywhere you look there is a foreign word, brand, or poster. Even in local store names, now they use, let's say, 'star' instead of *yıldız* to promote admiration for Western culture in an insensible way. Or perhaps they're [referring to the present and past ruling parties] deliberately preparing the country to be a colony; brainwashing people, destroying the local culture… (Vural, Artist, Male)

---

[1] I utilize Saktanber's (2002, p. 257) use of the term Islamist as individuals who are not just "much more pious than other Muslims, but also search for an alternative Islamic life politics and new social order". This meaning of the term also concurs with Sandıkçı and Ger's (2005, p. 80) use of Islamist as "those who are politically religious to distinguish it from secular Muslims who are believers without an affiliation to political Islam".

Such consumer narratives become even more striking considering Turkey, unlike other developing countries of Asia and Africa did not experience any direct colonial rule. Accordingly, these narratives may suggest that colonial history may indeed motivate consumer resistance in emerging markets of Latin American, North African, and some Southeast Asian countries that fall behind India and China in participating in the global economy.

In addition to the discourses of cultural imperialism and Islamism, this study identified situational resistance and concessionary acceptance as emergent practices of resistance, shaped by the socio-historical conditions peculiar to this field site. For example, concessionary acceptance is a curious form of resistance that requires consumers to break their resistance stance and forego ideologies by consuming global brands in the absence of satisfactory local alternatives. Even though consumers yield to the global brand, the consumption practice entails a great deal of reluctance, regret, and a fervent criticism of import substitute industrialization policies of 1960s. These statist policies are condemned for providing a protectionist environment for local industrialists to thrive in the absence of adequate regulation and direct foreign competition at the expense of consumer safety and product quality; yet they were tolerated at the time for the nationalist development ideology they espoused (Zürcher 2001). The following informant quote vividly describes the dilemma consumers experience in practicing concessionary acceptance and reluctantly yielding to global brands:

I wish we had not witnessed the *Anadol*s (first mass-manufactured Turkish car by a joint venture with Ford) on fire. Who knows how many people died because these cars would go on fire out of the blue? There were rumors about a missing bolt causing these fires…that it just cost, I don't know, 30 or 50 *kurus* (one hundredth of a Turkish Lira) but Koç (local partner of JV) wouldn't use it to save money…I truly want to support the local industry but after all that one has to be stupid to do that. With small items like I don't know, a mixer or toaster, it is okay, like my food processor is Arçelik (produced by Koç) …but when we need an appliance I go for a Siemens, Bosch, or Miele. (Ayse, Manager, Female)

Collectively, these discourses and practices suggest nuanced meanings and ways of consuming global brands that have not been well explored in the extant literature. Interpretations of global brands as "colonizers" or "infidels" are striking in this country context given lack of Turkey's experience with direct colonial rule and commitment to a secular democracy, yet become intelligible when read in light of the country's prolonged experimentation with modernization, democracy, and globalization. As such, these discourses and practices cannot be simply attributed to ethnocentrism or anti-Americanism.

In conclusion, this study extends both the conceptual and the geographical scope of research on consumer resistance by introducing new discourses and practices of resistance through an examination of the phenomenon in a developing country context in view of globalization. This research may also offer insights into consumer resistance in other emerging economies experimenting with modernization and democracy, as well as countries with colonial history.

# Cries from the Goblin Market: Consumer Narratives in the Marketplace

Shakeel Siddiqui, Dublin City University, Ireland
Darach Turley, Dublin City University, Ireland
Farida Rifai, HSE, Ireland

## EXTENDED ABSTRACT

The contemporary understanding of consumption is that it comprises mutable and malleable sets of acts that go beyond acquisition, use and depletion of consumables; consumption is a narrative of empowerment aimed at self-articulation. When consumption is viewed as a narrative, the study of consumer behaviour in turn becomes a search to understand consumption narratives. However, within consumer research, consumption narratives are typically studied through the lens of either brand semiotics or normative cultural identity.

Like other facets of social and cultural life, consumption narratives permeate the marketplace, but because marketplaces are ruled and governed by marketers, these narratives are generally more marketing communication inspired than what might be termed consumer originals. Thompson's (2004) work demonstrates that commercial narratives are created and tailored to provide meanings and metaphors to consumers to serve ideological agendas, and that the dynamically evolving nature of marketplace mythologies indicates an ever-present discourse of power among marketplace stakeholders. Because ordinary market structures do not empower consumers *within* exchange (Holt 2002) or allow them to freely create commercial as well as consumption narratives, some consumers may turn to alternate platforms such as flea markets (Sherry 1990) or the burning man festival (Kozinets 2002).

This paper explores online auctions as alternate marketplaces where the consumer becomes the marketer, and studies '*consumer generated*' commercial narratives. Selling in online auctions is primarily aimed at disposal, but consumer experimentation has resulted in popular sites like eBay becoming as much a platform for social and communal action as a platform for acquisition and disposition. This paper looks at narratives on eBay, to study how consumers create narratives that are imbued with social and cultural meanings and metaphors, archetypes and mythologies in order to promote their own ideological agendas.

*Methods and Findings*: Making use of an eighteen-month immersive ethnography on eBay, this article takes a broad overview of consumer generated narratives on two of the largest eBay regional websites, US and UK eBay. The extensive database (over 10,000 listings, more than 2,000 pages of printout) included many forms and formats of narratives: textual and visual product descriptions, audio-visual enhancements as well as statistical records, narratives that were inspired by and followed on commercial narratives, as well as originals that resisted pervasive brand semiotics.

*Consumer empowerment through alternate marketplaces*: In the relevant research literature there is arguably no universal definition of an 'alternate marketplace', but ordinarily a marketplace entails the presence of a buyer, seller and offering in a common place, a place where buyers and sellers exist in non-overlapping spheres. Online auctions where consumers act on both sides of a transaction represent a significant change in this centuries old marketplace structure by allowing a role malleability which effectively dissolves the buyer-seller boundary and makes the consumer a potent force in contemporary marketplace discourses of power (Siddiqui and Turley 2005).

eBay empowers a consumer by allowing her to play the roles of marketer, communicator, audience and buyer and thus grants her ultimate authority in her market interactions. Empowered consumers use this authority to create narratives of action, and apply them to both constructive and deconstructive ends.

At one level, consumer narratives on eBay highlight the sense of bargain hunting common to the larger eBay community, and underscore its alternate market ethos. At another level, these narratives also indicate a commonality of interest which results in the emergence of multiple communities of collectors and consumers centered on material objects and brands as well as ideologies. We found that these narratives are used both constructively and deconstructively to foster various ideological agendas.

*Discussion*: If the Foucauldian view that social and communal movements always invoke resistance to prevailing power structures is applied to alternate marketplaces, this might explain why and how new modes of trade become active subjects in the larger marketplace discourses of power. When these discourses of resistance originate as consumer actions, they have the propensity to emerge as social movements (Kozinets 2004) based on the attribution of an emancipatory universal to a particular social group (Poster 1984). In the case of eBay, simply being advertised on this platform invokes 'get it cheap', 'rock-bottom bargain' and 'value for money' themes built upon knowledge, beliefs and assumptions of the larger eBay community of bargain hunters. At one level, these themes are essentially an indication of a resistance to contemporary market structures and assume that removal of the profiteering middleman from the equation is in best interest of the consumer. However, this '*removal of middleman*' assumption is countervailed by the other popular '*from rags to riches through selling trash*' assumption held by the larger eBay community. Although many consumers do not find the juxtaposition of these two metaphors to be contradictory, they can be seen as representing historically countervailing views of alternate marketplaces. On eBay the postmodern notion of consumer freedom (Venkatesh 1998) by escaping the marketplace (Kozinets 2002) is manifested through opting for an alternate marketplace, which, ironically, attracts many consumer-entrepreneurs in quest of the Marxian prospect of becoming an active subject in the very economy they are trying to escape.

# Contested Consumption in Everyday Life

Marius K. Luedicke, University of Innsbruck, Austria
Markus Giesler, York University, Canada

## EXTENDED ABSTRACT

The study of ideological conflict over meanings and methods in market economies constitutes a central research program in consumer culture theory (Arnould and Thompson 2005). Since the beginning of the 1970s, consumer researchers have accumulated an insightful body of knowledge on the motivations, ideological agendas, and empirical behaviors that consumers evolve for resisting reportedly scrupulous market forces (Peñaloza and Price 1993). For a better understanding of the various motives, expressions, and implications of market-based conflict, the emerging literature advanced theoretical notions such as consumer boycott (Friedman 1985; Garrett 1987), consumer emancipation (Kozinets 2002), consumer resistance (Holt 2002; Peñaloza and Price 1993), consumer movements {Kozinets and Handelman 2004;Thompson and Coksuner-Balli 2007}, cultural jamming (Handelman 1999; Lasn 2000), and marketplace drama (Giesler forthcoming).

Building on the initial work of Dameron (1938; 1941) and Sorensen (1941) on consumerism, this line of studies theorizes on antagonistic social behaviors as individual or collective conducts of consumers that feel reluctantly domineered by hegemonic business forces, including corporations (Thompson and Arsel 2004), brands (Klein 1999; Thompson et al. 2006), ideologies (Rumbo 2002), or the capitalist market system per se (Kozinets 2002; Kozinets and Handelman 2004). Emancipation from and resistance against such dominant powers was first expected to find its fruition outside of the "totalizing logic of the market" (Firat and Venkatesh 1995). However, in line with contemporary sociologists de Certeau ([1974] 1984), Fiske (1989), and Willis (1991), consumer culture theorists came to agree that resistance is not only a market-inherent mechanism but also an important function for rejuvenating (Holt 2002) and transforming the market (Giesler forthcoming).

Our point of departure is that due to its focus on the dramatic David-versus-Goliath types of consumer struggles against unwanted forces-such as anti-Starbucks, anti-Nike, or anti-Branding activism–current theory has largely overlooked the consumer cultural influence of the mundane everyday negotiations of consumption meanings among equally influential, individual consumers.

To best reveal the cultural grounds and social practices of consumer-consumer conflicts, we offer the concept of "contested consumption." Contested consumption comprises a set of influential interactive practices by which consumers explicitly challenge and critique each other's consumption choices, behaviors, and ideologies. Central to understanding these processes is the existence, perception, and enforcement of power in social relationships. We use the Foucaultian idea of power as "multiple and mobile field[s] of force relations" (1980, p. 102) in order to reveal the motivations for contestation and discuss the structuring influences of the phenomenon within a larger consumer cultural context.

This research reveals two vital discourses-authenticity and sociality–in the ideological realm of which consumers negotiate the legitimacy of Hummer ownership. These discourses also draw from and contribute to a multitude of dialectical tensions, including individualism vs. collectivism (Triandis 1985), open vs. closed (Pitt et al. 2006), sharing vs. owning (Giesler 2008), or modesty vs. conspicuity (Veblen [1899] 1927), that provide further ideological grounds for the Hummer conflict in the American culture. The practice of contested consumption comprises five expressive forms of contestation that Hummer owners and adversaries evolve for achieving ideological predominance in their respective cause: vigilant justice, insult, discredit, ridicule and instruction. These forms differ by their directness of contestation and explicitness of formulation.

In summary, the analysis reveals classic, but previously unexplored practices of consumer antagonism that offer valuable insights into the creation and proliferation of ideology, culture, and brand meaning from a consumer perspective. Previous research has located antagonistic consumer behaviors exclusively within consumer-versus-producer domains (Klein 1999; Kozinets and Handelman 2004). Our study illuminates that consumerist action also resides within the mundane everyday contestations among people that are endowed with similar social and economic capital but pursue different ideological agendas.

The Hummer case illuminates that consumers defend and reinforce their ideas of a desirable market culture not only by throwing stones at Nike store windows or symbolically burning wooden men at distant desert festivals, but also and even more by passionately contesting the behaviors of individuals that transgress their perceived boundaries of legitimacy in everyday life. In addition, what has previously been theorized as a domain of leftist and somewhat more enlightened elitist consumer activists (cf. Thompson 2004), appears as a more profane practice in the light of the Hummer case. Consumerism can no longer be viewed as the exclusive domain of committed individuals such as Naomi Klein (1999) or Noreena Hertz (2001) who dedicate their lives to consumerism and possess particular expert knowledge, but as a continuum of cultural influences beginning with the practices of ordinary people expressing their beliefs by insulting Hummer owners or discrediting Toyota Prius owners in turn.

Our empirical account of contested consumption is a preliminary one. We hope that the present study will inspire fellow researchers to inquire deeper into the dynamics of the phenomenon in various social and cultural contexts in order to refine the concept and test the integrity of the findings.

# Choice with Inference is Different From Choice without Inference

Kunter Gunasti, Penn State University, USA
William T. Ross, Jr., Penn State University, USA

## EXTENDED ABSTRACT

Products and services are seldom described completely; therefore, consumers often need to form inferences that go beyond the information given (Kardes et al 2004). Some researchers have argued consumers do not form inferences in many situations even if it is logical to do so (Simmons and Lynch 1991). Others have suggested ways that consumers make inferences such as using other available attributes for the given brand (within-brand processing) or comparing the same attribute among other brands in the choice set (across-brand processing). In one stream of research, respondents were typically given a single product option with a number of attributes, one of which was missing. The inferences they provided for the missing value were compared with available attributes within-brand and the inference making processes were modeled based on the existing information about the target product (e.g., Johnson and Levin 1985). In another stream of research, participants were given multiple choice options one of which had a missing attribute. Participants' inferences for that missing value were compared to the available values for the same attribute in other choice options (e.g. Huber and McCann 1982; Ross and Creyer 1992).

Both streams of research developed important insights for inference making, such as the models that explain the effects of available attributes and the discounting of inferences. On the other hand, an implicit assumption has been that forcing participants to make explicit inferences leads to the same process as not prompting decision makers to infer missing attribute values. Would people make the same choices if they were not required to make explicit inferences? The focus of past studies has been on the inferred values solicited from research participants, whereas the effects of missing information and being asked to make inferences about them on decision outcomes have largely been overlooked. How does making inferences about missing attributes change consumers' perceptions of the options in a choice set and affect the final decisions compared to when they are not required to make inferences during their choice process? Do explicit inferences make it harder or easier for consumers to choose? Does prompting inferences lead to a more analytical processing style? How do consumers make inferences if there are multiple missing attributes for multiple product options?

Another potentially important factor that has not been considered in the inference making literature is that consumers in the market place usually have the option of not selecting any of the available alternatives. Do inferences affect indecisiveness (lack of choice)? These are the questions this manuscript seeks to address. Our research is an important attempt to discover the differences of choice made with prompted inferences from choice without prompted inferences and investigate the above questions. Drawing on the inference making and the missing information literature, we conduct three experimental studies to investigate the effects of multiple inferences in multi-attribute, multi-product choice environments. We also compare the forced choice situations that dominate the literature with more realistic conditions in which a no choice option is available. Our findings contribute to past literature by providing a better understanding of the inference making process in more complicated choice situations and by demonstrating the important consequences of inferences for consumer choices.

In study 1, missing attribute information and inference making were manipulated. The choice sets consisted of product-attribute matrices for three product categories. A different attribute was missing for each of the three options in all product categories. Participants were randomly assigned to two conditions. Those in the *Non-prompted Inference* condition were simply asked to make choices, whereas those in the *Prompted Inference* condition were asked to make inferences for missing attribute values before making choices. Results indicated that choices made after inferences were significantly different from choices made without inferences. Assigning different values to missing attributes significantly decreased perceived choice difficulty, increased attractiveness of chosen options and decreased the focus on availability (absence) of important attributes as a reason for (not) choosing particular options. In addition, inferences made across brands for different attributes were significantly correlated with each other suggesting that participants have used a combination of within-brand and across-brand processing strategy.

In study 2, an identical design was used with one exception. Besides the three options in each choice set, a "no choice option" was included, such that participants also had the alternative of not choosing any of the options as in real purchase situations. Results showed that being asked to make explicit inferences significantly decreased the selection of the "no choice option" (indecisiveness) as well as reducing perceived difficulty of decisions for all product categories. Finally, study 3 replicated the findings in the previous studies and verbal protocols collected in study shed light into the underlying process and provided more direct support for predictions.

Our research has an important role in integrating past studies on inference making based on alternative-based and attribute-based processing. We used a more complex choice environment with multiple missing attributes for multiple brands from a diverse set of product categories. Inferences about missing attributes are not only affected by other available attributes for the same brand and by the same attribute for different brands but also by other attributes for the other brands in the choice set. In addition to providing a better understanding of the nature of the inference making process, a major contribution of our research is that it demonstrates the important consequences of making explicit inferences. While our introduction of a no choice option increased the realism of decision context, more importantly, it allowed us to observe that making inferences reduced the tendency to select the no choice option. Given the prevalence of missing information in online shopping environments, there are important opportunities for marketers to manipulate choice sets or design advertising messages that encourage consumers to make inferences and thereby increase the probability of purchase decisions.

# Effects of Two Dimensions of Psychological Distance on Consumer Judgments

Kyeongheui Kim, University of Toronto, Canada
Xiuping Li, National University of Singapore, Singapore
Meng Zhang, The Chinese University of Hong Kong, Hong Kong

## EXTENDED ABSTRACT

Imagine that you are planning a trip to Las Vegas for the coming weekend and are reading some reviews on a particular hotel written by other travellers on an on-line forum. Will the identity of the reviewer (e.g., someone with the same occupation as you or someone from a different walk of life) influence your judgments of the hotel? How would your reactions be different if you are planning a trip in six months from now instead? Prior research on construal level theory (CLT) suggests that an individual's judgment of an event (e.g., hotel) is contingent on the psychological distance from the event (e.g., whether it is temporally near or distant; Liberman, Sagristano, and Trope 2002; Trope and Liberman 2003). According to CLT, individuals represent psychologically proximal events in low-level construals, whereas they represent psychologically distal events in high-level construals. These differences in the construals of events lead to differences in individuals' evaluations of the events. However, the prior research on construal level theory has focused only on a *single* dimension of psychological distance; little, if any has examined how *multiple* dimensions interact to influence individuals' evaluations. In the present paper, we extend the CLT literature by investigating how these two dimensions of psychological distance, namely, temporal and social distance will influence consumers' evaluations of events and products.

We examined three possible alternative accounts concerning the effect of two dimensions of psychological distance (representational account, anchoring account, and mental distance account) and tested these accounts in three experiments. Specifically, in experiment 1, we manipulated social distance of an event (i.e., an event occurs to self vs. to an unknown person) first and temporal distance (event for tomorrow vs. one year later) second, and investigated the effects on a variety of decision making situations. In experiment 2, we adopted a different manipulation of social distance (i.e., in-group vs. out-group) and examined the effects of two dimensions on consumers' evaluations of a new product. In experiment 3, we changed the order in which the two psychological distance dimensions were induced. We manipulated the temporal distance first, followed by the social distance. Converging evidence, which strongly supported the mental account distance account, emerged across the three experiments, with different manipulation methods, different orders of manipulations, and different stimuli.

The mental distance account posits that when two dimensions of psychological distance (e.g., temporal and social distance) are involved in a decision situation, these two dimensions would interactively affect the perceived distance of an event along an individual's mental distance horizon, which in turn will influence construals and evaluations of the event. Specifically, when both of the two dimensions are proximal, the event will be perceived as proximal and construed at low-level construals, resulting in evaluations more consistent with the value associated with low-level construals. However, when either one of the dimensions is psychologically distal, the event will be perceived as distal and construed at high-level construals, resulting in evaluations more consistent with the value associated with high-level construals. Therefore, the well-documented effects of a single psychological distance dimension on event construals will only hold when the other dimension is psychologically proximal.

# Feast or Famine: How Expectations Polarize Judgments of Ambiguous Alternative Set Sizes

S. Adam Brasel, Boston College, USA

## EXTENDED ABSTRACT

The current proliferation of online storefronts and inventory customization techniques make judgments of choice set size increasingly difficult. As choice set size becomes ambiguous, the role of expectations in determining consumers' actual set size perceptions becomes increasingly important. This paper explores into how set-size expectations impact set-size judgments for various-sized alternative sets, and how the role of expectations is constrained to ambiguous sets where expectations serve as the major cue for set-size judgments. Are judgments of variety malleable, or does objective experience dominate once consumers are presented with the actual consideration set?

We propose that expectations are especially important when it is difficult to objectively judge the size of the choice set. When a choice set is truly limited and sparse, or overwhelmingly extensive, the reality of the choice set should overpower any incorrect expectations and the set size should be perceived accurately. In contrast, a moderately-sized set is at neither size extreme, and thus more difficult to judge. Expectations, then, can serve as a highly salient cue with which ambiguous choice sets can be evaluated.

Prior research suggests that expectations tend to negatively bias shopping experiences, and expectations tend towards contrast rather than assimilation, especially when the expectations are directly relevant to the target category. In light of these findings, we propose that when consumers are presented with a limited or extensive choice set, however, expectations will have no effect on set-size judgments. But when consumers are presented with a moderate alternative set, set size judgments will exhibit expectation contrast regardless of whether the expectations were for a limited or extensive set. In short, the reactions to a moderate alternative set given prior expectations should follow a "mirrored" pattern: consumers expecting a large set should perceive a moderate set as similar to a limited set, while consumers expecting a limited set should perceive a moderate set similarly to an extensive set.

To test these propositions, an online choice study was conducted using choice sets of digital cameras at a fictitious online electronics store. Expectations were manipulated by telling participants to expect either a very limited or very extensive set, then participants presented with a choice set of either four, twelve, or twenty-four cameras. Six separate websites were created to ensure that subjects did not see the stimuli from other conditions, and attribute scores ensured no camera was strictly dominant. After choosing a camera, participants entered measures as to how restrictive and overwhelming they perceived the set to be, as well as measures of set completeness and error likelihood.

An ANOVA revealed a main effect for expectations on the outcome variables. Participants who expected an extensive set viewed their alternative sets as significantly more incomplete, more restrictive, less overwhelming, and felt they were significantly less likely to make an error in choice than participants who expected a sparse set. So overall, extensive expectation participants felt their sets were more limiting, while limited expectation participants felt their sets were more extensive.

The analysis also revealed an important significant expectation by set-size interaction effect. Consistent with propositions, the effect of expectations is largely confined to the moderate set size. When the actual set size was limited or extensive, no significant differences were revealed between extensive and limited expectations conditions on any DV in planned-contrast t-tests. When the actual set-size was moderate, however, those expecting a limited set viewed the moderate set as significantly more overwhelming, less restrictive, and more complete, but found the choice more difficult and were more concerned that they had chosen suboptimally when compared with those expecting an extensive set.

The results support the propositions: expectations of set size significantly affect ambiguous set perceptions, but have little effect when the presented set is actually limited or extensive. The ambiguous set appears to disconfirm expectations regardless of whether they were for an extensive or limited set; those expecting a limited set view the moderate set as extensive while those expecting an extensive set view the moderate set as limited. This carries beyond perceptions of the set, and impacts judgments of choice difficulty, frustration, and error likelihood.

In order to attempt to tease apart ambiguity from set size, a follow-up study utilized only the moderate level of alternatives. Online digital camera choice sets were retained as the stimuli. Expectations were manipulated by telling the participants to expect a limited set, a sparse set, or telling them nothing. Ambiguity was then manipulated by introducing a set size descriptor to the top of the camera set labeled as limited, labeled as extensive, or not labeled.

An ANOVA reveals that participants in the extensive set descriptor condition perceived the moderate choice set as significantly more overwhelming and significantly less restrictive than participants in the limited set descriptor condition regardless of expectations. Both the limited and extensive set descriptor conditions were also each marginally different from the no descriptor control condition in the expected directions. In contrast, the difference between the limited and extensive set expectation conditions for feeling restricted or overwhelmed by the set size was only significant in the no set descriptor condition. When a set descriptor was present, participants rated the set in line with the descriptor and expectations had no significant effect upon set size judgments. These results are consistent with the proposition that expectations only play a role in set-size evaluations when the set is ambiguous. By giving participants an external size descriptor, expectation effects were reduced to insignificance.

In summary, expectations of limited or extensive set sizes had little effect on evaluations of actually limited or extensive sets. But when the choice set was of ambiguous size, participants expecting either a limited or extensive set exhibited expectation contrast rather than assimilation. Extensive expectations made the moderate set appear limited while limited expectations made the moderate set appear extensive. A second study focused on the moderate set size, and showed that decreasing the ambiguity of the set by directly labeling it as sparse or extensive significantly decreased the effect of expectations on set-size evaluations.

# The Learning (and not) of Effort and Accuracy Tradeoffs

Jeffrey S. Larson, Brigham Young University, USA

## EXTENDED ABSTRACT

For obvious reasons, deciding on a house is likely to inspire more deliberation than deciding on a brand of peanut butter. But precisely how much or how little cognitive effort should an individual invest in either of these decisions? Answering that question requires consideration of multiple factors, including the relative utilities of the available products, the cost of cognitive effort (both in negative utility of thinking and in opportunity cost terms), etc. It is a complex optimization problem that is also fundamental—decision makers have to solve it hundreds of times a day.

Despite its fundamental nature, we still know relatively little about how this metacognitive decision input develops. Existing frameworks dealing with effort and accuracy tradeoffs come with no formalized knowledge about how decision makers determine the precise amount of cognitive effort merited by a decision task, much less how they learn to map that given level of desired effort and accuracy onto the correct decision strategy (Beach and Mitchell 1978; Payne, Bettman, and Johnson 1988). Instead, they seem to imply that, where this learning is necessary, it takes place quickly and without detriment to the decision process.

This research proposes an alternate hypothesis. Adapting to a change in task constraints requires metacognitive learning on multiple fronts. First, the decision maker may not immediately know the extent to which a constraint change affects the desired balance of effort and accuracy. The effort and accuracy goals from the decision maker's first encounter(s) with a decision task will form an anchor from which goals will be adjusted to account for the task constraint change. The use of the anchoring and adjustment mechanism should result in the expected underadjustment of effort and accuracy goals, which will result in poor adaptation to the constraint changes (Epley and Gilovich 2001; Tversky and Kahneman 1974). I call this contributor to poor adaptation *goal persistence*.

Second, the mapping of a new effort-accuracy level to an available decision strategy may also require learning. Studies of decision strategy selection in the multi-cue probability learning literature show that changes to a cue environment often cause perseveration—that is, the continued use of an ill-suited strategy, even when the participant has received explicit feedback that the cue is invalid (Restle 1962). This perseveration is likely also to occur in the strategy selection phase when a change in the decision environment requires the selection of a new decision strategy. This is called *biased selection*, as the perseverative tendency biases the selection of an appropriate decision strategy.

Third, the fuzzy nature of the feedback in this domain might serve to reinforce rather than correct poor adaptation. Effort, as measured by duration of time, is a perceptual continuum known to display a number of distorting biases documented in the psychophysical literature (Stevens 1957). Chief among these biases, at least for the current research, is perceptual distortion (Sherif, Taub, and Hovland 1958). This *scale distortion* causes poor adaptation to a decision task constraint change because insufficient adjustments to the accuracy and effort levels will be evaluated as sufficient due to skewing of the evaluation scale by prior experience.

Thus, I hypothesize that decision makers will adapt poorly to task constraint changes. The core contribution of this research is the discovery of the nature of this poor adaptation as well as its multiple contributing mechanisms. The following hypotheses result:

$H_{1a}$: If a new constraint increases desired accuracy or decreases desired efficiency, decision makers will be less accurate and more efficient than a control.

$H_{1b}$: If a new constraint decreases desired accuracy or increases desired efficiency, decision makers will be more accurate and less efficient than a control.

$H_2$: Constraint changers will perform worse than the appropriate control group.

$H_3$: Goal persistence causes underadjustment of relative goal strengths.

$H_4$: Biased selection causes use of previous (and poorly suited) decision strategies.

$H_5$: Scale distortion exaggerates the perceived size of effort and accuracy adjustments.

All three studies utilize a similar experimental paradigm. Participants make evaluations of product prices that are knowable, but whose solutions are cognitively taxing and thus amenable to the use of shortcut heuristics. In study 1, participants attempted to identify the least expensive of three two-part tariff pricing plans, like those used by cell phone companies. In studies 2 and 3, participants saw a list of prices from four different retailers for five separate products and attempted to identify the retailer offering the lowest overall price for the five products.

In all studies, participants were rewarded based both on the total number of correct evaluations and the percentage of correct evaluations. Participants were self-paced, making as many or as few evaluations as they wished. Incentive schemes were created that would encourage either fast, heuristic-based evaluations or slow, careful evaluations. After some experience under one incentive scheme, participants moved to the opposite incentive scheme. In all three studies, participants who moved from the fast to the slow constraint made decisions more quickly than a control group, while those moving from slow to fast constraint made decisions more slowly than a control, as predicted by hypothesis 1. In study 1, this bias resulted in lower earnings for constraint changers than the appropriate control, confirming hypothesis 2.

In study 1, participants evaluated their perceived effort and accuracy between each phase of evaluations. Consistent with hypothesis 5, scale distortion, perceptions of both effort and accuracy were significantly distorted by previous experience. In study 2, the initial incentive scheme caused the stronger goal (accuracy maximization or effort minimization) to affect unrelated decisions after the experimental task, consistent with hypothesis 3, goal persistence. In study 3, process tracing methods demonstrated that after a constraint change, participants continued to utilize previous processing patterns, consistent with hypothesis 4, biased selection.

# The Global Brand's Meaning Mélange: Seeking Home Abroad through Global Brands

Anders Bengtsson, Suffolk University, USA
Meera Venkatraman, Suffolk University, USA

## EXTENDED ABSTRACT

The importance of standardizing a brand by using a uniform visual identity and establishing a consistent global brand image has been reinforced as it is recognized that consumers have become increasingly mobile and encounter global brands in markets other than their home culture (Matthiesen and Phau 2005). In the brand management literature, it is generally recommended to use a common marketing platform including consistent brand names and symbols so that the brand and its marketing communication is instantly recognized by consumers who are traveling to different countries (Aaker and Joachimsthaler 2000, p. 307; Kapferer 2004, p. 402). The conventional wisdom is that when a brand is consistently executed across markets, it evokes a consistent set of brand associations which helps to maintain consistency of brand image (Keller 2003, p. 684).

Although this viewpoint may have intuitive appeal, a review of previous research reveals that the link between a brand's common marketing platform and a consumer's development of a consistent brand image for a brand that is consumed in multiple cultural locales has not been empirically studied. As well as assuming that standardized global brands deliver identical values when consumed across markets we could anticipate that consumers value global brands differently in unfamiliar cultural settings because they offer a sense of order and predictability. This suggests that when consumers travel or temporarily cross cultures (Davies and Fitchett 2004), the cultural context has a profound impact on the symbolic meaning evoked by the brand (Eckhardt and Houston 2002; Miller 1998). The purpose of this study is to explore the multidimensionality of global brand meaning and develop an understanding of consumers' meaning development for standardized global brands consumed in multiple cultural locales.

The empirical data for this study consists of accounts of U.S. residing consumers' experiences of either Starbucks or McDonald's both at home and when traveling in China. Our informants are 29 entry and mid-level professionals enrolled in graduate business programs at a university in United States. Data collection took place before, during, and after the informants made a two week trip to Beijing and Shanghai as part of courses in doing business in China. The empirical material was gathered through a number of techniques including personal reflection essays about the brand before they traveled, journals of food consumption while in China, and visits to the study-site documented using photographs taken by the informants, and in-depth interviews using photo-elicitation when they returned (Heisley and Levy 1991). All interviews were recorded and transcribed verbatim. The transcripts were analyzed using a hermeneutic approach as laid out by Thompson (1997).

The study shows that when consumers cross cultures and experience global brands in milieus different from their everyday consumption context, global brands take on new meanings despite the standardization of the marketing platform as perceived by the consumers. Our findings challenge conventional thinking in brand management and revise the theoretical notion that standardized global brands generate consistent brand images when experienced in different cultural locales. It is apparent that oftentimes the brands take on new symbolic roles helping consumers to cope with the uncertainties of the cultural contexs. Sometimes, encountering Starbucks and McDonald's in China triggers a meaning that is diametrical to the meaning ascribed to the brand in the U.S. Thus, the prevailing assumption that consistently executed brands generate consistent brand images does not hold true. When consumed in China, the brands evoke meanings of comfort and predictability and offer an instant symbolic connection to the individual's everyday consumption context.

Our study lends support to the contention that consumers ascribe contextualized meanings to brands, shaped by the cultural context in which the consumption occurs (Kleine and Kernan 1991). This means that a consumer can be negatively (positively) oriented towards a brand in the everyday consumption context and be favorable (unfavorable) towards the brand when consumed in an unfamiliar cultural locale. It is evident that even when the brand platform is consistently executed across markets, consumers activate multiple meanings for global brands. This meaning discrepancy suggests that global brand images can be construed as a meaning mélange that through its consistent inconsistency captures the different values and meanings consumers seek from a brand in the various cultural contexts in which it is consumed. The role of marketplace cultures and brands for consumer identity projects has been an important avenue in CCT research. We contribute to this line of research by illustrating that brands can provide relief from the uncertainties of unfamiliar cultural contexts and evoke meanings of home. This finding highlights an important, yet unknown role of brands.

# Do Sales Promotions Necessarily Erode Brand Equity? Maybe Not

Joshy Joseph, Indian Institute of Technology Madras, India
Bharadhwaj Sivakumaran, Indian Institute of Technology Madras, India

## EXTENDED ABSTRACT

### Introduction

Sales promotions are generally seen as detrimental to brand equity, even though they produce positive impact on sales and revenue (Winer 1986, Mela, Gupta and Lehmann 1997). Contrary to research evidence that sales promotions erode brand equity, the ratio of advertisements to sales promotion in the IMC budgets of companies, which was heavily skewed towards ads earlier, has now shifted towards promotions (Spethman 1998, Joyce 2006). This widespread usage of sales promotions by the industry, despite the conflicting research findings forms the background for this paper.

### Conceptual Framework

One way of classification of promotions is into consumer franchise building (CFB) and consumer non-franchise building (Non CFB) promotions (Belch and Belch 2004). CFB promotions communicate distinctive brand attributes and contribute to the development and reinforcement of brand identity while non CFB promotions try to generate immediate sales or shorten the buying decision.

CFB promotions would thus contribute to the development of brand equity, while non CFB promotions could reduce it as the focus is to provide incentives for buying now, without considering brand development. However, this need not be true always, as different customer groups have different individual characteristics and purchase intentions and thus may not always be influenced by the above logic. In addition to customer-related factors like personality traits and purchase motivations, there are other factors too that make the customers develop positive evaluations of the brand, leading to higher brand equity during non CFB promotions.

Individuals with high levels of deal proneness respond more to deals and they are seen more appreciative of promotions than low deal prone customers (d'Astous and Jacob 2002). Involvement is the subjective perception of the personal relevance of an object to an individual. Highly involved customers relate to a product as a part of their lifestyle and are likely to learn more about the product category and search more during their purchase processes. They pay more attention to the product's ads and read and cognitively process the fine print (Lockshin and Spawton 2001). Advertising affects brand equity through brand associations and perceived quality. Perceived advertising spending contributes to brand equity (Villarejo-Ramos and Sanchez-Franco 2005). Advertising also increases product knowledge of customers. Therefore, we hypothesized that brand equity would be different in customer segments with high and low levels of deal proneness and involvement and when the product is supported with high and low levels of advertising.

### Methodology

Two experiments were conducted to test these hypotheses in which students at graduate level participated. Brand equity, deal proneness and involvement were measured using standard scales. Experiment 1 was based on a 2 x 2 factorial design where respondents were exposed to two types of promotions (CFB and non CFB) and two levels (high and low) of involvement. The second study also had a 2 x 2 design with two levels of promotions and two levels of advertising (high and low).

### Results and Discussion

We found that at high levels of deal proneness and involvement and at low levels of advertisement support, non CFB promotions lead to higher brand equity.

This study would be one of the pioneering efforts to investigate the positive impacts of sales promotions on brand equity. The reasons for increased promotional spending by companies, as mentioned earlier, could be due the presence of large numbers of high deal prone and high involvement customers and the high levels of ad spending by companies.

In sum, it is the characteristics of the market and the marketing actions taken by the company that decide whether CFB or non CFB promotions will contribute to building brand equity, and not just the promotion, as believed earlier.

### Future Research

This research has studied sales promotions by classifying it into CFB and non CFB promotions. Future works can find out the effect of each type of promotion on brand equity, including at different levels of discounts offered.

Study on the differential impact of promotions on dominant and non dominant brands and customers with differing loyalty levels can also be taken up. Culture could significantly influence the results and hence the study may be replicated in different cultural settings to find the respective effects.

# The Effects of Centrality and Distinctiveness on the Usage of Co-promotions

Hurrem Yilmaz, State University New York, Oneonta, USA
Amna Kirmani, University of Maryland, USA
B.P.S. Murthi, The University of Texas at Dallas, USA

## EXTENDED ABSTRACT

Co-promotion coupons have become popular as marketers manipulate tight promotional budgets to cope with increasing clutter (Varadarajan, 1986). Examples of co-promotions include saving $1 with the purchase of two packages of Keebler Sandies Cookies and 1 jar of Taster's Choice Coffee; and getting Campbell's Chicken Noodle Soup free with the purchase of two packages of Oscar Mayer Cold Cuts. The basic idea behind such a promotion is to use the target market and equity of each partner brand to increase the sales of both.

Although co-promotions share some features of brand alliances, most of the literature on alliances has focused on corporate alliances and co-branding in the context of services and durables. There is little theoretical literature about factors that may influence co-promotions of frequently purchased products. In this paper, we examine factors that affect the impact of co-promotion coupons on consumers' usage intention. We focus on co-promotion at the product rather than brand level and address the specific question of how managers may evaluate which product category to partner with in a co-promotion.

Using schema theory, we suggest that consumers may evaluate co-promotion coupons in the context of a given usage situation, e.g., Thanksgiving dinner, birthday party, coffee time. We propose that when prompted with usage situations, consumers will have higher usage intention for co-promotion coupons that belong to the same usage situation than co-promotion coupons that do not belong to same usage situation. Moreover, we propose that the effectiveness of a co-promotion will be a function of two aspects of the promoted product categories: 1) centrality, which refers to importance; and 2) distinctiveness, which refers to uniqueness (Galambos, 1986). For example a shopping goal for Thanksgiving Dinner may activate turkey and vegetables (corn and beans) as highly central products. The centrality of a product provides direct access during the encoding of material to be remembered and during production of that material (Nottenburg and Shoben, 1980; Galambos and Rips, 1982) and this accessibility may help with retrieval and choice (Nedungadi, 1990). Therefore, co-promotion coupons with central products will have a higher chance of being preferred than those with noncentral products. Similarly, if a usage situation schema is activated and a coupon is encountered, distinctive products will associate with the activated usage situation easier than they associate with another usage situation. This match is expected to create a positive feeling which then may reflect on the intention of the consumer to use the coupon.

We predict that effective co-promotion coupons will involve partners that are either high on centrality or distinctiveness, and that distinctiveness can make up for low centrality. Specifically, we predict that when the centrality of one of the partner products is low, higher distinctiveness will lead to higher usage intentions.

These predictions are tested in a 2 (Focal Product Centrality: high vs. low) X 2 (Partner Product Centrality: high vs. low) X 2 (Partner Product Distinctiveness: high vs. low) between subjects design. Subjects were 204 students randomly assigned to conditions. Centrality and distinctiveness of products in a Thanksgiving dinner usage schema were manipulated, and coupon usage intention and complementarity were measured.

A 2 X 2 X 2 ANOVA revealed significant main effects of Focal Product Centrality ($F_{(7, 184)} = 124.65$, $p < .0001$), Partner Centrality ($F_{(7, 184)} = 105.50$, $p < .0001$), and Distinctiveness ($F_{(7, 184)} = 17.20$, $p < .0001$), as well as a significant three-way interaction ($F_{(7, 184)} = 9.7$, $p < .05$). The significant main effects showed that use intentions for co-promotion coupons were higher when the centrality of the focal product on the coupon was high rather than low (MFC= 5.82 vs. MFN= 4.00), when the centrality of the partner product was high rather than low (MPC= 5.75 vs. MPN= 4.07) and when the distinctiveness of the partner product was high rather than low (MPD= 5.25 vs. MPN= 4.57).

The three-way interaction was consistent with our predictions. When centrality of one of the products was low, high distinctiveness led to higher usage intentions than did low distinctiveness. Specifically, usage intentions were higher when a central focal product was partnered with a non central partner who was distinctive than non distinctive [MCND=5.67; MCNN=4.54, $F_{(1,184)}=11.87$, $p<.001$]. Similarly, usage intentions were higher when a non-central focal product was partnered with a central partner who was distinctive than non distinctive [MNCD=5.58 MNCN=4.33; $F_{(1,184)}=14.65$, both $p<.001$].

Finally, complementarity did not account for the effects, suggesting that the effects of centrality and distinctiveness are separate from the effects of perceived fit. This is one of the theoretical contributions of the paper.

# Brand Visualization: Effects of 'Product Shape-Typeface Design' Congruence on Brand Perceptions and Price Expectations

Thomas Van Rompay, Twente University, The Netherlands
Ad Pruyn, Twente University, The Netherlands

## EXTENDED ABSTRACT

Research indicates that congruence, as opposed to incongruence, of symbolic meanings connoted across or within marketing mix elements positively affects consumer response (Bottomley and Doyle 2006; Erdem and Swait 1988, 1994). However, controlled studies addressing congruence effects of visual product features are non-existent. Since products comprise multiple visual 'channels' (e.g., shape and typeface) through which symbolic meanings are communicated, and considering that a product's visual appearance is the most important determinant of consumer choice (Bloch 1995), such studies are called for. Hence, two studies were conducted addressing effects of congruence of symbolic meanings connoted across shape and typeface of a fictitious brand of bottled waters on brand perceptions and price expectations.

In accounting for effects of various forms of congruence on consumer response, recent theorizing on processing fluency is insightful. According to such accounts, stimuli that can be easily processed are generally evaluated in positive terms and inspire favorable attitudes (Lee and Labroo 2004; Reber, Schwarz, and Winkielman 2004). The basis for these effects can be traced to the finding that fluent processing is experienced as positive (Reber et al. 2004). Of particular relevance for the present context is the finding that fluent stimuli are experienced as more credible or true (Reber and Schwarz 1999; Unkelbach 2007) and aesthetically pleasing (Reber et al. 2004) than non-fluent stimuli.

As for product appearance, perceived congruence of symbolic meanings connoted across visual product features is expected to facilitate processing. Arguably, products high in congruence facilitate impression formation, as opposed to products low in congruence. In line with the claim that fluent processing generally inspires favorable product evaluations (Lee and Labroo 2004), and the finding that symbolic qualities expressed through product appearance steer brand perception (Childers and Jass 2002), shape-typeface congruence, as opposed to shape-typeface incongruence, is expected to positively impact perceptions of the corresponding brand.

In line with processing fluency accounts, a particular type of brand perception that should benefit from fluent processing concerns perceptions of brand credibility, i.e., the believability of the product information contained in the brand. Hence, products high in shape-typeface congruence should elicit ratings of the corresponding brand as more credible than products low in shape-typeface congruence. Elsewhere, it has been proposed that brand credibility is an important determinant of consumer-based brand equity (Erdem and Swait 1998), defined as the value of a brand to consumers (Keller 1993). Since product- or brand value is, among others, reflected in product price, it is expected that shape-typeface congruence positively affects price expectations via perceptions of brand credibility. These predictions were tested in study 1.

Study 2 tested the proposed relation between congruence and perceptions of brand aesthetics. Based on the finding that processing fluency positively affects aesthetic responses (Reber et al. 2004), it is expected that congruent, as opposed to incongruent, products trigger perceptions of the corresponding brand as higher in aesthetic value. In addition, study 2 sought to replicate the effect of shape-typeface congruence on price expectations using another set of stimuli.

In study 1, two shape variants and two typeface variants of a fictitious brand of bottled waters connoted either *luxury* or *casualness*, effects confirmed by a pretest. Cross pairing the two shapes with the two typefaces resulted in two congruent variants (shape and typeface both connoting *luxury*, or shape and typeface both connoting *casualness*) and two incongruent variants (product shape connoting *luxury* and typeface connoting *casualness*, or vice versa). One hundred and forty-four undergraduate students were randomly presented with a congruent or incongruent product variant, after which they filled out a measure of brand credibility. Price expectations were assessed by prompting participants to indicate what they thought would be the average price of the product presented (in Euro-cents) at supermarkets. Results showed that the two congruent product variants induced, as expected, higher perceptions of brand credibility and higher price expectations than the two incongruent variants. The expected mediation of the latter effect by perceived brand credibility was not confirmed.

In study 2, the proposed relation between shape-typeface congruence and perceived brand aesthetics was tested. In addition, study 2 sought to replicate the effect of shape-typeface congruence on price expectations with another set of stimuli. This time, the two shape and the two typeface variants (again using the same fictitious brand of bottled waters) either connoted *masculinity* or *femininity*. Similar to study 1, two congruent product variants and two incongruent variants were created by cross pairing the two shape and the two typeface manipulations. One hundred and twenty-six undergraduate students were randomly presented with a congruent or incongruent product variant, after which they filled out a measure of perceived brand aesthetics. As in study 1, price expectations were assessed by prompting participants to indicate what they thought would be the average price of the product presented (in Euro-cents) at supermarkets.

Although congruence effects were stronger for the feminine typeface variant than for the masculine typeface variant (indicating that the feminine typeface induced higher price expectations and higher ratings on perceived brand aesthetics than the masculine typeface), results showed, as in study 1, overall positive effects of congruence on both measures. Mediation analysis showed that congruence affects price expectations via perceived brand aesthetics, indicating that aesthetic value is not just an important determinant of consumer choice (Creusen and Schoormans 2005), but may also contribute to commercial success by shaping price expectations.

In addition, the findings presented suggest that shape-typeface congruence facilitates processing. Future research should incorporate more direct measures of processing fluency (e.g., reaction speed), and establish how fluency can be related to 'design principles' other than shape-typeface congruence. To further elucidate the described mediation, measures of brand aesthetics and brand credibility should be incorporated in the same study. Finally, future research should address effects of variations in product design on perceptions of existing brands characterized by a relatively stable brand image, usually the resultant of many more factors besides product appearance. Awaiting research addressing these issues, in the meantime, our results underscore the importance of controlled studies addressing effects of product design on consumer response.

# Remembering Words and Brands after a Perception of Discrepancy

Antonia Mantonakis (Kronlund), Brock University, Canada
Bruce W. A. Whittlesea, Simon Fraser University, Canada

## EXTENDED ABSTRACT

Online advertising has grown at a tremendous rate in the last few years. Banner advertising is the most common form of online advertising and is found on most if not all websites. Typically a panel is displayed either at the top or the bottom, or at either side, of a website, displaying various advertisements that change from time to time. One example reads "Unlimited local and long distance calling from VONAGE", appearing for only 4 seconds. How is it then that viewers would remember VONAGE given such a short duration of exposure? Many theories of memory are based on studies that examine accuracy towards targets. More recently, marketers have begun to consider the phenomenological aspects of memory, which lead to illusions of recognition towards brands, as would be the case if a consumer would recollect "AT&T" after seeing a VONAGE ad (see Kronlund, Yoon, and Wagner 2007 for a retrospective).

We examined the consequences of experiencing what we call a "perception of discrepancy" on later interactions with the same stimuli. By this, we mean a <u>perception</u> of a mismatch in cognitive processing. This is why we speak of a 'perception' of discrepancy, rather than 'discrepancy' alone. The term we use is not meant to describe the stimulus (a 'discrepant' stimulus, such as "Starbucks" would not be expected in the example above), rather, it is meant to describe the subjective feeling of surprise, arising from some sort of uncertainty given the context. We experimentally create surprise by placing a brief pause between the stem and brand.

We employed the stem-completion method (Whittlesea and Williams 2001), whereby we presented a high constraint stem with a brief pause, and target item, during exposure. To illustrate: "unlimited local and long distance calling" was presented for 3 seconds; before presenting VONAGE, allowing a brief pause between the stem and brand. We argue that the high constraint stem causes one to develop an indefinite expectation, or a readiness to incorporate one of a restricted number of concepts (without projecting a specific target). The pause causes a fleeting sense of uncertainty (a realization that one does not know exactly what is coming). This experience causes the target, when shown, to feel surprisingly well fitting.

This type of exposure acts to increase attention towards the target, allowing it to be remembered more accurately later (experiments 1 and 2), even though the recognition test target word was shown in isolation, and so did not have an additional cue to help reinstate the encoding process. Our results add to the literature (e.g., previous work by Kronlund and Whittlesea 2006) by demonstrating that the pause effect is due to the combination of an indefinite expectation, uncertainty and surprising resolution, or what we call the "perception of discrepancy", and the perception of discrepancy is a powerful source of learning key words and brand names in ads.

The effects of the pause caused participants to be more likely to accurately claim to have seen the brand once in experiments 1 and 2. In experiment 3 we presented brands with stems either once or repeated after viewing other brands with stems. A different process occurred in experiment 3: During the second presentation of a brand in an ad (e.g., seeing the VONAGE ad for the second time), even with a pause, the person forms a *definite* expectation of a schema for that brand category, or a specific projection of which brand is about to be shown. The pause then contributes to this learning experience by allowing the participant the opportunity to actually generate that brand (an act that is verified by the presentation of the target brand a moment later). This act of generation allows them to realize, at the moment of generation during the second exposure presentation, that they are experiencing this brand for the second time, encoding the brand *as* a repetition, which would make it much easier to remember that brand.

Our findings introduce the notion that marketers should consider the basic cognitive processes that consumers use when reading such ads containing written sentences ending with key words (e.g., MINIVAN), or brand names (e.g., WINDSTAR). This is especially important in light of recent trends for traditional ad agencies offering "automated ad creation": Omnicom Group offers automotive advertisers a "Pick 'n' Click" option to tailor their messages. A recent television spot for the Toyota Camry provides an example of an ad employing a written sentence stem to present the brand name in question. At the end of each spot of the campaign, the words "The modern family sedan" appear, and following a brief pause, the brand name "CAMRY" appears adjacent to the sentence stem. Both the stem and the brand name are presented in silence, allowing viewers of the ad to read it, to encode the brand in a way that can later be remembered. We suggest that the optimal exposure method, given only about 4 seconds, would be to present the stem, followed by a brief pause, and end with the target. These conditions lead to better memory for the target as opposed to presenting the entire message all at once. By using the results of this research, marketers should be able to tailor their marketing efforts in a fashion to better allocate marketing dollars in an era of shrinking budgets. The effectiveness of the presentation of brand names in sentences in this way, although used as a technique in advertisements, has not been examined empirically. The experiments in this article provide insights into the underlying cognitive mechanisms involved when consumers encounter such words and brands in ads, and suggest that the optimal presentation method for brands in sentences is through the use of a pause between the stem and the brand.

In summary, we investigated the effects on consumer memory of experiencing a perception of discrepancy during an original encounter with a word or brand. This experience increased the accuracy of recognition of the targets, even though the total exposure time of the target was shorter relative to the control. We conclude that a perception of discrepancy in an initial encounter with a keyword or brand in an ad is a valuable aid to memory, especially for brand names.

# Should I Stay or Should I Go? Mood Congruity, Self-monitoring and Retail Context Preference

Nancy M. Puccinelli, Northeastern University, USA
Rohit Deshpande, Harvard University, USA
Alice Isen, Cornell University, USA

## EXTENDED ABSTRACT

The vast majority of retailers appear to focus on optimizing customers' positive mood. The stores will feature cheery lighting, upbeat music, and reward sales staff for conveying positive feelings (Grimsley 1998). This makes intuitive sense. Retailers know that a customer's buying behavior is influenced by the atmosphere of the store (Swinyard 1993). The more positive the atmosphere the more positive the customer's perception of the store would seem to be (Schwarz and Clore 1983). Yet imagine the following scenario. After shoveling out your car on a particularly snowy day you finally make it to the store. As you enter, feet soaked and struggling to close your umbrella, you encounter bright lights, upbeat music, and beaming salespeople. You find the contrast between the cheery store environment and your dour mood makes you feel distinctive and different from the retail setting and people in it. Our study evaluated the counterintuitive prediction that under some circumstances customers in a bad mood will react negatively to a positive, upbeat retail environment. Further, it examined how self-monitoring may moderate this effect.

The primary hypotheses were as follows:

H1: Self-monitoring will significantly moderate the effect of a mood-congruent versus a mood-incongruent context on felt mood-distinctiveness such that low self-monitors will feel more distinctive in a mood-incongruent context than high self-monitors.

H2: Self-monitoring will significantly moderate the effect of a mood-congruent versus a mood-incongruent context on retail context preference such that high self-monitors will prefer a mood incongruent context more than low self-monitors.

## Experiment 1

*Method*

The experiment was a 2 (retail context: mood-incongruent or mood-congruent) x 2 (self-monitoring: low or high) between-subjects factorial design.

*Independent Variables*

*Mood Manipulation*. A film mood manipulation was used to induce a good or bad mood. Participants who watched *Big* felt significantly more Positive Mood than participants who watched *Steel Magnolias* ($M$s=7.36 vs. 3.33; $t$ (14)=7.88, $p$<.001).

*Mood-Congruence Manipulation*. Participants imagined that they needed to buy a book and saw an ad for a "Standard Barnes and Noble" or a "Celebrating Barnes and Noble" store. For bad mood participants the Celebrating Barnes and Noble store was a mood-incongruent context and the Standard Barnes and Noble store a mood-congruent one (vice versa for good mood participants).

*Self-Monitoring*. To measure participants' tendency to modify their behavior in response to a social context, participants completed a standardized measure of self-monitoring (Snyder 1974).

*Dependent Variables*

*Reaction to Retail Outlet*. To examine the effects of a mood-incongruent context on Felt Mood-distinctiveness, distinctive, unique, different current mood and different mood were combined to form a Felt Mood-distinctiveness composite (α=.65).

*Procedure*. After watching the mood induction clip participants saw one of the two ads and completed the ratings.

*Results*

*Reactions to Retail Outlet*. Consistent with hypotheses, participants who imagined a mood-incongruent context reported feeling more Felt Mood-distinctiveness ($M$=5.50, $SD$=1.33) than participants who imagined a mood-congruent context ($M$=4.32, SD=1.33; $F$ (1, 31)=9.59, $p$<.01). Consistent with expectations, the interaction of self-monitoring and Mood-distinctiveness was significant ($F$(1,31)=6.61, $p$ <.05). Low self-monitors showed a stronger effect of Mood-distinctiveness on Felt Mood-distinctiveness compared to high self-monitors. Thus it seems that low self-monitors feel a great deal more distinctive when imagining an incongruent context.

## Experiment 2

The second experiment examined consumer behavior in a preference context. If customers who feel good or bad perceive that a somber or happy retail context, respectively, will make them feel distinctive and different from the context, they may be inclined to avoid that context.

*Method*

The experiment was a 2 (retail context: mood-incongruent vs. mood-congruent) within x 2 (self-monitoring: low or high) between-subjects factorial design.

*Procedure and Materials*. The procedure and materials for Experiment 2 were virtually identical to those used in Experiment 1 and rated their preference for each retail context.

*Dependent Variable*

*Store Preference*. To measure participant reactions to the retail outlets, participants indicated how much they would like to visit the store.

*Results*

*Store Preference*. Consistent with Hypothesis 2 low self-monitors were less likely to prefer a mood-incongruent context than a mood-congruent context ($F$ (1, 37)=7.89, $p$<.01). In contrast, high self-monitors were more likely to prefer a mood-incongruent context than a mood-congruent one.

## Conclusions

Experiment 1 found that whereas low self-monitors report feeling more distinctive in a mood-incongruent context, high self-monitors do not. So, while a happy low self-monitor feels they would fit right in at a happy retail environment, a sad low self-monitor anticipates that a happy retail environment would make them feel distinctive so they avoid this retail environment. Experiment 2 provided further evidence that low self-monitors react negatively to a mood-incongruent context and are inclined to avoid such a context.

# The Impact of Language Code-Switching on Ad Claim Recall

Melissa Maier Bishop, University of Texas at Arlington, USA
Mark Peterson, University of Wyoming, USA

## EXTENDED ABSTRACT

The purpose of this study is to examine how using language code-switching in advertising interacts with the context language of the medium to influence message recall. Code-switching refers to the practice of alternating between two languages during conversation (Scotton 1988). The Spanish/English code-switching that occurs among bilingual Mexican-Americans is of interest in this research.

According to the Markedness Model (Myers-Scotton 1993), a term is marked when it stands out in conversation. Luna and Peracchio (2005a) state that the direction of code-switching determines which language is marked. For example, if a person is speaking in Spanish and then switches to English, English is marked. Markedness is similar to perceptual salience, in which part of a message is salient when it stands out from its immediate context (Fiske and Taylor 1984). Code-switching has the inherent ability of making code-switched elements salient (Heller 1988). Salience is important in terms of its ability to positively influence message recall, as perceptually salient attributes are easy to recall (Hutchinson and Alba 1991). Therefore, message elements that are made more salient through code-switching should stand apart from non-salient message elements.

Furthermore, the language of the media context (e.g., magazine, television program) in which a code-switched ad is placed may influence recall. It is proposed that the language of the media context in which an ad occurs may serve to alter the degree of salience of the matrix ("switched from") and the embedded ('switched to") elements of a code-switched message. In this study, the code-switched message is presented in two forms, depending on the direction of code-switching (switching from English to Spanish or Spanish to English). The context language refers to the language of the medium in which the ad appears (all-Spanish vs. all-English). In code-switched advertising, when the embedded text differs from the context language of the medium, the embedded elements are made the most salient. Therefore, when the embedded text does *not* match the language of the medium context, level of recall of embedded elements will be higher than when the embedded text matches the language of the medium context (H1).

Alternatively, although the attribute of salience in message processing may increase recall, it has been shown in brand research that salience can serve to hinder recall of non-salient alternatives (Alba and Chattopadhyay 1985). When one brand is made increasingly salient, this brand will be easier to recall while other non-salient brands will become harder to recall during memory-based tasks. Thus, as salience may inhibit recall of non-salient brands, this same effect may be observed among message recall elements. That is, message elements that are made more salient should cause inhibition of other message elements that are not as salient. When the context language of the medium in which an ad appears does not match the embedded language of a code-switched ad, the embedded elements will stand out more. This will lead to decreased salience of the matrix (the "switched-from" ad language) elements in these conditions. Hence, when the matrix language of a code-switched ad matches the context language of the medium, recall of matrix language elements will be lower than when the matrix language differs from the medium language (H2).

## Study

To test these hypotheses, 122 Mexican-Americans between the ages of 18-30 with some reading ability in both English and Spanish were recruited. Each individual randomly received one of four treatments, consisting of an advertisement for a fictional cell phone company placed in between two magazine articles. The ad was either in mostly Spanish with several noun code-switches in English (Spanish-to-English code-switching) or vice versa. For example, a statement in the English-to-Spanish code-switched ad said, "We offer affordable prices! Our rates fit almost any *presupuesto*". The magazine articles that occurred before and after the ad were both written either in only English or only Spanish. This produced a 2 (direction of code-switching) by 2 (language context of the media) factorial design.

Participants were given strict time limits for reading all materials and were then required to complete two recall tests—unaided (first) and aided (second). In the unaided recall test, individuals were given three minutes to record any statements, words, etc., that they could recall from the ad onto a blank piece of paper. Responses could be recorded in Spanish, English or in both. Individuals were then given 2.5 minutes to complete an aided recall test, which had a fill-in-the blank format. In this test, subjects viewed the language version of the ad which they had received in full, with several omissions of phrases that included the code-switched words. They were instructed to fill in as much missing information as they could remember. For both tests, independent coders awarded one point for each of the correct number of items recalled.

## Results

ANCOVA was used to test all hypotheses as several covariates were measured in the study, including Spanish and English reading ability, involvement in the ad and articles and age of respondent. H1 stated that recall of code-switched elements would be higher when their language differed from the language of the context medium. This was supported at both the unaided level of recall [F(1, 121)=12.65, p=.00] and the aided level, though less strongly [F(1, 121)=3.31, p=.07].

H2 stated that recall of matrix (non-code-switched) elements would be lower when their language matched that of the medium language. Only partial support was found for this hypothesis, in that recall of matrix elements in the Spanish context, English-to-Spanish code-switching condition was significantly higher (p<.05) than that of the Spanish context, Spanish-to-English condition. No significant differences were found in either of the conditions when English was the context language of the medium.

In summary, results from this study suggest that advertisers may be able to strategically increase recall of code-switched ad elements when their language differs from the context language of the medium in which the ad is placed. However, code-switching may also result in diminished recall of matrix elements in certain cases, representing a possible double sword for advertisers wishing to use this language strategy.

# Pick me, Pick me! An Extension of Theory Regarding Human Branding through Investigation of Editorial Fashion Models

Marie-Agnes Parmentier, York University, Canada
Eileen Fischer, York University, Canada
Rebecca Reuber, University of Toronto, Canada

## EXTENDED ABSTRACT

In contemporary consumer culture, anything from soup to soccer players can be branded. Yet whereas a significant volume of research has shed light on the manner in which products may be effectively branded, much less systematic attention has been paid to the manner in which humans may become branded.

It can, of course, be argued that all research on branding is relevant to human brands as well as to consumer packaged goods, industrial goods, services, and every other entity. However, recent efforts to understand "human brands" (defined here, in an adaptation from Thomson (2006), as people who are the subject of marketing communication efforts) suggest that there are unique aspects to developing human brands such as celebrities. Moreover, there are reasons to expect that brand building will differ even within the category of "human brands." While it may be fair to call both an actor and a self-employed accountant a human brand, the institutional fields in which each competes vary dramatically, and we would expect that characteristics of those institutional fields could influence not only what constitutes a viable human brand, but also what tactics are likely conducive to creating viable brands.

The purpose of this paper, then, is to investigate a) the characteristics and b) the strategies for building human brands within one type of institutional field. We undertake this industry-specific investigation in order to begin to shed light on what may be unique about building human brands, what may be common with human branding in multiple contexts, and what may be common with branding in general. The paper, informed by an institutional theory perspective, draws on interview and archival qualitative data to develop insights into the nature of human brand building in the editorial fashion modeling industry. Our methodology can be situated within contemporary approaches to grounded theorizing.

The editorial modeling context has features that make it a useful one in which to study human brand building. First, it is attractive because of the high volume of human brands in the industry, and because of the constant influx of new individuals seeking to become successful brands. Second, while it features famous brands such as Cindy Crawford, Heidy Klum and Tyra Banks who are relatively well known to many end-consumers, the majority of those who are among the most successful brands within the field (e.g. Carolyn Murphy, Daria Werbowy, and Gemma Ward) in terms of their income, power and status (see www.models.com) remain virtually unknown to the general public.

Consistent with this observation, we note that the modeling industry is a context where customers (in the form of fashion designers, magazine editors and photographers) are typically more influential than the end-consumers of fashion products. The modeling industry thus represents a highly institutionalized setting that contrasts with other contexts in which human brands have been studied and in which it appears that there are varied means of being and becoming a successful human brand.

Our analysis suggests that models competing for editorial fashion work have attempted to build one of two different types of brands, and have adopted contrasting strategies depending on which type they seek to become. We label the first brand type "chameleon conformist" and the second "archetypecast."

Models who achieve the "chameleon conformists" type of brand are those whose names and faces are likely to be unfamiliar to the general public for much of their modeling career, but whose visibility within the editorial fashion field is immense. These are models who, for much of their careers, conform to the norms typically preferred by the powerful designers in the industry, in that they promote the designer's work more directly than their own fame. As part of conforming to the rules of the game within their field and the preferences of the powerful, these models constantly re-invent themselves. They are "chameleons" in the sense that they adapt their look to the evolving tastes in their field.

We have coined the term "archetypecasts" to refer to models who build successful human brands by achieving not only recognition within their field, but renown well beyond it. Theses models' names and faces are widely known not only by industry insiders, but also by those who are relatively peripheral to the industry. Moreover, like iconic brands of products, they hold a set of distinct meanings for fashion consumers that may be difficult to completely articulate, but that appear to be tacitly understood by both insiders to the field, and outsiders. It is in this sense that these models' branding efforts both "typecast" them and render them "archetypes." It is significant to note that, in the modeling industry, this type of brand is *not* built by behaving in a manner that is isomorphic with norms in the field and the preferences of those powerful within the industry. Rather, these models are highly selective in their enactment of normal industry practice.

Our analysis suggest that both are potentially viable strategies, but also that a model may, partly due to institutional actors such as media, be effectively repositioned. Yet most models who are regarded as successful human brands can be seen to conform to one branding strategy or the other.

The paper concludes by discussing what appears to be relatively unique to branding within this field owing to characteristics of the institutional setting and to dynamics within it, versus what may have some more general relevance. It suggests that there may be a number of other institutional settings where high quality conformity constitutes one viable human branding strategy, while celebrity-seeking is a sometimes-suitable alternative. It briefly considers both similarities and differences between the human branding strategies identified here, and alternative branding strategies suggested in the prior product focused literature, highlighting the need for theoretical attention to human branding as distinct from other types of branding.

# The Branding of Next-Generation Products

Marco Bertini, London Business School, UK
John T. Gourville, Harvard Business School, USA
Elie Ofek, Harvard Business School, USA

## EXTENDED ABSTRACT

The majority of innovative activities undertaken by firms are aimed at improving existing products (Griffin 1997; Urban and Hauser 1993). As a result, the introduction of successive product generations is typical of many industries. These next-generation products often embody new technology or confer enhanced benefits, and hence have the potential of replacing or obsolescing products previously introduced in the same category (Norton and Bass 1987). Microsoft, for example, has introduced 10 distinct versions of its Windows operating system over the last 21 years, each delivering more capabilities and a friendlier interface than its predecessor. In the home video game market, Nintendo has launched five generations of game platform since 1986, while Sony has introduced three generations of its popular PlayStation console in a little over 10 years. More broadly, Nike's Air Jordan basketball sneaker has been updated every year since 1985, Callaway will soon introduce the eleventh generation of its Big Bertha golf club, and Mercedes-Benz now boasts a redesigned sixth generation of its legendary Sport Leicht (SL) class of automobile.

Interestingly, when one examines the branding strategies employed by firms engaged in next-generation product introduction, several distinct naming conventions emerge. These range from the ongoing use of a single name (e.g., Cadillac's Coupe de Ville) to the use of an entirely new name with each successive generation (e.g., Sega's Master, Genesis, and Saturn consoles). A common naming convention falls between these two extremes, with firms retaining a core name and adding a sequential indicator, such as an ordered numeral (Palm I, III, V), a date (Microsoft Windows 95, 98, 2000), or even a superlative (Callaway's Big Bertha, Great Big Bertha, Biggest Big Bertha).

The presence of these different naming strategies begs the question of what motivates firms to choose one naming convention over another. The degree to which a firm wants to signal novelty and innovation might be one important factor. For example, firms may decide to 'skip' one or more steps in a naming sequence in an attempt to convey greater improvement. Thus, TaylorMade went from its 300 Series of golf clubs straight to the 500 Series (skipping the 400 Series) (Kramer 2005). Other firms have purposefully switched names to communicate certain aspects of their next-generation products, as when Microsoft decided to name its latest video game console the Xbox 360 rather than Xbox 2 (Rojas 2005).

What inferences do consumers draw from brand name changes and, more importantly, how do such changes impact a consumer's decision to adopt a next-generation product? The goal of the present research is to address these questions. To that end, we develop several propositions. First, we propose that consumers tend to associate a departure from an established naming convention with greater product change, with particular emphasis on innovation through new (rather than existing) features. Second, this heightened perception of change triggers expectations of both greater potential *risks* (product failures, learning costs, etc.) and greater potential *rewards* (product quality, functionality, etc.) of adopting the new product. Finally, a consumer's ultimate decision to adopt the next-generation product will be driven by the relative salience of these perceived risks and rewards, as determined by the purchase context or even personal disposition. We test these predictions and related implications across three studies.

In study 1, we demonstrate that individuals infer the level of product change offered by a next-generation product by its name relative to that of its predecessors. When the brand name deviated from an established naming convention, participants inferred significantly greater change than when it was a continuation of that naming convention. Furthermore, we show that the effect is driven by expectations of innovation through the introduction of new features rather than improvements on existing features.

We expand on this basic result in studies 2 and 3 and show that individuals perceive both greater risks and greater rewards under a brand name change than under brand name continuity. We find these effects particularly compelling, as they occur despite holding constant the physical product profile across the two naming conventions. In turn, we show that these perceptions of risks and rewards have a systematic and predictable effect on product adoption. Across the two studies, when risks were either highly salient or more salient than rewards–which we achieved by manipulating the purchase context (study 2) or simply measuring regulatory focus at the individual level (study 3)–product adoption was greater under brand name continuity than under brand name change. But, when risks were not salient or less salient than rewards, product adoption was greater under brand name change. Finally, we also demonstrate that these effects are highly dependent upon the degree to which an existing naming strategy has been established. When the existing naming convention spanned many generations, the effect of a brand name change was pronounced. But when the existing naming convention spanned only a few generations, the effect of a brand name change was negligible.

# Effectiveness of Abstract vs. Concrete Challenge Strategies in Response to the Competitive Threat of Extensions from Mega Brands

Kalpesh Kaushik Desai, State University of New York, Binghamton, USA
Kevin Lane Keller, Dartmouth College, USA
Wayne D. Hoyer, University of Texas, Austin, USA

## EXTENDED ABSTRACT

Prior research has shown that parent brands characterized by abstract vs. concrete associations can extend into many dissimilar categories (Dacin and Smith 1994). However, this does not necessarily mean that consumer preferences for and choices of these extensions relative to other high quality competitors entrenched in the extension category will be high. In other words, non-competitive and competitive evaluations of brand extensions (evaluation of extensions without and with reference to an existing specific brand, respectively) are different (Broniarczyk and Alba 1994) and prior studies have typically investigated extension's non-competitive evaluation which is largely a reflection of extension fit.

Although mega extensions are often introduced in the presence of strong typical exemplar brands in extension categories, which serve as cognitive reference points for comparison (Loken and Ward 1990), little is known about how they will fare. Prior research suggests that despite its transferability, a mega brand could suffer in competing against a typical exemplar brand because typicality of a brand is positively correlated to its evaluation, inclusion in the consideration set, and its choice as a standard of comparison (Loken and Ward 1990). Similarly, pioneering literature highlights the challenges that late entrants into a category face vis-à-vis incumbents (Carpenter and Nakamoto 1989).

Our study has three key purposes. First, we investigate and confirm that non-competitive and competitive evaluations of brand extensions differ. Second, we explore the extent that far extensions of mega parent brands pose a threat to exemplar competitor brands. Third, we test the efficacy of potential abstract vs. concrete attribute based competitive positioning strategies that could be employed by exemplar competitor brands to defend themselves against mega extensions. We examined these objectives by employing four pairs of real parent brands, 8 far and 8 close extensions, and 16 exemplar competitors that were selected through extensive pretesting involving 500 undergraduate subjects. Both quantitative and protocol results across all replicates in Study 1 supported H1 showing a slight competitive advantage for exemplar competitors. However, given the brand strength of mega brands, exemplar competitor brands cannot let their guard down and need to deploy strategies to defend themselves from mega extensions for which we draw upon the alignment and adjustment model of Pham and Muthukrishnan (or PM) (2002). They showed that the magnitude of judgment revision of a defending brand following a competitor's challenge will depend upon the commensurability of the challenging information and the defending brand's positioning (e.g., concrete positioning is better challenged by concrete attribute based strategy) provided the latter is accessible.

Thus, in Study 2 we employed two abstract attribute-based challenge strategies. We selected abstract strategies based upon an examination of abstract thoughts for mega extensions in Study 1 protocols. The *expertise* strategy dealt with undermining the performance of mega brand extensions on abstract attributes (PM 2002). It encouraged consumers to believe that exemplar competitor brands are likely to have greater manufacturing expertise in the extension category because they manufacture only a few products, as compared to the mega brand whose manufacturing capability has been diffused across multiple categories. The *relevance* strategy

attempted to reduce the relevance of abstract attributes for mega extensions by imploring consumers to ignore the reputation of the mega brand because its performance on specific concrete attributes that are important in the extension category is unknown to consumers. We also decided to use a concrete attribute-based strategy (labeled *ability* strategy) to play upon mega extensions' weak linkage with concrete attributes. Study 1 protocols revealed that subjects preferred not to use concrete attributes (in comparing the two brands). Thus, if such information were to be provided to subjects, the competitive evaluation of the mega brand extension could perhaps be mitigated.

Results of Study 2 revealed that, despite their inherent logic, none of the three defensive strategies mitigated the competitive evaluations of far mega extensions. In fact, the ability strategy backfired and the process measures and protocols suggested that it failed to make the challenge alignable. Thus, we used a more direct and stronger manipulation that we label the *performance* strategy in which we not only named the mega extension, but also provided explicit concrete attribute performance ratings from an independent source (*Consumer Guide*) which slightly, albeit not overwhelmingly, favored the exemplar competitor brand relative to the mega brand extension. The expertise and relevance abstract strategies were also made more direct and compelling:

The *heritage (revised expertise)* strategy specifically named the mega brand extension in the manipulation and then made the point that the exemplar competitor brand had been marketing its product for a long time and that typically, longer experience resulted in a better understanding of consumers' tastes and preferences and higher product quality.

The *fit (revised relevance)* strategy specifically named the mega brand extension and then tried to undermine its key abstract associations by noting that although the abstract brand may have been well-known in other product categories, there would be very little in common between its existing products and the extension product category.

Study 3 findings revealed that only performance strategy mitigated the competitive evaluations of mega extensions whereas the two abstract attribute based strategies did not work. Comparing the process measure and protocol results of Study 2 and Study 3 strongly suggests that performance strategy in Study 3 worked because it successfully achieved alignability unlike in Study 2. Given the pattern of protocol and process results and its differences from those of Study 2, the performance result cannot be attributed to demand effect. Regarding the abstract strategies, despite being made more direct and compelling, they did not mitigate the competitive evaluation of mega extensions. Protocol and process measure results suggest that exemplar competitor brands struggled in achieving alignability (and thus, diagnosticity) with their abstract strategies. One possible explanation is that subjects attempted to see linkage or map the concrete attributes of exemplar competitors (e.g., *cleans* and *softens hair* for Pantene exemplar competitor) on the abstract attributes highlighted in these strategies (e.g., longer experience, little commonality) and found it difficult to do so.

Two additional possible explanations for why abstract strategies failed in our studies stem from the use of real brands in our research. That is, the influences of the strength of positionings of the

challenger brand in mounting a credible challenge and of the target brand to withstand a challenge were ignored in PM (2002) but accounted for in our research. Specifically, we find some support for the argument that exemplar competitors which are characterized more by concrete attributes had less credibility in launching abstract strategies. Another possibility is that abstract positioning of mega extensions is so strongly linked to mega brands that it is not easy for any brand (including exemplar competitor) to dislodge it. Both these were mute issues in PM (2002) because they used fictitious challenging and target brands. These results suggests a boundary condition to PM (2002) finding that abstract challenge will be effective in attacking a brand with abstract positioning. Only a more direct and stronger concrete attribute based challenge worked in mitigating the competitive evaluation of mega extensions with strong abstract positioning in our study.

# Whatever People Say I Am That's What I Am: Social Labeling as a Social Marketing Tool

Gert Cornelissen, Universitat Pompeu Fabra, Spain
Luk Warlop, Catholic University of Leuven, Belgium
Siegfried Dewitte, Catholic University of Leuven, Belgium
Vincent Yzerbyt, Catholic University of Leuven, Belgium

## EXTENDED ABSTRACT

In this paper we studied the potential of "social labeling" for the promotion of pro-environmental consumer behavior. Social labeling is a persuasion technique that consists of providing a person with a statement about his or her personality or values (i.e., the social label) in an attempt to provoke behavior that is consistent with the label. Like a bottle of wine carries a label, describing its content, we can "label" other people, describing some aspect of their personality. For example, Miller, Brickman, and Bolen (1975) showed that telling a group of fifth-graders that they are very tidy was more efficient in making them keep their classroom free of litter than an explicit plea for tidiness. The technique is believed to rely on a self-perception process and the fact that people's (interpretation of) past behavior guides future action (Albarracín and McNatt 2005; Burger and Caldwell 2003; Ouellette and Wood 1998; Tybout and Yalch 1980).

We propose and test an adapted version that allows this technique to be applicable as a social marketing tool. In a first step of this two-step procedure, the individual is provoked to perform a certain pro-environmental act. This could be, for example, the purchase of an environmentally friendly variety of a product, like bio-products or propellant-free deodorant. In some cases this will require some type of external motivation, like a price promotion. In other cases, the consumer might simply prefer the environmentally friendly product, because of other product features than its environmental friendliness. In a second step, a social label is communicated which attributes the purchase to the consumers' environmental values. For example, one could print a message on the packaging (e.g., "[brand X]–For those who care about their environment"), which invites the consumer to (mis)-attribute the ecological purchase to their value of caring for the environment. We hypothesized that if this reattribution process is successful, the individual is likely to perceive himself as more concerned with the environment and act upon this new self-perception subsequently.

In four studies we applied such a procedure which suggests an internal attribution of an externally motivated pro-environmental choice. Participants were asked to indicate which TV-set they preferred from a list of seven TVs. These were evaluated on seven dimensions, including "Image quality", "sound quality", and "environmental aspects". One TV-set, which was most popular (chosen by 95-100% of participants) scored best on image and sound quality, but it also happened to have a maximum score on environmental aspects. Subsequently, we provided a social label describing the typical consumer who preferred this particular TV-set as "very concerned with the environment, and ecologically conscious".

Results indicated that this procedure is most successful at eliciting pro-environmental choices, if participants were distracted, either at the moment of processing the label or at the moment of making decisions. This suggests the labeling effect is an automatic one and that it works best in common, cognitively demanding circumstances. Additionally, results indicated that the label is not merely used as a guide in subsequent decisions; it also results in a re-attribution of the initial pro-environmental behavior to pro-environmental motives.

# How Self-View and Type of Processing Affect Context Effects Produced by Viewing Products on Various Display Table Surfaces

Rui (Juliet) Zhu, University of British Columbia, Canada
Joan Meyers-Levy, University of Minnesota, USA

## EXTENDED ABSTRACT

Suppose that you were shopping for a set of trendy new coffee mugs and noticed some on a nearby table or shelf. Might your evaluation of how trendy the mugs are be subject to context effects arising from the display fixture's surface material, namely the sheath of glass or wood beneath the product? It seems possible. In the present research, we focus on an important theoretical and practical question that has been ignored in the context effects literature: Whether and how the mode of cognition that people use can affect the likelihood and direction of context effects that may emerge when a product is viewed on a display table made of different surface materials. Specifically, we focus on two dichotomous modes of cognition: (a) holistic versus analytic cognition as induced by a person's interdependent versus independent self-view, or (b) relational versus item-specific processing.

Emerging from two separate streams of work, self-construal theory (Markus and Kitayama 1991) and type of elaboration theory (Hunt and Einstein 1981) identify alternative dichotomous modes of cognition that people often use. Self-construal theory holds that people possess multiple views about how the self relates to others and the environment. Interdependents activate predominately interdependent self knowledge such that the self is viewed as fundamentally connected to both others and the context. However, those who activate an independent self-view, hereafter termed independents, perceive the self as a unique and autonomous entity with distinct boundaries that distinguish it from the background (Markus and Kitayama 1991). Of particular relevance to our inquiry is the contention that these alternative views about the self affect people's cognition more generally. Interdependents' emphasis on the inseparability of objects (e.g., the self, others) and their settings appears to prompt holistic processing, whereas independents' focus on separating the object from the background encourages analytic processing, whereby objects are treated as well-bounded units of data (Nisbett 2003).

Seemingly similar to the aforementioned holistic and analytic forms of cognition are two different modes of processing, which are the focus of type of elaboration theory (Hunt and Einstein 1981; Meyers-Levy 1991). This theory distinguishes between relational and item-specific processing. Relational processing involves actively organizing or integrating data by emphasizing commonalities or relationships shared by separate pieces of data. This contrasts with item-specific processing, which entails focusing on the particulars or precise details that comprise each piece of information.

We contend that each of the modes of cognition outlined by the preceding two theories might influence the context effects that could occur on people's evaluations of a target product when it is viewed on a display table made of different surface materials. Supporting this possibility, extant research suggests that people often develop shared associations to objects (e.g., surface materials) due to their experience with them (Peracchio and Meyers-Levy 2005). While most people are likely to associate glass with the concepts of modernity and artificiality, they tend to associate wood with the opposite concepts of tradition and naturalness. Thus, to the extent that these concepts are activated by the glass or wood surface of a display table and product viewers use a mode of cognition that either blurs versus accentuates the boundaries between these activated concepts and the target product, alternative context effects may arise.

We reason that, like relational processing, holistic cognition prompted by an interdependent self-view involves perceiving separate pieces of data as related or continuous parts of a larger integrated unit. This implies that people who use relational processing or holistic cognition are likely to exhibit an assimilation effect on their product evaluations. On the other hand, although both item-specific processing and analytic cognition prompted by an independent self-view entail treating individual pieces of data as separate and autonomous elements, we expect individuals who rely on either of these modes of cognition to use the contextual data in a different way. Specifically, item-specific processors, who are claimed to focus on "highly specific information denoting a single event" (Hunt and Einstein 1981) while ignoring all relationships (i.e., comparisons) that may exist, are expected to treat all pieces of data entirely separately and thus exhibit no context effects on product evaluations. However, because independents who engage in analytic processing not only treat each element of data as a bounded, self-contained unit of analysis, but they also purportedly seek "to understand what an object's distinctive properties" are vìs a vìs others (Nisbett 2003), they are expected to exhibit a contrast effect on their product evaluations.

We report one (of three) experiments that were conducted to test our theorizing. We began with a pretest, which established that people associate glass (wood) with trendiness (naturalness). Then, in our study, participants were first primed with one of the four modes of cognition (i.e., relational or item-specific; holistic or analytic processing). Then, they examined a neutral product (mug) displayed atop either a glass or a wood table, and evaluated the product on the dimensions of its trendiness and naturalness. Additional measures, such as thoughts and a choice-related measure also were obtained. Results upheld our theorizing. Specifically, interdependents, who engage in holistic cognition, exhibited assimilation effects, such that they evaluated the mug as more modern and/or less natural when it was displayed atop a glass rather than a wood table. Independents, who employ analytic cognition, displayed contrast effects, such that the mug was viewed as more modern and/or less natural when it was displayed on a wood rather than a glass tabletop. In addition, individuals who employed relational processing revealed an assimilation effect, whereas individuals who employed item-specific processing exhibited no context effects.

Our work contributes to the dual processing and context effect literatures by clarifying for the first time how and why the direction of context effects can depend on people's mode of cognition. Our research also sheds light on both why parallels and distinctions exist between two seemingly similar dichotomous modes of cognition that people commonly use (i.e., holistic versus analytic, and relational versus item-specific). Finally, we add to atmospherics literature, showing that omnipresent fixtures in retail milieus can influence product evaluations.

# Temporal Response to Opportunities: A Look at the Last Name Effect

Kurt A. Carlson, Duke University, USA
Jacqueline M. Conard, Vanderbilt University, USA

## EXTENDED ABSTRACT

Everyday life presents numerous opportunities to claim scarce resources, however, relatively little is known about what determines how quickly a consumer will act to take advantage of such an opportunity. To better understand this, we begin by noting that children with surnames that begin with a letter at the beginning (ending) of the alphabet are privileged (disadvantaged) in childhood. We propose that children develop response tendencies to manage these inequities and that these response tendencies persist into adulthood. Specifically, we hypothesize that individuals with a last name beginning with a letter late (early) in the alphabet will respond relatively quickly (slowly) to opportunities to claim resources.

*Study 1*. Students enrolled in a large wine evaluation course were told they would receive $5 and a bottle of wine for participating in a 30-minute study. In line with the last name hypothesis, we predicted that individuals with names later in the alphabet would respond to the offer more quickly than those with names early in the alphabet. Consistent with the last name effect, there was a significant negative correlation between last name and response time ($r$=-.156). The existence of the last name effect for these students begs the question of whether the last name effect will exist for older adults in situations, where there is a clear pressure to respond quickly.

*Study 2*. Graduate students were sent an email and invited to respond by email to receive up to four free tickets to attend a top-ranked women's basketball game. As in Study 1, the first letter of each respondent's last name ($n$=76) their email address and was transformed into a number equivalent. Response times were measured by computing the difference between the time the offer was emailed and each respondent's reply email (in minutes). Here too there was a reliable negative correlation between response time and the number equivalent of the last name ($r$=-.271). Thus, the last name effect exists for adults in their late twenties who were aware that the opportunity was highly constrained.

*Study 3*. To learn about the origin of the last name effect, we conducted a study that allowed us to speak to the question of when individuals developed the response tendencies that underlie the effect. By moving to a sample of older adults (many of whom are married and have changed their name), we can determine whether the effect exists for current last name, childhood last name, or both. If it exists only for childhood last name, then the last name effect is likely rooted in a response tendency learned during childhood.

Participants were 280 adults (average age=39.1 years) who responded to an email invitation to participate in a survey in exchange for a chance to win $500. Participants' response times were calculated from the time the email invitation was sent to the time each participant began taking the study. The first letter of each respondent's adult last name and the first letter of the last name during childhood were obtained during the debriefing of the survey, which was unrelated to the last name effect.

The correlation of childhood name and response time reveals a significant last name effect for the sample as a whole ($r$=-.128). However, when we compute the correlation between response time and adult name, the effect is much smaller ($r$=-.070). This decline is attributable to name changers, for whom there is no correlation between adult name and response time ($r$=.000). In sum, it seems that the last name effect is driven by childhood name, not adult name, suggesting that it derives from a response tendency learned during childhood.

*Study 4*. Each spring, a survey of first-time academic job seekers in marketing is conducted and then posted on the ELMAR listserv. The first posting presents job placement data for individuals who responded within three weeks; these respondents are coded as *early* responders. After another month, a second Who Went Where report is released. Participants were 114 PhD students who reported job placement data to ELMAR over a two year period. We reasoned that the opportunity to share the good news of a successful job search with one's peers would be acted on more quickly by those with rapid response tendencies. As such, we expect that individuals with last names late (early) in the alphabet will be more likely to be early (late) responders.

The data indicate that PhD students with a surname beginning late in the alphabet were quicker to announce their job search success than those with surnames beginning with letters early in the alphabet. This is evidenced by a comparison of the average letter equivalent code for those who responded early ($M$=11.76, letter L) to that of those who responded late ($M$=7.23, letter G), $t$(113)=2.78, $p$=.006, $d$=.523. Though individuals with names of Asian descent had last names that began with letters that were slightly farther into the alphabet, they were as likely to be on the late report as non-Asians, indicating that the last name effect does not stem from cultural response norms.

*Conclusion*. These studies find a robust effect of one's childhood last name on temporal responses to opportunities, a finding that has implications for scholarship and policy ranging from issues of sampling validity, organizing structures, and the effectiveness of various marketing strategies. On this last point, the implication is that various purchase incentives will be taken up more quickly by those later in the alphabet.

# Self-Construal and Temporal Distance

Gerri Spassova, Cornell University, USA
Angela Y. Lee, Northwestern University, USA

## EXTENDED ABSTRACT

Different research streams have examined how the temporal distance to an event influences responses to this event by changing the way people represent it in the mind. Temporal construal theory (Liberman and Trope 1998) posits that the further away into the future is an event, the more likely it is represented in abstract, high-level terms rather than specific, low-level terms. The inverse of this relationship is less clear. Does elaborating on the low-level contextual features of a future event make it appear closer to the present? And does abstracting from the contextual details shift the event further in mental time?

This research identifies a possible antecedent of temporal construal and explores the implications for persuasion in a consumer context. We suggest that the view people hold about themselves as individuals and in relation to others influences the extent to which they represent future events in abstract or in specific terms and the perceived temporal distance to these events. Research on cross-cultural differences in information processing suggests that individuals with an interdependent self-view form representations of the self in relation to others that are concrete and often embedded in specific social contexts. In contrast, those with an independent self-view tend to ignore the specific situation and focus more on global, context-invariant features (Markus and Kitayama 1991; Masuda and Kitayama 2004; Morris and Peng 1994). Based on these findings, it is plausible that individuals with a more accessible interdependent self-view form more elaborate context-dependent representations of future events and hence perceive these events as more proximal. In contrast, those with a more accessible independent self-view form more abstract context-invariant representations of future events, and therefore perceive the events as more distant in time.

A different line of support for the proposed relationship between self-view and temporal construal comes from the regulatory focus literature which suggests that promotion goals are perceived as more temporally removed from the present compared to prevention goals (Pennington and Roese 2003). Similarly, the "pros" of an action are more salient in decision making for the more distant future whereas "cons" are more salient in decision making for the near future (Eyal et al. 2004). Previous research has shown that individuals with an independent self-view are likely to be promotion focused and sensitive to gains and non-gains, and individuals with an interdependent self-view are more likely to be prevention focused and sensitive to losses and non-losses (Lee et al. 2000). Thus, we propose that an independent self-view, relative to an interdependent self-view, should induce a distant temporal perspective when construing future events; we further explore the implications of the proposed relationship for persuasion and for consumer behavior by examining the effect of a fit between one's self-view and the temporal framing of a marketing message on the message effectiveness and the attractiveness of the advertised product. We demonstrate that when the temporal framing of an advertising message is compatible with the self-view of the recipient, the message is more persuasive and the target product receives more favorable evaluations. We explore the mechanisms underlying these persuasion effects and show that they are driven by greater attention to information compatible with the recipient's self-view.

In experiment 1, we tested whether situationally activating an independent or an interdependent self-view resulted in varying degrees of mental abstraction. We first prompted participants to think either of themselves or of close others and then examined their performance on a task involving the classification of objects into categories. According to construal level theory, high-level abstract categories are more inclusive than low-level specific categories (Liberman, Sagristano, and Trope 2002). Therefore, if an independent self-view, relative to an interdependent self-view, leads people to construe objects at a more abstract level, independent individuals should use fewer and broader categories to classify objects. Consistent with our hypothesis, participants in the independent-prime condition formed significantly fewer groups in the categorization task than participants in the interdependent-prime condition.

In experiment 2, we tested if thinking about goals related to the self vs. goals related to close others resulted in temporally extended estimates of goal initiation and completion times. Results indicated that when the self (vs. close others) was central in the motivation for working towards a goal, the goal was perceived as requiring a more substantial investment of time, hence the event was construed as occurring further into the future.

Finally, in experiment 3 we explored the persuasive implications of the relationship between self-view and temporal construal in a consumer context and showed that a match between one's self-view and the temporal framing of an advertising message resulted in more favorable evaluations of the message. We further demonstrated that these persuasion effects were driven by differential attention paid to a message that was compatible vs. incompatible with the recipient's self-view, as manifested in greater interest and enhanced ability to assess the quality of the message arguments under conditions of compatibility.

In summary, this research suggests that the way people represent events in time may in part be a function of the view they hold of themselves in relation to others. The proposed relationship between self-view and temporal construal has implications for consumer research as it suggests strategies to enhance advertisement effectiveness and product appeal. The findings also contribute to the literatures on self and on temporal construal theory.

# Sneaky Small Sins Flying Under the Radar: Package Sizes and Consumption Self-Regulation

Rita Coelho do Vale, ISEG-Economics and Business School, Portugal
Rik Pieters, Tilburg University, The Netherlands
Marcel Zeelenberg, Tilburg University, The Netherlands

## EXTENDED ABSTRACT

Products are increasingly offered in various package sizes, in particular single serving-sizes, and these single serving sizes are becoming smaller. For example, *Kraft Foods Inc.*, in 2003, started putting a cap on the portion size of single serve-packages as a social measure to help consumers fight obesity (http://www.kraft.com/newsroom/07012003.html, 20/10/2003). Also *McDonalds*, in 2004, as part of its initiative "Eat Smart, Be Active", downsized the super-sized portions to cater to consumers' growing preference for healthier foods. Also, various products such as Häagen-Dazs and Ben and Jerry's ice-cream, and Pringles and Lays chips are now being offered in small, single-serve packages. Moreover, growing numbers of multi-packs with individually-wrapped single-serve portions are being offered, such as chips (Potato Heads, Ruffles), cookies (Filipinos, LU) and candy (KitKat, Toblerone, Twix).

These developments rest on the assumption that when products, especially tempting products as the ones mentioned, are offered in these small packages, consumers are better able to exert self-regulation by restraining the total quantity consumed. This view is consistent with findings that small packages are perceived to be helpful in exerting self-control (Wansink and Park 2000), with consumers often even paying premiums for them (Wertenbroch 1998). For example, cigarettes are in many countries sold in a 10 cigarettes-pack instead of the more traditional 20 cigarettes-pack, with consumers paying higher unit costs with the 10 units pack than the 20 unit pack —a premium to presumably keep control over the "daily amount". The question that arises then is to what extent the offer of tempting products bundled in these smaller package sizes indeed contributes to consumers' better self-regulatory ability.

In the present research we propose that the presentation of tempting products in these small single-serving sizes (the small "sins") may have, contrary to what is intended, a negative effect on consumers' self-regulatory ability. In order for self-regulatory behavior to occur, consumers need to perceive the current consumption act as a self-control conflict in which attraction to a temptation hinders the pursuit of an overarching goal (Fishbach and Shah 2006). If behaviors do not produce a self-regulatory conflict, consumers will not activate self-regulatory strategies that could restrain the tempting consumption, thereby actually falling into temptation.

The apparent tendency of consumers to believe that smaller quantities of tempting products are "acceptable" and to consider small single-serving packages as helpful self-regulatory tools can contribute to a higher likelihood of consumption than if products were offered in quantities considered to be "unacceptable", which could instigate consumption restraint. Therefore, we propose that large package sizes may actually be better self-regulatory facilitators than small single-serving packages, because they are more likely to activate a self-control conflict and preventive control strategies to deal with it. In this way, small single-serving package sizes can lead to the perverse effect of increasing rather than reducing likelihood of consumption, and thus possibly to the long-term negative effects that they intended to prevent.

The present research examines this phenomenon, in the context of different package formats for tempting products that usually imply eating regulation (e.g., chips, chocolates, and candies). Packaging characteristics may influence usage behavior long after it has influenced purchase (Wansink 1996) with previous research showing that stockpiling increases the consumption quantity (Chandon and Wansink 2002), that consumers tend to consume more of a product when they perceive the unitary costs to be lower (Wansink 1996), that product elongation influences product perceived capacity (Raghubir and Krishna 1999; Wansink and Ittersum 2003), and that the perceived supply of the product raises the quantity that is consumed (Folkes, Martin and Gupta 1993). However, we are not aware of research analyzing whether, independent of the supply, package size influences consumption and, more specifically, consumers' self-regulatory ability.

Study 1 (n=59; 2 (package formats: large, small) x 2 (reasons to choose, reasons not to choose) x 2 (self-regulatory concerns: high, low) within-subjects design) analyzes the type of beliefs and predictions that consumers have regarding the consumption of tempting products in different package formats. We assess consumers' beliefs with respect to offering products in different package sizes, asking them to list reasons that could lead to choosing and not choosing tempting products in different package sizes. Results indicate that small package sizes tend to be considered self-regulatory facilitators, especially by those that have high self-regulatory concerns, while larger packages are perceived to be self-regulatory threats.

In study 2 (n=140; 2 (package sizes: small vs. large) x 2 (self-regulatory concerns: control vs. activated) between-subjects design) we assess the influence of offering tempting products in different package sizes on real consumption behavior. Using behavioral measures of consumption while consumers supposedly participated in an "ads evaluation study", we tested to what extent larger as compared to smaller packages indeed lead to higher ability to exert self-control, analyzing the likelihood of opening packages and actual consumption behaviors. Findings suggest that large package sizes, compared to small package sizes, are more likely to activate a conflict between indulging in short-term temptation versus long-term self-regulation, which prompts efforts to exert self-control. Results indicate that compared with smaller packages, large packages contribute to better self-regulation reducing the likelihood of initiating consumption and leading to lower total quantities consumed.

In sum, findings from the two experimental studies provide support for the idea that although smaller packages are the ones more often chosen for self-regulatory purposes and indicated as self-regulatory facilitators, large packages actually contribute to better self-regulation. This demonstrates that, contrary to common belief, offering products in small package sizes may reduce self-control ability. This sneaky "small sin" effect contributes to consumption misregulation, and it reveals that in the case of self-regulation, small is not better since it flies under the consumers' radar.

# Self -Medication versus Pure Pleasure Seeking Compulsive Consumption

Xiuping Li, National University of Singapore, Singapore
Qiang Lu, University of Sydney, Australia
Rohan Miller, University of Sydney, Australia

## EXTENDED ABSTRACT

The purpose of this research is to understand compulsive consumption from a motivational perspective. Especially, we rely on the goal-systems theory (Kruglanski et al. 2002) to examine the distinct problems associated with different motivations. Previous consumer research has shown features and consequences of impulsive and compulsive behaviors (Hock and Rook 1985; Rook 1987). More recently, Hirschman (1992) proposes that compulsive consumers might differ in their motivation to consume. She suggests that some compulsive consumers consume as a way of self-medication (i.e., self-medicationers), whereas others consume purely to seek pleasure or gain from the substance or activity (i.e., pure-pleasure seekers). Using a qualitative method, Hirschman documents the unique characteristics associated with the two types of compulsive consumers. In this research, we extend the current understanding of compulsive behavior by (1) making new predictions based on goal-systems theory; (2) testing our hypotheses with field data collected at a clinic center for problem gamblers over a period of 8 years.

Drawing on the theory of goal-systems (Kruglanski et al. 2002), which suggests that different means to achieve an end are substitutable to each other, we first hypothesize that a self-medication motivation would lead to a greater possibility of having compulsive behavior in different domains (hypothesis 1). In other words, we propose under a motivation to escape from the current depression state or painful reality, different domains of compulsive consumption (e.g., drugs, alcohol, binge eating) are substitutes to each other. Compulsive consumption itself is not the end state a compulsive consumer desires but a means towards an ultimate goal to forget the pain. On the other hand, for pure-pleasure seekers who have already developed a problem with a domain of consumption, their ultimate goal is the pleasure derived from the particular domain of consumption. The different domains of consumptions are therefore exclusive to each other, and the activation of one would devaluate the other (Brendl, Markman and Messner 2003). Hence, we argue that self-medicationers are highly likely to have compulsive consumption across domains than pure-pleasure seekers. To illustrate, compulsive shoppers who shop to escape from reality, are more likely to engage in other compulsive acts such as drinking, smoking, binge eating, and even taking drugs as long as the alternative forms of consumption also make them forget. It is compared to compulsive shoppers who shop for the excitements they can get from the shopping itself.

Our second hypothesis is that the substitutability among different forms of compulsive consumption will make self-medicationers less likely to conduct, or more likely to withdraw from, a compulsive behavior domain. Since the different domains of consumption are substitutable, if self-medicationers believe that the future costs for engaging in one particular domain are higher than the other, they could shift to the other domains (Becker and Murphy 1988; Hirschman 1992). In this sense, self-medicationers' choice and behavior are more consistent with the mathematical model proposed by Becker and Murphy (1988), or in their words, more rational. To illustrate, if compulsive gamblers who gamble to escape know that their behavior is going to have very severe consequences such as going to prison, they would be more likely to discontinue their gambling activities and seek other domains of consumption such as drinking alcohol. However, pure-pleasure seekers' dependence on a substance is more exclusive in nature, and they would do whatever they can to gamble, even illegal acts.

We used data from a clinic center for problem gamblers in the Gold Coast area in Australia to empirically investigate our two hypotheses. Results of the logistic regression supported the idea that self-medicationers (Mean=39%) were more likely to have other substance dependencies than pure pleasure seekers (Mean=7%, $Wald$=22.28, $p$<.001). As an extension of our hypothesis 1, we further argue that with the problem of compulsive consumption getting more severe, people with different consumption motivations would demonstrate different evolving patters in terms of having problems in the other domains. Supporting this prediction, our analyses revealed that when the magnitude of gambling problem was escalating (from non-diagnosed problem gamblers, who indicated some problems with gambling behavior, but were not diagnosed as a behavior disorder yet, to diagnosed problem gamblers), the possibility of having other substance dependency increased for self-medicationers but declined for pure pleasure seekers. More specifically, we found a statistically significant interaction between the two independent variables ($Wald$=15.94, $p$<.001). If non-diagnosed gamblers were gambling for self-medication purposes, the problem of other substance dependency (i.e., comorbidity between different addictions) would get worse when they became diagnosed problem gamblers (31% for non-diagnosed problem gamblers versus 39% for diagnosed problem gamblers). But if non-diagnosed gamblers were gambling purely because of the pleasure they derived from it, the possibility of their having other substance dependency actually decreased when they became diagnosed problem gamblers (24% for non-diagnosed problem gamblers versus 7% for diagnosed problem gamblers).

Although self-medicationers were found to have a higher likelihood of having problems across domains, they were also found to be less likely to conduct illegal conduct to facilitate their problem consumption (in this case, gambling. $M_{medic}$=14%, N=369 versus $M_{pleas}$=77%, N=287, $Ward$=57.51, $p$<.001). Our second hypothesis was supported.

The implications of our study are twofold. First, to investigate the correlation between different domains of compulsive consumption, we should not ignore the underlying motivational factors. Second, different motivations of compulsive consumption call for different solutions to these problems. For self-medicationers, simply stopping them from doing one form of problematic behavior would push them to develop problems in the other domains. It is equally important to teach them a healthy way to solve their current problems. Our analyses based on the clinical data were subjected to the following limitations. First, all tests were correlational, and the underlying mechanisms were not being directly examined. Second, the changes in the social and economical contexts, which were not coded in our data might provide alternative explanations which we could not fully rule out.

# Is High-Caloric Food Consumption an Addictive Behavior in Our Modern World of Plenty? A Test of the Relationship between Inhibitory Performance in a Neuropsychological Positive-Emotion Shifting Task and Everyday Snacking Behavior in Non-Obese Adult Women

Ji Lu, McGill University, Canada
Laurette Dube, McGill University, Canada
Antoine Bechara, University of Southern California, USA

## EXTENDED ABSTRACT

### Research Background

Eating behavior has evolved over billions of year in an environment of food scarcity. Therefore, in the modern world of plenty, where cues for food and high caloric food (HCF) in particular are ubiquitous, it is reasonable to expect that HCF consumption, even for normal weight consumers, can be viewed to some extent like an addictive behaviour.

There is evidence supporting common mechanisms mediating the rewarding properties of natural rewards like food and addictive drugs. Researches have for long shown that sugar and fat, the two core ingredients in most HCF, do induce more intense pleasure than their counterparts. Furthermore, neuroimaging techniques showed that the HCF cues, compared to low caloric food cues, are associated with more intense reward system responses. In other words, HCF foods are highly rewarding, intensely positively valenced cues that are tempting fruits hard to resist.

In this paper, we propose to test whether everyday HCF consumption conforms to an addiction-like model. This model builds upon the most immediately relevant features of addiction to account for a person's everyday HCF consumption in the context of modern affluence where the food itself and related cues are ubiquitous. The addiction-like model of HCF consumption lies on three central premises. The first is that HCF are intrinsically pleasurable stimuli tied to a biologically-wired and culturally-reinforced prepotent approach response. The second premise of the addiction-like model of HCF consumption is that consumers are not only wired for impulsively react to one's pleasurable objects and cues in the environment in a passive manner. They are also able to exercise inhibitory control over such impulses and possibly turn to alternative internal or environmental cues, or to alternative goals. The third premise is that, while both impulsive responses and inhibitory control are basic features of the human brain anatomy and processes, there are individual differences in one's susceptibility to impulses and one's ability to exercise inhibitory control, and such differences at the neuropsychological level can be linked to a person's every day's HCF consumption.

Addiction has been tied to two types of psychological mechanism, these being attentional and inhibitory. Thus, building upon recent models of addiction, we see HCF consumption as being due to two related processes: (1) biased attention, upon exposure to the HCF cues, the reward system draws the person's attention selectively towards the addictive-like stimulus, thereby making its recognition faster and easier and being accompanied by motor preparation in order to move towards the object of addiction; (2) poor inhibitory control, that translates into one's difficulty to stop or inhibit such motor impulse, as the first step towards a possible controlled responses of maladaptive behaviour and/or a shift to alternative environment cues and goals.

### Research Objective

The present study used a computer-administered measure of neuropsychological performance in inhibitory control, namely Affective Shifting Task (AST), which can measure individuals' attentional/impulsive response to rewarding cues and the ability to inhibit such impulses. By exploring the relationship between individuals' performance in AST and their everyday eating behavior, the AST is validated as an assessment of individual neurobiological vulnerability to HCF temptations.

### Methods

132 non-obese (BMI<30) women enrolled an experience sampling study, in which participants reported their lifestyle behavior six times a day for in ten reporting day. The reported eating behavior included whether they had been snacking and craving for food, especially those HCF, in the last two hours.

The same individuals also performed computer-administered AST that assess individual pre-frontal cortex activity in terms of attentional and inhibitory processes to affective stimuli. In the AST, where positive and neutral stimuli were varying in different conditions, participants were put into an environment to focus on the things they want to approach or to shift attention away from them. Similar tasks showed that individuals addicted to highly rewarding objects such as drugs, nicotine and alcohol demonstrated impaired performance. For each participant, performance measures on the AST, including response latency, and parameters reflecting its underlying process, in terms of discrimininability and dis/inhibition, were computed. AST parameters used as predictors of everyday HCF snacking were constructed from the within subject differences on these attentional and inhibitory measures between relevant manipulated conditions built into the structure of the AST. Those parameters including (1) the emotional bias, which is a set of indices revealing individual attentional bias to positive cues, (2) the mental flexibility, which reflects participants' adaptability to changing environment, and (3) mental flexibility reflected in emotional bias, which takes the individual difference of two parts: mental flexibility when positive stimulus were set as attentional targets compared with neutral stimuli as targets.

### Results and Conclusions

In series logistic hierarchical models, the individual performances and parameters in AST served as predictors of the everyday eating behaviors reported by participants, specifically, the reported HCF snacking and experienced craving. In a series similar model, the HCF craving was used to predict the snacking, and the predicting power (i.e., the weight of craving carried in snacking behavior) was further explained by the same set of predictors. The results conformed to some extent to the three primary premises of the addiction-like model of eating but there is clearly no perfect mapping with an addiction-like pattern of HCF consumption. The most interesting and robust finding of this study is the critical role played by inhibitory performance on the AST in accounting for a person's HCF consumption, in particular at the level where the individuals has to show mental flexibility in responding to a environment (task conditions) in which stimulus-reward associations are reversed. At this level, individuals who showed superior inhibitory performance in these conditions, over their own neutral

baseline, were better able to resist to the world of plenty and were less likely to have engaged into HCF snacking. Most importantly, this relationship persisted, even after the effects of other AST parameters had been partialled out in a subsequent analysis that includes all of them. As further evidence of the critical role played by inhibitory performance in this context, compared to attentional measures comes from results of the follow-up analysis in which the signal detection's measure of inhibitory performance was dissected into its components, CR (an attentional index) and CR, a direct measure of one's ability to inhibit responses. Here, results showed that superior inhibitory performance on this more direct index remains predictive of lower HCF snacking, while a superior attentional performance, as indexed by CR, was predictive of higher HCF snacking. It is noteworthy that all these effects remained significant after episode-level and individual controls.

# Exploring Needs, Desires, and Hopes: A Study of Impoverished Migrant Consumers

Berna Tari, Bilkent University, Turkey
Ozlem Sandikci, Bilkent University, Turkey
Sahver Omeraki, Bilkent University, Turkey

## EXTENDED ABSTRACT

Realizing differences in the consumption behaviors of economically better-off and impoverished consumers, many consumer behavior researchers explored how poor consumers cope with economic restrictions. Impoverished consumers are generally assumed to be living in the center of the city, such as the urban poor (Hill 2002a, 2002b) or homeless people (Hill and Stamey 1990); therefore, they are assumed to know the prevailing rules, norms, values, and orientations in the city, as well as meanings attached to consumption objects. However, poor and immigrant consumers present a different case than homeless or urban poor consumers because they have migrated from village to the city, without any advance knowledge of city culture and prevalent consumption practices. We argue that immigrant consumers are different from other poor consumers because they experience a change in their lives, mainly in the form acculturation (e.g. Oswald 1999; Penaloza 1989, 1994; Sandikci et al 2006; Ustuner and Holt forthcoming).

On the other hand, studies of economically impoverished consumers have mostly studied these consumers in terms of their basic needs and wants, i.e. what they essentially need in order to survive. However, desires and hopes seem to be other important factors influencing their consumption practices. As Belk et al (2003) note, how consumer desires are negotiated among people who have not grown up in an urban, marketizing society remains an understudied area. We aim to contribute to existing literature on consumption patterns of economically deprived consumers by explicating their needs, wants, desires, and hopes in an integrative manner. Therefore our main research question in this study is how poor, immigrant consumers talk about their needs, desires, and hopes and how their interpretations are structured by various institutional and cultural discourses and norms.

The context of our study is rural-to-urban migrants in Ankara, capital city of Turkey. Turkey provides an interesting context to study poor, migrant consumers because there are different modes of modernities that involve Western and non-Western imaginations at the same time. Ethnographic data collection method was chosen in order to understand an 'unfamiliar world' and bring the lived experience of consumers living in shanty towns (Van Mannen 1988). Ten in-depth interviews were conducted in two different regions of shantytowns in Ankara.

Results indicate that immigrants' needs and wants were mostly shaped by what they observe in each others' houses in the squatter area, which is a close-knit community, somewhat isolated from the city culture. Relatives and friends provide sources of comparison for migrated consumers. As a community, they together create their own consumption relationships, providing support for Bourdieu's (1984) observation that different ways of life involve different systems of thinking about what is 'necessary'. Immigrant poor consumers' 'baseline standard' (Hill 2002b) does not depend on the dominant consumption culture prevalent in the city, but on what other poor consumers in the same squatter area have.

There was also support for the idea that immigrant consumers' desires were not achievable. The pleasure, creativity, and fantasy of consumption liberate their desires (Firat and Venkatesh 1995), however these consumers were consciously convinced that they would not achieve their desires because of two main reasons. The first reason is money; apparently, they lack the resources needed to purchase the desired objects. Secondly, the desired object requires a dramatic transformation of the individual. This dramatic transformation is achievable but totally inappropriate because of the nature of their desires. For example, one of our female respondents stated her desire to be a very attractive woman. Although this was not impossible, it would require her to be open, apply make-up, and exercise, most of which, she believes, are against her values and religious beliefs.

Contrary to Belk et al.'s (2003) findings, we found that desire is not kept alive until the object is acquired; it is kept alive as long as it brings enjoyment since the object will never be acquired. Desire is beyond hope but it still exists, yet this does not create depression. The relation between desire and hope in our case reveals a different situation where one might desire an object without necessarily hoping it. Hope is towards a goal-congruent outcome (MacInnis and de Mello 2005); and like a plan, it shapes immigrant consumers' consumption routines. But desire is not goal-congruent; to desire is to live, to hope, and to be alive (Belk et al. 2003).

Our study was limited in terms of the depth of information collected. Future studies might focus on different contexts, differentiate between first- and second-generation immigrants, and include male respondents and children. Continuation of this research has the potential to extend the notion of the 'desire for the other', in ways that reveal who the other is and what that desire involves in relation to hope.

# We Happy Few: Redefining Community in Marketing

Aubrey Fowler III, University of Nebraska, Lincoln, USA
Michael Krush, University of Nebraska, Lincoln, USA

## EXTENDED ABSTRACT

Community has seen an increasing level of interest with marketing scholars both as a context for a variety of consumer behaviors as well as a consumer behavior unto itself. We have seen marketers investigate the impact community has upon various consumption activities (Cova 1997; Hill and Stamey 1990), the rites and rituals of various consumption communities (Celsi, Rose, and Leigh 1993, Schouten and McAlexander 1995), and the process of how certain communities develop and grow around various brands (McAlexander, Schouten, and Koenig; 2002; Muniz and O'Guinn 2001; Muniz and Schau 2005). However, despite this growing interest and the wealth of knowledge garnered by such studies, a consistent definition of community in the marketing literature is elusive.

As a result, there are three main challenges to the exploration of community in marketing. First of all, the notion of community is inexact in a definitional sense both in terms of how one identifies a community and in how it is distinguished from subcultures or other such social units. Second, a set of challenges arises when we attempt to outline the boundary conditions of what constitutes a community, and third, there is a need to consider the variations between different types of communities or, at the very least, the varieties of communal relationships that exist within communities. Our purpose is to attempt to resolve these challenges and provide a definition of community that allows marketers to move forward with an examination of community both in theory and in practice.

To do so, we first draw upon various sociological, psychological, and ecological literatures to understand the fundamental components of community. Collectively, these streams suggest that community is a social system that possesses two components, a structural and an inter-relational component, that exist between and amongst its inhabitants. We draw from Brint's (2001) notion that community is driven by "aggregates of people." These collections share something—be it a set of beliefs, ideals, desires, activities, or concerns—that binds them together; yet, we also believe that there is something more to community than simple collections of people. Brint's definition, though thorough, remains vague in that it may also describe a family, a classroom, or a group of friends enjoying a camping trip.

Building upon the work of Giller (1984) who defined ecological communities as made up of smaller "guilds" or groups of animals, plants, and bacteria as well as the efforts of Cooley (1909), Durkheim (1893), and Simmel (1950), we argue that a community is formed when subgroups of intimately related people who are bound by strong ties develop relatively weaker ties with other subgroups of people. Ultimately, we arrive at the following definition: *Community is a structured and inter-related network between groups of people where each individual group as well as the collective network of groups is bound together by relations that may include affect, loyalty, common values, personal concerns, common activities, and/or beliefs and where the tie strength of relationships within groups is relatively greater than the tie strength that exists between groups.*

From this definition, we attempt to align the components of our proposed definition with the existing marketing literature on community. Then we apply our definition of community to marketing and, specifically, brand community. First, we find that marketing research has alluded to collections of distinct sub-groups that form a broader aggregate community (Schouten and McAlexander

1995). Second, the extant literature suggests that marketing can facilitate ties between groups of consumers (Cova 1997; Price and Arnould 2000). For example, two of the main arenas in which marketing exhibits its ability to bind sub groups into a larger entity is through the utilization of brands (Muniz and O'Guinn 1995; Muniz and Schau 2005) as well as the construction of communitas between consumers (Celsi et al. 1993; Arnould and Price 1993).

We also submit that our definition of community aids in the conceptualization and identification of brand community. We argue that a brand community occurs when the brand facilitates the relatively weaker ties that bind subgroups together. We also make a further delineation. Specifically, we examine the ties within subgroups, suggesting that if the ties that exist within sub-groups are not a result of the brand but rather a result of other attributes associated with affect, loyalty, common values, etc., then it is not a brand community. In this case, the brand has been adopted by the community. We describe this structure as a *community's brand*, arguing that if the brand is consequently removed from the community, the community would carry on without the brand. These brands, rather than assisting the formation and development of a community and its rituals, are invited into the community much as Kates' (2004) informant suggests when he states "if a company chooses to acknowledge us, we will tend to shop there, or purchase that product with an almost blind devotion… Levi-Strauss has been in the community for years" (458).

Thus, we posit that certain communal bodies may in fact constitute both brand communities as well as a community's brands. For example, The Harley Davidson subculture of consumption identified by Schouten and McAlexander (1995) appears to be a collection of various subgroups such as the Mom-and-Pops, RUBs, Dikes on Bikes, and Hard Core bikers (to name a few). Each subculture has strong ties within their specific groups based on such elements as loyalty, affect common values, personal concerns, common activities or beliefs; and these groups have adopted Harley Davidson as a community brand. However, when the various subgroups come together at Sturgis, the brand facilitates the between-group weak ties that bind these subgroups together. Harley Davidson's marketing vis a vis the biker rally at Sturgis then helps facilitate a brand community.

Ultimately, we believe that community, both as a concept and a reality, is a complex and difficult web of human relationships within varying environments; and the importance of understanding such phenomena has been noted within sociology, ecology, psychology and marketing. This paper is an attempt to provide one perspective that may aid in clarifying what community is in terms of its structure and the various types of community that may appear. It is our hope to take the study further and explore its ramifications within particular contexts.

# The Relationship between Online Brand Community Participation and Consciousness of Kind, Moral Responsibility, and Shared Rituals and Traditions

Vivek Madupu, University of Minnesota Duluth, USA
Balaji Krishnan, University of Memphis, USA

## EXTENDED ABSTRACT

In the last few years scholars have shown tremendous interest in researching brand communities (Algesheimer, Dholakia and Herrmann, 2005; McAlexander, Schouten and Koenig, 2002; Muniz and O'Guinn 2001). The three characteristics of brand communities that were identified by several scholars are consciousness of kind, moral responsibility, and shared rituals and traditions (McAlexander et al. 2002; Muniz and O'Guinn 2001; Schau and Muniz 2002). However, there are no existing scales to measure these characteristics. The lack of scales for measuring these three defining characteristics complicates the efforts of researchers to understand brand communities better.

Likewise, over the past few years, rapid advancements in the field of Information Technology, especially the Internet, have facilitated the formation of numerous online/virtual brand communities. For example, we found nearly 2000 Yahoo groups dedicated to different brands of motorcycles; nearly 500 Yahoo groups devoted to Harley-Davidson motorcycles alone. Though members' participation is considered the core of a community's existence and a key indicator of the performance of online communities (Bagozzi and Dholakia 2002), there is no scale to measure the extent of members' participation in online brand communities. Hence one of the goals of this paper was to develop scales for these four constructs.

The other goal of this paper was to investigate the relationship between members' participation and their consciousness of kind, moral responsibility, and shared rituals and traditions. While current literature clearly identified that consciousness of kind, moral responsibility, and shared rituals and traditions are present in members of brand communities, what is *not* clear is when these three characteristics are developed. McAlexander et al. (2002) ethnographic study of brandfests suggests that these characteristics are developed in members *after* participating in brandfests. They report that, "…these characteristics of brand community did not all and equally exist before the brandfest events (p.42)." In line with McAlexander et al. (2002), in this paper we argue and provide empirical support for the positive relationship between online brand community participation and the three brand community characteristics.

In order to develop new scales, an initial list of items was generated based on the review of relevant literature on brand communities and virtual communities. These items were examined by a pool of experts and four members of different online brand communities for ambiguity, clarity, and relevance to the domains of the constructs. In the first study, data were colleted from a convenience sample of 328 students. A number of internal consistency and item-based statistics were examined for item retention. The goal of this study was to refine the initial list of items that was generated.

In the second study, data were collected from members belonging to six Yahoo groups formed around different motorcycle, car and camera brands. Yahoo! Groups were chosen for the following reasons: Yahoo! Groups is the most popular and well-known provider of electronic mailing list facilities compared to Google groups, or MSN groups. Also, for any group formed around a particular brand, it was found that Yahoo! Groups had the largest membership compared to Google or MSN. Additionally, similar to McKenna and Bargh (1998), only those groups with at least 400 posts/month for the last six months were included in the survey. A web based survey hosted by surveymonkey.com was utilized for data collection. After discarding incomplete responses, there were 470 usable responses. The majority of the respondents were from the USA. Ninety-two percent of respondents were male.

Data were analyzed using SPSS and LISREL 8.51. All of the four scales exhibited acceptable level of reliabilities of alpha $\geq 0.70$. Convergent and discriminant validity of the constructs was assessed as suggested by Fornel and Larker (1981). All the three hypotheses were supported. Online brand community participation is positively related to members' consciousness of kind ($\alpha$=0.67, t=13.10), shared rituals and traditions ($\alpha$=0.53, t=9.58) and moral responsibility ($\alpha$=0.72, t=11.69).

# Responding to Ethical and Competence Failures

Sekar Raju, Iowa State University, USA
Priyali Rajagopal, Southern Methodist University, USA

## EXTENDED ABSTRACT

Extant research on failures has typically not considered the effect that the firm's response has on consumer perceptions (Folkes and Kamins 1999). The present research reports the results of two studies that examine the effects of alleged failures by the firm and different responses of the firm on consumer's attitudes towards the firm. Specifically, the first study establishes the interactive effect of failure (ethical or competence) and the firm's response (denial, acceptance or no response) on consumer's attitude and examines the mediating role of trust and affective responses. The second study extends this result by examining the effect of knowing the true outcome of the allegations (whether the allegations were found to be true or not) on consumer evaluations of the firm.

A review of the literature suggests three broad approaches to responding to allegations of failure-deny, accept responsibility, or not respond (Tybout, Calder, and Sternthal 1981). Accepting responsibility for a failure has been shown to help in reducing the negative emotions felt by the aggrieved person (Tomlinson, Dineen, and Lewicki 2004) but others have argued that accepting responsibility for a failure is likely to strongly link the negative event to the brand in the minds of the consumer (Johar 1996). Similarly, some researchers have argued that denying the allegations is more effective than accepting responsibility for a failure, while others have found that denying responsibility for a failure results in a decreased level of trust in the firm (Sirdeshmukh, Singh, and Sabol 2002).

Therefore, the effectiveness of accepting responsibility or denying allegations would appear to depend on some factor other than the type of firm response. Researchers have identified that consumers typically attribute two separate characteristics to firms–competence and ethics (Dacin and Brown 1997). While competence deals with decisions affecting the ability of the firm to produce goods or deliver services in a capable manner, ethics deals with the moral aspect of conducting business. Interestingly, failures can occur on both these dimensions. The research on dispositional inferences suggests why people might perceive competence and ethical failures differently. Reeder and Brewer (1979) argued that people infer different information from competence and ethical failures. People believe that ethical people always behave ethically, but unethical people can behave both ethically and unethically at times. On the contrary, the belief about competent people is that they can at times behave incompetently, but incompetent people can never behave competently because they lack the ability to do so (Skowronski and Carlston 1989).

In the context of a firm, assume that an allegation of ethical wrongdoing by a firm surfaces in the media. If the firm accepts responsibility for the failure, it means that a consumer knows with certainty that the firm did something that was not expected of it. This, as argued previously, will generate negative affective reactions. Further, since the acceptance relates to a failure in the ethical dimension, the information is highly diagnostic in inferring the character of the firm. This will lower the trust and result a less favorable attitude to the firm. However, if the allegation is denied, consumers would not readily be able to associate an ethical failure with the firm (Riordan et al. 1983). Therefore, consumers are relatively less likely to experience negative emotions. Further, since the denial makes the information less diagnostic, it is less likely to lower trust or attitude to the firm (Folkes and Kamins 1999).

When it comes to allegations of a competence failure, even if the firm accepts responsibility for the failure, it does not provide diagnostic information to the consumer about the competence or incompetence of the firm. Since consumers assume that competent firms can also at times falter, accepting the failure is less likely to lower trust. However, by accepting the failure and working on a resolution (e.g., apology), the focus of the consumer is likely to be on the resolution and not on the failure (Ohbuchi et al. 1989). This shift in the focus is likely to reduce negative emotions associated with the failure (Folkes 1984). If a competence failure is denied, it will limit the association between the alleged failure and the firm. But the denial also signals unwillingness on the part of the firm to initiate a failure resolution. This is likely to increase the negative emotions associated with the failure (Smith and Bolton 2002).

As expected, the results of the first study finds that denying an ethical failure results in a more favorable attitude to the firm compared to accepting responsibility for the failure. However, the results were less clear when the allegation related to competence failure. Accepting responsibility for a competence failure resulted only in a directionally more favorable attitude to the firm compared to denying the allegations. A mediation analysis supported the argument that trust and affect were critical in shaping consumer's response to the failure. The second study addresses the question of what happens when the allegations are later found to be true or false.

The results of the second study indicates if the allegations have an element of truth, it may be better to accept the failure initially and work on a recovery process, rather than deny the failure initially and then respond after the truth becomes known with certainty. Although denying an alleged ethical failure was better than accepting responsibility, using a denial as a cover up seems to have very serious repercussions when the allegation are fond to be true. Even for ethical failures, consumers seem to be willing to give some credit to the firm when it accepts the fault and starts to work on repairing the damage. When evidence of a failure is known with certainty, it may be better to accept the failure and work on regaining the lost trust. However, if one is sure that no failure has occurred, denying the error initially is the better course of action, because both immediately after the response and after the truth is known the attitude continues to be relatively more favorable.

# Making Probability Judgments of Future Product Failures: Packing versus Unpacking the Problem

Dipayan (Dip) Biswas, Bentley College, USA
L. Robin Keller, University of California, Irvine, USA
Bidisha Burman, Appalachian State University, USA

## EXTENDED ABSTRACT

While making product use or purchase decisions, consumers often make explicit or implicit judgments regarding potential product failures in the future. In a related vein, through advertisements and other actions, managers and regulators often have the flexibility to influence what types of information are presented to consumers. For instance, in their magazine advertisements and package inserts, anti-depressant drug PROZAC® unpacks the adverse reactions related to "digestive system" in the form of "nausea, diarrhea, anorexia, dry mouth, and dyspepsia."

Prior research has found that people often do not follow the extensional logic of probability theory while making probability judgments and are frequently influenced by the information format (Kahneman et al. 1982). Specifically, in the context of the PROZAC® example outlined above, would consumers have differential judgments for "packed" ("adverse reaction related to the digestive system") versus "unpacked" ("adverse reaction in the form of nausea, diarrhea, anorexia, dry mouth, and dyspepsia") information? Prior research (e.g., Fiedler and Armbruster 1994; Rottenstreich and Tversky 1997; Tversky and Koehler 1994) would suggest that people would have a higher probability judgment for potential adverse reactions for the unpacked than for the equivalent packed condition. This is because people tend to assign probabilities to descriptions of events, called *hypotheses*, rather than to actual events (Tversky and Koehler 1994). As a result, consumers' probability judgments for the focal hypothesis relative to the alternative hypothesis are influenced by how events are described. In this context, Support theory "predicts that the judged probability of an event increases by unpacking the focal hypothesis and decreases by unpacking the alternative hypothesis" (Rottenstreich and Tversky 1997, p 406). Support theory also predicts that the judged probability assigned to an unpacked description of an event is greater than the packed description (Tversky and Koehler 1994). Hence, when the description of an event is unpacked into its individual components, people are likely to assign an overall higher probability judgment for the event's occurrence. This phenomenon has been termed as "subadditivity" in probability judgments. Many other research streams (e.g., Fiedler and Armbruster 1994; Fischhoff, Slovic and Lichtenstein 1978; Teigen 1974, 1983) have found similar patterns of results.

We extend the basic premise of information packing/unpacking, and examined scenarios where participants themselves generated the unpacking variables, unlike as in prior studies where participants were given explicit unpacking questions. We also examined how prior general negative/positive experiences with the product can influence the evaluation outcomes for packed versus unpacked information formats.

When a consumer is asked to make probability judgments about future product performances, in light of past experiences, in essence it translates into making a conditional prediction. Conditional predictions conform to the format of asking participants the probability of an outcome $y$, given condition $x$ has occurred (Koriat, Fiedler, and Bjork 2006). In the context of the present research, $y$ can be conceptualized as the probability judgment regarding future product failure, while $x$ can represent past experiences with the product (e.g., negative experience in the form of product failures). Koriat, Fiedler, and Bjork (2006) found that "in making conditional predictions, people are subject to a prediction inflation bias, over-estimating the likelihood of occurrence of the stated outcome given the stated envisioned condition" (p. 430). This implies that if people have had prior negative experiences with a product class, they are more likely to have unfavorable predictions regarding future product failures. However, more interestingly, people are likely to have a greater level of prediction inflation bias, when they can build "a causal scenario leading from the condition to the outcome" (Koriat, Fiedler, and Bjork 2006, p. 443).

We are proposing that a general negative experience with the product in the past, would lead to a stronger causal mapping in the "packed" data condition, since a general experience can be more directly mapped with a general (than specific) problem in the future. In contrast, when the questions are unpacked, consumers are less likely to form a direct causal mapping between the past experience and making the conditional prediction regarding the future, for more specific problems. Hence, we hypothesized that a general negative product experience in the past would enhance probability judgments regarding future product failures to a greater degree when the problem is packed (than unpacked).

In contrast, prior general positive experiences with a product would lead to lower probability judgments regarding future product failures, to a greater extent for unpacked (than packed) conditions. This is because, since reliable performances by a product is the norm (Meyvis and Janiszewski 2002), there will be a greater degree of "seizing" and "freezing" for the focal hypothesis under prior positive experience conditions (Kruglanski and Freund 1983).

In Study 1, the results of a 2 (packed vs. unpacked) X 3 (negative prior experience vs. positive prior experience vs. no prior experience) between-subjects experiment supported our hypotheses.

The two critical questions asked in Study 2 were: (1) Do participants have higher probability judgments of future product failures for "packed" versus "unpacked" formats when they themselves generate the unpacking variables? (2) Do participants have increased probability judgments for unpacked versus packed conditions, in an increasing linear fashion? That is, if 4 levels of unpacking lead to greater probability judgments than a packed scenario, will a 12-level unpacking lead to an even greater probability judgment? We hypothesized that when the generation of unpacking variables is easy, consumers would have a higher probability judgment of future product failure for the mentally "unpacked" than "packed" conditions; when the generation of unpacking variables is difficult, consumers would have similar probability judgments of future product failure for the "unpacked" and the "packed" conditions. Moreover, these hypothesized relations will become stronger for high (vs. low) need for cognitive closure participants. The results of 3 (packed condition vs. unpacked with 4 variables generated vs. unpacked with 12 variables generated) X 2 (Need for Cognitive Closure: High vs. Low) between-subjects experiment supported our hypotheses.

Combined, the two experiments showed that a general prior negative experience had a stronger impact on participant judg-

ments, for future product failures, in the packed (than the unpacked) condition, with the pattern of results getting reversed for prior positive experience with the product. Also, when asked to generate the unpacking variables, participants had higher probability judgments of future product failures only when they were able to generate the unpacking variables with relative ease.

# Consumers' Evaluation After a Service Encounter: The Effects of the Actions of Company Unrelated Party

Jessica Y. Y. Kwong, The Chinese University of Hong Kong, China
Candy K. Y. Ho, The Chinese University of Hong Kong, China

## EXTENDED ABSTRACT

Existing literature has shown that consumers' evaluation after a service encounter is determined by the performance of the company and the extent to which consumers attribute the performance to the company (Bitner 1990; Griffin, Babin, and Attaway 1996). Particularly, it is documented that consumers react more negatively to unexpected negative outcomes to the extent that the outcomes are the results of a company's actions and that the actions are relatively stable and are under the company's discretion (i.e., stability and controllability). Studies thus far share a focus on how a *company's* actions and the characteristics of these actions determine consumers' postpurchase evaluations. Yet, we argue that this view is inadequate for a full understanding of the evaluation process. Clearly, for most situations in real life, the actions or decisions of a company happen *within* a dynamic context where the actions of other parties also change. Failing to acknowledge the joint effects of the actions of a company and that of another party on consumers' evaluation after a service encounter will undermine our full understanding of the process. In the present research, we studied the joint effects from an attribution perspective.

To begin, we hypothesized that consumers would generally respond more negatively to a service failure when the actions of a company committed before the failure were seen as more mutable (Kahneman and Miller 1986). This is because the highly mutable company action provides a cue for consumers to hold the company accountable for the service failure. And this tendency is further reinforced by the cognitive inertia in rejecting an initial belief once formed (*a.k.a.* confirmation bias, Snyder and Swann 1978). More importantly, however, we proposed that this effect would be attenuated when another party involved in the situation had done something unusual or abnormal. This is because the presence of unusual aspects in a situation should somehow break consumers' cognitive inertia in rejecting a prior belief. They may now feel compelled to consider additional alternatives that may explain the service failure. Thus, albeit the presence of highly mutable elements in the company's part, consumers are less inclined to hold the company accountable. In sum, we expect that consumers' evaluation of a service failure should be a joint function of the action of a company and that of another party, and that this interactive effect should be driven by the tendency to ascribe the failure to the company.

Study 1 tested the focal interaction by manipulating a company's action (the commencement date of annual sale was kept unchanged vs. the commencement date was changed) and consumers' behavior (they visited the usual store vs. they visited a store that they rarely went to). Across all four conditions, the participants experienced a purchase failure–that is, the target laptop computer that they intended to buy was out of stock. Undergraduate students participated in this study in exchange for course credits and were randomly assigned to one of the four conditions. After they read the scenario, they reported their dissatisfaction toward the service failure.

Results of this experiment support our prediction. An interaction between the mutability of company's action and the behavior of consumers was found. Consistent with our contention, respondents were more dissatisfied when the company changed the date than when it did not. More importantly, these effects were tempered when the consumers visited a store that they rarely visited than when they went to the usual store.

Study 2 was conducted to show that the focal interactive effect was driven by the attribution of the service failure to the company. We replicated study 1 with the addition of attribution measures and a thought listing task. Consumers' evaluation of the service encounter was captured by their negative postpurchase intention. Again, we obtained support for the focal interaction. The focal interaction emerged on both the negative postpurchase intention and the attribution ratings. More importantly, the mediation analyses supported our argument that the focal interaction was driven by the tendency to hold the company accountable for the failure. The thought protocols from the respondents further showed that the relative proportion of company related thoughts versus company unrelated thoughts mirrored their tendency to hold the company accountable and their negative postpurchase intention.

A third study reported in general discussion section replicated the key findings in another context. In this study, the other party existing in the situation referred to a partner company (whether there was a machine breakdown in the partner company). Thus, the three studies taken together show that consumers' evaluations after a service encounter are not only governed by company's related issues but also the actions of parties (customers and partner company) that are independent of the company. Implications of the findings are discussed.

# It is not Whether You Win or Lose, But How You Play the Game: The Role of Memory in How Consumers Feel After Lying

Christina Anthony, University of Sydney, Australia
Elizabeth Cowley, University of Sydney, Australia

## EXTENDED ABSTRACT

*Sam is about to finalize the negotiation for the SUV he has had his eye on at ACME used car lot. He left the lot last time promising that he would look around for a better offer on a similar vehicle. Sam weighs his options, he can tell the truth, he was unsuccessful in finding a better deal, or he can lie by telling the dealer he found a comparable SUV on sale privately for $300 less than ACME's asking price. He hates lying, but he believes the dealer is overcharging for the vehicle.*

Research investigating deception in marketing has focused on acts of deception by marketers and their effect on the consumer (i.e. Burke et al. 1988; Gaeth and Heath 1987). There are at least two parties in every exchange of information. The objectives of this study are to investigate how lying during a negotiation with a salesperson can affect the consumer's affective reactions to the encounter and whether the consumer's memory of the exchange will moderate the relationship.

## The Risks Involved with Lying

When entering into a negotiation with a salesperson, a consumer must choose a strategy for the exchange. At the most general level, the consumer must decide whether they will tell the truth about the information they have or not. Lying should reduce the risk of an unsuccessful outcome (Aquino 1998; Lewicki and Litterer 1985; Lewicki and Stark 1996; O'Connor and Carnevale 1997). However, lying during a negotiation may increase the risk of experiencing negative feelings such as guilt, shame and/or regret (Ellsworth and Tong 2006).

## Affect and Perceptions of Fair Play Associated with the Outcome

Consumers that navigate the negotiation such that they get a good deal will feel positively toward the outcome of the negotiation while consumers that do not successfully negotiate an outcome will feel negative affect toward the experience. However, the strategy taken during the negotiation may moderate the affective reactions resulting from the positive or negative outcome. Truth tellers may feel no negative affect in a deal situation and plenty of negative affect when facing an unsuccessful outcome because they told the truth and did not receive the expected deal. Liars may not experience different levels of negative affect when they face an unsuccessful outcome compared to when they get a good deal. Why? When liars get a deal they should feel more negative affect because they got something they didn't deserve (Baumeister, Stillwell, and Heatherton 1994; Skitka, Winquist, and Hutchinson 2003; Van den Bos et al. 2005). When liars face an unsuccessful outcome, they should feel relief because they didn't get something they didn't deserve.

## The Role of Memory

After the outcome of a negotiation between a salesperson and a consumer has been established, the consumer will reflect back on the exchange to make sense of the outcome and to determine whether both actors were 'playing fair.' Remembering the details of

the experience allows for an objective determination of the negotiators' behavior.

If the details of the exchange are not remembered well, then truth telling consumers might not be willing to report that they were behaving in a fairer manner than the salesperson. Incomplete memory for liars, however, may provide an opportunity for them to convince themselves that they were playing by the rules (Cowley and Farrell 2007).

## Method

One hundred and nine undergraduate students participated in a negotiation task. Students negotiated with a salesperson on-line. The outcome of the negotiation was associated with tickets to a lottery for a cash reward. The information provided to the participants for the negotiation task either encouraged them to tell the truth or to lie. The outcome of the negotiation was manipulated such that half the participants received a good deal, while the other half faced an impasse in the negotiation. After the negotiation, affective reactions and perceptions of fair play were collected, as well as memory for the exchange. Memory was measured with a free recall task which was coded and split into complete or incomplete memory.

## Results

When memory is complete, truth telling consumers report a higher level of negative affect in the impasse condition. Truth telling consumers may be: i] regretting their tactical decision to tell the truth or ii] feeling indignation at the lack of 'playing fair' on the part of the salesperson. It appears that truth telling consumers felt indignation that the salesperson did not play by the rules. They were more irritated and angry, but not more regretful in the impasse condition. When memory is complete, truth telling consumers report that they played more fairly than the salesperson in the impasse condition compared to the deal condition. This is consistent with the suggestion that truth telling consumers felt indignation because they played by the rules and the salesperson did not.

When memory is incomplete, lying consumers report a higher level of negative affect in the impasse condition. The lying consumers may have convinced themselves that they were playing by the rules and may have felt the same indignation reported by remembering truth tellers because the salesperson was not perceived to be playing by the rules. Lying consumers felt more irritation and anger in the impasse condition. When memory is incomplete, lying consumers report that they are more satisfied with their choice of strategy than the salesperson's choice in the impasse condition. Although the effect is only weakly significant, it suggests that the forgetful liar reacts the same way the remembering truth teller does to an impasse.

## Discussion

Forgetful liars convince themselves that they were playing by the rules when they are faced with an unsuccessful outcome to the negotiation: they report the same pattern of affective reactions as the remembering truth tellers. Importantly, we did not manipulate the completeness of the consumer's memory. It is unclear whether the forgetful liars were motivated to selectively remember the

experience or whether their incomplete memory affected their reactions to the outcome of the negotiation. This is a significant issue for future research.

The results also revealed that remembering liars reported similar levels of negative affect as forgetful truth tellers: both showed no difference between their level of negative affect for a deal and impasse. Remembering liars presumably experience more negative affect with a deal because they remember playing unfairly, while forgetful truth tellers may not be willing to judge the salesperson as playing less more fairly without a detailed memory of the exchange. The inability to report themselves as fairer players may have been reflected in their reduced feelings of pride. The bottom line, both matter, whether you win or lose and how you play the game.

# The Role of Creative Cognitions on Consumer Feature Reliance

Huifang Mao, University of Central Florida, USA
Xiaojing Yang, University of Wisconsin-Milwaukee, USA

## EXTENDED ABSTRACT

Creative thinking is prevalent in consumers' daily life. The existing creativity literature, has focused on identifying the antecedents of creativity (e.g., Burroughs and Mick 2004; Forster, Friedman, and Liberman 2004). This paper goes beyond by exploring the consequences of a creative process. Specifically, we predict that the types of creative process consumers utilize (generative or exploratory) affect consumers' reliance on various levels of product features, and ultimately their performance on categorization and memory tasks.

## Theory and Hypotheses

The cognitive approach of creativity is built on the Geneplore model, in which creative thinking is composed of the top-down generative and the bottom-up exploratory processes (Finke, Ward, and Smith 1992). When the generative type of creative cognition is in use, individuals generate a preliminary mental representation of a solution, or a "preinventive structure," as a primary element that guides the search for final solutions (Finke et al. 1992). The preinventive structure, which may appear in the form of an idea, a concept, a picture, a sound or even just a feeling, points out the direction to solve a particular problem. On the other hand, when the exploratory type of creative cognition is employed, individuals evaluate different contexts or perspectives, and search for limitations and meanings that may attach to potential solutions. Such evaluations and searches will lead individuals toward certain directions and away from others (Moreau and Dahl 2005).

Types of creative cognitions consumers have can either be determined by situational factors or individual intrinsic preferences. For example, Moreau and Dahl (2005) show that, depending on the specific creative task, generative or exploratory creative cognitions may become dominant. In addition, difference can also be observed at an individual level. When looking for solutions for a problem, some consumers emphasize on coming up with ideas via a generative process, others focus on examining the existing resources and limits via an exploratory process. We expect that once an alternative cognition (generative or exploratory) is adopted, through either intrinsic personal preference or situational priming, it will trigger reliance on different types of brand or product features.

The generative type of creativity process often relies on abstract thinking. Individuals will focus on the ideals and goals that need to be achieved and come up with an abstract concept or idea that could represent the solution of the focal problem. Consumers engaging in the exploratory type of creative process, however, evaluate and interpret the preinventive structure from a concrete or specific perspective. They delve into the details in order to use the existing information/resources to the maximal degree. Therefore, generative creativity attracts attention to abstract features while exploratory creativity triggers reliance on concrete features. Accordingly, we expect that when generative versus exploratory creative cognition becomes salient, consumers will exhibit differences in categorization and memorization.

## Categorization

The categorization literature suggests two broad approaches of categorization: goal based (i.e., products that serve the same goal or objective are grouped together) versus feature based (i.e., products that share similar features are grouped together) (Loken and Ward 1990; Ratneshwar et al. 2001). Since goal-based categories are constructed based on the abstract overall values or benefits (e.g., healthiness, cleanliness, happiness), we expect that it occurs more often with consumers who emphasize on abstract information. On the other hand, since feature-based categorization is constructed based on specific concrete product features (e.g., dairy content), it is more likely to be adopted by individuals who attend to concrete information.

Consumers who are chronic adopters of generative creativity construe solutions at an abstract level, and we expect that their reliance on abstract information will lead them to utilize more of goal-based categorizations. Consumers of the exploratory creativity type rely more on concrete information and tend to engage in feature-based categorization.

## Memory

Literature has shown that the more attention consumers pay to a particular piece of information, the better it will be registered in consumers' memory, and the more likely it will be retrieved later (Craik and Lockhart 1972). When generative (exploratory) creativity cognitions are salient, consumers tend to pay more attention to abstract (concrete) features, which will result in better recognition of abstract (concrete) information.

## Experiments and Analysis

Two studies were conducted to test the effect of creative cognitions on the level of product information consumers rely on. In the first study, we examine the first hypothesis in the context of product categorization. Individual preference of types of creativity is measured using a personality scale adapted from existing literature (Moreau and Dahl 2005). In the second study, we examine the second hypothesis in the context of memory of abstract versus concrete brand information, and creativity type is manipulated by asking participants to perform tasks that involve more of generative versus exploratory cognitions. Through a) using both situational prime and measure of individual preference of creativity types, and b) testing the robustness of the theory in both product categorization and memory contexts, we found consistent support for our proposed theory that whereas generative creativity leads to reliance on abstract information, exploratory creativity increases the use of concrete features.

# A ReExamination of Post-Experience Advertising Effects: The Moderating Role of Accuracy Motivation

Kunter Gunasti, Penn State University, USA
Hans Baumgartner, Penn State University, USA
Min Ding, Penn State University, USA

## EXTENDED ABSTRACT

Many studies have shown that advertising messages preceding product experiences can affect product evaluations by creating expectations that are subsequently confirmed in a direct experience with the product (Hoch and Deighton 1989; Hoch and Ha 1986; Olson and Dover 1979). In an interesting extension of this research, Braun (1999) demonstrated that even when the advertising *follows* a direct product experience, it can still transform consumers' memory of the original experience and result in more favorable product evaluations. Participants were asked to taste a bad mixture of orange juice, described as a new brand. Those exposed to positive advertising messages after the taste experience provided more favorable evaluations and, when asked to identify the original juice from a range of options varying in taste, systematically picked better juices than the one they had originally tasted. This impact of advertising after actual experiences (i.e. after-the-fact) was referred to as the *post-experience advertising effect*. It is a novel phenomenon that has important implications for both consumers and marketers. While demonstrating the critical role of advertising for marketers, it also draws attention to the vulnerability of consumers to exaggerated advertising claims.

The effects of post-experience advertising were conceptualized based on cognitive theories suggesting that information acquired after an experience can transform people's memory of that experience (e.g., Garry et al. 1996). Braun (1999) argued that since memory is malleable, information from the advertising may be used to reconstruct the original experience, leading to an overshadowing of experiential information by suggestive advertising claims. Braun emphasized that the post-experience advertising phenomenon was not simply a matter of advertising affecting consumer judgments of a product in addition to or apart from the product information stored in memory, but that the advertising actually altered consumers' memory of the original experience. Although subsequent consumer research has uncovered some boundary conditions of the effect by showing that factors increasing the cognitive ability of the respondent (e.g. product knowledge and familiarity) tend to reduce the misleading effects of advertising (Chang 2004; Cowley and Janus 2004), the basic post-experience advertising effect appears to be a robust phenomenon.

All of the explanations offered for the influence of post-experience advertising have implicated cognitive factors, such as consumers' knowledge and ability, as the culprit of memory distortions caused by marketing communications. Our contention in this paper is that motivational factors have to be considered as well. McDonald and Hirt (1997) demonstrated that motivation not only biases what a person recalls from memory (biased memory search), but also how the contents of memory are interpreted (biased memory reconstruction). Since consumers have different types and levels of motivation when they experience products, process ad messages, or make purchase decisions, motivational factors may be expected to play a crucial role in how susceptible consumers are to the post-experience advertising effect. In a recent review article, Johar, Maheswaran and Peracchio (2006) make a similar point by stating that "Braun (1999) argued for a cognitive source memory explanation for [the post-experience advertising] phenomenon, but it is likely that motivation also plays a role" (p. 139).

The goal of our research is, therefore, to investigate the role of different types of motivation in post-experience advertising effects. In two studies, we replicate past findings on memory distortion due to post-experience advertising. However, we extend this result by introducing manipulations of accuracy during memory retrieval using diverse methods. We show that increasing accuracy motivation during memory reconstruction and product evaluation eliminates the effects of post-experience advertising. We also control for respondents' impression motivation and demonstrate that participants high in social desirability are more susceptible to the effects of post-experience advertising claims.

# Protection of Prior Learning in Complex Consumer Learning Environments

Juliano Laran, University of Florida, USA
Marcus Cunha, Jr., University of Washington, USA
Chris Janiszewski, University of Florida, USA

## EXTENDED ABSTRACT

A large number of hypotheses have been advanced to describe the adaptive learning process. The current research investigates consumer learning environments in which cue-outcome relationships evolve overtime, starting with very simple relationships (e.g., French cuisine ? high quality food) and ending with more complex ones (e.g., French cuisine, poor location ? high quality food, poor ambiance). Of particular interest is the influence of prior learning about one benefit (e.g., cuisine ? quality) on predictive learning about a second benefit (e.g., cuisine ? ambiance) when additional predictive cues (e.g., location, price point) are available, as is the case in many product categories (e.g., restaurants, wine, hotels). Associative-learning theories disagree about the extent to which new learning will lead to the updating of associations between product features and product benefits. An efficient-learning hypothesis, based on the work of Mackintosh (1975), proposes that consumers will use cues (i.e., features) that have been relevant before to predict new outcomes (i.e., benefits). A protected-learning hypothesis (Kruschke 1996; Kruschke and Blair 2000; Kruschke et al. 2005) proposes that consumers will protect learning about cues that have been relevant before and will not use these cues to predict new outcomes. A series of experiments favors the protected-learning hypothesis.

Experiment 1 investigated the role of previous feature relevance in subsequent learning about this feature in a task involving learning about restaurants. A total of 194 respondents learned that feature A predicted outcome 1 ($A \rightarrow O1$) and that feature B predicted outcome 2 ($B \rightarrow O2$). The learning procedure in stage 2 taught that features A and C predicted outcome 3 ($AC \rightarrow O3$), features A and D predicted outcome 3 ($AD \rightarrow O3$), and that features E and F predicted outcome 4 ($EF \rightarrow O4$). In the test phase, respondents decided whether AE, AF, CE, CF, DE, and DF predicted O3 or O4. If people learn as predicted by the protected-learning hypothesis, a respondent who has learned that feature A predicts O1 in learning stage 1 should be resistant to learning about feature A in the AC and AD in stage 2 trials and feature A should be a weak predictor of O3. Features C and D should become strong predictors of O3. While test compounds AE and AF should predict O4, compounds CE, CF, DE, and DF should predict O3. In line with the protected-learning hypothesis, respondents expected restaurants having the AE and AF features to have benefit O4 ($\pi_{O3}=.345, \pi_{O4}=.655$; z=4.53, p<.05) and the CE, CF, DE, and DF features to have benefit O3 ($\pi_{O3}= .575, \pi_{O4}=.425$; z=2.11, p<.05). Once people learned that feature A predicted O1 in learning stage 1, they became less likely to learn that feature A predicted O3 in learning stage 2, provided that feature A was also paired with feature C or D. People pay less attention to a feature that they have learned about in the past when novel competing features are available.

Experiment 2 investigated how cue irrelevance resulting from previous blocking of this cue influences subsequent learning. Traditional blocking evidence has shown that learning a relationship between one cue and an outcome blocks subsequent learning about a second, co-occurring, cue and the same outcome. The protected-learning hypothesis predicts that learning the irrelevance of a cue for predicting one outcome attenuates subsequent learning about this cue and *a different* outcome. This attenuated learning is not predicted by the efficient-learning hypothesis. Learning stages 1 and 2 consisted of a standard blocking procedure. In learning stage 1, respondents learned $A \rightarrow O1$ and $B \rightarrow O2$. In stage 2, they learned $AC \rightarrow O1$ and $HI \rightarrow O5$. We then asked respondents to select either O1 or O5 as the outcome for features CH and CI. If blocking was successful, CH and CI should predict O5. In learning stage 3, respondents learned $A \rightarrow O1, B \rightarrow O2, CD \rightarrow O3, CE \rightarrow O3, FG \rightarrow O4$. We then asked respondents whether CF, CG, DF, DG, EF, and EG predicted O3 or O4. Within-subject tests of responses by 61 participants showed that, as predicted by the efficient-learning hypothesis, they expected restaurants having features CF and CG to have benefit O4 ($\pi_{O3}=.312, \pi_{O4}=.688$; z=3.18, p<.05) and restaurants having features DF, DG, EF, and EG to have benefit O3 ($\pi_{O3}= .633, \pi_{O4}=.367$; z=2.27, p<.05). An additional analysis confirmed that the stage 1 and stage 2 learning resulted in blocking.

In experiment 3, respondents learned that a feature was relevant to predict a benefit and a second feature was irrelevant (irrelevance was learned in a blocking procedure as in experiment 2). These two features were subsequently paired to predict a new benefit, and none of the features acquired predictive strength of the new benefit, as indicated in the test phase with a similar procedure as the one in experiments 1 and 2.

Our research also suggests opportunities for applied research. In most mature product categories, consumers have lay theories regarding attribute-performance relationships based on prior experiences and/or learned information from advertising campaigns. One strategy marketers use to deal with decreasing sales in mature markets is to identify new uses and benefits for current products. Our findings indicate that when people have learned a given brand is associated with a benefit, they may be resistant to accepting the introduction of a new benefit for the current set of features.

# The Effects of Outcome versus Process-Oriented Thinking on Decision Difficulty

Debora Thompson, Georgetown University, USA
Rebecca Hamilton, University of Maryland, USA
Petia Petrova, Dartmouth College, USA

## EXTENDED ABSTRACT

Imagine that you are looking for an apartment to rent and are deciding between two options that entail an attribute trade-off. One apartment is spacious but far from your workplace; the other is closer but much less spacious. Construal level theory (Liberman and Trope 1998) suggests that when deciding between these two alternatives, consumers who engage in process-oriented thinking will prefer the smaller and closer apartment because they tend to focus on the feasibility of the alternatives, while consumers who engage in outcome-oriented thinking will prefer the larger and less convenient apartment because they tend to focus on the desirability of the alternatives. However, although earlier research has tried to predict which alternatives will be chosen in a situation like this one, research has not addressed the subjective experience of the decision process for outcome- and process-oriented consumers. In this paper, we examine the impact of process and outcome-oriented thinking on perceived decision difficulty.

Previous studies have recommended process-oriented thinking over outcome-oriented thinking because it tends to be more effective in helping consumers achieve their goals (Taylor et al. 1998), increasing the consistency of their preferences (Hamilton and Thompson 2007; Zhao, Hoeffler and Zauberman 2007), and making them more discerning in their use of ad information (Escalas and Luce 2003). Although these findings tend to favor process-oriented thinking, they are based on scenarios in which consumers are evaluating a single goal or product, rather than choosing among two or more alternatives. In this research, we investigate the effect of process and outcome-oriented thinking on decision-making difficulty. In a series of three studies, we present participants with trade-offs between two alternatives, involving desirability and feasibility attributes. Our central prediction is that when consumers are faced with these trade-offs, inducing process-oriented thinking will significantly increase decision difficulty relative to outcome-oriented thinking, affecting their likelihood to postpone choice and likelihood to select a compromise option at a later point.

Because outcome-oriented thinking triggers elaboration primarily on the benefits associated with attaining one's goals, the desirability of the goals is expected to be more salient than the feasibility of the goals when individuals are evaluating alternatives. In contrast, process-oriented thinking should activate action-outcome linkages, making both feasibility and desirability considerations salient to process-oriented individuals. Thus, for decisions that require tradeoffs between desirability and feasibility, the decision should be more difficult for those who engage in process-oriented thinking than for those who engage in outcome-oriented thinking. In turn, this increased difficulty may affect subsequent judgments such as satisfaction with the decision process, willingness to postpone choice, and likelihood to switch to a compromise option.

In a series of three studies using two product categories (apartments and dietary supplements), we present participants with choice sets involving desirability vs. feasibility trade-offs (e.g., presence of vitamins vs. number of required tablets per day) and give them instructions to adopt either outcome-oriented or process-oriented thinking. In study 1, we find that process-oriented participants indicated significantly greater choice difficulty and lower

satisfaction with their decisions than outcome-oriented participants. Supporting our proposed mechanism, process-oriented thinking seems to increase the difficulty of making attribute trade-offs by encouraging consumers to focus on both the feasibility and desirability of the alternatives. Study 2 shows that participants instructed to use process-oriented thinking reported significantly more choice difficulty and more willingness to postpone choice than participants instructed to use outcome-oriented thinking, regardless of the vividness of the alternatives. Moreover, process-oriented participants were more inclined to select a compromise option than outcome-oriented participants. Finally, study 3 demonstrates that process-oriented thinking decreases the spreading of the alternatives. We find that the tendency to perceive the alternatives as more similar in attractiveness (lower spreading) mediates the negative effect of process-oriented thinking on decision difficulty. Supporting our prediction, analyses of participants' thought protocols suggest that process-oriented thinking makes decisions more difficult by encouraging consumers to focus on the process of using a target product as well as the outcomes. Process-oriented participants feel more conflicted when choosing between a desirable option and a feasible option because they tend to elaborate equally on both dimensions (forming action-outcome links), compared to outcome-oriented participants who focus primarily on desirability information (end benefits).

Our research adds to the literature on consumer decision making by exploring a factor independent of the choice set or attributes of the alternatives that affects preference fluency: the subjective feeling that choosing is easy or difficult. In addition, our results extend the literature on process- and outcome-oriented thinking by showing a negative effect of encouraging participants to engage in process-oriented thinking during decision making. Although process-oriented thinking can aid goal implementation, our findings suggest that it may hinder decision making, especially when consumers must make trade-offs between desirability and feasibility attributes.

# The Persistence of Fictional Character Images beyond the Program and their Use in Celebrity Endorsement: Experimental Results from a Media Context Perspective

Anja Spilski, Saarland University, Germany
Andrea Groeppel-Klein, Saarland University, Germany

## EXTENDED ABSTRACT

When consumers recollect media personalities familiar from television or movies, they think of them either as an actor or as the fictional character played by this actor. For instance, when consumers watch TV and Daniel Craig (the current James Bond actor) appears on the screen, they can perceive him as "this is Daniel Craig" or "this is James Bond." Celebrities known from film and TV can give endorsements *in character*–i.e. playing fictional roles in films and also in commercials. A celebrity known from fictional media is a composite of his or her fictional roles (McCracken 1989, 312). His/her image therefore depends not on the actor's qualities as a private person or celebrity, but on the qualities created in the stage persona in TV series and films. The fictional media provide information on fictional character traits that consumers may use to evaluate endorsers in-character. In this paper, we consider whether an appropriate media context–that creates the stage persona of an endorser–compared with an inappropriate media context for an in-character endorsement, can enhance the evaluation of ad characteristics and the evaluation of the endorser's perceived expertise and trustworthiness.

Several research findings on media-context effects support the hypothesis that congruency between the program and the advertisement with respect to characteristics like mood, feelings, involvement, humor, etc. leads to greater advertising effectiveness. A theory that is frequently cited as a possible reason for these effects is the congruency/accessibility hypothesis (Goldberg and Gorn 1987). A subsequent stimulus that is congruent to the media context is easier to perceive and process. This ease of processing is associated with a positive affect (Winkielman and Cacioppo 2001). The thematic congruency between program and advertisement is of major relevance in this paper, since an endorsement in character in the context of an appropriate program, forms a thematic connection between program and advert. Therefore, this paper deals with the issue of which fictional media context (thematically congruent or incongruent) represents the best placement for an in-character commercial. In order to address this issue, we conducted two studies analyzing different media context conditions. In Study 1, we compared one media context including an actor as a character congruent to the in-character advert, with another media context including another actor in another role (incongruence). In Study 2, in both media context conditions, the same actor was presented, but in a role that matches, versus one that does not match the in-character advert.

When program and advertising overlap–for example, when the advert features a character in a scene similar to one in the film or TV series–the advert represents a continuation of the film or TV series, and may evoke a more positive response due to viewers' familiarity with the character and the advertising story.

H1: The presentation of an in-character endorsement within a congruent fictional media context results in more positively perceived ad characteristics than a presentation of an in-character endorsement in an incongruent fictional media context.

Accessibility may also be the reason why information about fictional characters persists over time. When considering fictional worlds, the term celebrity is taken to mean the fictional characters rather than actors themselves (Stern, Russell, and Russell 2007). Here, we have to differentiate between two cases. In a long-term perspective, consumers are able to build up a parasocial relationship with a fictional character and come to regard this character as a friend or counselor. Thus, fans might also rely on the advice of the person playing this character if they see him or her advertising a specific product. However, when we–as in our studies–consider a rather short-term persistence of character images and consider media context effects, even if there is no close relationship between the recipient and the fictional character, a film character presented in a program might prime viewers, so that they evaluate this endorser as more competent and trustworthy. In our first study, we assume that consumers who watch a TV series will consciously or unconsciously transfer the meanings of the fictional character to an advertisement, if the same actor appears as a celebrity endorser (congruent context). This is assumed to result in more positive evaluations of the endorser than in a media context, where this actor has not been presented in a preceding film, so that no knowledge on character traits is available (incongruent context). In order to rule out a mere repeated-exposure effect due to the *actor* and to analyze whether there are actually effects of the persistence of *fictional character* traits beyond the program, we present a second study, in which we showed the actor in both media contexts conditions, but in different fictional roles. Accordingly, we assume that consumers who watch a TV series will consciously or unconsciously transfer the meanings of the fictional character to an advertisement, if the same actor appears as a celebrity endorser in a role that matches (congruent context), compared with a role that does not match (incongruent context) the preceding media context.

H2: The presentation of an in-character endorsement within a congruent fictional media context results in a more positive evaluation of the endorser's expertise and trustworthiness than a presentation of the in-character endorsement in an incongruent fictional media context.

However, conscious reactions, such as an evaluation of a spokesperson or of ad characteristics, may be subject to contrast effects (Stapel, Koomen, and van der Plight 1996) or source monitoring effects (Johnson 2002). These phenomena refer to consumers' ability to identify the sources of potential influence and "correct" (or even "overcorrect", Stapel, Koomen, and van der Plight 1996) their memories. We therefore decided to measure consumer responses simultaneously with the perception of the stimuli. In this respect, we are interested in the positive responses to the advertisement in different media contexts and therefore used a measurement process that was also able to capture unconscious processes in relation to emotional approach behavior. In particular, we examined phasic arousal, measured by electrodermal registration, as evoked by the advertisements presented in a congruent versus incongruent media context. With respect to this approach

response, we assume that congruent information attracts more attention and is processed more effectively than incongruent information, because the subject of information is already in people's minds prior to the ad exposure.

H3: The presentation of an in-character endorsement in a congruent fictional media context results in higher phasic arousal reactions to the advertisement than a presentation of the in-character endorsement in an incongruent fictional media context.

The results of our experimental studies show that an endorser presented in a media context which is thematically congruent to the role presented in the advertisement leads to higher phasic arousal responses. These can be interpreted as more attention in terms of empathic approach responses. This result was consistent in both studies. Furthermore, the endorser's expertise and trustworthiness was evaluated as more positive in a congruent media context across both studies. Thematic congruence was not found to exert a clear affect on ad characteristics, with the exception of the enhanced evaluation of the advert as "easy to understand". This indicates that viewers understand the advertisement story better with the help of the associated film or TV series. Our results have implications for media selection for advertisements including celebrity endorsers known from TV or films. Future research conducted in this area should determine whether these effects are strong enough to impact product evaluations and choice. A further interesting avenue is to analyze whether the congruency between a fictional program and an advert has the potential to undermine evaluations if the associations being primed are negative rather than positive in nature. Level of "transportation" (Green and Brock 2000) into a fictional "world" should be considered in order to further understand the persistence of fictional character images beyond the program.

# Evaluation of Brand Alliances: Product Fit and the Moderating Role of Brand Concept Consistency

Even Johan Lanseng, Norwegian School of Management, Norway
Lars Erling Olsen, Norwegian School of Management, Norway

## EXTENDED ABSTRACT

Brand alliances or co-branding, involving combinations of two or more individual brands (Rao and Ruekert, 1994; Simonin and Ruth, 1998) is a growing marketing strategy. Even though brand alliances is arguably a close cousin to brand extensions, a surprisingly few studies have investigated this phenomenon extensively. The few articles in this area (e.g. Simonin and Ruth 1998) build on the underlying logic of brand extensions studies, using product fit as key variable in predicting alliance success (c.f. Völckner and Sattler, 2006). In brand extension studies, it has been shown that a positive effect of fit is not only a question of product fit, but also brand concept consistency (Park, Milberg and Lawson, 1991). Brand concepts are based on the motives consumers have for buying products and services, and brands can be classified as having either a functional, expressive, or experiential concept. Focusing on expressive and functional brand concepts, the current study extends the brand extension research investigating brand concept consistency to brand alliance. The purpose of this article is to get a richer understanding of the role of fit in attitudes toward brand alliances and investigate how brand concept consistency might moderate the effect of product fit.

## Method

We examined how product fit and brand concept consistency influenced attitudes toward an alliance using a 3 X 3 between subjects factorial design. In the experiment, three combinations of brand concepts (functional-functional, expressive-expressive and functional-expressive) and three levels of product fit (high, moderate and low) were pretested and used to form nine different brand alliances. The brands were combined in promotion alliances, in which each logo was displayed together with another logo. In the study, 180 undergrad students from a large European university were randomly assigned to one of the nine different versions of the brand alliance. Respondents first answered questions regarding familiarity with and prior attitudes toward the brands, second they provided answers of perceived brand fit, and finally after an unrelated filler task they were asked about their evaluation of the brand alliance. All of the measures used seven-point bipolar semantic differential scales drawn primarily from the work of Simonin and Ruth (1998). The dependent measure, attitude toward the alliance, was constructed as an attitude index using the average of 3 seven-point items (Cronbachs alpha=.93).

## Major findings

The main effect of product fit on attitude toward the brand alliance was significant ($F(2) = 14,375$, $p=.000$). The results confirm our predictions and show that attitudes toward the alliance of low fit were less positive than attitudes toward the alliances of high fit ($M_{low}-M_{high}=2.31-3.79=-1.48$, $p<.001$) and moderate fit ($M_{low}-M_{moderate}=2.31-3.44 =-1.13$, $p<.001$).

The main effect of brand concept consistency on attitudes toward the brand alliance was also significant ($F(2)=7,89$, $p<.01$). The estimated mean attitude toward the alliance was higher for functional alliances than expressive alliances ($M_{functional}-M_{expressive}=3.81-2.82=.99$, $p<.001$) and mixed alliance ($M_{functional}-M_{mixed}=3.81-2.92=.89$, $p<.001$). More interestingly, these results were qualified by a significant interaction effect between brand concept consistency and product fit on attitude toward the alliance ($F(4)= 2,57$, $p<.05$). The results reveal that for alliances of expressive brands differences between high and low fit are insignificant ($M_{high}-M_{low}=2.90-2.50=.40$, $p>.1$) whereas for functional ($M_{high}-M_{low}=4.65-2.93=1.72$, $p<.001$) and mixed alliances ($M_{high}-M_{low}=3.82-1.50=2.32$, $p<.001$), the differences on attitude toward alliance in the high and low product fit conditions are statistically significant.

The results in the experiment clearly confirm that perceptions of product fit have important implications for evaluation of brand alliances (e.g. Park, Jun, and Shocker, 1996). In addition, we demonstrate that brand concept consistency, not only the level of product fit, is an important variable in these evaluations. Alliances consisting of two high-product fit functional brands are preferred compared to expressive brand alliances and mixed brand alliances. The study further shows that for expressive alliances, there are no differences in the evaluation for different levels of product fit. It can be argued that expressive brands generally tend to have more superordinate brand associations, connected to the consumers' self image expression and group membership. Thus, it is likely that consumers will have more problems in evaluating the product fit of an alliance consisting of two expressive brands. Hence, the observation of no differences in evaluation of expressive brand alliances for different levels of product fit can be explained by both the consumers' general problems in evaluating the fit and that a necessary judgment process will demand effortful cognitive processing. We have not included any measures of cognitive processing in our study, for example cognitive responses, so we do not know to what extent the respondents reflected on our stimuli. On the other hand, there are no specific reasons of why the respondents should spend excessive cognitive efforts in evaluating the fit, since with did not introduce any specific reasons or motivations for effortful elaboration. Future research should take this into account and introduce involvement manipulations.

In the study we combined brands in promotional alliances and obtained the respondents general evaluations of these combinations. However, we did not include specific products or product categories in the alliances, and the respondents were asked to evaluate the alliances only in general. It can be assumed that by introducing specific co-branded products the evaluations of the alliance will differ depending on the fit between the alliance brands and the product. An important question is whether the results found in the present study depend on the type of co-branded product. For example would the importance of product fit for the evaluation of expressive brand alliances increase if the brands were combined on a specific expressive product? Future research should heighten external validity and introduce specific co-branded products with varying levels of fit with the partner brands

# Need for Closure and Media Use and Preference of Young Adults

Iris Vermeir, Hogeschool Gent, Belgium & Ghent University, Belgium
Maggie Geuens, Ghent University, Belgium

## EXTENDED ABSTRACT

According to the uses and gratifications approach (Blumer and Katz 1974), people make different media choices depending on personal characteristics. Previous research points out that people use different media depending on their personality (Henning and Vorderer 2001; Kraaykamp and Van Eijck 2005; Persegani et al. 2002; Weaver 2003). People gravitate to particular kinds of media because they have particular personality characteristics, issues and/or needs that are either reflected in the media they choose or that the medium satisfies. Kraaykamp and Van Eijck (2005) suggested that personality is linked to a more general preference for more predictable, simple media types on the one hand versus more cognitively stimulating or unconventional media types on the other hand. In this respect, the personality characteristic -Need for Closure (NFCL)- seems very relevant. The need to obtain closure is related to cognitive processing and the approval of conservative, traditional ideas (Webster and Kruglanski 1994). Since different media and different genres and channels demand a different cognitive capacity and differ in predictability and traditionalism of ideas, NFCL can be expected to be related to the preference for specific media, genres and channels. In view of the potential relevance of the Need for Closure and the fact that NFCL has not been linked yet with media and program preferences, the objective of the current study was to shed some light on the relation between personality and preference for (un)structured, (un)predictable and (un)traditional media and genres by incorporating NFCL.

The personality characteristic Need for Closure (NFCL) reflects the desire for clear, definite, or unambiguous knowledge that will guide perception and action, as opposed to the undesirable alternative of ambiguity and confusion (Kruglanski 1990). A high NFCL is a motivation to draw a conclusion quickly and terminate cognitive processing related to the issue (Webster and Kruglanski 1994). High NFCL individuals neglect new, alternative information and views different from their own because high accessible structures (like pre-existing knowledge structures or stereotypes) afford immediate closure (Ford and Kruglanksi 1995), Low NFCL individuals are sensitive to new, alternative information and competing, divergent views when closure is "in danger" of forming. The main idea behind the NFCL theory is that individuals with a high NFCL level experience a negative feeling when closure is threatened and a positive feeling is evoked when closure is attained or facilitated. The motivation to avoid these negative feelings prompts activities aimed at the acquisition of closure and consequently biases the individuals choices and preferences toward closure-bound pursuits (Kruglanski and Webster 1996).

Based on previous research on NFCL on the one hand and the characteristics of particular media types on the other (TV viewing and listening to the radio are cognitively less demanding, more predictable and linearly structured compared to leisure activities like reading and Web surfing (Eveland and Dunwoody 2002, Eveland 2003, Spencer, Seydlitz, Laska and Triche 1992)), we expect that high (versus low) NFCL individuals watch more TV, listen more to the radio and to music, read less magazines and newspapers and spend less time surfing the Web. Furthermore, we expect that young adults with the same NFCL level have a preference for similar scopes of channels and genres across media. More specifically, we argue that high (versus low) NFCL individuals prefer more structured, predictable and traditional channels and genres.

In total, 1350 young adults (age between fifteen and twenty four), who were randomly addressed in a shopping mall or street, agreed to complete our questionnaire containing questions on their media behavior and need for closure levels. Furthermore, a panel of three independent judges who were unaware of the subject of the study, rated the newspapers, TV channels, radio channels, magazine types, TV program genres and music styles listed in the questionnaire on degree of cognitive stimulation, conventionality and predictability by ($\alpha$=.82).

Statistical analyses showed no significant difference for the amount of watching TV, listening to the radio or to music on weekend or weekdays, while significantly more low NFCL respondents read newspapers, read them on a more regular basis, are more likely to use the Web, use it more frequently and have a longer history with Web surfing. Furthermore, high NFCL individuals have a higher preference for light entertainment and TV guides; national music, and pop music, whereas low NFCL individuals prefer fiction, general news, science and alternative information/entertainment magazines, and alternative and street music. Moreover, high (versus low) NFCL individuals have a higher preference for more popular and straightforward newspapers, and vice versa for intellectual and alternative newspapers. Finally, high NFCL individuals rank ordered commercial, family TV and commercial pop/techno or family radio higher, whereas low NFCL consumers assigned a higher rank to intellectual and comedy/movie related TV channels and alternative or classical radio.

These results confirmed that high NFCL individuals are in favour of popular, straightforward, cognitive less constraining genres irrespective the medium that is under consideration, whereas low NFCL individuals prefer alternative, unpredictable, and intellectually stimulating things regardless the medium.

In general, our results show that the content of the medium is important rather than the delivery system. Although previous research would suggest that the choice of a particular medium is personality driven (e.g. Finn 1997; Henning and Vorderer 2001), it seems like different personality types can satisfy their needs in similar media (cfr. Cohen 2002; Schwartz and Fouts 2003; Weaver, 2003), McIlwraith (1985) also concluded that personality and preferred media content are associated rather than the particular medium (movies, books and music). Both the rejection of our "medium related" hypothesis and the confirmation of our "content related" hypothesis suggest that the medium itself has little to do with cognitive processes. Rather, the same medium could satisfy the needs of different personality types through very different content.

# When I Grow Up: The Moderating Role of Aspiration in Intergenerational Code-switching

Sangwon Lee, University of Central Florida, USA
Carolyn Massiah, University of Central Florida, USA

## EXTENDED ABSTRACT

Code-switching refers to the practice of mixing languages, such as English and Spanish, within a sentence, a common practice among bilingual consumers (Myers Scotton 1983; Luna and Peracchio 2001, 2002, 2005abc). Existing research within the marketing literature examines the impact of code-switching on the persuasiveness of advertising messages directed at bilinguals (Koslow, Shamdasani and Touchstone 1994; Luna and Peracchio 2001, 2002, 2005abc). Specifically, the direction of code-switching has been studied primarily among bilingual consumers. For example, minority language (e.g., Spanish) slogans switching to the majority language (e.g., English) result in greater persuasion than majority language slogans switching to the minority language (Luna and Peracchio 2001, 2002, 2005abc).

The current study extends existing bi-lingual code switching research in the following two ways. First, existing bi-lingual literature (Luna and Perrachio 2005) investigates the code switching effect at the *group-level* (e.g. Majority and minority language speaking populations). However, the current research also investigates the consumer's reaction to code-switched ads driven by an underlying, *individual-level,* construct; aspiration level, and tests the role of aspiration as a moderating variable between code-switching and attitude toward the ad (Aad). Also, the current research contributes to the code-switching literature by introducing a social theory (aspiration) to the previous sociolinguistic treatment (e.g. Markedness Model, Accommodation Theory) of code switching.

According to bi-lingual code-switching research, the activation of the majority language culture and schemas (e.g. English) will lead to positive evaluation because minority language speakers (e.g. Spanish) have more positive associations with majority language and culture (e.g. English) and want to belong to a majority society (Luna and Peracchio 2005a, Luna and Peracchio 2005b). However, the current research suggests that majority language and culture schemas (e.g. older adults use of the standard English) in an intergenerational context will lead to negative evaluation because minority, or rather contemporary, language speakers (members of generation Y) may react unfavorably towards authority and disrespectful towards a majority (older adults) (Lauer 2006). The present research investigates the effect of values ("aspiration") on attitudes toward different language varieties used in advertising in intergenerational context.

In exchange for extra credit, 170 undergraduate Business students at a major southeastern university participated in the experiment. Subjects were provided with two different kinds of questionnaires that manipulated code switching direction with scenarios. Study 1 has two main purposes: 1) to test whether standard-to-contemporary English code switching in ad slogan will lead to more positive attitude toward the ad than contemporary-to-standard English code switching; and 2) to examine if aspiration moderates the relationship between code-switching and Aad.

A between subject experiment was conducted in which two factors were examined (2 x 2 ANOVA): code switching (standard-to-contemporary code switching or contemporary-to-standard code switching) and aspiration level (high or low). The code-switching factor was manipulated while the aspiration was measured. Older adults' formal English was designated as the standard English and Generation Y's simplified English as the contemporary English. Code switching was manipulated by two different scenarios respectively.

Study 1 results provide empirical support for the notion that for Generation Y, standard-to-contemporary code switching direction will lead to more positive attitude towards the ad (Aad). This research hypothesized direction effect with salience or marked contemporary English. Standard-to-contemporary code switching makes the contemporary language portion salient, or marked, as compared with the standard English, thus activating a Generation Y language and culture schema, which is related to with more positive association. This is an interesting result. Common thought would suggest that, if Generation Y prefers contemporary English, more contemporary English in advertising messages would lead to positive responses. Our findings show the counter-intuitive results. The results show that having one or two salient contemporary words in an advertising message leads to a more positive response from Generation Y than having many less salient contemporary words in an ad message.

Study 1 also supports the notion that aspiration level for the position of older adults moderates the relationship between the code-switching and Aad such that a high level of aspiration for the position of older adults leads to more positive Aad toward contemporary-to-standard code switching and more negative Aad toward standard-to-contemporary code switching. The hypothesized moderating role of aspiration is based on research which demonstrates that the individual's aspiration level would assimilate with the aspiration group. The individual's wish to belong to an aspiration group makes a positive self-standard language connection if he or she perceives that an aspiration group uses standard language. Thus, the more Generation Y members wish to belong to an older adults' group, the more their attitude is positive toward the ad message which has salient standard English (contemporary-to-standard). The current research suggests that even in the same code-switching direction, the impact of code-switching can be stronger or weaker depending upon each individual's aspiration level.

This research extends the existing code-switching literature by identifying an underlying individual level construct, aspiration level, which acts to explain or influence the effects of code switching. In the existing code switching literature, the framework presented is meant to be applicable to all situations in bi-lingual groups as a whole. The key questions here are, "Does code switching direction effect apply to all bi-linguals to the same degree? Is the consumer's cognitive or affective reaction to code switching driven by an underlying individual-level construct?" The current research extends the existing bi-lingual code-switching literature by examining aspiration as an *individual level* construct which explains the different effects of code switching. Additionally, in the socio linguistic and code switching applications, the Markedness model has been used mainly in multi-lingual socio-linguistic context and has been examined through how bilinguals produce code switched utterance. In our research, the Markedness model is extended to the perception of uni-lingual communication within an intergenerational context in an experimental setting. An aspiration level explanation is also offered in our application of the Markedness model.

# FILM FESTIVAL

### "Disney Dreams in China"
*Eric Li, York University, Canada*
*Russell Belk, York University, Canada*
*Annamma Joy, Hong Kong Polytechnic University*

This research explores the meanings of "Disney Magic" in the new Disneyland theme park–Hong Kong Disneyland (HKDL). Our study investigates the translation of Disney Magic in HKDL and its the degree to which it is perceived this way among consumers. It finds that for Mainland Chinese visitors, Disney Magic is the key template for their experiences at the theme park and they come with a set of expectations conditioned since childhood exposure to Disney movies and cartoons. They seem willing to follow the carefully structured and mapped fantasy realization of their childhood dreams and report that they attain the ultimate goal of their trip–happiness.

### "Cross Border Shopping: Family Narratives"
*Raquel Castano, Tecnologico de Monterrey, Mexico*
*Maria Eugenia Perez, Tecnologico de Monterrey, Mexico*
*Claudia Quintanilla, Tecnologico de Monterrey, Mexico*

Cross border shopping is a common practice for Mexicans who live in cities near the US frontier. Through the examination of family rituals that are passed down from generation to generation and which construct family identity, and in the context of the concepts of globalization and malinchismo, this videography provides a framework on the experience of cross border shopping. Essentially this experience is constructed on narratives that move beyond the simple description of experienced events to provide explanatory frameworks and emotional evaluation of what these events mean to the individual. In-depth interviews with three generations of Mexican women were conducted.

### "Hoarding Behavior & Attachment to Material Possessions"
*Tresa Ponner, University of Sydney, Australia*
*Hélène Cherrier, University of Sydney, Australia*

In a society where buying new products is cheaper and easier than repairing, it is not surprising that much of consumer behavior has focused on the pleasures associated to a 'throw away society'. Intriguingly, informants in this study spoke about the utter joy they received in finding, keeping and passing on objects. They defined themselves as functional hoarders, individuals who accumulate objects privately

and are unable to dispose without clear conscious motivation or control. Through the use of video ethnography the dynamic nature of possession attachment and its obstruction to disposal practices is illuminated.

## "Stay-at-Home Dads Unite: Coping with Stigma and Isolation"
*Gokcen Coskuner-Balli, University of Wisconsin*

Based on video ethnographic research at Stay-at-Home Dad (SAHD) playgroups, 2006 SAHD convention and in-depth interviews, this film explores the challenges SAHDs face as they undertake the primary caregiver role and the strategies they employ to negotiate their gender positioning vis-à-vis more hegemonic masculinities. While prior CCT research has mainly studied consumption communities (e.g. Salomon snowboarders, Cova and Cova 2002; Apple computer users, Schau and Muniz 2002; Harley Davidson bikers, Schouten and McAlexander 1995) for what they do for individuals, the film discusses SAHDs' organized activities as collective efforts to transform what it means to be a man and a father.

## "Living a Theme"
*A. Fuat Firat, University of Texas-Pan American, USA*
*Ebru Ulusoy, University of Texas-Pan American, USA*

This video studies thematization, a phenomenon that has attracted much attention. Themed environments are all around us and there is an interest in knowing why this is a phenomenon of our time. The video raises the question as to whether this is a phenomenon of our time or a phenomenon that has been with us for a long time.

The video begins with images from Las Vegas, exploring the different sites and people's reactions. This phenomenon of people visiting, enjoying and appreciating themed environments, recognized by many astute observers of contemporary culture has resulted in a respectable sized literature, and several theses have been advanced. These theses are briefly reviewed in the video.

Two themes that are common to many of these theses are that (1) thematization is driven by corporations and (2) contemporary consumers are accomplices in the theming of the world. Davis (1999) sees theme parks as models of reality that identify issues that need solutions, and that also provide corporations with opportunities to have philanthropic answers to world's problems. Gottdiener (2001) further argues that many old themes are recycled in present day theme parks in which people find comfort and seek to actualize their consumer selves. Sorkin and colleagues (1992) see theme parks as the privatization of public space as well as a regulated and pleasurable substitute for the democratic realm. Ritzer (2004) also sees theme parks as centrally created and controlled, as spaces where space, things and people lose any personality becoming generic followers of scripts. Beardsworth and Bryman (1999) introduce the concept of quasification to emphasize that both those who engineer and those who purchase themed spaces are active and knowing accomplices. Finally, Baudrillard (1988) presents a postmodern perspective, where themed spaces are seen as timeless–that is, without a past, present or future–places that don't simply simulate reality, they constitute the real as the theme park–reality becomes the theme park.

The video then moves to EPCOT (the acronym for Experimental Prototype Community Of Tomorrow) Center, a theme park within Walt Disney World in Orlando, Florida, especially its World Showcase section featuring several countries of the world, to show segments from interviews with visitors to find out how they feel about themed environments. In these segments we find that many visitors have visited EPCOT several times and that they enjoy and appreciate the experience of visiting different 'countries'. It is seen that people do not seem discomforted by thematization, rather they see EPCOT as an experience of different cultures and places.

To explore why, the video continues with a visit to a city in Texas, San Antonio. This is a city that has become a tourist destination due to the historic site of the Alamo, but also because of the fact that the city's heart is built around the San Antonio Riverwalk. Many parts of San Antonio that can be considered to be themed areas are visited and observed, and it is noticed that these were not created as themed spaces, but as places for people to live in. The video shows people, tourists and residents of San Antonio, in their daily activities at these sites.

The video moves back to EPCOT Center where further segments from interviews indicate that people who visit EPCOT Center do not seem to be keen on making a distinction between theme parks and the world 'outside'. Then, images from many places, all around the world that can be seen as themed spaces are exhibited. The point is made that all of our humanly constructed environments are themed. Images from New York and Phoenix are displayed to further make this point.

The video concludes that intellectuals and scholars are more dedicated to maintaining a distinction between the thematic and the everyday, between the 'real' and the 'fantasy' than are lay people. It is suggested that this promises to be a fruitful issue to investigate.

## "Luxury Value Pyramid: What are the Dimensions of Luxury"

*Junko Kimura, Hosei University, Japan*
*Hiroshi Tanaka, Hosei University, Japan*

This study aims to investigate the meaning of luxury to consumers. Luxury goods tend to be interpreted synonymous to excessive or conspicuous consumption. Solomon (2007) argued for a division of consumers into three groups based on their attitudes toward luxury: (1) Luxury is functional. (2) Luxury is a reward. (3) Luxury is indulgence. He claimed that as consumers' age, the more they required functional dimensions to luxury items. Although we agree with his theory as far as it goes, we believe that it does not go far enough. After conducting extensive in-depth interviews with female consumers in the United States and Japan, in which we explored the meaning of luxury, we created a luxury value pyramid consisting of luxury's dimensions.

## "Consumer Innovation in Online Computer Tuning Communities"

*Johannes Gebauer, University of Innsbruck, Austria*
*Johann Füller, University of Innsbruck, Austria*

This movie introduces joint innovation creation activities in computer case molding and over clocking communities. Our documentary aims to provide in-depth insights into creative consumer behavior in online communities -beyond pure cognitive understanding -capturing emotions, gestures, and impressions of computer tuning valuable to get a deep understanding of online consumer innovation. The film explores why consumers modify and even create new computers. Further, it sheds light on the role of online communities during innovation creations and in the meaning and relevance of self-created computers for their builders. Our findings are based on 12 in-depth interviews conducted at the Games Convention in Leipzig, Germany in August 2006.

## "Body and Appearance Perceptions of Latino Youth"

*Samuel Doss, University of Texas–Pan American*
*Ebru Ulusoy, University of Texas–Pan American*

The "body" has been a focus of many philosophical and sociological debates. In modernism, "mind" was a more privileged attribute than "body." With the emergence of postmodern consumption conditions, the concept of the body acquired new meanings and importance. Additionally, perceptions of body by people in the consumer culture are getting more complex as it becomes the focus of many marketing practices. Marketing practices use and shape the perceptions of the body through advertising. Additionally, for consumers, body's relation with the concepts of self and pleasure makes it an important aspect of consumer culture. Studies examining the body and its perceptions are currently attracting scholars from different fields of social and behavioral sciences.

According to Gallagher (1986), body image is a complex phenomenon with at least three aspects: perceptual, cognitive, and emotional. In consumer society, it is this complex phenomenon that plays the determining role in the evaluation of the self. Turner (1994) argues that the surface of the body is the target of advertising and self-promotion, and body surfaces themselves are sites of stigmatization. According to Featherstone (1991), who states the notion of the body as a vehicle of pleasure and self-expression, "images of the body beautiful, openly sexual and associated with hedonism, leisure and display, emphasizes the importance of appearance and the "look""(p.170).

In the complex cultural context of consumer society, subjects are subject to many sociocultural influences (Thompson and Hirschman 1995). Today, extensive amounts of products and services related to the body are globally promoted by marketers. Joy and Venkatesh (1994: 337) propose:

> "Looking around us, we see the full force of marketing linking the body to numerous products and services–perfumes, fashion, clothing, dining, all kinds of sensual and pleasurable objects, exercise machines, fitness centers, dietary products, cosmetic surgical procedures and the like."

With the commodification of body, the body became something to be consumed through fashion, body modification, overall image and style. Thus, it became a part of production and reproduction of a desired identity by individuals (Velliquette and Bamossy 2001). In consumer culture, body and its parts have many symbolic meanings (Schouten 1991, Belk and Austin 1996). These symbolic meanings are the orientations for consumers to play with/alter their bodies and appearances. Regarding the symbolic perspective, "The term "body maintenance" indicates the popularity of the machine metaphor for the body. Like cars and other consumer goods, bodies require servicing, regular care and attention to preserve maximum efficiency." (Featherstone 1991: 170).

With the emergence of postmodern consumption conditions, specifically fragmentation, the body became to be perceived more in terms of its parts rather than being perceived as a whole. Consumers' fragmented perceptions are also substantiated by the fragmentation in the marketing activities that are promoting different products and services addressing different parts of the body. Firat and Dholakia (2000: 84) state this postmodern condition as:

> "Each body part-the lips, the hips, the thighs, the abdomen, the chest- is considered separately, each as a means of enhancing a required or desired image. In the process of (re) shaping or (re)dressing each body part, with marketability in mind in each there is a decontextualization of body parts and their perception as distanced from the individual's own being."

Taking these theoretical perspectives into consideration, we in-depth interviewed nine Latino students from The University of Texas-Pan American concerning their thoughts and feelings about their bodies and appearances. We also questioned their views of external influences, their ideal appearance, and what and how they change their appearances in regards to positive and negative considerations. The results of the interviews showed that interviewees' body and appearance perceptions are mostly influenced by their families and friends, their moods are closely related to how they feel about their bodies and appearances. The results also showed that bodies and appearances are considered fragmented, mostly in terms of clothing, weight and exercise, hair, and body ornaments.

## "The Responsibility of Respect in the Marketplace: Opening Doors for Community"

*Carolyn Costley, University of Waikato, New Zealand*
*Lorraine Friend, University of Waikato, New Zealand*

The literature says little about respect as it pertains to the marketplace. Four cases from creative industries tell of how they live respect. Their stories reflect both provider and consumer perspectives. They feel responsible to accept individuals and protect people who walk through their doors. They call it respect; they think it should be the norm; and they expect it in return. They lived respect in listening and being heard, in empathizing and being understood, and in being considerate, honest and looked after. Although not mutually exclusive, the themes help us begin to craft a theory of respect's responsibility well-being.

# ROUNDTABLE
# Introduction to Structural Equations Models and Lisrel

**Discussion Leader:**
Dawn Iacobucci, Vanderbilt University, USA

**Participants:**
Pankaj Aggarwal, University of Toronto, Canada
Simona Botti, London Business School, UK
Katherine Burson, University of Michigan, USA
Jennifer Escalas, Vanderbilt University, USA
Americus Reed, University of Pennsylvania, USA
Breagin Riley, Northwestern University, USA
Nicole M. Verrochi, University of Pennsylvania, USA

Forty-five marketing scholars attended a two-hour Sunday morning session during which structural equations models (s.e.m.) were introduced. The session began with an overview motivation regarding when s.e.m. models are appropriate, how they are extensions of regression models and factor analytical models, etc. Three major classes of models were presented: confirmatory factor analysis, path models, and their combination in the full structural equations model. The models were discussed conceptually, and Lisrel syntax offered and explained for each. Advanced topics were also discussed, including how to incorporate moderators into s.e.m. models, how to look at mediations, what fit indices are expected to be reported, and briefly, how to think about multi-group analyses.

# Defining and Exploring Exorbitant Buying Behavior

**Discussion Leader:**
Alvin C. Burns, Louisiana State University, USA

**Participants:**
Stacey Baker, University of Wyoming, USA
Russell Belk, York University, Canada
Mousumi Bose, Louisiana State University, USA
Ronald Faber, University of Minnesota, USA
Judith Anne Garretson Folse, Louisiana State University, USA
James Gentry, University of Nebraska , USA
Thomas O'Guinn, University of Wisconsin, Madison, USA
Nancy Ridgway, University of Richmond, USA
Dennis Rook, University of Southern California, USA
Ann Veeck, Western Michigan University, USA
Lan Wu, California State University, East Bay, USA

Why do consumers have ten pairs of black shoes or fifty t-shirts or fifteen fishing rods? Questions like these have motivated us to explore "heavy" buying behavior more carefully and have led us to identify a phenomenon that we believe is different from those that have been studied earlier: compulsive buying, impulsive buying, excessive buying, collecting, fixated buying or conspicuous buying. Preliminary exploratory qualitative research has led us to define exorbitant buying as: An extensive buying of goods to augment one' inventory of goods (of a certain category such as shoes, clothing, tools and electronic equipments), for which a logical justification, defensible in the mind of the buyer, exists.

Moreover, based on our preliminary research, we have identified some key elements that characterize exorbitant buying:

- More articulated needs per product category and average or more products per articulated need.
  - o Owing to more refined preferences.
  - o Ever expanding list of needs to be acquired (exacting in the way products are differentiated).
  - o Elaborate consumption vocabulary.
- An insider-outsider phenomenon where the insider justifies the need for a product while the outsider deems it superfluous.
- A sense of being prepared and in control in response to current or anticipated event(s).
- Variety seeking based on needs.
- High self-control in terms of shopping.
- Active and purposive search for products.
- Short span of consumption of products:
  - o May have unused ones.
  - o Like to move on.
  - o Older products used sometimes/selective usage.
- No pronounced feelings of regret or guilt on the part of the buyer.
- May or may not lead to financial stress.

The roundtable was organized to present the above findings, to understand whether the participants agreed to the general definition of exorbitant buying and to know whether they recognize this phenomenon separate from all others that have been studied before. To this end, a pre-roundtable discussion was initiated amongst the participants and a summary of the discussion was also presented at the roundtable. The roundtable panelists comprised of members who are experts and have interest in the various types of buying that have been mentioned earlier.

The roundtable members acknowledged that exorbitant buying is a phenomenon different from all other forms of heavy buying that have been studied earlier and merits further investigation. However, the members suggested that the name "exorbitant" was value-laden and may hold different meanings for different people. Therefore, they suggested that the name should be changed to highlight the refined and articulated needs of the buyers. Some potential names may be "Micro-discriminatory consumer," "minute-difference, variety-seeking consumer," and "fastidious consumer."

It was suggested that the definition as was presented might be viewed as that developed from an "outsider's" point of view and the insider (buyer) may have a different perspective. What may be considered average in terms of buying may be different for the buyer (insider) compared to the non-buyer (outsider). Besides, the definition should contain elements to distinguish it from other forms of buying. Following these suggestions, the definition has been modified and an insider's point of view has also been considered. A probable definition is presented: An extensive buying to augment one's inventory of certain product categories (clothes, shoes, electronics), for which buyers have highly differentiated and articulated needs within product categories and buy accordingly, to satisfy their needs for personal consumption.

Finally, the roundtable members agreed that this phenomenon should not be positioned with other forms of heavy buying such as impulsive, compulsive, excessive or fixated buying. The aforementioned buying types portray an image of lower self-control whereas the buying type discussed at the roundtable comprised of individuals with greater self-control. Hence, this form of buying should be positioned along with average buyers though these buyers possess certain unique characteristics not shared by average buyers.

To summarize, with the changes incorporated, there was overall agreement that this buying type has not been investigated before and further research is important to better understand it.

Forty-five marketing scholars attended a two-hour Sunday morning session during which structural equations models (s.e.m.) were introduced. The session began with an overview motivation regarding when s.e.m. models are appropriate, how they are extensions of regression models and factor analytical models, etc. Three major classes of models were presented: confirmatory factor analysis, path models, and their combination in the full structural equations model. The models were discussed conceptually, and Lisrel syntax offered and explained for each. Advanced topics were also discussed, including how to incorporate moderators into s.e.m. models, how to look at mediations, what fit indices are expected to be reported, and briefly, how to think about multi-group analyses.

# Philosophy and Consumption: Discussions on Trust and Brands

**Discussion Leaders:**
Janet Borgerson, University of Exeter, UK
Clara Gustafsson, Stockholm University, Sweden

**Participants:**
Olga Kravets, Bilkent University, Turkey
Susan Fournier, Boston University, USA
Kent Grayson, Northwestern University, USA
Douglas B. Holt, University of Oxford, UK
Breagin Riley, Northwestern University, USA
Jonathan E. Schroeder, University of Exeter, UK
Marie Taillard, European School of Management ESCP-EAP, UK
Tiffany White, University of Illinois, Urbana-Champaign, USA

Consumers' brand trust makes brands more powerful. Moreover, whereas trust is part of good relationships, trust relationships often involve vulnerability. Further, trust is inherently asymmetrical, suggesting profound consequences for its ethical communication. By approaching discussions on trust and brands philosophically, we expanded approaches to, and investigations into, trust's modes, manifestations, and mappings that offer potentially productive insights for consumer research. Past years' Philosophy and Consumption roundtables have focused on 1) issues of materiality and 2) epistemological and ontological foundations and inspirations for consumer research. In this year's roundtable, discussions continued with a focus on "Trust and Brands".

Trust is one of the crucial components creating meaning in consumer-brand relationships, and thus in the branding process (see e.g. Fournier 1998; Holt 2002). From a philosophical viewpoint, trust can be seen as "reliance" on another's "good will". This definition suggests that there is an uncertainty resting in the other, as one cannot know for sure whether the other is dependable. Further, one party may have to trust more than the other in a trust relationship (Baier 1994). Thus, one party may rely more heavily on the other party's willingness to treat her justly. In other words, trust is inherently asymmetrical, and this has profound consequences for the ways in which it can be communicated ethically (Gustafsson 2005). Moreover, trust in brands has raised questions of ethical considerations partially in response to a basic consumer reality: Consumers rarely see what is going on behind the surface of the brand (see Holt 2002). For instance, brands can use visual representation to create an image of trust. For example, bank advertisements often make visual reference to stability and history by the use of design and pictures that feature e.g. heavy pillars and ancient looking designs (see Schroeder 2002). From a corporate perspective on trust relationships, Grayson, Johnson, and Chen (2008) suggest that corporations have to develop individual trust relationships with customers no matter how much customers trust the business context of the firm. These findings have important implications for corporate communication of trust, and bring to the fore the question of what actually constitutes trust in business. Philosophical considerations allow epistemological and ontological assumptions and concerns to emerge, encouraging reflective discussion that incites recognition of integral intersections, including those between consumer research, the ethics of consumers' brand relationships and corporate social responsibility.

The most prominent discussion point was the meaning of the concept of trust, especially in relation to brands and in relation to consumer research on brand trust relationships. As researchers, we all have different ideas about what trust is; this is a constant question and there has been a constant controversy about it. Do we, as consumer researchers, need a common definition of trust and brand trust or can we all have different definitions? Looking at brand trust from the legal side, goodwill is a key word and the brand can be seen as an embodiment of trust starting with the trade mark. When trust becomes separated from the brand and built in its own right, agency becomes a related issue to brand trust. In other words, consumers' capacity to act in the world impacts on notions of relationships and materiality (Borgeson 2005), and intersects with brand trust as brands are not necessarily trustworthy. Looking at global brands with outsourced production, they have become increasingly questioned from a trust perspective over the last few years, critics suggesting that the only thing that is there for consumers to trust is a relatively empty logo (c.f. Holt 2002; Klein 2000), implying ethically dubious consequences of brand trust. Participants largely agreed that there are different qualities of trust, making it possible for different consumers to trust the same brand to do completely different things for them. In addition, brand trust in each brand is dependent on the consumers' personal history with that particular brand, several roundtable participants argued.

The interpersonal dimension is really what makes trust relevant and interesting to the social sciences, and it is an integral part of the trust concept, several participants argued. The consumer-seller relationship is crucial to brand trust. Starting from that relationship, we can unpack the concept of trust to explore what brand trust means. This could firstly entail deciding whether we are talking about trust as a verb (trusting behavior) or an adjective (trustworthy) because these two constantly get intermingled. Trust may be about exposing oneself to risks, making oneself vulnerable to others (Levinas 1985). The salience of risk to the concept of trust should be explored further. However, for certain, consumers do not always calculate risk. Further, when there is a large risk involved, people actually pay more rather than less for brands. To look at the foundations of trust we could look at trust from a historical perspective and at how different trust is in different countries. Moreover, when only one supplier is available, the trust in that one supplier surprisingly tends to be very strong. In addition, often trust seems to become apparent or to come into existence only when it is tested. Thus, the brand trust becomes apparent, grows, or breaks, with *use* rather than at the time of purchase. Perhaps uncertainty is a better word than risk to describe an important

antecedent of trust. Then trust becomes an outcome of dealing with uncertainty. As discussions centered on trust and brands, the aim of this roundtable remained to open further philosophically aware investigations into the concepts and practices of trust and brands within consumer research.

ROUNDTABLE
# Internet Tracking and Clickstream Data: Methodological Issues

**Discussion Leader:**
Maureen Hupfer, McMaster University, Canada

**Participants:**
Anne-Francoise Audain, Group ESC, France
Ulf Bockenholt, McGill University, Canada
Brian Detlor, McMaster University, Canada
Andy Edmonds, FreeIQ.com and Smart Marketing Inc., USA
Dan Goldstein, London Business School, UK
Umar Ruhi, McMaster University, Canada
Sylvain Senecal, HEC, Canada
Gunter Silberer, University of Goettingen, Germany
Valerie Trifts, Dalhousie University, Canada

The theme of this year's ACR conference was building bridges. Our roundtable was in a unique position to build such bridges by fostering discussion and collaboration among industry and academics from two different disciplines (marketing and information systems) at all levels of the professoriate. Session participants communicated via email and through the ACR Knowledge Exchange Forum before the conference and some were able to meet for informal discussion before our scheduled session. In addition, participants indicated their interest in furthering the discussion after the conference by posting to the Knowledge Exchange.

We began by discussing the different types of navigational and tracking data that could and/or should be collected and noted that researchers and practitioners now are focusing more closely on clickstream rather than only Web log data. Sen, Dacin and Pattichis (2006) note the remarkable growth rate in the market for web analytics, but they also assert that most firms underutilize clickstream data because of a) data problems, including incomplete, messy and very large files; and b) too many analytic methodologies, including web-based, marketing metric, navigational and traffic methodologies. Our group agreed that both absolute data (e.g., number of pages visited) and relative data (e.g., comparison of the proportions of pages visited across sites) are useful, and that invariably second-order measures must be calculated from first-order data such as time per page or number of revisits. Some participants expressed interest in examining successful task completion of either information gathering or actual purchase whereas others were more interested in sequences of behavior (Hilbert and Redmiles 2000). We also discussed the usefulness of second-order measures of "linearity" or "lostness" (Smith 1994) in helping to understand individual's navigational styles and the desirability of linking mouse clicks with eye-tracking. The group noted the difficulties posed by tabbed-browsing, and were informed that the new version of FireFox will have a session id built into the history file. New methods of tracking use client-side logging to the server. In addition, the difficulty in recording the exit of a page has now been addressed with an auto PING feature that will allow the browser to send a final event to the server.

Next, we considered the best methods for analyzing this non-normal count and proportion data and determined that logistic regression, generalized linear models, cluster analysis and Bayesian methods should be used as appropriate for the particular metric (Bapna, Goes, Gopal and Marsden 2006). We also discussed the need to understand rather than simply describe online behavior. Various tactics are being used to produce this deeper understanding, including the linking of tracking data to that which pertain to individual differences in cognitive styles, Internet and topic expertise; video capture; and the collection of think-aloud protocols or interviews to try to determine if individuals are engaging in cycles of search or are hitting "dead ends".

We spoke about methods for linking various data sources, and how this could be best accomplished while respecting participants' privacy. Session cookies are of limited value in that they do not permit the collection of data pertaining to an individual over an extended period of time. However, the assignment of a unique participant ID and the development of individuals' profiles over time could compromise their privacy. Even with large scale search log data bases, the potential exists for identifying individuals if the search parameters are idiosyncratic, as the AOL fiasco in the summer of 2006 demonstrated (Barbaro and Zeller 2006; Hansell 2006; Zeller, Jr. 2006). Academics, industry analysts and privacy advocates also have raised concerns about the vast amount of data that is collected using passive devices, such as adware, cookies, spyware and Web viruses, to record online behavior (Marshall and Swartwout 2006). Such calls for privacy protection are warranted. One participant pointed out that data could be made anonymous if a random number generator were used to introduce "noise".

We briefly touched on methods for distributing incentives to remote participants. Draws for gift certificates or other cash prizes were found to work well. In addition, a professional Mass Pay account can be set up so that participants can be remunerated through PayPal. Short HITs (Human Intelligence Tasks) also can be set up on Amazon's Mechanical Turk (http://www.mturk.com/mturk/welcome).

We concluded our session by speaking about opportunities for further contact between academics in marketing and information systems with practitioners and consultants. The ACM World Wide Web conference (W3C) (www.2008.org) was recommended as a conference with substantial practitioner presence. The General Online Research (GOR) forum (http://forum.questionpro.com/jforum/forums/show/2.page) also may provide a point of contact for academics and practitioners. Finally, the group indicated that they were most interested in applying their findings in the spirit of transformative consumer research by, for example, helping consumers to navigate more efficiently, read and understand privacy policies, and make better use of online decision-making aids.

# Conducting Consumer Research in India and China: Issues, Challenges and New Directions

**Primary Organizers:**
Humaira Mahi, San Francisco State University
Giana Eckhardt, Suffolk University

**Participants:**
Anders Bengtsson, Suffolk University, USA
Rajesh Bhargave, Wharton, University of Pennsylvania, USA
Dipankar Chakravarti, University of Colorado, Boulder, USA
Haipeng (Allan) Chen, Texas A & M University, USA
Rosana Vieira de Souza, Brazil
Shan Feng, Drexel University, USA
Doug Hausknecht, University of Akron, USA
Ying (Annie) Jiang, University of Ontario Institute of Technology, Canada
Anjala Krishen, University of Nevada at Las Vegas, USA
Jing (Jill) Lei, University of Ontario Institute of Technology, Canada
Xuiping Li, National University of Singapore, Singapore
Ashesh Mukherjee, McGill University, Canada
Raj Raghunathan, University of Texas at Austin, USA
Sridhar Samu, Indian School of Business, Hyderabad, India
Rajiv Vaidyanathan, University of Minnesota, Duluth, USA
Jeff Wang, City University of Hong Kong, Hong Kong
Xin Zhao, University of Hawaii at Manoa, USA

While cultural research in consumer behavior has examined consumers in India and China, there are many unanswered questions, especially with regard to how the rapid changes occurring in these markets are affecting consumption practices. The way consumption occurs in these markets has fundamentally changed in a short period of time, giving researchers an unprecedented opportunity to document how consumer cultures evolve and how consumer learning occurs.

This roundtable session was organized to examine some of the challenges and issues facing consumer researchers while conducting consumer research in these two countries. We conducted pre-conference discussions via an online group forum, used ACR's knowledge exchange website for some discussions, and had an informal meeting at the ACR reception on Friday to meet participants before the roundtable session.

We identified some key questions to begin our discussions:

1. Ontological/theoretical:
   a. Can we successfully use established consumer behavior theories or do we need to develop new ones to understand the consumption contexts found in China and India?
2. Methodological:
   a. What are some of the methodological hurdles in collecting data in China or India? What are some useful techniques to overcome them?
3. Expanding the Respondent/Subject Base:
   Consumers both in India and China are spread across a large spectrum of socio-economic differences. The focus in research has just now started shifting from focusing solely on the middle class, urban consumers. What are some specific challenges and insights that may come with researching BOP (bottom-of-the-pyramid) consumers?

Online participants (almost forty participants) asked whether theories from a Western Cartesian mindset can be used to gather and assess meaning-making processes in these cultures without bringing in a major cultural bias. Some researchers were interested in discussing the significance of historical influences and unique cultural aspects such as the caste system in India and its influence on present day consumption. Others wanted to know whether consumers in these countries exhibited any tensions in embracing consumption i.e. whether consumers thought that new products were a 'cultural invasion from the West.'

At the roundtable there were 19 participants, and we began our discussion by examining whether we were studying consumers in China and India to develop new theories, or whether these were just new contexts and therefore interesting only for that reason. Opinions on this were divided. Researchers working in cross-cultural research were of the view that cross-cultural studies using the same theories across cultures are a start at understanding the differences across cultures. Researchers that engage in cultural research were of the view that cross-cultural research ignores key cultural nuances and hence does not capture the essence of a culture and its uniqueness by using the same theory or methodology across cultures. Instead, the view was that studies in specific countries should focus on understanding the unique cultural nuances there to build theory from the ground up. This led to a broader discussion on the way to capture these cultural nuances best which led to questions about methodology.

Some researchers were of the belief that without interpretive and qualitative work, it would be difficult to understand the local conditions that affect consumer behavior and hence the research would not be very informative. Other researchers felt that in some areas,

it may be worthwhile to begin with quantitative studies based on existing theories and then to slowly adapt existing theories to the new cultural contexts. Some participants were of the view that agnosticity towards research methodology might be a good approach–wherein any method that elicits more information about the consumer's motivations and underlying biases would be used to inform the design of the study and data collection. In this context, the use of qualitative methods used first to inform theory and then subsequent use of quantitative methods if needed was thought to be useful. Also, a key point to come out of the methodological discussion was for researchers to document the methodologies that they are employing to overcome data collection hurdles in China and India and to publish them so other researchers will have access to this information. Also related was a question about human subjects protection protocols in these countries and an understanding of these issues on the part of researchers working there. Researchers need to work closely with their universities to clarify human subject study rules and protocols before starting fieldwork.

From a substantive perspective, we discussed whether cognitive abilities differ in cultures like China and India where choice is constrained because the economies are still developing. Some researchers are examining economically constrained classes of consumers. The view was that it would be useful to understand how consumers that have constrained choice sets and smaller endowments engage in consumption. Also relevant is the question of how consumers that cannot engage in consumption are coping with the new choices available in the market. Also, from a motivational perspective, we discussed the potential for conflict between old and new values. Studying how this impacts consumer behavior was thought to be useful.

Finally, participants felt that this discussion should continue at future ACR conferences and should expand to include other transitional economies around the world. We agreed to continue the online discussion forum, and to discuss adding other emerging markets in the future.

In sum, the on-the-ground reality of conducting research in these markets is still one of great difficulty, from logistical, methodological and theoretical points of view. Discussion needs to continue to take place on issues such as the best ways to collect data, and the dialogue needs to continue.

We will expand the online forum to discuss these and other ideas on an on-going basis, and add more participants as we move forward. In addition to providing insights and creating a robust discussion on the topic, this forum will provide direction to younger and newer researchers and allow researchers in this area to meet other interested researchers and foster possible co-authorships and collaborations. The number of people working on issues relating to China or India within consumer research is still relatively small, hence, it would be immensely beneficial to have this type of network available for sharing ideas and for providing opportunities for potential collaboration.

# ROUNDTABLE
## Interrogating Fashion: Fashion Cultures and Fashion Discourses

**Discussion Leaders:**
Annamma Joy, Concordia University, Canada
Diego Rinallo, Bocconi University, Italy

**Participants:**
Alice Chu, The Hong Kong Polytechnic University
A. Fuat Firat, University of Texas-Pan American, USA
Lynne Nakano, Chinese University of Hong Kong
Michael Solomon, St. Joseph's University, USA
Alladi Venkatesh, University of California, Irvine, USA
Luca Visconti, Bocconi University, Italy

This round table session is a follow-up on the round table held at the European Association of Consumer Research, Milan, on the topic "Fashion cultures and Fashion discourses" The prime purpose is to interrogate all aspects of fashion –its past, its present and its future. We also hope to pursue this further with a special issue on the topic in *Consumption, Markets & Culture*. At the outset we want to specify that for a topic this broad, we include a caveat–that materialism and society are indelibly entwined. A multi-disciplinary and cross-cultural approach allows us to tie together the different strands that form the world of fashion.

We outline some key themes that may be pursued for this roundtable discussion although fashion cannot be circumscribed in such a manner. These are by no means exhaustive but they provide some contours as starting points:

(1) Fashion reveals. Marcel Mauss once described fashion–the way we dress and accessorize ourselves–as techniques of the body that reflect not only how we want others to view us but also how we see ourselves. Judging by the number of bestsellers on the topic, it seems that we can't get enough of "the fashioned body." But, fashioning the body and reflecting fashion with the body are two subtly different concepts.

(2) Fashion makes social statements. Designer brands (e.g., luxury and /or trendy labels) provide a sense of worth, place and self-expression. According to Erwing Goffman, what we choose to wear pantomimes a performance of everyday life, one in which we focus on materials and images as a way of negotiating the boundaries between who we are and our surroundings.

(3) Fashion labels. Styles encourage stereotypes. It draws us into the cultural practice of judging by appearances yet does not resolve the ambiguity of what a particular look means. Appearances could be one thing, identity something else. Dress and decoration do not always "speak" or even need to be "read."

(4) Fashion sells. Couture drives a multi-billion-dollar industry, a global phenomenon–but not necessarily a western phenomenon. However, the historical development of the fashion industry in the West meant that at times, in the name of profit-making, purveyors of styles have deemed it necessary to downplay or obscure altogether the country of origin (e.g., East Asia), where most of the clothes manufacturing occur. Nonetheless, fashion is part and parcel of global capitalism and the divide between global and the local in this fluid industry is never clear-cut.

(5) Fashion is sexy–and sexist. Dressing the female body commonly occurs as the result of a male's ideal of femininity and beauty. That said, times, like fashion, they have been a-changing. Some power suits look more formidable in heels and can be playful, esthetic and empowering. At the same time men have encountered similar problems with male beauty ideals and so on. Gender is no longer the central issue here.

(6) Fashion, by its own definition, is perpetual change and metamorphosis, feeding on the consumer's predilection for everything and anything new, different and interesting. In this industry, "new" could quickly turn passé, while "old" becomes hip "retro" and "vintage."

(7) Fashion defies boundaries. The trend toward a multi-cultural fashion regime has somewhat blunted the dominance of the West in defining style since international, ethnic, alternative, and street fashion have all paraded down Europe's runways. But could these "exotic" looks and images be anything more than stereotyped versions of the "other?" On the other hand, the editors of *Fashion Theory* have defined fashion as "the cultural construction of embodied identity."

(8) Intentionally, "anti-fashion" offers an alternative to the dominance of *Haute Couture*. On its own, anti-fashion could be *avant-garde*. It could also be counterproductive if the rebellious designers were only perpetuating Western couture's ideal of "*dress* (as opposed to *fashion*) from the rest of the world."

(9) Fashion has an ongoing relationship with art. There is a dilemma here-how best to allow for aesthetic expression while keeping commercial intent in mind.

(10) Fashion has to reconsider ecological and social responsibility considerations. Fast fashion particularly leads to a lot of waste. Lastly,

(11) Fashion evolves. Innovations and changes in the world of styles are being spearheaded and influenced by new digital technologies, which always look to creating the next "in" look. The connections between materialism and society have hardly been explored, and the social conditions that drive new innovations are ripe for examination.

Since three of the confirmed participants are from Hong Kong but with expertise on various aspects of the fashion industry in Hong Kong, and the PRC, we expect to start a dialogue about the future of the fashion industry in Asia. Japanese designers are already known in the global context and there are up and coming designers from both Hong Kong and the PRC. Further, since some of the participants also have industry experience (as designers and merchandisers etc.), we expect the discussions between researchers and practitioners to be an insightful one. Finally, we believe that a cross-cultural approach to fashion cultures and discourses is crucial and will provide cutting edge knowledge of the ever-changing fashion industry.

**Pre-conference Discussion on the topic:**

We would like to open this topic up for discussion on the website, by soliciting responses and references particularly on issues such as "reorienting fashion," "cheap chic" and "fashioning the body." The inclusion of cities like Hong Kong and Shanghai as future fashion hubs might sound a little futuristic, but the major presence of world-renowned companies (Louis Vuitton group, the Gucci group, etc.) in these cities indicates otherwise.

# If Only I Switched Instead: Exploring the Consequence of Regret & Consumer Brand Switching Behaviors

My Bui, University of Arkansas, USA

A wealth of research has been devoted to exploring brand-switching behavior among consumers (Nowlis and Simonson 2000). Brand switching can be driven by various reasons, particularly perceived superior quality, lower prices of alternatives (Blattberg et al. 1995), lower levels of satisfaction and regret (Inman et al. 1997). Generally, the invalidation of information may lead consumers to question their past judgments and reassess the strategies they previously employed to inform their judgments (Bettman 1979). As a result, a central aim of brand-switching research is to further understand how consumers cope with regret, given that this is expected to influence post-purchase behavior.

Researchers have been using regret theory to help explain consumer behavior and decision-making (Zeelenberg and Pieters 1999). Regret prompts an assessment of whether or not the consumer can amend the situation, which then facilitates the consumers' use of coping strategies. It is typically the invalidation of information or expectation that prompts the experience of regret and consequently the promotion of these coping strategies. Specifically, in an attempt to cope with the invalidation, switching processing mode to an enhanced cognitive demand is imposed (Mazursky and Schul 2000).

Treating coping as a defense system (i.e., to reduce tension and restore equilibrium) can be distinguished as reactive coping or future-oriented coping. Reactive coping refers to a harm or loss experienced in the past (Schwarzer and Knoll 2003). In contrast, the proactive coping process (i.e. future-oriented coping) consists of constructing a reserve of resources that can be used to either prevent or minimize future net losses (Aspinwall and Taylor 1997)–particularly switching brands.

Despite the quantity of research done on brand switching, little is known about the behavioral determinants of switching on previous evaluation of expectations. In order to understand what influences post-purchase behavior, understanding previously purchased product evaluations are key elements. Furthermore, Folkman and Moskowitz (2004) call for more attention to be devoted to understanding future-oriented coping.

The purpose of this research is to better understand how consumers' regret coping behaviors influence brand switching. We predict that the level of regret induced and level of expectations validated will moderate consumers' attitude toward the brand bought, consumers' satisfaction levels, and consumers' choice to either stay or switch brands.

## Study

The experiment is a 2X2 between-subjects design with regret and validation serving as between-subjects factors. All participants were exposed to hypothetical purchase-decision scenario manipulations of regret and validation. Participants were either exposed to one of four conditions: induced regret with validation; induced regret with invalidation; reduced regret with validation; or reduced regret with invalidation. For example, for the induced regret by validation condition, subjects had experienced a positive outcome (i.e. contentment with purchase decision); then regret was induced due to the participant learning that their purchase decision was not the best decision they could have made. A total of 81 students from a southern university in the United States participated in the study.

*Attitude Toward Brand Bought.* The ANOVA yielded a regret by invalidation interaction (F $(1, 77)$=23.33, p<.001). When expectations were invalidated, attitude toward the brand bought was significantly lower when regret was induced ($M$=3.70), whereas when expectations were invalidated, attitude toward the brand bought was significantly higher when regret was reduced ($M$=6.00). No effect was found for validation and regret on attitude toward the brand bought. The analysis also revealed a strong significant effect for regret (F $(1, 77)$=24.48, p<.001), indicating that reducing regret lead to more favorable attitude toward the brand bought ($M$=6.06 vs. $M$=4.89). In addition, the analysis revealed a strong significant effect for validation (F $(1, 77)$=28.11, p<.001), indicating that validation lead to more favorable attitude toward the brand bought ($M$=6.10 vs. $M$=4.85).

*Satisfaction Toward Purchase Decision.* The ANOVA revealed a regret by invalidation interaction (F $(1, 77)$=12.86, p<.05). When expectations were invalidated, satisfaction toward purchase decision was significantly increased when regret was reduced, ($M$=6.02 vs. $M$=3.03); however when expectations were validated, satisfaction toward purchase decision was lower when regret was induced ($M$=5.17 vs. $M$=6.30). The analysis also revealed a strong significant effect for regret (F $(1, 77)$=63.84, p<.001), indicating that reducing regret lead to higher satisfaction toward purchase decision levels ($M$=6.16 vs. $M$=4.10). In addition, the analysis revealed a strong significant effect for validation (F $(1, 77)$=22.01, p<.001), indicating that validation lead to higher satisfaction levels toward purchase decision ($M$=5.75 vs. $M$=4.53).

*Brand Switching.* An ANOVA was performed, and the analysis approached significance for the regret by validation interaction (F $(1, 76)$=3.27, p=.07). When expectations were invalidated, brand switching was more likely to occur when regret was induced ($M$=6.02) than when regret was reduced ($M$=3.95). No significant effect was found for induced/reduced regret and validation on brand switching. The analysis also revealed a strong significant effect for regret (F $(1, 76)$=14.97, p<.001), indicating that inducing regret lead to a higher likelihood of brand switching ($M$=5.19 vs. $M$=3.80). Additionally, the analysis revealed a significant effect for validation (F $(1, 76)$=6.69, p<.05), indicating that invalidation lead to a higher likelihood of brand switching ($M$=4.96 vs. $M$=4.03).

These results highlight the importance of the emotion of regret and validation on attitude, satisfaction, and brand switching likelihood. The results show how regret can be used as a marketing instrument for advertisers and brand managers. As a marketing tool, regret can be used to both urge potential consumers to switch from an old brand or to stay with an existing brand. Ultimately, the use of regret is an excellent approach for firms seeking to increase sales, manage brands, or retain existing customers. More research is needed however to further explore and validate the findings of this study since a marginally significant interaction was found for brand switching. A limitation of the study is that hypothetical scenarios were used instead of actual scenarios. Actual consumer branding switching behavior may be

more likely to occur in real life situations instead of hypothetical situations when both regret and validation are induced. The results of this research contribute to further extending the existing literature on regret and consumer behavior, specifically building upon the understanding of future-oriented coping.

# The Effect of Surplus Avoidance on Completing a Goal in Loyalty Program

Jessica Y. Y. Kwong, Chinese University of Hong Kong, China
Kin Fai Ellick Wong, Hong Kong University of Science and Technology, China

It has long been recognized that goals guide individuals in channeling their efforts and in selecting and creating courses of action that can produce desired outcomes (Bandura 1997; Feather 1982; Locke and Latham 1990). One robust phenomenon observed in this process is that people exert greater effort as they get closer to the goal (Bagozzi and Dholakia 1999; Bandura and Locke 2003). For instance, Kivetz, Urminsky, and Zheng (2006) found that consumers purchase more frequently and in greater quantity when they get closer to the goal of a loyalty program. Another robust phenomenon documented in time-discounting literature indicated that people perceive the value of an object to be higher when it is temporally proximal than when it is temporally distant (Kirby and Herrnstei, 1995; Loewenstein 1987). Accordingly, consumers are likely to prefer an immediate reward than a future one.

In this article, we focus on consumer decisions by investigating the effect of overshooting a goal on consumers' motivation toward achieving a certain goal in loyalty programs. Contrary to the goal-gradient phenomenon and the findings in time-discounting literature, we argue that when consumers evaluate the attractiveness of making a repurchase after joining a loyalty program, consumers will be deterred from repurchase when they anticipate that such a repurchase will lead to surplus loyalty points, i.e., getting more points than needed to complete the goal. In other words, consumers will follow a surplus avoidance principle such that they are reluctant to proceed when it will overshoot their goal, thus the surplus avoidance tendency also lead consumers to choose a distant rather than an immediate reward.

The surplus avoidance principle is consistent with the central idea of the psychology of waste (Arkes 1996), which postulates that humans avoid being wasteful. This drive, which is referred as a "Don't waste" rule, is applied to a wide variety of contexts. When evaluating the attractiveness of an action, people tend to equate it with the extent to which such an action will lead to waste (Arkes 1996). However, previous research has shown that people often over-generalize this rule to various situations. They will go to great lengths to avoid being wasteful, and this desire often leads to behaviors that violate the normative definition of rationality (Arkes 1996; Arkes and Blumer 1985; Larrick, Morgan, and Nisbett 1990). For example, while consumers strive to maximize their loyalty points, they may end up with more than enough loyalty points (i.e., surplus points). It is possible that consumers will interpret the surplus points as waste because they feel that they are paying more than necessary to finish the loyalty program. However, this interpretation is inappropriate because consumers are paying *not* for the loyalty points but for the products they are buying. Thus, as long as they need those products, their spending will be fixed. In situations where wastefulness is no longer appropriate, consumers may still embrace the "Don't waste rule," which leads to behaviors that are non-optimal and are opposite the typical goal-gradient and time-discounting findings.

In an experiment, we test the central prediction that consumers will find a particular store less attractive when purchasing there will incur surplus loyalty medium (e.g., loyalty stamps) than when it will not. Participants in this experiment were told that the two major supermarket chains that they often visited, Supermarket Near and Supermarket Far, offered two separate loyalty programs that are equivalent in every aspect. In both programs, they would earn one stamp for every US$10 they spend, and 10 stamps would earn them a restaurant voucher. In the no surplus condition, they collected six stamps from Supermarket Near and seven stamps from Supermarket Far. In the surplus condition, they collected six stamps from Supermarket Near and nine stamps from Supermarket Far. They were informed that Supermarket Near was just a five-minute walk, whereas Supermarket Far was a 15- to 20-minute walk. The participants were informed that they were going to shop for items for a student union gathering and were expected to spend around US$30. They would get three stamps if they go to either supermarket. The participants were asked which supermarket they would go and were also asked to indicate their

likelihood to go to each supermarket using seven-point ratings (1=very unlikely; 7=very likely). Results on choice and repurchase intention ratings supported our central prediction that the preference for an option is reduced when it is associated with a surplus than when it is not. Specifically, the willingness to walk an extra distance to make a repurchase and get an immediate reward was significantly reduced when the repurchase would lead to surplus loyalty stamps than when it would not, despite the shorter distance from the goal in the former than in the latter case.

Our results provide preliminary evidence showing that the robust effects of goal-gradient could be reversed when completing a goal and getting the reward is associated with surplus stamps. Thus far, we have argued that surplus avoidance stems from an overgeneralization of the "Don't waste" rule, but we have not assess this psychological mechanism. According to Arkes and Hutzel (1997), waste is less of an issue when an item is reusable or when it has some scrap values. However, it becomes a prominent concern when the item cannot be reused. To test this idea, the next step would be to compare the surplus avoidance effects in two different reusability conditions involving the surplus stamps. If the surplus avoidance pattern are found to be stronger when surplus stamps are non-reusable than when they are reusable, our argument that surplus avoidance stem from an overgeneralization of the "Don't waste" rule will be supported.

# On the Compatibility of Orientation, Task and Preference: The Role of Brand Information

Jingjing Ma, University of California, Los Angeles, USA
Shi Zhang, University of California, Los Angeles, USA

### Hypotheses

Consumer choices are often driven by their hedonic and utilitarian preferences. Existing research has shown that orientation (promotion versus prevention) and task (choose versus give-up) are two important determinants of such preferences. Based on the earlier research and the regulatory fit theory, we propose that promotion orientation, choose task and hedonic preference are compatible, whereas prevention, give-up task and utilitarian preference are compatible. Given this proposal, the following specific hypotheses will follow.

H1a. Participants with prevention orientation in give-up task prefer utilitarian products more than participants with promotion orientation in give-up task.

H1b. Participants with prevention orientation in give-up task prefer utilitarian products more than participants with prevention orientation in choose task.

H2a. Participants with promotion orientation in choose task prefer hedonic products more than participants with prevention orientation in choose task.

H2b. Participants with promotion orientation in choose task prefer hedonic products more than participants with promotion orientation in give-up task.

Given products and brands are inseparable (Keller 1998; Samiee, 1994), we further propose that one cannot only examine preference towards hedonic/utilitarian products without considering the role of the brand information in hedonic/utilitarian preferences. For example, both hedonic and utilitarian products can be evaluated as utilitarian when they are perceived to be utilitarian brands, whereas both can be evaluated as hedonic when they are perceived to be hedonic brands. Thus, the difference between preferences for hedonic and utilitarian products on the hedonic/utilitarian measure would diminish or even disappear when brand information is included.

To illustrate, American brands are more utilitarian than French brands, while French brands are more hedonic than American brands. Many French products are perceived by Americans as hedonic products even when they belong to utilitarian product category. Hedonic and utilitarian are in relative terms. Chinese brands are seen in general to be more utilitarian than American brands, while American brands are seen to be more hedonic than Chinese brands. Therefore, Chinese consumers may perceive American products as relatively more hedonic products even when those products belong to utilitarian product categories (American brand shampoo, American brand towel). In contrast, Chinese consumers may perceive Chinese products as relatively more utilitarian products even when the products are in hedonic product categories (e.g. high-end Chinese brand cosmetics and boots). We refer to this kind of brand information effect as "suppression effect".

We suggest that the suppression effect occurs when both hedonic and utilitarian products have hedonic/utilitarian brand information, and under such condition, participants may not perceive much difference between hedonic and utilitarian products. As a result, the influence of promotion and prevention orientation on choice between hedonic and utilitarian products may diminish. Specifically, promotion orientation may not lead to more choices of hedonic products, and prevention orientation may not lead to more choices of utilitarian products. In other words, the early noted compatibility effect may not hold. We thus predict:

H3a:  When neither hedonic nor utilitarian products have brand information, prevention focused participants in give-up task are most likely to prefer utilitarian products while promotion focused participants in choose task are most likely to prefer hedonic products.

H3b:  When both hedonic and utilitarian products have hedonic/utilitarian brand information, a brand suppression effect occurs such that promotion and prevention focused participants should have similar preferences for hedonic and utilitarian products.

We further suggest that that the brand suppression effect can lead to a consequence regarding how orientation affects hedonic/utilitarian product preferences, and that such consequence can only be observed in choose task condition but not in give-up task condition. Brand characteristics are more likely to tap into emotional, symbolic, subjective and affect-related decision making, while product characteristics are more likely to be used for rational, objective and cognition-driven decision making. In the choose task mode, participants undergo a relatively simple thinking process, and their responses an be driven by emotional and affective elements and sometimes can be impulsive (Bazerman Tenbrunsel, and Wade-Benzoni, 1998). Thus, particpants are more likely to be influenced by brand information than product information. However, in given up task mode, participants undergo a more careful process, and their responses are more detailed driven, and elaborate (Strahilevitz and Loewenstein, 1998), thus they are more likely to be influenced by product information than brand information.

H4a:  When both hedonic and utilitarian products have hedonic/utilitarian brand information in choose task, a brand suppression effect occurs that leads to the consequence such that promotion and prevention focused participants have similar preferences for hedonic and utilitarian products.

H4b:  When both hedonic and utilitarian products have hedonic/utilitarian brand information in give-up task, a brand suppression effect occurs, but participants still can perceive the difference between hedonic and utilitarian products, which leads to the consequence such that promotion focused participants prefer hedonic products more than prevention focused participants.

## Method

In experiment one we test the compatibility of promotion and prevention orientation, choose and give-up task, and hedonic and utilitarian preference in both no-brand and with-brand situations. This constitutes a 2 (promotion and prevention orientation) X 2 (choose and give-up tasks) X 3 (None, Chinese and American brands) between subjects design. The dependent variable is participants' choices between a hedonic product and a utilitarian product. In experiment two we further test brand effect in choose and give-up situations with brand information provided for the hedonic and utilitarian products.

## Discussion

Our research extends the noted two-variable compatibility to a three-variable compatibility effect. We found that promotion-choose-hedonic and prevention-give-up-utilitarian are the compatible situations. Promotion-focused consumers in choose task prefer hedonic products more than both prevention focused consumers in choose task and promotion focused consumers in give-up task. Prevention-focused consumers in give-up task prefer utilitarian products more than both prevention focused consumers in choose task and promotion focused consumers in give-up task. However, this compatibility only holds in no-brand information situation. In with-brand information situation, the compatibility effect goes away. We further found that brand suppression effect only works in choose task situation but not in give-up task situation. The choose situation is more emotion involving than give-up situation which is more elaborate and effortful. Since brand information is more subjective than product information, participants would rely more on brand information in choose task and more on product information in give-up task. Thus, we have uncovered interesting new results that intersect information processing, decision tasks and hedonic/utilitarian preferences that can help further research in this area.

# The "Sticky Choice" Bias in Sequential Decision-Making

Aaron Brough, Northwestern University, USA
Mathew Isaac, Northwestern University, USA
Alexander Chernev, Northwestern University, USA

Consumers often encounter product information in stages rather than all at once. Sometimes new information favors an option that was not favored by the initial information set. Because the basis for a choice is restricted to whatever information is available at the time, new information may challenge a choice that was predicated on earlier information. In response, consumers might be expected to switch to the option favored by new information rather than sticking to their original selection.

To illustrate, consider two consumers with identical preferences deciding between dessert options at a restaurant (cheesecake or tiramisu). Consumer A reviews the dessert menu and selects cheesecake. After taking the order, the waiter mentions that tiramisu (the non-selected option) is the restaurant's specialty and asks whether she would like to reconsider her choice. Consumer A must now decide whether to stick to her original choice (cheesecake) or switch to the option favored by the new information (tiramisu). In contrast, Consumer B reads the same dessert menu, but is informed by the waiter that tiramisu is the restaurant's specialty prior to placing her order.

Several divergent predictions could be made about the final decision outcomes for the above scenarios. Since the same set of information was available in both scenarios, Consumers A and B might be equally likely to choose the option favored by the new information (tiramisu). Alternatively, Consumer A could be more likely than consumer B to choose the favored option. The basis for this claim is that people often experience regret immediately after making an initial choice because other high utility options have just been sacrificed (Carmon and Ariely 2000). As a result, when new information favors the foregone option, individuals in a repeated choice task may be extremely motivated to switch. Another possibility is that Consumer A could be less likely than Consumer B to choose the favored option. The theory behind this notion is that the mere expression of an initial choice creates a "sticky choice" bias so that the final decision is biased toward the initially selected option, even when new information favors another option. Our research provides evidence supporting the last prediction—that consumers who make sequential choices are less likely than those who make a single choice to ultimately choose an option that is favored by new information.

We identify three antecedents that could generate the "sticky choice" bias in repeated decisions: reevaluation of initial information, discounting of new information, and consistency-seeking across repeated decisions. First, the act of expressing a choice may alter the perception or evaluation of the *initial* set of information (i.e., prior to the provision of any new information). Perhaps consumers who make an initial choice assess alternatives or weight attributes differently than those who do not make an initial choice. Additionally, choosing itself may make one's preferences more certain or salient. The notion that choice affects evaluations of one or more members of the original option set is supported in the literature (Botti and Iyengar 2004) and consistent with research on mere-possession (Sen and Johnson 1997), loss aversion (Kahneman and Tversky 1984), and the endowment effect (Thaler 1980).

A second explanation for a "sticky choice" bias is that the act of selecting an option may cause *new* information that challenges the initial choice to be processed incompletely or less discriminately than it would have been otherwise. Brand loyalty research has demonstrated attentional blocking of new information within a consumer learning context (van Osselaer and Alba 2000) but has focused primarily on blocked associations of specific attributes. Even if new information is processed thoroughly, it may be discounted to resolve cognitive dissonance (Festinger 1957) or biased by confirmatory reasoning (Klayman 1995, Chernev 2001).

Finally, the "sticky choice" bias may arise from the repeated choice context itself; consumers who make an initial selection may demonstrate persistence in choice that is driven by desire for consistency or resistance to change rather than by differential information processing. Behavioral consistency describes the tendency of individuals to regulate actions—and, we would argue, choices—so as to be consistent with prior behavior and choices (Funder and Colvin 1991). Resistance to change suggests that an earlier choice prompts a tendency towards inaction inertia (Arkes, Kung, and Hutzel 2002) or maintaining the status quo (Samuelson and Zeckhauser 1988).

Across four experiments, we attempt to demonstrate the "sticky choice" bias and isolate its underlying mechanism(s). In experiment 1, we compare the choice shares of two options in a scenario where all participants receive the same set of information. Participants begin by setting attribute values so as to equate their preference for two products. Then, some participants choose between the two products and other participants do not. Next, new information about a third attribute is provided to all participants that clearly favors one option. Finally, participants make their final decision between the two products based on the complete set of information. We find that the final decision outcome of participants who express an initial choice is biased toward the initially-selected option (relative to those who make a single choice after all the information is available). In the remaining experiments, our goal is to show that the "sticky choice" bias occurs when consumers seek consistency across repeated decisions, even after controlling for changes in the evaluation of initial and new information.

Overall, this research demonstrates the robustness of choice consistency in a sequential decision context even in the presence of contradictory information. We provide evidence that when new information favors an option that was not favored by the initial information, the final decision of consumers who express an initial choice is biased toward the initially-selected option relative to consumers who make a single choice after complete information is available. We aim to attribute this "sticky choice" bias to consistency-seeking across repeated decisions.

# Fantasizing About Winning: Motivational and Congnitive Determinants of Narrative Transportation

Brent McFerran, University of British Columbia, Canada
Darren Dahl, University of British Columbia, Canada
Gerald Gorn, Hong Kong University of Science and Technology, China
Heather Honea, San Diego State University, USA

Recent research in psychology has identified a process, called transportation, that may be useful in explaining the behavior in reaction to advertising that encourages vivid daydreams or fantasy. Transportation is defined as "immersion into a text" (Green and Brock, 2000, p.702; Gerrig 1993).

What has been lacking in the literature, however, is a theory that explains when and how transportation is more or less likely to occur. This paper identifies specific moderators for transportation, where people become absorbed by an advertisement. As well, all prior literature on transportation views it through a cognitive lens; this paper looks at motivational mechanisms (extrinsic motivation from the attractiveness of what is being advertised and intrinsic motivation from the belief its acquisition is possible) that may affect consumer image generation and persuasion. An additional contribution of this paper is to extend transportation theory out of the context of narratives and in to the medium of television advertisements. The lottery is an ideal setting to examine consumer fantasies and transportation, as they are notorious for encouraging participants to dream or imagine, and outcomes that are salient and easy to imagine carry disproportionate influence in decision making (McGill and Anand, 1989; Keller and McGill 1994).

In a pilot study (with 3 cells: a lottery ad an ad encouraging consumers to fantasize, a control lottery ad, and a no ad condition) we show that advertisements that encourage imagination lead to more transportation, and that this increase in transportation mediates the effects of differential ad exposure on desire to purchase. Although the commercials could have differed on dimensions other than how much transportation was encouraged, the dream ad was actually liked less than the control ad. A subsequent study controls for this, and extends the results of the pilot study by directly manipulating the underlying process.

In study 1, 3 new factors were introduced to examine moderators for the effect, filling a gap in the literature (Escalas 2007; Wang and Calder 2006). The procedure used the ad encouraging consumers to fantasize from the pilot study, and this time used the guise of evaluating a new commercial for TV. The ad featured a man deciding how to spend his lottery winnings. The advertisement was altered by video editing professionals to create two new advertisements. One advertisement claimed the size of the lottery jackpot this week was $1000 (as there are many small lotteries with prizes in this range), while the other claimed it was $10 million (a relatively large prize for the jurisdiction of the study). The same announcer was used in both conditions, the ads were the same length, and otherwise featured exactly the same visual stimuli, ensuring a high level of internal consistency. A second factor was belief in luck, as some individuals believe that luck can act as a force in their favor, while others believe that luck is simply random chance that is unreliable (Darke and Freedman 1997). The manipulation for transportation was adapted from Green and Brock (2000). Participants in the increase transportation condition were instructed before viewing the commercial to "Immerse yourself in the commercial, imagining what it might be like to be in that situation. You are now the main character". In the neutral condition subjects were told "While watching the commercial, use your attention". Finally, the manipulation to decrease transportation was "While watching it, try to identify any claims or words that might be confusing to people who do not speak English as their native language". A manipulation check supported the efficacy of our manipulations. If transportation is indeed driving the effects we observe, then directly manipulating it should result in a change in the effects we observe. Thus, the study was a 2(prize size large/ small) x 3(transportation increase/ neutral/ decrease) x measured belief in luck.

We predict and find support for a 3-way interaction: In the large prize condition, when the motivation to transport is high and subjects are encouraged to transport, we observe the largest amount of desire to purchase, and transportation mediates this effect. In the small prize condition, since belief in luck is a more stable individual-level trait, only a main effect for belief in luck influences desire to purchase. People who believe in luck are generally more willing and likely to allow themselves to be transported and play the lottery, regardless of prize size, and transportation mediates the effects of these factors on desire to purchase.

A second study examines the process underlying the effects in greater detail, with the inclusion of new measures that capture measures of what subjects thought about. The study was a simple design where the $10 million prize ad from the prior study was shown and belief

in luck was regressed on, and significantly predicted: desire to purchase, the extent to which subjects could visualize a win, had fantasies that centered on hedonic items (car, clothes, house, vacation, and what they'd spend their winnings on). Participants' thoughts also centered more on themselves than on the protagonist in the ad if they believed in luck and reported more positive affect, consistent with transportation.

A third study further examines the relationship between transportation motivation, and manipulates how lucky subjects feel about luck by first reading a gender-matched story for an ostensibly unrelated experiment about a protagonist that has everything go his or her way (fortunate), or against him or her (unfortunate). The story did not affect participants emotions, as there were no significant differences across a battery of 14 positively and negatively-valenced items, ruling out mood effects as an explanation for our results. This was crossed with size of prize (large or small) in a 2x2 between subjects factorial. Transportation was shown to be highest in the large prize/feel fortunate condition, as compared to the average of the other 3 cells, and subjects in this condition imagined themselves winning more so than the main character in this cell. They also reported significantly higher willingness to pay (in $, log transformed) for a lottery ticket of the same expected value (1 in 1000 odds in the $1000 prize and 1 in 10,000,000 odds in the large condition) in the big/fortunate condition (all p's <.05).

Across four studies, we show that ads that encourage subjects to imagine an outcome are effective in persuading via transportation, and that this effect is stronger when consumers are motivated to process with themselves as the protagonist. When people lack sufficient motivation, how the ad is processed is shown to make little difference. Intrinsic (belief in luck) motivation is more stable than extrinsic (large prize) in influencing this effect, however a synergistic effect is shown for ads, where ads that appeal to consumers' imagination work best under both high intrinsic and extrinsic motivation. Future research should consider motivation to transport in other domains: potential companions (dating services), changing their look (elective surgery), or a more general improved life (soap operas, romance novels).

## Friend and Foe? The paradoxical Dynamics of Intergroup Conflict in a Cooperative

Katherine Loveland, Arizona State University, USA
James Ward, Arizona State University
Blake Ashforth, Arizona State University, USA
Peter Reingen, Arizona State University, USA

While there are many examples of groups of consumers coming together to pursue shared consumption goals (e.g. neighborhood associations, collector's societies, co-ops, etc.) these types of groups remain relatively unexplored in the consumption literature. Consumption associations are characterized by members that not only consume the focal product/experience but also help to co-produce the experience. While members initially come together to join/form the group in order to meet a common consumption goal, subsequent division into subgroups often becomes inevitable. For this reason, one particularly compelling avenue of investigation is the role that conflict plays in consumption associations. Given the virtual inevitability of conflict within organizations (Kramer, 1991), it does not at first seem surprising that conflict would exist in consumption associations. However, when one considers that many of the solutions commonly prescribed to mitigate and minimize conflict (strong organizational identity, member agreement on core organizational values, frequent interpersonal interactions across group lines) tend to be present in these types of organizations, the pervasiveness and intensity of conflict within the consumption associations is rather arresting.

This paradox of intense conflict existing in an environment that theoretically should be relatively conflict free is what lead us to our research questions. We first ask: why does strong intergroup conflict persist when the structural and social-psychological conditions that supposedly mitigate conflict appear favorable? This paradox begs our second research question: how does such paradoxical intergroup conflict play out? Finally, we ask: what keeps the consumption associations together and functioning reasonably effectively?

In answering these questions, we found an exploration of the role of collective identity to be particularly fruitful. While an organization's overarching identity is often fairly abstract (cf. meta-identity; Pratt & Foreman, 2000), smaller subunits that tend to focus on more concrete facets of the overarching identity are nested within the organization. In order to enhance group member distinctiveness and self-esteem while reducing uncertainty about social structure and members' place within it, these sub-units will seek to differentiate themselves by maximizing intergroup differences and minimizing intragroup differences (cf. self-categorization theory; Turner, 1985;

Brewer and Gaertner, 2001). This suggests that at least part of why different groups emerge is precisely so that they can act as foils to one another.

## Method

To explore these issues we investigated a natural foods co-op in a large southwestern city. The co-op offered a particularly compelling environment for exploring a consumption association since members explicitly act as both consumers and managers of the consumption experience. Within the co-op two groups—"idealists" and "pragmatists"—formed around different *emphases* on certain values leading to ongoing and intense conflict. The first phase of investigation was a year long ethnography. Notes from participant observation, meeting transcriptions, and archival data were all analyzed. Throughout this process emerging insights were discussed with a co-author and member checks were performed.

As the research questions crystallized, a questionnaire was developed to measure an array of constructs related to intragroup and intergroup dynamics. This survey was given to 24 individuals identified as highly active in the co-op's governance. Twenty participants returned completed questionnaires.

## Major Findings

In broad terms the two groups, "pragmatists" and "idealists", coalesced around shared beliefs concerning either business practices or cooperative ideals respectively. Much of the conflict centered on how to insure that the co-op continued to meet communal consumption needs while remaining economically viable in the face of increased competition from the opening of "supernatural" chain stores. The idealists felt that the best way to preserve the co-op was to focus on communal consumption needs by staying true to the founding ideals: non-hierarchical management, stocking only healthy, ethically produced foods, and providing extensive services for member's education and alternative lifestyles. The pragmatists, while also valuing these ideals, were more concerned about continued economic viability and as such felt that some compromise—e.g. more power for the store manager, more non-organic produce, and reinventing some cash flow—was warranted.

In answering the first research question— why does strong intergroup conflict persist when conditions that should mitigate conflict exist?—values were quantitatively examined. This analysis revealed all value clusters were shared. The difference that emerged was the relative *weight* that was given to each value cluster. In other words, both groups felt that meeting communal consumption needs took precedence over profitability, however the pragmatist still gave more *relative* importance to profitability than did the idealists. Interestingly this indicates that the two groups were much more alike than they were different, allowing for strong overarching group identity when the boundary between outsiders and group members was salient. However, when "outsiders" were not salient, small between group differences lead to intense conflict. Thus, following optimal distinctiveness theory, inclusiveness may, ironically, actually encourage subgroup differences.

In answering the second research question— how does such paradoxical intergroup conflict play out?—we examined perceptions of the in- versus out-group members. As social identity theory argues, identities are relational and comparative (Tajfel & Turner, 1986); much of how one group identifies itself is how it differs from the other group. This was supported by the finding that in general, perceptions of the values of the out-group tended to be more extreme than was actually the case. In other words, intergroup conflict plays out through the mutually reinforcing mechanism of value polarization.

Finally, in answering our third research question—what keeps the co-op together and functioning reasonably effectively?—we examined organizational rituals. Three rituals in particular were observed that seemed to keep members united despite the divisive conflict: reaffirmation of members' belief in cooperation, appointment of "vibes watcher" to interrupt debates that became too heated, and expression of regret and shock about behavior. At a deeper level, part of what allows the co-op to continue functioning in a relatively stable manner is the tension between these two groups. In other words, in order to continue to meet group consumption needs, the co-op does need to stay true to the founding ideals, however if it doesn't remain economically viable it will not be able to meet the consumption needs of anyone.

# The Role of Congruence Theory in Consumer Response to Business-to-Consumer Gift Giving

Atul Kulkarni, University of Illinois, Urbana-Champaign, USA
Cele Otnes, University of Illinois, Urbana-Champaign, USA
Julie Ruth, Rutgers University, USA
Tiffany White, University of Illinois, Urbana-Champaign, USA

Although business-to-consumer (B2C) gifts are prevalent in practice, few studies explore the motivations and consequences of this activity. In this paper, we examine how perceived congruence between a gift and the promoted product influences key consumer response variables. Perceived congruence between product-related stimuli has been found to have an impact on consumers' impressions (Meyers-Levy and Tybout 1989; Kamins and Gupta 1994).

In promotions, "gift" typically refers to an additional good a consumer receives for free when purchasing the promoted product. Free gift differs from the other promotions such as price cuts, rebates, and coupons (Chandon et al. 2000) because a free gift does not affect direct monetary cost of the promoted product.

We found only two studies that explore B2C gift giving. Raghubir (2004) finds consumers may perceive free gifts as not valuable unless they receive price information to judge the value of the gift. Bodur and Grohman (2005) find a prior relationship with the business and an implicit request for reciprocation positively affect consumer responses to gifts.

We believe congruence theory can help understand consumers' reactions to B2C giving. Congruence refers to the degree to which two or more objects, entities, people or groups share essential characteristics. Sirgy (1985) and Kamins and Gupta (1994) found that high congruence leads to favorable evaluation and a positive attitude toward the target, whereas Meyers-Levy and Tybout (1989), and Jagre et al. (2001) found that moderate incongruence leads to more favorable product evaluations than either high congruence or extreme incongruence. These studies suggest when consumers encounter schema incongruence, object novelty increases arousal, and greater cognitive elaboration may occur in an effort to resolve the incongruence.

We use consumer evaluation of the gift/product offer, and consumers' attitude toward the brand associated with the offer as the two key consumer responses variables. We propose when perceived congruence between in the gift/product combination is low, consumers are more likely to perceive the gift offer as a "promotion" than as a "gift", resulting in lower purchase intent and unfavorable brand attitude for promoted product (Forehand 2000; Bodur and Grohmann 2005). Following Mandler's (1982) thesis, we hypothesize an inverted U relationship between perceived congruence and consumer evaluation of the offer.

H1: Consumers will evaluate the offer most favorably when the perceived congruence of the gift/product combination is moderate, rather than high or low. High congruence will result in more favorable evaluation than low congruence.

Extant research is less certain about formation of attitude toward the target object (brand) in the stimulus. In B2C gift context, we argue that the arousal in object novelty and enhancement in cognitive elaboration caused by moderate incongruence is attributed more toward the offer and less toward the brand associated with the offer. Therefore, we do not expect significantly more positive attitude toward the brand in case of moderate versus high congruence. We agree with Mandler (1982) that extreme incongruence does not lead to satisfactory resolution even after extensive elaboration, resulting in least positive attitude toward the brand.

H2: Consumers will form more positive attitudes toward the brand in the gift offer when perceived congruence of the gift/product combination is moderate or high, rather than low. Attitudes will not be significantly different for moderate versus high congruence.

A between-subjects factorial design with three levels of perceived congruence (low, moderate, high) of the gift/product combination was used for the laboratory experiment. After pretesting several sets of stimuli, music CDs (and car insurance) was used as the promoted product and a free music CD (free extension to insurance policy), a free radio receiver (free safety check of car), and a free pair of garden clogs (free barbeque grill) were used as gifts corresponding high, moderate, and low congruence respectively. Participants (n=199) were recruited from undergraduate students enrolled in business courses at a large Midwestern university, and were offered extra course credit for participation. They received booklets containing one of the randomly assigned experimental stimuli (one of the six different gift/product combinations) and filler materials. Following the stimulus booklet, the participants turned to the booklet containing the dependent measures, and manipulation checks.

We adopted a ten-item scale (alpha=0.97) by Beltramini and Stafford (1993) to measure consumers' evaluation of the offer. For attitude toward the brand, we used a three-item scale (alpha=0.94) used by Chattopadhyay and Basu (1990). Just prior to the conclusion of the study session, participants were asked to rate the degree of congruence (nine-point scale anchored with highly congruent/not congruent at all) for the gift/product combination in the offer they received during the experiment.

Results showed the manipulations worked (correlation of 0.8 between expected and reported congruence). A one-way ANOVA with evaluation of the offer as the dependent variable was significant ($F(2,195)=11.055$, $p<0.000$). The mean evaluation scores corresponding to low, moderate and high congruence were 5.13, 6.42 and 5.85. Pairwise mean comparisons for low/moderate ($p<0.000$), moderate/high ($p<0.041$) and low/high ($p<0.008$) were statistically significant, confirming the hypothesized inverted U relationship between perceived congruence and consumers' evaluation of the offer. A one-way ANOVA with attitude toward the brand as the dependent variable was also significant ($F(2,195)=7.169$, $p<0.001$). We found a significant difference ($p<0.002$) between attitude scores corresponding to low (mean=4.64) and high (mean=5.71) congruence. The difference between attitude scores corresponding to moderate (mean=5.81) and high congruence was not significant ($p<0.771$). Thus, the results are consistent with our argument that the arousal in object novelty and enhancement in cognitive elaboration caused by moderate incongruence in gift/product combination is attributed more toward the offer

(thus, increasing favorability of the offer) and less toward the brand associated with the offer (thus, not showing significant difference in the brand attitude).

These results provide evidence that perceived congruence systematically affects consumers' evaluations of business-to-consumer gifts and the brands that offer them. We plan to follow up this study by testing the underlying mechanisms via measurement of arousal and cognitive elaboration, and by examining the moderating effects of consumers' need for cognition and style of thinking (analytic/holistic) on their response to perceived congruence.

# Luxury Versus Humor: Contrasting the Use of Art in Advertising

Henrik Hagtvedt, University of Georgia, USA
Vanessa Patrick, University of Georgia, USA

Visual art has been used extensively in advertising (Hetsroni and Tukachinsky 2005). Indeed, such "high-culture images reach more people more often through advertising than through any other medium" (Hoffman 2002). However, while the use of visual art is widespread in advertising, its impact is not clearly understood and has not been systematically studied. We therefore pose the question *whether*, *when* and *how* visual art works in advertising.

Since antiquity, art has been associated with a heritage of culture, it has represented a special kind of quest for excellence, and it has connotations of luxury and exclusivity (Hoffman 2002; Margolin 1992; Martorella 1996; Tansey and Kleiner 1996). Indeed, recent research on the art infusion phenomenon (Hagtvedt and Patrick 2006) has suggested that art has a positive influence on the evaluation of products with which it is associated. This research demonstrates that this influence stems from an automatic and content-independent spillover of luxury perceptions.

Importantly, this research has relied on the influence of art in its original form. In advertising practice, however, advertisers use artworks in their original form or modify them to fit their purposes (Hoffman 2002). For instance, the use of the original Rodin's "Thinker" lends the gravity of art and philosophy to an ad for Dewar's whiskey, connoting the luxury and sophistication of the brand. On the other hand, artworks may be modified to convey the advertising message with a humor appeal. For example, an ad for Clear Blue pregnancy tests features a painting by Fra Angelico, where the angel Gabriel informs the Virgin Mary that she will bear forth a child. Mary responds: "Thanks, but I already know."

In this research, we propose that this latter use of art in advertising presents a boundary condition for the art infusion effect. We theorize that artworks in their pure form have integrity, a quality of completeness and incorruptibility. The integrity of an artwork refers to its "wholeness, intactness or purity" (Cox, LaCaze, and Levine 2005). Visual art, like other art forms, maintains this integrity when it remains untouched or untarnished. Consequently, we would expect that any modification of a work of art interferes with this integrity, diluting its impact on the viewer and limiting the potential for art infusion to occur.

Specifically, we propose that when art is used in its original form, the positive spillover of luxury connotations results in a more favorable evaluation of the product and the ad. Conversely, we argue that a modified artwork is no longer categorized as art, but as a humorous image, thus diminishing or eliminating completely the art infusion effect. We test this assertion in two studies.

### Study 1: Examining the Relevance and Modification of Art

In study 1, we examine the influence of original (vs. modified) art on product and ad evaluation. In addition, we examine the "fit" of the artwork, i.e. the extent to which the visual image is relevant to the ad message. In investigating the fit of music in advertisements,

MacInnis and Park (1991, 162) define fit as "… consumers' subjective perceptions of the music's relevance or appropriateness to the central ad message." We expect that while the image, whether modified or unmodified, has a function in the ad, the copy of the ad may enhance the effect of that image by causing the image and the product to be more intimately linked to each other. Therefore, we expect that the connotations of art conveyed would be magnified by the increased fit between the image and the message of the ad. In other words, we would expect an interaction of fit and modification such that when fit is high we would expect polarized responses to modification.

Study 1 was a 3 x 2 between-subjects experiment, with 191 undergraduate participants, manipulating modification of the art (original vs. slightly modified vs. highly modified) and relevance (established via the copy of the ad: relevant vs. irrelevant). A fictitious advertisement, using the Mona Lisa by Leonardo da Vinci, was created for a real product: Prince Spaghetti Sauce.

Results revealed that general evaluations and perceptions of luxury for both product and advertisement were higher for the unmodified artwork, and the expected polarization caused by the relevance was confirmed by the expected interactions. Also, as expected, the modified artwork was evaluated as more humorous, but did not benefit from the positive connotations of art. Further, luxury perceptions mediated the effect of original art on evaluations of the product and the ad.

### Study 2: The Role of Brand Positioning

Study 1 suggests that art in its original form serves as an effective luxury appeal while modified artworks operate as humor appeals in advertising. We extend this result in study 2 to examine the match of ad appeal with brand positioning (luxury vs. value). Prior research has demonstrated that consistency in brand communications leads to more favorable brand evaluation (Park, Milberg and Lawson 1991; Sjödin and Törn 2006). We expect that an original (modified) artwork conveying a luxury (humor) appeal is more likely to be consistent with a luxury (value) brand positioning, and we expect that an inconsistent brand positioning will diminish the favorable influence of art on product and ad evaluation.

The study was a 2 x 2 between-subjects experiment with 122 undergraduate participants in which modification of the art (original vs. highly modified) and positioning of the advertised brand (luxury vs. value) were manipulated. The same images were used as in study 1. Brand positioning was manipulated via ad copy that emphasized luxury (with phrases like "Classic Italian", "Another Italian masterpiece") versus value ("Priced-less" and "Why pay more?"). The results replicate the finding that modifying the artwork in the ad caused less favorable evaluations of the product and the ad, and this was moderated by the brand positioning.

In sum, the results of these two studies reveal that art used in its original form connotes a luxury appeal and is best utilized with a luxury brand positioning. Modified artworks, on the other hand, work as effective humor appeals and may be best utilized for brands conveying a value positioning.

# Social Identity Threat and Consumer Preferences: The Role of Self-Protection
Katherine White, University of Calgary, Canada
Jennifer Argo, University of Alberta, Canada

Using social identity theory (e.g., Tajfel and Turner 1979) as a theoretical framework, where social identity refers to the component of the self-concept that is derived from actual or perceived membership in social groups, we tested across three experiments whether exposing consumers to a social identity threat would result in the avoidance of products associated with that identity. The present research contributes to the marketing and psychology literatures in several notable ways. To our knowledge, this is the first research to examine how consumer preferences are influenced by social identity threat. Second, this research extends previous findings that consumers often demonstrate preferences that are congruent with self-perceptions (Sirgy 1982) and primed self-identities (Mandel 2003; Reed 2004). Third, we build upon social identity theory by highlighting a behavior that is unique to the consumption context—the avoidance of products associated with a threatened identity. Fourth, the present research demonstrates that this avoidance tendency is related to a desire for self-protection and not related to other motives such as self-enhancement and self-verification. Finally, we identify key moderators of this avoidance tendency—self-esteem and ingroup identification.

Social identity theory proposes that identity is comprised of two components: personal identity (i.e., identity related to a person's individual sense of self) and social identity (i.e., identity related to groups to which a person belongs or is affiliated). We propose that when one aspect of consumer social identity becomes threatened, under certain conditions, consumers will become motivated to avoid products associated with that threatened aspect identity and will instead prefer products associated with an alternative identity. This notion differs from a priming account of shifts in consumer preferences which suggests that priming activates relevant concepts in memory and increases the accessibility of related information when making judgments (Srull and Wyer 1980). Thus, priming often leads consumers to prefer products that are consistent with currently activated concepts. We suggest that when consumers are motivated to protect the self from identity threat, they will prefer products that are inconsistent with the threatened aspect of identity. We differentiate self-protection (e.g., the desire to avoid negative consequences for the self) from self-enhancement (e.g., the desire to attain positive consequences for the self), and suggest that the mechanism underlying our effects in self-protection.

In study 1, we provide preliminary evidence that consumers will avoid products associated with a threatened aspect of identity. Participants were either presented with information that threatened their gender identity, enhanced their gender identity, or was neutral with regards to their gender identity. Participants then evaluated films that were either related to their own gender identity or that were related to their university student identity. As predicted, participants who received threatening information about gender as a social identity showed a significantly weaker preference for films associated with their gender as compared to those who received gender enhancing information or neutral information. No such differences were found for evaluations of products associated with an alternative identity (i.e., university student).

In study 2 we examine self-esteem as a moderator of reactions to social identity threat. While those high in self-esteem are often characterized as being motivated by self-enhancement, those low in self-esteem are often motivated by self-protection (e.g., Baumeister,

Tice, and Hutton 1989; Kunda 1999). Because we believe the avoidance of products associated with a threatened aspect of identity is related to self-protection, we anticipate that this avoidance tendency would be particularly pronounced among low self-esteem individuals. Participants were first provided with information that either threatened gender as a social identity or was neutral regarding identity. They then made a choice between a publication that was either associated with their own gender identity or that was associated with university student identity. People low in self-esteem tended to avoid choosing a product associated with a threatened facet of identity, whereas product choice was not influenced by social identity threat when people were high in self-esteem. This effect was mediated by a desire to protect the self, but not by other motives such as self-enhancement or self-verification.

In study 3 we investigated the moderating role of ingroup identification because research demonstrates that ingroup identification individuals exhibit self-protective responses to threat. Further, we attempted to rule out alternative explanations for the findings. Because the gender-related products in the first studies were low in perceived intellectual depth, participants may have responded to threats to the self by simply choosing a more intellectually-oriented option, rather than avoiding products associated with a threatened aspect of identity. Second, it is possible that consumers avoid products associated with any identity that is described negatively, not only products associated with an aspect of their own identity when it is threatened. To test for these alternatives, we had female participants receive a threat to their own gender identity, threat to the opposite gender identity, or neutral information, and then evaluate both male and female biographies. In contrast to the two alternative explanations, our conceptualization predicts that females would only avoid female-related products (and not male-related products) when female identity is threatened and not when male identity is threatened or when no threat is present. In addition, we had participants evaluate both positive and negative biographies. If motivated by a need for self-protection, those low in ingroup identification should avoid both positively and negatively valenced products associated with a threatened aspect of identity. Our design allows participants to enhance the self by preferring products with positive connotations related to their identity. Results revealed that, females motivated by self-protection (i.e., those low in ingroup identification) avoided positive and negative female-related products (and not male-related products) when their own gender identity was threatened.

The current research builds on social identity theory by demonstrating a unique response to social identity threat—shifts in product preferences and choices. Taken together the results of three studies suggest that the avoidance of products associated with a threatened aspect of identity is related to the desire for self-protection.

## I Know a "Guy": The Consequences of Using Social Capital to Facilitate Consumption Experiences
Bryan Johnson, Penn State University, USA
William T. Ross, Jr., Penn State University, USA

**Conceptualization**

As the fabric of civilization, social relationships play an important, yet often inconspicuous role in society by binding individuals together and facilitating correspondence and collaboration among them. Because of their inherent function in social interactions, relationships influence many different aspects of human behavior, including those related to consumption. Consequently, the purpose of this paper is to investigate consumers' use of personal relationships to facilitate purchases. Interestingly, the basic questions of whether, how, and why consumers utilize personal relationships to improve their purchase outcomes remain largely unaddressed in the marketing literature. However, given the extent to which consumers are connected to one another, answering such questions becomes important if scholars are to fully understand this novel and intriguing dimension of consumer behavior.

We approach these important questions using a social capital theory framework, which posits that individuals utilize resources embedded in social relationships to create benefits or returns (Coleman, 1988, 2002; Portes, 1998, 2000; Lin 2001). From an individualistic perspective, social capital theory focuses on the resources ingrained in an individual's social relationships and how using these resources benefits the individual. These resources are considered social because they can only be accessed through direct and indirect ties with others. Common forms of social resources include advice, information, ideas, and support. Ultimately, to possess social capital, an individual must have relationships with others; it is only through social interactions that social capital can exist and benefit the individual (Coleman, 1988, 2002; Portes 1998; Lin 2001).

Given the communicative nature of this phenomenon, it is important to briefly distinguish social capital from word of mouth behavior. Whereas word of mouth typically refers to informal information transmission related to existing products, services, or events, social capital extends this conceptualization by focusing specifically on the nature and the strength of the relationships among those involved in the communication of information. In addition, the information transmission resulting from social capital mobilization tends to be more structured, intentional, and proprietary than that of word of mouth communication. As a result, consumers utilizing social capital to make purchases may intentionally and systematically draw upon their personal relationships to find the right person, place, product, or price, thus enhancing their returns in the marketplace.

**Method**

As suggested previously, we seek to understand how consumers utilize social capital to make purchases, the benefits of doing so, and the impact of this behavior on the consumption experience. Given that research on this topic is sparse, our research represents an initial stride into this realm. As a result, we utilize grounded theory methodology (Glaser & Strauss, 1967; Strauss & Corbin, 1998) to extend and refine social capital theory in the context of consumption. We conduct semi-structured depth interviews with 19 U.S. consumers, yielding 72 unique social capital consumption experiences. Participants were selected using established theoretical sampling techniques (Glaser & Strauss, 1967; Strauss & Corbin, 1998; Charmaz, 2006).

Our analysis of the qualitative data involves several concurrent processes. We employ *open coding* to identify important concepts in the data, including properties and dimensions (Strauss & Corbin, 1998). We utilize *axial coding* to reassemble the data that were disjointed during the open coding process and to understand how emerging codes relate to larger categories of interest (Strauss & Corbin, 1998). These two processes combine to yield a concise set of conceptual categories. In addition, we use *selective coding* to identify the relationships among the main categories that emerge from our data during *open coding* and *axial coding* (Strauss & Corbin, 1998). To ensure that the developing theory is well-grounded in the data, we adhere to the "constant comparative approach" proposed by Glaser & Strauss (1967). Finally, to establish trustworthiness, we conduct member checks with all study participants by mailing interview transcripts to respondents and asking them to verify that the written record accurately represents their thoughts and experiences (Lincoln & Guba, 1985).

### Findings

Our analysis illuminates several important findings with respect to how consumers use social capital to facilitate their consumption experiences. We find that consumers utilize three main types of social connections to mobilize social capital in the marketplace. We identify these as *primary*, *secondary*, and *extended linkages*. Further, we highlight the different methods that consumers use to mobilize social capital, including *intentional*, *cooperative*, and *serendipitous approaches*.

In addition, we also identify why consumers utilize social capital to facilitate their consumption experiences. We glean twelve distinct benefits of social capital use from the data, which subsequently constitute four broad outcome categories. These categories include *economic*, *informational*, *procedural*, and *affective benefits*. Furthermore, we identify the unique relationships among these emergent categories to delineate and refine social capital theory in the context of consumption. Finally, we uncover several negative aspects of using social capital in the marketplace, including *recourse bridling*, *trust decay*, and *relationship atrophy*.

This paper makes several new and important contributions to the consumer literature. First, it identifies the distinct processes that consumers use to mobilize social capital, including the type, strength, and nature of the relationships involved. Second, it derives the benefits that consumers achieve by leveraging their social relationships, while also identifying the relationships that exist among these key constructs. In addition, it also uncovers several unforeseen drawbacks associated with consumer social capital mobilization. Identification of these adverse aspects of social capital adds richness and depth to social capital theory, both inside and outside of the consumer domain. Finally, the paper integrates various findings to arrive at a dynamic conceptualization of social capital theory in the context of consumption. Doing so helps to provide new theoretical insight into this interesting and important dimension of consumer behavior.

Finally, our data suggest that the outcomes derived from social capital mobilization impact other important aspects of consumer research, including: reactions to persuasion attempts, customer satisfaction and loyalty, cognitive biases, consideration and choice sets, and referral behavior. As a result, understanding the ways in which consumers utilize social capital to make purchases may illuminate other important dimensions of consumer behavior.

# Making Choices Depletes the Self's Resources and Impairs Subsequent Self-Regulation

Noelle M. Nelson, University of Minnesota, USA
Kathleen D. Vohs, University of Minnesota, USA

Choice is a complex aspect of human life. Each day, consumers make choices that range from integral to trivial. Choices that at one time were fairly simple (e.g., small, medium, or large coffee) have become extremely complex (e.g., in 2003 Starbuck's patrons could choose from 19,000 different beverage selections). Although most consumers would agree that choice, in general, is desirable, choice is not without drawbacks. For one, the information overload that accompanies large choice sets can confuse and frustrate consumers (Huffman and Kahn 1998; Maholtra 1982), even to the point of lessening the odds that consumers will purchase a product out of a large choice set, as compared to when consumers are faced with smaller choice sets (Iyengar and Lepper 2000).

Our investigation provides one explanation for choice's disadvantageous outcomes. We hypothesized that choice is costly to the executive function and can have harmful effects on subsequent tasks. Recent work has focused on an internal resource, resembling energy, upon which the self draws to power the executive function. This resource has been shown to be depleted by the executive function's actions,

and mainly previous research has focused on the debilitating effects of self-regulation. Specifically, people who engage in self-regulation are less successful at subsequent self-regulation tasks as compared to those who had not self-regulated (Baumeister 2002; Muraven, Tice and Baumeister 1998; Vohs and Heatherton 2000). Behavior problems (e.g., overeating) can even follow from depletion of the resource (Vohs and Heatherton 2000).

Choice is defined here as a conscious weighing of alternatives and, along with self-regulation, is a process governed by the self's executive function. The Rubicon Model of Action (Heckhausen and Gollwitzer 1987; Gollwitzer 1990; 1996) characterized choice as a leap between deliberation (thinking about options) and implementation (acting on a choice). Moreover, the two decisional stages of deliberation and implementation are conceptualized as two distinct mindsets. Therefore, moving from one stage to another (i.e., making a choice) requires switching mindsets, which means going from one way of thinking to another that is qualitatively different. Akin to self-regulation requiring energy to alter responses, choice may also require energy to make the leap from deliberation to implementation. Therefore, we proposed that choice may deplete the executive resource.

Following from the idea that choice and self-regulation draw on the same resource, our hypothesis was that making choices depletes the internal resource which, in turn, leaves less of that resource available for self-regulation. Therefore, participants who make choices will be less successful at subsequent self-regulation tasks as compared to participants who do not make choices.

Experiment 1 was designed to show the effect of choice on self-regulatory performance. Participants either made a multitude of choices between two options (choice condition) or evaluated advertisements (no choice condition). Participants' self-regulation task was a test of pain tolerance measured by the length of time they could hold their arm in near-freezing water. As predicted, participants who had not made choices (i.e., who had not depleted their regulatory resources) tolerated the cold water longer than participants who had made choices, showing ego depletion through poorer self-regulation.

A field test of the choice effect was conducted in Study 2. Consumers in a shopping mall were approached with the opportunity to participate in a questionnaire concerning the choices they had made during their shopping trip. The questionnaire was followed by an arithmetic task consisting of three pages of three digit addition problems. Consistent with the hypothesis, shoppers who had reported making more choices spent less time on the math problems and completed fewer problems than shoppers whose choices had been few.

To disentangle the effect of choice on self-regulatory depletion from its constituent parts (deliberation and implementation), we conducted Experiment 3. Participants went to dell.com in order to carry out one of three sets of instructions: full choice (selecting components they would prefer in a computer by entering them into the website), deliberation (thinking about what they would prefer but not entering), or implementation (simply selecting pre-established components on the website). Self-regulation was operationalized as persistence on a solvable anagram task. The results showed that participants in the choice condition spent less time solving anagrams than participants in the deliberation or implementation conditions. This finding supported our hypothesis that choice depletes resources differently than deliberation or implementation alone.

Experiment 4 was designed to test two hypotheses. One prediction was that choice has cumulative effects on self-regulatory resource depletion (i.e., more choices lead to more depletion). Our second prediction was that enjoyment of the choice task moderates the depletion effects. Therefore, people who enjoy the choices they are making will not experience self-regulation failure to the same degree as people who do not enjoy making the choices. Participants made many choices (12 minutes on a bridal registry website), few choices (4 minutes), or no choices. They were then seated in front of a video that was actually only static. Self-control was measured by the time a subject took to alert the experimenter to the problem. More time indicated more passivity and hence less self-control. Indeed, those who had spent the most time making choices took the longest to alert the experimenter to the problem, followed by participants who had made few choices and participants who had made no choices at all (showing the least passivity). Further, enjoyment was only a moderator for those in the four-minute condition; participants who enjoyed the choices showed less passivity than those who disliked the task. Participants who disliked the choices showed similar patterns of passivity as participants who had made choices for 12 minutes. It seems that enjoyment can curb depletion, but only up to a certain extent.

Overall, these experiments demonstrate that making choices depletes resources that are needed for self-regulation. Choice-based depletion reduces the availability of the resource, which results in poor performance on subsequent self-regulation tasks. The effect is robust across domains (e.g., pain tolerance, math problems, anagrams, and passive responding). Our findings advance the importance of considering a general resource for the actions of the executive function of the self.

# Developing a New Measure of Materialism

Eda Gurel Atay, University of Oregon, USA
Joseph Sirgy, Virginia Polytechnic Institute and State University, USA

Richins and Dawson (1992) defined materialism as "the importance ascribed to the ownership and acquisition of material goods in achieving major life goals or desired states." What are these goals? We believe that people value material possessions for three reasons: (1) they may believe that these possessions bring happiness to their lives (Richins and Dawson, 1992; Belk, 1984); (2) these possessions symbolize achievement and success, which in turn generate social recognition and status (Richins and Dawson, 1992), and (3) possessions make people feel distinctive from others, which in turn promote self-importance. The existing measures of materialism do not capture these three dimensions comprehensively. Therefore, we set to develop a new measure of materialism to capture these three dimensions of materialism.

We developed 75 items based on the literature and our construct definitions. After reviewing the items, some of them were deleted because of heavy wording problems and the total number was reduced to 60: 20 items for each of the three dimensions (i.e. happiness, success, and distinctiveness). These items reflected four sub-dimensions: value, affect, belief, and behavior. The measure was administered to 324 students enrolled in a marketing class at a major east coast university.

Initial reliabilities were assessed for both individual subscales and the materialism scale as a whole and six items were deleted because of low corrected item-to-total correlations.

For each of the dimensions, an Exploratory Factor Analysis was conducted employing principal axis factor extraction and oblique rotation. A four-factor solution was achieved for *happiness*, explaining 45% of the variance. Factor analysis results indicated three-factor structure for *success*, explaining 49% of the variance. The first factor included all "affect" items. The second factor was composed of all "behavior" items and one "value" item and the last factor included all "belief" items and one "value" item. Two factors were extracted for *distinctiveness*. The first factor included all "behavior" and "affect" items whereas the second factor included all "belief" and "value" items. This structure explained 57% of the variance. Because of high cross-loadings and low communalities, two items were deleted, leaving 52 items.

Convergent validity was assessed by employing Confirmatory Factor Analysis (CFA) using AMOS 7.0 (Arbuckle, 2007). Two nested models were tested for each dimension: a first-order model that did not include the four subdimensions (value, belief, affect, and behavior) and a second-order model that included the four subdimensions. For each dimension, the second-order model fitted the data better than the first-order model. After deleting some of the items that did not load highly on the expected subdimensions, the selected number of items for each dimension was as follows: 13 for happiness, 10 for success, and 12 for distinctiveness.

Two more CFAs were conducted to see whether these dimensions represented the underlying conceptual structure. The first-order model included materialism as the only latent variable, whereas the second-order model included both dimensions and materialism. By using 35 items, both models did not fit the data well. After some of the items with low loadings were deleted, the second-order model with 14 items provided a better fit with $\chi2$ (74, N=324)=296.541 ($p<.001$), TLI =.905, CFI =.933, and RMSEA =.096.

The final selected items for *happiness* are "Acquiring valuable things is important for my happiness"; "Having luxury items is important to a happy life"; "To me, it is important to have expensive homes, cars, clothes, and other things. Having these expensive items makes me happy"; "Material possessions are important because they contribute a lot to my happiness." There are four items for *success*: "I love to buy new products that affect status and prestige"; "I like to own expensive things than most people because this is a sign of success"; "I feel good when I buy expensive things. People think of me as a success"; "I would pay more for a product if people think of it as a sign of success." The *distinctiveness* dimension includes six items: "My material possessions are important because they make me stand out from the crowd"; "I enjoy owning expensive things that differentiate me from other people"; "I enjoy buying unique and expensive things, because they make me feel different"; "I enjoy owning expensive things that make people think of me as unique and different"; "I usually buy expensive products and brands to make me feel unique and different"; "I usually buy expensive things that make me look distinctive."

Final reliability values were high with Cronbach's Alphas equaled to .882 for happiness, .881 for success, .921 for distinctiveness, and .946 for materialism.

The purified measure was further examined to check whether it performed as expected in a nomological network. Consistent with the literature, we hypothesized that both dimensions and the materialism as a whole would be negatively correlated with life satisfaction (Cole et al., 1991; Richins and Dawson, 1992). Life satisfaction was measured by a single item (Cantril, 1965). Bivariate correlations supported the hypothesis with Pearson correlations equaled to -.168 for happiness, -.189 for success, -.238 for distinctiveness, and -.226 for overall materialism scale ($p<.01$ in all cases). Past research has also indicated that materialistic people are less satisfied with their standard of living (SOL) (Richins & Dawson, 1992; Sirgy et al, 1998). Both the distinctiveness dimension and materialism were negatively related to SOL (measured by a scale adapted from Sirgy et al, 1998) with $r=-.155$ ($p<.01$) and $r=-.129$ ($p<.05$), respectively.

One of the most examined antecedents of materialism is exposure to materialistic advertising (e.g., Buijzen & Valkenburg, 2003). Both happiness and materialism were positively related to exposure to materialistic advertising (assessed by fourteen semantic differential items): $r=.114$, $p<.05$ for happiness; $r=.116$, $p<.05$ for materialism). Lastly, we looked at the relationship between peer communication (Churchill & Moschis, 1979) and each dimension, as well as materialism. All correlation coefficients were significant at .01 level: .278 for happiness, .212 for success, .236 for distinctiveness, and .273 for materialism.

Both reliability and validity assessments suggest that this new measure of materialism makes a contribution to the consumer behavior literature related to materialism.

# End of Life Decision Making: Examining Factors that Lead to Planning

Elyria Kemp, University of Arkansas, USA
Steven W. Kopp, University of Arkansas, USA

Given the financial outlay involved in purchasing death care products (Fan and Zick 2004), as well as the cultural and psychological significance of the funeral ritual (Kastenbaum 1992), consumers would presumably engage in more planning for this unique product. However, a national survey conducted in 2004 reported that although 72% of consumers expressed favorable attitudes about prearranging a funeral, less than 36% of those consumers had actually taken steps to make such plans (Wirthlin 2005). A lack of preparation for end of life may make consumers more susceptible to abuses in the purchase decision process when decisions may have to be made under severe time constraints and grief (Federal Trade Commission 1975, Gentry 1995).

Because of the significance and magnitude of making end of life decisions, a number of consumer protection and government groups have attempted to encourage consumers to plan ahead and make decisions about death care alternatives. This research develops and tests a model that examines some of the attitudinal and motivational constructs that lead to funeral planning behavior. Specifically, it introduces a death attitudinal construct known as death avoidance, which involves resisting considering thinking or talking about death in order to reduce death anxiety (Wonder Reker and Gesser 1994). The model helps to understand consumer behavior in this product category and provides some guidance for transformative consumer research that might address individual factors related to end of life decision making.

## Overview of Model

Making end of life decisions is a unique decision task, which may be affected by an individual's perceived degree of control over the planning process, age, income, opinions of "important others" or subjective norms, as well as an individual's attitude about death. Based on a review of the consumer research literature, we propose a model that predicts intentions to engage in funeral planning. The model is derived from attitudinal and motivational models that have been used to predict human behavior (Ajzen 1991; Netemeyer, Burton and Johnston 1990; Warburton and Terry 2000).

We hypothesize that an individual's attitude toward funeral planning is affected by that individual's degree of perceived behavioral control, or the perceived ease or difficulty in performing funeral planning behavior. In turn, we believe that perceived behavioral control is directly affected by an individual's age, death avoidance and income. Additionally, age is also predicted to moderate the relationship between death avoidance and attitude toward funeral planning.

Further, we offer that an individual's attitude toward funeral planning will have a direct effect on an individual's intentions to engage in funeral planning. Finally, subjective norms, or the perceived social pressure to engage or not engage in planning behavior, will also have a direct effect on intentions to engage in funeral planning.

Our model will also examine three mediating relationships. We believe that perceived behavioral control will mediate the relationships between death avoidance and attitudes toward funeral planning. In addition, we predict that perceived behavioral control will mediate the relationships between age and attitude toward funeral planning. Attitude toward funeral planning is hypothesized to mediate the relationship between age and intentions to engage in funeral planning.

## Methodology

To test the model, data were gathered from two hundred and nine non-student adults from a southern part of the United States. Respondents were presented with survey questions related to funeral planning and were given instructions that "planning" could include discussing plans, leaving instructions with family, or making decisions about funeral and burial goods and services that may or may not require payment in advance. Because direct and mediated effects as well as an interaction were hypothesized, hierarchical regression was used as an analytical approach (Aiken and West 1991; Baron and Kenny 1986; Muller, Judd and Yzerbyt 2005) to estimate the relationship between the constructs in our model.

## Results and Discussion

Results from our model suggest that perceived behavioral control is an antecedent to attitude towards planning, as was proposed. Incorporation of the additional variables—death avoidance, age, and income provided further insight. There were negative relationships between death avoidance and perceived behavioral control as well as attitude toward funeral planning. Individuals may experience lack of control in planning because of an inability to come to terms with their own mortality. These sources of resistance may be due to death avoidance.

Age had a positive, direct effect on an individual's level of perceived behavioral control and the relationship between age and attitude towards planning was partially mediated by perceived behavioral control. Although there was a positive relationship between age, perceived behavioral control, attitudes toward planning and intentions to engage in planning, it appears that an individual's age does not interact with an individual's level of anxiety about death. One explanation for this is that some older individuals do not feel "integrity," or a sense that their life has been meaningful and worthwhile. A lack of integrity could mean that individuals find it uncomfortable contemplating their own mortality and considering funeral planning, regardless of their age.

There was also not the predicted direct relationship between income and perceived behavioral control. This may be due to the fact that discretionary income, rather than gross income, has more impact on an individuals' perception of available resources to engage in funeral planning. Significant (and positive) relationships were found between attitude toward funeral planning and intentions to engage in funeral planning and subjective norms and intentions to engage in funeral planning. Additionally, partial support was found for all three mediating relationships proposed.

Systematic consumer research is needed to help in understanding the consumer decision making process in this unique product category. Our findings provide insight for transformative consumer research as well as social marketing efforts that might help in encouraging consumers to initiate dialogue about end of life preferences. In our study, we found that funeral planning might be subject to control factors such as money or psychological variables related to an individual's attitude about death. We also found that the subjective norm construct was significantly and highly related to intentions to plan. Historically, the subjective norm has been found to be a weak predictor of intentions (Azjen 1991). The relative importance of subjective norms or "important others" in funeral planning behavior may provide some useful insight into the importance of the family structure in this consumption behavior. Further, our model provides evidence that an attitude about death clearly have some effect on their propensity to engage in planning behavior. Marketing communications messages that use persuasive techniques (Knowles and Linn 2004) to mitigate the anxieties and resistance that individuals may have about death might be more effective than other types of appeals in encouraging planning behavior.

# The Moderate Effect of Customer's Brand Awareness on Attitude Change of a Well-Known Brand

Jinsong Huang, Beijing University of Aeronautics and Astronautics, China
Ping Zhao, Tsinghua University, China
Raymond Liu, University of Massachusetts, Boston, USA

Most heavily advertised brands in the market are well-known brands and it is important for us to know whether a well-known brand should still deliver advertising heavily. However, most ad researches simply divide brands into familiar and unfamiliar brands (e.g. Campbell and Keller 2003; Kent and Allen 1994), few researches pay attention to heterogeneity in consumers of well-known brand. This might be the cause for opposing views for effectiveness of well-known brand's ads. Kent and Allen (1994), and Campbell and Keller (2003) find that brand familiarity plays a positive role in communication effectiveness. This implicates that well-known brands should deliver

advertising heavily. However, similar to Machleit and his colleagues (1993), Campbell and Keller (2003) also find that attitude toward the ad has a more powerful impact on brand attitudes for unfamiliar than for familiar brands. Lodish and his colleagues (1995) find that the advertising tests are much more effective for new brands than for established brands. Therefore, well-known brands should not deliver advertising heavily.

We divide consumers of a well-known brand into low and high brand awareness (Laroche et al 2005) categories (in addition, assuming another group with none brand awareness for an unknown brand). These two categories may have different responses to a well-known brand advertisement. When we regard the audiences of a well-known brand as a whole (e.g., Kent and Allen, 1994; Campbell and Keller, 2003), the conclusion is highly contingent on the higher proportional audience type, which in turn might lead to some inconsistence of current research conclusions. In this article, we attempt to examine the moderate effect of brand awareness on brand attitude change.

Three experiments are respectively focused on host product, extended brands' product, and co-branding product with three well-known brands Pepsi, Lenovo and Coca-Cola. The number of participants in Pepsi, Lenovo and Coca-Cola experiments are 207, 405 and 207 respectively. Strong arguments printing ads with real positive information are used as stimulus. All of the participants know the brands but are quite unfamiliar with the ads. The measurement items of brand attitude, attitude toward ad, purchase intention, and message involvement are selected from the literature. Brand unfamiliarity/familiarity and unknown/known are used to measure brand awareness, and brand cognition is measured by thought listing. Reliabilities for all measurements are bigger than 0.7. Exploratory factor analysis was conducted in Lenovo experiment and confirmatory factor analysis in the other two.

The samples are collected one by one in similar self-study rooms by giving a small gift. The questionnaire is 3-paged. Pre-ad attitude, demographic items and other irrelevant questions are contained in the first page and filled out first. After that, the participants are required to read the ad and then to fill in questions in third page. It costs each participant 4-8 minutes to complete the process. Difference between high and low brand awareness is examined by brand usage experiences. Solomon four-group design in Pepsi and Lenovo experiments is conducted to verify whether the experimental stimulus is the only factor for the difference between the pre-experimental test and the post-experimental test.

Participants with low brand awareness in all the three experiments change their attitudes from pre-ad one to post-ad one. The correlation analysis of brand awareness and pre-ad brand attitudes shows that the higher brand awareness, the higher brand attitude evaluation. Further study in the cross effect of brand awareness X message involvement in all the three experiments shows that brand attitude does significantly change before and after ad only when participants have low brand awareness and high message involvement. Ad attitude of the participants with low brand awareness have significantly greater effect on brand attitudes than that of the participants with high brand awareness. However, the effects of cognitive brand response and pre-ad brand attitudes on post-ad brand attitudes are pretty much the same among different levels of brand awareness.

Brand awareness has a significant moderator effect on the three pre-ad brand attitudes, but message involvement has no significant moderator effect on pre-ad brand attitudes. However, when controlling pre-ad brand attitudes, message involvement has a significant moderator effect on post-ad brand attitudes, while brand awareness has no moderator effect on post-ad brand attitudes.

We find in this study that when the level of brand awareness is high, consumers' preference in the brand will increase. The result demonstrates that brand awareness could have a positive effect on ad effectiveness. However, this result only reflects comprehensive effectiveness of enterprises' past marketing effort, rather than the effectiveness of one ad exposure. Therefore, ad exposure has insignificant effect on brand attitudes change to people with high brand awareness. This could explain why the sales will not accordingly increase from ad during continuous large-scale ad delivery. Furthermore, this study implicates that the attitude curve is S shape with segments of none brand awareness, low brand awareness and high brand awareness. When an unknown brand is used to study ads, it is possible that participants do not obtain high awareness during the experiment. Therefore, the study results might be very different from using a well-known brand.

There are some limitations in this study such as limited experiment stimulus and without considering the effect of competitive interference groups and low level exposure groups. In the future study, we will use emotional advertising as experimental stimulus, and carry out experiments with competitive interference groups and low level exposure groups.

# More Than Meets the Eye: The Influence of Implicit versus Explicit Self-Esteem on Materialism

Ji Kyung Park, University of Minnesota, USA
Deborah Roedder John, University of Minnesota, USA

One of the most consistent findings reported in the materialism literature is the link between self-esteem and materialism, with lower feelings of self-worth related to higher levels of materialism (Mick 1996; Richins and Dawson 1992). Material goods are viewed as a way for individuals with low self-esteem to cope with or compensate for doubts about their self-worth.

Recent developments in self-esteem research suggest that the relationship between self-esteem and materialism may be more complicated. Two forms of self-esteem have been identified: explicit versus implicit self-esteem (Greenwald and Banaji 1995). *Explicit self-esteem* is defined as conscious evaluations of the self, whereas *implicit self-esteem* is defined as unconscious evaluations of the self. Consistent with Wilson, Linsey and Schooler (2000)'s dual attitude model, people can have two different attitudes toward the self, such as implicit versus explicit self-esteem. In fact, explicit self-esteem is only weakly correlated with implicit self-esteem, which is considered a distinct dimension of self-esteem (Bosson, Brown, and Zeigler-Hill 2003).

In this paper, we examine the importance of implicit self-esteem as a contributor to materialistic tendencies. We report two studies that demonstrate the usefulness of this construct for understanding materialism. Each of the studies and findings are described below.

## Study 1: The Interaction of Implicit and Explicit Self-Esteem

Prior research has found that individuals with high (explicit) self-esteem exhibit lower levels of materialism. However, individuals with high (explicit) self-esteem are not a homogeneous group. Depending on the level of implicit self-esteem, this group can be categorized into individuals with *congruent high self-esteem* (high explicit/high implicit self-esteem) and individuals with *discrepant high self-esteem* (high explicit/low implicit self-esteem).

Not surprisingly, these two groups exhibit different behavioral patterns. Individuals with discrepant high self-esteem have underlying self-doubts associated with low implicit self-esteem. To conceal such negative self-feelings, these individuals use various forms of self-enhancing strategies. Relative to individuals with congruent high self-esteem, they tend to exhibit overt grandiosity, higher levels of narcissism, and indirect forms of self-enhancement, such as out-group derogation and in-group biases (Bosson, Brown, and Zeigler-Hill 2003; Jordan et al. 2003; Kernis et al. 2005). In sum, individuals with discrepant high self-esteem possess some of the same characteristics usually attributed to individuals with low (explicit) self-esteem, with both groups engaging in self-enhancing strategies to compensate for negative self-feelings.

Thus, we predict that individuals with discrepant high self-esteem will exhibit high levels of materialism, compared to individuals with congruent high self-esteem. We measured intact levels of implicit and explicit self-esteem, comparing how combinations of these types of self-esteem relate to materialism. Explicit self-esteem was measured using the Rosenberg Self-Esteem Scale (Rosenberg 1965), and implicit self-esteem was measured using the self-esteem Implicit Association Test (IAT: Greenwald and Farnham 2000). In the computerized self-esteem IAT, the participants were asked to categorize words as quickly and as accurately as possible. This test is based on the logic that individuals with high implicit self-esteem will associate the self and positive affect automatically. They will respond faster when they indicate whether a word belongs to the *self + pleasant* category vs. the *other + unpleasant* category than when they indicate whether a word belongs to the *self + unpleasant* category vs. the *other + pleasant* category. Materialism was measured in two ways: (1) Richins and Dawson (1992)'s materialism rating scale; and (2) a qualitative task in which levels of materialism were revealed by asking participants to construct a collage to answer the question: "What makes me happy?" (see Chaplin and John 2007).

The results were supportive of our hypothesis. Individuals with discrepant high self-esteem (high explicit/low implicit self-esteem) were more materialistic than individuals with congruent high self-esteem (high explicit/high implicit self-esteem). Thus, contrary to prior materialism research, we find that individuals with high (explicit) self-esteem are not always immune to the appeals of materialism. Implicit self-esteem must be taken into account to understand what types of high self-esteem individuals are more or less susceptible to materialism.

Also of interest was the fact that the collage materialism measure was most effective in detecting the hypothesized differences. This appears to be related to the fact that the collage measure was less affected by socially desirable responding than the rating scale measure. In fact, when SDR was controlled, the rating scale measure revealed the same patterns as the collage measure. This finding parallels results from implicit attitude research, showing that implicit attitudes predict less controlled responses (Payne et al. 2005).

## Study 2: The Causal Impact of Implicit Self-Esteem on Materialism

Next, we examined the causal link between implicit self-esteem and materialism by priming implicit high self-esteem. Findings from Study 1 are suggestive, but do not rule out the possibility that materialism affects implicit self-esteem, rather than the reverse. In Study 2, we primed implicit self-esteem through subliminal evaluative conditioning (Dijksterhuis 2004), while measuring the intact levels of explicit self-esteem. In a lexical decision task presented on a computer, the participants were asked to respond as quickly as possible whether the target was a real word. In the priming condition, the self-depicting word "I" (for 17 ms) was immediately followed by a positive word; in the control condition, the word "I" was substituted with the letter "X." Materialism was measured using the collage task, given the results from study 1.

The results replicated those of Study 1. High implicit self-esteem priming reduced materialism; indeed, materialism was lower for the high explicit self-esteem participants in the priming condition than those in the control condition.

## Summary

Prior research has found that individuals with high self-esteem are less materialistic than those with low self-esteem. We add to these findings by distinguishing two types of self-esteem, explicit and implicit self-esteem, and demonstrating that they have a joint influence

on materialism. Specifically, we find that individuals with high explicit self-esteem vary in their tendency to self-enhance through material things as a function of their levels of implicit self-esteem. Thus, contrary to prior research, individuals with high explicit self-esteem can be susceptible to materialism.

# The Effect of Regulatory Focus on the Anchoring Bias

Shenghui Zhao, University of Miami, USA
Rongrong Zhou, Hong Kong University of Science and Technology, China

Consumers' numerical judgments (e.g., decisions on purchase quantity and willingness-to-pay) are often influenced by irrelevant anchor values provided by marketers (e.g., Wansink, Kent, and Hoch 1998). Although the research on anchoring bias is extensive, little extant research has investigated the moderating role of motivation or personality traits. The present research seeks to fill this research gap by examining the influence of regulatory focus on anchoring bias.

Recent theories of the anchoring bias highlight the role of biased memory retrieval process (e.g., Chapman and Johnson 1999; Strack and Mussweiler 1997). According to the selective accessibility model (Mussweiler and Strack 1999), for instance, the presence of the anchor activates a confirmatory retrieval process that favors anchor-consistent information at the expense of anchor-inconsistent information. As a result, anchor-consistent information becomes more accessible at the time of numerical judgment and thus exerts more influence on judgment than anchor-inconsistent information (Feldman and Lynch 1988). For example, when a decision maker is asked, "Is the Mississippi River longer or shorter than 12,000 miles?" the anchor value (12,000 miles) facilitates the recall of information that is supportive of the notion that the Mississippi River is very long. Information that suggests otherwise is inhibited. Thus, the decision maker will give a much higher estimate when she is later asked to estimate the actual length of the river. Consistent with these arguments, elaboration of the anchor value has been shown to increase the anchoring bias because such elaboration further enhances the relative accessibility of anchor-consistent information (e.g., Wilson et al. 1996).

Research on regulatory focus has offered growing evidence on the significant differences in processing style between promotion focus and prevention focus. As pointed out by Higgins (1998) and Pham and Higgins (2005), promotion focus generally facilitates a more explorative and inclusive processing style where alternatives are eagerly sought whereas prevention focus encourages a more vigilant and exclusive processing style that scrutinizes the information involved in the decision task. For example, Friedman and Förster (2001) showed that individuals who were primed with prevention focus were less creative in problem solving, more rigid in categorization, and more prone to associative interference. Likewise, decision makers under prevention focus have been shown to generate and endorse fewer alternative hypotheses than their promotion-focused counterparts (Liberman, Molden, Idson, and Higgins 2001). In the context of the current research, we propose that prevention focus is likely to exacerbate the confirmatory tendency of the memory retrieval process following exposure to the anchor value and thus further enhance the relative accessibility of anchor-consistent (vis-à-vis anchor-inconsistent) information. Due to such differences in processing style between promotion focus and prevention focus, we hypothesize that individuals under prevention focus should exhibit a stronger anchoring bias in numerical judgments than those under promotion focus.

This hypothesis was tested in two laboratory experiments. Both experiments used a 2 (regulatory focus; between-subjects) x 2 (anchor value: high vs. low; within-subjects) mixed design. In both experiments, participants were first primed with either promotion or prevention focus (using the priming procedure in Lockwood, Jordan, and Kunda 2002) and then made numerical judgments with either high or low anchor values. The data provided strong support for our hypothesis. The data revealed a significant regulatory focus x anchor value interaction such that answers from participants who were primed with prevention focus (vis-à-vis those primed with promotion focus) were closer to their anchor values, indicating greater anchoring effect. Moreover, in study 2, after numerical judgments, participants were also asked to list the thoughts that went through their minds as they were making the numerical judgments. These verbal protocols were coded as consistent, inconsistent, or irrelevant to anchor values. As expected, prevention-primed participants listed proportionally more anchor-consistent thoughts than did promotion-primed participants. A mediation analysis confirmed that the effect of regulatory focus was mediated by the relative proportion of anchor-consistent vs. anchor-inconsistent thoughts in the verbal protocols.

These results suggest that the effectiveness of anchoring-inspired marketing practices (e.g., displaying MSRP) is likely to vary depending on the regulatory focus of the customer. This research contributes to the growing literature on anchoring bias and regulatory focus. In particular, it offers interesting insights regarding the effects of regulatory focus on consumers' information processing strategies. It also holds important implications for cross-cultural marketing since Asian cultures are generally more prevention-focused than their western counterparts (e.g., American).

# Getting Begets Wanting: A New Theory about Long-term Changes in Strength of Motivation

Kathleen D. Vohs, University of Minnesota, USA

Andrew M. Kaikati, University of Minnesota, USA

Standard theories of motivation propose that satisfaction reduces subsequent motivational drive (Hull 1943; Spence 1956). These theories of motivation are based on the satiation cycle, which presumes a standard pattern of motivation, such that people have desires, pursue satiation of those desires, and when they are able to satiate those desires, their motivational strength for those desires is reduced. Although we agree with this account of motivation for desires in the short run, we contend that a new model better accounts for changes in motivational strength over the long run. Rather than extinguishing subsequent wanting, the effect of satiating a desire may trigger a stronger and longer-lasting wanting for a stimulus. This new theory of long-term changes in motivation is entitled "getting begets wanting" and three experiments were conducted to test it. In sum, the getting begets wanting theory predicts that satiation of desires will lead to a long term increase in motivational strength for an object.

We conducted three studies to test getting begets wanting. Our goal across these studies was to expose or increase exposure to an object or event, and then to test for changes in motivation to experience that object or event after some period of time.

In experiment 1, participants were randomly assigned to take home either a crossword puzzle book containing puzzles ranging in difficulty or a hand-held electronic Solitaire game (a control group served as a baseline for comparison and completed only pre- and post-experimental tasks). Participants in the two experimental conditions were asked to complete crossword puzzles or play their game for 20 minutes each day, and to complete questionnaires about their mood (before and after the activity), their success at the activity, and amount of time spent thinking about the activity. Results indicated that participants in the experimental conditions enjoyed their activities (crossword puzzle or video game) more, thought about them more, and felt more successful than did control-condition participants.

Furthermore, at the end of the five-day experiment, participants were asked to take part in another short, unrelated experiment with a different experimenter. They first completed several filler questionnaires which were intended to make the concept of the games less salient. Next, they were asked to choose between several activities, one of which was the game they had played during the previous five days. The results indicated that participants chose this option at a greater probability than would be predicted by chance and at a higher level than participants in the other condition.

Experiment 2 tested getting begets wanting in the context of napping behavior. Participants were randomly assigned either to take a nap for 15 minutes per day for four of eight days, or to *think about* taking a nap for eight minutes on each of eight subsequent days. This control condition equated the concept of napping as activated mentally. Results indicated that participants in the "actual-napping" condition thought more about napping, were more satisfied and enjoyed the experiment more as the days went by than did participants in the "think-about-napping" condition. This method provides a stronger test of the getting begets wanting theory than that in experiment 1: the control group in this study rules out the possibility that merely *thinking about* an activity is sufficient to increase subsequent motivation for an action or event. Only actually *getting* (i.e. becoming satiated) increases subsequent wanting.

Experiment 3 tested getting begets wanting in the context of reading the news. Participants were randomly assigned to one of three conditions, two of which were control conditions. Participants in the experimental condition completed an initial questionnaire regarding their news-related behaviors. Next, they were asked to read the top 10 news stories on a popular news website every day for a two week period. Participants in a monitoring condition similarly completed an initial questionnaire, but they were then asked to keep a daily diary of their news-related behaviors. Participants in the second condition completed only post-experimental measures (as a no-treatment control). At the end of the two-week period, all participants were asked about their news-related behaviors over the previous two weeks. Results indicated that participants who were randomly assigned to consume news were later more involved in consuming the news at the end of the two week period, compared to participants assigned to monitor their news-related behaviors and participants in a control group. Relating directly to the tenets of the getting-begets-wanting model, participants in the condition assigned to consume news later considered themselves to be more of a "news junkie" than did participants in either control group. In short, consuming news makes people want to consume more news in the future.

There were several benefits of this study over the previous two studies. First, we tested the getting begets wanting theory in a new domain. Second, we tested against a control condition that was also tracking participants' 'getting-related' behaviors (control condition 1), but we were not manipulating those. Instead, this control condition group was high in monitoring, as was the group who was in the getting condition, but the former also consumed more media overall, which in our model should stimulate the wanting response. Third, we tested whether a more generalized motivational state arose after daily consumption of news.

The results of all three studies supported the getting begets wanting theory: that getting people to engage in an activity leads them to want to perform the activity more over time. We expect that the reason the getting begets wanting theory works is because of the expanded time horizon in human beings, known as the "extended now." This model is also expected to apply to changes in appetitive desires, such as those for sex, alcohol, food, money, and gambling, as well as to consumer behaviors such as being a sports fanatic, cooking, and running.

# Remembering What Was New: The Role of Stimlus Novelty in Retrospective Evaluation of Experiences

Rajesh Bhargave, University of Pennsylvania, USA

People harvest their past experiences through memory. For instance, a pleasurable wedding provides memories that can be enjoyed over a lifetime of reminiscence. Conversely, memory of a stressful medical procedure imparts valuable lessons that guide future choices. Though we regularly draw on our memories, we can only remember the gist of the past, and this limitation impacts how we form evaluations of past experiences. When people form a retrospective evaluation they rely on a series of snapshots of important moments in an experience rather than an integration of all moments in the experience (Fredrickson and Kahneman 1993). According to this snapshot model, the most important gestalt characteristics of an experience are its peak, end, beginning, trend, and rate of change for the affect derived from the experience (Ariely 1998; Hsee and Abelson 1991; Kahneman et al. 1993; Schreiber and Kahneman 2000).

Service providers are particularly interested in people's global evaluations of experiences, because consumers rely on these evaluations when deciding whether to repeat experiences. Many service experiences are composed of discrete moments that are aggregated together to form a sequence, resulting in a partitioned experience (Ariely and Zauberman 2000; 2003). The discrete moments in a partitioned experience differ not only in their placement in time and their affective intensity, but also in the particular stimuli they are associated with and the specific emotions they evoke. For example, vacations include various activities that generate different moods, and dental appointments include procedures that vary in their form of discomfort. In this paper I ask, how do people arrive at an immediate global evaluation of these partitioned experiences, and how do they remember these experiences after a passage of time?

I argue that the level of familiarity people have with affectively-charged stimuli impacts their immediate, global evaluation of partitioned experiences and their later, retrospective evaluations. I propose that when people are familiar with the stimuli in a partitioned experience, they are able to perceive the discrete moments in a partitioned experience as a whole, resulting in a global evaluation heavily predicted by online ratings. However, when remembered after a delay, these mundane experiences assimilate to prior experiences in the

stimulus domain, resulting in devaluation of actual experience and over reliance on category knowledge (see Tulving 1972). In contrast, novel experiences exhibit a different hedonic calculus over time. In forming an immediate, global evaluation, people are less able to integrate the moments in a novel, partitioned experience. However, after a delay, they are able to integrate the experience because this greater temporal distance is associated with more holistic processing (Liberman and Trope 1998). Thus, I predict that for novel experiences, gestalt characteristics of the experience become more important in determining remembered utility over time, but for mundane experiences, gestalt characteristics of the experience become less influential over time.

The proposed mechanism has some preliminary support in the literature. Ariely and Carmon (2000), and Ariely (1998) show a muted effect of peak pain on retrospective evaluation when the focal experience is one of many such encounters with the stimulus domain. In their study, participants were long-term patients in a bone marrow transplant unit. These patients were asked to report overall evaluations of the pain experienced during a medical procedure. Long-term patients tended to provide retrospective evaluations that were based less on their online ratings of the focal experience. While these authors did not test the role of stimulus familiarity directly, their results would suggest that new patients in this unit would have a different evaluation process than long-term patients.

I tested the proposed mechanism with a controlled experiment. Participants were asked to listen to five aversive sounds for a total duration of five minutes. While listening to the sounds, participants provided their real-time ratings of the pleasure or displeasure they derived from listening to the sounds. As a between-participants manipulation, some participants listened to a mundane 'jackhammer' sound and others listened to a novel 'electric surge' sound at the final position of the five-sound sequence. These two sounds were selected to be the most unpleasant sound of each set. These peak sounds were pre-tested and validated with the same participants for perceived familiarity; the jackhammer sound was much more familiar to participants than the electric surge sound, though these two sounds were rated as equally aversive. After listening to all sounds, participants provided a global evaluation of the experience. Two days later, they were e-mailed and asked to provide another retrospective evaluation of the five-sound sequence. The results demonstrated that participants who listened to the mundane jackhammer sound as their peak sound tended to report global evaluations that were heavily determined by this peak. However, after a delay, their retrospective evaluations did not depend on their online evaluations of the peak, as would be predicted by the snapshot model. In contrast, participants who listened to the novel electric surge sound as their peak sound tended to report global evaluations that were not based on online ratings. However, after a delay, their retrospective evaluations were heavily predicted by their online evaluations.

Findings from this first study motivate further work on the role of stimulus novelty in retrospective evaluations of experience. In addition to testing the proposed mechanism for partitioned experiences, this research aims to address more broadly how consumers evaluate experiences they are already familiar with. This issue is relevant to marketers, because consumers regularly encounter the same experiences over and over again. For instance, a consumer may frequent the same restaurant, barber shop, and website. How might such a consumer arrive at a global evaluation of each repeat experience? Would the evaluation process for a familiar experience differ from that for the first encounter, when the experience was fresh, unfamiliar and novel? Further research will tackle these and other questions.

# Sources of Brand Personality: A Survey of Ten Brands

Natalia Maehle, Norwegian School of Economics and Business Administration, Norway
Magne Supphellen, Norwegian School of Economics and Business Administration, Norway

A brand, like a person, can be characterized as being "dependable", "lively", "exotic" or "old fashioned". Brand personality is defined as the set of human characteristics associated with a brand (Aaker 1997). Aaker developed a measurement scale of brand personality consisting of five dimensions and 42 traits. This scale, or parts of it, has been used in a number of studies of consumer behavior (e.g. Okazaki

2006; Supphellen and Gronhaug 2003; Venable and Rose 2003). The primary focus of these studies has been either on the effects of brand personality or on measurement issues. Less attention has been devoted to the sources of brand personality.

The traditional view is that personality traits become associated with a brand through the people who represent it-such as the typical user of a brand, the company's employees or CEO, and the brand's endorsers. This way to form brand personality is described as the *direct way*, because the personality traits of the people associated with the brand are transferred directly to the brand (McCracken 1989). However, perceptions of brand personality traits have a more diverse origin. They can be formed not only directly but also *indirectly* through product-related attributes, product category associations, brand name, symbol or logo, advertising style, price, and distribution channel (Batra, Lehmann, and Singh 1993). Thus, there are diverse sources of brand personality and the question is how marketers can understand and use them to develop desired personalities for their brands.

The Aaker scale encompasses five different dimensions: Sincerity, Excitement, Competence, Sophistication, and Ruggedness (Aaker 1997). We suggest that these dimensions differ in their nature and are typically formed by different sources. A survey was conducted to test this assumption. A pretest was conducted in order to select appropriate brands for the main study. To qualify for the main study, the selected brands should have high scores on one of the five brand personality dimensions. First, a list of ten well-known brands with presumably high scores on the Sincerity dimension was developed. Ten respondents (undergraduate students) were asked to choose the two brands which in their opinion scored highest on Sincerity. The same procedure was used for brands with presumably high scores on the other four dimensions of brand personality (Excitement, Competence, Sophistication, and Ruggedness). As a result of the pre-test, ten brands were chosen for the main study: Lego and Ikea (Sincerity), Apple and MTV (Excitement), Volvo and IBM (Competence), Rolex and Gucci (Sophistication), Jeep and Harley-Davidson (Ruggedness).

For the main study we generated an extensive list of possible sources of brand personality based on the existing literature (McCracken 1989; Batra, Lehmann, and Singh 1993; Aaker 1997) and our own experience from doing research on brand personality. The list included fourteen different sources: *company's employees, company's managing director, endorser, typical brand user, product attributes, own experience when using the product, product category, brand name, brand logo, advertising style, price, retail stores, country of origin, and company's moral values.*

One hundred thirty-nine undergraduates participated in the main study. First, the concept of brand personality and brand personality scale were explained to the respondents. Then, they were asked to evaluate to which extent the suggested sources of brand personality were relevant for their perception of brand personality characteristics for each brand. A 7-point scale ("7"="Extremely relevant"; "1"="Not at all relevant") was used. After comparing the relevance of different sources of brand personality for every personality dimension we observed the following pattern of results. For Lego and Ikea the most relevant sources of Sincerity were *own experience when using the product* ($M_{exp}$=5.90), *company's moral values* ($M_{mor}$=5.58), and *price* ($M_{pr}$=5.52). For Apple and MTV the most relevant sources of Excitement were *endorser* ($M_{end}$=5.71), *company's employees* ($M_{empl}$=5.58), and *advertising style* ($M_{ad}$=5.41). For Volvo and IBM the most relevant sources of Competence were *company's employees* ($M_{empl}$=5.80), *company's managing director* ($M_{dir}$=5.59), and *product attributes* ($M_{att}$=5.45). For Rolex and Gucci, the most relevant sources of Sophistication were *endorser* ($M_{end}$=6.11), *typical brand user* ($M_{use}$=5.77), *brand name* ($M_{nam}$=5.75) and *logo* ($M_{log}$=5.71). For Jeep and Harley-Davidson, the most relevant sources of Ruggedness were *typical brand user* ($M_{use}$=5.65), *product attributes* ($M_{att}$=5.22), *endorser* ($M_{end}$=5.21), and *logo* ($M_{log}$=5.20). Most of the differences between the relevance of different sources were found statistically significant ($p<0.05$).

The results support our assumption that brand personality dimensions differ in their nature and come from different sources. The most important sources of Competence and Sincerity are company-level sources such as *company's moral values*, *the CEO* and *company employees*. Also, *price* (Sincerity) and *product experiences* play a role.

Sophistication and Ruggedness seem to be formed to a large extent by brand symbols such as *endorsers*, *typical brand users*, *brand name* and *brand logos*. Ruggedness has one more source (product attributes). The rugged nature of brands such as Jeep and Harley-Davidson is partly communicated through their special attributes (high speed, rough design, etc.).

Excitement seems to be formed by a blend of company-level sources (employees), symbols (endorser) and advertising style. It is somewhat surprising that product/service experience is not a more relevant source of Excitement. Apparently, for the two brands included in the study (Apple and MTV) the excitement represented by other people (endorser, employees and people in the ads) is more relevant than our subjects' own personal experience of excitement.

This study of ten brands demonstrated that brand personality dimensions tend to come from different sources. Moreover, we found systematic differences regarding which sources are relevant for building each dimension. The next step will be to test the generalizibility of the results with a larger number of brands and examine the psychological processes behind the observed patterns.

# Transferring Meaning from Cultural Entities to Brands

Margaret C. Campbell, University of Colorado, Boulder, USA
Caleb Warren, University of Colorado, Boulder, USA

Because of their implications for marketplace success, brand personality and equity are highly important issues for marketing researchers and practitioners. Researchers from varying theoretical backgrounds suggest that brands can gain meaning from the cultural entities—e.g. people, places, images, words, events, and other brands—with which they are associated (e.g., Keller 1993, 2003; McCracken 1986, 1989). However, while this idea is well-accepted, surprisingly little research has investigated how and when meaning transfers from a cultural entity to a brand. In particular, questions remain as to whether meaning transfer depends on the conditions under which the brand is paired with the cultural entity.

Although consumers accept brand meaning, they often actively participate in the negotiation or formation of the meaning for a brand (e.g., Allen, Fournier, and Miller forthcoming). Research on the persuasion knowledge model, attribution theory, and consumer resistance suggests that the transfer of meaning from a cultural entity (CE) to a brand may depend on consumers' inferences of why the CE is paired with the brand (Friedstad and Wright 1994; Holt 2002). If consumers believe that a marketer is pairing a CE and a brand as a commercial tactic, consumers may resist or discount meaning that they feel is inauthentic or forced upon the brand. Hence, meaning transfer may be inhibited if consumers perceive a co-occurrence of brand and cultural entity as commercially "contaminated" (Grayson and Martinec 2004).

This research explores the transfer of meaning associated with a CE to a new brand. Importantly, we also investigate the extent to which the pairing of the CE and the product seems authentic versus commercially-motivated influences the transfer of associations from the CE to the brand. Whereas the research cited above suggests that inferences of commercial intent would inhibit meaning transfer, work on memory suggests that transfer may occur from the pairing, regardless of such inferences.

## Method

This study manipulated the cultural entity paired with a new brand to explore the transfer of meaning. The study also manipulated the implied motivation for the pairing. Since brand personality traits are one facet of a brand's meaning that may readily transfer from a brand's user to the brand itself (Aaker 1997; Keller 1993), we selected two celebrities with distinctive and strongly associated personality traits to be paired with the brand (pretests indicated that Clint Eastwood and Jessica Simpson have relatively low personality overlap, with Eastwood more rugged and tough, and Simpson "ditsy" and young ($p$-values<.001)). We manipulated which celebrity was described as wearing the brand, and the extent to which inferences of motive were activated, and then assessed the extent to which the personality traits originally associated with the celebrity endorser were transferred to the brand.

Students at the University of Colorado (147) were randomly assigned to a 2 (celebrity: Clint Eastwood or Jessica Simpson) x 2 (endorser motivation: genuine interest or paid sponsorship) between subjects design. Participants first completed a study in which they read a series of three brief fashion articles. The second article was one of four versions that contained the celebrity pairing and the endorser motivation manipulations.

Two purportedly independent studies followed: a five-minute distracter task and a "brand personality survey" in which participants rated Slade watches plus three filler brands (counterbalanced) on a series of personality traits. The brands were rated on seven-point, "disagree" and "agree" scales for intelligent, strong, young, sexy, honest, ditsy, dull, tough, exciting, rugged, attractive, foolish, old, and sincere (e.g., Aaker 1997).

## Results

A 2 x 2 ANOVA revealed a main effect of celebrity on the following personality traits: tough, rugged, strong, old, young, and ditsy. Slade watches were seen as significantly tougher ($t$=-4.47, $p$<.0001), more rugged ($t$=-4.70, $p$<.0001), stronger ($t$=-1.91, $p$=.058), older ($t$=-3.10, $p$=.002), less young ($t$=2.59, $p$=.01), and less ditsy ($t$=4.12, $p$<.0001) when participants read about Clint Eastwood wearing the watch versus Jessica Simpson. The endorser motivation manipulation did not have a significant main effect on any of these trait ratings. There was only one significant interaction effect. The effect of celebrity on ratings of "old" interacted with the endorser motivation such that Slade was perceived as significantly older when paired with Clint Eastwood in the genuine interest condition versus the paid sponsorship condition ($t$=2.38, $p$=.02). Other than this one case, the effect of celebrity pairing was not influenced by the endorser motivation, even though a check showed that the manipulation resulted in significantly more inferences of commercial motive in the paid sponsorship than the genuine interest condition.

## Discussion

Our data provides some of the first evidence in a controlled experimental setting showing that meaning transfers from a celebrity to a brand. Interestingly, we did not find evidence that meaning transfer is attenuated when participants infer that a celebrity endorses a brand because of a financial incentive rather than a genuine interest in or liking for the brand. Although there are many possible explanations for a null result, the absence of an effect of the endorser motive is somewhat surprising. Given that our endorser motivation manipulation check succeeded, these results suggest that meaning transfer resulting from pairing a cultural entity to a brand may be fairly robust. At a minimum, the results suggest that even when consumers think about the marketing intent behind a cultural entity-brand pairing, they may learn the presented brand meanings.

Our first experiment documents a main effect of meaning transfer from a cultural entity to a brand. While evidence of an effect is a first step, we propose to investigate the specific processes that mediate and factors that moderate meaning transfer. A better understanding of meaning transfer will help marketers more efficiently construct desired brand identities, consumers better resist undesired marketer influences, and public policy makers formulate more informed decisions concerning marketing practices such as celebrity endorsement, product placement etc. that attempt to create brand meaning through the co-occurrence of cultural entities and brands.

# The Everyday Practices Surrounding Young People's Food Consumption

Pepukayi David Chitakunye, Keele University, UK
Pauline Maclaran, Keele University, UK

This research explores the everyday food consumption practices that young people adopt in response to mealtime interdependencies at home and at school, and the meanings embedded in these practices. The nuanced meanings of food consumption have been somewhat overlooked in consumer research. The majority of extant studies in this area concentrate on experimental or survey-based approaches to look at regional, ethnic or class-based food attitudes (i.e. Verbeke and Lopez ,2005; Tomlinson,1994), or speciality markets such as organic food consumption (Squires, Juric and Cornwall, 2001), with a view to discovering potential new market segments. A few studies in the Consumer Culture Theory tradition have explored more deeply the symbolism of eating in relation to: the food culture of particular societies or ethnic groups (Ahmad, 1998; Hetzel, 1999); consumer micro-cultures (Thompson and Troester, 2002); and specific consumption events (Wallendorf and Arnould, 1991). However, apart from Hirschman et al. (2004), there has been little research that examines the differing contexts of eating, especially among young people, and how these affect the meanings attached to food consumption.

Given the ever-increasing trends towards obesity in the developed world (Barnwell et al., 2005; Farah and Buzby, 2005), it seems especially important to gain insights into such practices. Research that places more emphasis on phenomenological meanings in contemporary food consumption practices can lead to a better understanding of intergenerational conflicts over mealtime practices, and help unpick the symbolic dynamics that emerge between parents and children; and between children and teachers in institutions of social control (the family and the school).

In light of the structural, sociological transformation of key social institutions such as the family and schools, it seems appropriate to explore the way social relationships, and interdependencies between parents, teachers and young people are re-negotiated over contemporary everyday food consumption practices, especially at mealtimes. The transformation in social institutions also means that social relationships have to be renegotiated because people (young people in particular) have been liberated from traditional roles and constraints, and individuals are removed from status based classes (Beck and Beck-Gernsheim, 2002). We are interested to discover whether the same long-term changes in the structure of societies which Norbert Elias argues in his book, The Civilising Process (1939), brought about changes in manners, in the expression of emotions, and in personality structure (Mennell, 1985), are reflected in the patterning of the everyday practices surrounding young people's food consumption. This still remains an area requiring further investigation.

Whilst anthropologists and sociologists have shown that food consumption that takes place through the family meal, is a core activity in family life (Douglas, 1972; Douglas and Isherwood, 1979; Murcott, 1983, 1997; Charles and Kerr, 1988; De Vault 1991; Warde, 1997), and in particular a meeting point in everyday life (Lupton, 1996), an analysis of the practices through which children and their parents consume is largely absent. So, too, the part played by consumers as individuals and as members of interrelated social groups appears to have been missed in empirical and theoretical accounts of children's consumption (Martens et al, 2004; Martens, 2005).

Participants to the meal occasion *'eat and drink together'*, and *'are by this very act tied to one another by a bond of friendship and mutual obligation'* (Smith, 1889:247 in Mennell et al, 1992:115). If at mealtimes, young people, parents and teachers are *'bound together through interdependence with each other, they have power over each other- sometimes very unequal and one-sided, sometimes rather evenly balanced, usually fluctuating to some extent, and often changing in a definite direction over time* (Mennell, 1985: 16). The very fact that young people, parents and teachers are interdependent with each other implies that they exert forces over each other, forces which shape not just their overt behaviour but their tastes and the way they think about themselves and their activities (cf.Mennell, 1985: 16).

Given this background, we explore the dynamics in parent-child and teacher child relationship, as reflected through the everyday practices surrounding young people's food consumption. What are the everyday food consumption practices that young people adopt in response to mealtime interdependencies at home and at school, what meanings are embedded in these practices, and how are these interdependencies mediated by marketing phenomena?

This study uses an interpretive research strategy. Stage 1 of the research was school-based and gathered data from school children aged between 13 and 17 through observation, semi-structured and in-depth interviews as well as visual diaries. Stage 2 was an observation during family mealtimes; we talked informally with family members. The research followed a theoretical sampling approach for recruiting informants, i.e. a sample that typifies the population, the theoretical category or the phenomenon to be studied and was chosen purposefully with consideration to representativesness (Mason, 2002; Silverman, 2000). In addition, online research was used to sensitise the researchers to the culturally resonant categories (Hirschman et al., 2004). In total the dataset so far consists of 13 personal interviews, 9 online interviews, 23 visual diaries, mealtime observations with 3 families, and 42 days of school-based observations. The data analysis is following the principles for the analysis and interpretation of qualitative data as recommended by Spiggle (1994) and others (Strauss and Corbin, 1998; Arnould and Wallendorf, 1994), and continuing in an iterative fashion across offline and online environments.

A key theme that is emerging at meal times in relation to the meanings created with food consumption is the relationship between formal and informal environments (Warde and Martens, 2000) for food consumption and between parental and teacher control, and how these are mediated by marketing phenomena. Informants described a life world which they energised by the goals of individualism. In response to mealtime interdependencies at home and at school, informants adopt practices such *as 'play-eating', 'eating-in-front-of-the-telly', 'eating-making-a-mess', 'eating-at-any-time'* and *'speed-eating'*. Evident from our field notes, is the successful and collective orchestration of these practices through trickery, mischief, cheating, deception and non-conformity (Willis, 2001). The emergent practices were shared by most informants, regardless of their social or economic status. This is contrary to dominant perspectives in consumer research that centers on the premise that taste classifies and classifies the classifier (Bourdieu, 1984:6), and that consumption is indicative of social categories (Douglas and Isherwood, 1979).

Drawing on our fieldwork, we argue that the emergent practices are not only indicative of intergenerational conflict over food consumption practices and values. Other considerations include, (1) the re-creation of community amongst young people in a world where parents reportedly find work more rewarding than family life (Hochschild, 1997); (2) a search for a relationship of equality rather than one which is asymmetrical and based on authority and inequality; (3) a rebellion by young people against social control exerted by parents and teachers; (4) a form of escape from traditional roles inscribed in the family and the school in search of freedom and independence; (5) a challenge posed by young people to values of traditionalism that some parents and teachers might seek to uphold; (6) an expression of individuality and search for self-identity; and (7) an ongoing opposition to dominant lifestyle norms and formal food consumption practices such as eating round the table and obeying traditional meal-time rituals.

# Toward a Better Understanding of the Effects of Customer Education on Usage Behavior and Satisfaction

Benoit Aubert, Grenoble Ecole de Management, France

Despite the growing interest of consumer goods manufacturers for customer education and the recent awareness in marketing literature of this concept (Mittal and Sawhney 2001; Hennig-Thurau et al. 2005), research on customer education remains scarce. This work aims to understand the effects of customer education on the skills level, usage behavior and satisfaction of consumers.

## Conceptual background

*Defining customer education*: Customer education is defined as the companies' investments in improving customer expertise in relation to the goods and services they market (Honebein and Cammarano 2005). It relies on instructional activities, such as face-to-face seminars, implemented to leverage product usage related skills of a company's potential or actual customers.

While early investigations showed that customer education had its place in all phases of the decision-making process (Honebein 1997), attention has recently been given to post-purchase customer education (Hennig-thurau 2000). The main reasons are: the importance given to consumption in value creation (Vargo and Lusch 2004), the increasing complexity of products (Thompson et al. 2005), and the expertise that customers must develop to unlock product value (Hennig-Thurau et al. 2005).

*The post-purchase outcomes of customer education*: At the post-purchase stage, three outcomes of customer education are considered. First, consumers may increase their level of product usage related skills (Hennig-thurau 2000; Shih and Venkatesh 2004). Second, customer education may positively affect the way customers use their product, either by ensuring compliant behavior (Bowman et al. 2004) or by unlocking the product's value (Hennig-Thurau et al. 2005). Finally, an increased ability to use a product can lead customers to express a higher degree of satisfaction (Shih and Venkatesh 2004).

## Hypotheses

No quantitative evidence of customer education outcomes was found in marketing literature. Our main research hypotheses analyze the impact on skills, usage and satisfaction. They also investigate the moderating role of product category expertise.

H1: The more the consumer perceives he has been educated about a product's usage by the product manufacturer, the more he thinks he has increased his skills on this product

H2: The higher the product-category expertise of a consumer, the higher the impact of customer education on the consumer's skills improvement

H3: The more the consumer perceives he has increased his skills, the higher the usage intensity (frequency and variety) of a product

H4: The more the consumer perceives he has increased his skills, the higher the product satisfaction

H5: The higher the product's usage intensity (frequency and variety), the higher the product satisfaction

H6a: The lower the degree of customer expertise, the higher the impact of usage variety on product satisfaction

H6b: The higher the degree of customer expertise, the higher the impact of usage frequency on product satisfaction

## Method

A study was carried out on a sample of 321 consumers who owned a digital camera for about 8 months. Digital cameras are multiple-featured products which induce important learning costs for consumers and require important educational support from companies.

We used the Churchill paradigm (Churchill 1979) to develop an original scale which measures customer education efforts as perceived by the customers. We used self-report measures of skills improvement, usage intensity-frequency and variety according to Ram and Jung's (1990) recommendations -, product category expertise and product satisfaction.

## Findings and discussion

Structural equation modeling was used to validate the model (*GFI*=.968, *AGFI*=.945, *CFI*=.968, *NNFI*=.954, *RMSEA*=.0456). All hypotheses but H5 were supported.

*The importance of skills improvement on customer satisfaction*: Customer education has a significant impact on consumers' skills improvement (H1; $\gamma = 0.201$, p<.005). Skills improvement positively impacts customer satisfaction (H4; $\beta= 0.284$, p<.001). It confirms the suggestion made by Hennig-Thurau et al. (2005) whereby simply being aware of gaining skills reinforces customer satisfaction. Such a result should incite industrials to communicate skills to consumers.

The moderating role of product category expertise on the "customer education–customers skills" equation was also analyzed. Experts differ from novices in the degree, content and organization of their knowledge (Mitchell and Dacin 1996). Thus, we hypothesized (H2) that experts may be more aware of their skills improvement than novices. A multi-group analysis confirmed this moderation effect (novices: $\gamma = 0.078$, p>.005; experts: $\gamma = 0,282$, p<.001).

This finding should incite industrials to segment their customer education initiatives according to the degree of product category expertise.

*The importance of skills improvement on usage intensity*: Skills improvement has a significant effect on product usage intensity (H3; Frequency: $\beta= 0.284$, p<.005; Variety: $\beta= 0.247$, p<.001). Specifically, the more customers are skilled with a product, the more they develop variety-seeking behavior and multiply the number of features they use. As such, customer education represents a consistent way of avoiding the risk of multiple-featured products disadoption (Thompson et al. 2005).

*The absence of direct relationships between product usage intensity and satisfaction*: There is no significant impact of usage intensity on customer satisfaction (H5).

The few studies that exist in marketing literature conclude that results are contingent (Ram and Jung 1990; Shih and Venkatesh 2004). We hypothesized that product category expertise may moderate the relationship between usage intensity and satisfaction. Thompson et al. (2005) show that novices encounter difficulties in adopting the multiple features of a product. Thus, the ability to vary usages could be more of a satisfaction driver for novices (H6a) than for experts. In parallel, the time spent using a product is probably a stronger driver of satisfaction for experts than for novices (H6b). Both H6a (novices: $\beta= 0.169$, p<.005; experts: $\beta= 0.023$, p>.005) and H6b (novices: $\beta= -0.027$, p>.005; experts: $\beta= 0.145$, p<.005) are verified in our study.

Such findings should also lead industrials to define their customer education strategy in relation to product category expertise and usage ability objectives.

**Further research**

We are carrying out complementary studies to consolidate the model of customer education outcomes. The ambition is to define new mediating/moderating personal variables and to show that results are not dependent on a particular product.

# Cause Related Marketing: Improving People Willingness to Donate by Selling Them a Product

Ilaria Baghi, University of Ca' Foscari Venice, Italy
Marcello Tedeschi, University of Modena and Reggio Emilia, Italy
Enrico Rubaltelli, University of Padova, Italy

Cause related marketing (CRM) is a way to link products with socially responsible activities following a strategy, which is directed to strength the emotional image of the product and to increase the market shares (Varadarajan, Menon, 1988). CRM programs allow consumers to buy a product which devolves part of its revenues to a social cause and to integrate the donation into the price of the product. In order to implement a successful CRM program it is relevant to understand how consumers perceive the social cause. Previous research has shown that people has a diminished sensitivity in valuing life saving interventions against a background of increasing numbers of lives (psychophysical numbing, Fatherstanhough,et al., 1997). In addition, Kogut and Ritov (2005) found people less willing to contribute in favor of a group of victim rather than in favor of a single, victim. People seem to perceive a charitable program supporting a great amount of people less emotional and effective than a charitable program which aims to collect money in favor of one identifiable victim.

The aim of the present study is to investigate people's perception of CRM programs in different evaluation modes (joint versus separate). In addition, we seek to assess if different description of the charitable program could influence consumers' choices and their willingness to support a social cause through the purchase of a product.

*Hypothesis 1*: If people are presented with two different CRM programs (joint evaluation) then they should be more willing to choose a product associated with a social project describing the total amount of people needing help rather than a product associated with a cause describing an identifiable victim.
*Hypothesis 2*: If people are presented with only one CRM program (separate evaluation) then they should be willing to pay an amount of money not significantly different for the two products.
*Hypothesis 3*: If people are presented with two different fund raising campaigns (JE) then they should choose significantly more often to donate money toward the campaign describing the total amount of people needing help rather than donating money toward the campaign describing an identifiable victim.
*Hypothesis 4*: If people are presented with only one fund raising campaign (SE) then the should be significantly more willing to donate in favor of the campaign describing an identifiable victim rather than donating money to the campaign describing the group of people needing help.

In the Experiment, 276 (36% males; mean age 22 years) students were asked to either judge CRM programs or fund raising campaigns. A first group of participants was presented with two products (spaghetti and toothpaste) associated with a CRM program they were supporting. A second group of participants was presented with the description of two fund raising campaigns supporting the same campaigns associated to the products in the other condition. The first pair of charity campaigns was in favor of the Ethiopian starving population whereas the second pair of campaigns was in favor of the medical research. In joint evaluation, participants were presented with two different description of the same social cause: one was described as a program aiming to help the group of people needing help whereas the other was described as a program aiming to support a single identifiable victim. In separate evaluation people were presented with either one or the other campaign. In JE participants were asked either to choose the product they prefer to buy or the campaign they prefer to support. In SE participants were asked to indicate either their willingness to pay for each product or their willingness to donate to each fund raising campaign.

In JE condition, participants chose significantly more often the product associated with the social cause describing the total amount of people needing help rather than the product associated with the social cause describing the single identifiable victim: respectively, $\chi^2$ (1, 27)=13.37; $p$<.01 for the toothpaste and $\chi^2$ (1, 39)=16.03; $p$<.01 for the spaghetti. On the other hand, no significant differences have been found in SE condition.

Participants in the "fund rising campaign condition" chose significantly more often the campaign describing the amount of people needing help rather than the campaign describing the identifiable (respectively $\chi^2$ (1, 25)=23.12; $p$<.01 for the campaign in favor of the Ethiopian starving population and $\chi^2$ (1, 25)=20.48; $p$<.01 for the campaign in favor of medical research). However, in SE participants were willing to donate less to the campaigns describing the total amount of people in need (M=?39.63; M= ?40.28) rather than to the other format of the same campaigns (M=?60.73; M=?68.46). Respectively $t$ (67)=1.95; $p$=.05 for the campaigns against starvation and $t$ (65)=2.49; $p$<.02 for the campaigns supporting medical research.

In the present study, we investigated if people willingness to support a charitable project was less influenced by the identified victim effect when individuals are presented with a CRM program rather than being asked to donate money. The results of the present study showed that people have not a reduced diminished sensitivity in valuing the number of lives saved when they evaluate or choose among products devolving part of their revenues to a social cause. These results seem to suggest that CRM programs should induce people to focus on the product they are buying therefore reducing the role of their affective reactions toward the social cause and the victims needing help. On the other hand in the "fund raising campaigns" condition result showed that participants were more prone to the psychophysical numbing effect.

# Who Has Mixed Feelings About Consumption? Self-Monitoring and the Antecedents of Attitude Ambivalence

Sandor Czellar, HEC Paris, France
Elizabeth Cowley, University of Sydney, Australia
Gilles Laurent, HEC Paris, France

Social psychologists have shown a recurring interest for the study of attitude ambivalence (Crano and Prislin 2006). Consumer researchers have also investigated the effect of attitude ambivalence in wedding purchases (Otnes, Lowrey, and Shrum 1997), blood donation (Jewell 2003), fashion (Thompson and Haytko 1997), technological products (Priester, Petty, and Park 2007) and advertising response (Williams and Aaker 2002). Importantly, ambivalent attitudes lead to less predictable consumer judgments and behaviors than non-ambivalent attitudes (Armitage and Conner 2000; Conner et al. 2002). Therefore, understanding the formation of ambivalent attitudes is a significant research issue (Priester and Petty 1996, 2001).

Subjective attitudinal ambivalence is the "individual feelings of conflict that a person experiences when an attitude object is considered" (Priester and Petty 1996, p. 432). The main antecedents of subjective attitudinal ambivalence are intrapersonal and interpersonal discrepancy vis-à-vis the object (Priester and Petty 1996, 2001). Intrapersonal discrepancy reflects the simultaneous presence of negative and positive thoughts about the attitude object, while interpersonal discrepancy refers to the perceived differences between one's own thoughts/feelings and the thoughts/feelings of other people about the attitude object.

Priester and Petty (2001) provide compelling evidence that interpersonal discrepancy contributes to attitudinal ambivalence, over and above the effect attributable to intrapersonal discrepancy. The effect of intrapersonal discrepancy on attitudinal ambivalence is moderated by an individual's preference for consistency (Newby-Clark et al. 2002) which provides evidence that individual differences may moderate the weight of intra/interpersonal discrepancy in the formation of attitudinal ambivalence.

We propose that the relationship between interpersonal discrepancy and subjective attitudinal ambivalence should be moderated by an important individual trait–self-monitoring. According to self-monitoring theory, the behavior of *low self-monitors* is guided more by inner beliefs and attitudes while *high self-monitors* tend to adapt their appearance and acts to the specificities of social situations. Attitudes serve a mostly social-adjustive function for high self-monitors, whereas attitudes serve mostly value-expressive functions for low self-monitors (DeBono 2000, 2006). Therefore, high self-monitors may construe attitudes on the basis of social interaction more than low self-monitors. We propose to apply this reasoning to the formation of subjective attitudinal ambivalence with respect to consumption objects. If high self-monitors are more attuned to social cues than low self-monitors, then they should also be more attentive to potential divergences between their own attitudes and others' attitudes. We therefore hypothesize that interpersonal discrepancy should contribute more to attitudinal ambivalence for high self-monitors than for low self-monitors.

Ninety-seven students participated in exchange for credit in an undergraduate course. Five attitude consumption topics (objects) were used from the lists in Priester and Petty (2001): Working out, watching television, eating junk food, eating vegetables, and drinking alcohol. All participants reported their positive/negative personal reactions, their subjective ambivalence, their own attitudes, their parent's attitudes, and their responses to the self-monitoring measure.

Participants completed a scale assessing the degree to which they felt conflict, indecision, or mixed reactions to each of the consumption objects. Participants answered three items anchored from 0 to 10 (feel no conflict at all/feel maximum conflict; no indecision at all/maximum indecision; completely one-sided reactions/completely mixed reactions, a = .82). Subjective attitudinal ambivalence was measured as the average of these items. Intrapersonal ambivalence was calculated with the Gradual Threshold Model of Ambivalence (see Priester and Petty 1996).

Participants also completed an 18-item self-monitoring scale (Snyder and Gangestad 1986). All items were assessed on seven-point scales, ranging from 1 (strongly disagree) to 7 (strongly agree). The self-monitoring score is a sum of the 18 items ($\alpha = .74$).

Finally, we created dummy variables for each consumption object. These dummy variables are included (except for one object serving as reference level) in the multiple regressions reported below. This controls for the propensity of different products to generate different levels of conflict, indecision or mixed reactions.

We used multiple linear regressions with interactions following Aiken and West's methods (1991) to analyze the data. To test the moderating role of self-monitoring on the link between interpersonal discrepancy and attitude ambivalence, we ran a multiple regression analysis using intrapersonal discrepancy, interpersonal discrepancy, the dummy coded object variables, an intrapersonal x interpersonal discrepancy interaction term, the self-monitoring score, a self-monitoring x interpersonal discrepancy interaction term as independent variables and subjective ambivalence as the dependent measure. The results of the regression revealed four significant effects: interpersonal discrepancy, $t(473)=4.03$, $p<.001$, intrapersonal discrepancy, $t(473)=6.17$, $p<.001$, self monitoring, $t(473)=1.97$, $p<.05$, and the self-monitoring x interpersonal discrepancy interaction, $t(473)=2.00$, $p<.05$. The significance of this latter interaction indeed indicates that, with respect to consumption objects, high self-monitors feel more subjective ambivalence as their degree of interpersonal discrepancy increases compared to low self-monitors.

Our first study shows that the relationship between interpersonal discrepancy and subjective ambivalence is moderated by a consumer's tendency to self-monitor. The interpersonal discrepancy antecedent is more important to high self-monitors than to low self-monitors. Prior research has shown that preference for consistency moderates the effect of intrapersonal discrepancy on subjective attitudinal ambivalence (Newby-Clark et al. 2002). Our first study provides evidence that individual differences also matter with respect to the role of interpersonal discrepancy in subjective attitudinal ambivalence.

Priester and Petty (2001) found that whether the important other was liked or disliked affected the impact of interpersonal discrepancy on the resulting subjective ambivalence. An increase in interpersonal discrepancy heightened subjective ambivalence only when the important other was liked. It is possible that not only will high self monitors show increases in subjective ambivalence in the *presence* of interpersonal discrepancy with *liked* others, but they may also show increases in subjective ambivalence when there is an *absence* of interpersonal discrepancy with *disliked* others. A plausible rationale for this proposition is that high self-monitors are more attuned to social status and hierarchy than low self-monitors (Gangestad and Snyder 2000). For this reason, when forming attitudes and judgments, high self-monitors may care not so much about their own liking/disliking of the other person as about the other person's low/high social status. We are currently conducting an experiment to investigate this proposition.

Overall, this research offers guidance for promising new research directions, with the long-term perspective of constructing a comprehensive framework of the formation of attitudinal ambivalence towards products, services, and brands.

# The Dynamic Nature of Customers' Criteria for Assessing Customer Value: A Longitudinal Investigation

Jeroen Bleijerveld, Universiteit Maastricht, The Netherlands
Dwayne Gremler, Bowling Green State University, USA
Jos Lemmink, Universiteit Maastricht, The Netherlands

Organizations are continuously searching for new ways to obtain and defend competitive advantage in order to survive and prosper in the increasingly competitive market. Recently, literature has suggested a switch from product quality to customer value as the next source of competitive advantage (Lai 1995; Woodruff 1997).

Customer value has been defined as "a customer's perceived preference for and evaluation of those product attributes, attribute performances and consequences arising from use that facilitate (or block) achieving the customer's goals and purposes in use situations" (Woodruff 1997). Customers thus assess customer value on the basis of their means-end type structure of criteria (Woodruff 1997; Woodruff and Gardial 1996). According to means-end theory consumers' criteria or beliefs about product attributes (the means) are linked to beliefs about the benefits derived from these attributes (consequences), which in turn are linked to beliefs about the values (ends) served by these benefits (Gutman 1982). For any single product a consumer may hold many chains of beliefs resulting in a hierarchical (means-end) structure of beliefs (Gutman 1982; Overby, Gardial, and Woodruff 2004).

Although claimed as dynamic (Parasuraman 1997; Woodruff 1997), customers' criteria for assessing customer value have essentially been treated as stable as research on the concept has focused on the consequences of the gap between desired (pre-purchase) and received

(post-purchase) customer value for consumer satisfaction (Parasuraman 1997; Spreng, MacKenzie, and Olshavsky 1996; Woodruff 1997). However, research on pre- and post-purchase evaluations has indicated that these are not based on the same beliefs or criteria (Gardial et al. 1994).

The dynamic nature of customer value criteria seems especially important for relationship marketing. Gaining more specific knowledge on how customers' criteria structures develop during their relationship with the organization is not only beneficial to customer value theory and measurement, but also essential for marketers looking for a better understanding of their customers' loyalty / defection decisions (Parasuraman 1997). The dynamic is likely to be most pronounced for services as they are inherently higher on experiential properties (Ostrom and Iacobucci 1995), which makes consumers even more dependent on their experiences with the service to develop their structure of criteria for assessing customer value.

This study analyzes the changes that occur in customers' criteria structures for assessing customer value during their patronage of a service provider. Generally, it is thought that evaluation criteria become increasingly abstract as first time customers become long-term clients (Parasuraman 1997). A thought that finds some indirect support in findings that consumers use more abstract criteria for product evaluations after purchase than for product evaluations before purchase (Gardial et al. 1994). The current study investigates this thought by testing whether the number of consequence and value criteria in a customer's means-end belief structure increases over the duration of the customer-provider relation.

The service chosen as context for this study is university education as it is relatively rich in experience properties (Ha 1998). It is also a service for which consumers are highly involved in purchasing it, which facilitates value retrieval during laddering (Pieters, Baumgartner, and Allen 1995). Furthermore, the high frequency with which they experience the service during their patronage of the university provides university customers (students) with relatively many opportunities to develop their criteria structure.

In the study the developments in students' means-end beliefs structures are monitored longitudinally. From $T_0$ in the beginning of the current fall semester to $T_1$ in the end of the spring semester first, second and third year undergraduate students of two universities in two countries will receive two Association Pattern Technique (APT) questionnaires (Hofstede et al. 1998). These measure their means-end structures of criteria for choosing a university. In APT questionnaires, respondents are presented with all possible attribute-consequence (AC) and consequence-value (CV) combinations. In the questionnaire they are asked to indicate for every attribute (consequence) the consequences (values) to which it in their opinion is linked (Hofstede et al. 1998). Input for the attributes, consequences and values used in the APT questionnaires is gathered by conducting 60 laddering interviews with students of the two universities. In these laddering interviews salient attributes for choosing a university are elicited from respondents. These are subsequently used as starting point for the actual laddering, which entails probing the respondents with "why is that important to you" questions in order to elicit the more abstract consequences and values linked to the attribute (Reynolds and Gutman 1988). The raw data from these interviews is subsequently content analyzed and categorized, after which it can be used in the APT questionnaire.

In addition to being asked to make AC and CV linkages in the APT questionnaire, respondents are also asked to indicate the importance of the attributes, consequences and values on a 7-point scale ranging from very unimportant to very important. This allows for monitoring not only developments in the number of criteria on all levels of abstractness, but also developments in the relative importance of these criteria. Several control questions will also be added to the survey, including one to determine whether the respondent is the actual purchase decision maker.

Preliminary comparisons of the means-end criteria structures obtained from the laddering interviews indeed indicate a higher number of consequence and value criteria in the structures of graduate students than in those of undergraduate students. This suggests that consumers make use of increasingly abstract value criteria as their relation with the service provider continues. Consumers' loyalty / defection behavior is dependent on their value evaluations. So as the relationship between customer and service provider continues, the loyalty of customers should increasingly depend on the more abstract benefits and values offered by the service.

# The Incremental Utility of Adding New Functionalities to Products: The Role of Goal Congruence and Perceived Brand Quality

Tripat Gill, University of Ontario Institute of Technology, Canada
Jing Lei, University of Ontario Institute of Technology, Canada

Recent convergence in the electronics and telecommunications industry has allowed for the introduction of new functionalities into existing products (e.g., Cell Phones with camera, mobile TV, etc.). The current research investigates the incremental utility of adding different types of functionalities to products (e.g., adding Satellite radio versus GPS system to an MP3 music player). It is proposed that two factors–goal congruence and perceived brand quality–affect the relative utility of the new functionality added to a product. *Goal congruence* refers to the extent to which the added functionality is congruent with the base product (i.e., associated with the same goal), and perceived brand quality is related to the brand introducing the product. The effects of these two factors are investigated in an experimental study using hypothetical new products (with added functionalities) as stimuli.

Prior research on product adoption suggests that the impact of a new feature is influenced by two factors: (1) the "value" or benefits accrued by adding new features; and (2) the "performance uncertainty" associated with the added feature (Gatignon and Robertson 1993). Using the principle of diminishing utility, Nowlis and Simonson (1996) showed that high quality brands are expected to gain less than the low quality ones from the addition of a new feature. This is because, when a new (positive) feature is added to a high quality brand, it is assimilated into the overall positive evaluation of the product and the incremental gain for the brand may not be significant. On the other hand, for a low quality brand, the addition of the new (positive) feature contrasts with the otherwise inferior product and therefore contributes more significantly to the overall evaluation of the brand. This research, however, assumes that the value accrued by adding new features is the major determinant of brand evaluations and that consumers may or may not consider the performance uncertainty of the added feature. Moreover, it also does not distinguish between the different types of added features. We argue that both performance uncertainty and the characteristics of the added feature are important in the context of adding a new functionality to a product. For example, consumers may have concerns about the reception and picture quality in the case of watching TV on a Cell Phone. In such cases, the high quality brand may gain more than the low quality one as it can help reduce the performance uncertainty associated with the added functionality. Also, the type of added functionality (e.g., adding mobile TV versus e-mail to a Cell Phone) may have a differential impact on whether the added functionality is assimilated or contrasted with the base (low or high quality) brand.

We propose that the goal congruence between the added functionality and the base product would moderate the relative gain for low and high quality brands. While most added functionalities may originate from distinct product categories, they may or may not be associated with the same consumption goals as the base product (wherein, "goals" are defined as abstract benefits sought by consumers, as per Huffman and Houston 1993). For instance, adding e-mail capability to a Cell Phone combines a new functionality with the same underlying goal as the base product (i.e., the goal of "communication"), whereas adding the ability to watch TV on a Cell Phone combines a functionality associated with a different (incongruent) consumption goal (of "entertainment"). We propose that when a functionality with congruent goals is added to a product, the principle of diminishing utility of added value would be operative, and accordingly low quality brands would gain more than high quality brands (H1). On the other hand, when a functionality with incongruent goals is added to a product, the role of performance uncertainty would become more important. For instance, consumers might perceive that since the added functionality is contrasted from the base and is now to operate on a new interface (e.g., watching TV on a Cell Phone), it implies new tasks (Glazer 1999) and more possibilities for failure (Ziamou and Ratneshwar 2002). In such cases, high quality brands could serve as a strong signal for performance quality and can reduce the high performance uncertainty associated with the incongruent functionalities. Thus, we propose that when functionalities with incongruent goals are added to a product, high quality brands would gain more than low quality ones (H2).

The above-proposed effects were tested in an experimental study using two hypothetical new products as stimuli, which each had either a congruent or an incongruent functionality added to a base product. The base product used in the study was an MP3 music player and the added functionality was either a Satellite Radio (congruent goal) or a GPS system for getting directions (an incongruent goal). In a 3 (added functionality: none, congruent, incongruent) X 2 (brand quality: high, low) experimental design, participants compared two brands of the base product and indicated the price that would make the two brands of equal value. The incremental utility to each brand was measured by comparing the congruent and the incongruent conditions with the control group (with no functionality added). As predicted in H1, it was found that a low quality brand gained more than a high quality one when a congruent functionality was added to the base product (a gain of $64 vs. -$12, respectively, for *MP3 + Radio*; $t_{50}$=3.02; p<.01). However, when an incongruent functionality was added, both low and high quality brands gained equally (a gain of $27 vs. -$2, respectively, for *MP3 + GPS*; $t_{56}$=0.98; p=.33). As a corollary, the low quality brand gained more when a congruent functionality was added as compared to an incongruent one, while the high quality brand gained equally in both cases. These findings have implications for brands introducing new products with added functionalities, which have become increasingly common in the context of convergence in the consumer electronics industry.

# Developing a Better Understanding of Co-Creation: Consumers' Motivations to Create and the Underlying Processes

C. Page Moreau, University of Colorado, Boulder, USA
Kelly Herd, University of Colorado, Boulder, USA

With the help of internet technology, companies are allowing consumers to co-create their products by specifying colors, designs, and features. In doing so, companies are outsourcing the design task while providing a product better suited to the consumer's needs. Empirical studies on the practice of co-creation and mass customization, however, are scarce (Franke and Piller 2003). The articles that have been published largely deal with the technical aspects for the manufacturer rather than with the experience and value created for the consumer (for an exception, see Franke and Pillar 2004). The purpose of this research is to understand the factors that 1) motivate consumers to engage in co-creation and 2) influence their experience and product satisfaction.

While facilitating a strong match between a consumer's idiosyncratic preferences and a new product, mass customization also has its potential limitations. The infinitely large solution space created by the number of options could drive up the cognitive costs of the decision process, overwhelming the expected value generated by the option of an individualized product (Zipkin 2001). Satisfaction with the customized choice may also be diminished as a result of the overwhelming size of the choice set (Iyengar and Lepper 2000).

To date, we are unaware of any experimental studies designed to identify 1) the factors motivating the co-creation process and 2) the specific processes underlying the value creation that results from it. Thus, we designed and ran an experiment. In this study, all participants were presented with a color picture of a standard L.L. Bean backpack and reported their preferences for it. They were then given 1) the opportunity to customize its design by picking colors from a palate and 2) the chance to enter a lottery to win either the standard backpack or their customized version. If the customizing option was selected, preferences for the customized backpack were also collected. Three factors were manipulated between-subjects yielding a 2x2x2 design:

1) *Creativity prime: present vs. absent*: This manipulation primed creativity goals using an ostensibly unrelated task. Participants receiving the prime were hypothesized to customize the backpack more frequently than those receiving no prime and were expected to report higher preferences for their backpacks if they did customize.

2) *Standard backpack designer: professional vs. amateur*: Participants were shown the picture of the standard backpack along with one of two manipulations. In the professional condition, the text indicated that the marketing department picked the color combinations for the backpack. In the amateur condition, the text indicated that the color combination was the winning result of a consumer contest. It was expected that those in the amateur designer condition would be more likely to customize the backpack than those in the professional condition. This manipulation was also expected to influence preferences for the customized backpack since it manipulated beliefs about the reference backpack.

3) *Customization instructions: present vs. absent*: Participants were offered the chance to customize the color and design of the standard backpack. If they chose to customize, they were asked to explain their reasons and then they received the third manipulation (customization instructions: present vs. absent). It was hypothesized that this manipulation would influence participants' propensity to enter the lottery and their satisfaction with their own backpack. Once they completed their designs, participants provided their preferences for the customized backpack.

## Results

A three-way ANOVA revealed a main effect of designer ($F_{1, 172}$=5.58, p<.01) such that participants told the standard backpack was designed by another consumer reported higher preferences for their own customized pack than did those told it was designed by L.L. Bean's marketing staff (39.2 vs. 36.5). The ANOVA also revealed a three-way interaction ($F_{1, 172}$=5.02, p<.05).

Chi-squared tests were used to determine the influence of the manipulated factors on participants' decision to enter into the lottery. The creativity prime significantly increased participation in the lottery ($\chi^2$=7.8, p<.01), but neither the designer or guide manipulations had an effect. This study provides encouraging and interesting results, but a series of follow-up experiments is planned to better understand the findings.

## Study 2

Why would the designer of the standard backpack (professional vs. other customer) influence one's own preferences for the self-designed pack? Open-ended protocols collected in Study 1 suggest a possible explanation (e.g., the customer-designed backpack encouraged competition: "If s/he can do it, I can do it better"). To determine whether such competitiveness was responsible for the effect, Study 2 would manipulate the salience of competition. In one condition, participants will be told that their customized pack would be

entered into a similar contest; in another condition, participants will be told that there is no competition. Thus, this experiment will be a 2 (designer: professional vs. amateur) by 2 (competition: present vs. absent) between-participants design.

### Study 3

Open-ended responses from Study 1 demonstrate that direct involvement in the creation process is an important aspect of designing a product. This study is designed to examine whether consumers will still feel a part of the process if there is an intermediary involved. Further, it will test to see whether the amount of material inputs (and thus decision options) moderates the influence of that intermediary. The design is a 2 (design intermediary: yes vs. no) by 3 (number of available materials: low vs. medium vs. high). One possible focal task is the design and construction of a necklace. Participants would either construct the necklace on their own or give step-by-step instructions to the experimenter (allowing for changes along the way). The materials would be manipulated by varying the number of beads provided (low, medium, high).

Participants would report their own satisfaction with the process and the outcome as well as provide measures of the potential sources of value. The influence of the manipulations on those judgments would be tested. Further, pictures of the final products would be taken and would be evaluated by a set of target consumers. Self-valuations would be compared to the target consumers' valuations, and the sources of value would be tested as potential mediators of any differences.

# Formation of Consideration Set and Consumer Decision-Making Process under Brand Extension Signal

Yi Zhang, University of Manchester, UK

Jikyeong Kang, University of Manchester, UK

### Abstract

This research aims to understand consumers' decision-making process under brand extension strategy which might work as signals in the marketplace. The proposed model utilises a consideration set theory working as the core element of the decision-making process in providing a better understanding of the impact of brand-related activities. More specifically, the proposed model combines perceived quality and perceived risk simultaneously to generate inclusion probability of consideration sets by utilising a Bayesian manner utility maximum model with dynamic structure.

### Conceptualisation

Traditionally, consumers' purchasing behaviour was thought to be determined by a decision-making process which consists of need-arousal, information retrieval from memory, external search, and brand evaluation and choice (Bettman 1979; Howard 1989). This one-stage process, however, neglects the limitation of human beings' memory and computational capabilities (Simon 1955), and the crowded and competitive marketplace that today's consumers face (Paulssen and Bagozzi 2005). Consideration set, which can be created based on evoke set (Howard 1963), can factor in these various aspects, and can be used to determine consumers' purchasing decisions more accurately (Mehta, Rajiv, and Srinivasan 2003).

Since consideration set is based on brand selection theory (for example, Hauser and Wernerfelt 1990; Wright and Barbour 1977), extensive research in this area focus on a brand's impact toward the decision-making process (for example, Erdem and Swait 2004; Erdem, Swait, and Valenzuela 2006; Paulssen and Bagozzi 2005). Some of them borrowed ideas from economics of information theory to estimate the effect of inclusion probability in the consideration set of a certain brand (Mehta et al. 2003, for example). Other researchers adopted the signalling theory to approximate how brand strategy affects consumers' subjective knowledge and further influences their consideration set formation (for example, Heaney and Goldsmith 1999; Urbany, Dickson, and Wilkie 1989; Victor V 1997). Both streams of the consideration set formation model partially explain the process of decision making, but they fail to illustrate the process from both receiving (i.e., the signalling theory) and screening (i.e., the information search theory) aspects. The proposed research, therefore, aims to improve the existing models by considering the effects of brand extension from both directions of information flow.

### Methods

The proposed model is based on a revealed consideration set since the data will not contain consumers' actual consideration set information, but only their purchasing time points and their previous choice information. The proposed model is based on two existing models: Mehta, Rajiv, and Srinivasan's (2003) *consumer search model* and Erdem and Keane's (1996) *forward looking dynamic structure*.

In the model by Mehta et al. (2003), a Bayesian manner utility maximum model is introduced and price as an uncertainty factor is carefully examined. More importantly, they employed the Monte Carlo simulation method to obtain perceived quality data which resolved the problem of unobservable factors. However, their model considered price as the only uncertainty/risk that the consumer faces and

assumed that risk can only be presented by price, thus neglecting possible signalling outside consumers' subjective knowledge to affect consumers' perceived risk. Thus, in this research, the proposed model will also consider an improved risk factor within the utility framework to replace the over-emphasised price uncertainty.

Erdem and Keane's (1996) model gives a more comprehensive explanation of decision making and contains price, risk (perceived risk), attributes of products (perceived quality), and signalling factors. Although it provides a good starting point as a decision-making model, unfortunately they did not regard the process as a two-stage decision process which can view the consideration set as an essential latent process. In the proposed model, this problem can be resolved since the entire structure of the model is based on the two-stage decision process.

Another main contribution of Erdem and Keane's model is that it considers the current decision for future reference, which is also referred to as a forward-looking structure. Since consumers do sometimes try some products in order to gain experience for their future decisions, the proposed model will also utilise the forward-looking concept in formulating a final choice process.

### Data Collection and Analysis

Two sets of data will be employed for this research. One is based on ERIM data which include supermarket purchasing data for five different categories. Another set of data is from Hewlett-Packard, which will include not only revealed data but stated data for comparison.

### Summary

The proposed research will provide a more sophisticated way of investigating consumers' purchasing behaviour while firms employ brand extension strategies. From a managerial perspective, this model can be used as an important tool for investigating consumers' possible reaction toward a brand strategy.

# Effects of Spatial Location of Price Information on Consumers' Perception of Prices and Products

Rajneesh Suri, Drexel University, USA
Rajesh Chandrashekaran, Fairleigh Dickinson University, USA
Dhruv Grewal, Babson College, USA

Often time, retailers' advertisements place price information in the proximity of the advertised products. Past research suggests that the relationship between numerical information and its spatial representation is deeply rooted in the brain's organization for these capacities (Dehaene 1997**;** Thomas and Morwitz 2005). The simplest demonstration of such relationship is research showing that responses to larger numbers are quicker when responses are made on the right side of space, whereas responses to smaller numbers are quicker when the responses are made on the left (Hubbard et al. 2005). Despite the obvious implication of such phenomena in the marketing context, the marketing literature has not yet researched the issue of how the location of prices to the left or the right side of an advertised product influences the processing of price information and consequently the evaluation of the product. Based on past research on the effects of hemispheric lateralization and arousal on information processing this research develops predictions about the effects of the location of price information on product evaluation. The conceptualization leads to the following hypotheses:

H1: For highly motivated consumers, low (high) price information presented in the right visual field will be associated with a lower (higher) perceptions of sacrifice and higher (lower) perceptions of quality and value than when it is presented in the left visual field.

H2: For consumers who are less motivated, low (high) price information presented in the right visual field will be associated with a higher (lower) perceptions of sacrifice a lower (higher) perceptions of quality and value than when it is presented in the left visual field.

Past research has also argued that price information is more accurately recognized than recalled (Monroe and Lee 2000). Krugman (1977) showed that right brain processes facilitate recognition, whereas recall requires the involvement of the left-brain processes. Consequently:

H3a: Price information presented on the right visual field will be recalled more accurately than when the same information is presented in the left visual field.

H3b: Brand information presented on the right visual field will be recalled less accurately than when the same information is presented in the left visual field.

**Methodology**

An exploratory study examined the placement of prices in relation to products advertised in advertising inserts in weekend newspapers for four weekends (n =750 price points). Three additional studies measured reaction times (n=20), recall accuracy (n=32) and the evaluation of the dependent measures for stimuli manipulated in a 2 (price: high and low) X 2 (motivation: low versus high) X 2 (visual field: left vs. right) between subjects design (n=128).

Results show that competing retailers use different price presentations in their weekly advertising inserts with value oriented retailers more likely to present prices in the right visual field than competing retailers ($F_{(1, 741)}$=18.90, p<.001, $\rho$=.41). As expected though there was no difference in the perceptions of sacrifice (p>.20), the reaction times were significantly higher when price information was presented in the left visual fields with the lowest reaction times being achieved by price information presented in the top right visual field ($F_{(1, 36)}$=3.82, p<.05, $\rho$=.31) . Consistent with H3 the price recall was more accurate when price information was located in the right visual field ($\chi^2$=2.93, p<.05) while the brand information was more accurately recalled ($\chi^2$=6.31, p<.05) when it was located in the left visual field. The results from the fourth study (Manova interaction: Pillai's . $F_{(3, 118)}$=3.56, p<.05, $\rho$=.29) showed that the perceptions of quality and value were higher for the lower price cue when it was in the right visual field and the participants were motivated or in the left visual field when the participants had low motivation to process information. Opposite results were observed for the high price cue.

# Information Sort and Consumers' Evaluation of Prices

Rajneesh Suri, Drexel University, USA
Jane Z. Cai, Drexel University, USA
Mrugank V. Thakor, Concordia University, USA

Many online retailers provide customers with information filtering tools that enable them to sort products by brand name or price. While research has studied factors underlying information search online (Lynch and Ariely, 2000), the effect of such filtering approaches on consumers' processing of information has not received much attention. Some questions that arise are: Does sorting of information on competitive products by either price or by brand name influence the information processing on a focal product? Does such a filtering approach improve or hinder the evaluation for a relatively high or a low priced focal product? We investigate these issues using previous research regarding consumers' reliance on covariation beliefs.

**Conceptual Framework**

A covariation belief such as "you get what you pay for" is often used by consumers (Monroe, 2003). Several studies have shown that people have a tendency to rely on such covariation beliefs rather than on the objective data (Baumgartner, 1995; Pechmann and Ratneshwar, 1992), which may lead to quicker but less accurate judgments (e.g., Broniarczyk and Alba, 1994). Alloy and Tabachnik (1984) pointed out that people rely on prior beliefs about covariation only when situational factors impede their use of data driven judgments. Similarly, it is argued that as the diagnosticity of the data increases, encoding of information is easier and consumer reliance on past covariation beliefs is reduced (Pechmann and Ratneshwar 1992).

Both price and brand name are extrinsic cues that consumers use to infer a product's quality, but consumers integrate inferences of quality with perceptions of monetary sacrifice associated with a product's price to arrive at conclusions about the value of a product (Monroe, 2003). Thus brand name might guide perceptions of quality but the dual role of price in assessing sacrifice and quality will make price information more diagnostic to consumers (see also Maheswaran, Mackie, and Chaiken, 1992). Since the ability to evaluate non-diagnostic sequences requires substantial attentional components of working memory (Baddeley, 2000), sorting of information by brand is likely to strain consumers' ability to process information, while a price sort consistent with memory for prices may be less burdensome.

Based on process theories on attitude formation and change (Chaiken et al. 1989) it is predicted that when there is low motivation to process information consumers will use heuristic processing that takes less effort and capacity. On the other hand, when there is high motivation to process information and the competitive information is sorted by price, it is expected that systematic processing will occur. However, when information is sorted by brand names consumers may resort to heuristic processing despite a high motivation to process.

## Method

Undergraduate students participated in a between-subjects experimental design: 2 (motivation to process: low vs. high) x 2 (price of focal product: low vs. high) x 2 (information sort: price vs. brand name). The focal product was a DVD player which was described along with its price and the participants were given the description of this product along with a booklet containing sorted information (either by price or brand name) on additional products. The dependent variables included measures for perceptions of sacrifice, quality and value.

## Results and Conclusion

The results supported the hypothesized interaction between motivation to process information and sorting of information on the evaluation of high and low priced target products. As expected, the perceptions of quality and sacrifice mediated the effects of the independent variables on perceived value. The results suggest that sorting of product information by brand name (vs. price) resulted in an increased reliance on price-quality heuristics when evaluating a product. These results are consistent with Pechmann and Ratneshwar's (1992) finding that when information is not diagnostic, consumers rely more on the heuristics to assess the given data. However, the results from the current study also point the important role played by consumers' motivation to process information, as in the low motivation condition, neither the brand name sort nor the price sort influenced the use of product information.

# Discounting Pleasure? Lay Intuitions about the Value of Deferred Hedonic Experience

Elaine Chan, Hong Kong University of Science and Technology, Hong Kong

Anirban Mukhopadhyay, University of Michigan, USA

Lay beliefs have been shown to affect consumer judgments and behavior in a number of domains (e.g. Ross and Nisbett 1991). This research explores the role of discounting as another lay belief that people use to evaluate hedonic consumption at different temporal distances. Given familiarity with financial markets (e.g. interest rates), individuals generally believe that money in the future is worth less than money in the present. Indeed, research has shown that individuals discount the monetary value of consumption that is temporally distant (Ainslie 1975). Over time, this may become a well-learned lay belief or rule (Amir and Ariely 2007) that generalizes across situations (Hsee et al. 2003) and is invoked and applied in situations involving monetary considerations. Accordingly, we propose that when evaluating consumption in terms of money, people consistently discount delayed consumption irrespective of its temporal framing.

However, monetary considerations are not the only means that individuals use to evaluate consumption (e.g. Soman 2004). Consumption may also be evaluated in terms of predicted enjoyment. This is a relatively unquantifiable measure of value, where such rules are less likely to be invoked (Amir and Ariely 2007). In this case, we hypothesize that individuals may not positively discount delayed consumption across the board. Instead, judgments of predicted utility may be based on how the consumption is construed. We study two

specific temporal framings– "forward" sequences (i.e., evaluations of immediate consumption elicited before delayed) and "backward" sequences (i.e., delayed consumption evaluated first). According to temporal construal theory (Liberman and Trope 1998), people may have different initial construals of these sequences. Based on the assumption of 'blocking' (Feldman and Lynch 1988), these initial construals may influence subsequent decision processes. We predict that in backward sequences, as per construal level theory (Trope and Liberman 2003) individuals focus on desirability when evaluating delayed consumption. This increases the salience of desirability considerations, which carries over to their subsequent assessment of the immediate consumption. The increased salience of desirability considerations makes the immediate consumption more attractive, since the consumption is hedonic to begin with. As a result, the immediate consumption is judged to be more positive than the delayed consumption, consistent with the standard discounting effect. In contrast, in forward sequences, individuals focus on feasibility when evaluating immediate consumption. Later, when they evaluate delayed consumption, they again focus on feasibility considerations. This increases the attractiveness of the delayed consumption, since constraints and effort requirements are often underweighted when they are in the distant future (Soman 1998). Hence delayed consumption is judged more favorably than immediate consumption, resulting in negative discounting.

In this research, we test these predictions in three studies. In experiment 1, we manipulate the temporal framing of the consumption episodes in terms of the order in which they were evaluated (i.e., forward versus backward sequences). Participants were told to imagine that they would enjoy a delicious dinner in a fancy restaurant, either tomorrow or one month later, and were asked to evaluate the consumption. They were then asked to evaluate the consumption assuming it was instead one month later (or tomorrow). The order of sequences was counterbalanced. Further, some participants made their evaluations in terms of willingness to pay (i.e., a monetary metric), while others predicted their enjoyment ratings. Results showed that given the monetary metric, participants consistently discounted the delayed consumption in a manner consistent with discounting theory, regardless of whether they first considered the immediate or the delayed consumption. A different pattern of results was observed when the evaluations were made in terms of enjoyment ratings. Here participants discounted the delayed consumption only in the backward sequence, if they first evaluated the delayed dinner. In contrast, when the immediate dinner was evaluated first, the delayed consumption was evaluated more positively than the immediate consumption, thereby showing negative discounting.

Experiment 2 had two aims. The first was to show that lay beliefs in discounting are applied consistently across monetary assessments, and the second was to illustrate that negative discounting in the forward sequence occurred due to a focus on feasibility considerations. In this study, the procedure was similar to that in experiment 1. Participants were asked to evaluate either immediate or delayed consumption first, and in terms of either WTP or enjoyment ratings. Unlike experiment 1, they were told to imagine that they would attend a concert that featured their favorite singer. In addition, we manipulated feasibility by the location of the concert. In the high (vs. low) feasibility condition, participants were told that the venue was near (vs. far from) their home. Results showed that when evaluating in terms of monetary considerations, participants consistently discounted delayed consumption irrespective of temporal framing and feasibility condition. However, when evaluating using enjoyment ratings, participants discounted delayed consumption if they first evaluated the delayed concert—irrespective of feasibility condition. When the immediate concert was evaluated first, negative discounting was observed only in the low feasibility condition, thereby supporting our predictions.

Experiment 3 investigated the effect of the accessibility of the lay belief in discounting. If an alternative way to evaluate the consumption is made salient (e.g. via a prior task involving enjoyment ratings), individuals are less likely to use their lay belief in discounting as an input in their WTP assessment. Participants were asked to imagine that they would enjoy a delicious dinner in a fancy restaurant, either tomorrow or one month later. All participants first reported enjoyment ratings and then their WTP for both the immediate and the delayed dinner, evaluating either the immediate or the delayed consumption first. The results of study 1 were replicated for the enjoyment ratings, with participants discounting delayed consumption if they first evaluated the delayed dinner, but not when they first evaluated the immediate dinner. The WTP metric showed a different pattern. Here, when participants first evaluated the delayed dinner, they discounted it in a manner similar to the enjoyment ratings. However, WTP for the immediate and delayed dinners did not differ when participants first evaluated the immediate dinner. In other words, since participants reported negative discounting when they first evaluated both dinners in terms of enjoyment ratings, they later also showed less discounting of WTP assessments. This demonstrates that when evaluations in terms of enjoyment ratings are made salient, individuals are less likely to use their lay beliefs in monetary discounting, thereby supporting our hypothesis.

To summarize, we demonstrate that people hold a lay belief in discounting of monetary considerations. This lay belief is utilized irrespective of the framing of the temporal orientations unless alternative ways of valuation are made accessible. In contrast, since people are less likely to hold this lay belief in discounting of enjoyment ratings, they are more likely to focus on the consumption itself when making the predictions. Therefore, different framings of temporal orientations will have different effects on the valuation of immediate and delayed consumption– with discounting only being observed if the lay belief is made accessible.

# The Single Consumer: Avoiding Tradition and Extending the Self

Angeline G. Close, University of Nevada Las Vegas, USA

Aubrey R. Fowler III, University of Nebraska, USA

Due to increasing divorce rates, the popularity of the single lifestyle, and marriages later in life, there is an escalating need for a focused understanding of single consumer. The single person, defined as one who lacks a serious romantic relationship or a "sex and everything else partner" (DePaulo 2006), may find him or herself consuming in a world that is geared towards the married or otherwise attached consumer. By the general populace, the single person is perceived as incomplete (DePaulo 2006), abnormal (Waehler 1996) or not yet adult (Schwartzberg, Berliner, and Jacob 1995); by the government, the single person is defined by what he or she is not—married (U.S. Census Bureau 2003). Essentially, the single person is perceived as lacking, which then may carry over to their self-perception. This may become particularly apparent during marketplace events geared for couples (including Valentine's Day), which may prompt single people to seek out possessions that proudly state their single status. Else, the event may prompt singles to revert to the private sphere of consumption and avoid the public marketplace, celebration of certain holidays, or attendance at events.

We suggest that singles are sometimes faced with a "lack of self", or a perceived missing part of the self as triggered by not having a spouse or other romantic partner at various marketplace events or holiday celebrations. A single person may find him or herself surrounded by a marketplace that promotes couplehood and disengages the single consumer. As one instance, Valentine's Day is an annual "event" that celebrates romance and the institution of the couple. At more frequent events (including weddings, informal gatherings of coupled friends, or even simply attending a restaurant, movie, or other such public arena), a single person may at times feel incomplete or out of place.

How does the single consumer respond to Valentine's Day and other marketplace events positioned towards couples, and how does he or she adjust his or her own identity in accordance? Here, we seek to advance understanding of single consumers via assessments of their attitudes and their symbolic, identity-reflecting purchases. Specifically, we maintain two objectives: 1) to understand and explain single consumers' experiences and identity-reflecting purchases, and 2) to extend the theory of the extended self. Just as things or experiences that single people have or exchange reflect and contribute to their identity, we show how the things people do *not* have or exchange also reflect and contribute to one's identity.

To reach the objectives, we employ multiple qualitative methods, including open-ended projective questionnaires of single consumers, depth-interviews, and observations. We extend theory to show the meaning associated with singles' purchasing and non-purchasing during various markets that cater to non-singles. For instance, during Valentine's Day, many single consumers elect not to buy, receive, or exchange traditional romantic items (e.g., cards, roses, chocolates, upscale dinners) (Close and Zinkhan 2006). Just as possessions reflect the identity of the possessor, and in turn contribute to that identity (Belk 1988); we find that a lack of these possessions/ traditional exchanges reflects the identity of the single person. Further, lack of attendance or participation at events where a romantic partner or date is common also reflects and reinforces the single person's identity.

On the one hand, some singles opt-out of such traditional purchases because they feel excluded from the market. By not exchanging the traditional items for Valentine's Day, the single consumer reinforces their identity as a single person. A lack of these possessions (albeit often temporary possessions, such as flowers or chocolates) contributes to the single person's identity. On the other hand, some single people receive or exchange items to embrace or announce their singlehood. For example, some single consumers wear t-shirts that say "single and proud", or go to sponsored parties that are "singles only". We aim to understand single's possessions in terms of the meaning invested in them by the purchaser (Belk 1988).

As both Bateson (1982) and Belk (1988) note, people may incorporate others into the extended self. Belk argues that "If other people are apart of our extended selves, it follows that there should be a sense of self-loss during divorce and at the death of a spouse, child, or close friend" (156). Singles may experience jealousy as a fear of loss of part of the self to another person. In turn, they may feel personal injury when someone who has been incorporated into the extended self is hurt or offended in some way.

Our findings are potentially moderated by the individual's perception of their single status and the type of single that they are. The classification of singles includes: divorced, separated, widowed, and never-married. Of those that have never married, there are three subgroups: the transitional, the permanent, and the unwilling single (Barkas 1980). Transitional singles view their single status as a stepping stone to coupled status. They fully expect to be in a coupled relationship at some point in the future. The permanent single is actually committed to his or her single status and finds great joy in living as a single person subject only to her or her own whims. The unwilling single is one who views the single status as a temporary one but, as of yet, has been unable to find someone to be un-single with.

In continuing research, we propose that the unwilling single is more likely to exhibit a "lack of self" than the transitional or permanent single. These are also probably the singles who will be the most affected by days and events such as Valentine's Day and deal with social comparison in an alternative manner (e.g., by avoiding the formal marketplace traditions, by impulsively seeking Mr. or Ms. Right Now). We also expect that the permanent single is more likely to seek out the "single and proud" items. In other words, the permanent single will refuse to be defined by what he or she is not and, instead, seek to reinforce the single self at such times through various consumption activities and possessions. Here, the self is not missing a part. The unwilling single, on the other hand, may use various consumption activities fill in the part of the self that is missing.

# "Effort-as-Information": The Impact of Decision-Related Effort on Subsequent Evaluation and Price Judgment

Jungkeun Kim, University of Minnesota, USA
Jae-Eun Kim, University of Minnesota, USA

## Background

Decision-related effort is an important factor in understanding consumers' decision-making and consumption behavior. For example, it is assumed that consumers attempt to reduce decision-related effort in their decision-making (Bettman, Luce, and Payne 1998; Payne, Bettman, and Johnson 1993). In fact, several research streams suggest a direct relationship between effort and decision-making. Particularly speaking, they suggest that effort influences: (i) the selection of decision heuristics (e.g., compensatory vs. noncompensatory rules, Payne, Bettman, and Johnson 1993); (ii) the justification for choosing luxury over necessity goods or choosing a more-risky over a less-risky option (Kivetz 2003; Kivetz and Simonson 2002); and (iii) the evaluation of objects (Kruger, Wirtz, Boven, and Altermatt 2004).

Specifically, Kruger et al. (2004) introduce the concept of "effort heuristics." They propose that people have a tendency to use effort as a basis for their evaluations. They provide empirical evidence by showing that the participants in their study evaluated a poem more favorably when they thought that the poet took more time (i.e., 18 hours) to write the poem than when they thought that the poet took less time (i.e., 4 hours). In this study, the effort that the poet spent, however, is not related to the decision per se, and the decision-maker did not generate any decision–related effort. Thus, the effort investigated in Kruger et al. (2004)'s research involves other- rather than self-generated effort.

In this study, we are more interested in investigating the impact of decision-related effort on product evaluation and price judgment toward a chosen option. The purpose of this study is to examine the impact of self-generated or/and decision-related effort on the evaluation of a decision outcome (i.e., a chosen alternative).

## Hypotheses development

We propose that consumers' evaluations and price judgments will be higher when making a choice with much versus less effort on the basis of several theories. The first theory concerns "escalation of commitment," which suggests that people have a motivation to preserve previous effort in a subsequent task. Specifically, studies of escalation of commitment have shown that people's previous investment affects their future decision-making (Brockner 1992; Staw 1981). For example, Arkes and Blumer (1985) asked participants to choose one trip from two trips mistakenly reserved for the same day. They found that half of the participants chose the "more expensive and less attractive trip" over the "less expensive and more attractive trip," even though the chosen option is considered to be less enjoyable. Hence, based on "escalation of commitment," we can expect that people tend to use previous effort as important information for their decision-making.

Second, "cognitive dissonance theory" suggests that people have a motivation to preserve their previous effort. According to Festinger (1957), people have a strong motivation to reduce this cognitive dissonance after making a choice, in that making a choice or selecting one option from various possibilities increases psychological discomfort, known as *dissonance* (Festinger 1957). The effort required to resolve a decision problem can generate an uncomfortable state of mind. Specifically, if people use a great deal of effort for their choice, but their evaluation toward the chosen choice is not favorable, their cognitive dissonance will be high, and they will experience discomfort. We expect that one way to reduce this cognitive dissonance is to change the evaluation of the chosen alternative requiring a great deal of effort. If the decision-maker evaluates the chosen option favorably, then he or she can easily justify his or her effort incurred in the decision process. Therefore, based on "cognitive dissonance theory," we propose that people will evaluate a chosen option favorably when making a choice with more versus less effort.

Finally, "attribution theory" suggests that people use effort as information in judging the quality of performance (Kelly 1967). For example, consumers can reward firms for high effort, such as showing a higher willingness to pay for a product conveying high effort on the part of the company (Morales 2005). This result suggests that effort as information can work as a heuristic cue for product evaluation and price judgment.

Therefore, based on "escalation of commitment, " "cognitive dissonance theory," and "attribution theory," we expect "effort-as-information" to be relevant, inasmuch as product evaluation and price judgment for a chosen option are more likely to be higher when individuals put much versus little effort in the decision-making process.

## Hypotheses

H1: Consumers' evaluations will be higher for objects associated with high effort than they will for objects associated with low effort.

H2: Consumers' pricing judgments will be higher for objects associated with high effort than they will for objects associated with low effort.

## Studies

In Study 1, we examined the relationship between self-generated effort during a decision process and an evaluation of an object. The participants in this study were asked to imagine that they were going to buy a lottery ticket. First, the participants in the high-effort condition were asked to write down numbers from 1 to 60. They were then asked to select five numbers from 1 to 60, which was written by them. On the other hand, the participants in the low-effort condition were merely asked to select five numbers from 1 to 60, which was already given to them. Next, the participants in both conditions were asked to provide their willingness to accept (WTA) selling their lottery ticket to someone else. The results supported H2. The participants in the high-effort condition (mean=$17.64) showed a higher WTA to sell their lottery ticket than those in the low- effort condition (mean=$10.98, F (1, 45)=3.13; p=.08).

In Study 2, we examined the relationship between decision-related effort during a decision process and an evaluation of an object; additionally, we suggest the boundary condition for the "effort-as-information" effect in decision-making. We expect that different formats of product information display (e.g., an easy vs. difficult format) will require different levels of effort. Consequently, these different levels of effort will influence evaluations of a chosen object. This manipulation (e.g., an easy vs. difficult format) is directly related to "preference fluency," which is defined as the subjective feeling of ease or difficulty experienced while making a decision. Recently, Novemsky, Dhar, Schwarz, and Simonson (2007) have suggested the role of preference fluency in consumer choice. Empirically, they show that participants prefer high- versus low-preference fluency options, which contradicts the results of Study 1. I propose that the boundary condition between the effect of *preference fluency* and *effort-as-information* is the time interval between tasks. Preference fluency is based on "experiencing processing" (Meyers-Levy and Malaviya 1999), or is a type of feeling related to a decision. Hence, the impact of preference fluency (based on temporal fluency experience and feelings) should be reduced as time passes. We expect that the effect of *preference fluency* will be higher when there is no time interval between a choice and a subsequent judgment for a chosen option. Specifically, study participants will show higher evaluations for a chosen option from an easy-display format if we measure the subsequent evaluation immediately after the choice. On the other hand, the effect of "effort-as-information" will be higher when there is a time interval between a choice and a subsequent judgment. We expect that study participants will show higher evaluations for a chosen option with a difficult-display format if we measure the subsequent evaluation after a delay.

The participants in this study were randomly assigned to each cell of a two (level of effort: high vs. low) by two (time interval between the choice and the subsequent judgment: no-delay vs. delay) between-subjects design. They were asked to imagine that they were going to purchase one printer from four different brands of printers. The information format was manipulated in order to differentiate the effort demands of the decision. In the low-effort condition, we provided the participants with well-organized information about the four different printers. On the other hand, in the high-effort condition, we provided the participants with disorganized information, such as mixing attribute order across the brands. The product did not include any price information. The time interval was manipulated after choosing one printer. In the no-delay condition, the participants were asked to respond to subsequent dependent variables (i.e., evaluation and willingness to pay [WTP] to obtain the chosen printer) immediately after choosing one printer. In the delay condition, they were asked to do another irrelevant task (e.g., providing a summary of a story). They were then asked to respond to other dependent variables.

We found a significant interaction effect for evaluation and price judgment of the chosen option (evaluation: F (1, 76)=5.38, p=.018; WTP: F (1, 76)=4.36, p <.05). Specifically, when there was a time interval between choice and judgment, the results indicated that participants' evaluations and price judgments were higher for the chosen option associated with high effort compared to the one associated with low effort. Therefore, the results support our "effort-as-information" prediction as described in H1 and H2. On the other hand, when there was no time interval between choice and judgment, the pattern was the opposite. Therefore, the results of this condition support Novemsky et al. (2007)'s "preference fluency" prediction.

## Discussion

This study examined the impact of self-generated and decision-related effort on the evaluation and price judgment for decision outcomes. Two experiments demonstrated that consumers' evaluations and price judgments are higher for an option associated with high versus low effort. In addition, this research shows that this result can be moderated by the time duration between choice and the subsequent judgment. In sum, this study can contribute to understanding the role of decision-related effort on consumer judgment.

# Commodifying the Self: Online Social Networking Profiles as Brand Communities

Lucy Atkinson, University of Wisconsin–Madison, USA

From motorcycles and cars, to the *X-Files* and *Xena: Warrior Princess*, brand communities can emerge and coalesce in the most varied and surprising of places. (Kozinets 1997; Muniz & O'Guinn 2001; Muniz and Schau 2005; Schouten and McAlexander, 1995) In the six years since Muniz and O'Guinn (2001) explicated the concept of brand community, the model has been applied to a number of different brands and goods, but rarely has it been applied to the context of people. While numerous studies have explored the boundaries and functions of brand community, both online and offline, they have been restricted to the context of tangible goods, such as Macintosh computers (Belk and Tumbat 2002), or experiential products, such as the television program *Star Trek* (Kozinets 2001).

The research proposal outlined here addresses this shortcoming by applying the concept of brand community to a new context, one in which the individual consumer is the brand. Specifically, it argues for exploring the degree to which individuals think of their online profiles on social networking sites like Facebook as self-branding and the degree to which these profiles represent brand communities. The research uses as its foundation a definition of brand community as "a specialized, non-geographically bound community based on a structured set of social relationships among admirers of a brand." (Muniz & O'Guinn, 2001, p. 412)

Methodologically, it argues for the use of qualitative methods, specifically focus groups or in-depth interviews with young adults who use Facebook regularly. Focus groups are well suited to exploratory research that is still in the beginning stages. Based on these group interviews, this paper explores the meanings individuals attribute to their profiles, the way in which profiles represent the individual as a brand to be marketed, and the manner in which this self-branding fosters a community or social network around the individual-as-brand.

While most young adults might not explicitly think of themselves as brands or their online profiles as marketing campaigns in support of brand communities, Facebook users doubtless carry out significant message framing and maintenance work. Indeed, about two-thirds of Facebook users log on daily to update their online profiles and to check the updated profiles of their peers. (Arrington, 2005) As well, members of this generation are used to–and are not entirely put off by–advertising's encroachment into most aspects of their daily lives. While their impression maintenance may not be overtly construed as 'brand' management, the motivations are not dissimilar. Just as Harley-Davidson must carefully craft and monitor its public image, so too must individuals with online profiles on social networking sites.

This paper defines social network sites as a collection of online profiles that allow users to paint carefully circumscribed and easily updated electronic portraits of themselves. A fundamental dimension of the profile, and therefore of the self, entails the extent of social connectedness someone claims, as evidenced by the number of links to 'friends' someone purports to have.

Following Muniz and O'Guinn (2001), brand community is conceptualized as comprising three components or attributes: consciousness of kind, or a sense of connection between members and a shared knowledge of belonging; shared rituals and traditions, or common actions that help socialize new members into the community while perpetuating a shared history and consciousness; and moral responsibility, or a sense of shared duty or obligation to the community.

As a brand community centered on an individual, online social networking profiles offer valuable insight into the tension between the often conflicting notions of traditional and postmodern communities, a tension raised by Tonnies (1887/1957) in his distinction between Gemeinschaft (community) and Gesellschaft (society). The former is seen as natural, real and organic, whereas the latter is seen as depersonalized, mass and inauthentic. Indeed, the modern consumer society is often blamed for the demise of intimate, premodern community. At the same time, social networking sites are often decried for the false or shallow communities they create. Online relationships in this sense are seen as tenuous substitutes for meaningful offline interactions. But thinking of these online networks as brand communities suggests, just as Muniz and O'Guinn found with their research, that at least to some degree, real community can be found in these unlikely situations. Just as a community of Saab owners is a legitimate, noncompensatory kind of community, so too are brand communities that revolve around an individual and their online self or brand.

As a way of exploring online profiles as a form of brand community, this paper also seeks to understand how profiles are branded, who the customers for these brands are, and how the brand identity and brand community are promulgated. Do these profiles reinforce the brand to existing 'consumers' thereby maintaining already established social networks, or are they efforts at winning new converts to expand the social network or brand community? If they are efforts at capturing a greater slice of the social network pie, then who represents the competition and are individual profiles pitted against one another? Lastly, by highlighting the self as a brand and social interconnectedness as a desirable attribute, does it offer a form of resistance against the homogenizing forces of mass marketing or is it

merely a form of false consciousness that fetishizes the individual and diminishes the value of genuine social relationships? The implications of these trends are explored.

# Fairness in Consumer Markets: Price Expectation, Cost Saliency, and Competition

Mark Ratchford, University of Colorado, Boulder, USA
Atanu Sinha, University of Colorado, Boulder, USA

Consumer perceptions of price fairness have received increasing research attention over the past several decades. Kahneman, Knetsch, and Thaler (1986; hereafter KKT) were among the first to experimentally show that price changes may engender concerns of fairness on the part of consumers. Their basic findings were threefold. First, it is fair for a firm to raise prices when faced with increasing costs. Second, it is fair for a firm to maintain prices as costs decline. Third, it is unfair for a firm to benefit from shifts in demand by raising prices. Their cumulative findings are known as the notion of dual entitlement (DE), as a firm and buyer are both considered "entitled" to certain economic gains or losses given increases or decreases in product supply or demand.

Following KKT, several researchers empirically tested the basic tenets of the DE principle and have suggested conditions which either qualify or counter KKT. Kalapurakal, Dickson, and Urbany (1991) challenged DE by showing that an alternative cost-plus rule and a buffer rule are both observed to be fairer than the rule derived from the DE principle. Bolton, Warlop, and Alba (2003) showed that increases in some firm costs lead to increased perceived fairness, however some costs are considered unfair for price increases. Vaidyanathan and Aggarwal (2003) suggest that even cost-justified price increases can be perceived as less fair when the locus of causality is internal to the seller and/or when the price increase is within the volitional control of the seller. Homburg, Hoyer, and Koschate (2005) reveal that as customer satisfaction increases, the negative impact of the magnitude of a price increase is weakened. Finally, Bolton and Alba (2006) show that the perceived fairness of the price increase will also depend on the alignability of the cost and price increases, such that alignable increases are perceived as more acceptable than non-alignable increases.

The current research investigates several phenomena that may impact fairness perceptions. First, we consider whether there is a psychological difference between a price deemed "fair" and a price that one expects to pay given a change in economic condition. It has been forwarded that consumers have preconceived ideas about what is a fair price for a given item, and are unwilling to spend more than that amount for the particular item (Kamen and Toman 1970). However, it is not clear how fairness and the price one expects to pay are related in the consumer's mind. Second, we consider when and under what conditions unfairness perceptions can be attributed to different entities in a distribution channel such as a retailer, wholesaler, or manufacturer. Third, we consider the impact of the nature of competition on perceptions of price fairness. Specifically, we consider whether a price is deemed to be more unfair when the seller is a monopolist versus when the seller has close competitors. Lastly, we note that in most of the hypothetical price or cost change scenarios outlined in KKT, fairness perceptions may be highly sensitive to the explicit reason given for the change. Thus, we attempt to delineate between when the amount of the price change versus the reason given for the change predominate unfairness perceptions.

The results of five scenario-based studies with undergraduate subjects yield several interesting findings. First, a price increase caused by a decrease in supply is found to be fairer than a price increase caused by an increase in consumer ability-to-pay (wealth). In addition, a price increase caused by an increase in demand is found to be fairer than a price increase caused by an increase in consumer wealth. These two findings are not qualified by whether or not the price fluctuation was caused by the actions of the seller (retailer) or the upstream manufacturer.

Second, perceptions of the fairness of a price change may depend on whether the seller of the product (a video game console in our scenario) is a retailer or an individual (the latter becomes relevant in today's Internet marketplace). Specifically, a price increase is found to be more fair when the seller is an individual rather than when the seller is a retailer. It is less fair for a retailer that one frequently visits to raise prices, given a change of demand or supply, than it is for an individual who may or may not be known to a consumer.

Third, using KKT's famous snow shovel scenario, we find that on average people expect to pay more than $15 for a snow shovel given an increase in demand, and think it is fair for the firm to increase their price by a "reasonable" amount (about 10% in this instance). Subjects, on average, expect to pay more than the price they deem to be fair. Moreover, both the average 'expect to pay' price and the

average 'fair' price are significantly higher than $15. Thus, KKT's conception of fairness may not fully incorporate consumer price expectations or willingness to pay.

Fourth, given a wholesale price increase, subjects find it to be fairer for a monopolist retailer to increase the price of a product than for a retailer in a competitive market. However, we do not find a significant difference between a monopolist and a competing retailer in what people expect to pay. Given a cost increase, the price deemed to be "fair" is higher for a monopolist retailer than for a retailer with many competitors.

Lastly, we find that when the amount of a price change is made explicit (i.e. subjects are explicitly told that the price increases by $15 from, say, $130), the resulting price is considered more unfair than when subjects simply see the final price which includes the change (i.e. subjects are told that the final price after the change is $145). The latter is the scenario that one would expect to see more often in "real" stores, as the amount of the price change is rarely advertised to customers. This result indicates that some of KKT's prior results may be partially attributable to demand effects.

# The Antecedents of Image Transfer–An Empirical Study of Event Sponsorship

Lee Zhang, Peking University, China
Song Lin, Peking University, China
Tingting Fan, Peking University, China

A literature review reveals that the factors influencing sponsorship effectiveness can be partitioned into three categories. The first is associated with a sponsored event per se such as event image, audience's interest and involvement in the event, event exposure and quality of the event. The second is the fit between the event and the sponsor brand. The third includes sponsor brand associated factors such as consumer's attitude toward brand, brand image and brand prominence. This study focuses on a sponsor brand having no awareness before the event and investigates the factors that may influence the effects of the sponsorship. Therefore, only the first two categories of factors are taken into consideration.

Similar to the American Idol in the U.S., Super Girl is a popular Chinese TV event that had drawn nationwide attention recently. This event was sponsored by a Chinese dairy brand called the Mongolian Cow Sour Yogurt. The target market of the brand and the major audience of the event is young people. The antecedents investigated in this empirical study include audience's attitudes toward the event, audience perceived event-sponsor brand fit, event exposure, perceived event quality and audience's involvement in the event. The extent that event image transfers to brand image is taken as the measure of the sponsorship effect. Hypotheses are developed based on a comprehensive review of the literature.

*Audience's attitudes toward event/Perceived event-sponsor brand fit/Event exposure/Perceived event quality/Audience's involvement in the event significantly influences image transfer*.

Considering the moderating effects of the involvement reported in previous literature, another hypothesis, *The higher level of event involvement, the stronger influences of attitude, fit, exposure and quality on image transfer, is put forward*.

### Method

A sample of enrolled students was drawn from two high schools and three universities located in Beijing, China. One thousand and five hundred questionnaires were distributed and 1,277 useable ones were returned. Measures of the independent and dependent variables were developed based upon a literature review, and were revised after pilot in-depth interviews. Reliabilities and validities of the measures were checked before statistical analyses were conducted.

### Results

First, a factor analysis on audience's attitudes toward the event was conducted. The result reveals two components of the attitude, personal liking of the event and perceived status of the event (whether the event is perceived to be socially valuable).

Then a multiple linear regression was conducted and the results indicate that perceived event-sponsor brand fit and event quality significantly influence image transfer. Inconsistent with the previous findings, personal liking and perceived status of the event, exposure and involvement are found insignificant. Finally, hypothesized moderating effects of involvement are not supported.

In order to fully explore the roles played by perceived event quality, event exposure and involvement, another two regressions were conducted to investigate these factors' impacts on personal liking and perceived status of the event respectively. Results show that perceived event quality, event exposure and involvement all significantly influence both personal liking and perceived status of the event.

In summary, the study identifies two influential factors of image transfer, perceived event quality and event-sponsor brand fit. Besides, though exposure and involvement are found to have no significant effects on image transfer, they both significantly affect personal liking and perceived status of the event, the two components of the attitude toward the event. Finally, it is found that perceived event quality significantly affects both image transfer and personal liking and perceived status of the event.

## Discussion

First, findings presented in this study indicate that event quality and event-sponsor brand fit are two critical factors in sponsorship because they influence image transfer, one of the most valuable goals for sponsors in pursuit of long-term brand image development. Second, based on our findings, we suggest that event relevant factors could be partitioned into two groups in terms of their roles: one group of factors affects brand image transfer, such as event quality and event-sponsor brand fit; the other group of factors influences audience's attitude toward event, such as exposure, involvement and event quality. Finally, event quality is a factor deserving special attention because it affects both image transfer and audience's attitude toward event.

Our study provides meaningful implications for practitioners. On one hand, before marketers contemplate what events to sponsor for, they should be aware of the effect of sponsorship on image transfer and the factors influencing such effect. To maximize image transfer and thus establish or strengthen brand image, sponsors may need to pay enough attention to event-brand fit and event quality. They shall be aware that high event exposure and involvement do not necessarily result in effective image transfer from the events to the sponsor brands. On the other hand, event organizers should realize that event exposure, audience's involvement and event quality are important in that they influence audience's attitude toward event. Besides, to meet the sponsors' demands for strengthening brand image, event organizers shall communicate with sponsors on how to create event-sponsor brand fit.

# Avatar and Extended Self in Online Gaming

Jeff Wang, City University of Hong Kong, China
Xin Zhao, University of Hawaii, USA
Gary J. Bamossy, Georgetown University, USA

How material possessions influence identity construction has attracted continuous interests in consumer research (Belk 1988, 2001; Arnould and Thompson 2005). Previous studies have examined meanings of possessions from different cultures and how they contribute to and extend a sense of self (Mehta and Belk 1991; Wallendorf and Arnould 1988), not only in home settings but also in workplaces (Belk and Watson 1998; Tian and Belk 2005). However, most existing studies have focused on self extension through tangible material possessions (Belk 1991), or self presentation (Goffman 1959) through digital associations on personal web pages (Schau and Gilly 2003). Although it has been found that avatars influence consumption (Holzwarth, Janiszewski, and Nuemann 2006), how intangible game avatars and virtual possessions in online games extend a sense of self is unclear. We seek to contribute to this theoretical tenet of self extension through a netnographic inquiry (Kozinets 2002, forthcoming) of the online gaming community in China. Specifically, we examine how consumers manipulate avatars in the virtual world to extend a sense of self in the Real World. Online gaming community also constitutes a fantasy consumption space (Belk and Costa 1998) that allows long term involvement and vicarious self construction. We explore strategies of self extension in this fantasy consumption space.

In addition to non-participant observations, we conducted depth-interviews with both experienced and amateur gamers in urban China. The interviews started with grand tour questions and were followed by probing questions for meanings of online games (McCracken 1988). The interviews lasted from twenty minutes to three hours. They were conducted in Chinese and then transcribed and analyzed. Our analysis proceeded through an itinerate process (Arnould and Wallendorf 1994; Spiggle 1994). Initial analysis has generated rich insights about identity construction and self extension within the online gaming communities in urban China. Chinese gamers construct a game avatar by projecting an ideal self and the well being of this game character is decided by the sum of its virtual possessions. For many gamers, the constructed avatar extends and enlarges a sense of self in the following ways. First, the avatar is used by gamers to extend the self beyond social taboos in real world, such as multiple marriages at the same time. Gamers seek idealized romance and experience love through the extended self of game avatar. The strong emotional involvement is experienced as "irresistible", even with the presence of actual partners in real life. Gamers seek to maintain the marriage in the game and at times such virtual relationship even results in actual marriage in RW. Second, the game avatar extends a sense of self by expanding the gamers' social network both within the game and in RW. Social capital (Bourdieu 1986) accumulated within the game empowers the gamer with a sense of control in real life. Third, the gamer and the game avatar are united by the flow of play and the gamer does not differentiate him or her self from the game avatar during the game. The avatar frames the gamers' identity and negative reputation of the avatar often evokes a strong sense of shame, or what Goffman (1959) calls the stigma of social identity. Forth, gamers seek to experience a sense of achievement through the extended self of game avatar and strive to accomplish what they cannot do in RW. Lastly, gaming is taken as a process of socialization through which gamers can learn and practice various skills needed in real life. Game avatar extends a sense of self not only through creating but also through knowing (Belk 1988).

Accompanying the rise of consumerism there is often a sense of loss (Giddens 1991), for which consumption is celebrated as a form of compensation. Online games provide an ideal arena in which gamers can seek to experience an idealized and *hyperreal* past. It is in essence a play of the lost values in rapidly changing Chinese society. In addition to pursuing these values through consumption, gamers also seek to enact the desirable in play (Huizinga 1970). Different games emphasize different values and offer a wide range of psychological remedies for everyday problems faced by Chinese gamers. The variety of experiences sought after in online games goes well beyond excitement, novelty, and relaxation. Gaming experiences are used to understand and guide actual lives in real world, and to help the gamer co-opt with frustrations in daily life. Gamers freely transgress between game and reality, and project experiences in the two different realms onto each other. We conclude our study with broad discussions of online game's impact on society and social well being.

# The Role of Commitment on the Customer Benefits–Loyalty Relationship in the Service Context

Won-Moo Hur, Hoseo University, Korea

Minsung Kim, Inha University, Korea

Kyungdo Park, Sogang University, Korea

**Introduction**

The purpose of this study is to examine the relationships among customer's perceived benefits, commitment, and loyalty. This purpose was developed based on the limitations identified in the previous loyalty studies. First of all, studies investigating antecedents of loyalty heavily focused on satisfaction (Fornell et al, 1996; Bolton, 1998), overlooking the importance of commitment as an antecedent of loyalty. Considering that satisfaction is the result of a service experience (backward looking) whereas commitment is critical for long-term relationship with a service (forward looking), the relationship between commitment and loyalty should be examined in detail (Gustafsson et al, 2005). Secondly, even though a number of recent studies identified that loyalty is not unidimensional (Ganesh et al. 2000; Dick and Basu, 1994), its relationships with various dimensions of commitment was under-researched (Verhoef, 2003). This study reflected multi-dimensional aspect of loyalty, so that customer retention, cross-selling, and positive word-of-mouth were distinguished and included to measure loyalty. By doing so, customer loyalty management strategies were developed, based on the resulting causal relationships between the types of loyalty behaviors and the dimensions of commitment. Third, there has been studies dealing with benefit-loyalty relationship with satisfaction as a mediator (Lee and Cunningham, 2001) the role of commitment in the relationship between benefit and loyalty has not been investigated enough. In this regard, this study compared two models, 'benefit → loyalty,' vs. 'benefit → commitment → loyalty,' to identify the effect of commitment on the relationship.

**Concepts and Hypotheses**

Considering of the previous studies and the applicability of the research constructs to mobile communication industry (e.g. Bolton 1998), benefit in this study was defined and measured by functional, economic, experiential, and symbolic benefit. In terms of commitment, this study distinguished affective commitment as a psychological aspect from calculative commitment as a physical and economic gain/loss aspect. This study agreed on the previous studies supporting that loyalty behaviors, such as customer retention, cross-selling, and positive word-of-mouth, are varied as the type of loyalty differs (Ganesh et al. 2000; Dick and Basu, 1994). Nine hypotheses are derived from the definitions of constructs in this study, reflecting the relationships among benefits, commitment, and loyalty. In detail,

it is hypothesized between benefits and commitment that functional and economic benefits with calculative commitment (H1 and H2), while experiential and symbolic benefits with affective commitment (H3 and H4) as having positive relationships. In terms of the relationships between commitment dimensions and loyalty behaviors, affective commitment is hypothesized as having positive relationships with all three types of loyalty behavior (H6, H8, and H9), whereas calculative commitment is hypothesized as having positive relationships only with customer retention and cross-selling (H5 and H7).

## Methods

225 Respondents were randomly selected and participated in the survey, and 204 cases were used in this study after screening process. Total 27 items were used in the survey to measure four types of benefits, two of commitment, and three types of loyalty behaviors. Reliability of the measurement was tested using Cronbach's $\alpha$, and it ranged from 0.704 to 0.954, implying that all constructs have internally consistent items. On the other hand, validity of the measurement model was tested using confirmatory factor analysis; resulting lambda and phi values showed good discriminant and convergent validity.

## Results and Conclusion

Hypotheses are tested through structural equation modeling using LISREL (8.50). Structural model showed a good fit to the data, suggesting that the research model was well developed ($\chi^2/df$= 1.382, GFI=0.908; CFI=0.972; RMSEA=0.040). About each hypothesis, eight were accepted and only the relationship between calculative commitment and additional sales was not supported. Affective commitment, on the other hand, significantly affect on all three types of loyalty behavior, including from the passive loyalty of "customer retention (t=0.174, p<0.05)" to the active loyalty of "positive word-of-mouth (t=0.535, p<0.05)." Especially that affective commitment showed the strongest effect on positive WOM pointed out the important role of affective commitment to induce active and strong type of loyalty. The mediating role of commitment was tested by comparing two models 'benefit → loyalty' and 'benefit → commitment → loyalty.' As a result, the model with commitment as a mediator showed better fit (Maruyama, 1998), indicating that the effective loyalty enhancement should focus more on letting benefits link with commitment appropriately than simply offering benefits directly.

## Implication and Future Research

This study identified two distinctive paths; one is functional and economic benefits → calculative commitment → customer retention (passive loyalty), the other is symbolic and experiential benefits → affective commitment → cross-selling or positive WOM (active loyalty). This provides notable implications. First of all, companies should be able to design their own benefits and relative customer relationship marketing strategy depending upon their goal (e.g. passive loyalty vs. active loyalty). Second, calculative commitment is mainly useful for defensive strategies, such as customer retention, whereas affective commitment helps to enhance three types of loyalty behaviors. This means that the economic benefit based marketing tools (e.g. price discount) on which marketers have heavily depended so far are not enough to establish a stronger loyalty, and marketing activities boosting up the emotional bonding with customers should be exercised to enhance loyalty. Thirdly, the benefits alone, without the link with commitment, did not significantly affect on loyalty, suggesting that companies are better to concentrate on building and maintaining the link between the two, instead of focusing on benefit offerings.

A number of directions for future research were also proposed. First, this study defined and limited benefits having four dimensions even though there are still other types of benefits. Including other types of benefits in relation to commitment and loyalty will help the external validity of the results. Second, this study treated three types of loyalty behaviors as static because the main issue was about the causal relationships among constructs. However, incorporating the dynamic model reflecting the relationships among loyalty behaviors (e.g. customer retention, cross-selling, and positive WOM) will be a further interesting study.

# The Velocity of Time: Primacy and Recency Effects on Time Perception

Doreen Kum, National University of Singapore, Singapore
Yih Hwai Lee, National University of Singapore, Singapore
Catherine Yeung, National University of Singapore, Singapore

**Abstract**

This research proposes that time may be perceived to "accelerate" or "decelerate" during an event and aims to address how a change in the velocity of "time" affects time perception in Internet environment. We motivate the theoretical relationship between prospective and on-line processing as well as retrospective and memory-based processing to investigate how established primacy and recency effects in serial information relate to our variable time velocity issue. Our findings show that duration estimates are influenced by one's time paradigm and the variable velocity with which time passage was perceived. Follow-on studies extend the framework to include consideration of boundary conditions and moderators.

Waiting time has been found to negatively influence satisfaction (Katz, Larson, and Larson 1991). Although substantial research has been devoted to the examination of factors influencing time perception, to our knowledge, they have conventionally viewed time as a linear construct where it proceeds as a constant flow of equal units. To this end, we propose that time may be perceived to "accelerate" or "decelerate" during an event. For instance, in the loading of a web page, a progress indicator may display the time to completion either in accelerating (from slow progress to fast progress) or decelerating (from fast progress to slow progress) fashion. How would a mere change in the velocity of "time" affect subjective downloading time perception?

As a start, we propose that one answer lies in the specific instance when time perception is formed. Consistent with Soman (2003), we expect that estimations of duration are dependent on when the judgment is made. We compare between prospective and retrospective time perception.

We motivate the theoretical relationship between prospective and on-line processing as well as retrospective and memory-based processing to investigate how established primacy and recency effects in serial information relate to our time velocity issue. Similar to on-line processing, prospective time is more amenable to primacy effects where judgment is made as the raw data becomes available (Hastie and Park 1986). Hence, we hypothesize that on-line processing leads to shorter time duration evaluations if the user initially encounters fast processing speed. In contrast, retrospective time and memory-based processing is more consistent with recency effect, where judgment is made based on information retrieved from memory. Thus, more recent information will make a greater impact. We therefore hypothesize that these users will judge the processing duration for a decelerating progression condition to be longer than for an accelerating progression.

The study employed a 2 (Time Paradigm: Retrospective vs. Prospective) x 2 (Processing Speed Pattern: Accelerating vs. Decelerating) between-subjects design. The total waiting time for each condition was held constant at 1 minute.

The findings revealed a significant interaction effect of time paradigm with processing speed pattern on perceived duration [$F(1, 74)=10.4, p<.002$]. Planned contrasts showed that the participants in the prospective condition rated the processing duration to be shorter in the decelerating condition [$\bar{x}_{\text{fast initial}}=51.11, \bar{x}_{\text{slow initial}}=64.47, F(1, 74)=4.49, p<.05$]. In contrast, those in the retrospective condition perceived time duration to be longer when the processing speed decelerated [$\bar{x}_{\text{fast initial}}=63.25, \bar{x}_{\text{slow initial}}=48.57, F(1, 74)=6.01, p<.03$]. Thus, our hypotheses are supported.

In reality, time paradigms of Web users are usually unknown. Thus, a follow-on study tries to uncover the most ideal (if any) method of psychologically managing perceptions of download time when time paradigms of Web users are unknown, by exploring an inverted-U rate of progression, that is, a fast-slow-fast pace. Theoretically, users in both prospective and retrospective conditions should perceive shorter durations given that the salient cues used for judgment are at the beginning and end respectively. However, we believe that the issue is not as straightforward.

Preliminary, we think that the wait duration needs to be long enough to allow for fast-slow-fast transition. If the duration is "too" short, the transitions may simply be too obvious to the extent that consumer's recognition of the varying velocities may overcome any primary/recency effects. We liken this to the schemer's schema (Wright 1986) notion where consumers may interpret the fast-slow-fast (or any obvious) transition to be mere marketing tactics. At the same time, we explore the moderating effect of the importance of the website, since the value of time is context dependent (Leclerc, Schmitt, and Dube 1995). For instance, a download time of the same duration may be perceived to be longer or shorter depending on the importance of the website to the user. In other words, we are suggesting that the manipulation of time velocity to favorably affect perception may require careful boundary considerations; which the current research is trying to develop.

The concept of variable velocities of wait time may also be tested in a services marketing context (such as call centers) or its application to behavioral cues. For instance, common wait management strategies for restaurants include taking the guest's order before s/he is seated. Our findings in this research suggest that the timing of this order-taking would impact the perception of the wait duration, as it signals an "accelerated" process. We can also explore the effect of partitioning the experience (such as in a five-course western meal) versus a cohesive one (e.g., a Chinese meal where all courses are served at once) on the variable velocities effect we saw in our study. Ariely and Zauberman (2003) found that for retrospective experiences, partitioning of experiences attenuates the pattern of sequences on judgments. Instead, their evaluations are based more on each component's momentary performance. Other studies on retrospective evaluations show that the Gestalt characteristics on which evaluations are based are usually the peak and final states of the experience (Ariely and Carmon 2000). It would be conceptually interesting to examine these relationships in a services marketing context with the inclusion of prospective conditions.

# A Meta-Analysis of the Moderation Effect of Regulatory Focus

Ahmad Daryanto, Maastricht University, the Netherlands
Ko de Ruyter, Maastricht University, the Netherlands
Martin Wetzels, Maastricht University, the Netherlands

**Abstract**

We conduct a meta-analysis on the existing literature integrating a large number of empirical findings of regulatory focus studies. Our study is aimed at making two important contributions to the RF literature. First, we give an overview of the impact of regulatory focus fit in terms of the magnitude of the interaction effect. Second, we identify and show the influence of potential moderators that may contribute to the magnitude of effect size: (1) feeling-right operationalization, (2) type of regulatory focus, (3) research domain, (4) use of incentives, (5) type of student sample and (6) participants' cultural background. We employ meta-regression analysis (MRA) to assess the association between these factors and effect size heterogeneity. Findings and limitations of the study are addressed.

**Overview of the Research**

One of the most popular and fascinating topics in consumer research is the impact of consumer's regulatory focus (Higgins 1997) on emotions, judgments, and behaviors. This theory proposes that consumers differ in how they present and experience basic needs (i.e. advancement or security), how they act in the course of goal pursuits, and how they react toward either positive or negative outcomes. Regulatory focus theory discerns consumer focus into two distinct foci: promotion and prevention focus. Promotion focus is related to nurturance needs, concerned with advancement and progress, and focused on gain-nongains outcomes. In contrast, prevention focus is related to security needs, concerned with duty, obligations, and responsibility, and focused on loss-nonloss outcomes.

Recently, regulatory focus has been branched out to regulatory fit theory (Avnet & Higgins 2006, Kruglanski 2006). This theory aims to explain the relationship between the way the goals are pursued and customer's regulatory orientation of promotion or prevention. According to regulatory fit theory, the means of goal pursuit can sustain or disrupt the orientation (Avnet & Higgins 2006). Prior research has documented the consequences of the fit between these two factors. When the manner of goal pursuits fit customer's regulatory focus, they (1) put a higher value on their chosen objects, (2) are more motivated and enjoy more goals pursuit, (3) feel right about their goal pursuits.

**Significance and Implication of the Research**

Despite the aforementioned findings, regulatory fit theory is still "in the stage of discovering new ideas and discoveries" (Kruglanski 2006, Avnet & Higgins 2006). Thus, if the research is to progress research is needed that summarize the theory and quantify the impact of regulatory focus. Thus, the current study attempts to examine this issue. In addition, we assess the impact of a number of moderators that influence the effect of the interaction between regulatory focus and other variables on consumer's judgment and behaviours.

We conduct a meta-analysis on the existing literature integrating a large number of findings of experimental studies. We use partial eta-squared that can be transformed to r contrast and Fisher-Z transformation as effect sizes. Partial eta squared is defined as the proportion variance in the dependent variable accounted for by the independent variable divided by the amount of variance in the dependent variable that is unexplained by any other systematic factors in the design (or after these other systematic factors have been partialled out (Cohen 1973). The rationale for the partialling is that because these systematic factors (i.e. any experimental variables) may induce additional variance in the dependent measures that make comparison of an intended effect size across studies became unreasonable. Pertaining to our meta-analysis context, this effect size of variance proportion explained is consistent with the conceptualization of RF as a moderating factor (i.e. cell means approach see Jaccard 1998).

In total, we obtained 83 effect sizes collected from 20 studies. Our meta-analysis study reveals that the effect size of the interaction effect varies between moderate and large: the estimate of r contrast is 0.321, which is equivalent to partial eta-squared of 0.103. We use a meta-regression procedure with REML estimator (Borenstein & Rothstein 2001) to test for the homogeneity of the effect sizes across studies. Following Card and Krueger (2005), we also estimate the model with OLS, adding standard error in the regressor in order to check for publication bias (i.e., the bias stemming from the fact that research with statistically significant results is has a greater chance of being

submitted and published than research that reports no significant results). The results show no potential publication bias. In addition, the majority of moderator variables were insignificant. We cross-checked this result by calculating the fail-safe N of Rosenthal (1979) i.e. the numbers of 'missing' studies needed to nullify the result. The fail-safe N seems very unlikely to exist (N>1000). Hence, we conclude that there is no threat for the publication bias in our meta study.

We find that homogeneity test is significant, which means that there is systematic variability in the effect sizes. We identify five moderators: type of feeling-right operationalization (process-based vs. outcome based); type of regulatory focus (trait vs. ideal-ought priming vs. identical task priming vs. approach-avoidance strategic priming vs. attribute priming), research domain (laboratory task vs. health vs. education vs. other), type of incentive for participation (voluntarily vs. money vs. personal gift vs. course credits), type of student sample (high school vs. college), and cultural background (independent vs. interdependent). It appears that types of RF priming, research domain, type of incentives, and type of student sample were found to be significant predictors of the magnitude of effect sizes.

Our findings should be interpreted in the light of their limitations. First, we were only able to use a relatively small number of articles as only these met the imposed criteria for inclusion in the sample. Many articles did not contain enough information for calculation of the interaction effect size. Second, treating multiple effect sizes of the same studies as statistically independent may also create a certain degree of bias in the findings. As more effect sizes become available, future meta-analyses can be conducted by taking into account dependency among effect sizes. Third, in addition to the major study variables included in our analysis, other potential moderators may help to explain variation in effect sizes. For instance, we were unable to record the amount time participant spent in experiments; as such information is frequently not reported by researchers. The availability of such information may, for instance, help to better interpret the level of participants' involvement in the study. Overall, our review of the literature demonstrates the relevance of the regulatory fit effect in consumer decision-making.

# Development of an Instrument for Measuring Consumers' Perception of Atmosphere

Morten Heide, University of Stavanger, Norway

Kjell Gronhaug, Norwegian School of Economics and Business Administration, Norway

Kirsti Laerdal, University of Stavanger, Norway

The concept of atmosphere is important both in everyday life and business. For example, consumers use time, energy and economic resources to create atmosphere in their homes involving costly activities such as decoration and purchase of art. Also, in business, atmosphere is considered vital. In the hospitality sector atmosphere is perceived an essential, if not the key factor, to attract and satisfy guests. The same interest applies to the retailing industries. To improve the atmosphere of their establishments, firms often make costly– and risky investments. However, the concept is vague and difficult to grasp, which represents a considerable challenge with regards to improving and managing atmosphere.

In this study, the hospitality industry was selected as the empirical setting. Despite considerable interest worldwide, targeted survey instruments to assess consumers' perceptions of atmosphere in hotel settings are lacking. This paper reports the process of developing such an instrument.

Several attempts have been made to define the concept. For example, atmosphere has been described as "the air surrounding a sphere" (Kotler, 1973). Mehrabian and Russell (1974) developed an influential framework for analyzing the effects of different environments on individuals. Bitner (1992) highlighted the concept of servicescape, i.e. the physical environment in which services are delivered, which can be an important aspect, but in no way fully captures the phenomenon of atmosphere. A review of relevant studies (see reference list) points toward three essential elements that can be combined to create the desired atmosphere: (1) atmospherics (background features such as temperature, scent, music and lighting), (2) social factors, and (3) design factors. Consumer responses to atmosphere might include cognitive, affective, physiological and behavioral reactions. However, the literature offers few indications regarding what the concept really captures, nor how to measure it. Consequently, an empirical approach was found necessary.

The development work was based on recommendations from previous scale development and measurement studies (see reference list). The work included two phases, i.e. an inductive and a deductive phase. In the *inductive* phase, we examined how the concept has been applied in relation to hotels. An internet search on "hotel" and "atmosphere" in combination yielded several million hits and a search routine was employed for identifying adjectives used for describing atmosphere. Every time a new adjective for describing hotel

atmosphere was encountered, this word was registered in an inventory of hotel atmosphere descriptors. Alternative search engines were used to expand the search, as well as synonyms (ambience, charm, appeal and resorts, motels, inns). We also scrutinized a large number of hotel design books, architectural books and travel magazines. When no more new descriptors were found, we concluded that the search was exhaustive. At this stage the inventory had *600 unique descriptors*, which we consider as the universe of hotel atmosphere descriptors.

In the *deductive* phase, we tested the relevance of each descriptor and reduced the number in order to remain with the most fundamental ones. The 600 descriptors were first reduced to 458 by employing judgment-based criteria. Thereafter the 458 descriptors were empirically tested using a three-stage randomized experimental design. Subjects were shown a ten-minute presentation of a hotel randomly selected from a total of 12 presentations. Afterwards they rated how relevant each descriptor was for describing the hotel's atmosphere on a seven-point Likert scale. In the first stage (n=78 undergraduate students, specializing in hotel/tourism management at a leading university in Norway) the number of descriptors was reduced from 458 to 201. The second stage (n=77, different sample from the same student population) yielded a further reduction to 135 descriptors. These descriptors were tested in the third stage (n=278, using a heterogeneous sample of students, i.e. from a wide range of disciplines), which gave the 43 descriptors that were subsequently tested in the exploratory field survey. Here we collected data from actual hotel guests in six hotels, all members of a leading hotel chain in Norway.

A total of 559 guests were invited to participate, of which 369 responded (i.e. a response rate of 66 percent, which we consider satisfactory). The composition of the sample (gender, nationality, age, type of guest) was found to be representative of the guest population of the respective hotels. In addition to questions about the respondent and ratings of various aspects of the hotel, the questionnaire included the 43 descriptors (in randomized order). The respondents were asked to indicate how relevant each was for describing the atmosphere in the hotel.

Following exploratory factor analyses of the responses on the 43 descriptors, we decided to proceed with a four-factor solution. The first factor could easily be interpreted as *distinctiveness* (high loadings on descriptors like special, fascinating and different). The second factor was interpreted as *hospitality* (loaded mainly on descriptors like welcoming, hospitable and professional). The third factor had powerful loadings on descriptors such as pastoral, resort and holiday and could consequently be interpreted as *relaxation*. The fourth factor loaded on descriptors like classical, traditional and upper-class and was thus labeled *refinement*.

The factor structure was further tested by confirmatory factor analysis using LISREL (Linear Structural Relations, Jöreskog and Sörbom, 2004). Atmosphere profiles were produced for the six hotels by plotting the mean factor scores. These profiles give a visual picture of the type of atmosphere that characterizes the hotel (there were highly significant differences between the hotels on the four factors). To test the predictive power of the indicators we used discriminant analysis. The random probability of predicting which of the six hotels the respondents had stayed in is 16.7 percent (i.e. 1/6). By including the atmosphere measurements, the probability increased substantially, i.e. 87.4 percent of the respondents were correctly classified.

The research presented here represents a step towards developing an instrument to measure atmosphere perceptions. Given the considerable interest, and consequently the presumed value of atmosphere as an intangible asset, there are a number of areas where a targeted measurement instrument would be useful. For example, the instrument could be employed to assess the extent to which the atmosphere of a particular establishment differs from that of its competitors, and whether the atmosphere offered satisfies the demand of the market segment aimed at. Also, the measurement instrument could be used to explore the relationship between atmosphere and key variables like customer loyalty, word-of-mouth, and repeat visits to mention a few.

Most managers have predefined goals to follow. To establish and create a desired atmosphere is often left to design experts (e.g. architects and interior designers), or handled by the owner's gut feeling/intuition. Being involved in atmosphere measurement can help the manager to improve his or her professional judgment and consequently reduce the risk of bad investments based on feelings more than facts. The measurement instrument could also be useful in identifying gaps (e.g. areas where staff members' perception of the atmosphere differs from that of the guests), as well as for measuring the effect of various interventions (e.g. pre- and post measurements in connection with investments to improve the atmosphere or training programs to enhance hospitality). Finally, the instrument could be used for testing how effectively different promotional material can communicate the salient aspects of the establishment's atmosphere to potential consumers.

# The Impact of Regulatory Focus on the Effect of Two-sided Advertising

Arnd Florack, University of Basel, Switzerland
Simon Ineichen, University of Basel, Switzerland
Rahel Bieri, University of Basel, Switzerland

Advertisers attempt to present products as positive as possible, praising the advantages of the advertised products. Sometimes, however, it is beneficial to rely on two-sidedly communicated-ads mentioning not only the benefits but also the shortcomings of a product

(Crowley and Hower 1994; Etgar and Goodwin 1982; Insko 1962; Kamins and Assael 1987; Lumsdaine and Janis 1953; Pechmann 1992). However, the persuasive effects of two-sided ads are limited and cannot be generalized (Belch 1981; Bohner et al. 2003; Golden and Alpert 1987; Hovland, Lumsdaine and Sheffield 1949; for an overview see Crowley and Hower 1994). In this paper, we argue that the recipients' regulatory focus (e.g. Higgins 1997; Higgins et al. 1994) is an important factor that accounts for differential effects of two-sided advertising.

The regulatory focus influences to what extent individuals rely on substantial arguments of a message and/or on affective responses when forming judgments (Florack, Scarabis and Gosejohann 2005; Pham and Avnet 2004). Prevention-focused individuals rely more on the substance of a message than promotion-focused individuals, whereas promotion-focused individuals are more likely to rely on their affective responses toward an ad. The feeling of credibility elicited by an ad is an affective response, and this feeling is elicited to a greater extent by two-sided ads (Golden and Alpert 1987; Settle and Golden 1974; Smith and Hunt 1978; Sternthal, Phillips and Dholakia 1978). Therefore, we expect a generally higher credibility of the two-sided ads compared to the one-sided ads. We also expect participants with a promotion focus to more heavily rely on this positive cue. As for the substantial content, regulatory focus theory suggests that prevention-focused individuals are more sensitive to negative information (Higgins 1997, 1998, Higgins and Tykocinski 1992). Combined with the differential relevance of mentioned product shortcomings, the differences in reliance on affective responses and substantive arguments should lead to more positive effects of two-sided advertising for promotion-focused recipients than for prevention-focused recipients.

To test these hypotheses we conducted two experiments. In experiment one, we measured chronic regulatory focus and then presented to the participants a series of three ads, either one-sided or two-sided. For every product, there was a one-sided ad that mentioned only the product advantage, and a two-sided ad that mentioned both, the product advantage and the product disadvantage. After the presentation of each ad, participants rated the advertised product. We averaged the dependent measures for the three ads. All analyses were computed with the aggregated scores. Regression analysis revealed a significant interaction between ad type and regulatory focus on the evaluation of the products: The stronger the promotion focus was, the stronger the positive effect of the two-sided ads compared to the one sided ads.

In experiment two, we applied a 2 X 2 Design, with the factors *regulatory focus* (promotion vs. prevention) and *ad-type* (one-sided vs. two-sided). Both factors were manipulated between participants. We measured the credibility of the ads and the evaluation of the products. Regulatory focus was primed with a modified version of the d2 attention test (Brickenkamp, 2002). The instruction was altered to either highlight loss- and non-loss feedback for priming a prevention focus or gain- and non-gain feedback for priming a promotion focus. Again, participants saw a series of three ads that were two-sided in one condition and one-sided in the other condition. After the presentation of each ad, participants judged the credibility of the ad and evaluated the product. As expected, participants rated the two-sided ads as more credible than the one-sided ads. An ANOVA with the factors ad-type (two-sided vs. one-sided) and regulatory focus (promotion vs. prevention) and the evaluation of the product as dependent measure yielded a significant interaction between ad-type and regulatory focus. In the promotion focus condition, participants evaluated the products more positively when two-sided ads were presented than when one-sided ads were presented.

In order to investigate the underlying process of the effects of two-sided ads in the promotion focus condition, we tested whether the effects of the two-sided ads were mediated by the credibility of the ads in the promotion focus condition (Baron and Kenny, 1986). In line with the results of the ANOVAs, regression analyses showed that the type of the ad was significantly related to the product evaluation and the credibility of the ad. Furthermore, the effect of the ad-type on the product evaluation is no longer significant when credibility is also entered in the regression equation, while the effect of the credibility of the ad is significant. A subsequent *Sobel test* showed that the reduction of the effect of the ad-type on the product evaluation is significant.

Taken together, the analyses show that in the promotion focus condition, the effect of the ad-type on product evaluation is mediated by the credibility of the ad. Further, our results have implications for marketing managers and advertisers. They suggest that two-sided ads are more effective when consumers are in a promotion focus and, therefore, rely on their affective responses. In particular, two-sided advertising might be effective for products linked to a promotion focus. Recent research has found that a regulatory focus is associated with certain product categories or the framing of a product category (Florack and Scarabis 2006; Zhou and Pham 2004). For advertising in such categories, two-sided ads should be effective.

# Negative Emotions as Motivators of Consumption

Harish Kapoor, Acadia University, Canada

Emotions are central to human experience and greatly affect us on a day-to-day basis in making all types of decisions, including consumption decisions. In a famous and often quoted article, James (1884) raised the issue, "*What is an emotion*?" This question has been repeatedly asked by philosophers and psychologists (and marketers as well!) for more than a century now with limited. Defining and measuring emotions remains a challenge as they rarely are either fully present or absent at any given time and tend to be highly individual and context specific (Ben-Ze'ev 2000). There is a lack of unanimity on the definition and measurement of emotions, and more importantly, differentiate it from other affective states.

The importance of the role of emotions in marketing is well understood (see Bagozzi et al 1999 for a review) and have been studied under a variety of contexts, such as, advertising (Aaker et al 1986; Batra and Holbrook 1990), attitude (Bagozzi 1992; Batra and Ahtola 1990), product usage (Holbrook et al 1984), brand evaluation (Yeung and Wyer 2005) and consumption (Havlena and Holbrook 1986; Richins 1997). These studies have largely examined how various types of consumptions invoke different emotions in the form of consumer response, as well as, how to measure emotions in a marketing context using scales and measurement techniques developed in psychology. Limiting the focus of research to emotions as a response to some marketing stimuli restricts the understanding of the role of emotions as it treats them as an outcome while ignoring the role of emotions as an antecedent or motivator to a behavior. Emotions, be they positive or negative, are more than appraisals of events and include action tendencies (Frijda 1986), therefore, their role should be examined involving all stages of consumer decision making.

At the same time, a survey of the marketing literature suggests that most research in the past has focused on examining the role of positive emotions and the measurement issues associated with them in consumer decision making. The role of negative emotions in consumer decisions has largely been ignored with a few exceptions, such as (Andrade and Cohen-in press) where they examine the consumption of negative feelings. The positive as well as negative emotions can serve as motivators for setting consumption goals and have both marketing and public policy implications. Gardner (1985) suggests suggested that, "… *the behavioral effects of negative moods may be more complex that the effects of the positive moods*," (p. 283). Therefore, it is important to understand when, why and how individuals would engage in consumption behaviors motivated by negative emotions. To that end, *the objective of the present research is to explore the role of negative emotions as motivators of consumption.*

To that end an exploratory study was conducted in which 117 undergraduate business students enrolled in a marketing course were asked to describe a real-life consumption situation triggered by negative emotions. Given the sensitive nature of the task, the researcher removed himself from the classroom while the subjects typed the descriptions on their laptops. A couple of USB flash drives were circulated in the class room to save the descriptions without any respondent identifier. A total of 53 students submitted the descriptions.

A content analysis of the data was conducted to identify the motivations for engaging in the consumption, the type of consumption experience, the intensity of the emotions involved, and consequences of the consumption. The consumption situations described by the subjects covered a very wide range of activities from purchasing simple products out of envy to spiteful behaviors targeted at family members, friends and, in some cases, at strangers. Though envy and jealousy were often mentioned as the motivation, it is noteworthy that a very large proportion of the respondents used the words such as "*spite*" and "*revenge*" to express their primary motivation for

consumption. The end goal, according to many, was to assert a control over a situation even at the cost of suffering more pain, both physical and emotional, accompanied with financial losses. Such behavior is contradictory to the hedonic assumptions underlying most consumer behavior that individuals seek to maximize their pleasure and minimize any associated pain/losses. This suggests that there is more to negative emotions than identified in the extant marketing literature and the concept of spite must be examined as a motivator

In identifying the Consumption Emotions Set (CES), Richins (1997) identified seventeen categories of emotions out of which Envy is one category comprised of *envy* and *jealousy* as its dimensions. However, the findings from the present exploratory research suggest that among the negative emotions, spite may be a much stronger emotion than envy and jealousy and might be the primary motivator behind some of the consumption decisions resulting from negative emotions. . Literature in psychology has differentiated between envy and jealousy and examined their role on individual actions and feelings–*schadenfreude* (Hareli and Weiner 2002; Smith et al 1996; Smith and Kim 2007). Surprisingly, to the best of our knowledge, no distinction is been made among envy, jealousy and spite or the role of spite has been examined in consumption. "*Spite implies a particular kind of hostile motivation,*" (Lazarus 1991, p. 227), and appears to be a more intense negative emotion than envy and jealousy and its role on consumption and public policy implications must be examined more systematically.

# Narrative Transportation in Concept Tests for Really New Products: Are All Protagonists Equally Convincing?

Ellis A. van den Hende, Delft University of Technology, The Netherlands
Dirk Snelders, Delft University of Technology, The Netherlands
Darren Dahl, University of British Columbia, Canada

When consumers are asked to evaluate really new products, they are helped by mentally simulating product use (Hoeffler 2003). Here we apply this finding to early concept testing, in which really new product concepts are presented to consumers. We propose that presenting such concepts in a narrative format may stimulate mental simulation. While reading a narrative of another consumer (the protagonist) who uses a new product, consumers are thought to place themselves in the events taking place. The result is a melding of attention, imagery and feelings, known as narrative transportation (Green and Brock 2000).

Narratives evoke imagery more easily than non-narrative formats (Deighton, Romer, and McQueen 1989), including bulleted lists of product characteristics (Adaval and Wyer Jr 1998). Applied to concept testing, we propose that a narrative format will enhance transportation and, through this process, to a more empathic (i.e., higher) evaluation of the new product. A potentially moderating factor is the portrayal of the protagonist, whose (mis)match or similarity to the reader might influence the degree of connection that is felt, and thus of the level of transportation (Green 2004). We will investigate this with senior consumers in two experiments that both make use

of a concept product that was pre-tested as highly innovative (Ebook; an electronic book). Senior consumers were chosen because they constitute an important and growing market in which the acceptance rate of highly innovative products tends to be low.

## Experiment 1

Participants (n=85) from activity centers (aged 55-80) were asked to evaluate the Ebook in a take home questionnaire. The design was a 2 (format: narrative vs list) x 2 (protagonist ethnicity: reader match vs reader mismatch) between subjects design. The narrative was written first. The bulleted list was constructed later by removing the protagonist, the temporal order of events, and their logical interrelatedness (after Adaval and Wyer 1998). In the ethnicity match condition the protagonist was Matthew, who had recently moved from the US to the Western country of the reader, and in the mismatch condition this was Mohammed who had moved from Morocco. In the instruction it was stated that the text originated from a forum, and was by someone who had written about the protagonist and his product.

After reading the concept, participants filled in questions about product evaluation (two items), transportation (12 items, (adapted from Green and Brock 2000) and a manipulation check (one item assessing the protagonist's similarity to the reader). Exploratory factor analysis of transportation showed four subscales: transportation, protagonist imagery, product imagery and attention. Of these, attention had an alpha<.7 and will not be discussed further.

After a successful manipulation check on (mis)match, the first result showed a format x ethnicity effect on product evaluation ($F=4.29, p<.05$), with the narrative match condition more positively evaluated than the other three conditions ($Z_{contrast}=2.00, p<.05$). A format x ethnicity effect in the same direction was found on the transportation subscale ($F=3.78, p=.05$). In addition, ethnicity had a main effect on the transportation subscale (match>mismatch, $F=5.28, p=.05$). Finally, there was an effect of format on both imagery subscales, with narrative higher than list (protagonist imagery: $F=25.59, p<.001$; product imagery: $F=2.99, p=.08$). Mediation analysis (Baron and Kenny (1986) shows that transportation mediates the interaction effect of format by ethnicity on product evaluation. A Sobel Test of this indirect effect is marginally significant ($Z=1.64, p=.05$, one-sided).

Experiment 1 shows that respondents are transported most by a matching protagonist in the narrative. It is this that leads to a higher product evaluation-not the evoked imagery. However, some mismatches may be more acceptable to the reader than the one used here. In addition, the (moderated) effects of format may be related to the fact that less protagonist information was present in the list than the narrative. Experiment 2 addresses these two issues.

## Experiment 2

In this laboratory experiment 92 men from a household panel participated, aged 55-75. A 2 (format: narrative vs protagonist-list) x 2 (protagonist age/gender: reader match vs reader mismatch) between subjects design was used. For format, the same level of protagonist information was now present in both the narrative and list, so the two conditions only differed in the temporal order and logical interrelatedness. In the protagonist age/gender manipulation, the matched protagonist was a man, always three years younger than the reader to avoid guessing. The mismatch was a woman of 23. We pretested protagonists' names so that they suited their age. Procedure and measures were similar to experiment 1.

After a successful manipulation check on (mis)match, we found a format effect on product evaluation (narrative>list, $F=4.24, p<.05$). We found format effects in the same direction on all transportation subscales (all alpha's>.70, transportation: $F=5.28, p<.05$; protagonist imagery: $F=33.74, p<.001$; product imagery: $F=6.60, p<.05$). A mediation analysis with the three transportation subscales as mediators revealed transportation and protagonist imagery as mediators of the format effect on product evaluation. Separate Sobel Tests showed an indirect effect for both variables (transportation: $Z=2.16, p<.05$; protagonist imagery: $Z=4.02, p<.001$).

## Discussion

The two experiments show that narratives lead to a higher evaluation than lists in concept tests, and that this effect is mediated by transportation. Mediation corroborates a finding of Escalas (2004) in advertising, where transportation was found to mediate the effect of mental simulation on attitude towards ad and brand. We also find that product imagery does not mediate evaluation, and protagonist imagery only in experiment 2. An explanation for this last effect might be that the protagonist in experiment 1 was liked less in the mismatch than the match ($F=13.47, p<.001$), while in experiment 2 she was liked more in the mismatch than the match ($F=5.34, p<.05$). Thus, the transportation subscale mediates the (moderated) format effect on evaluation, and protagonist imagery mediates only when the protagonist is liked.

The difference between experiment 1 and 2 in the evaluation of the mismatch narratives can also be explained by protagonist liking. Earlier it was shown that a lack of familiarity with the protagonist reduces transportation (Green 2004). However, we show that a reader-protagonist mismatch does not reduce transportation when the protagonist is liked by the reader. Thus, it seems that transportation, which implies that the reader simulates *being* the protagonist, is determined more by liking than similarity, which is relevant for concept testing.

# Transforming Self and by Extension Society. An Exploration of Activism Against Consumerism

Simona Romani, University of Sassari, Italy

## Introduction

This paper aims to contribute to a deepened understanding of activism against consumerism in contemporary consumer culture, a topic that only recently has started to feature in consumer research debate (see among others, Dobscha and Ozanne, 2001; Cherrier and Murray, 2002; Kozinets and Handelman, 2004; Thompson, 2004; Gabriel and Lang, 2006). Making use of a theoretical framework inspired by Foucault's ideas on power and resistance, focussing on an ethical, anti-consumeristic campaign as a research domain and applying a combination of qualitative research techniques, this research attempts to investigate how radical activists, usually cited as "others" within dominant discourses on consumption, position themselves and resist traditional materialistic consumption culture.

## Theory

Consumer research addresses the issue of the movements that seek to undermine consumeristic ideology using several different theoretical perspectives, ranging from NSM theory to eco-feminism from Foucault's ideas on power to Plummer's framework of identity construction.

This paper, following Thompson's suggestions (2004), aims to study consumer activism that seeks ideological and cultural change in the market using the conceptual categories introduced by Foucault.

An analysis of power and resistance in Foucault's works has been conducted (among others, Foucault, 1978; 1983; 1985; 1988). Consideration of some of his later publications clearly reveals an interesting evolution in the notion of resistance, which ultimately emerges as much richer and viable than that initially put forward in Volume I of *The History of Sexuality* in 1976.

In fact, Foucault concludes that resistance to power is better understood not merely in terms of agonistic force relations, but also in the sense of creative movements in the field of possible actions; resistance is no longer just the sabotage of a dominant agenda but also concerns the constitution of novel types of subjectivity, forms of agency that develop a genuine alternative to mainstream contemporary life. Therefore, an important point of resistance is in forging new forms of living, or innovative, non-conventional modes of existence; in short, self-formation.

Building on this more complex notion of resistance, I study how activists involved in an extremely active, ethical, anti-consumeristic, Italian campaign named "Bilanci di Giustizia" (*Balance Sheets of Justice*) engage in resistance to consumption.

## Methods

The investigation of the Bilanci di Giustizia activists commenced in 2002. At that time I began informally observing their highly active, group partecipants' Internet community and downloading and analyzing their computer mediated communications. Additionally, pertinent articles, documents and other cultural data available through mass media and via Internet were collected and analyzed.

After approximately one year of building a knowledge base, I undertook participant observation at the two day annual meeting in 2003. Following this, I subscribed and contributed to the Bilanci di Giustizia mailing list and maintained e-mail contact with several participants I had met and interviewed. This more intensified online activity was followed by participation in the successive annual meetings. During immersion in these events I kept detailed written field notes. The ethnography also encompassed interviews and interactions with several activists. All the material was transcribed, coded, repeatedly read in detail and analyzed using constant comparative analytic techniques (e.g., Glaser and Strauss 1967).

## Findings

Findings demonstrate that the activists' adoption of counter-discourses drawing on cultural models of fairness, environmental sustainability and quality of life ideals results in the undermining of existing dominant discourses on consumption in general, and thereby the creation of conditions for the establishment of a permanent critique of all consumerism.

However, these simultaneous and ubiquitous forms of resistance that focus on transforming power relations combine with activists' creation of new forms of subjectivities more in line with their anti-consumeristic ideology and contrasting their received subjectivities as "western mainstream consumers". Activists transform themselves in accordance with their ideals and standpoint on what is genuinely beneficial and meaningful in life, rejecting their traditional roles as consumers.

These new forms of subjectivities, these "alternative" approaches in relating to society, nature and oneself are creatable through their coherent linkage of modes of organizing thoughts, conduct and ways of being.

In particular, the philosophy of "sobriety" appears to be the most marked issue activists consider in transforming themselves, with which they aim to "make the difference" in relation to mainstream consumers, considered to be dozing in conformist behavior or, as in one respondent's words, a "*comfortable torpor*".

With this philosophy guiding their everyday and concrete actions, activists can become credible evidence that change is possible and that this can significantly contribute to the attainment of a better world.

In synthesis, this idea of transforming themselves and by extension the society in which they live could prove to be of great interest in enriching the discussion on activism against consumerism in contemporary consumer culture.

# When Ads Make Drama Seem Silly and Comedy Seem Dull: Role-Fulfillment Effects of Mood on Evaluations of Emotional Television Commercials

Joseph Lajos, INSEAD, France
Nailya Ordabayeva, INSEAD, France
Amitava Chattopadhyay, INSEAD, France

Previous consumer research has examined how moods induced by emotional television programs influence viewers' evaluations of commercials. For example, Goldberg and Gorn (1987) showed that happy and sad television programs induce parallel moods among viewers, that viewers continue experiencing these happy and sad moods during commercial breaks, and that these moods influence their reactions to individual commercials. Drawing on research on mood congruency and accessibility (e.g., Bower 1981; Isen et al. 1978), Goldberg and Gorn hypothesized that viewers evaluate commercials more favorably when they appear during happy (vs. sad) programs, and provided experimental support for this hypothesis.

We believe that previous consumer research only captures part of a more complex relationship between the emotional valence of television programs and viewers' evaluations of commercials.

**Role-Fulfillment Evaluation Processes**

In this paper, we draw on psychological research on mood as an input to role-fulfillment evaluation processes. Whereas most theoretical models of the relation between mood and evaluations suggest that people in positive moods provide more favorable evaluations than do people in negative moods (e.g., Bower 1981; Isen et al. 1978; Schwarz and Clore 1988), role-fulfillment research suggests that the more people experience the feelings (positive or negative) that they would expect to feel if some mood-inducing object or event had fulfilled its role, the more favorably they evaluate that object or event.

For example, Martin et al. (1997) showed that participants in an experiment evaluated a comedic television program more favorably after being incidentally placed in a happy (vs. sad) mood, whereas they evaluated a dramatic television program more favorably after being incidentally placed in a sad (vs. happy) mood. Martin et al. argue that happy participants evaluated the comedy more favorably than did sad participants, because, for them, the comedy seemed to have fulfilled its role: they expected it to make them feel happy, and (due to the positive incidental mood induction) they indeed felt happy. Similarly, Martin et al. argue that sad participants evaluated the drama more favorably than did happy participants, because, for them, the drama seemed to have fulfilled its role: they expected it to make them feel sad, and (due to the negative incidental mood induction) they indeed felt sad.

**Hypothesis**

In this paper, we propose that when a television program establishes a mood, viewers expect to continue experiencing that mood throughout the duration of the program, including commercial breaks. Then, based on research on role-fulfillment processes, we hypothesize that viewers evaluate commercials more favorably when they support, rather than break, the moods established by programs. Based on this hypothesis, we predict that viewers like happy commercials more than sad commercials during happy programs, and that they like sad commercials more than happy commercials during sad programs. The notion that, under some circumstances, viewers may prefer sad (vs. happy) commercials is counterintuitive and a key contribution of this paper.

**Experiment 1**

The goal of Experiment 1 was to test our hypothesis that viewers evaluate commercials more favorably when they support, rather than break, the moods established by programs.

*Design*: The experiment had a 2 (program mood: happy vs. sad) X 2 (chronological positioning of commercial in program: middle vs. end) X 2 (commercial mood: happy vs. sad) X 2 (commercial replicates) between-subjects design.

*Procedure*: Participants watched a 15 minute clip from a happy vs. sad television program, followed by one of two happy vs. sad

commercials which were chronologically positioned such that they either interrupted the program or followed its conclusion. Then they evaluated the commercial.

*Results*: Consistent with our hypothesis, the results showed that following happy program clips, participants evaluated happy commercials significantly more favorably than sad commercials, and that following sad program clips, they evaluated sad commercials significantly more favorably than happy commercials. This interaction effect was significant both when the commercials interrupted the program and when they followed its conclusion, providing evidence that the effect is robust.

## Experiment 2

The goal of Experiment 2 was to test whether the theorized role-fulfillment process underlies the interaction effect observed in Experiment 1.

*Design*: The experiment had a 3 (focus: cognitive vs. affective vs. none) X 2 (commercial mood: happy vs. sad) X 2 (commercial replicates) X 2 (awareness of potential biasing effects of mood on evaluations: aware vs. unaware) between-subjects design.

*Procedure*: Participants utilized a computer program which displayed instructions that implemented the focus manipulation (for a discussion of cognitive vs. affective focus see Millar and Tesser 1986). In the cognitive focus condition, the instructions stated that participants should carefully attend to the details of the ensuing program clip's plot, characters, and scenes in preparation for a memory test. In the affective focus condition, the instructions stated that participants should carefully attend to their emotional responses to the ensuing program clip in preparation for an empathy survey. In the no focus condition, the instructions did not indicate what participants should focus on during the ensuing program clip.

Participants then watched a 15 minute clip from a sad television program, followed by a happy vs. sad commercial. Following the video, the computer displayed instructions that implemented the awareness manipulation. In the aware condition, the instructions described psychological research which has shown that people's incidental moods may sometimes bias their evaluations of stimuli. In the unaware condition, the instructions did not mention this research. Finally, participants evaluated the commercial.

*Results*: There were four interesting results. First, among participants in the affective focus and no focus conditions, evaluations of the sad commercials were significantly more favorable than those of the happy commercials. Since these commercials followed a sad program clip, this result is consistent with our hypothesis that television viewers evaluate commercials more favorably when they support, rather than break, the moods established by programs.

Second, among participants in the cognitive focus condition, evaluations of the sad commercials and the happy commercials were statistically equal. By demonstrating that when viewers ignore their moods the difference in evaluations between mood-matching vs. mood-mismatching commercials disappears, this result provides support for the theorized role-fulfillment process.

Third, among participants in all three focus conditions, evaluations of the sad commercials in the aware condition were either significantly lower than or statistically equal to evaluations of the sad commercials in the unaware condition, in support of the theorized role-fulfillment hypothesis and contrary to the predictions of the competing HDIF heuristic (see Schwarz and Clore 1988).

Fourth, among participants in all three focus conditions, evaluations of the happy commercials in the aware condition were either significantly higher than or statistically equal to evaluations of the happy commercials in the unaware condition, in support of the hypothesized role-fulfillment hypothesis and contrary to the predictions of the HDIF heuristic.

## Conclusion

Our results have implications for consumer research on the effects of mood in advertising, for psychological research on role-fulfillment and the interplay between competing mood models, and for important aspects of marketing practice such as commercial design and scheduling and the pricing of television airtime.

# Being Hedonic and Becoming Prudent

Camille S. Johnson, San Jose State University, USA
Danit Ein-Gar, Stanford University, USA

"I am who I am or I am what I intend to be?"
*Anonymous*

People often make choices as a form of self-expression (e.g. Belk 1988, Malhotra 1988, Kleine). It remains unclear whether these self-statements are derived from consumers' perceptions of their current selves or their future selves. That is, are consumers purchasing an item in order to say "this is who I am" or in order to say "this is what I want to become"?

The current research suggests that consumers do both; that consumption choices and preferences shift depending on their mindset. More specifically, we show that when consumers think about their current selves (i.e. are in a "being" mindset) they are more likely to show hedonic preferences and choices. However, when consumers think about their future selves (i.e. are in a "becoming" mindset) they are more likely to show prudent preferences and choices. This notion integrates two literatures. The first is literature demonstrating the impact of time-orientation on consumer preferences and choices. This literature demonstrated that time-orientation influences consumers' choices between two computer software options (Lieberman and Trope, 1998). When asked to make a decision about the distant future, desirability aspects are more important. In contrast, when asked to make a decision about the near future, feasibility aspects of new software are more important. The second is literature demonstrating the relation between time-orientation and self-control. This literature has shown that individuals high in self-control are more future-oriented than individuals low in self-control (e.g. Zimbardo and Boyed 1999, Strathman, Gleicher, Boninger and Edwards 1994).

Unlike the literature that manipulate time-orientation by changing the timing of the decision outcomes (e. g., tomorrow versus next year), we manipulate time-orientation by asking individuals to think about their current selves or their future selves: to adopt a "being" mindset in which decisions are made with the purpose of evaluating and defining the current self or to adopt a "becoming" mindset in which decisions are made with the purpose of elucidating future outcomes (Johnson & Stapel, 2007).

We extend literatures by demonstrating that consumer's mindset can influence subsequent consumption choices and preferences in the domain of self-control. Because a being mindset is associated with defining the current self, a being mindset was expected to have a short-term time orientation associated with the desire to "seize the day". As a result, a "being" mindset should be associated with hedonic choices and preferences. Because a "becoming" mindset is associated with moving towards future selves, it should lead to a long-term time orientation associated with prudent choices and preferences.

Three studies test these hypotheses. In each study, participants were assigned to a "being" mindset (e.g. write a brief essay about "who you are right now") or a "becoming" mindset (e.g. write a brief essay about "who you will become in the future"). Then, they were asked to report preferences and make choices for day-to-day consumption scenarios.

In Study 1, we tested the influence of mindsets on spending preferences. After writing a "being" or "becoming essay", participants (N =64, Age $_{mean}$ =36.4) were asked to imagine that they had won a prize of \$1000. Participants reported how they would spend their winnings. The preferences were coded as hedonic (e.g. plasma TV) or rational (e.g. pay bills). As hypothesized, participants in the "being" condition were more likely to report hedonic ($N$=17) versus rational spending preferences ($N$=11), while participants in the "becoming" condition were more likely to report rational ($N$=23) versus hedonic spending preferences ($N$=13), ($x^2$(4, $N$=64)=3.83, $p$=.05).

In Study 2, we tested the influence of mindset on gift-receiving preferences. After writing the mindset essay, participants (N=72, Age $_{mean}$=19.5) were asked to imagine that they had recently purchased a home and were assembling a gift registry for a house-warming party. They were asked to put together a 10-item Amazon.com gift registry drawing from a list of 20 items that had been pre-tested by nine judges as hedonic (e.g. Martini glasses) or rational (e.g. pots and pans). We examined the first two items selected. Participants in each mindset were equally likely to make balanced choices (one rational, one hedonic). However, participants in the "becoming" mindsets were more likely to make two rational selections ($N$=16) compared to participants in the "being" mindset ($N$=6). And, participants in the "being" mindset were more likely to make two hedonic choices ($N$=8) than were participants in the "becoming" mindset ($N$=3),($x^2$(2, $N$=72)=6.39, $p$=.04).

In Study 3, we further tested our hypothesis in a consumer choice setting. Participants (N=84, Age $_{mean}$=19.3) were asked to read an ad that asked them think about who they are now or who they may become. Then, they were given a choice between two snacks: a granola or a chocolate bar. Participants in the "being" mindset were more likely to choose the chocolate bar ($N$=24) over the granola bar ($N$=17) while those in the "becoming" mindset were more likely to choose the granola bar ($N$=24) over the chocolate bar ($N$=14), ($x^2$(1, $N$=84)=5.72, $p$=.01).

In sum, the current studies extend our understanding of the relationship between time-orientation and consumer's choices and preferences in demonstrating that consumer's tendency to be hedonic or rational is based upon their view of their self. Focusing on current selves drives consumers to be hedonic while focusing on their future selves drives consumers to be prudent. Across three studies and three different consumption situations, when consumers thought about their current selves, they were more likely to make hedonic choices and preferences. That is, shifts in mindsets influenced preferences and choices, even when the time of the decision and timing on of decision consequences remained the same. Thus, time is not simply a characteristic of the decision, but an alterable characteristic of the consumer.

# Nice Guys Finish First: An Examination Customer-First Strategies on Consumer Attitudes and Loyalty

Rishtee Kumar, Boston University, USA

In a memorable scene from the American classic, "Miracle on 34th Street," the Macy's Santa Claus directs prospective customers to a competing store because the competitors' prices are lower. Customers delighted by Macy's customer service, choose to shop in-store, despite higher prices. Is this simply cinematic fiction or do nice guys really finish first? This paper explores the impact of customer-first strategies, those that put the interest of the consumer before that of the retail establishment (termed here as the "Miracle on 34th Street Effect"), through the lens of three theoretical frameworks.

The most basic tenet of the norm of reciprocity proposes that people help those who have helped them in the past. Simply put, patrons may feel obliged to return the favor of the salesman by means of immediate or future purchases or other indirect methods such as positive word of mouth. However, the mood congruency hypothesis offers another possible explanation for the proposed effect. Existing literature on affect indicates people are likely to remember and recall those events that are congruent with their current moods and that people's social perceptions are mood-congruent. (Bower, 1981). Therefore, an extremely positive interaction with a salesperson might induce a positive mood, leading the customer to act congruently with the positive mood and shop in-store rather than going to a competitor. Finally, we should also consider the concept of disconfirmation of beliefs as a means of expectation management. Typically, customers do not expect salespeople to engage in behaviors that benefit the customer at the risk of the company. This explanation predicts that when expectations based on historical information are compared to the actual consumption experience and are significantly different, prior beliefs are elaborated upon and new attitudes are formed, causing consumers to reappraise the situation and take appropriate action. (Oliver, 1981)

In sum, though the relative strength of these three processes in explaining the Miracle on 34th Street effect is not clear, the outcomes of the three processes are similar. More specifically, it is hypothesized that customers who interact with salesmen exhibiting a customer-first strategy will be more likely to favor the target store: When choosing it over a competitor for an immediate purchase ($H_1$), through more positive evaluations ($H_2$), have more positive evaluations of the sales associate ($H_3$), purchase an unrelated item even when it is costlier at the target store in the future ($H_4$), be resilient to negative information ($H_5$), and tell others about their experiences ($H_6$).

A 2X2 design (sales associate strategy X price difference) was used (n=78) and participants had to imagine that they were using a gift certificate to buy a DVD. In all conditions, the DVD was out of stock at the target store. The sales associate strategy was manipulated by having the sales associate refer the customer to a competitor who carried the DVD in stock (experimental condition) or simply stating that the store was out of stock (control condition). All subjects were then told that they could either purchase the DVD at the target store but would have to wait 1 week while the store ordered it, or they could purchase immediately at a neighboring store, at the same price. Subjects also completed a mood identification scale and a brief exercise that probed them about their schema of sales associate behavior. In the second part of the survey, participants were first asked how likely they were to make a second unrelated purchase (CDs) at the target or competitor store. Price difference was manipulated so that the price of the target product was either identical at both stores or about 7% higher at the target store. Next, they were asked about a third unrelated purchase with a similar price manipulation. In the third section of the study, participants were given a fourth scenario involving a friend's purchase where negative information regarding the target store was presented. The four parts of the study were separated by distracter tasks to create temporal and cognitive distance from each other.

Data analysis provided support for $H_1$-$H_3$, wherein participants in the customer-first strategy (experimental) condition were more likely than control participants to choose the target store over the competitor $F(1, 78)=7.77$, $p<.01$, even though this required a one week wait and the same DVD was available at a neighboring store in the mall. Furthermore participants in the experimental condition had more positive store, $F(1, 78)=46.449$, $p<.00$, and sales associate evaluations, $F(1, 78)=36.588$, $p<.00$, were more likely to counter negative information about the store, $F(1, 78)=13.276$, $p<.00$, and were also more likely to make a future, unrelated purchase at the target store, even when the cost of the product was cheaper elsewhere, $F(1, 78)=60.388$, $p<.00$, supporting $H_4$-$H_5$. The only measure that was not significantly different was the likelihood to tell others about their experience at the target store, $F(1, 78)=3.105$, $p =.082$, thus rejecting $H_6$.

This study provides us with preliminary support for two of the process explanations proposed. There seems to be evidence for a mood congruency effect as subjects in the experimental condition had significantly more positive moods than their counterparts, $F(1, 78)=103.183$, $p<.00$. However, there also seems to be evidence for an expectation management explanation. When asked the extent to which the sales associate's behavior was typical of most sales associates, experimental subjects were more likely to find the behavior atypical than their counterparts, $F(1, 78)=56.551$, $p<.00$. They were also more likely to indicate that the sales associate exceeded their expectations, $F(1, 78)=61.432$, $p<.00$.

It is not very clear as to whether the norm of reciprocity was a factor in subjects' purchase decisions and store evaluations. While subjects in the experimental condition were more likely to make a second unrelated purchase at the target store, $F(1, 78)=60.388$, $p<.00$ they were also more likely to choose the target store over the competitor for a third unrelated purchase, $F(1, 78)=8.088$, $p<.00$. If the norm of reciprocity is strictly transactional, the customer need only make one more purchase at the target store). However here either participants felt obligated to extend other favors (a third purchase) or there were other factors in play.

The findings and discussion in the present paper are preliminary and merit future research effort. Future studies planned will test the process explanations more directly by manipulating their presence or absence. It is also possible that the explanations work in conjunction

and we will attempt to explore this. We also propose to explore the role of perceived authenticity of the sales associate as a moderator in this framework.

# Leapfrogging over the Joneses: Can Wealth Redistribution Reduce Conspicuous Consumption by Relatively Worse-Off Consumers?

Nailya Ordabayeva, INSEAD, France

Pierre Chandon, INSEAD, France

It is a well-known and well-deplored fact that poor people spend more on status-enhancing positional goods and save less money overall (as a proportion of their income) than people who are better off (Bagwell and Bernheim 1996; Christen and Morgan 2005; Duesenberry 1949). Economists have argued that one solution to this problem would be to increase endowment equality by redistributing wealth through income or consumption taxation (Frank 1985, 1999). Although increasing endowment equality can undoubtedly reduce social envy and overall positional spending, this argument overlooks that it can increase the exclusivity benefits of positional spending (i.e., the improvement in people's relative social rank) for relatively poor people. For this reason, raising endowment equality may have the unintended effect of actually encouraging poor people to choose conspicuous consumption over savings, especially for goods consumed in public and that enhance social status.

In this research, we examine how the distribution of endowment across people affects the spending vs. saving tradeoffs and the social envy of people in the lower tier of the endowment distribution. We make three key hypotheses. First, improving endowment equality (i.e., increasing the proportion of people with an average endowment) reduces social envy because an equal distribution reduces differences among people. Second, a more equal distribution of endowment increases the improvement in status brought about by positional spending because it enables the worse-off people to jump ahead of the now larger number of people with average endowment. Finally, raising endowment equality causes relatively worse-off people to prefer consumption over savings more when the product provides observable status-enhancing benefits (e.g., a prestigious brand) than when it provides unobservable personal benefits (e.g., a higher durability).

In contrast to welfare economics studies, which are either theoretical or rely on secondary data, we test these hypotheses in three experimental studies. The first two studies examine the effect of equality of endowment with a product, whereas the last third study examines the effect of equality of income on spending and saving decisions.

In the first study, we examine how endowment equality affects envy and spending by relatively poor people. We manipulate between subjects the distribution of a positional good, the number of rose bushes in people's front gardens. In a scenario initially 10% of people have no rose bushes. In the equal distribution condition, 40% of gardens have two rose bushes. Buying three bushes enables the 10% of poor people (who initially have no roses) to be in the top 50% of gardens. In the unequal distribution condition, only 20% of gardens have 2 rose bushes and most gardens have a lot more. Buying three bushes therefore still leaves people with no rose bushes in the bottom 50% of the distribution. As expected, we find that poor people are less envious, yet spend more in the equal distribution condition than in the unequal distribution condition. Second, we find that the social comparison tendency of participants influences envy, but not their positional spending decision. This shows that envy and exclusivity gains are dissociated and that conspicuous spending decisions are driven by their status-granting effectiveness, not just by social envy.

In study 2, we distinguish between positional and non-positional spending and examine if exclusivity gains explain the effect of endowment equality on spending vs. saving decisions. We use a 2 (endowment distribution: equal or unequal) X 2 (positionality: high or low) X 2 (task: saving vs. spending decision or rating of exclusivity benefits) between subject design. The participants read 2 scenarios (house garden and ski trip) and judge how willingly a relatively worse-off person in an equal or an unequal distribution would spend on positional products (rose bushes and branded scarves for a ski trip) or non-positional products (pine trees and fabrics quality scarves for a ski trip) and to which degree each type of spending provides status gains. We find that positional spending is higher in an equal than in an unequal society, but only when the product is positional. We further show that endowment equality increases exclusivity gains for both positional and non-positional goods. This indicates that wealth equality leads relatively worse-off people to choose consumption over saving only for status-enhancing conspicuous goods.

In our final study, we examine the effect of the distribution of overall wealth, rather than the effects of the distribution of endowment with a particular product. We also study the moderating effects of social rivalry by manipulating whether the reference group consists of friends or rival co-workers. Finally, we manipulate the salience of self utility vs. status goals through a scrambled sentence manipulation. We use a 2 (wealth distribution: equal or unequal) X 2 (reference group: rivals or friends) X 2 (priming: status or personal utility) between-subjects design. After the priming task, participants are asked to evaluate their (low) salary by studying the distribution of salaries of either rival co-workers or childhood friends. In the final stage, participants read a scenario in which they have to choose whether to go to a lowbrow or highbrow fashionable restaurant with a friend or co-worker and whether to take a bus or a taxi to get home afterwards. We find a significant three-way interaction. Income equality leads to more conspicuous spending when people are primed with status than when they are primed with self-utility, but only in the rival co-worker condition. This result supports our thesis that the effect of endowment equality on spending is fueled by social rivalry and concern for status.

Overall, the studies provide insights about the drivers of conspicuous consumption by relatively worse-off people. They also have implications for the debate on what should be done to encourage poor people to save more rather than spend so much money on conspicuous consumption.

# 'When the Chips are Down': The Relation between Stress, Social Support, and Food Product Attitudes

Claartje L. ter Hoeven, University of Twente, The Netherlands
Marieke L. Fransen, University of Twente, The Netherlands*

To exercise sensible judgment it is conducive to be cool and collected (e.g., Raghunathan and Pham 1999). Despite this widely shared knowledge, this emotional state is not always within reach. Several studies have demonstrated influences of various affective states on decision processes (e.g., Shiv and Fedorikhin 1999; Isen 2001) and attitudes (e.g., Clore et al. 2005). One affective state that has important consequences for decision-making processes is stress (e.g., Keinan 1987). We argue, in the present studies, that stress is not only related to different decision-making strategies but also to consumers' product evaluations.

Under conditions of stress, self-regulatory mechanisms break down more frequently. According to the self-regulation model (for a review, see Baumeister, Heatheron, and Tice 1994), we only have a limited amount of regulatory strength. When this reserve is worn out, depletion is the result and self-regulatory performance is often weakened (Schmeichel, Vohs, and Baumeister 2003). This limited self-regulatory resource can be exhausted by self-regulatory demands (Vohs and Heatherton 2000). Once depleted, people buy (Vohs and Faber 2007) and eat (Baumeister and Heatheron 1996; Vohs and Heatherton 2000) more, and more impulsive. Obviously, the consequences for consumer behavior are far-reaching.

However, thus far, little is known about product preferences once depleted through stress. Therefore, in the present studies, we explore the influence of stress on explicit food product attitudes. Building on the theory of self-regulation, we propose in study 1 that stressed consumers not only eat more, but also prefer unhealthy food products over healthy food products, because they lose self-control. In addition, a growing body of literature has pointed out the importance of social support in the reduction of stress and stress related behavior (see Antonucci, Fuhrer, and Jackson 1990; Siebert, Mutran, and Reitzes 1999; Yacono Freeman and Gil 2004). Therefore, it is expected, in study 2, that social support has a stress declining effect, which reduces the impact of stress on food product attitudes.

## Study 1

To test the hypothesis that stress is related to food attitudes, participants' stress level was measured using the State version of the State Trait Anxiety Inventory (STAI; Spielberger 1983). A median split was applied to classify participants as experiencing high versus low levels of stress. Subsequently, consumers rated, on a five-point scale, their attitudes towards different food products (three healthy and three unhealthy food products). A measure of product preference was created by calculating the difference score between the mean score

---

*Both authors contributed equally to this work.

on the healthy products and the mean score on the unhealthy food products. Hence, higher scores indicate a more favourable attitude towards healthy food product whereas lower scores indicate a more favourable attitude towards unhealthy food products.

As expected, the results demonstrated that participants with a high level of perceived stress scored lower on the product preference measure than participants with a low level of perceived stress, indicating that stressed participants have a more positive attitude towards unhealthy food products in comparison with unstressed participants.

## Study 2

In study 2 we aim to extend the results found in study 1 by manipulating levels of stress instead of measuring levels of stress. Furthermore, we examine the moderating role of perceived social support. We hypothesize that high levels of stress result in more positive evaluations of unhealthy food products than low levels of stress. Moreover, we expect this effect to be stronger for participants who are not satisfied by the social support they receive from friends and family.

We tested our hypotheses in a 2 (stress level: stressed vs relaxed) x 2 (social support: unsatisfied vs satisfied) between subjects design. Participants' satisfaction with the overall social support they receive was measured by the Social Support Questionnaire (Sarason, Levine, Basham, and Sarason 1983). Based on a median split, participants were classified as satisfied or unsatisfied with the social support they receive from friends and family. Stress was induced by adopting the procedure used by Coffey and Lombardo (1998), in which participants completed a number task, while hearing an audio novel in the background. Participants in the control condition were instructed to relax and to do so they could choose to listen to some music or to just wait. To test whether participants in the stress condition experienced more stress and felt more depleted than participants in the relax condition, they responded to the state version of the State Trait Anxiety Inventory (STAI; Spielberger 1983) and to a shortened version of the depletion scale (Ciarocco, Twenge, Muraven, and Tice, unpublished manuscript; Janssen, Fennis, Pruyn, and Vohs 2008). These measures were followed by the product preferences measure used in study 1.

The results demonstrated that participants in the stress condition experienced more stress and felt more depleted than participants in the relax condition, indicating that the stress manipulation was successful in inducing stress, and furthermore, it revealed that the stress manipulation resulted in depletion. Moreover, the results yielded a significant main effect of stress on product preferences showing that the stressed participants, compared to the relaxed participants, evaluated the unhealthy food products more positively than the healthy food products. In addition, this effect was qualified by a significant interaction between stress levels and social support satisfaction; the effect of stress on product preference appeared more pronounced for participants who are unsatisfied with the social support they receive.

When stress drains a consumer's strength, failing self-regulation becomes a possibility (Baumeister and Heatheron 1996), and can end up in compulsive (eating) behavior. The findings of the present studies show that being stressed may result in different food product attitudes as well. Moreover, participants who are satisfied with the social support they receive seem better in coping with stress and related feelings of depletion. Consequently, the impact of stress on food attitudes diminishes for those who experience satisfying social support.

Taken into account the enormous growth of stress (Schabracq, Winnubst, and Cooper 2003; Schaufeli and Enzmann 1998), the findings reported have important implications for consumers and producers on a large societal scale. The current studies contribute to the literature on the relation between stress, social support and product attitudes. It seems that social support can function as a resource to inhibit stress-related behaviors.

# Who's Got the Power?
# A Social Power Perspective on Teen Purchase Influences

Kendall Goodrich, Florida Atlantic University, USA

Two main agents of social influence on teen purchase, parents and peers, are evaluated in by applying social power theory (French and Raven 1959). The five types of social power (French and Raven 1959) are summarized *briefly* below:

1. Expert power: expert knowledge.
2. Legitimate power: legitimate right to influence behavior
3. Referent power: personal identification
4. Reward power: ability to confer a reward
5. Coercive power: ability to confer punishment

Prior consumer research called for examination of peer and family influence (Bachmann and Roedder John 1993; Roedder John 1999), but social power theory has not been evaluated.

### Conceptual Development

Parents and peers significantly influence teen purchase decisions (Rousseau 1982; Rousseau 1984; Mascarenhas and Higby 1993; Moschis and Moore 1979; Martin and Bush 2000; Boyle, Claxton, and Forster 1997; Felsher, Derevensky, and Gupta 2003), while siblings have significant, but lesser influence (Cotte and Wood 2004). This study's focus is on parental and peer influence.

Most corporate studies of social power indicate that expert and referent power positively influence subordinates while legitimate power effects are mixed (Backman 1968; Elangovan and Xie 2000; Frazier and Summers 1986; Skinner, Dubinsky and Donnelly 1984). Reward power can motivate, but coercion negatively affects work performance (Frazier and Summers 1986; Elangovan and Xie 2000). Similarly, consumer research suggests informational and referent influence on teen purchase decisions (Mangleberg, Doney and Bristol 2004; Moschis 1976), while normative influence can have a negative effect (Mangleberg, Doney and Bristol 2004). Although peer influence increases as teens mature (Koester and May 1985; Feltham 1998; Simpson and Douglas 1998; Mangleburg and Bristol 1998; Lueg et al 2006), parental influence strongly affects teen consumption (Martin and Bush 2000; Blood and Wolfe 1960).

H1: Parental expert and referent power will have a positive effect on teen purchase decisions, while reward power will have a lesser positive effect.

H2: Parental coercive power will have a negative effect on teen purchase decisions

Corporate research on peer influence indicates that expert, referent, reward and legitimate powers are rated highest (Gemmill and Wilemon 1972; Pitts 1990; Thomas 1982), but that legitimate power and reward power might have lesser positive effect (due to mixed research results; Yukl and Falbe 1991; Fiorelli 1988), while coercive power has a negative influence (Fiorelli 1988). Consumer research (e.g., Mangleberg, Doney and Bristol 2004; Moschis 1976) is largely consistent with corporate results.

H3: Peer expert and referent power will have a positive effect on teen purchase decisions, while peer legitimate power and peer reward power will have a lesser positive effect.

H4: Peer coercive power will have a negative effect on teen purchase decisions.

Two other factors, family and product characteristics, potentially moderate parental and peer influence. Socio-oriented family communication (child avoids controversy and does not argue; Foxman, Tansuhaj and Ekstrom 1989; Moschis and Churchill 1978; McLeod and Chaffee 1972, McLeod and O'Keefe 1972) is associated with stronger peer influence (Moschis and Moore 1979; Bristol and Mangleberg 2005), while concept-orientation (child encouraged to develop own ideas) allows greater parental influence (Aribarg, Arora, and Bodur 2002).

H5:  Family communication style will have a moderating effect on social power influence, with socio-orientation having a more positive effect on peer influence and concept orientation having a more positive effect on parental influence.

Product category (e.g., public or private, luxury or necessity) moderates informational ("expert"), utilitarian ("reward" and "coercive") and value-expressive ("referent") influences (Park and Lessig 1977). Necessity products have greater value-expressive and utilitarian influences (Bearden and Etzel 1982), while luxury goods have greater peer influence, particularly for value-expressive and informational components (Childers and Rao 1992).

H6:  Product type will have a moderating effect on social power influences, with greater peer expert and referent power for higher-priced public/luxury products and greater parental and peer reward, coercive and legitimate power for necessity products.

## Methodology

Data were collected via written survey (175 Southeastern U.S. high school students). Social power scales (Gaski 1986; Hinkin and Schriesheim 1989; Flurry and Burns 2004) were adapted to teens, and socio/concept scales were used from prior research (Moschis and Moore 1979). Product was student-defined with an open-ended question ("last product you bought for yourself for more than $40, with your own money, in the past 12 months"). Product categories were assigned post-survey by two Ph.D. students using prior definitions (Childers and Rao 1992). Interrater reliabilities were .88 and .84, with disagreements resolved through discussion.

Exploratory factor analysis yielded 9 social power factors. Reward and coercion factors loaded unidimensionally (e.g., Beier and Stern 1969; Gaski 1984; Kohli 1989) for peers but yielded only one unique parental coercion factor. All factors had good reliability ($\alpha$>.70; Nunnally 1978). Confirmatory factor analysis indicated acceptable measurement model fit (CFI =.90, IFI=.90, $\chi^2$/df<2; Bentler and Bonett 1980; Kline 1998) and acceptable discriminant validity (high item loadings of .50 or more, low cross-loadings, and low inter-factor correlations (.63 or below); Bagozzi 1994).

## Preliminary Results

Peer and parental social power factors, as well as their interactions with socio and concept factors, were regressed against product type, using logistic regression. Grade level was a control factor. Preliminary results indicate that parental expert (p<.05) and coercive (p<.01) power, as well as peer expert (p<.05) and legitimate power (p<.01), significantly predict the type of product teens purchase, partially supporting H1-H4.

Furthermore, concept orientation significantly interacts with parental expert (p<.05) and coercive power (p<.01) but also with peer expert (p<.01) and legitimate power (p<.05), while socio orientation significantly interacts with peer reward/coercive (p<.01) and legitimate (p<.10) power but also with parental coercive (p<.01) power, partially supporting H5.

The results suggest that parental coercive (p<.05) but also peer legitimate (p<.05) power significantly influence "public necessity" purchases relative to "public luxuries," while peer expert power (p<.05) significantly influences public luxury purchases, consistent with H6.

Referent power was marginally significant for parental referent power for concept teens (p<.10). As expected, high school grade was significant. Overall, these results support prior teen purchase decision research, but lend greater insight into specific factors, such as legitimate power, that affect teen purchase.

## Exploring the Role of Shopping Efficacy on Customer Satisfaction and Behavioral Intentions

Eda Gurel Atay, University of Oregon, USA
Joan Giese, University of Oregon, USA
John Godek, University of Oregon, USA

Research has conceptually and empirically augmented customer satisfaction models with antecedents and mediating satisfaction constructs. Abstract desires (Spreng, MacKenzie, and Olshavsky 1996) and multi-channel awareness and usage (Wallace, Giese, and Johnson 2004) impact customer satisfaction. Satisfaction with product and service attributes (Mittal, Kumar, and Tsiros 1999; Oliver

1993), satisfaction with the process and choice (Tanner 1996; Zhang and Fitzsimons 1999), and utilitarian and hedonic judgments (Mano and Oliver 1993) influence the overall customer satisfaction response. These findings have greatly enhanced researchers' and managers' understanding of customer satisfaction. Yet, important satisfaction questions still remain; the general focus of this research is to examine the role of the customer in customer satisfaction.

Current satisfaction research considers that customer differences may have a strong impact on the satisfaction process, the satisfaction response, and the resulting consequences. Mittal and Kamakura (2001) identified three possible customer characteristics: satisfaction thresholds, response bias tendencies, and nonlinearity between satisfaction ratings and repurchase behavior. Similar to satisfaction thresholds, Grace (2005) found consumer differences in disposition toward satisfaction. In the present research, we introduce a new construct, *shopping efficacy*, proposing that shopping efficacy will differentiate customers and will influence overall satisfaction and subsequently behavioral responses to the satisfaction episode.

Shopping efficacy is defined as the degree to which one can efficiently find a particular product for which one is shopping. Some people are able to buy a product they need or want without spending as much time as others. These consumers know which products and brands they are going to buy as well as where to purchase these products. As such, consumers who are high in shopping efficacy do not take as much time to locate and purchase products, relative to others and relative to the type of product. For these consumers, shopping efficacy is salient across different retail channels.

Previous studies have identified several kinds of market experts, including opinion leaders (Rogers and Cartono, 1962), market mavens (Feick and Price, 1987), and consumer innovators (Steenkamp, Hofstede, and Wedel (1999). These market experts may or may not be efficient at shopping. Similar to market mavens and opposed to opinion leaders and consumer innovators, efficient shoppers are not tied to a specific product category and they have general market knowledge, e.g. product information, promotions, price, and quality, for different kinds of products. Moreover, they are well-informed about both newly released and established brands and products. In addition, consumers high in shopping efficacy are adept with the search and shopping processes. Unlike market experts, efficient consumers are focused on their personal abilities to minimize the time needed to purchase products. Shopping efficacy is not strongly tied to interpersonal communication about products.

To develop a measure of shopping efficacy, an item pool was generated based on a focus group study and relevant literature. These items were tested on a sample of 43 students at a major west coast university. Based on initial reliability analysis, exploratory factor analysis, and confirmatory factor analysis, four Likert items were retained (1=strongly agree/5=strongly disagree; Cronbach's alpha=.89): 1) When I go shopping, I can quickly buy the product I want; 2) I can find the product I am looking for without spending much time; 3) I can shop quickly; and 4) I have the skills to find the product I am looking for in a short amount of time.

Shopping efficacy is related to differences in how consumers perform the shopping process; we expect that those who are high in shopping efficacy would be especially attuned to the retailer-provided efficiency of the shopping process. Thus, for those high (low) in shopping efficacy, an illogical or unorganized product display or website would result in lower (no effect on, possibly higher) process satisfaction This should impact their overall satisfaction more than for those who are low in shopping efficacy. This research examines the effect of shopping efficacy on overall satisfaction, and resulting behavior intentions.

To test these effects, an online study was conducted with 169 university students (80 males and 87 females). Randomly assigned participants visited one of two online florist shopping websites designed for this study. The websites differed in efficiency to check out with one requiring three clicks and the other requiring approximately 20 clicks. Participants examined two bouquets and then went through the checkout process (without actually paying for the bouquet). After checking out, participants answered questions related to the website, manipulation checks, and the shopping efficacy scale. In order to make the online shopping experience more realistic, the day after participants completed the product choice, each received an email with a message reflecting a good or bad product from the bouquet recipient. At this time, participants completed scales to measure their overall satisfaction (Spreng, MacKenzie, & Olshavsky 1996) and behavioral intentions (adapted from Mittal, Kumar, & Tsiros 1999). Regression analysis indicated a positive relationship between shopping efficacy and overall satisfaction ($\beta$=.145, $t$=1.896, $p$<.06). Behavioral intentions related to the product were measured by three questions: repurchase intentions from the same website; from the same florist; and likelihood to recommend the florist. SEM results revealed that the relationship between shopping efficacy and behavioral intentions was evident when including overall satisfaction as a mediator ($\chi 2$ (1)=0.884, TLI=1.001, CFI=1.000, and RMSEA=.000). Shopping efficacy also had a direct effect on behavioral intention related to the experience (the likelihood that the participant would tell others about the experience with the florist) with $\beta$=.199, $t$=2.625, $p$<.01.

These results indicate that shopping efficacy has a direct impact on overall satisfaction and that those high in shopping efficacy are more likely to talk about the experience. The positive relationship between shopping efficacy and overall satisfaction significantly influences consumers' intentions to repeat purchase and make recommendations. Overall, these results suggest that shopping efficacy makes a contribution to both consumer behavior literature and marketers. Indeed, it is expected that satisfaction ratings and behavioral intentions results will be more meaningful if this construct is taken into consideration.

# Nature and Function of Scripts in the Evaluation of Service Experiences

Mark P. Healey, University of Leeds, Leeds, UK

**Abstract**

This research examines how cognitive scripts shape the evaluation of service encounters. Based on an updated conceptualization of the script concept, script-based norms are theorized to be cognitively constructed from extant script knowledge to act as standards of comparison that shape evaluations. Findings from a two-stage experiment confirm that experienced consumers draw heavily on script-based norms to comparatively evaluate service transactions, and that these norms are consistent with the nature of script knowledge both as conceptualized and as elicited prior to consumption. The findings offer to challenge and enrich current models of consumer satisfaction and reactions to service experiences.

# The Effect of Promotion Framing on the Evaluation of Price Bundling

Nai-Chi Yeh, National Chengchi University, Taiwan

Lien-Ti Bei, National Chengchi University, Taiwan

Different promotional frames affect consumer price perceptions and internal reference prices (IRP) differently (Urbany, Bearden, and Weilbaker 1988; Lichtenstein, Burton, and Karson 1991). Similarly, when products are bundled, consumers are sensitive to the framing of price information (Yadav and Monroe 1993; Janiszewski and Cunha 2004). Whether the bundle consists of similar or different products, previous research has shown that consumer perceptions of products are influenced by different promotional frames (Sinha and Smith 2000; Janiszewski and Cunha 2004).

Although many studies have investigated how consumers perceive and evaluate bundle offers under various price frames, no research has targeted how the IRP shifts and mental accounts vary under price discount frames. Thus, the first purpose of this research is to examine consumer IRP under different promotional frames. Promotional frames may also affect the components of the bundle differently, a topic that has also been neglected in the research literature. Thus, the second purpose of this study is to elucidate the effects of promotional frames on the IRP of the focal versus tie-in products. The third purpose of the study is to observe the variation in IRP when bundles of similar or different products affect consumer perceptions.

In this article, three different types of popular promotional frames are used: "buy one, get one free," "buy one and get the second for only $1 (equals to 3 cents in US dollars)," and "buy two, get 50% off." The bundles have similar monetary values and are analyzed and discussed based on mental accounting theory (Thaler, 1985), in order to explain how consumers perceive these three frames. First, in the "buy one, get one free" situation, consumers open two "mental accounts": one is coded with a gain in the focal product's value, and the other is coded with the extra gain of the free product. It is not likely that the free product will be used to correct value of focal one for the consumer (Campbell and Diamond, 1990). Thus, IRP increases to match the advertised selling price in this situation.

The second frame, "buy one and get the second for only $1," may also make consumers open two mental accounts, one maintaining a gain via receiving value for the focal product and the other holding a gain by virtue of paying a nominal amount of money. However, the tie-in product is so cheap that consumers may regard this product as essentially free. Therefore, when consumers regard the second product as a free gift, the IRP also rise as a result of the advertised selling price.

Finally, the third promotion, namely, "buy two, get 50% off" inherently implies a purchase precondition to purchase two units to receive the reduced price (Sinha and Smith, 2000). Although consumers may also receive a gain of value for the focal product of this purchase, the precondition of purchasing a second product to reduce the price also reduces the consumer's perceived gain. Thus, consumers are likely to open one mental account, wherein they code one gain in the focal product's value with a small loss of payment for the tie-in product. Consequently, the advertised selling price is probably split to decrease the IRP.

Two studies were conducted using 3 (promotional frames) between-subjects experimental design. In study 1, 146 undergraduate students were randomly assigned to one of three conditions. We simulated shopping situations experimentally, and then let the consumers use real money (NT$100) to purchase scarves (priced at NT$99), which as also served as their "thank you" for participation in a study

of product quality examination under different promotional frames. After the shopping process, we forced all participants to divide their price perceptions of the promotion frames into two mental accounts by asking them to sell back the scarves one by one to the experimenter. This enabled us to detect their IRP separately for the focal and tie-in products under different promotional frames. In study 2, all procedures above were repeated, excluding bundles providing different items (i.e., pitchers and chopsticks each priced at NT$79). 107 undergraduate students participated in study 2.

Results showed that when bundled with the similar products, consumers perceived "buy one, get one free" as two mental accounts, since their IRPs for focal and tie-in products were different (Mean$_{(focal)}$=99.66 vs. Mean$_{(tie-in)}$=75.96, t=-2.873, p<0.05). In addition, consumers perceived the highest IRP under the "buy one, get one free" frame. By contrast, the "buy one, and the second one is only $1" frame (Mean$_{(focal)}$=65.58 vs. Mean$_{(tie-in)}$=57.30, t=-0.519, p=0.61) and the "buy two, get 50% off" frame (Mean$_{(focal)}$=75.33 vs. Mean$_{(tie-in)}$=59.76, t=1.763, p=0.09) were perceived as only one mental account. However, when different products were included in the bundle, the "buy one, the second one is only $1" frame was perceived as two mental accounts (Mean$_{(focal)}$=69.23 vs. Mean$_{(tie-in)}$=43.58, t=5.477, p<0.05). Further, the IRP of the focal product was highest in the "buy one, the second one is only $1" frame, followed by "buy one, get one free", and "buy two, get 50% off".

The investigation of the IRP of the focal product shows that consumer perceptions are influenced by not only the promotional frames but also by the bundled components. When the focal and tie-in were similar products, "buy one, the second one is only $1" and "buy two, get 50% off" seem to be coded as one mental account. That is probably the result of both frames providing discounts linked to price directly, since consumers probably categorize them as price-off promotions (Sawyer and Dickson 1984). Further, since consumers may integrate the price reduction after a "% off" and "$1" but not after an extra-product promotion, they perceive the highest IRP of focal product in the "buy one, get one free" frame.

When the bundle consists of different products, the "buy one, the second one is only $1" frame is perceived as two mental accounts. Because the tie-in product is different from the focal one, the IRP of the tie-in product is less easily computed. Hence, most consumers ignore the insignificant payment of NT$1(about 3 US cents) and regard the tie-in product as an extra, free product. Our studies reveal that the "buy one, the second one is only $1" frame may pull down the IRP of the focal product of the bundle if the products are similar, but not if they are different. Our research shows that marketers should be careful when manipulating bundle promotional frames and take composition of the bundle into consideration when accounting for consumer responses.

# Examining Advertising Practitioners' Ethical Considerations and its Implications for Consumer Welfare

Linda Tuncay, Loyola University Chicago, USA
Catherine Coleman, University of Illinois at Urbana-Champaign, USA

Past research indicates that literature on advertising ethics has neither adequately addressed the range of problems faced by practitioners (Hunt and Chonko 1987) nor those by consumers (Treise, Weigold, Conna and Garrison 1994). Little work has been done in consumer research to address decision makers'—that is, advertising practitioners'—beliefs about ethical dilemmas (exceptions include Drumwright and Murphy 2004; Hunt and Chonko 1987; Moon and Frank 2000). In fact, advertising ethics seems to have largely eluded consumer researchers (Hyman, Tansey and Clark 1994).

However, one issue that has arisen as significant in popular and scholarly discourse and through efforts in feminist literature (Kilbourne 1999; Bordo 1993; Wolf 1991) is that of gendered stereotyping in advertisements, and specifically its implications for women. These discourses, generally portraying women as a "vulnerable" audience, draw from a history of gendered expressions of the marketplace (Bristor and Fischer 1993; Hirschman 1993; Ramsay 1996; Schroeder 1997; see also Baker, Gentry and Rittenburg 2005 for a discussion of boundaries of vulnerability). Within the framework of consumer theory, vulnerability is not associated with maleness or male consumers as a category. These dialogues, focusing on female vulnerability but neglecting male responses have affected not only the practices of the advertising industry, but also ethical determinations of those practices.

Recent research has demonstrated men compare themselves to advertising ideals and may experience feelings of inadequacy and vulnerability (Tuncay 2006). Yet, no research to date specifically considers how or *if* advertising practitioners identify ethical dilemmas that involve male consumers.

## Methodology

To investigate how advertising practitioners conceptualize the impact of advertising on consumers, particularly males, a qualitative approach consisting of interviews, focus groups, and field observations was used. One of the researchers was allowed access to a large advertising agency in the U.S. where she was fully immersed in the day-to-day operations of a team of advertising professionals working on a brand targeting men. The researcher conducted formal and informal interviews, as well as focus groups with a total of 20 individuals working in a broad range of agency functions. During the interviews, informants were asked "grand tour" questions (McCracken 1988), as well as focused questions on how advertising impacts consumers. For purposes of anonymity, neither the sex of the informant, nor his/her job title are attributed to informants' quotes. To analyze the data, both researchers sought emergent themes in the text while also referring back to the literature, a process called dialectical tacking (Strauss and Corbin 1998).

## Findings

Our data revealed evidence of "moral myopia" or a "distortion of moral visions that prevents moral issues from coming into focus" as discussed by Drumwright and Murphy (2004, p.7). For example, one informant reflected a "going native" attitude, stating while he/she found some ads offensive, "I push them through because that's my job, my loyalty is with [the client]." However, while our findings resonated with past research, a new type of moral myopia was illuminated.

*Women as a Protected Audience/Men as an Immune Audience:* While several informants were concerned about how advertising portrayed women, there was little recognition that men were impacted by advertising depictions. For example, during a creative review, an ad script was read in which a joke was made about a woman. Immediately after, both the female researcher and female practitioner were consulted to ensure the ad was not offensive or demeaning.

Such consideration was not given to men. While negative representations such as "womanizer" and "stupid dad" were mentioned by informants, many felt men were not significantly impacted by them. During one interview, an informant acknowledged that while men may feel "a little bit of pressure" to fulfill ideals portrayed in advertising, he/she stated, "I feel like the female side of it's a little bit stronger," and that men "put it on themselves." Another informant stated that men would not likely be impacted by or be offended by ads, "…if women see even themselves objectified in advertising? that maybe would cause a stronger aversion to something than if men… [had] been picked on." When probed by the researcher, he/she stated, "Maybe its just gender differences." Thus, while men were often seen as immune to the influence of advertising, when this impact was recognized, it was often discounted. Informants also discussed relatively narrow gender portrayals of men in advertising. One informant stated, **"…**if some boy…says something that's not in man code, they get made fun of. So there's definitely…defined roles that I think males play in advertising but then also in culture…"

## Discussion

Thus, women were discussed as an audience who needs protection while men were deemed to be immune to the negative impact of advertising. Moreover, male role portrayals seemed to be strictly defined by practitioners and required adherence to a "man code." These findings reflect broader cultural and gender discourses in American society. Societal ideals about gender suggest that men are powerful, show little emotion, and should be resistant to pain (Harris 1995; Lindsey 1997) while women are passive (Scott 2005). Moreover, other researchers have discussed the conflicting and restricting notions of masculinity in advertising and in broader cultural discourse (Firat 1994; Pleck 1981).

In contrast to Drumwright and Murphy's (2004) findings of widespread moral myopia, we observed a prevalent concern among practitioners about how women are impacted by ads. However, this consideration did not extend to men. From a theoretical perspective, this research questions the constructions of vulnerable audiences, an issue with important repercussions on advertising practice and regulatory measures as well as public perception. Just as with women, men are impacted by ads (Tuncay 2006), and limited portrayals restrict the roles that men experience in their own lives. However, a positive implication of the results indicates that advertisers are responsive, even if slowly, to popular and scholarly discourse about advertising images' implications; and, as Drumwright and Murphy noted, advertisers can be successful while at the same time ethically cognizant. This responsiveness suggests an opportunity for consumer researchers to take an active role in addressing constructions of audience vulnerability and influencing consumer welfare.

# The Activation-Striving Model: When Will the Same Prime Lead to Goal Activation and When Will It Lead to Trait Activation?

Aner Sela, Stanford University, USA

Baba Shiv, Stanford University, USA

Environmental cues can have nonconscious effects on behavior through activation of either goal or non-goal representations. According to the automaticity literature, goal activation has behavioral effects that increase over time until the goal is fulfilled (Bargh et al 2001). Conversely, priming of associational, non-goal constructs such as traits and stereotypes leads to behavioral effects that tend to diminish over time, as the impact of the prime fades out (Bargh 1997).

Despite this crucial distinction, the question when exactly the same environmental cue activates a goal and when it activates a non-goal, such as a trait, has remained a mystery. The literature has by and large compromised for ex-post indicators: namely, if behavioral effects of priming persist and manifest after a delay then the activated construct was a goal, but if the effects dissipate quickly then the activated construct was a trait (e.g., Chartrand et al, forthcoming).

Furthermore, studies often feature surprisingly similar priming manipulations that seem to lead to stereotype activation in some cases and to goal activation in other cases. For example, unscrambling words related to rudeness led to trait activation in Bargh et al (1996), but unscrambling words related to frugality led to goal activation in Chartrand et al (forthcoming). The growing recognition that nonconscious effects play a significant role in consumers' daily experiences (e.g., Dijksterhuis et al 2005) renders this theoretical shortcoming especially disturbing.

The present research directly addresses this deficiency by exploring the antecedents of goal vs. non-goal activation, leading to temporally-escalating vs. temporally-diminishing behavioral effects, respectively. We propose a theoretical framework, the activation-striving model, which integrates the distinctive features of goal and non-goal activation processes and leads to testable hypotheses about the motivational and attentional antecedents that moderate the activation of goals vs. traits.

The activation-striving model hinges on the notion of self-discrepancies (Higgins 1989, Custers and Aarts 2005), namely, the perceived discrepancy between the activated concept and one's actual state. Recent findings (Custers and Aarts 2005, 2007), suggest that such self-discrepancy is necessary for the activation of the motivational drive associated with goal pursuit. According to the activation-striving model, a self-consistent prime is likely to lead to stronger initial activation of associated constructs because it is consistent with one's self-schema (Markus 1977), which acts as a perceptual filter. On the other hand, a self-consistent prime is less likely to lead to goal activation, resulting in initially-strong but temporally-diminishing effects. Conversely, because self-inconsistent primes by definition do not match self-schemata, their initial activation is weaker than that of self-consistent primes. However, a self-inconsistent prime is more likely to instigate motivational striving and lead to temporally-escalating effects.

The activation-striving model thus captures the tradeoff between strong initial activation without motivational striving, resulting in temporally-diminishing effects, and weaker initial activation with motivational striving, resulting in temporally-escalating effects.

STUDY 1 examined the effect of match vs. mismatch between specific attributes and people's respective self-perceptions, on the pattern of activation. 120 participants were asked to reflect on their own behavior when buying consumer electronics and to rate themselves, on a 1-7 scale, as either frugality-oriented or luxury-oriented in that domain. Following an unrelated filler task, they were asked to complete a word recognition task in which they were briefly exposed to words related either to frugality or to luxury. Thus, each participant was exposed either to a self-consistent prime or to a self-inconsistent prime. Finally, half the participants were immediately asked to choose between luxurious and frugal brands of sound systems. The other half first completed a neutral 5-minute delay task and only then was asked to choose between the luxurious and frugal brands.

**FIGURE**
Prime-consistent choice as a function of delay and prime-reg. focus congruence

Consistent with the activation-striving model, participants were more likely to choose the prime-consistent option after a delay (reflecting a goal activation pattern) when the prime was inconsistent with their self-rating ($p<.046$). Conversely, participants were more likely to choose the prime-consistent option without a delay (reflecting a trait activation pattern) when the prime was consistent with their self-rating ($p<.042$).

STUDY 2 constituted a conceptual replication of study 1. However, instead of measuring self-ratings on specific attributes, in this study we measured people's chronic regulatory orientation (prevention vs. promotion). In a pretest, 227 participants rated frugality as consistent with the values one is ought or obliged to have (i.e., prevention-consistent) and luxury as consistent with the values one hopes or aspires to have (i.e., promotion-consistent). Regulatory focus thus serves as a proxy, in this study, for personal orientation on the frugality-luxury continuum.

In the study, we examined the effect of congruence between prime and regulatory-focus on goal vs. trait activation using a 2 (congruence: congruent vs. incongruent) x 2 (measurement: immediate vs. delayed) design. 96 participants completed a selves-questionnaire (Higgins 1987), which provides a measure of people's regulatory orientation (prevention vs. promotion). Following an unrelated filler task, they were asked to complete a sentence-unscrambling task in which they were primed with words related either to frugality (prevention) or to prestige (promotion). Thus, each participant was assigned a binary prime-regulatory focus congruence score. Finally, participants in the immediate condition were asked to choose between prestigious and frugal brands of socks. Participants in the delayed condition were first asked to complete a neutral 5-minute filler task and then asked to choose between the prestigious and frugal socks.

Consistent with the activation-striving model, participants were significantly more likely to choose the prime-consistent option after a delay (thus reflecting a goal activation pattern) when the prime was incongruent with their chronic regulatory orientation ($p<.038$). Conversely, participants were significantly more likely to choose the prime-consistent option without a delay (thus reflecting a trait activation pattern) when the prime was congruent with their chronic regulatory focus ($p<.048$). Regulatory focus did not interact with the other predictors (see graph).

Taken together, these studies support the activation-striving model, which fills a crucial gap in understanding why subtle environmental cues can sometimes lead to such theoretically and behaviorally divergent effects.

# Is the Internet a New Eldorado for Counterfeits?

Bruno Kocher, University of Lausanne, Switzerland
Brigitte Muller, University of Lausanne, Switzerland
Vincent Chauvet, University of Savoie, France
Bjoern Ivens, University of Lausanne, Switzerland

This research explores to what extent reputation and type of retailer affects consumer's evaluation and purchase intention of original goods, counterfeits and imitations in the luxury industry. In the last decade, the counterfeit phenomenon passed from a handcrafted and regional stage to an industrial and worldwide one, accounting for 5-9% of world trade and representing losses around 200-300 billon euros (Guillemin 2006). One of the factors responsible for this rapid evolution is the possibility to buy counterfeits over the Internet, as around 30% of counterfeit items seized within the European Union come from this distribution channel (Ducourtieux 2006). Although several scholars (e.g. d'Astous and Gargouri 2001; Warlop and Alba 2004; Eisend and Schuchert-Güler 2006, de Matos et al. 2007) studied counterfeits and imitations, past research remains scarce concerning the effects of retailer type.

In this research, we distinguish original products from counterfeits (strict and less expensive copies of genuine products (Kay 1990), designed to *be like* the original) and from imitations (designed "to *look like* and make consumers *think of* the original brand", d'Astous and Gargouri 2001, 153). According to Penz and Stöttinger (2005), products with a high brand image and low production technology are the preferred targets of counterfeiters. The luxury industry is therefore particularly adapted for this study.

Our main proposition resides in the influence of type of retailer on consumers' attitude and buying intention of originals, counterfeits and imitations. First, we investigate consumers' attitude toward originals, counterfeits and imitations and examine which factors generally hinder a consumer from buying a counterfeit or an imitation. Then, we examine to what extent distribution channel may moderate buying intention or potential factors hindering the purchase. The effects of personal variables like innovativeness, risk aversion or integrity are included in the research, in order to characterize the counterfeit buyer.

Therefore, our first research question concerns the way consumers perceive counterfeits and imitations compared to original products. By describing counterfeits as products that offer good value for money (Grossman and Shapiro 1988) and "satisfy buyers' appetite for symbolic meanings" (Dubois and Duquesne 1993, 37), consumers may buy counterfeits for labels (logo, brand) or design characteristics which are themselves valuable for them (Tom et al. 1998). The second research question refers to factors that could hold back a consumer from purchasing counterfeits. Is it the same to buy a counterfeit on a market during holidays or to buy it on a website? Therefore, type of distribution channel and trust in the seller may interfere in the purchasing process of counterfeits and imitations on the Internet. Previous research already explored the role of retailer type, but concentrated mainly on shopping malls and flea markets (Bloch et al. 1993; Cordell et al. 1996; Tom et al. 1998).

Our final research question handles with personal characteristics. Can we say that a person buying counterfeits or imitations is less risk averse, more brand conscious or less integer?

**Research methodology and results of two exploratory studies**

Two exploratory studies with identical designs were carried out to experimentally test the possible mechanisms at play. The three stimuli of the experiment were composed of a scenario and an illustration (visual/semantic) describing one of the three studied type of products. Respondents were asked to rate their prior attitude toward the brand (Sujan and Bettman 1989), their attitude toward the product in the scenario and their purchase intention. Manipulation checks indicated that counterfeits and imitations were perceived as having different levels of similarity compared to the original product. In addition, we asked respondents to rate eight items which could possibly hinder their purchase of the evaluated product. These items were chosen based on a literature review and on personal considerations emanating from the authors.

In the first data collection, 62 undergraduate students evaluated two brands (handbags, polo shirts) and 79 undergraduate students in the second data collection evaluated two out of three brands (handbags, polo shirts and watches) from the luxury industry. For both studies, results indicate that attitude toward original products, counterfeits and imitations is different (*Study 1: $M_{original}$*=4.44, $M_{counterfeit}$=3.75, $M_{imitation}$=3.11, $F(1,102)$=7.38, $p$=0.01; *Study 2*: $M_{original}$=5.90, $M_{counterfeit}$=3.23, $M_{imitation}$=2.69, $F(1,125)$=87.31, $p$=0.01). Planned contrasts reveal a significant difference between originals/imitations and counterfeits/imitations for the first study and between the three types of products for the second study.

Multiple regression analyses with purchase intention as a dependent variable were performed in order to determine which of the eight pre-selected items could hinder a consumer to buy either a counterfeit or an imitation. Results indicate that, in the first study, external aspect of the product was of particular importance for consumers in determining not to buy counterfeits ($R^2_{adj.}$=.255, $\beta$=-.505, t=-3.463, $p$<.01) and imitations ($R^2_{adj.}$=.191, $\beta$=-.460, t=-3.192, $p$<.01). In the second data collection, legal issues influenced negatively intention to purchase counterfeits ($R^2_{adj.}$=.231, $\beta$=-.498, t=-3.814, $p$<.01). For imitations, the image perceived by others during purchase appeared to be a stumbling block for purchase intentions ($R^2_{adj.}$=.237, $\beta$=-.503, t=-3.951, $p$<.01).

**Discussion and next step**

These two studies tried to enhance knowledge concerning evaluations of original products, counterfeits and imitations in the luxury industry. Originals and counterfeits were repeatedly rated more positively than imitations. And as results suggest, counterfeits are not always evaluated more negatively than original products. In addition, they provide significant insight into key variables managers ought to carefully consider in their struggle against the rising dark side of the luxury industry. Results indicate that not only legal aspects play a role in consumers' purchase decisions of counterfeits and imitations. Luxury products are bought much more for what they represent (Nia and Zaichkowsky 2000; Penz and Stöttinger 2005). Thus, the external aspect of a counterfeit is of great importance.

The next step of our research consists in a new experiment, including four different types of distribution channels and personal variables in order to describe more precisely the counterfeit buyer. As trust in seller or store affects directly consumers' attitude toward this entity, influencing in consequence purchase intentions (Jarvenpaa et al. 2000; Lim et al. 2006), screen shots of three different types of websites (original vs. well known vs. unknown) and an illustration of a market are used to construct the experimental stimuli. We are talking more precisely about cognitive-based trust which is "developed based on rapid, cognitive cues or first impressions" (Lim et al. 2006, 236). In fact, on the Internet, first impression is largely based on interface and design features of the website. The main contribution lies in the identification of *who* buys counterfeits and through what channel much more than *why*.

# International Festivals: Reverse Acculturation or the Peddling of Ethnicity

L. Wakiuru Wamwara-Mbugua, Wright State University, USA

Every year thousands of people attend festivals all over the United States. Indeed many cities pride themselves with the diversity of festivals that they have in their city. It is one of the marks of cultural diversity of an area. Why do individuals attend these festivals? This research was conducted to examine the reasons why people attend international festivals. The International Festival that was the focus of this research occurs over a three day period and draws over 20,000 participants every year. Research efforts have concentrated on understanding the consumption behavior of individuals from many different lands, yet there has been a paucity of research seeking to understand why natives of a given country choose to attend international festivals.

Reverse acculturation might be the reason why individuals attend these festivals. In a recent study Chen (1997) examined the concept of reverse acculturation among Anglo-Americans. Chen (1997:18) defined reverse acculturation as "a process in which Anglo-Americans acquire values, attitudes and behavioral patterns via direct and or indirect contact with people from cultural origins other than their own." It has been suggested that the level of reverse acculturation will vary by individual since some individuals may enthusiastically accept influences from other cultures while others may resist. As such Chen (1997:19) conceptualized reverse acculturation on a continuum from multiculturalism to monoculturalism.

The oldest model of acculturation or assimilation was developed by Gordon (1964). Marketing researchers have examined levels of assimilation or acculturation and the impact on consumer behaviors (Mehta and Belk 1991, Penaloza (1994). Berry (1980) developed a model that examined the level of acculturation that was based on the responses to two questions: a) whether the immigrant wanted to retain their original culture and b) the immigrant's desire to have a good relationship with the dominant culture. The responses to these questions result in acculturation strategies ranging from a) assimilation, rejection, separation and integration. Cross-cultural psychologists have shown that immigrants who want to have the best mental health follow an integration strategy. Research has shown that rather than assimilate, many immigrants integrate or separate themselves. Thus, the analogy for the United States has moved from that of a melting pot to a salad. This is because U.S. immigrants have retained enough of their original culture, and are thus, as discernible as a cucumber would be in a salad.

Many immigrants retain their original culture and consequently, they can share this culture through their participation in cultural festivals. In the United States the dominant population has slowly embraced multiculturalism. This embracing of the "other" has led to the de-ethnicization of products such as bagels, salsa etc. Another way of experiencing the "other" is through participation in ethnic/ cultural activities such as the festival that is the focus of this research. Values guide our behavior, and as such one's attitude towards new experiences is crucial in determining their acquisition of foreign modes of behavior.

To develop the measurement instrument, 50 written interviews were conducted with individuals who had attended the festival. Two different coders analyzed these written interviews to identify the main motivations for attending the festival. A survey was developed and pre-tested. Respondents were asked to indicate their level of agreement to questions such as: [My decision to attend the festival was most influenced by: ethnic food, ethnic merchandize, learning about other cultures etc. We also utilized the uniqueness: desire for unique consumer products (DUCP scale) developed by Lynn and Harris (1997). This is an 8 item scale and sample scale items include: I am very attracted to rare objects etc. Cronbach's α test for reliability of DUCP scale was α 0.85. We also used the Multi-item measures of Values (MILOV) scale, excitement dimension developed by Herche (1994). This scale measures level of agreement to such items as: I consider myself a thrill-seeker etc. This scale has a reliability of 0.72 and our scale was also reliable and had α coefficient of 0.79.

650 surveys were collected over a three day period by students from a local university. The festival organizers promised the respondents the opportunity to win a gift certificate to a restaurant, bookstore etc. In order to vary the type of respondents, the data was collected at varying times during the festival. Preliminary findings indicate that individuals attend these festivals to experience the "other." The decision to attend the festival was mostly influenced by Ethnic foods (91.1%) Ethnic Drinks (73.6%), Dancing (76.7%) Ethnic Merchandize (63.5%), Learning about other cultures (78.7%). Only 24.3% of the respondents indicated that they were members of the participating organizations/cultural groups. Word of mouth was found to be the most important in learning about the festival. T-test results indicate that there were significant differences in the motivations to attend the festivals by gender. For example, women were more interested in the ethnic merchandize than the men. (t=4.473, p-value <= 0.05). Some interesting findings with regards to the desire for unique products as well as the thrill seeking were also found.

# Language Domain Effects on Bilingual Advertising

Ryall Carroll, Baruch College, USA
David Luna, Baruch College, USA

In recent years there has been a greater focus on bilingual research in marketing journals. This research has focused on various bilingual linguistic phenomena such as the impact of code switching on ad persuasion (Luna and Peracchio 2005), to the influence of how different languages are processed on recall and attitude of advertising (Tavassoli and Lee 2003). In Koslow, Shamdasani, and Touchstone's

(1994) research, U.S. Hispanics' response to the use of the Spanish language in advertising was investigated. Their research found that the positive effects of Spanish language, or minority subculture language, in advertising could be partially explained by the sociolinguistic theory of accommodation. The theory of accommodation predicts that "the greater the amount of effort in accommodation [using the language of the listener] that a bilingual speaker of one group was perceived to put into this message, the more favorably he would be perceived by listeners from another ethnic group, and also the more effort they in turn would put into accommodating back to" the speaker (Giles, Taylor, & Bourhis 1973 p.177). Koslow et al. (1994), using the theory of accommodation, found that the use of Spanish language not only has an impact on a Hispanic individuals message comprehension, but also communicates a message about the advertiser's sensitivity to the Hispanic culture. This sensitivity to the Hispanic culture can result in a significant and positive influence on the individual's attitude toward the advertisement (Koslow et al. 1994).

Koslow et al.'s (1994) research supports advertiser's attempt to target linguistic minorities by translating advertising messages into the linguistic minority's native language. A potential moderator of Koslow et al.'s (1994) findings is the presence of the language appropriateness indicated by the language domain framework. Currently there is no language domain research on the effectiveness of bilingual advertising. This paper examines the appropriateness of a language in different multilingual situations.

The framework of language domains is based on a corpus of sociolinguistic studies that observed bilinguals in various multilingual speech communities around the world (e.g., Hoffman 1971; Barker 1975; Scotton 1979; Nishimura 1992; Goebel 2005). Through observation of various multilingual speech communities, a theory was established that language use in multilingual settings is not random. By observing the interactions of multilinguals in different speech communities, ethnographers were able to uncover underlying patterns that repeatedly emerged and dictated the proper use of a language at particular times and places surrounding particular topics.

The language appropriateness that corresponds to a particular topic area is a result of many different factors, such as bilinguals having learned how to deal with a topic in a particular language, a language's lack of specialized terms for a particular topic, or simply because the use of a certain language would be considered strange or inappropriate for discussion in that language (Grosjean 1982). It is important to note that the reason for a particular language to be more appropriate than another may simply be a result of certain languages having been traditionally used when discussing a certain topic. This would suggest that the bilingual has learned from an early age to deal with a certain topic in a certain language. This indicates that there is probably a greater accessibility of a particular language over another with which a bilingual can discuss a certain topic in. It may be the case that the bilingual knows more vocabulary in a particular language surrounding a topic area, or that the bilingual uses particular words more often in one language over another. These situations will result in a greater ease and comfort in discussing a topic in one language over another.

Since the appropriateness of a particular language is so ingrained into a multilingual that it is chosen unconsciously with no extra time or effort (Grosjean 1982), the choice process may be an automatic process of which the bilingual is unaware. The corpus of language domain research would indicate that, for print ads dealing with certain topic areas, there is a particular language that is more appropriate than others.

The empirical study shows the impact of the language domain framework on advertising. The hypothesis of this study is that when ad language is congruent with language domain factor of topic area, the ad evaluation would be higher than when ad language is incongruent with language domain factor of topic area. This study had a 2 (language: Spanish or English) x 2 (Topic area: Work or Family & Friend) between-subject design. Language and Topic area were between-subjects factors. Every subject was presented with the same number of advertisements: three advertisements from the target topic areas and the remaining advertisements were practice and filler ads. The order of the filler and target advertisements in the questionnaire was varied. Ad evaluations were collected on a 7-point six item scale, where higher scores meant more favorable evaluations (Luna and Peracchio 2005). The ad evaluation index yielded a two-way interaction between Language and Topic area (F (1, 52)=11.889, p<.01). These results confirm the expectations, that when advertisements focused on the topic Friends and Family, the Spanish language ads were evaluated higher than the same ads in English (Friends & Family ad, Spanish, M= 4.647 vs. Friends and Family ad, English, M= 3.769 F (1, 26)=6.775), p<.05). Also, confirming expectation when the topic area of Work used, the English language ads were evaluated higher than the same advertisement in Spanish (Work ad, English M= 5.207 vs. Work ad, Spanish M= 4.659 F (1, 26)=4.945, p<.05).

One plausible explanation for these results could the accessibility of these words in one language over another. Future studies will hopefully show that there is an increased accessibility for a particular content area in a particular language. This increased accessibility for a particular content area in a particular language could then be resulting in an enhanced processing fluency. This enhanced processing fluency will result in a more favorable attitude toward the target (Lee 2004). Since individuals usually cannot distinguish clearly between the different sources of affect they may be experiencing at any given time, they may misattribute their current mood to the object they are judging (Schwarz and Clore 1983, 1996). The results then equate to a preference for the ad with the increased accessibility.

This study contributes to the consumer behavior research by bringing to light the fact that each multilingual speech community has language domains that dictate the proper use of each language. This article also contributes to the field of sociolinguistics in showing that language domain norms are not just verbal, but also transfer to the written language as well. Most of the sociolinguistic research in this area relied on observational studies with little to no experimental research. This study adds further validity to the prior research in language domains as well as showing the impact that these language domains can have on liking of an advertisement.

# The Morphing Self: Changing Self-Concept as a Response to Threats

Christian Schmid, University of Alberta, Canada
Jennifer J. Argo, University of Alberta, Canada

Reminders of mortality regularly appear in the media where consumers are exposed to death counts from events such as 9/11 or Hurricane Katrina. Research on Terror Management Theory (TMT; e.g., Greenberg, Pyszczynski and Solomon 1986) that focuses on how people respond to death related information has shown that such information significantly influences individuals' actions, thoughts and emotions. In consumer research it has been shown that when mortality salience (MS) is high individuals tend to over-consume, engage in conspicuous consumption, risky behavior, and spend more money (e.g., Arndt et al. 2004; Bonsu and Belk 2003; Ferraro, Shiv, and Bettman 2005). Additionally, threats to the self can elicit reactions that resemble MS effects (Burris and Rempel 2004). While research provides insight into the impact of MS threats on product acquisition and consumption, it has not considered the implications of threats on the retention of possessions which consumers consider part of their extended self. Thus, in the present research we explore the possibility that in the face of symbolic threats, consumers will reconstruct their self-identity (i.e., morph the self into a recreated self) through the use of their possessions. We also test whether the tendency to morph the self when threatened is moderated by two individual differences: self-esteem and materialism.

The self is not permanently defined but rather evolves over time. Changes of the self occur naturally, but also arise during stressful life events such as death or divorce. This process of identity reconstruction is described by the concept of rites of passage (van Gennep 1960) consisting of three stages: separation (disentanglement from a social role), transition (adaptation and change to fit a new role), and incorporation (integrating the self with the new role). One way individuals shape their new identities is by the products they consume (e.g., Pavia and Mason 2004; Price, Arnould, and Curasi 2000). Indeed, possessions are important for expressing a person's self because they represent memories and feelings that link people with their historical identity (Belk 1988). For example, following a divorce a woman might dispose of a once sacred Mickey Mouse watch that was related to a fun/dependent self-identity in exchange for a new Rolex that conveys a new identity as a strong, independent woman. In the present research we predict that when people are exposed to a threat they will attempt to redefine the self through the possessions they consider a part of their immediate identity. They will do this by both distancing the self from possessions once considered a central part of their identity and drawing possessions once considered to be an extraneous component of the self closer.

Following TMT we expect that this effect is moderated by self-esteem and materialism. First, according to TMT, high self-esteem individuals are able to protect their self-evaluations, as their self-esteem can serve as a buffer against self-threatening information (Harmon-Jones et. al. 1997). We expect that low self-esteem individuals will have a stronger tendency to morph the self in the presence of a MS threat compared to consumers with high self-esteem. Second, TMT predicts that MS should lead to increased efforts to live up to the standards of value from which self-esteem is derived. High material values are defined as the use of possessions to judge the success of others and oneself, the centrality of possessions in a person's life, and the belief that possessions and their acquisition lead to happiness and life satisfaction (Richins and Dawson 1992). Given this we expect that people high in materialism should be more likely to redefine their self-concept by shifting possessions when MS is high, whereas tendencies to redefine the self through possessions are not expected to differ for those low in materialism regardless of whether a threat is present or not.

The first study was conducted to explore the notion of the morphing self. The study was administered in two parts. During the first session participants either completed the threat or control topic manipulations following previous research (e.g. Goldenberg et al. 2005). The threat was a MS threat, a gender identity threat, or a social comparison threat. After completing a distracter task they were given a piece of paper on which nested circles were printed, the innermost circle labeled "SELF" and subsequent rings labeled "A" to "H", described as elements in a participant's life ranging from "very closely related to your self" to "not at all related to your self". Participants were asked to place as many possessions as they could think of into the drawing, taking into account how closely related to their self they considered the possession. The dependent variable was the distances between the center of the circle and the cross that marked the

placement of each of the possessions. One week later, participants completed the manipulation they were not assigned to during the first session, distracter task and dependent measure (i.e., circle task).

Results revealed that participants facing a threat placed possessions they considered closely related to their selves further away from the self as compared to the control condition. In contrast, possessions that under the control condition were placed far away from the self were placed significantly closer to their self in the threat condition. This effect generalized across all three types of threat.

In the second study we explored the moderating role of self-esteem and material values. This study followed the same procedure with two exceptions: only one threat was used and participants completed both a self-esteem (Rosenberg 1965) and material values (Richins and Dawson 1992) scale. The effect of the morphing self was qualified by both individual difference measures. Participants who were both low in self-esteem and high in materialism used possessions to redefine their self-concept when MS was high (as compared to absent) to a greater extent than participants high in self-esteem and low in materialism.

In general, the results indicate that the presence of a threat can pose a significant challenge to consumers' self. One way consumers respond to a threat is to redefine the current self through product acquisition and disposition decisions.

# A Bibliographic Survey of Experiential Consumption Research

Johnny Chen, University of Oregon, USA

Robert Madrigal, University of Oregon, USA

Two and a half decades have passed since Hirschman and Holbrook (1982; Holbrook and Hirschman 1982) detailed the nature of experiential consumption. The experiential perspective emphasizes the study of consumption phenomena, and consumers' hedonic responses during consumption and usage experiences. This view suggests that subjective experience, product meaning, and consumer emotions are intrinsic to consumption. In particular, the experiential perspective is concerned with consumption episodes that consumers engage in for fun, enjoyment, and leisure. It is particularly well suited for studying the consumption of experiential products such as movies, concerts, and sporting events. More importantly, more businesses these days are trying to make conventional product use more like entertainment experiences rather than merely meeting functional requirements. Understanding how to create and shape consumer experiences is essential in today's marketplace, regardless of product category. There is a great urgency to better understand experiential consumption in marketing practice. But after 25 years, what do we know about experiential consumption?

The current research reports the results of a bibliographic analysis of the two seminal articles on hedonic or experiential consumption produced by Hirschman and Holbrook (1982; Holbrook and Hirschman 1982). The analysis enhances our current understanding of hedonic consumption by providing a taxonomy classifying research that has emanated from these two articles. Citation and abstract information was extracted from three major databases and organized thematically using a word-based statistical analysis and visualization software. Based on 599 total articles that cited one or both of the articles, our initial analysis yielded 24 content groups. Titles and abstracts for each of the computer-generated groups were examined and subsequently classified into one of ten thematic areas.

Each of the ten thematic areas was then further divided based on whether the article was premised on a hedonic or experiential theme, or whether the article merely referenced the seminal article(s) but was actually focused on a broader marketing or consumer behavior issue. The former group was referred to as core themes and the latter as supportive themes. Six of the ten thematic areas were classified as core

themes and included articles pertaining to (a) hedonic and utilitarian value, (b) experiential products, (c) shopping, (d) ritual and symbolic consumption, (e) multisensory stimuli, and (f) qualitative methodology. The supportive themes was comprised of articles related to (a) hedonic choice, (b) buyer behavior, (c) service experience, and (d) advertising.

The core theme articles are considered to be the ongoing conversations that distinctly define hedonic and experiential consumption research. A solid base of research aimed at the differentiation and measurement of hedonic and utilitarian value support the initial conceptualization of hedonic consumption and forms the basis of subsequent research in hedonic choice and service experience. Consistent with the original propositions regarding product classes, a substantial body of research has accumulated regarding experiential products that include vacation and travel, performing arts, entertainment, and high culture products.

Surprisingly, shopping was highly represented in the literature citing the two seminal articles. Shopping occupies a boundary position in that it is both an experiential activity and an antecedent to product purchase. Shopping topics include shopping motives, hedonic shopping value, satisfaction, and retail experience and satisfaction. Contexts for shopping include malls and retail outlets, mail catalog shopping, and online shopping. Also included in this group of articles are the dark-side consumption topics of uncontrolled, compulsive, and addictive shopping habits.

Ritual and symbolic consumption represents a significant and unique contribution to experiential consumption research. Ritual consumption is rich with social and life meanings (Rook 1985). Articles in this group are associated with conspicuous or lifestyle consumption. Symbolic consumption, on the other hand, is more focused on the relationship between a consumer and a target object or experience (Fournier 1991; Mick 1986). Further, social and self-identity were inextricably associated with ritual and symbolic aspects of consumption (Meng 2005; Richins 1994). Included in this theme are articles detailing the dark-side consumption topics of gambling and addiction.

A predominance of postmodern and qualitative methodologies was also strongly represented in research originating from Hirschman and Holbrook (1982; Holbrook and Hirschman 1982). Techniques designed to study hedonic consumption include hermeneutics, semiotics, and ethnography. Grounded theory was the basis for many of the studies in this category. Many of these methods were useful for understanding subjective and symbolic meaning, but also echoed the original limitations noted by Hirschman and Holbrook (1982) about inadequate empirical methods that would be needed to study many imaginal or subjective aspects of hedonic experience. Finally, multisensory research was greatly underrepresented in this area of research within consumer research.

The four supportive themes provide a conduit from hedonic research to theory and application in consumer behavior and marketing. In many instances, hedonic value was used as an affective predictor of choice, intentions and decisions, behavior, and ultimately linked to satisfaction. It is evident in this group of articles that hedonic and experiential consumption research has direct application to service, retail, and advertising. Services are experiential products by definition and thus highly relevant to service management and marketing. Similarly, the experiential nature of the retail experience was also well represented by articles in this category. Interestingly, no discernable pattern was found for advertising articles citing the two seminal articles by Holbrook and Hirschman.

Finally, we examined the research gaps based on the original propositions posited by Hirschman and Holbrook. Progress has been made on all substantive areas and propositions stipulated by Hirschman and Holbrook (1982), albeit progress has been unevenly distributed. Looking forward, our understanding of consumers would benefit with a greater research emphasis on multisensory stimuli and emotive post-purchase processes related to ownership, usage, and disposition.

# When Images and Words don't Agree, Images Win: the Shielding Effect of Imagination on Attitude Change

Massimiliano Ostinelli, McGill University, Canada
Ulf Böckenholt, McGill University, Canada

Imagine a consumer who comes across an imagery-provoking critique portraying the excellent attributes of a new restaurant and, after having spent some time mentally savouring the elegant atmosphere and the delicious food of the restaurant, finds a customer survey rating the restaurant as a wretched 3 out of 10 stars. How would the consumer use the two contradictory pieces of information to arrive at an overall evaluation of the restaurant?

One approach to resolve the inconsistency between contradictory evaluations of the same target is to weigh each argument and express a judgment that takes into consideration each piece of information (e.g., Anderson 1971). We expect that integrating contradictory pieces

of evidence processed through distinct mental codes (i.e., pictures and numbers) is more difficult than integrating equivalent pieces of information processed within the verbal code (i.e., different ratings of the same product). We suggest that this greater difficulty, in turn, makes the inconsistency between the two evaluations more salient, thus motivating a consumer to favour one of the two arguments. Since mental imagery generally leads to greater message-relevant elaboration than verbal processing does (Kisielius and Sternthal 1986) and greater elaboration increases the strength with which an attitude is held (e.g., Haugtvedt and Wegener 1994; Petty, Haugtvedt, and Smith 1995), we propose the existence of a "shielding effect" of imagination to indicate that attitudes generated through mental imagery, compared to those derived from information processed through the verbal code, are more resistant to contradictory analytically-presented information.

We test this hypothesis through a 2 (type of information: imagery-analytical vs. analytical-analytical) x 2 (presentation order: positive-negative vs. negative-positive) between-subject experimental design. Sixty-five (37 females, average age=20.27 yrs) participants were presented with an evaluation of a restaurant, supposedly made by a food critic, unexpectedly followed by a second evaluation of the restaurant, supposedly made by five customers of the restaurant whose age happened to range between 50 and 60. The food critic's review was presented either in an imagery-provoking (i.e., vivid critique preceded by imagery instructions) or in an analytical format (i.e., ratings of the restaurant along different dimensions preceded by instructions to be careful and well-reasoned), whereas the second evaluation was presented always in an analytical format.[1] The order in which positive and negative information was presented was also manipulated; in one condition the food critic's review was positive and the customer survey was negative and vice versa. A pre-test conducted on 69 participants from the same population as the main study, revealed that, given the valence of the review, the evaluations of the imagery and analytical versions were statistically indistinguishable ($M_{imagery\_positive}$=7.39, $M_{analytical\_positive}$=7.66; $t_{27.5}$=1.00, p=.326; $M_{imagery\_negative}$=2.43, $M_{analytical\_negative}$=2.97; $t_{30}$=1.51, p=.143). After being exposed to the first message, participants were asked to describe the images (thoughts) experienced while reading the food critic's review and answer few questions about them; self-reported evaluations of the extent to which participants imagined (thought) what it would be like to be in the restaurant were used as a measure of message-relevant elaboration. Finally, before reporting their attitude toward the restaurant on a semantic differential scale ($\alpha$=.96), participants were shown again both evaluations on the same page. In all cases, we used 9-point items.

Results from ANOVA showed a significant main effect of presentation order ($F_{(1,59)}$=12.91, p<.001) and a non-significant main effect of type of information ($F_{(1,59)}$=1.09, p=.300) qualified by a significant interaction ($F_{(1,59)}$=4.21, p=.045). When the first evaluation was presented in an analytical format, presentation order had only a minor effect on attitude ($M_{analytical\_pos/analytical\_neg}$=5.59; $M_{analytical\_neg/analytical\_pos}$= 5.06; contrast: $F_{(1,59)}$=1.27, p=.265), whereas the effect was significant when the first evaluation was imagery-provoking ($M_{imagery\_pos/analytical\_neg}$=5.93; $M_{imagery\_neg/analytical\_pos}$=3.99; contrast: $F_{(1,59)}$=14.97, p<.001). The finding that the effect of the imagery-provoking review was stronger in the negative than in the positive condition might be explained by the fact that, although statistically indistinguishable, the imagery provoking review, compared to the analytical one, was evaluated somewhat more negatively in the negative condition and slightly less positively in the positive condition.

To investigate whether elaboration mediated the interaction effect between type of information and presentation order on attitude (mediated moderation), we followed the procedure proposed by Muller and colleagues (2005) which requires testing three regression models. The first model showed that the type of information/presentation order interaction effect on attitude was significant (est.=.35, p=.045). The second model showed that the effect of type of information on elaboration was significant (est.=.54, p=.046), whereas the effects of presentation order and the type of information/presentation order interaction were non-significant (all p's>.26). Finally, the third model showed that, controlling for the effects of elaboration (est.=.04, p =.668) and the marginally significant effect of the elaboration/ presentation order interaction (est.=.16, p=.0795), the effect of the type of message/presentation order interaction on attitude became non-significant (est.=.28, p=.122). Sufficient conditions to demonstrate mediated moderation entail that the effect of type of message on elaboration and the elaboration/presentation order interaction effect on attitude are significant and the effect of the type of information/ presentation order interaction is significant in the first but not in the third model (Muller et al. 2005). In this view, the analysis provided preliminary evidence that elaboration moderated the effect of the information type/presentation order interaction on attitude.

Although much attention has been paid to the effect of mental imagery on decision-making, little is known about the strength of attitudes generated through mental imagery; we address this gap in the literature by proposing that mental imagery increases attitude resistance to contradictory analytically-presented information. In addition to replicating the present findings, future research should address more specifically the mechanisms (e.g., generation of counterarguments, attitude accessibility, etc.) underlying this effect and whether the order in which different types of information are presented affects the final judgment.

[1]The restaurant review created by Pham end colleagues (2001) was used in the imagery-positive condition, whereas a modified version of the rating scheme proposed by Petrova and Cialdini (2005) was used in the analytical-positive condition. Although the consumers' surveys and the analytical reviews provided the same evaluation of the restaurant's attributes, the former did not present further details about each rating (e.g., atmosphere: intimacy and elegancy). Since all descriptions included meat dishes, observations from two vegetarian participants were not included in the analysis.

# Accessibility and Availability: The Role of Prior Preferences in Judgment Formation

Maria Kratcholova, McGill University, Canada

Ulf Bockenholt, McGill University, Canada

It is well established that consumers who are psychologically invested in a desired outcome tend to exhibit biased recall and to overpredict the probability of the desired outcome. (Markman and Hirt, 2002). In a brand evaluation context, the present research investigates further the role of motivational biases in judgment formation based either on accessibility experiences or on generated cognitive content. We show that prior opinions are an important moderator in predicting a person's choice between these sources of information.

An increasing number of studies in psychology and marketing indicate that the ease with which information comes to mind may influence judgments. A typical finding is that participants perceive a person or an issue more favorably when they are asked to think of a small as opposed to a large number of reasons in support of their inference. For example, Wänke et al. (1997) reported that a BMW car was rated as more attractive when respondents were asked to think of 1 rather than 10 reasons to drive it. Such findings are seen as evidence that judgments are based on the perceived ease (or rather difficulty) of reason-generation and therefore referred to in the literature as "ease of retrieval" phenomena.

However, several studies identified a number of conditions, related to expertise, knowledge and involvement under which people are more likely to draw on the content of the information retrieved than on "the ease of retrieval" experience in forming a judgment (see Schwarz, 1998, for a review). Notably, employing the car brand evaluation paradigm by Wänke et al. (1997), Tybout et al. (2005) show that brand familiarity moderates the diagnosticity of the "ease of retrieval" experience. They replicate the findings of Wänke et al. (1997) when consumers are moderately familiar with the target brand (BMW) but observe the opposite pattern for a less familiar brand (Hyundai) with consumers giving less favorable ratings when asked to think of 1 rather than 10 reasons to drive a Hyundai.

We suggest that preformed judgments may moderate a person's tendency to rely on the subjective retrieval experience. In previous studies, the effect of prior judgments on the target topic has not been considered explicitly. For instance, Biller, Bless and Schwartz (1992) asked subjects to estimate the percentage of Germans who suffer from chronic diseases and, similarly, Winkielman, Schwarz and Belli (1998) asked participants to evaluate how well they remembered certain episodes in their childhood. In both examples, subjects had no clear prior judgments about the topic and had to construct them as part of the experimental task. However prior preferences for brands and companies are inherent to our marketing environment and their effect needs to be taken into account to understand effectively when consumers rely on the accessibility experience and when on the generated cognitive content.

Our tenet is that prior judgments and preferences moderate the diagnosticity of ease of retrieval: With a positive prior opinion about the target brand (i.e. BMW) consumers may consider the subjective experience of reason-generation as diagnostic probably due to the contrast effect between their appreciation for the brand and the experienced difficulty of generating a long list of reasons. However, in conditions with a less positive prior opinion, the difficulty of generating a large number of reasons favoring the brand may already be expected. Now consumers may experience a different type of contrast effect resulting from the difference between their low prior opinion and the accessibility of many reasons favoring the brand.

In Study 1, we disentangle the effects of (1) familiarity and (2) valence of prior judgment in the context of brand evaluations. As a pretest, hundred and twelve students from McGill University indicated on a 10-point scale their prior opinion as well as their familiarity with the features of 22 car brands. We selected 4 car brands and formed a 2x2x2 between-subject design with high/low familiarity, high/low prior preference for the brand and "1 and 10 reasons to be generated" for driving the target brand. Hundred ninety-seven students from the same population participated in the experiment. After generating 1 or 10 reasons, they evaluated one of the 4 target brands on seventeen 10-point, bipolar items forming a one-factor scale ($\alpha$=0.83). The results provide support for our hypothesis and indicate a similar pattern of evaluation for the two liked brands-BMW and Lamborghini. Consumers rated them more favorably when asked to think of 1 ($M_{BMW\_1}$=8.73, $M_{Lamborghini\_1}$=7.45) than of 10 reasons - $M_{BMW\_10}$ 10= 7.58, ($F(1,44)$=54.23, $p$<.001) and $M_{Lamborghini\_10}$=6.77 ($F(1,47)$=32,69, $p$<.001), The reversed pattern however is observed for less-liked brands-KIA and Isuzu. Consumers rated them more favorably when asked to generate 10, $M_{KIA\_10}$=5.45 and $M_{ISUZU\_10}$=5.03, than 1 reason(s) in their favor $M_{KIA\_1}$=4.26 ($F(1,48)$=26.32, $p$<.001) , $M_{ISUZU\_1}$=4.14 ( $F(1,50)$=71,83, $p$<.001).

In Study 2, we intend to investigate further the generalizability of the findings by manipulating the strength of the prior opinion. We conjecture that consumers with well-defined rather than diffuse prior opinions are less likely to be influenced by the experienced difficulty in generating a large number of reasons. Furthermore, we expect that when consumers have a very strong opinion, the number of reasons they are asked to generate does not affect their judgment formation. Preliminary support for this hypothesis is provided by the results of Haddock (2002) in the context of a study on subjects' attitude towards a political leader (Tony Blair). The favorability ratings of politically interested participants (with a supposedly strong preformed opinion) were unaffected by the number and type of assessed attributes, whereas participants with more diffuse positive prior opinions rated Blair more favorably when they had assessed either a small number of positive or a large number of negative attributes.

We conclude that considering prior opinions about a brand is vital for marketers since the same response process (i.e. reason-generation) may lead to the opposite result depending on the prior preference for the target brand. With a prior positive attitude, consumers tend to perceive the subjective experience as diagnostic, whereas for a less-liked brand, consumers tend to rely more strongly on the generated cognitive content. In both cases we may be observing an updating of consumers' preferences reflecting contrast effects caused either by the unexpected difficulty of the task to generate a high number of reasons favoring a highly liked brand or by the accessibility of a long list of reasons favoring an a priori less-liked brands.

# Perhaps it Would be Better if Materialistic Birds of a Feather Did Not Shop Together: Materialism, Accountability, and Luxury Brand Consumption Experiences

Dan Freeman, University of Delaware, USA
Brent McFerran, University of British Columbia, Canada
Karl Aquino, University of British Columbia, Canada
Stefan Thau, London Business School, UK

### Introduction

Considerable scholarly effort has been directed toward understanding the causes and consequences of materialism. For example, prior work suggests that family dynamics (Rindfleisch et al. 1997) as well as television programming (Shrum et al. 2005) and advertising (Buijzen and Valkenburg 2003) contribute to the development of materialistic values. Extant research also links the possession of materialistic values with compulsive consumption and reduced well being (Rindfleisch et al. 1997; Burroughs and Rindfleisch 2002).

As materialistic values tend to result in negative consequences for consumers, an important transformational research question is: to what extent do situational factors encourage (or discourage) the expression of materialistic values? If factors that encourage (or discourage) the expression of materialistic values can be identified, then it may be possible to devise efficacious tactics for improving consumer welfare. Drawing on accountability theory from psychology (Sedikides et al. 2002; Tetlock 1999), we posit that the expression of materialistic values will be moderated by expectations about the conveyance of social status by others.

### Conceptual Framework

Materialism has been defined as "the importance ascribed to the ownership and acquisition of material goods in achieving major life goals or desired states," (Richins 2004, p. 210). For materialistic individuals, product consumption provides a path for obtaining happiness and status (Richins and Dawson 1992). Based on this conceptualization, materialistic individuals can be expected to exhibit greater positive emotions as a consequence of acquiring luxury brands than non-materialists, as materialists should be more likely to perceive themselves as obtaining affluence and elevated social status from luxury brand consumption.

The notion that materialistic individuals perceive the consumption of luxury brands as a means for status enhancement suggests that status enhancement expectations will play a key role in the expression of materialistic values. It also suggests that situational factors that affect such expectations may moderate expressions of materialism. Based on this rationale, we sought to identify factors with the greatest potential to impact status enhancement expectations. One such factor is accountability.

Sedikides et al. (2002, p.592) define accountability as "the expectation to explain, justify, and defend," and also show that it deters self-enhancement through identifiability. To predict how accountability will affect status enhancement expectations, it is important to note that status is a social construct. In other words, status must be conferred by others. Therefore, if a materialist believes that others will be impressed with the purchase of a luxury brand and validate its status-elevating properties, then he or she should anticipate a wellspring of positive emotions. On the other hand, if a materialist believes that others will view his or her attempt to gain status through luxury brand consumption as invalid, then he or she should expect a muted consumption experience. Based on this logic, we hypothesize:

*H1a*:  As materialistic values increase, accountability to a like-minded peer will amplify positive emotions generated from luxury brand consumption.

*H1b*:  As materialistic values increase, accountability to a non-materialistic peer will attenuate the experience of positive emotions generated from luxury brand consumption.

## Methods

A two-part study was utilized to test our hypotheses. In part I, participants (N=95) completed a survey that included a measure of materialism (Richins and Dawson 1992), and several unrelated measures. In part II, participants completed an ostensibly separate computer-based experiment. The experiment utilized a simple one-factor design, including three levels of accountability (accountable to a materialistic peer, accountable to a non-materialistic peer, and a no accountability control condition).

To provide a plausible cover-story for manipulating accountability, all participants were asked to describe themselves in terms of their group memberships, favorite activities, and career aspirations. Those in experimental conditions were then told they had been randomly matched by the computer with a peer and given a description that suggested that the peer was materialistic (e.g., they wanted to be an investment banker or consultant) or non-materialistic (e.g., they wanted to do economic development in Africa). They were also informed that they would have to "explain, discuss, and defend" their subsequent responses to the peer at the end of the experiment.

Participants in all conditions were asked to indicate the extent to which they would expect to experience positive emotions if they had just purchased two luxury brands-Prada and Gucci (4 items, ?'s=.90 and .93). After completing these measures, participants in the experimental conditions were informed that they would not be required to actually justify their decisions "due to insufficient time."

## Results

*Manipulation check*. Peer impressions items were included in the experimental conditions as manipulation checks. As desired, the description of a materialistic peer produced perceptions of an interaction partner who was more career-oriented and caring about money and image than the non-materialistic partner (*M*=6.01 v. 3.02, p<.01). In contrast, the non-materialistic partner was seen as more concerned about the environment and making the world a better place (*M*=6.50 v. 4.44, p<.01).

*Main study*. Regression analyses were utilized to examine the effects of materialism and accountability on luxury brand consumption emotions. Scores for the two brands were summed to serve as dependent variables. Dummy coding of experimental conditions was utilized, with the control group serving as the reference group. Interaction terms were mean centered.

The analysis of positive emotions detected a significant main effect of materialism, qualified by significant interactions with both the materialistic peer (p<.05) and non-materialistic peer justification conditions (p<.05). Inspection of the interaction coefficients revealed support for H1a and H1b, as materialism was positively related to the experience of positive emotions in the materialistic peer accountability condition and negatively related to the experience of positive emotions in the non-materialistic peer condition.

## Discussion

Consistent with the notion that status elevation expectations play an important role in the expression of materialistic values, we find that the relationship between materialism and the experience of positive emotions from luxury brand consumption is moderated by accountability. When participants believed that they would be accountable to a materialistic peer, materialism enhanced the expectation of experiencing positive emotions from the purchase of luxury brands. In contrast, when participants believed that they would be accountable to a non-materialistic peer, materialism reduced the expectation of experiencing positive emotions. One potential implication of our findings is that who a materialist goes shopping with may make the difference between unbridled spending and relative thrift. Shopping with a like-minded (dissimilar) other seems likely to encourage (discourage) the expression of materialistic values.

# Much Ado about Nothing: Avoiding Products Because of the Negative Impressions They Never Create

Laurence Ashworth, Queen's University, Canada
Maggie Mattear, Queen's University, Canada[2]

Individual behaviour is often motivated by self-presentation or impression management concerns (Tedeschi 1981). Impression management involves controlling personal expressions and behaviors in order to influence the opinions and responses of others (Leary 1995). Research in marketing has shown that personal possessions affect observers' impressions (Gosling et al. 2002) and that consumers will strategically buy and display products for this reason (Burroughs, Drew, and Hallman 1991). Recent work has also shown that consumers will avoid products that might cause them to be perceived as members of dissociative reference groups (White and Dahl 2006).

The current work extends the existing literature in two ways: first, by demonstrating that product attitudes and willingness to pay are importantly influenced by the extent to which products help consumers achieve or avoid certain impressions; second, by investigating the validity or accuracy of impression management concerns. We show that consumers tend to overestimate the extent to which products are likely to create an undesired impression, as evidenced by a discrepancy between their impression of other consumers using a particular product and their own beliefs about the impression they would create using the same product.

## Study 1

Study 1 explored whether impression management concerns influenced product evaluation and willingness to pay. We chose an item that was likely to be used in public (an MP3 player) and manipulated its color to evoke impression management concerns. Specifically, we predicted that when the product was offered in a feminine color, men–but not women–would worry about the impression it conveyed.

### Method

Ninety-eight students (47 men, 51 women) participated in a 2 (product color: pink vs. black) x 2 (gender) between-subjects factorial design. Participants placed bids in an actual auction for either a pink or a black MP3 player. To ensure participants bid their true willingness to pay (WTP), the auction winner paid only the amount tendered by the second highest bidder. After placing sealed bids, participants completed a survey to assess product attitude ($r$=.81), liking of the color, and the extent to which they would be concerned about using the product in public (impression management concerns, $\alpha$=.91).

### Results

There were significant interactions between product color and gender on all dependent variables ($F$'s(1, 94)=19.34, 10.44, 21.98, and 45.53, $p$'s<.01). Men bid less for the pink player ($M$'s=\$41.20 vs. \$84.43; $F$(1, 94)=22.54, p<.001), liked it less ($M$'s=1.27 vs. 2.13; $F$(1, 94)=12.38, $p$<.001), liked the color less ($M$'s=.25 vs. 2.48; $F$(1, 94)=44.62, $p$<.001), and were more concerned about their impression ($M$'s=1.29 vs. 2.95; $F$(1, 94)=73.17, $p$<.001). No differences were significant for women ($F$'s<1). Mediation analyses (Baron and Kenny 1986) of the men's results found that the effect of product color on WTP was mediated by impression management concerns (product color–WTP: $\beta$=.52, $p$<.001; product color and impression management–WTP: $\beta$'s=.08 and .58, $p$>.66 and p<.001), but not liking of the color (product color and liking of color–WTP: $\beta$'s=.35 and .22, $p$'s=.09 and .29). Identical effects were found for attitudes.

## Study 2

Study 2 examined the accuracy of consumers' impression management concerns by comparing their beliefs about the impression they would create using a product to impressions of another consumer using the same product.

### Method

Ninety-one students (37 men, 52 women, 2 unspecified) participated in a 2 (product color: pink vs. black) x 2 (gender) x 2 (target: self vs. other) between-subjects factorial design. Participants were told that they would be participating in a study about people's impressions of one another. In the "self" conditions, participants saw an MP3 player (embedded in a variety of other products) and rated what they thought other people would think of them if they were seen using this product. In the "other" conditions, participants saw a picture of a male in a gym setting who happened to be wearing an MP3 player. The MP3 player was either pink or black. All participants completed two items ($r$=.53) designed to assess the positivity of the impression they thought they would convey [their impression of the other person], as well as ratings of how masculine and feminine (reverse scored) they thought they would be perceived [they perceived the other person] ($r$=.46). All items were embedded in a general trait assessment inventory.

### Results

The general impression measure showed the predicted three-way interaction ($F$(1, 81)=6.98, $p$<.01). Men, but not women, thought they would be perceived significantly less positively wearing a pink player ($M$'s=2.08 vs. 3.35; $p$<.001). However, both men and women's impressions of the other person were unaffected by the color of the player (overall $M$=3.71). A significant color x target interaction ($F$(1, 81)=10.65, $p$<.01) on the masculinity/femininity measure demonstrated that both men and women thought the color of the MP3 player would have a stronger effect on others' perceptions of them than it did on their own perceptions of another person. In short, both men and women appeared to overestimate the impact the color of the player would have on others' perceptions of their masculinity/femininity. Only men, though, believed this would have a negative impact on others' perceptions. Importantly, there appeared to be no basis for such concern, given that impressions of a third party were unaffected by the color of the MP3 player.

## General Discussion

The current work demonstrated that consumers' desire to avoid creating a particular impression exerted an important influence on their attitudes and ultimately their willingness to pay for a product. Consumers' concerns, however, appeared to be somewhat unwarranted. Both men and women overestimated the impact the product would have on the impressions they created. In the current context, these

impressions (i.e. femininity) were considered most undesirable by men. Interestingly, neither men's nor women's impression of another person were affected by the very product men sought to avoid.

# Assessing Consumer Reaction to New Product Ideas: Does it Matter Where You Live and How Old You Are?

Jing Wang, University of Iowa, USA
Catherine Cole, University of Iowa, USA

At a certain moment, when a new product is introduced into a market, sales increase rapidly (the takeoff point). Prior research shows that the patterns of new product take off and time to takeoff vary in different European countries and across product categories (Tellis, Stremersch, and Yin 2003). This prior research suggests that so called brown goods take off faster than white goods and that cultural characteristics such as need for achievement, industriousness and uncertainty avoidance partly explain these differences in takeoff patterns. We build on this work by studying how individual level cultural variables and age affect how people respond to new product ideas.

We address this problem by categorizing new product information in two different ways. One way to categorize product information is to separate factual information from emotional information. Companies can launch their product by providing comprehensive factual information or by attaching features of the product to emotional benefits.

According to socioemotional selectivity theory, as people age, regulating feeling states becomes more important than priorities such as acquiring knowledge (Carstensen 2006). As a result, older adults prefer and have better recall for emotional information than factual information, whereas younger adults prefer and have better recall for factual information than emotional information (Fung and Carstensen 2003; Williams and Drolet 2005). What has not been tested is whether older adults will actively seek out emotional vs. factual information. Based on their research, we predict that older adults will search for emotional information about product attributes, while younger adults will search for factual information about product attributes.

Another way to categorize product information is by the type of goals the product can help consumers achieve. Consumers with a promotion orientation are concerned about achievements and winning, whereas consumers with a prevention orientation are concerned about security and not losing (Higgins 1997). Product information can be categorized in the same way. Promotion information highlights achieving desirable outcomes (e.g., toothpaste that whitens your teeth) whereas prevention information emphasizes avoiding undesirable outcomes (e.g., toothpaste that prevents cavities; Wang and Lee 2006). Consumers are not only more persuaded by information that is compatible with their orientations, they are also more likely to actively seek out compatible information (Wang and Lee 2006). As people age, they shift their regulatory orientations. Elderly adults are more likely to adopt a prevention orientation whereas younger adults in general take on a promotion orientation (Lockwood, Chasteen and Wong 2005). Therefore, we hypothesize that elderly adults will search for prevention information and younger adults will search for promotion information.

From a theoretical perspective, a key contribution of our research is how consumers' age interacts with both information content (factual vs. emotional) and information orientation (promotion vs. prevention) in determining willingness to purchase a new product. We divide information into four categories—factual promotion information, factual prevention information, emotional promotion information, and emotional prevention information.

Although our hypotheses suggest that older adults will favor emotional prevention information, while younger adults will favor factual promotion information, there is ambiguity about how each age group will related to factual prevention information or emotional promotion information. Specifically, although younger adults prefer factual promotion information, they may not respond well to factual *prevention* information. Similarly, whereas elderly adults prefer emotional prevention information, emotional *promotion* information might not engage them. In such situations where information content and information orientation are competing, we hypothesize that the cultural influence, in the form of chronic regulatory focus, will break the tie.

Chronic regulatory focus varies across cultures. In particular, North American consumers have a chronic promotion orientation, whereas East Asian consumers have a chronic prevention orientation (Aaker and Lee 2001; Briley and Aaker 2006). We hypothesize that consumers' chronic orientations will dominate the information content when information content and information orientation are competing, such that promotion oriented consumers, such as those typically found in North American, will prefer emotional promotion information (even if they are young) and prevention oriented consumers, such as those found in East Asia, will prefer factual prevention information (even if they are elderly).

One hundred and thirty seven US undergraduates participated in Study 1. They read definitions of factual vs. emotional information and then completed a quiz to make sure they understood the difference. Participants could not advance the program until they answered

all the quiz questions correctly. Then they completed a practice task related to toothpaste. On the first experimental task, participants reviewed information about an Innovative MP3 Player. They selected emotional or factual information on six dimensions for a new MP3 like device. Consistent with our predictions, these young people obtained more and spent more time on factual information than on emotional information (Factual Acquisitions 4.62 , Time 14.91 seconds vs. Emotional Acquisitions 3.12, Time 7.39 seconds). Additionally they acquired and spent more time on promotion information than prevention information, although these differences were not significant.

Study 2 has a 2 (age group: young vs. old) x 2 (culture: American vs. Chinese) x 2 (information content: factual vs. emotional) x 2 (information orientation: promotion vs. prevention) mixed factorial design. In this study, we recruit 150 American consumers and 150 Chinese consumers, half of each group are elderly consumers (average age>60). We match the groups from the two countries by several demographic variables such as age and gender. Participants select information for different products (a practice task, a new type of multi-function cell-phone, mp3 player and a new form of mutual fund). For each product, they can select factual or emotional information on both prevention and promotion dimensions. The dependent variables are the content and orientation of information selected, the time spent reviewing each type of information and participants' attitude toward the innovative products. Covariates include participants' age, cultural orientation, chronic regulatory focus and product familiarity. At the conference, we will present preliminary results of this study.

Theoretically, we will learn to what extent age and culture affect consumers' preference and search for information about really new products. Managerially, the older market is an important new segment as a significant proportion of population is entering this segment. Finding ways to position new products to this segment is important to the success of many companies. In addition, our research helps companies adjust the positioning of their innovative products across cultures. Note that existing research does not suggest how consumers respond to emotional promotion and factual prevention information. Culture plays a key role here because we predict that consumers' chronic orientations will dominate information content when consumers process information on new products. Without our cross-cultural results, implications on these two types of information are unclear.

## Power and Donation: Does Perceived Power Decrease or Increase Charitable Contribution?

Xianchi Dai, INSEAD, France
Anne Fries, University of Cologne, Germany

The psychology of power has long been of interest for psychologists and economists (e.g., Bierstedt, 1950; Kipnis, 1976; Winter, 1973; Browne, 2006). Recently, researchers started to systematically study the role of power in decision making. For example, having power increases the tendency to approach and decreases the tendency to inhibit, i.e. people with power are more likely to notice rewards and less likely to perceive threats (Anderson/Berdahl, 2002). High power people are also more inclined to take risks (Anderson/Galinsky, in press). In addition, research focuses on the negative effects power evokes in people, namely that the powerful only focus on their own interests and desires and are not interested in others (Fiske, 1993; Kipnis, 1972). It has also been found that the powerful are less capable of experiencing empathy, i.e. they are not able to correctly adjust to others' perspectives. Apparently, the powerful do not fully comprehend how other people see, think and feel (Galinsky et al., 2006). Galinsky et al. state in their paper that perspective taking has been associated with altruism and helping behavior whereas power is typically related to malfeasant social behaviors.

In the current paper, our question is whether perceived power leads to increased or decreased charitable contribution. The answer is not ready from the existing literature. On the one hand, the sense of power may lead people to believe that they themselves can help more. This might be driven by the perceived resources they have at their disposal (Keltner et al., 2003). That is, perceived power leads to believe that they themselves have more resources available to help others, thus donate more to others. On the other hand, research has shown that power leads to less empathy and perspective taking (Galinsky et al., 2006), which presumably would lead to decreased charitable contribution. In the current paper, we hypothesize that the sense of power leads to higher self focus, which includes two aspects. First, consistent with literature, the sense of power leads to less empathy and perspective taking, and thus leads to less sympathy toward a suffering victim. Second, it also makes people focus more on external stimuli which potentially can bring positive return (e.g., make

them happy) to them. Based on the above mentioned reasoning, we predict that 1) high power people donate less to suffering subjects (rather than less suffering subjects) than low power people do; 2) high power people donate more to attractive subjects (rather than unattractive subjects) than low power people do. We tested these predictions in three studies.

In study 1, subjects were first shown pictures of attractive and unattractive children from Third World countries. We presented them with pictures of 4 children and asked them to freely split a sum of 30 ? to them. These 4 children varied in attractiveness (two attractive ones, two neutral ones), but were hold constant in the suffering dimension. After the allocation task, the subjects were asked to rate themselves on a power scale (Smith et al., 2006). As we hypothesized, the correlation analysis showed that high power people tended to give more to attractive subjects (rather than unattractive subjects) than low power people did.

Study 2 adopted exactly the same procedure as in study 1, but this time they were asked to allocate their donation to children varying only in the suffering dimension, whereas the attractiveness dimension was held constant. Again, our hypothesis was confirmed. That is, high power people donated less to suffering subjects (rather than less suffering subjects) than low power people did.

To establish the causal link, in study 3, we manipulated power by priming subjects with either high or low power. After the priming procedure, they were asked to allocate donations either among a set of children varying only in the attractiveness dimension, or among a set of children varying only in the suffering dimension. Consistent with our hypotheses, comparing to low power people, high power people donated less to suffering children (rather than non suffering children); whereas they donated more to attractive children, rather than unattractive ones.

Overall, these results suggest that whether the perceived power leads to increased or decreased charitable contribution depends on the nature of the subjects they face. Specifically, as we have shown in the studies, high perceived power leads to more donation to attractive subjects but less donation to suffering subjects. These results resolve important controversial predictions based on power elicited resource abundance and power induced (less) perspective taking. The findings also have important implications for marketing practice of fundraising organization. For example, they should segment their potential contributors and provide different types of ads (e.g., attractive versus suffering) to maximize their charitable contributions.

# Do All-or-Nothing Reference Points Support Regular Savings?

Caezilia Loibl, Ohio State University, USA

Do implementation intentions support regular savings? A growing number of studies have demonstrated how the formation of implementation intentions positively influences goal progress (Gollwitzer 1999; Schweiger Gallo and Gollwitzer 2007). Little has been written on the limitations of this method (e.g., Powers, Koestner, and Topicu 2005). In this working paper, we examine another case in which implementation intentions appear to moderate goal progress. We find that committed savers who use implementation intentions to attain a specified savings goal perform significantly worse than do those who did not use an implementation plan. This suggests that implementation plans may have the effect of demotivating committed individuals who seek to implement narrowly specified plans, ultimately resulting in a deterioration of performance toward the goal.

The consumer behavior literature yields a number of explanations as to why implementation intentions may moderate progress toward a savings goal. First, forming all-or-nothing types of implementation intentions set a target that must be met for the effort to be considered a success. Otherwise, it is considered a failure and may discourage subsequent goal progress. Second, people's spending behaviors may have created counterintentional habits that are stronger than implementation intentions. Implementation intentions may not be able to interrupt this negative influence on reaching a savings goal. Third, forming an implementation plan may increase peoples' attention toward their savings behavior. The implementation plan, specifying the target behavior, may heighten a person's self-focused attention. This allows for self-criticism which, in turn, interferes with goal progress. Fourth, people's self-control to act on an implementation plan may be depleted if they set too many goals or they set goals that conflict with their savings goal.

In this working paper, we study participants of a community-based savings campaign. Because the campaign encourages regular, at least monthly savings deposits, we can infer that achievement of the savings goal is considered difficult to implement by the participants.

Similarly, we can also safely assume that participants in the past experienced self-control problems in achieving their savings goals. Thus, they might be particularly anxious about their performance within the savings campaign.

Two frameworks are currently developed to explore whether an all-or-nothing reference point moderates the impact of implementation intentions on achieving a savings goal. First, we use an implementation intention manipulation to assess the interaction of these plans with savers' income. We are examining whether implementation plans motivate higher income individuals to save more than those with lower incomes. The second framework adds savers' goals and time horizon to assess monthly goal progress. Together, the dynamics of pursuing a savings goal suggests the following testable hypotheses: (1) Participants who form implementation intentions concerning when, how, how much, and from what source of income they will deposit money into their savings accounts will be more likely to save more the higher their income than participants who do not form such intentions. (2) Participants with shorter time horizons to reach their savings goal will be more likely to respond to implementation intentions than those with longer time horizons. (3) Participants who form implementation intentions will save in a manner consistent with their intentions.

Data were generated by a mail survey in fall 2006 distributed to the 599 America Saves campaign participants in a city in the U.S. Midwest. A total of 94 campaign participants completed questionnaires at all three time points: baseline questionnaire, first follow-up four weeks, and second follow-up eight weeks after the baseline questionnaire. Fifty participants happened to be in the treatment group who were asked to form implementation intentions and 44 participants were in the control group.

Following the procedure described in Orbell et al. (1997) and Sheeran and Orbell (1999), the baseline questionnaire assessed intention, attitude, normative belief, perceived behavioral control, and previous behavior. Following Gollwitzer (1993), participants in the treatment group were asked to make implementation intentions specifying when, how, how much, and from what source of income they will deposit money into their savings account during the following month. In the first and second follow-up, participants were asked to indicate whether they intended to deposit money during the past four weeks and whether they actually deposited money into their savings account in the past four weeks. The treatment-group participants were then asked the four open-ended implementation questions.

Preliminary analyses indicate satisfactory scale reliabilities, ranging from .767 to .920 for the Theory of Planned Behavior variables. An ANOVA showed no significant differences between treatment and control groups on preintervention measures of intention, attitude, subjective norm, perceived behavioral control, or previous behavior. These findings indicate that prior to the intervention, the two groups held similar beliefs concerning regular savings. Similarly, there were equivalent proportions of men and women ($F$=1.966, NS), races ($F$=.018, NS), educational levels ($F$=.084, NS), marital status' ($F$=1.155, NS), savings goals (F=1.816, NS), and postal ZIP codes ($F$=1.966, NS) in the control and treatment group. There was no significant difference of age ($F$=.769, NS), income ($F$=.004, NS), and length of participation in the savings campaign ($F$=.548, NS) between the groups. The correlations between past behavior and intention for the two groups showed that past behavior is significantly associated with intentions for the treatment ($r$=.733; $p$=.000) and the control group ($r$=.666; $p$=.000). Both groups had positive intentions, attitudes, subjective norms, and perceived behavioral control. Behavioral intentions were strong in both conditions, with mean scores of 15 on a 3-21 scale (*mode*=21).

We can conclude that both groups base their intentions to save regularly upon their previous savings behavior and that both groups are highly motivated to save regularly. Differences between the groups on the amount saved must, therefore, be attributed to volitional rather than motivational factors. Based on our current timeline, I fully expect that data analysis and discussion of the findings will be completed by the conference in October.

# Culture, Social Comparison and Responses to Advertising

Theresa A. Wajda, Slippery Rock University, USA
Annie Peng Cui, Kent State University, USA
Michael Y. Hu, Kent State University, USA

With events such as the fall of the Berlin Wall, formation of the European Economic Community and advent of the Internet, the movement of goods, services and people appears to have no bounds. However, in these increasingly global times, it is also evident that all persons have not been created equal. Rather, it has been discovered that individuals from different cultures often think and emote in ways very different from one another. These differences, at all levels of analysis, have been captured in a number of different constructs by researchers hoping to quantify and measure these effects. The goal of this research is to incorporate the three variables of culture, structure and person into one theoretical model via the processes of social comparison. Specifically, it is the aim of this study to ascertain how differences in culture impact the manner in which individuals engage in processes of social comparison with advertisements.

In order to accomplish the objective of this research, two separate, but related studies will be conducted. The first study will seek to ascertain how culture influences information processing (via the process of social comparison) when individuals are asked to compare

themselves with models in an advertisement. The second study will seek to determine if individuals from different cultures vary in the manner in which social comparisons are made.

The first study will attempt to determine if individuals from collectivist and individualistic cultures process social comparison information differently in terms of how an advertisement's content is used to make a comparison. The research of Miller (1984) and Shweder and Bourne (1983) has suggested that individuals from collectivist cultures process information about themselves and others differently than persons from individualistic cultures. Individuals from a collectivist culture are more apt to hold an interdependent view of self and others. By definition, an interdependent view of self is based on a conception of self that is defined relative to one's membership in a collective. As a result, an individual's self-conception is inexorably tied to social roles and functions as well as to the moral responsibilities owed the group. Conversely, in individualistic cultures persons are more apt to hold an independent view of self and others. An independent construal of self is founded on the belief that the self is a unique, autonomous being that maintains an existence outside of the social environment in which it operates. Thus, a person from an individualistic culture is more apt to conceive of self with respect to personal thoughts, feelings, attitudes, etc. In a similar vein, this same individual is likely to conceive of others relative to their unique attributes, characteristics, feelings, etc. Thus, based on an independent view of self, the person is abstracted from social roles and moral responsibilities. Consequently, persons in individualistic cultures typically view the world from a personal vantage point and are more likely to rely on dispositional-based casual explanations. Therefore, unlike collectivists who describe and compare persons by reference to actions, individualists describe and compare persons primarily through means of personality traits (e.g., he is a very mean person.).

Based on the above cultural differences in person and self-conception, there are important implications for how an individual will process information in an advertisement when asked to make a social comparison with the content (i.e. model/models, background setting, product) of an advertisement. We hypothesize that H1) individuals from a collectivist culture will process contextual and relational aspects of an advertisement when making a social comparison with greater frequency than individuals from an individualistic culture; and H2) individuals from an individualistic culture will process trait and dispositional aspects of an advertisement when making a social comparison with greater frequency than individuals from a collectivist culture.

The purpose of the second study is to determine if individuals from different cultures vary in the manner in which social comparisons are made. Based on Festinger's theory, it is being argued that a micro-level theory (i.e. at the individual level of psychological functioning) be extended to incorporate macro-sources of influences (i.e. cultural influences as they are mediated through the social structure's definition of the in-group. Thus, in making the above arguments for cultural differences in self-construals based on variations in the meaning and significance attached to the in-group, there is expected to be cultural variations in the definition of what constitutes a "similar other." Thus, it is likewise anticipated that there will be variations in the amount of attention paid to various sources of social comparison data. Hence, when an individual is exposed to both a culturally-congruous and culturally in-congruous advertisement, the following hypothesis are proposed with respect to attention to social comparison information:

H3:   Individuals with an interdependent construal of self will pay overall less attention to social comparison information when exposed to both culturally-congruous and culturally-incongruous advertisements.

H3a:  Individuals with an interdependent construal of self will pay more attention to social comparison information when exposed to a culturally-congruous advertisement.

H3b:  Individuals with an interdependent construal of self will pay less attention to social comparison information when exposed to a culturally-incongruous advertisement

H4:   Individuals with an independent construal of self will pay overall more attention to social comparison information when exposed to both culturally-congruous and culturally-incongruous advertisements.

H4a:  Individuals with an independent construal of self will pay more attention to social comparison information when exposed to a culturally-congruous advertisement.

H4b:  Individuals with an independent construal of self will pay more attention to social comparison information when exposed to a culturally-incongruous advertisement

The two studies will be implemented with participants from collectivist and individualist cultures respectively. The extent to which attention is paid to social comparison information will be gauged using the Attention to Social Comparison Information (ATSCI) instrument constructed by Lennox and Wolfe (1984). The extent to which a person is motivated by an external versus internal source of influence while engaged in the social comparison process will be measured by assessing internal versus external locus of control.

This paper represents an initial inquiry into how differences in culture impact the manner in which individuals engage in processes of social comparison with advertisements. Results from this research will help further the understanding of the interactions of cultural influences, self-evaluations and information processing.

## The Effect of Brand Personality on Evaluations of Utilitarian Product Benefits

Adrian Peretz–Norwegian School of Economics and Business Administration, Norway
Magne Supphellen–Norwegian School of Economics and Business Administration, Norway

Since Aaker's (1997) article, more than 30 studies have empirically explored the effects of brand personality on attitudes towards a brand (e.g. Johar, Sengupta and Aaker 2005; Batra and Miles Homer 2004; Aaker 1999; etc). However, most studies have explored the effects on attitudes that serve *social identity* functions. Some studies have included products that primarily serve utilitarian functions, but none have explicitly explored the indirect influence of brand personality on brand attitudes via evaluations of *utilitarian* benefits.

Brand personality associations may include dimensions such as Sincerity and Competence (identified as first and third in terms of importance in Aaker's 1997 study), that are not typically relevant for social identity brand concepts. Rather, these dimensions may be perceived as diagnostic (Feldman and Lynch 1988) for evaluating product functionality, in particular at higher levels of perceived risk.

When consumers feel that uncertainty about whether a product will deliver the expected utility is high–perceived risk increases (Bettman 1973, Dowling and Staelin 1994). Utilitarian products that have significant credence qualities (Darby and Karni 1973) are associated with higher levels of perceived risk. We suggest that under such conditions, consumers may perceive certain brand personality dimensions as diagnostic for evaluating expected utilitarian benefits–specifically those that invoke perceptions of expertise and/or trustworthiness: *Competence* and *Sincerity*.

$H_1$: *In conditions of high (but not low) perceived risk, brand personality affects evaluations of utilitarian brand benefits.*

We further suggest that the degree to which consumers find brand personality information relevant will moderate the effect of brand personality on evaluations of utilitarian benefits.

$H_2$: *The effect of brand personality on evaluations of utilitarian brand benefits is moderated by the perceived relevance of brand personality information.*

**Method**

115 undergraduate students were randomly assigned to conditions in a 2 (perceived risk: high or low) x 2 (strength of brand personality associations: strong or weak) between-subjects design. Subjects were told they would be evaluating a new consumer magazine (fictitious). The uncertainty manipulation was incorporated into an excerpt from this magazine as a product category review. After reading about the magazine and the example product review, subjects viewed an ad containing descriptions of product attributes and the brand personality manipulation.

Based on pretests, electric toothbrushes was selected, as this product was rated as primarily utilitarian, and average on the level of credence involved (3.35 on scale from 1= no uncertainty to 7=great uncertainty).

For the uncertainty manipulation, subjects received one of two product category reviews stating either that i) all electric toothbrushes perform equally well (low uncertainty) or, ii) there are great differences between brands, with some causing serious wear on teeth and gums.

The brand personality dimension *Competence* was manipulated in an ad for the Dentox (fictitious) electric toothbrush. In addition to (typical) product attributes the ads contained a statement informing subjects either that the electric toothbrush was developed by the highly qualified team of researchers at Dentox (strong condition), or that the electric toothbrush was developed by a team at Dentox (weak condition).

*Dependent variables*. Subjects rated the product's utilitarian benefits on three scales (7-point) anchored by very good/very bad, very effective/not very effective, and very gentle/not very gentle. These items were averaged to form an index ($\alpha$=.72).

*Independent variables and moderator variable*. Subjects reported perceived uncertainty involved with purchase of an electric toothbrush on a 3-item scale adopted from Dowling and Staelin (1994) index ($\alpha$=.77). Brand personality (competence) was rated on a nine-item (5-point Likert scale) scale adapted from the Aaker scale. Perceived relevance of brand personality was rated on a single item using a 7-point Likert scale (very relevant–not at all relevant).

Factor analysis of the items used to measure competence revealed that five of the items loaded on a factor closely resembling personal competence, so these five were kept for further analysis as an index of competence. Notably, the four items that were dropped are linked to technical expertise, and had no effect on evaluations.

**Results**

*Manipulation checks*. An ANOVA on the perceived uncertainty index showed a main effect of level of uncertainty ($F(1, 113)$=36.12, p<.001). An ANOVA on the brand personality index showed a main effect of strength of brand personality ($F(1, 113)$=7.99, p<.01).

*Test of H1*. The two-way interaction between perceived uncertainty and strength of brand personality associations on evaluation of utilitarian benefits was significant ($F(1, 113)$=4.57, p<.05). In high risk conditions, evaluations of product functionality were more favorable in response to strong (versus weak) brand personality associations (Ms=4.9 versus 3.9; $F(1, 56)$=31.26, p<.01). In low risk conditions evaluations of utilitarian benefits did not vary significantly as a function of brand personality information (Ms=4.9 versus 4.5). Thus support is found for $H_1$: brand personality affects evaluations of utilitarian brand benefits under conditions of high perceived risk.

**Moderation analysis**

Performing separate analysis of low versus high conditions of uncertainty, we (1) regressed the evaluations of utilitarian benefits on the index of brand personality; (2) regressed the evaluation of utilitarian benefits on the index of brand personality and the perceived relevance of brand personality; and (3) regressed the evaluation of utilitarian benefits on the index of brand personality, the perceived relevance of brand personality, and the interaction between these two (Baron and Kenny 1986). Under conditions of low uncertainty, relevance of brand personality had no significant effect (standardized coefficients; all relevant p-values>.1) However, under conditions of high uncertainty the perceived relevance of brand personality significantly moderated the effect of brand personality on evaluations of utilitarian brand benefits (standardized coefficients; all relevant p-values<.05). Thus support is found for $H_2$.

**Limitations**

This study extends research on brand personality by identifying conditions under which brand personality may *indirectly* affect consumer attitude via utilitarian benefits. However, to improve the generalizability of our findings, further work is needed to identify the potential impact of other brand personality dimensions–e.g. Sincerity. Moreover, overall brand attitude should be included in future research in order to examine both indirect effects and potential direct effects of brand personality.

# "Want to watch? You've got to pay": The Link between Intrusiveness and Outcomes Typifying the Customer-Firm Relationship

Marco Lalos, Université de Lausanne, Switzerland

Individuals' risk appraisal about products and services can be source of unwanted outcomes for firms. Perceived risk can be elicited by different means and can emerge in a myriad of contexts. In particular, this research investigates the causal relationship between intrusiveness as an antecedent of risk and its impact on moderating constructs and relevant outcomes which typify the customer-firm relationship.

According to Rust et al. (1999), risk is an important variable that influences perceived quality which in turn affects individuals' overall satisfaction assessment about a firms' performance (Johnson et al. 2006). In addition to commitment and trust, overall satisfaction mediates the relationship between perceived quality and outcomes such as loyalty (Chiou and Droge 2006), cooperation, future intentions and propensity to leave (Morgan and Hunt 1994; Garbarino and Johnson 1999).

Risk, as epitomized by Dahl, Manchanda & Argo (2001) in the context of disclosure of personal information, is related to the loss of privacy. Additionally, different authors claim that losing control over one's personal information will lead to an increased perception of risk and to personal disclosure avoidance (Culnan, 1993; Zeithaml et al., 2002; White 2004). Throughout the marketing literature, the disclosure of personal information and related problems has been widely discussed (Culnan 1993; Culnan 2000; Hoffman and Novak 1999; Milne 2000; Phelps, Nowak and Ferrell 2000), nevertheless, few authors have addressed the loss of privacy and the risk associated from the perspective of intrusiveness and the intrusiveness perceived by individuals, i.e.: how company activities that are perceived by individuals as intrusive, affect privacy, firm performance and the customer-firm relationship.

Intrusiveness in marketing is considered to have profound implications on customer-firm relationships, as it is considered to be an important variable that triggers individual negative emotional reactions and unwanted outcomes (Aaker and Bruzzone 1985; Ha 1996; Edwards et al. 2002). In the advertisement literature, recent researches proved that intrusive commercials can elicit irritation feelings, less favourable attitude toward advertised products and ad avoidance (Li et al. 2002; Wang and Calder 2006; Edwards et al. 2002). Differing slightly from previous definitions of intrusiveness, in this research it was conceptualized as the act of getting into one's life without permission.[3] Thus considering that intrusiveness, as a result of its nature, could be perceived as affecting a person's privacy and elicit negative emotional feelings which in turn could lead to undesirable outcomes (negative word-of-mouth, customer churning and loss).

As a first step, it was judged important to determine the existence of intrusiveness as conceptualized and assess its global effect on an outcome. Because loyalty is thought to predict buying behaviour, in this first study, perceived intrusiveness by individuals and its global effect over loyalty were sought. A scenario based design was contextualized in a retail environment, following the work of Larson et al. (2005) and Klabjan (2005). The choice seemed appropriate as it provided latitude to manipulate variables such as communication and compensation, and because intrusiveness could be conceptualized in the form of data collection techniques with the correspondent implications (loss of control and privacy).

The study was divided in two tests. The first one aimed ascertaining that different data collection techniques (loyalty cards, video cameras and RFID[4]) could trigger different levels of perceived intrusiveness. Two variables identified for their importance were manipulated: communication (positive: allowing control over personal data, neutral and negative: not allowing control over personal data) and compensation (provided or not).

---

[3]Adapted from Encyclopedia Britannica

[4]Radio Frequency Identification

H1: Technologies which allow controlling ones' personal data elicit lower levels of perceived intrusiveness than technologies that do not allow controlling ones' personal data

H2: Individuals perceive the use of technologies as less intrusive when compensation is provided and perceive the use of technologies as more intrusive when compensation is not provided

Using scenarios which combined each of the data collection techniques with a particular communication style (positive, neutral or negative) and compensation, a group of 241 undergraduate students answered the questionnaires. A seven-item scale measuring intrusiveness was adapted from Li et al. (2002). The most significant differences were found when comparing the loyalty card systems communicated neutrally, with RFID communicated negatively ($T$ (3.539), $p = 0.001$), RFID communicated neutrally ($T$ (2.892), $p = 0.006$) and RFID communicated positively ($T$ (2.132), $p = 0.039$). A planed contrast indicated that RFID was perceived as more intrusive than loyalty cards and video cameras ($p = 0.002$). Finally, compensation had a significant effect on the perceived intrusiveness of RFID under neutral communication scenario ($T$ (2.044), $p < 0.05$). These results show clearly that under certain conditions, different data collection methods used by retailers bring about different degrees of perceived intrusiveness in consumers' minds.

Building on the previous results, a second test (on 120 students) aiming to prove the global effect of intrusiveness over loyalty was carried. A 2 X 2 (Loyalty card vs. RFID; compensation vs. no compensation) between subjects ANOVA was performed to measure the effect of the treatments over the degree of loyalty. The loyalty scale from Zeithaml, Berry and Parasuraman (1996) was used to test the following hypothesis:

H3: Individuals elicit lower levels of loyalty when more intrusive technologies are used, compared to higher levels of loyalty when less intrusive technologies are used

H4: When compensation is provided, individuals experience similar levels of loyalty regardless of the technology employed, compared to the levels of loyalty experienced when no compensation is provided

Results sustained the hypotheses as expected. When no compensation was provided, respondents elicited higher levels of loyalty with non intrusive technologies ($M = 3.503$, $SD = 0.812$) compared to the lower loyalty level elicited with an intrusive technology ($M = 2.864$, $SD = 0.944$; $F$ (1,115) $= 8.07$, $p = 0.005$). Finally, a two-way interaction term between the technology used and the compensation type was found ($F$ (1,113), $p = 0.03$), satisfying H4.

The results of this first study are encouraging as they suggest that an effect due to intrusiveness could be lying beneath key moderating construct (overall satisfaction, commitment, trust) and additional relevant outcomes (future Intentions, cooperation). In the near future, a refined series of experiments will be carried including moderating variables (individual characteristics, situational context and company characteristics) over a heterogeneous population.

# From Luxury to Populence: Inconspicuous Consumption as Described by Female Consumers

Elad Granot, Cleveland State University, USA

Thomas Brashear, University of Massachusetts, Amherst, USA

Rising standards of living and increasing consumer product knowledge have given rise to a democratization of traditionally top-of-the-range products, (Bialobos 1991; Sharpe 2002). The result has been a much broader conception by consumers with regard to the concept of luxury. Fiske and Silverstien (2002) note that a $9 million Faberge egg and a $40.00 Victoria's Secret bra are both referred to as luxuries (Faberge being "old luxury" and Victoria Secret as "new luxury").

"Old luxury" conceptions can be traced to Veblen (1899) who wrote that the rich communicate social advantage by buying and, more importantly, displaying luxury goods, their medals of status. Conspicuous consumers can be categorizes as conformists or snobs. Snobs prefer limited products and while refraining from products consumed by many (Dubois, 1993; Leibenstein 1950; Corneo and Jeanne 1997).

In an effort to delineate luxury, Dubois' (1995) found that luxury producers buy into the idea that their customers focus on two attributes of the luxury goods: a) a very high price, in absolute and relative terms, and b) luxury goods have no utility. Subsequently, Dubois et al. (2001) found that French subjects classified luxury goods as expensive, polysensual, with a sense of legend or history, exclusive, aesthetic and superfluous.

Thus, luxury as we have known it, "old luxury" has been defined by snobbish, class oriented exclusivity-goods and services that only a small segment of the population can afford or is willing to purchase. "Old luxury" is the facilitator and result of conspicuous consumption (Veblen 1899). However, "new luxury" includes products for mass-market appeal to consumers across various income and social classes. Our study looks into the phenomena through the eyes of consumers describing their experiences with "new luxury" which we call Populence-popular opulence. To explore how consumers make meaning of Populence, we perform a hermeneutic phenomenological investigation, using in depth interviews in a modified method of Seidman's (1998) three interview structure.

Our interviews yielded two types of information: 1) a first-person description of the participant's history in context and (2) contextual details concerning the participant's lived experience. Products in this study included intimate apparel as well as shoes and accessories. Sixteen women, between the ages of 20 to 28 were interviewed. Stories describing the genesis, evolution, and usage of new luxury brands in the participant's repertoire were elicited. To begin, participants were asked to "tell the story" behind any products under consideration that they were wearing at the time. The remainder of the interviews were driven by participants. We recorded and transcribed interviews and the authors conducted the analysis. Our findings are based on the views, comments, and meaning offered by participants on various consumption patterns, brands and products. Seven categories surfaced which help define and structure the cognitive domain of content. They are presented below.

*Overall superiority*-All of the participants stressed the importance of quality in their purchase decision and attachment processes. This omnipresent characteristic is indicative of Populent goods offering a high level of quality, much higher than conventional middle-market goods and often higher than "old luxury" goods. Participants who consume Populent undergarments expect the product to be free of faults of manufacture and assembly and to perform precisely as promised.

*Fashionable and 'cool'*–This emergent theme is about expressing personal taste, differentiating oneself from others, and demonstrating sophistication, discerning abilities, and success. This theme is also about being hip and looking stylish and feeling unique. For sophisticated and discerning spenders, Populent goods provide a rich and broad vocabulary with which to speak-without saying a word.

*Moonshooting and Bottombarreling* –Participants say they are willing to pay a significant premium for goods that are emotionally important to them and that deliver the perceived values of quality, performance, and emotional engagement. But in other categories that aren't emotionally important, they become value driven bargain hunters: the same participant who splurges on intimate apparel also buys generic earrings at target at $5.99 for three pairs.

*Signaling*–Signaling is about finding, building, maintaining, and deepening relationships with people who are important to them. Signaling includes the following subspaces: attracting mates, belonging (Bandwagoning) with friends and groups, and social signaling. To help attract mates, participants buy clothing, lingerie, jewelry, accessories, and cosmetics to make themselves more appealing. Populent goods provide participants a means to align themselves with people who have similar values and interests- to join the club

*Self-Catering*–Most of the participants say they are looking for ways to get a few moments alone, reward themselves after a tough day of studies and working, rejuvenate their body, and soothe their emotions. Self-Catering is also about indulging oneself but buying luxuries is no longer a guilty self-indulgence; it is exercising a right and almost an obligation to make sure consumers are feeling their best.

*Exploring*–Exploring is about seeking out new experiences and experimenting with added identity dimensions. Participants describe their sense of adventure and liberation when they complete their appearance by using and exhibiting Populent goods. In addition, participants appreciate the sense of freedom that comes with switching brands and consumption situations. Intimate apparel (underwear

and lingerie) provides participants with a canvas for experimenting and variety seeking that does not pose a threat of social scrutiny. Finally, exploring provides participants with a legitimate experience of product trial and evaluation.

*Inconspicuous Consumption*–The most conspicuous difference between "old" luxury goods and consumption and Populence is the element of display and the degree to which it applies. Participants purposely chose to select goods that are high quality and relatively expensive, but that do no display any visual brand elements.

Our data also serve to induct a new luxury Populence paradigm that is radically different from the traditional "old" luxury. This paradigm stems from significant mass market shifts, rather than exclusive, snobby elite segments. We call it the Populence paradigm because it involves the mass production and distribution of premium goods and services, enabling the majority of consumers to pick and choose their consumption of New Luxury brands.

# The Surprising Influencers: How the Inferred Attributes of Observed Consumers Shape Observer Consumers' Buying Intentions

Edith Shalev, New York University, USA
Vicki Morwitz, New York University, USA

The ways in which consumers influence each other is of major importance for today's marketers. The majority of influencer research examined processes of verbal communication between consumers. However, less is known about "silent" processes in which consumers are influenced by others merely through observation. The current paper examines how surprising personality traits or identity of an *observed* consumer influence the purchase intentions of *other (observing)* consumers. For example, does watching an excessively overweight person carrying an organic-store grocery bag increase or decrease the probability that the observer will visit that organic store? How does observing an elderly lady using a cutting edge cellular phone affect an observer's cell phone purchase plans?

We hypothesize that such observations elicit social comparison processes (Festinger, 1954) wherein the observing consumer compares himself to the observed consumer on a "product-salient attribute." The *"product-salient attribute"* is defined here as an attribute which highly characterizes the *typical-consumer* of the product in question. For example, the typical organic food consumer is perceived as particularly health aware, so health awareness is the organic-food salient attribute. Past research has shown that unfavorable comparisons (comparisons in which the comparer is outperformed) on subjectively important attributes (Tesser, 1988) are often ego deflating (Morse and Gergen 1970; Wills 1981; Pyszczynski et al. 1985), especially when they are unexpected (Festinger 1942; Alicke 2000). For example, an expert chess player will be more disturbed by a loss to a chess novice than by a loss to another chess expert, presumably because losing to a novice may suggest his personal chess ability has deteriorated. In order to enhance their depleted self evaluation following unfavorable comparisons, individuals employ a variety of coping strategies (Gibbons et al. 1994) including direct attempts to improve their standing on the compared attribute. Similarly, we hypothesize that when a non-typical consumer surprisingly outperforms us by owning a product with a salient attribute which we consider important (but we do not yet own such product), our self esteem is threatened. In response to this threat, our purchase likelihood will increase.

In Study 1, we asked participants to read a description of an innovative, expensive MP3 player and indicate their buying intentions and attitudes towards it. Participants in one group learned that a 47-year old grocery packer (low social status) has purchased that MP3 player. Participants in the second group learned that a 25-year old architect (high social status) purchased it. The grocery packer and architect were picked based on a pretest which validated that these individuals were viewed to be comparable on most dimensions (e.g., likability, looks) but differ on social status and perceived innovativeness. In addition, all participants reported how important it was for them to be innovators in technological products and in MP3 players. Since innovativeness requires financial resources, observing a low social status consumer is surprising and presumably more threatening than observing a high social status consumer. The results were consistent with our predictions: participants for whom innovativeness was important had higher mean purchase likelihood following exposure to the grocery packer than to the architect. Participants that regarded innovativeness as less important were not affected by the observed consumer manipulation.

In study 2, participants rated their buying intentions and attitudes towards a different product–a premium organic sandwich. A pretest indicated that health awareness is the salient attribute associated with organic sandwich consumption. In addition, the majority of students in our sample viewed health awareness as highly important. As in study 1, half the participants learned about a prototypic customer (a fit woman wearing a gym outfit) and half learned about a non prototypic customer (an overweight woman in ordinary clothing). Again these individuals were selected based on a pretest which showed that the two customers were viewed to be comparable on other important dimensions. Preliminary analysis indicated that two unintended factors affected buying intentions: belief in the functionality of the organic sandwich and participant's ethnicity. After adjusting for these two factors, we obtained results that replicated the expected effect: participants reported greater purchase likelihood and judged the price premium to be fairer following exposure to the overweight woman than to the fit athletic woman.

In sum, we find across studies that in *non verbal settings*, consumers who consider the product-salient attribute important are more likely to be influenced by a non-typical than by a typical consumer. Our results support the hypothesis that consumers learn through social comparisons about their relative position on product-salient attributes and respond to potential ego threats by increasing their personal purchase intentions. If further validated, these findings may have important managerial implications because they suggest that product adoption processes may be faster if advertising and promotion plans include target populations that are traditionally neglected. Finally, the research contributes to the growing body of knowledge on social comparison processes between consumers. Since our findings cannot be accounted for by classic predictions of reference group theory, they open challenging avenues for future research.

# How Personal Are Consumer Brand Evaluations?
# Disentangling the Role of Personal and Extrapersonal Associations in Consumer Judgments

Sandor Czellar, HEC Paris, France
David Luna, Baruch College, USA
Benjamin Voyer, HEC Paris, France
Alexandre Schwob, HEC Paris, France

Consumers often write or voice brand evaluations based on information they retrieve from memory (reporting brand attitudes in surveys, discussions and advice to friends about brands, etc.). Research has highlighted a variety of types of brand associations consumers may retrieve from memory to evaluate a brand (e. g. attributes, stereotypes, global impressions; Maheswaran 1994; Dillon et al. 2001). However, we know little about the extent to which brand evaluations really reflect personally-held attitudes. One reason for this is self-presentation, whereby consumers may distort and edit their evaluations in a socially desirable way (Paulhus 1998). However, even in situations where self-presentation is not a major concern, a brand evaluation may not reflect consumers' underlying attitudes about a brand.

A recent conceptualization proposes that consumers may hold associations that contribute to their personal attitudes about objects but also object associations that they have in memory but do not necessarily agree with (Han, Olson, and Fazio 2006; Olson and Fazio 2004). Personal associations reflect how the individual thinks/feels about the object regardless of what the rest of society believes (e. g. knowledge based on personal experiences). Extrapersonal associations reflect the individual's perception of what other people would think—any information about an attitude object in society at large. These extrapersonal associations may be formed on the basis of information from social interaction and from the media, often reflecting stereotypic knowledge (Karpinski and Hilton 2001). Self-reported brand evaluations may be influenced by these extrapersonal associations, which may not reflect the nature of the individual's personal attitudes.

We argue that the proportion of extrapersonal associations in memory is related to the level of consumer expertise with the brands in the product category. For example, research shows that experts base their brand evaluations on concrete attribute knowledge whereas novices use general impressions to form brand evaluations (Dillon et al. 2001). Furthermore, novices are more prone to use stereotypes rather than attribute information in product judgments, while the converse holds for experts (Alba and Hutchinson 1987; Maheswaran 1994). We therefore hypothesize that novices' brand evaluations will be predominantly based on extrapersonal associations; while experts' brand evaluations will be predominantly based on personal associations. Our first study tests these hypotheses.

We assessed the link between brand judgments and type of associations on which those judgments are based (personal vs. extrapersonal) in two different ways. The first assessment was a thought measure, whereby participants made brand evaluations, reported the thoughts they relied on to make the evaluation and then self-coded those thoughts according to whether the thought reflected their own opinion or someone else's opinion. The second assessment was through administering two different versions of the Implicit Association Test (IAT)—the traditional IAT (Greenwald, McGhee, and Schwartz 1998) and the personalized IAT (Olson and Fazio 2004). The traditional IAT, according to Olson and Fazio (2004), is affected by extrapersonal associations that are accessible at the time of categorizing the target object. Olson and Fazio (2004) devised a "personalized" version of the IAT that taps into personal associations to a greater extent than the traditional IAT. We expect that if brand evaluations are mostly based on extrapersonal associations, then the correlation between traditional IAT measures and brand evaluations should be positive and the correlation between traditional IAT measures and brand evaluations should be non-significant; the reverse pattern is expected if brand evaluations are mostly based on personal associations.

Ninety-six undergraduates participated in this study in exchange for course credit. The study comprised two sessions, with an interval of three weeks between the two. In the first session, each participant completed a randomly assigned IAT (traditional or personalized), in which the target objects were the *Mercedes* and *Fiat* brands. In the second session, participants completed a questionnaire including evaluations of the *Mercedes* and *Fiat* brands on six-item scales (a=.93 and .91). After that, they wrote down the reasons for their evaluation of each brand. Participants were then asked to self-code their own thoughts according to thought valence (positive/negative/neutral) and whether the thought reflected a personal opinion or an opinion shared by most people in their community. Participants then reported their expertise with cars on a four-item scale (a=.93; Mitchell and Dacin 1996).

As expected, experts wrote more total thoughts than novices (*M*=11.50 vs. *M*=9.00; *F*=12.84, *p*<.01). Regarding thoughts based on personal vs. extrapersonal opinion, novices wrote a higher proportion of non-personal thoughts than experts (*M*=.69 vs. *M*=.55; *F*=11.74, *p*<.01). We also performed regressions of type of thought on the IAT effect, to check the kind of associations influencing IAT effects. For novices, the valence of thoughts based on extrapersonal opinion was a significant predictor of IAT effects (*t*=2.34, *p*<.05) but the valence of thoughts based on personal opinion was not (*t*=1.09, *ns*). Conversely, for experts, personal opinion thought valence was a significant predictor of IAT effect (*t*=2.27, *p*<.05), but extrapersonal opinion thought valence was not (*t*=.95, *ns*).

We regressed explicit brand evaluation on IAT effect, expertise, IAT type, and on the following cross-products: IAT effect x expertise, IAT effect x IAT type, expertise x IAT type and IAT effect x expertise x IAT type. The three-way interaction was significant at *p*<.05. Probing this interaction showed that when novices completed the traditional IAT, their IAT effects and explicit brand evaluations were positively associated (*t*=1.81, *p*<.05). However, when they completed the personalized IAT, IAT effects and explicit brand evaluations were not associated (*t*=.10, *ns*). These results support our first hypothesis: Novices' brand evaluations seem predominantly based on extrapersonal associations. When experts completed the traditional IAT, their IAT effects and explicit brand evaluations were not associated (*t*=.29, *ns*). However, when they completed the personalized IAT, their IAT effects and explicit brand evaluations were positively associated (*t*=2.28, *p*<.05). These results provide support for our second hypothesis: Experts' brand evaluations seem predominantly based on personal associations.

To better understand the processes by which the types of associations affect explicit brand evaluations, the next steps of this research involve experiments manipulating the salience of personal vs. extrapersonal associations through priming. We expect a priming of personal associations to have a differential effect on experts such that their brand attitudes (as measured by the IAT and explicit scales)

should be more based on personal associations than in a control condition. Conversely, we expect a priming of extrapersonal associations to have a differential effect on novices such that their brand attitudes (as measured by the IAT and explicit scales) should be more based on personal associations than in a control condition.

Overall, we believe the present research project promises important insights for our understanding of the different influences consumers rely upon when constructing and reporting judgments about brands.

# Impact of Value Aspirations, Age, and Gender on Television Viewing Connectedness among Preteens and Teens

David S. Bickham, Children's Hospital, Boston, USA
Velitchka Kaltcheva, Loyola Marymount University, USA
Suzanne Martin, Just Kid Inc., USA
Anthony Patino, Loyola Marymount University, USA
Michael F. Smith, Temple University, USA

We examine the effect of three value aspirations (academic achievement, popularity and physical attractiveness) on connectedness with reality television. We find that both popularity and physical attractiveness are positively associated with connectedness. For males, popularity appears to be more strongly associated with connectedness that physical attractiveness. For females, teens who strive for popularity are more likely to be connected to reality TV; popularity is not associated with connectedness to reality TV for preteens. Girls who desire to be physically attractive are generally more likely to be connected to reality TV; however, this relationship becomes weaker with age.

# The Use of Humor in Promoting Healthy Eating and Better Communication in Parent-Child Dyads and the Moderating Role of Attachment: A Web-Related Intervention

Aida Faber, McGill University, Canada
Laurette Dube, McGill University, Canada
Sophie Belanger, L'Oreal Canada, Canada

**Background**

Adopting a healthy lifestyle is paramount to reduce the incidence and impact of health problems, to better recover and cope with life stressors, and to improve quality of life. Because healthy diets rich in fruits and vegetables are part of a healthy lifestyle, they consequently contribute to better health and longevity. The objective of this research is to make web nutrition information more effective by incorporating humor appeals that render the information more enticing and more likely to be fully explored.

Humor is a fundamental ingredient of social communication and has been wildly used in ads throughout the world to improve persuasion outcomes such as attitudes, memory and behavior. The persuasiveness of humor has also been successful in educational and health settings. When neutral appeals are used to present a communication, components of the appeal are generally abstract and objective, in order to keep the focus of the viewer on processing and reasoning on the information content. Humor appeals, in contrast, are designed to trigger fun and other pleasant affective responses and thus can help individuals engage in healthier lifestyle behaviors, i.e. increased

vegetable and fruit consumption. Consequently, we hypothesize that child-parent dyads in the web-communication humor appeal will increase more their consumption of fruits and vegetables than their counterparts in the neutral appeal condition.

Nevertheless, individual differences may mediate the humor effectiveness of our web-communication intervention. Research showed that high masculinity individuals, i.e. more independent, forceful and dominant, have a distress-avoidant orientation, and, thus prefer humor appeals to neutral ones. Building upon these findings, we believe that attachment styles may mediate the effectiveness of humor appeals. According to attachment theory, interaction with significant others in times of stress facilitate the formation of a sense of attachment security. This sense of attachment is formed during childhood and guides responses to any distressful situation, such as preventative health behaviors. Specifically, individuals can be classified among three types of attachment styles. Secure attachment styles describe children that are strongly supported by their caregivers, who can acknowledge distress and turn to others for support. Avoidant attachment styles reflect children less supported by their caregivers, who faced rules restricting acknowledgement of distress and seeking of support. Anxious/ambivalent attachment styles develop from insensitive or inconsistent care giving and involve hyper-vigilance for negative affect. In this study, we hypothesize that humor appeal will be more effective for people with avoidant and anxious/ambivalent attachment styles as opposed to those with secure attachment styles because the former are not used to face the stressful situation.

Lastly, we expect humor to impact communication as well. Laughter, fun feeling and other responses typically associated with humor have been found to be the most contagious affective responses and to decrease tensions between individuals, thus enhancing communication effectiveness. Hence, we hypothesize that dyads in the humor appeal condition will have an enhanced communication that their counterparts in the neutral appeal condition.

## Method

*Design and Procedure:*

In order to test our hypotheses, a nutritional web-intervention was developed called Marathon- Nutrition where type of appeal was manipulated. The Marathon-Nutrition website was created on the server of a major Canadian university using existing nutritional material developed by health Canada and the Canadian Produce Marketing Association.

This study required dyads of parents and children to participate in a virtual race aiming to increase their fruits and vegetable consumption. The entire study took place at home. There were 5 conditions in total (4 experimental and 1 control). The four experimental conditions followed the same 12-step template, step 1 and step 12 being pre- and post-questionnaires to assess the intervention. The intervention lasted a total of 6 weeks. Each of the remaining 10 sessions had a total duration of 25 minutes where the participants were 1) presented with an information blurb on the importance of eating healthy, 2) followed by simple tricks to increase fruit and vegetable consumption during the day, i.e. breakfast, dinner, snack, 3) and a short quiz. At the end of each session, participants fixed themselves as an objective to try a new fruit and a new vegetable.

The control condition only required participants to log in and complete the pre- and post-questionnaires at 6 weeks of interval. Meanwhile, the participants in this condition were provided with a list of nutrition websites and were invited to go on these websites in teams, i.e. parent/child dyads.

200 dyads, 400 participants in total, took part in this study. Participants were children between 8 and 12 years old and one of their parents. 3rd, 4th and 5th grade children were recruited from 31 French primary schools with a middle socio-economic status in a major Canadian city. Within each school, classes were randomly assigned to one of the 3 conditions: humor appeal, neutral appeal, or control.

*Manipulations:*

The *humor appeal* of the website was manipulated by varying the funniness of the virtual agent that guided the participants through the online content. Depending of the condition, i.e. high or low humor appeal, Yip, the virtual coach, introduced nutrition concepts in a funny or neutral way.

*Measures:*

The web strategies' persuasion impact was estimated using primary outcome measures, i.e. the number of children's daily servings of fruits and vegetables. The humor elements of the website were measured using the Attitude Towards the Brand and Ad scale adapted to children. The Romantic Attachment Scale adapted to reflect the child/parent relationship was used to measure attachment.

## Conclusion and Discussion

Results analyses seem promising and are being completed at the present time.

We are confident that this study will identify the importance of well-known humor appeals in presenting information and increasing consumer fruits and vegetable consumption. It will further enrich the existing literature on the effects of humor and will help bridge the gap between peripheral communication appeals, i.e. humor, and healthy lifestyles, i.e. nutrition.

# Effect of Country-of -Targeting on Product Evaluations

Mahesh Gopinath, Old Dominion University, USA
Leoan Tam, Old Dominion University, USA
Myron Glassman, Old Dominion University, USA

There has been great deal of research examining the country-of-origin effect on product evaluations (Li and Wyer 1994; Maheswaran 1994) and its determinants (Gurhan-Canli and Maheswaran 2000The basic premise of the country of origin effect is that consumers categorize products and apply organized prior knowledge about the categories (schemas) to evaluate new products (Meyers-Levy and Tybout 1989; Sujan 1985). These categorizations and the application of prior knowledge is based on inferences. These inferences are based on whatever information is known about the product at that point rather than on product observation. . In the country of origin effect, one piece of information known when of making the evaluation is the country of origin. The purpose of this paper is to investigate the effect of another piece of information available to consumers when inferences are made, the perceived country of targeting (COT) of the product. We introduce this concept because, more and more, products sold in the U.S. have product information in different languages. .

We hypothesize that one piece of extrinsic information that consumers use to make inferences about the product is the language used on the product packaging.

Specifically, we hypothesize:

H1: When consumers are presented with product descriptions in English and another language, they form inferences about the targeted countries as being both the U.S. and the country that speaks the language seen on the package. .

The three products we selected (after pretesting) to test this hypothesis were a compact refrigerator, tortilla chips, and wine. These products were chosen for their expected country of origin effect and product familiarity. Color pictures of these three products with

products descriptions in different languages were created One version had product descriptions in English; a second had product descriptions in English and Spanish; and a third had descriptions in English and French. Ethnocentrism, prejudice, and the relative dominance of the three languages were measured so that they could be used as mediating variables. Perceived country of origin and perceived country of targeting were also determined. These questions were followed by manipulation checks.

We hypothesize that product evaluations will be affected by the country of origin effect as well as the country of targeting effect. For example, the country of origin effect should result in higher valuations when the country of origin is perceived to be France. The same wine perceived to have originated in France should have differential evaluations when the perceived country of targeting is the U.S. as opposed to Mexico. The relative dominance (between the U.S. and Mexico) of the language/culture will determine the direction of the difference in product evaluations.

*H2-H5 (Summary)*: After controlling for the country of origin effect, products perceived to be targeting more dominant cultures will have higher evaluations than products seen as targeting less dominant cultures.

Data were collected online at a large, public mid-Atlantic university from 112 subjects. Each subject evaluated each product in one language condition which yielded a sample size of 112 per product. Preliminary analyses of our data confirm most of our hypotheses.

In Study 2, the country of origin is part of the product description and, as such, is constant. This is a more rigorous test of the country of targeting effect.

We are introducing the country of targeting because of the current debate over multilingualism in the U.S. and the prevalence of multilingual packaging. We believe this concept has great theoretical and managerial implications.

# Anticipating Consumption: The Impact of Expectations on Decision-Making for Healthy Products

Diane M. Phillips, Saint Joseph's University, USA
Jason Keith Phillips, West Chester University, USA
Nancy M. Childs, Saint Joseph's University, USA

Making a decision in the marketplace is rarely easy. Consumers are frequently faced with many conflicting pieces of information regarding a particular purchase. This often makes decisions difficult and confusing. The decision-making environment itself rarely offers clear alternatives in which there is one obvious "best" alternative. Consumers can, however, better anticipate consumption by creating a set of expectations that can be used as a benchmark, so to speak, against which actual consumption can be compared. The well documented expectation-disconfirmation paradigm has been used to better understand consumer decisions for a myriad of different types of products, including, for example, automobiles, cable television, and university courses (Mano and Oliver 1993; Oliver 1993; Oliver et al. 1997; Westbrook 1987; Westbrook and Oliver 1991). Research has also been done on how consumers form expectations about products that are more experiential in nature (cf., Wilson, et al. 1989; Klaaren 1994; Phillips 1996; Phillips, Olson, and Baumgartner 1995; Phillips and Baumgartner 2002).

The importance of making a more informed decision is especially important in situations in which consumers are making decisions about their own health and nutrition (Kahn and Luce 2003; Moorman 2002). In these kinds of situations, where the consequences of an uninformed decision can impact an individual's health, it is critical that consumer researchers and policy makers better understand how consumers anticipate consumption. Making decisions about one's own health is complicated by the fact that consumers sometimes need to wait a long time before they can reach the conclusion that a given diet or exercise regimen was "successful." The presence of healthier immune systems (from consumption of multivitamins) and stronger bones (from consumption of calcium) is difficult to discern. Further, the pursuit of good health through the prevention of chronic disease means that success is measured by endpoints that do not occur: avoidance of hypertension, osteoporosis, cardio vascular disease, and cancer, for example. The purpose of this study is to examine the importance of expectation formation for health-related products in which the product benefits are not immediately apparent.

### Study 1: Internally- vs. Externally-Derived Expectations

Study 1 is designed to examine the extent to which the formation of an initial expectation is important to the decision-making for healthy products. In the absence of obvious, tangible product results, we hypothesize that the initial formation of expectations will have

a very important impact on how consumers view the performance of the product. Because there are no tangible features and benefits of the product, consumers will be able to gain knowledge about the more intangible, experiential aspects of product consumption and, hopefully, use that information to help make a decision.

Participants were either given the chance to form their own expectations about a new product or were given written testimonials from other consumers about the product's positive or negative performance. Not surprisingly, for individuals who consume high quality products, we find that when they create their expectations from external information, they are more likely to have higher levels of satisfaction, purchase intention, and recommendation intention. The decision-making process is strong and positive, from the formation of the initial expectations, to the consumption of the product, through to the decision about behavioral intentions.

The more interesting effects happen in the moderate and low quality product conditions. Compared to individuals who received testimonials, the individuals who created their own expectations formed impressions of the product that were, in general, more positive. Further, this tendency to form more positive impressions with self-generated expectations holds up even when the "objective" evidence of the performance of the product is taken into account. These self-generated expectations can actually result in less optimal decisions for consumers. Specifically, despite the fact that the products performed poorly, these consumers report higher levels of affect, satisfaction, purchase intention, and recommendation intention.

## Study 2: Expectations Derived from Scientific Reports

In Study 2, we sought to further clarify these findings by examining the extent to which information provided by an external, official source would be judged by individuals as providing useful information about the performance of a health-related product. The manipulations were designed to simulate news reports and other scientific information to which consumers may be exposed. Consumers are often exposed to news reports about the effectiveness of a vitamin, drug, or procedure. We also examined the extent to which approaching the decision-making task from a more functional frame of mind would differ from approaching it from a more experiential mindset.

We presented consumers with credible information about a new product in the form of a published news report on a scientific study. We found, not surprisingly, that when consumers approach the task from a cognitive, logical framework, their expectations about the likely performance of the product increase as the success of the scientific study in the news report increases. However, when consumers approach the task from a more affective, experiential framework, the formation of their expectations follows a slightly different pattern. Here, as the success of the scientific study in the news reports increases, the strength of a consumer's expectations about the likely performance of the product increases but does not peak with the case of the strongest scientific outcome. In fact, paradoxically, expectations decrease with the news report that discusses the best performing product. These expectations then impact affect, satisfaction, and behavioral intentions.

Public policy makers oftentimes work under that assumption that consumers make decisions about health-related products on logical, rational grounds. However, consumer research has found that this is not always the case (cf., Kahn and Luce 2003; Moorman 2002). The results of this study shed further light on health-related decision making for consumers who approach the task from a more affective or experiential framework. These consumers form very different expectations about how a product will likely perform and these expectations impact the rest of the decision making sequence from assessments of satisfaction through behavioral intentions.

# Consider the Consequences: The Effect of Consequence Information on Consumer Choice of Snack Foods

Andrew Wilson, Florida State University, USA
Gavin Fox, Florida State University, USA

## Abstract

This paper examines how the inclusion of consequence information in nutrition labeling affects food choice. A sample of 98 undergraduates participated in an experiment designed to assess the value of consequence information. Consumption goals and presence of consequence information were manipulated experimentally. Overall health goals were measured as an additional predictor. Preliminary results indicate that consequence information is capable of spurring healthier food selections, but that this effect is contingent upon the level of health goal and the specifics of the snacking situation. Implications for academics, brand managers, and government policy makers are discussed.

## Conceptualization

The obesity rate is rising at an alarming rate in the United States. The rate among American adults doubled between 1980 and 2000. During the same time, the rate doubled among children and tripled among adolescents. This rapid rise in obesity rates has profound implications for human health as well as the economy (US Department of Health and Human Services, 2005a). One response to this crisis has been to provide consumers with information that aids choice. The Nutrition Labeling and Education Act (NLEA) of 1990 led to a number of studies of use of nutrition information and consumer behavior. An overall conclusion of this research stream is that for many, nutrition labels do not have a strong affect on food choice (Wansink and Huckabee 2005). If labels can help consumers make better choices, new approaches are called for.

This research examines one such opportunity-the addition of consequence information to labels. Specifically, we investigate whether consumer choice is affected by inclusion of weight gain and physical activity consequence information. Food labels required under NLEA provide nutritional information, including quantitative facts about calories, macro- and micro-nutrients. These are relatively abstract concepts. It is thought that the provision of consequence information will ease the consumer's information processing burden by providing a direct comparator closely linked to consumers' goals.

## Self-Regulation

Self-regulation refers to the mental processes used to control one's functions, states, and inner processes, that when combined, transform the inner animal nature into a civilized human being (Vohs and Baumeister 2004). Several approaches have been used in the study self-regulation. The classical theory of Carver and colleagues (e.g., Carver and Scheier 1981; Carver and Scheier 1990) is most applicable to this research.

## Cybernetic Control and Feedback Loops

Carver's (2004) model of self-regulation is based upon an analogy of cybernetic control. Like a thermostat, cybernetic control switches actions on(off) in response to progress towards (away from) a goal state (Carver 2004). Cybernetic control operates in a four step cycle: 1) input function, 2) comparator, 3) output function, and 4) effect on environment. The input function (perception) brings information into the system about the state of the environment. In the present research, this includes nutritional information about the attributes of snack foods under consideration. A comparator is a mechanism that calculates a comparison between the input and the relevant goal or standard. If the comparison yields a discrepancy, then the output function (behavior) changes. In this research, it is expected that the projected consequences of eating a particular snack food are compared to the chooser's goal state.

Consequence information should enable choices that are more consistent with the chooser's goals. Using the standard NLEA nutrition facts panel, one must process relatively abstract concepts, such as number of calories and fat grams, to form a judgment of whether a particular snack choice supports one's goals. When straightforward consequence information is provided, a more direct comparison is possible. For example, if the amount of associated weight gain or the amount of exercise required to expend the calories contained were presented, a comparison to the goal state becomes straightforward. Finally, if the behavior change is effective, then some change results in the environment, which is detected in the next cycle of the input function. This part of the process falls outside the context of this study.

People possess both chronic and situational goals, which may at times conflict. For example, a person may hold the chronic goal of maintaining a healthy weight, but in a given situation have the goal of rewarding him or herself with an indulgent snack. Applying the analogy of cybernetic control to this situation, we can imagine multiple conflicting feedback loops in operation. Under conditions of such goal conflict, consequence information has the potential to enable the feedback loop associated with the chronic goal of weight loss/maintenance to become more dominant in the resolution of goal conflict.

## Method

### Participants

Participants were 98 undergraduate business students at a major southeastern university. Students were recruited from business classes and were awarded extra credit for participation.

### Procedure

The computer mediated experiment was a mixed design with one factor (consequence information; present or absent) manipulated between subjects, and another factor (consumption goal; hedonic or utilitarian) manipulated within subjects. Order of presentation of the choice tasks, content of the choice tasks, and screen position of the choices were counterbalanced, resulting in 16 versions of the materials to which participants were randomly assigned. Following a practice choice task, participants were asked to imagine themselves in a

scenario seeking a snack to either satisfy hunger (utilitarian goal) or to reward themselves for studying hard (hedonic goal). Prices of the two choices were not shown, but were reported to be equal, to avoid potentially confounding effects of price sensitivity.

All participants were shown package images and NLEA nutrition facts panels. Consequence information was manipulated by the addition of the following example text to the NLEA label:

*Nutrition Consequences*: If you do not use up the calories contained in this snack, and you eat a similar snack daily, you will gain 1 pound every 21 days.

To use up the calories in this snack, you need to walk or jog about 1.7 miles.

Participants were asked to put themselves in the scenarios and select between two snacks. One snack was higher in calories than other. The lower calorie option is assumed to be more consistent with the chronic goal of weight loss/maintenance.

### Major Findings

Cross-tabulation was used to evaluate the effects of consequence information and nutritional goals on product choice under each of two situational goals. Initial findings suggest that under conditions of a situational hedonic consumption goal, for consumers who possess a chronic goal of weight loss/maintenance, the addition of consequence information leads to selections more consistent with the chronic goal than the NLEA nutrition facts panel alone ($?^2$=2.746, $p$=.097). No other significant effects were found. If these results are confirmed by further studies, this research will have important implications to public policy.

# How Media and Advertising Jointly Affect Ad Effectiveness

Jing Wang, University of Iowa, USA
Bobby Calder, Northwestern University, USA

Advertising that appears in a media context can be affected by both consumers' experience with the media context and their experience with the ad itself. To date, the two issues have been studied separately. One line of research focuses on the media context effects and demonstrates that consumers' experience with the media context programs could affect ad effectiveness either positively or negatively. A second line of research studies consumers' experience with the ad itself and how that affects ad effectiveness. We look at both issues in our study and seek to show how consumers' experience with the media context interacts with their experience with the ad to affect an ads' ultimate effectiveness.

Many studies have looked at advertising context effects. Some of them show a positive effect (e.g., Anand and Sternthal 1992; Feltham and Arnold 1994) whereas others show a negative effect (e.g., Norris and Colman 1992; Soldow and Principe 1981). Rather than resolving the conflicting results, Wang and Calder (2006) propose a theory that predicts both a positive media context effect and a negative one. The authors argue that it is crucial to look at the relationship between the advertising and the media context that it's imbedded in. People come to media for its content and enjoy being transported into the media content. If the advertising is inserted in such a way that it is intrusive to consumers' media experience, a high level of media transportation leads to reduced ad effectiveness because of the ad intrusion. However, if advertising occurs without intruding on consumers' transportation experience with the media, this enjoyable experience enhances ad effectiveness. The authors also show that such transportation effects operate independently of another frequently studied construct—context involvement.

Consumers' experience with the ad itself could also affect ad effectiveness. Deighton, Romer, and McQueen (1989) find that more dramatic television commercials are processed differently from more argument oriented ones. More recently, Escalas (2004b) finds that narrative ad processing is positively correlated with brand attitudes and behavioral intentions. According to Escalas (2004a), a narratively structured ad increases ad effectiveness by connecting the ad to the self via narrative transportation.

In our research, we study both media context transportation and advertising transportation and examine how they jointly affect ad effectiveness. The study has a 2 (media context transportation: high vs. low) × 2 (advertising transportation: high vs. low) design. We manipulate both context transportation and advertising transportation by varying the narrative structure of each. Following Wang and Calder (2006), participants either read a story that has a linear chronological flow, or read another version of it where the chronological flow was broken. An ad for Chicago Tribune is inserted in the middle of the story at the climax for all participants.

The High Transportation Ad consists of three small cartoon pictures that together tell a story. The first picture shows a person lying on a couch, bored; the second picture features this person reading Chicago Tribune; and the third one shows the person enjoying a party. The three pictures are organized such that the antecedence and consequence of reading Chicago Tribune are clearly conveyed. In the Low Transportation Ad, we reordered the three pictures such that it started with the party picture, followed by the lying-on-the-couch picture and the reading-newspaper picture, in that order. We predict that disrupting the narrative flow of the story within the ad will reduce consumers' transportation experience with the advertising.

When transportation into the advertising was low, we replicated Wang and Calder's (2006) results. Participants who were highly transported into the media context had less favorable product attitude because the ad was perceived as intrusive. However, this negative media transportation effect on ad effectiveness disappeared when transportation into the advertising was high. Participants had equally favorable product attitude regardless of their media transportation experience.

Advertisers select popular media programs for their advertising. However, Wang and Calder (2006) showed that such placement could lead to reduced ad effectiveness. One way to offset the negative media transportation effect is to place advertising in a nonintrusive way (e.g., Study 1 in Wang and Calder 2006). Another is to improve the effectiveness of the ad itself. One way to achieve high ad effectiveness is to state the position in a narrative format so that consumers could be transported into the advertising. Such positive experience with the ad can compensate the negative media transportation effect on advertising.

# How Embarrassing: An Examination of the Sources of Consumer Embarrassment and the Role of Self-Awareness

Rishtee Kumar, Boston University, USA

Recognizing the discomfort that many consumers experience while purchasing seemingly day-to-day products, websites such as www.shopinprivate.com offer customers a safe-haven from embarrassment. Such retail channels allow consumers to avoid the stares, questions, and comments they anticipate from other shoppers as they make their purchase of socially embarrassing products. However, the effects of consumer embarrassment extend beyond the obvious class of products such as condoms and laxatives. In fact, embarrassment in the consumption context is manifested in many other ways, impacting a host of industries, such as online dating, a $473 million industry, the weight-loss industry weighing in at $65 billion, and the plus-size clothing industry, estimated at $32 billion. Considering the widespread impact of consumer embarrassment, it is imperative to understand the causes of consumer embarrassment and also address possible ways to mitigate embarrassment in hopes of improving consumption decisions.

Though there have been a limited number studies that examine specific aspects of embarrassment (Dahl et al 1998, 2001), marketing has yet to avail a comprehensive framework for understanding the dynamics of consumer embarrassment. Therefore, the goal of this paper is twofold- first, to examine the extent to which embarrassment, as identified in psychology literature, maps out onto the consumption context, and second, to identify and test the existence of factors that potentially affect consumer embarrassment. In study 1, an exploratory analysis reveals that the landscape of embarrassment in the consumption context might not entirely resemble that which was painted in psychology literature. Study 1 also serves to provide a better understanding of the situations in which consumers experience embarrassment and how they cope with it. Study 2 builds upon the findings of the first study to examine the effects of increased self-awareness on the purchase of socially embarrassing products.

In the extant psychology literature, authors have primarily reported the existence of two theoretical accounts of embarrassment- the social evaluation account (Miller and Leary, 1992; Miller, 1996) and the awkward interaction account (Parrott and Smith, 1991; Sabini et al, 2000; Silver et al, 1987). The former theoretical account posits that embarrassment is the result of a threat to one's desired social identity and belonging to a while the latter describes embarrassment as the result of a public disruption of a social performance. A third theoretical account, the loss of self-esteem account (Edelmann, 1987; Babcock, 1988), has received very little attention and appears to be somewhat discredited in psychology. According to this account, people feel embarrassed as a result of a disappointment with themselves, resulting in what researchers have dubbed a loss of situational self-esteem. This account holds that embarrassment might even be expressed privately, as people fail to act in accordance with their own standards.

The results of Study 1 (n=76), consisting of both scaled and open-ended items, indicate that in fact consumers have experienced all three forms of embarrassment in the consumption context. Surprisingly, although the psychology literature might have speculated otherwise, 77% of the survey respondents indicated experiencing a private embarrassment that might be best captured by the loss of self esteem account, with as many as 39% of all respondents stating that they had experienced this form of embarrassment somewhat frequently. In fact, 21% of all respondents indicated that this was the most commonly experienced form of embarrassment in a consumption context. Of the several examples of private embarrassment subjects provided were:

*"I felt embarrassed when buying embarrassing self-help books online from Amazon.com"*
*"I feel embarrassed when I try on a clothing that is a large size."*
*"I felt embarrassed in looking for singles online."*

The results also indicated that a desire to maintain one's social identity, consistent with the social evaluation account, was a source of consumer embarrassment for respondents, with 53% saying that they had experienced this form of embarrassment somewhat frequently and 23% agreeing that it was the most commonly experienced form of embarrassment in consumption situations. The following excerpts highlight the validity of the social evaluation account for embarrassment in the marketplace:

*"It's embarrassing to be seen shopping at a discount store like Marshalls or TJ Maxx. If I buy something from there I usually lie about where I got it."*
*"Buying condoms or 'feminine products' is embarrassing."*

Lastly, the awkward interaction account of embarrassment found a great deal of support, with 78% of respondents agreeing that they had experienced this form of embarrassment somewhat frequently, and 56% stating that it was the most common form of embarrassment in consumption situations. Participants provided examples including knocking over product displays and breaking products because they did not know how to properly use them.

The results of study 1 not only helped to create a guideline for understanding how embarrassment is manifested in the marketplace, but also provided help in shaping study 2. Existing literature suggests that several individual level differences have been known to impact

the effect of embarrassment. In one study, self-monitoring was shown to be positively correlated with the level of embarrassment experienced in certain situations. (Sabini et al., 2000) Building upon this research, study 2 chose to examine a closely related factor- self-awareness. In reexamining the open-ended responses from study 1, it appeared that among the most frequently mentioned embarrassing consumption situations were those involving the purchase of condoms and feminine hygiene products. A pretest consisting 20 day-to-day consumer goods confirmed that condoms and personal hygiene products were considered among the most embarrassing products.

Study 2 (n=76) was an exploratory investigation of the effects of primed self-awareness, consisting of a design in which subjects were asked to imagine shopping with a fictitious grocery list consisting of 6 neutral and 3 socially embarrassing products. Participants in the priming condition were given a self-awareness enhancing task that asked them to write twenty sentences beginning with "I am" and engage in a pronoun identification task, where all pronouns referred to the self (i.e. I, me). The remaining subjects were administered a distraction task. Subjects were then given a photograph and brief description of each item on the list, followed by six questions assessing their attitude toward the product and likelihood to use the product, if needed. Unfortunately, the results indicate that there were no significant differences in the attitudes toward the neutral or embarrassing products for primed and non-primed participants.

After answering questions regarding each of the 9 products, subjects were told that they could only select 6 products to purchase. Interestingly, there was a significant effect of primed self-awareness on the number of socially embarrassing products purchased, $F_{(1, 76)}=3.908$, $p<.05$. That is, although primed and nonprimed participants reported not having different attitudes toward the array of products, primed participants were more likely to remove socially embarrassing products from their shopping basket than nonprimed participants. Furthermore, a Chi-Square analysis corroborated that in fact, there was a difference in the proportion of embarrassing to non-embarrassing products chosen by primed and non-primed participants, $X^2=47.789$, $p<.01$. These results imply that although attitudes toward socially embarrassing products might not be affected by a state of heightened self-awareness, it might still impact purchase decisions. These findings are exploratory in nature and additional investigation would be useful in understanding what factors might moderate the impact of self-awareness on embarrassment, such as the ability to justify one's purchases.

# Product Failure and Warranty Purchase: Their Effects on Target-Specific Emotions and Attitude toward the Brand

Kiran Karande, Old Dominion University, USA
Mahesh Gopinath, Old Dominion University, USA

**Abstract**

This paper investigates the consumer affective responses to product failure as a result of making a decision to buy or not buy a warranty at the time of product purchase. Specifically, we present hypotheses about differences in consumers' emotional reactions to products failure, and consequently their attitude toward the brand, depending upon whether they have purchased product warranties. The hypotheses are derived by arguing that different types of counterfactual thinking and attributions are invoked under conditions of product failure or no product failure, and the purchase of a warranty or no warranty purchase by the consumer. Theoretical and managerial implications are briefly discussed.

**Introduction**

Approximately 15 billion dollars are spent by U.S. consumers each year on purchase of warranties. It is the contention of this research that consumers' emotional reactions to products failure, and consequently their attitude toward the brand differ depending upon whether they have purchased product warranties. The hypotheses are derived by arguing that different types of counterfactual thinking and attributions are invoked under conditions of product failure or no product failure, and the purchase or no purchase of a warranty by the consumer.

Counterfactual thinking refers to a consumer imagining alternatives to past outcomes. These are thoughts of what might have been if he/she had done something different. Counterfactual thoughts are typically generated in response to a conscious decision of the individual. In our case, the conscious decision is to buy or not buy the warranty coverage offered by the retailer when purchasing a consumer durable (e.g., a computer). When counterfactuals focus on outcomes that are better than the actual outcomes, they are referred to as upward counterfactuals; those focusing on outcomes that are worse than actual outcomes are referred to as downward counterfactuals. The effects of counterfactual thinking are rooted in one of the two underlying mechanisms- contrast effects and causal interference (Roese 2000). Contrast effects occur when a judgment becomes more extreme through juxtaposition of some anchor or standard. In a contrast effect, a factual outcome may become worse if a more desirable outcome alternative is salient. Counter factual thinking may also imply causal inferences that may have implications independent of contrast effects.

Counterfactual thinking has consequences for experience of a range of emotions such as regret, and social ascriptions such as blame (Byrne, Segura, Culhane, Tasso & Berrocal, 2000). Counterfactual thoughts are also generated by attributions of product failure, including, self ("I should have bought service plan"–same as counter factual), product itself ("Its because of this stupid brand Sony"- this could possibly lead to counter factual again–"I should have bought Cannon instead") or attributions about circumstances ("it is because of the way I used the camera"–this also could lead to counter factuals–"I should not have taken this camera for my hiking trip when it rained").

## Contribution

There has been no prior work looking at counterfactual attributions leading to how decisions are made subsequently and specifically in the context of service plans.

We apply the learning from a review of counterfactual literature and appraisal theories to the decision to buy or not to buy an extended warranty, and its effect on target specific emotions and attitude toward the brand. Based on this several hypotheses are proposed.

This research will contribute to the theoretical understanding of the counterfactual thinking process in an extended warranty situation, and develop a framework to predict emotions experienced under different situations, and subsequently their attitude toward the brand. The findings of this study will be relevant as conditions under which positive and negative target-specific emotions sand attitude toward the brand are generated will be identified.

## Hypotheses

*When the product fails,*
H1a: Those who bought the warranty will feel positive self-directed emotions (e.g., pride).
H1b: Those who did *not* buy the warranty will feel negative self-directed emotions (e.g., regret).
H1c: Those who bought the warranty will feel mixed emotions of relief and mild irritation toward the brand.
H1d: Those who did not buy the warranty will feel intense negative emotions toward the brand (e.g., anger and bitterness).

*If the product does not fail*
H2a: Those who bought the warranty will feel negative self-directed emotions (e.g., embarrassment and humiliation).
H2b: Those who did <u>not</u> buy the warranty would feel positive self-directed emotions (e.g., pride).
H2c: Those who bought the warranty will feel negative emotions of feeling deceived toward the brand.
H2d: Those who did <u>not</u> buy the warranty will feel positive emotions toward the brand (e.g., joy and contentment).

*Other hypotheses*
H3: The attitude toward the brand will be lower among subjects for whom product failed than among those for whom it did not.
H4: The decline in attitude toward the brand between subjects for whom the product failed (versus did not fail) is greater for those not buying the extended warranty than for those not buying it.

## Method

The hypotheses were tested using a 2 (warranty or no warranty) X 2 (product failure or no failure) between subjects on-line scenario-based experiment involving the purchase of a computer. The scenario required each subject to choose between a computer with no warranty and a computer with a warranty at a given price. This price was determined using pretests to find the indifference point for the purchase of a warranty for a $599 computer. A control condition that does not mention the availability of a warranty was also administered by offering subjects a choice between computer with a large screen for $ 699 and a small screen computer with a small screen for $ 599. In subsequent screens they were randomly assigned to one of the two conditions of product failure or no product failure. Counter factual thoughts, cognitive elaborations, anticipatory emotions, attributions, and target related emotions experienced and attitudes towards warranty, and brand were measured. Analysis show support for our hypotheses.

# The Impact of Brand Relatedness on Negative Spillover Effects in Brand Portfolios

Jing Lei, University of Ontario Institute of Technology, Canada
Niraj Dawar, University of Western Ontario, Canada
Jos Lemmink, Maastricht University, The Netherlands

Complex brand portfolios with multiple brands, sub-brands, and endorsed-brands are increasingly common in the marketplace. Marketers often cultivate relatedness/linkages between brands in the portfolio through a variety of marketing means including common brand names and logos, similar advertising, and promotion of complementary usage to gain marketing efficiency. However, relatedness also makes brands subject to "spillover" in which external information (e.g., negative news) about a brand can change evaluations of related brands that are not directly implicated. The purpose of this research is to investigate the impact of brand relatedness on such spillover effects.

Prior research has investigated the spillover between extension products and the parent brand (e.g., Roedder John et al. 1998) and between competing brands in a product category (Roehm and Tybout 2006). These studies show that the strength of linkages between brands is a good predictor of the extent of spillover between them. However, the linkages can be characterized by more than just strength. Based on network association theory, a process explanation for the strength of linkages suggests that linkages between information nodes are "pointers" whose properties include strength as well as directionality (Collins and Loftus 1975). But the impact of the directed nature of brand relatedness has not been examined in previous spillover research. In a brand portfolio (e.g., Kellogg's), sub-brands (e.g., Special K and Corn Flakes) are associated via a large number of linkages (e.g., common usage, logo, users' experience), and the frequency and direction of processing these linkages can influence the directional strength of association between sub-brands. Thus, we propose that spillover between sub-brands is a function of not only the strength but also the directionality of association between sub-brands. In particular, the spillover between sub-brands A and B will be asymmetric when the strength of association between them is asymmetric.

If asymmetric strength of association indeed leads to asymmetric spillover effects, a related question is, what factors influence the directionality of association strength, and under what conditions the directional strength of association can be changed. Two competing theories may explain the directionality of brand associations. First, network association theory indicates that, when judging the relatedness of brand A *to* brand B, brand A is primed and activated, and this activation spreads to brand B via linkages between them. The level of activation arrived at brand B guides consumers to judge the strength of A-to-B association (Ulhaque and Bahn 1986). The "fan effect" in network association theory indicates that, given a fixed level of activation at a brand node, the more links it radiates, the less activation emanates toward any one link. Thus, when brand A has more associative linkages emanating from it than does brand B, the strength of A-to-B association is weaker than that of B-to-A association. Alternatively, the contrast model (e.g., Tversky 1977; Tversky and Gati 1978) indicates that the perceived similarity between brand A and brand B is a function of their common and distinctive features. When judging the similarity of brand A *to* brand B, brand A's features are weighted more heavily than brand B's, and therefore the distinctive features of brand A detract more from similarity than do distinctive features of brand B. Thus, when brand A (e.g., Coca-Cola) has more distinctive features than brand B (e.g., Shasta Cola), consumers will perceive less similarity of brand A to brand B than B to A. In summary, in a brand portfolio, if sub-brand A is more salient and therefore has more associations than sub-brand B, both network association theory and the contrast model predict that sub-brand A is perceived less related to sub-brand B than sub-brand B to A.

However, these two theories may arrive at different predictions when investigating factors that influence the directional strength of association between brands. First, network association theory predicts that the strength of association from brand A to brand B will be strengthened when priming any associations of brand A. This is because priming increases the level of activation at brand A and therefore the level of activation arrived at brand B. However, the contrast model predicts that the strength of association from brand A to brand B will be strengthened when priming common associations of brand A, but it will be weakened when priming unique associations of brand A. Thus we propose two competing hypotheses for the impact of priming brand associations on the directional strength of association.

The above proposed effects were tested in two experiments. In experiment 1, we investigated the impact of brand relatedness on spillover using three sub-brands from an existing brand portfolio. We measured the directional strength of association using a computer-based sequential priming program, primed negative information at each brand, and measured the extent of spillover at related brands. In experiment 2, we investigated the impact of the number and salience of brand associations on the directional strength of association. In a 2 (number of associations: more vs. few) X 3 (priming: none, prime common associations, prime unique associations) factorial design, we measured the directional strength of association between fictitious brands and then replicated the design with real brands.

The results of experiment 1 suggest that the spillover between sub-brand A and B is asymmetric when the strength of association between them is asymmetric. Managers need to be aware of this asymmetric spillover to design efficient remedy strategies. The results of experiment 2 show that the strength of association from sub-brand A with more associations to sub-brand B with fewer associations is weaker than that of sub-brand B to A. Furthermore, the directional strength of association from sub-brand A to sub-brand B will be strengthened when brand associations of A, regardless of common or unique associations, are primed. This indicates that, when a sub-brand is affected by negative information, it may not be wise to prime the distinctive associations of that brand in the hope of limiting spillover. Instead, advertising emphasis should shift to underscore the positive equity of the parent brand and/or other sub-brands, while advertising of the affected brand is halted.

# Self and Social Signaling Explanations for Consumption of CSR-Associated Products

Aronte Bennett, New York University, USA

Amitav Chakravarti, New York University, USA

Consumers frequently encounter, and buy, products that have a corporate social responsibility (CSR) association (e.g., cell phones that promise a portion of proceeds to cancer research). It is well documented that products with a CSR-association are extremely popular among consumers; however, very little is known about the motivations underlying a consumer's decision to purchase these products. To date, the research on CSR-associated purchase decisions has focused on antecedents that influence evaluations and purchase decisions (Brown and Dacin 1997, Strahilevitz and Myers 1998, Sen and Bhattacharya 2001) but has failed to consider specific motivations that drive the decision to purchase a CSR-associated product. We address this gap in the literature through several studies.

Across several experiments we find that consumers like CSR-associated products for two distinct reasons. First, consumers like the fact that these products send out highly visible, *social signals* regarding their benevolence. We find that a consumer's likelihood of adopting a CSR-associated product varies positively with the product's social signaling potential, even when that signaling potential is subtly cued. Second, we also find that consumers like the more private, *self-signaling* potential associated with the purchase of these products, even when a strong social signal is absent. In sum, we find that the valuation of a CSR-associated product is jointly determined by its social and self-signaling potential.

Signaling refers to the act of conveying information about oneself in an implicit fashion, by engaging in behaviors that reveal one's traits and preferences to observers. Thus many behaviors are often valued for their ability to send out signals to observers, without requiring explicitly communication. Social signaling has been implicated in explaining several phenomena. In the marketing literature, it has been suggested that brands signal product quality (Erdem, Swait and Valenzuela 2006), and that a consumer's product choice sends social signals regarding their personality attributes (Holt 1995). Similarly, Glazer and Konrad (1996) examine the role of social signals in the realm of charitable behavior. Their model implies that charitable donations are observable signals, and consumers are more willing to donate when there is an increased potential for signaling. This implies that purchasing CSR-associated products, a specific method of making a charitable donation, should also serve as a social signal. We therefore hypothesize that the likelihood of purchase of a CSR-associated product would be positively related to the social signaling potential of the product.

Besides sending out social signals to observers, behaviors also have the capacity to *self-signal* to the individual in question. The self-signaling capacity of behaviors, although relatively under researched, was elegantly demonstrated by Quattrone and Tversky (1984). Quattrone and Tversky (1984) showed that people often engage in behaviors in order to signal to themselves that they possess a particular desirable trait, even when there are no social incentives. Thus, in addition to serving as social signals, we posit that CSR-associated products also allow for self-signaling. We hypothesize that the purchase likelihood of a CSR-associated product should be positively related to its ability to provide a positive self-signal. These two hypotheses were investigated in the studies described below.

In study 1, participants were randomly assigned to between subject conditions, presented with advertisements for a target product that manipulated perceptions of the product's social and self-signaling potential, and asked to indicate their purchase likelihood. Social signaling potential was manipulated by varying the suggested location of the product (private vs. public living spaces). The CSR-association was manipulated by the presence-absence of a CSR tag. The self-signaling potential was manipulated by the presence-absence of a reminder about how the purchase of the CSR-associated product would remind them of their kind-heartedness.

Our results indicate that when the products did not have a CSR association they were evaluated equally regardless of social signaling potential. However, when the products had a CSR-association, not only was the product evaluated more favorably in the high (versus low) social signaling potential condition, but also the low social signaling potential condition actually lead to lower evaluations than the control, no CSR association conditions. Interestingly, when the reminder was added to the CSR association conditions, this difference disappeared.

We also did a follow-up study, in which we manipulated the social signaling potential of the same product by describing it as being especially helpful either for social (entertaining friends) or for personal (indulging oneself) occasions. The results support our previous findings.

Our findings suggest that consumers generally reward CSR-associated products for their ability to serve as social signals and are willing to punish similar CSR-associated products that do not offer the same signaling potential. However, if consumers are provided with self-signals, the difference between high and low social signaling potential products is negated.

In sum, we address a gap in the literature on corporate social responsibility by showing that the valuation of a CSR-associated product is jointly determined by its social and self-signaling potential. Our findings also extend the literature on signaling by offering an addition to the relatively modest extant stream of research related to self-signaling.

# Consumers' Elaboration of Really-New-Product Messages
David Alexander, Duke University, USA

For consumers, really new products offer exciting new benefits but are also accompanied by uncertainty and behavior change (Hoeffler 2003). Recent research suggests that because of the extreme benefits and constraints characterizing really new products, firms would do better positioning their really new products as more incremental innovations (Alexander, Lynch, and Wang, forthcoming). Yet, really new products can convey the unexpectedness that allows a product idea to stick with consumers (Heath and Heath 2007) beyond the initial buzz. It seems that by downplaying a product's newness, marketers may lose a significant advantage their products have when consumers initially learn about new products.

The current research examines how a product's psychological newness affects consumers' elaboration of new product messages. A dual-mediator model (illustrated in Figure 1) is proposed wherein psychological newness affects new product message content elaboration indirectly by affecting consumers' curiosity and skepticism about the new product message's content. Psychologically newer products increase consumers' curiosity (P1) through their unexpected and original benefits and features. As product curiosity increases, consumers' elaboration of the product message (P4) is also expected to increase. Product newness also increases consumers' skepticism (P2) about the product's ability to deliver the claimed benefits. As message claim skepticism increases, consumers' curiosity about the new product (P3) and the elaboration of the product message (P5) decrease because the value (and validity) of the message's content is questioned. Depending on the product and the particular context, product newness can lead to an increase, decrease, or have no overall effect on elaboration of message content.

Three studies are planned to validate the proposed model and to examine contexts in which the relationship between a product's psychological newness and message claim skepticism (P2) is moderated. By identifying contexts in which psychological newness' effect on skepticism is dampened, marketers can increase message elaboration.

Study 1 examines how marketers may lower consumers' message claim skepticism by avoiding marketing hyperbole and providing more balanced product messages that acknowledge the potential costs/constraints inherent in new products. The extreme costs characterizing really new products likely reinforce consumers' efforts to resist marketers' persuasive messages, increasing consumers' skepticism towards message claims more than do the more moderate costs of incrementally new products. Balanced product messages,

because they are atypical, are less likely to be viewed as outright persuasion attempts and so may generate less message claim skepticism and increase message elaboration.

Participants (drawn from a national, Internet-based panel) will be shown a set of new cell phone services using either balanced or biased descriptions. Their perceptions of product newness, product curiosity, and message claim skepticism are then measured and participants are given the opportunity to examine more information about each service as an indicator of message elaboration. Product newness is expected to increase participant's skepticism less and increase message elaboration more for balanced vs. biased messages.

Study 2 investigates how marketers may lower consumers' message claim skepticism by reducing the social distance between the source and recipient of a new product message. For consumers encountering a new product, the compatibility of that product with their existing social system can have a significant effect on their new product adoption decision (Rogers 2003). Receiving new product information through word-of-mouth (WOM) from a close friend can be valuable because information about its compatibility with the recipient's social system may be conveyed along with product details reducing skepticism about those details.

Participants (from a small Midwestern university) will be shown product messages said to originate from a close friend or a marketer for a set of either really new or incrementally new products. Their thoughts while viewing the product messages will be collected for coding for message elaboration. Their perceptions of product newness, product curiosity, and message claim skepticism are then measured. After a filler task, participants are asked to recall the information in the message for each new product as another measure of message elaboration. Product newness is expected to increase participant's skepticism less and increase message elaboration more when the message originates from a close friend than when it originates with a marketer.

Study 3 investigates how changes in consumers' time frame for adopting new products affect their perceptions of the product and their skepticism about message claims. When consumers' expect to buy a product in the distant future they likely focus on the product's potential benefits while underweighting the potential costs and constraints of its adoption (Trope and Liberman 2003). Consumers encountering messages for a really new product likely see its extreme benefits as more feasible when adoption will occur in the distant rather than near future, reducing message claim skepticism. Procedures for Study 3 are the same as those for Study 2 except that participants are shown a set of print ad mock-ups rather than new product messages from different sources. Participants are told to look at the ads expecting that they would purchase the products in the ad in either one year or one day. Product newness is expected to increase participant's skepticism less and increase message elaboration more when the time frame to new product adoption is temporally distant vs. temporally near.

The extreme benefits and costs characterizing really new products create a challenge for marketers—maximize the advantages derived from the benefits while minimizing the disadvantages resulting from the costs. Three planned studies are expected to validate the proposed curiosity/skepticism framework for predicting the effect of a product's psychological newness on consumers' elaboration of new product information while also identifying contexts where the link between a product's psychological newness and message claim skepticism is moderated. These results would provide new product marketers important new insights into how consumers initially learn about their products and how a product's psychological newness can be used to increase that learning.

# The Cross-Cultural Effect of Trust on Subjective Well-Being

Dante Pirouz, University of California, Irvine, USA

Trust is an extremely important element of human social behavior and is critical to the development of economically stable civil societies. At the heart of all social, institutional, market and financial transactions is the level of trust that people perceive of their partners. This sense of trust is predicated on a number of antecedents found in common place, daily interactions. The level of trust found within a society would assumedly have a significant effect on the level of subjective well-being in the society. Subjective well-being (SWB) is defined as a field of analytical study that attempts to understand how positively or negatively people evaluate their lives (Diener, Suh, and Oishi 1997). Researchers try to understand both the negative set of emotions that people experience (i.e. depression, compulsion) and the positive ones (i.e. joy, happiness, satisfaction) in order to measure the relative ratio between the two emotional poles.

This study investigates the relationship between trust and subjective well-being in a cross-cultural context. This is based on a general equilibrium growth model by Zak and Knack (2001) which states that as the level of trust varies among countries there is a correlation with wealth and prosperity for that country. There are large differences between countries in their propensity to trust others. This trust is believed to allow for lower transaction costs among agents. In addition, it is believed that high trust societies may be able to devote more resources to productive activities versus low trust societies. The model developed by Zak and Knack predicts that trust may be positively correlated to the level of SWB across-cultural groups or countries.

This study will look at the relationship between trust and subjective well-being, or life satisfaction. This impact is analyzed, controlling for other variables such as income, savings, freedom of choice and age in order to better understand how the relationship between trust and SWB is moderated by these variables. The study seeks to look at the effect of trust on well-being or, more specifically, life satisfaction and the moderating effects of income, family savings, freedom of choice and age. We are including these additional independent variables in order to rule out any other explanations for the effect of trust on life satisfaction.

The data used is from the World Values Surveys (WVS) (Inglehart et al. 2004). The WVS is administered by a network of social scientists in countries around the world allowing for analysis of cross-cultural differences across countries and time. The survey was conducted in 82 countries and was collected in 4 waves: 1990, 1995, 2000 and 2005. This study uses data collected in 1990, 1995 and 2000. The sample size in each country is at least 1000 subjects.

Trust is defined by the variable "Most people can be trusted" which is similar to the variables used by Zak and Knack. The dependent variable for this study is "Life satisfaction" which is ordinal. Additional variables include scale of income, family savings, freedom of choice and age. These additional variables were selected because we would like to control for these to see if the effect of trust is still significant on life satisfaction even after controlling for income, freedom, age, and savings. Analysis of the data was conducted using regression and partial least squares (PLS) in order to compare the results.

### Results

The model in this paper describes a relationship between the overall feeling of trust and the sense of life satisfaction held by the citizens of a particular country. This study did find support for the hypothesis that a significant relationship between levels of trust in a population and the overall life satisfaction or subjective well-being exists. This model demonstrates that variables other than income and savings have an important impact on subjective well-being. The feeling of trust is a cognitive variable that has a significant impact on how happy people feel. This indicates that there may be other important cognitive factors that can affect happiness and that objective measures of income and socio-economic class are not always indicative of the factors that can moderate overall life satisfaction.

# The Subjective Well-Being of Buying: A Grounded Theory Analysis of Habitual Acts of Consumption

Dante Pirouz, University of California, Irvine, USA

People often experience a variety of emotional states, from happiness or excitement to sadness or depression when engaged in consumption activities such as shopping. These emotions are often directly tied to the ***process*** of consumption, for example the act of acquiring, storing, giving or throwing away products, rather than emanating from the consumption of the product itself. Acts of consumption, for the purposes of this paper, are defined as the search for, selection of, and the disposal of goods and services for the purpose of consuming versus the actual consumption of the product itself.

Subjective well-being (SWB) is a field of analytical study that attempts to understand how people evaluate their lives (Diener, Suh, and Oishi 1997). Researchers try to understand both the negative set of emotions that people experience (i.e. depression, compulsion) and the positive ones (i.e. joy, happiness, satisfaction) in order to measure the relative ratio between the two emotional poles. Many forms of consumption seem to have a significant effect on overall SWB. It would seem reasonable that the act of consumption could also have an impact on levels of SWB for individuals who are particularly attached to these acts such as shopping, browsing, purchasing, consuming, collecting and dispensing with.

This paper qualitatively examines the process of consumption in these various forms, and how habitual and hyperconsumption behavior impacts overall SWB. Particular interest is placed on analyzing the emotions, preferences, and the storage and dispensation habits tied to consumption. I hope to better understand how consumption increases and/or depresses SWB. The research questions investigated are:

What are the addictive qualities of shopping?
What drives people's decision making when they engage in hyperconsumption or compulsive consumption of products?
Why do people hoard goods? Why do people packrat?
What are the emotions associated with shopping?
How do people calculate values on things they desire, things they buy and things the keep or discard?
What conflicts arise from hyperconsumption?
What are the social contexts surrounding consumption and hyperconsumption?
Are there gender differences in how shopping, prices, hyperconsumption and hoarding are viewed?
What are the earliest experiences that influence consumption behavior?

What is unique in this study is that I develop a theoretical framework and a typology of how consumption impacts SWB.

Habitual behavior is often associated with addiction to various substances including alcohol, nicotine, cocaine, heroin, and marijuana and is a heavily researched area in the medical, economics, biochemistry, psychology and marketing literature (Becker and Murphy 1988; Bernheim and Rangel 2002; Carter and Tiffany 1999; Eisch and Mandyam 2004; Hassay and Smith 1996; Miyata and Yanagita 2001; Potenza et al. 2003; Stein et al. 1998; Ward and Hudson 1999; Wills, Pierce, and Evans 1996). More recent studies have looked into new areas of addictive or habitual behaviors that have deep emotional components for the user. Such new areas include, for example internet shopping, collecting and hoarding including trying to understand the neural substrates of addictive behavior (Anderson, Damasio, and

Damasio 2005; Belk, Ger, and Askegaard 2003; Frost and Hartl 1996; Hassay and Smith 1996; Maier 2004; Potenza et al. 2003; Reith 2004; Robinson and Berridge 1993; Young 2004).

Addictions often lead to out of control behaviors such as theft and lying or even more extreme circumstances such as violence and death. Compulsive buying may be similar to other types of addictive or compulsive consumption behaviors such as alcoholism, drug abuse, eating disorders and compulsive gambling in that it leads to a repeated behavior with detrimental outcomes (Hirschman 1992). O'Guinn and Faber define compulsive consumption as an uncontrollable impulse or desire to "obtain, use, or experience a feeling, substance, or activity that leads an individual to repetitively engage in a behavior that will ultimately cause harm to the individual and/or others" (O'Guinn and Faber 1989). Faber and colleagues analyzed self reported mood states for compulsive buyers and hypothesized that compulsive shopping may be a way of self medicating for depression and negative affect. The study found that compulsive buyers felt more extreme mood states and a wide array of mood states, particularly negative ones, before going shopping (Faber and Christenson 1996). It is believed that addictive behaviors like consumption may be a "dependent state acquired over time by a predisposed person in an attempt to relieve a chronic stress condition" (Gupta and Derevensky 1998; Jacobs, Marston, and Singer 1985).

This study is focused on understanding the relationship between addictive behavior patterns related to the acts of buying, storing and discarding, along with the emotional side affects of these activities. Structured long interviews were conducted with consumers on the topic of their consumption habits. This study used grounded theory to systematically analyze the data (Strauss and Corbin 1998). Grounded theory was used due to its suitability in generating theoretical insights from in-depth interviews (Venkatesh, Chen, and Gonzalez 2005). All data was put into a textual format in order to facilitate the coding process. Code memos were generated during and after the open coding process in order to document and identify some of the various concepts, categories, properties and dimensions emerging from the data.

In this study, several themes related to the emotionality of habitual shopping behavior emerge. The theoretical model developed out of the categories generated from the grounded theory process analyzes the impact of consumption on SWB. The model isolates the stages related to the acquisition and disposal stages of consumption. It shows categories of mental state, conflict, value, action and duration as the key variables that impact each of the consumption stages: searching, buying, storing and disposing.

# Consumers' Reactions to Acquisitions of Socially Responsible Companies

Eleni Zoi Papavasileiou, Boston University, USA,
Scott D. Swain, Boston University, USA,
C.B. Bhattacharya, Boston University, USA

Increasingly, multinational companies are acquiring smaller, socially responsible companies that have loyal customer bases and attractive corporate images (Ben & Jerry's by Unilever, Body Shop by L'Oreal, Stonyfield by Danone). At the market level, these acquisitions are widely discussed by analysts in terms of operational and cultural fit between the two organizations (e.g., *Business Week,* March 17, 2006). However, from an academic perspective, we do not yet have a good understanding of whether and how consumers react towards two companies after such an acquisition.

## Conceptualization

Consistent with the literature that examines consumer-company relationships (Bhattacharya and Sen 2003), we focus on an acquisition's consequences for consumer-company identification (C-C), as identification has been shown to be a key psychological substrate for relational consumer behaviors such as loyalty and advocacy and ultimately, market value. Based on research in acquisitions (Datta et al. 2001), consumer perceptions of company behavior (Niedrich and Swain 2003), CSR (Bhattacharya and Sen 2001), and our own focus group findings, we propose that the impact of acquisitions on C-C identification is a function of three factors: (1) the CSR profiles of the acquiring and the acquired companies, (2) consumers' attributions regarding the companies' CSR policies, and (3) consumers' Social Value Orientation (SVO).

*CSR Profile and Consumer Attributions*. Sen and Bhattacharya (2001) suggest that the information consumers receive about CSR policies influences C-C identification. However, Du, Bhattacharya, and Sen (2006) suggest that awareness of CSR activities does not necessarily lead to favorability. Rather, favorability depends on the influence of consumer attributions about why a company follows CSR policies. These attributions can be extrinsic, where the company is believed to be primarily concerned with increasing its own welfare, and intrinsic, where the company is believed to be primarily concerned with fulfilling its obligations to society (Batson 1998). Thus, we propose that the relationship between companies' CSR profiles and C-C identification is moderated to the extent that consumers make intrinsic attributions, while extrinsic attributions are not expected to have an effect.

*The Role of SVO*. According to SVO theory, prosocial individuals tend to define social dilemmas as questions of morality, where people can make good or bad choices, whereas proselfs tend to perceive social dilemmas as questions of intelligence, where people can make strong or weak decisions (Van Lange and Kuhlman 1994). Thus, prosocials can perceive the acquisition as a "sellout" by the acquired company or as an opportunity to do more societal good. Moreover, Batson (1987) suggests that proselfs may also identify with the socially responsible acquired company, as long as doing so serves their egoistic motivations. Applied to acquisitions, this suggests that proselfs are less likely to make nuanced judgments about the conditions of an acquisition. Accordingly, while we generally expect SVO to operate as a second order moderator (i.e., SVO moderates the effect of attributions, which moderate the effect of CSR profiles on C-C identification), we desist from directional predictions.

## Methodology

We used a 2 (acquiring company CSR profile: low, high) x 2(acquired company profile: product-focused, CSR-focused) between-subjects experimental design, with 184 college students participating. The experiment was conducted in three phases. First, we measured participants' SVO using the nine-item Decomposed Games Instrument (Cremer and Van Vust 1999). Items in this instrument require a participant to choose from among three different allocations of points between themselves and an unidentified "Other." Scores range from 0 (completely proself) to 9 (completely prosocial). Second, participants received information regarding the two companies' profiles and then indicated an initial level of C-C identification toward each, as well as the extent to which they attributed the companies' CSR policies to intrinsic motives. Finally, after performing distracter tasks for 30 minutes, participants read a news story indicating the acquisition. Afterwards, the C-C identification and attribution measures were recollected, along with potential covariates.

## Results

The data were analyzed in a moderated multiple regression framework (Aiken and West 1991). The dependent variables were the changes in participants' C-C identification with each of the two companies. The independent variables were each company's CSR profile and measures of the participants' attributions and SVO. The results provide broad support for our conceptualization. We find significant heterogeneity in consumers' reactions to acquisitions, and this heterogeneity varies meaningfully with both company and consumer characteristics. Due to space constraints, we focus on the relevant two-way (a) and three-way (b) interactions.

(a) Consistent with our predictions, the two-way interaction of acquiring company CSR image and acquiring company attributions had a significant effect on consumers' identification with both the acquired ($\beta_{\text{2-way interaction}}$=.362, p<.001)[5] and acquiring companies ($\beta_{\text{2-way interaction}}$=-.417, p<.001).

When the acquiring company has a high, rather than a low CSR image, consumers' identification with the *acquired* company increases, but only when consumers attribute the acquiring company's CSR activities to intrinsic motivations ($\beta_{\text{high attribution}}$=.514, p <.001; $\beta_{\text{low attribution}}$=-.008, p=.939). However, consumers' identification with the *acquiring* company decreases when they attribute its CSR activities to intrinsic motivations ($\beta_{\text{high attribution}}$=-.443, p <.001; $\beta_{\text{low attribution}}$=.157, p=.111).

(b) As expected, the three-way interaction of acquired company CSR image, attributions regarding the *acquired* company, and SVO had a significant effect on consumers' identification with the *acquired* company ($\beta_{\text{3-way interaction}}$=-.292, p=.012). When consumers do not attribute strong intrinsic motives for the acquired company to engage in CSR, they identify less with the acquired company, regardless of their SVO ($\beta_{\text{proself}}$=-.112, p=.378; $\beta_{\text{prosocial}}$=.119, p=.359). However, when consumers do attribute intrinsic motives, (a) proself consumers identify more with the acquired company when it is CSR-focused versus product-focused ($\beta_{\text{proself}}$=-.285, p=.023), whereas (b) the identification of prosocial consumers with the acquired company is unaffected by the profile of the acquired company ($\beta_{\text{prosocial}}$=-.167, p=.217).

Also as expected, the three-way interaction of acquired company CSR image, attributions regarding the *acquiring* company, and SVO had a significant effect on consumers' identification with the *acquired* company ($\beta_{\text{3-way interaction}}$=-.318, p=.034). When consumers do not attribute strong intrinsic motives for the acquiring company to engage in CSR, both proself and prosocial consumers identify less with the acquired company regardless of its focus ($\beta_{\text{proself}}$=-.084, p=.585; $\beta_{\text{prosocial}}$=.202, p=.199). However, when consumers do attribute strong intrinsic motives for the acquiring company to engage in CSR, (a) the identification of proself consumers with the acquired company decreases regardless of the acquired company's focus ($\beta_{\text{proself}}$=.107, p=.448) and (b) prosocial consumers identify less with the acquired company when it is CSR-focused but do not identify with it any less when it is product-focused ($\beta_{\text{prosocial}}$=-317, p=.042). Further, and consistent with Sen, Bhattacharya and Korschun (2006), extrinsic attributions towards the acquiring company do not impact consumers' identification in any of the two-way or three-way interactions (all p's>.10).

## Implications

When asked to comment on recent acquisitions, financial analysts tend to focus on the gains the multinational will achieve by "catching the organic train." However, our results suggest that consumers' reactions to acquisitions are varied, depending both on the companies' profiles as well as personal attributions and SVO. One way for low CSR companies to strengthen consumer affiliations is to acquire a socially responsible company and promote intrinsic motives (via communication). Concerning the acquired company, our results suggest that the only way to strengthen consumer relationships is by promoting intrinsic attributions via communication and by positioning themselves as manifestly socially responsible. While acquisition seems to be a "no win" situation, strategic reasons will often compel it. Thus, managers should gain understanding of their customers' SVO, minimize perceptions of "sellout" from prosocials, and emphasize strategic benefits to proselfs.

# MySimon Sez: Reducing Negative Consequences of Missed Sales via Online Shopping Agents

Demetra Andrews, University of Houston, USA

Previous research has shown that people can have negative reactions to a missed sale such as devaluation of the good or service (Arkes et al. 2002; Zeelenberg et al. 1996;), tenacious price expectations (Thaler 1985), and experienced (Arkes et al. 2002) and anticipated regret (Butler and Highhouse 2000; Tykocinski and Pittman 2001).

This research focuses on mitigating one possible negative consequence of missing a sale, inaction inertia, which occurs when missing a great deal causes a consumer to pass on a good offer (Tykocinski et al. 1995). In addition to forestalling realization of consumer utility, inaction inertia may have deleterious effects on commercial entities in that they are denied revenues and may experience negative word-of-mouth if the consumer believes the current offer to be unfair or unreasonable.

I hypothesize that use of an intelligent online shopping agent (OSA), such as MySimon, will counter the force of previous inaction by shifting the decision-maker's focus from the past to the present offer. This is because the OSA produces a list of recommendations ranked in order of ability to meet consumer criteria, a positive contextual comparison for the top-ranked recommendation regardless of previous price. This positive comparison will prompt adjustment of consumer focus (Mussweiler and Strack 1999) from the past to the present context, increasing likelihood of action.

## Method

*Participants and Procedure*. Two hundred fifty-four people participated in the study. Approximately 50% were undergraduate business students and 50% were recruited from the general population via email solicitation. Inaction inertia research typically features only one actor, the consumer. This research varies both the cause of the missed sale and the source of information on the current offer in order to provide a broader exploration of this sequential choice effect. The study used a 2 (price difference: low vs high) X 2 (cause at T1: Self vs OSA) X 2 (source at T2: Self vs OSA) between subjects design. Similar to much of the research on inaction inertia, an online scenario was employed in which the participant was first informed that he/she had missed an attractive sale. The missed sale was either 55% off (high difference) or 35% off (low difference) an $80 laptop backpack. The participant was then told that he/she got information on a 25% off sale on the backpack. Participants indicated whether or not they would buy the backpack at the 25% off price and then responded to a series of measures. Inaction inertia occurs when the proportion of respondents who choose not to buy is significantly higher in the high difference condition than in the low difference condition.

*Measures*. The dependent variable was acceptance or non-acceptance of the 25% off deal. The independent variables were: price difference (high/low), cause of T1 miss (Self/OSA), and T2 information source (Self/OSA). None of the covariates (race, age, whether the participant was currently in the market for a laptop backpack, and number of backpacks previously purchased) was significant.

## Results

*Self at T1*. To facilitate comparison with previous research, the analyses were separated by the cause of the miss at T1. Logistic regression revealed that when the consumer was told that he/she caused the miss at T1 and that he/she found the current offer (Self-Self), 58% chose not to purchase in the high difference condition vs. only 32% in the low difference condition (p< .021). When the actors were Self-OSA, 50% choose not to purchase in the high difference condition vs. only 17% in the low difference condition (p< .002). Logistic regression also revealed that employment of an OSA at T2 significantly reduced the likelihood of inaction inertia. An average of 48% chose not to buy when the actors were Self-Self versus 32% when the actors were Self-OSA (p< .05). Thus, the hypothesis was supported.

*OSA at T1*. Given the proliferation of online shopping agents, it is likely that a consumer may employ a shopping bot at T1. While these agents may be unlikely to miss a sale offered by well-known vendors, they might miss a sale offered by small or local retailers. The second analysis evaluates the likelihood of inaction inertia when the OSA causes the miss at T1. In this condition, there was no evidence of inaction inertia and there was far less inaction overall, 23% non-acceptance with the OSA at T1 vs 39% with the Self at T1.

**Discussion**

These findings suggest that inaction inertia is less likely when an OSA facilitates subsequent choice. Moreover, when an OSA causes a great sale to be missed in the first place, the overall likelihood of inaction is lower than when the consumer causes the miss. Different explanations may explain this occurrence. It may be that the OSA recommendation provides a positive contextual comparison that reduces focus on the past. Alternatively, the OSA may function as a scapegoat freeing the consumer to take any action, good or bad. Future research will seek to identify the mechanisms by which this reduction occurs.

# A Psychophysical Approach to Assessment of Relationship between Vehicle Color and Purchase Price

Keiko I. Powers, J. D. Power and Associates, USA

Psychological research on consumer behavior has shown that the emotional state of consumers can affect their purchase decision making in various ways. An interesting topic that has been the focus of these studies is the psychological or emotional impacts of various non-functional attributes of the products or the purchase environment that are not directly linked to their core properties. For example, Milliman (1982) found that the type of music played in a grocery store affects the consumers' shopping behavior, spending a longer time at the store when slow music is played. Other studies have also shown differential effects by color (e.g., Bellizzi and Hite, 1992; Gimba, 1998; O'Neill and Lambert, 2001). Gimba (1998) emphasized the importance of color in the marketing environment and stated that color affects the mind and body in different ways, and certain colors convey a different meaning not only to different cultures but also within a single culture.

The past studies have shown that in today's consumption environment with abundant and various products, such as seen in the United States, emotionally appealing attributes have a substantial impact on consumer's attitude toward a brand. Naturally, the level of impact of these 'emotional' attributes is expected to be high when the consumer purchasing experience is highly involved, such as an automobile. Powers (2006) demonstrated that when consumers are purchasing new automobiles with a high emotional appeal, such as sporty coupes or convertibles, the price they pay for the car is affected by its color. Though limited in its scope with only a selected group of vehicle types, the study was the first attempt to empirically assess the impact of color on vehicle purchase decisions in the real-world setting.

This paper presents an empirical study that further investigates the relationship between vehicle color and purchase decision making on an automobile, expanding its scope with respect to the number of vehicle types and segments being tested (i.e., midsize cars, pickup trucks, etc in addition to sporty cars). All the vehicle models sold in the US market were analyzed to assess the prevalence rate of price differences associated with vehicle color. The approach allows us to understand the generalizability of the color-price relationship found in the previous study by Powers (2006). In addition to examining the prevalence rate, the price 'elasticity' due to color differences is quantitatively assessed by applying the psychophysics concept. Analyses are based on point-of-sales data of new vehicles collected from automobile dealers in the California market. Utilizing the large historical database with over two million transactions from 1999 to 2003 that includes all the vehicle models sold in the United States, exhaustive statistical analyses were conducted to assess the differential impacts of vehicle color on purchase price. Statistical comparisons with analysis of variance (ANOVA) were performed while controlling for other attributes, such as engine type, door type, etc., to ensure that observed price differences were in fact due to the vehicle color. Approximately 400 vehicle models (e.g., Ford Taurus, Dodge Dakota, etc.) with a sufficient number of transactions were retained for analysis (n>100 for each cell count when considering the attributes). Out of these 400+ models, over 1000 comparison sets were created to control for these various attributes that could contribute to price differences.

Analysis results based on the 1000+ comparisons demonstrated statistically significant differences due to color at a respectable prevalence rate of 7.6% when all the tests were conducted at the alpha level of 0.05. The prevalence rate varied from segment to segment, showing results consistent with expectation. In particular, sporty cars, which are considered to have a high emotional appeal, indicated 13.2% of comparisons showing significant differences. The price 'elasticity' or the price difference ratio (i.e., % difference between highest-color mean price and lowest-color mean price) was found to be fairly consistent from segment to segment. The overall ratio across segment was 5.3% with the lowest and the highest being 4.1% (SUV) and 6.7% (Sporty Cars), respectively. This means, for a $30,000 sports car, a car buyer could pay approximately $2,000 more (i.e., $30,000 times 6.7%=$2,010), when the vehicle color is an important and emotionally appealing decision making criterion for the buyer.

These empirical results offered further evidence that consumers' perception and emotional evaluation of color plays such an important role in decision making that it has a noteworthy influence on consumer's evaluation about the price of an automobile. Furthermore, the present study provided quantitative information regarding the relationship between color and price with automobile purchase. There are many vehicles in the market that the color is a very important decision making criterion, and consumers are willing to pay more for a car of choice simply because of its color. This implies that purely emotional attributes can be a very powerful tool for pricing strategies of automobile sales. It is interesting to explore how these differences due to color are influenced by consumer characteristics (e.g., gender or age), regions (e.g., urban versus rural), and how they interact with vehicle types (e.g., luxury versus non-luxury). Further investigation in these areas will help us better understand the relationship between the emotional attribute and purchase price decision.

# Airing Dirty Laundry in the Public Square: An Examination of Public Complaining and the Mitigating Effects of Branding

Andrew Wilson, Florida State University, USA
Michael Giebelhausen, Florida State University, USA
Michael Brady, Florida State University, USA

### Abstract

"Customer created complaining websites" (CCCW's) are a potentially serious threat to brands. At least 50% of Fortune 1,000 companies have been targeted by CCCW's. Extant studies provide useful descriptions, but surprisingly, related empirical research does not exist. This paper attempts to fill this gap by empirically investigating effects on consumers' behavioral intentions, and the potential protection of strong branding. Results indicate a significant interaction between exposure to CCCW and strong branding, suggesting that CCCW's reduce consumer perceptions, but strong brands offer some protection. Consistent with reactance theory, if the targeted brand is among a consumer's favorites, perceptions are ironically increased.

### Conceptualization

The advent of the Internet into markets continues to force the evolution of market dynamics (Deighton 1997; Lamb et al. 2006). One such change is that customer complaining is being transformed from a relatively private behavior to a quasi-public activity (Ward and Ostrom 2006), such as on consumer created complaining websites (CCCW's). These sites are widespread, and a potentially serious threat to brands. It is estimated that half of all Fortune 1,000 firms have been the target of a CCCW (Trigaux 1999), including venerable brands as Wal-Mart, Allstate Insurance, Viacom, and Toys'R'Us (France and Muller 1999).

This study investigates 1) the effect of CCCW's on consumers' behavioral intentions regarding the brand and 2) the potential of a strong brand to protect against negative information attacks. This research contributes by extending findings of extant studies (Ward and Ostrom 2006; Ward and Ostrom 2003), which provide useful descriptions of the phenomenon.

### Customer Created Complaining Websites

The Internet is enabling consumers to become active broadcasters of market information. As a result, the marketplace is transforming into one in which marketers and consumers participate in a communication network. One particularly interesting instance of this is manifest in websites created by consumers to communicate their dissatisfaction to other consumers.

CCCW's share several similarities with civic protests: 1) CCCW often present firm failures as a betrayal of consumer rights, 2) CCCW often present stereotypes of evil executives, and 3) CCCW's typically emphasize individual and collective efficacy in standing up to the firm (Ward and Ostrom 2006). These features combine to create a potently persuasive message, especially in light of the negativity effect.

### The Negativity Effect

Consumers give greater weight to negative information than to positive (Ahluwalia 2000; Ahluwalia et al. 2001; Mizerski 1982). This well known finding is referred to as "the negativity effect" (Ahluwalia 2000; Ahluwalia et al. 2001; Anderson 1981; Fiske 1980). This is thought to occur because consumers consider negative information to be more diagnostic than positive. (Maheswaran and Meyers-Levy 1990; Skowronski and Carlston 1989). It is predicted that negative information will be disproportionately weighted, and will reduce consumer behavioral intentions.

*H1*: Exposure to negative information about a brand in the form of a customer created complaining website will reduce consumers' behavioral intentions related to repurchase.

**The Buffer Effect of Existing Brand Attitudes**

When a person is familiar with an object, the person's existing attitude guides the processing of new information related to that object (Petty and Cacioppo 1986). People pay selectively greater attention to information consistent with their attitudes (Frey 1986). Biased processing is also evident in people's ready acceptance of information consistent with existing attitudes (Kunda 1990; Petty and Cacioppo 1986), and in their perception of such information as more persuasive (Edwards and Smith 1996; Petty and Cacioppo 1986). Participants who are familiar with and like a brand are predicted to use these attitudes as a guide in processing negative information.

*H2*: The effects of exposure to CCCW specified in H1 will be attenuated when the brand is one that the consumer is familiar with and likes, as compared with one with which the consumer is unfamiliar.

**Study 1**

*Method*

In the first study, 122 undergraduate students (77 females) were randomly assigned in a 2 (negative information: present or absent) x 2 (brand: familiar brand or unfamiliar brand) between-subjects factorial design. Participants were shown a webpage based on a well known, or fictitious, service provider. Negative information condition participants were shown a CCCW modeled after a related website, while others proceeded directly to the questionnaire. The dependent measure-behavioral intentions related to repurchase-was measured using three items adapted from Zeithaml, Berry, and Parasuraman (1996).

*Major Findings*

A brand (familiar or unfamiliar) x negative information (present or absent) between-subjects analysis of variance (ANOVA) found significant main effects for brand $[F(1,121)=38.70, p<.001]$, and negative information $[F(1,121)=12.08, p=.001]$, qualified by a significant interaction $[F(1,121)=4.07, p=.046]$. Consistent with predictions, negative information reduced behavioral intentions more sharply for the unfamiliar brand. The main effect of negative information was interpreted as support for H1, while the interaction was interpreted as support for the H2.

**Study 2**

The context of study two was a tangible product-fashion clothing. Finding were extended by investigating circumstances under which an existing attitude goes beyond buffering. When existing attitudes are strong, negative information may enhance behavioral intentions, as predicted by reactance theory.

*Reactance*

Reactance theory (Brehm 1966; Brehm and Brehm 1981; Wicklund 1974) posits that resistance to persuasion results from a motivation to preserve personal freedom when such freedom is threatened by a communicator. The message recipient may reassert their freedom by moving their attitude further away from the advocated position. It is predicted that when negative information contained in a CCCW consists of such arguments, consumer's will react by raising their behavioral intentions.

*H3*: Negative information in the form of a CCCW consisting of arguments that threaten a consumer's freedom to disagree will enhance behavioral intentions towards familiar brand, but decrease them for an unfamiliar brand.

*Method*

A total of 125 undergraduate students (69 females) at the same university took part in a 2 (negative information: present or absent) x 2 (brand: familiar or unfamiliar) between-subjects factorial design. The same procedure was used, except the target brand was chosen through a process designed to elicit a personally relevant brand, eliciting reactance. For the unfamiliar brand conditions, an Australian brand of fashion clothing was used.

*Major Findings*

A brand (familiar or unfamiliar) x negative information (present or absent) between-subjects analysis of variance (ANOVA) was conducted. A significant main effect was found for brand $[F(1,116)=47.56, p<.001]$. The main effect of negative information was not significant $[F(1,116)=.409, ns]$. There was a significant brand x negative information interaction $[F(1,116)=5.62, p=.019]$. Consistent with H3, exposure to negative information resulted in an increase in behavioral intentions related to repurchase for a familiar brand, but a decrease for an unfamiliar one.

# Two Designer Skill Sets: Perspective Taking and Creativity

Jaewoo Joo, University of Toronto, Canada

Designers are those who create concepts for new products. Considering the impact of new products in business world, it is important to know what psychological skill sets are required to create successfully appealing new product concepts. As psychologists suggest creative tasks must be novel as well as appropriate (Amabile 1996), marketing scientists generally believe that appealing new products are not only novel (i.e., original, unexpected, innovative) but also appropriate (i.e., useful, practical, effective). As originality has been the more respected than appropriateness, concept originality is known to be enhanced by a list of skill sets including visual imagination, analogical thinking, and creativity (Dhal, et al. 1999, Dahl and Moreau 2002, Moreau and Dahl 2005). Then, how to enhance the other dimension, appropriateness?

There has been very little discussion about how to improve appropriateness because researchers on creativity have considered appropriateness as an unavoidable constraint of their research topic. New product researchers also have found that most skill sets that successfully enhance concept novelty either decreases concept appropriateness (Dhal et al. 1999; Jansson and Smith 1991) or have nothing to do with it (Moreau and Dhal 2005). In the present research, I propose that perspective taking is one of many skill sets that enhance the concept appropriateness. Since perspective taking is known to increased overlap between self and other (Galinsky, Ku, and Wang 2005; Galinsky and Moskowitz 2000), it will help people identify more quality needs of other. This proposition is partially supported by Dahl et al. (1999) that consumer participation improves appropriateness of new product concepts. Combining literature on creativity with the reasoning above, I claim that designers who create appealing new product concepts need two skill sets- creativity and perspective taking- and that two skill sets take different routes for an overall concept appeal: creativity enhances concept novelty, perspective taking improves concept appropriateness.

Study 1 investigated if measured perspective taking and measured creativity predict an overall appeal of new product concepts. Thirty four Engineering students in one course, Product Design, designed new mobile phone concepts for children. Their concepts are analyzed with their scores of trait perspective taking measured by IRI (Interpersonal Reactivity Index, Davis 1983) and trait creativity measured by Gough Personality Scale (Gough 1979). As expected, this study generally demonstrated that highly perspective taking subjects scored higher in their concept appropriateness than lowly perspective taking subjects and highly creative subjects scored high in their concept novelty than lowly creative subjects.

In the next two studies, the role and limit of perspective taking were examined under a hypothesis: perspective taking improves the performance of problem identification but it does not improve the performance of problem solution. In study 2, 32 commerce program undergraduate students were asked to list as many problems and solutions as possible that a preschool child may encounter when she uses a mobile phone designed for adults. One group of subjects were instructed to actively take the perspective of a child and the other group of subjects were asked not to be involved with perspective taking. Study results confirmed the hypothesis. Perspective-taking subjects reported significantly more problems (5.67) than non perspective-taking subjects (4.35, t=1.72, p<.10). Two groups of subjects, however, did not show significant difference in the number of solutions. As expected, the number of solutions was positively predicted by the number of problems ($\alpha$=1.16, t=5.43, p<.001), suggesting that solutions depend on problems.

In study 3, experimental stimulus was changed to a service product (i.e., emergency department) to generalize the findings and previous experience was measured to rule out an alternative explanation. In total, 36 commerce program undergraduate students were asked to list as many problems and solutions as possible that family members encounter when they are at emergency department. One group of subjects were asked to take the perspective of one member of family, whereas no instruction was given to the other group of subject. The results replicated those in study 2. Subjects who took the perspective of a family member reported more problems (3.81) than those who did not (2.13, t=2.92, p<.01). Again, two groups did not show any difference in the quantity of solutions. Interestingly, 22 subjects who had experience in emergency department reported fewer problems (2.45) than 14 subjects who had no experience (4.14, t=2.66, p<.05), suggesting that previous experience does not guarantee a better performance in problem identification.

The findings obtained from three studies generally supported that perspective taking enhances appropriateness of new product concepts by improving the performance of problem identification and it does not necessarily lead to improved problem solution that creativity is required. All in all, designers who create new products need both perspective taking and creativity to improve their appropriateness as well as their novelty.

# The Robin Hoods of the Information Age: The Differential Effects of Financial and Time Expenditures on Sharing

Yuliya Komarova, University of South Carolina, USA
Cait Poynor, University of South Carolina, USA

## Motivation

According to the research conducted by the Motion Picture Association of America (MPAA) one-third of all internet piracy is committed by college students in the United States. Moreover, the vast majority of Internet piracy in the U.S.-71 percent-is committed by individuals between the ages of 16 and 24. Furthermore, the MPAA states unequivocally that "downloading a movie off of the Internet is the same as taking a DVD off a store shelf without paying for it." Nevertheless, moviemakers, songwriters, and software designers alike lose billions of dollars every year as a result of mass pirating of their products. However, it is unclear what motivates consumers to forego their moral and ethical standards as they contribute to the online file sharing frenzy? How do they justify getting involved in illegal and potentially punishable pirating activities? While the extant literature on prosocial behavior may help explain the motivation for sharing (see Gilbert et al. 1998 for review), it does not elucidate why otherwise law-abiding citizens choose to get involved in unlawful product sharing practices. The present research is an attempt to answer these pressing questions.

## Conceptualization

While there is certainly a positive side to online sharing (e.g., Internet support groups), we focus on the harmful pirating activities. Furthermore, making use of online resources is a part of Internet sharing regardless of whether or not participants make similar contributions themselves (Belk 2007). For example, Nunes, Hsee, and Weber (2004) have documented consumer inclinations to pay for online goods and services as a function of whether the product's cost is principally attributable to variable cost or fixed cost. However, while economic gains of using unlawful (shared) products are obvious, the rewards and/or motivation for allowing others to use products one owns are still unclear. Hence, the present research addresses the latter issue.

Giesler (2006), in his netnographic study of a consumer gift system in peer-to-peer music file sharing practices at Napster, found this community to exemplify all classic gift system indicators. More specifically, the author suggests that "music sharing binds a complex consumer system of social solidarity" (p. 289). Gift giving, on the other hand, usually presupposes prior ownership with a right to give. Hence, we argue that consumers must assume such ownership of the products they make available to others in order to justify their otherwise unlawful actions. Moreover, we posit that time and effort one puts into making the product available to others (e.g., cracking, modifying, and uploading software) leads to such sense of ownership.

In addition, the dual entitlement theory (Kahneman et al. 1986) provides another potential explanation for how one may be able to justify participation in illegal product sharing. More specifically, when consumers consider a price they have paid for a product to be high and perhaps unfair; they may feel that fairness would be restored if they somehow increase the utility they gain from the acquired product. Hence, making the product available to others may increase the utility derived from the product by providing a sense of vindication, a positive feeling as a result of 'helping' or 'giving a gift', or all of the above.

Both, time spent on making the product available to others and the price paid for the product are expected to influence one's ability to justify sharing a product. Moreover, we predict an interaction of these predictors which we test in Study 1.

## Study 1

Study 1 followed a 2 (financial expenditure) x 2 (time expenditure) design, where both factors were manipulated at 2 levels (low cost: $15, high cost: $150; low time expenditure: 15 minutes, high time expenditure: 3 hours.) Participants read the following scenario:

Imagine that you were required to purchase a software package for a Business Statistics class to go along with the textbook. You found the required B-STAT Software at the university bookstore and purchased it for *$15 (150).* Later in the semester, you heard that there is an online community of college students who have taken, are currently taking, or are planning on taking a Business Statistics course. The community website offers a chat room in which students can ask and answer course-related questions, share tips, and even software. The website provides directions and leads you through a number of steps that are required in order to upload software you might be willing to share. Specifically, it would take one *15 minutes (3 hours)* to crack, modify, and upload the B-STAT package. Please provide your honest answers to the following questions. Note that your responses on this survey are strictly confidential!

Participants then responded to a 9-point Likert-type scale asking, "How likely would you be to share the B-STAT Software package with other online community members at this time?" where 1 indicated that they were "extremely unlikely" and 9 indicated that they were "extremely likely" to share. Following this measure, participants reported their affective response to sharing by stating their level of agreement with the following statements "Sharing software would make me feel proud," "Sharing software would make me feel satisfied," and "Sharing software would make me feel happy," with endpoints "Strongly Disagree" (1) and "Strongly Agree" (7), and labeled at the center with "Neither Agree nor Disagree."

**Major Findings**

Data was subjected to a 2 x 2 ANOVA, with likelihood of sharing and affective response as the primary dependent measure. Affective response was calculated by creating an index of the above three items (*alpha*=.93). The analysis showed a significant interaction of cost and time expenditures, such that individuals in the high cost condition were most likely to share only when they had also invested the greater amount of time in preparing the software to share ($M_{LowCost, LowTimeExpenditure}$=4.34, $M_{LowCost, HighTimeExpenditure}$=3.78, $M_{HighCost, LowTimeExpenditure}$=3.91, $M_{HighCost, HighTimeExpenditure}$=5.92, $F$ (1, 102)=5.93, p<.02). An analysis of the affective response index suggests that this increased propensity to share among participants who paid the higher cost for the software is associated with a more positive affective response to sharing attributable to their time investment ($M_{HighCost, LowTimeExpenditure}$=9.46, $M_{HighCost, HighTimeExpenditure}$=11.61, $F$ (1, 52)=2.82, p<.1). No similar relationship between time expenditure and affective response existed among participants who had paid less for the software (F<.1, p>.8).

**Future Studies**

Future studies will address specific rationales consumers use for justifying their unlawful actions and suggest potential remedies. Moreover, the extant literature on sharing suggests that these rationales may vary significantly across cultures (Belk 2007). Given the multi-cultural and multinational nature of online communities, we believe it would be of extreme importance to study the present phenomenon in a multicultural setting.

# A Three-Factor Model of Consumer Preference for Self-Designed Products

Xiaoyan Deng, University of Pennsylvania, USA
Wes Hutchinson, University of Pennsylvania, USA

In this research, we develop a three-factor (i.e., outcome accuracy, mere authorship, and process affect) model of consumer preference for self-designed products. We propose that the preference structure for self-designed products can be determined by one, two, or three of the factors. A study involving 512 participants designing, in different task formats, a Nike iD sports shoe and then evaluating, after different lengths of delay, their self-design embedded in a set of 30 different designs provides preliminary support for this model.

We define outcome accuracy as the extent to which the customized product created by consumers in the self-design process maximizes their pre-existing enduring preferences. When creating their self-design, consumers need to transfer their needs and wants into a concrete product specification by making a series of choices. Although finite, the solution space within which consumers make sequential design decisions can still be enormous. For example, the design task carried out in our study involved 60,374,160 different possible designs. As the solution space enlarges, the accuracy with which a solution within this space matches the pre-existing ideal point of an individual consumer increases. However, the effort that needs to be made by that consumer to find such a solution also increases. We expect that an accuracy-effort tradeoff is likely to be made by consumers. We thus consider outcome accuracy as the extent to which consumers' pre-existing ideal point is approximated by the outcome of the self-design process wherein consumers perform an effortful but not exhaustive search within the design solution space. We propose that as outcome accuracy increases during self-design, subsequent evaluations of the self-designed product will also increase (even after a delay). Consumer preferences can be stored evaluations or context-sensitive constructions (e.g., Wilson, Lindsey, and Schooler 2000). By assuming consumers make accuracy-effort tradeoffs, we allow for the existences of both types of preferences at the time of creating the self-design. Likewise, by proposing that outcome accuracy can partly or completely determine consumers' preference for their self-design, we also allow for the existences of both stored evaluation (as outcome accuracy) and context-dependent construction (as mere authorship) at the time of evaluation.

Mere authorship is the extent to which consumers prefer products that are believed to have been self-designed, regardless of the validity of that belief. People have been found to infer attitudes from observations of their own behavior (e.g., Fazio 1987). We propose that, at the time of evaluation (i.e., after the self-design process and in a different context), consumers might construct their preferences for a product based on whether they believe they self-designed the product or not. According to the positivity bias in human cognition (Heider 1958), this contextual inference can bias preference such that "I like it merely because I designed it."

Process affect is the extent to which the self-design process generates positive emotions that are associated with the self-designed product. The self-design process usually operates in an interactive online environment wherein consumers are allowed to work on different product components in a one-by-one, back-and-forth, self-paced fashion. As a result, they can gain a certain level of familiarity with their self-design. Companies also try to make the self-design process as user-friendly, intriguing, and entertaining as possible. According to research conducted on sensory affect (e.g., Schimmack and Crites 2005), such a process can give rise to positive emotions that are similar to innate sensory affect, classic conditioning, and mere exposure. They are also similar to integral emotional responses (Pham 2007). We

propose that the positive emotions consumers experience in the self-design process are attached to the outcome of this process. Therefore, at the time of evaluation, process affect contributes to consumers' preference for their self-designed product.

In this research, we experimentally simulated self-design creation and subsequently measured self-designed product evaluation. We manipulated the format of the creation task and the delay of the evaluation task. We measured consumers' memory and preference for their self-design. We propose that, first, if outcome accuracy is the major determinant, because this construct is enduring and context-independent at the times of creating and evaluating the self-design, neither format nor delay should have an effect on memory or preference. Second, if mere authorship is the major determinant, because this response bias is a context-dependent construction at the time of evaluation, both format and delay should have an effect on memory or preference. Moreover, these effects should be mediated by the recognition of the self-design. Third, if process affect is the major determinant, since this affect is generated by the self-design process, different types of format of the self-design creation task should have an effect on memory and preference. Depending on how long this effect can last different lengths of delay of the self-design evaluation task could also have an effect. However, these effects should not be mediated by recognition.

Our study used a 2 (format of self-design creation: online vs. paper-and-pencil) x 2 (delay between self-design creation and evaluation: one-week vs. four-week) between-subject design. 192 participants performed the online design task and 164 performed the paper-and-pencil task. Participants in the online design task were directed to a webpage at Nike's website, where they were able to self-design a Nike iD sports shoe of a pre-selected model for themselves. They could either start with one of four gender-specific "inspirations" (existing styles created by Nike's professional designers), modifying it into a new style or, alternatively, start with an all while shoe model, creating their own style from scratch. The self-design task involves choosing a color from a palette of colors (ranging from 6 to 12 in number) for each of the seven shoe components (i.e., base, secondary, swoosh, accent, lace, lining, and "shox"). Participants in the paper-and-pencil design task were given a coloring book and a set of color pencils, through which they were also able to self-design a sports shoe of the pre-selected model for themselves. Although the solution space for both design task formats was manipulated to be identical, the paper-and-pencil format lacks the interactivity, vividness, and user-friendliness that are unique to the online format. Before and after the self-design task of both formats, self-design process measures were taken including perceived ease, performance, and enjoyment of the design task.

Participants unexpectedly received an email inviting them to participate in the evaluation task either one week or four weeks after they had completed the self-design task. A set of 30 different shoe designs was prepared as stimuli. It consisted of ten "cluster designs," ten "random designs," nine professional designs, and one self-design. The ten cluster/random designs were created/selected based on the pool of 156 self-designs collected in a pretest conducted on a separate group of 156 participants. The nine professional designs were the eight inspirations (four for men and four for women) and the all white shoe model that participants encountered in the design task. The self-design was specific to each participant. Without being informed whether their self-design was included in the set, participants rated each of the 30 designs in terms of initial liking (yes/no), preference (1-100 scale), and likelihood of being their self-design (1-100 scale), as well as identified their self-design among the 30 designs.

Results showed that the number of unique self-designs equaled the number of participants. This high level of preference heterogeneity seems to argue for the role of mass customization in shoe industry because the larger the heterogeneity of consumers' preferences, the larger they can gain from customization the increment of utility of a product. Participants in the online self-design task format reported a significantly higher level of process affect than participants in the paper-and-pencil format. Moreover, participants demonstrated an accurate memory and a high preference for their self-design, relative to the other 29 designs in the set that were created by professional designers or by their peers. The memory rating for the self-design tripled the average rating over the 29 designs. The preference rating for the self-design doubled the average rating. Over two third of participants correctly identified their self-design. Further, we found a format and a delay effect on memory, as well as a format and a delay effect on preference as mediated by the recognition of the self-design. The pattern of results generally supports the proposed three-factor model.

# When Social Influences Have Far Reaching Implications

Monica Popa, University of Alberta, Edmonton, Canada
Jennifer Argo, University of Alberta, Edmonton, Canada

Recent research on the impact of social influences has highlighted the notion that consumers' thoughts, feelings and behaviors are influenced by their social environment. This research can be divided into work that either investigates the impact of an interactive social presence (e.g. Childers and Rao 1992) or simply the mere presence of another person (Argo et al. 2005; Dahl et al. 2001; Zhou and Soman 2003). In the present research we seek to explore a situation that encompasses both types of social influences by investigating a sequence

of social events and their combined influence on a consumer's tendency to engage in an altruistic act. In particular, we are interested in understanding how a partial interaction between two consumers (i.e., one shopper comments to another shopper without receiving a reply) can drive the consumer receiving the comment to subsequently assist a third person. Further, we explore the impact of two characteristics related to the comment on the likelihood that help is provided including valence (i.e. positive or negative) and agency (i.e., whether the social information received by the consumer during the interaction is self-caused or other-caused). To forward predictions about helping behavior we draw from two bodies of literature: affect (Barbee et al. 1998, Bagozzi, Gopinath and Nyer 1999, Schaller and Cialdini 1990) and social identity theory (Tajfel and Turner 1979, 1986).

According to research on altruism, mood is a key driver of helping behavior. For example, factors such as success or failure at a task (Berkowitz, 1987) or the weather (Cunningham, 1979) have been shown to influence helping because of the affect they elicit. Furthermore, people in experimentally induced states of happiness (vs. those in either neutral or negative moods) have been found to be more likely to provide help (Barbee et al. 1998). This affect-based account of altruism suggests that positive as compared to negative information received during an interaction should lead to a higher altruistic propensity. However, it is possible that affect may not function as a sole determinant of altruistic behavior and that under certain circumstances (namely, in the case of self-caused agency) emotionally charged social information may be used by the recipient to draw inferences about his/her social adequacy.

Social identity theory (Tajfel and Turner 1979, 1986) and the concept of ingroup identification imply that a person should behave in a manner that consolidates his/her position within the social group of interest. Thus, when consumers receive social information that is self generated (i.e., is directed to the self) and the information threatens their self and their role in the group, they will respond in such a way as to reaffirm their position as a good group member and will be likely to help a third person. In contrast, when the self generated information is enhancing (i.e., flattering), consumers will not feel the need to reaffirm their role in the group and will not be motivated to engage in helping acts. Note that, for the social identity mechanism to operate, the consumer must be able to draw inferences about his social adequacy from information conveyed by the other person. This happens in the case of self-caused agency (Bagozzi, Gopinath and Nyer, 1999). When the consumer receives a compliment, he can easily infer that he is a good (if not superior) member of the social group. By contrast, in the case of other-caused agency, inferences about self-performance are hard to make. For example, when encountering a fellow-shopper who curses, the consumer may simply attribute the negative signal to the other's character, instead of inferring a personal flaw. In sum, we believe that both affect and social identity are needed to account for altruistic behavior. Helping should be influenced by how people appraise the valence and agency of social information.

To investigate these influences, data was collected from North American undergraduate students. Participants read a scenario and were asked to imagine the situation described as if it was happening to them. The scenario described a shopping experience at the checkout of a supermarket. Participants read that while standing in line, a shopper behind them makes a comment specifically directed at them. They acknowledge the comment without giving a reply, pay for the groceries and head for the supermarket exit. The scenario ends by indicating that on the way out, they notice another shopper drop their grocery bags on the supermarket floor. The scenarios were identical across conditions, except for one phrase containing the comment provided by the shopper in line. This comment was used to achieve the manipulations of agency and valence of the social information: self/positive (the shopper "compliments you"); other/positive (the shopper "makes some friendly small-talk"); self/negative (the shopper "makes a negative comment that you find rude"); other/negative (the shopper "grumbles"). Participants then completed a survey that asked how likely they would be to help the shopper pick up the scattered groceries.

Results revealed the predicted interaction. In the other-caused agency conditions, the direction of effects supports the affect-based account of altruism, as participants were more likely to help when the previously encountered shopper was friendly (vs. grumpy). However, the direction of effects is reversed for self-caused agency, supporting social identity theory. Specifically, participants were significantly less likely to help when the comments of the shopper were flattering (vs. threatening). Overall, our study provides preliminary evidence for a powerful social influence on altruistic propensity, and suggests the need to bridge the literatures on affect and social identity in order to gain better understanding of helping behavior.

# You and Us: Causal Effects of Language Use on Consumers' Perceptions of Brands

Aner Sela, Stanford University, USA

S. Christian Wheeler, Stanford University, USA

"Imagine a global financial firm with the heart and soul of a two-person organization. A world-leading wealth management company that sits down with you to understand your needs and goals… You & Us. UBS." (www.ubs.com).

"Together, We're Making a Difference. For over 25 years, Whole Foods Market team members, customers and suppliers have worked to make the world a better place." (www.wholefoodsmarket.com)

The excerpts above illustrate the commonsense belief that portraying the affiliation between the brand and the consumer in terms of an intimate interpersonal bond should lead to more favorable attitudes among consumers. Referring to consumers and the brand in terms of 'you and us' in the UBS slogan as opposed to 'we' in the Whole Foods Market statement may seem equally effective. Likewise, whether these messages are perceived by existing customers or by potential ones may seem totally inconsequential.

The present research challenges both these assumptions. We demonstrate that language variations as subtle as pronoun use can have significant effects on consumers' attitudes toward brands. These effects can be either positive or negative, depending on people's relationship status with the brand (i.e., customers vs. non-customers) as well as on the specific brand domain. In domains in which brands are perceived as equal partners (e.g., banking), using the pronoun 'we' instead of the phrase 'you and the brand' can lead to more favorable attitudes among customers but to less favorable attitudes among non-customers. Conversely, in domains in which brands are perceived as partners in a hierarchical relationship (e.g., healthcare), using the phrase 'you and the brand' instead of the pronoun 'we' can lead to more favorable attitudes among customers but not among non-customers.

## Mediation Hypothesis

Consumers have implicit beliefs about what is appropriate in their relationships with different brands (Aaker et al 2004). They may rely on their knowledge of their affiliation with the brand when evaluating language use, to make dispositional attributions about the brand: when language is in harmony with their beliefs, the brand is perceived as more trustworthy, leading to more positive attitudes overall. When language is incongruent with consumers' beliefs, they may attribute this discrepancy to negative dispositions such as dishonesty, leading to less positive attitudes. We therefore hypothesized that the moderated effect of pronoun exposure on attitudes is mediated by perceptions of brand-honesty.

An alternative possible mediator is processing fluency: when consumers interact with brands for which they have stored linguistic representations, these are likely to become more accessible and, in turn, facilitate processing of congruent information but not of incongruent information. Fluency, in turn, leads to more favorable attitudes (Schwarz 2004).

In a pretest, we asked participants to rate as either equal or hierarchical their relationships with their real brands in several domains. The results indicated that consumers perceive their relationships with their banks as significantly more equal than their relationships with their health-insurance providers (p<.001). Consistent with the conceptualization above, we predicted that exposing people in a banking context to the pronoun 'we', as opposed to the phrase 'you and the brand', will lead to more favorable attitudes among brand customers but to less favorable attitudes among non-customers. Conversely, we predicted that exposure to the pronoun 'we' in a health-insurance context will lead to less favorable attitudes among customers and to more favorable attitudes among non-customers.

IN STUDY 1, 164 participants read a message advertising *Wells Fargo*, a prominent west-coast banking brand. Some participants read a message with the phrase 'you and Wells Fargo', whereas others read a message in which 'you and Wells Fargo' was replaced with 'we'. In the control condition, the consumer and the brand were not referred to jointly. Next, participants were asked to rate their agreement with four attitude items. Finally, they were asked whether they were banking with Wells Fargo, thus yielding a 2(customer-status: customer vs. non-customer) x 3(pronoun: 'we' vs. 'you and the brand' vs. control) design.

The results revealed a significant 3(pronoun) x 2(customer-status) interaction, p<.013. Customers rated their brand-attitudes more positively in the 'we' condition than in the 'you and Wells Fargo' condition and the control. Conversely, non-customers rated their attitudes less positively in the 'we' condition than in the 'you and Wells Fargo' condition and the control.

IN STUDY 2 we tested whether the effect found was mediated by either honesty perceptions or processing-fluency. The same design was used as in study 1 but with two banking brands (*Wells Fargo* and *Stanford Federal Credit Union*). In addition to attitude measures, we included mediating variables pertaining to brand-honesty and processing-fluency.

After reading ad excerpts as in study 1, 80 participants were asked to rate their agreement with seven attitude statements, two brand-honesty statements, and two fluency statements. Finally, they were asked whether they were banking with the brand, yielding a 2(customer-status) x 2(pronoun) x 2(brand) design.

The analysis revealed a significant 2(pronoun) x 2(customer-status) interaction, p<.021, with no effect of brand name, indicating that the effect found was not brand-specific. Again, customers rated their brand-attitudes more positively and non-customers rated their brand-attitudes less positively in the 'we' condition than in the 'you and the brand' condition. A mediated-moderation analysis (Muller et al 2005) indicated that this effect was mediated by perceptions of brand-honesty but not by processing-fluency.

IN STUDY 3 we tested the hypothesis that the effect of pronoun use will reverse when the brand domain is associated with a hierarchical consumer-brand relationship. 312 participants were assigned to a 2(domain: banking vs. healthcare) x 2(pronoun) x

2(customer-status) design. They read a message featuring either *Wells Fargo* (banking) or *Aetna* (healthcare), phrased using either the pronoun 'we' or the phrase 'you and the brand'. After reading the message, participants were asked to respond to attitude and honesty measures as in study 2 and to indicate whether they were customers of the brand featured in the message.

Consistent with our hypothesis, a significant pronoun x customer x domain interaction emerged, p<.002. Bank customers rated their attitudes more favorably in the 'we' condition than in the 'you and the brand' condition, but non-customers did not. Conversely, healthcare customers rated their attitudes less favorably in the 'we' condition than in the 'you and the brand' condition, but non-customers rated their attitudes more favorably in the 'we' condition than in the 'you and the brand' condition. Finally, a mediated-moderation analysis indicated that these effects were mediated by brand-honesty perceptions, in both brand domains.

# Investigating the Motivational Processes Underlying Bicultural Consumer Response to Cultural Product Cues

Alexandra Aguirre-Rodriguez, Bryant University, USA
Adriana Boveda-Lambie, University of Rhode Island, USA

This research examines the motivational processes underlying bicultural consumer response to cultural product cues, such as ethnic brands or products symbolic of cultural meaning. Given the high percentage of immigrants in the United States population, understanding how biculturals respond to marketing stimuli that carry cultural meaning is an important subject.

As immigrants undergo the acculturation process they internalize the dominant culture, which is a learned knowledge system consisting of values, ideas, symbols, and customs, while maintaining the cultural knowledge system of their culture of origin. Both cultural knowledge systems co-exist in biculturals' minds (Benet-Martinez and Haritatos 2005; Haritatos and Benet-Martinez 2002). According to the dynamic constructivist approach, the issue then becomes: which cultural frame of reference guides the individual's judgment and decision making and, under which conditions will one culture dominate versus the other (Hong et al. 2000).

Hong and colleagues (2003; 2000) examine a process called cultural frame switching (CFS), which is a cognitive process by which a bicultural's mindset or "frame" with respect to the dominant culture or culture of origin is activated by situational cues and applied in processing the given situation. An important concept overlooked in CFS research is cultural identity, which refers to "a sense of self in relation to a culture of origin and who one is within and without that cultural context" (LaFramboise et al. 1993, p. 402). Although biculturals appropriately use their dominant culture to process many situations, it may be appropriate in certain situations to access their original culture mindset to maintain a healthy cultural identity and self-concept. Balancing one's identity with respect to culture of origin and the dominant culture is important because not only is the knowledge system still embedded in the individual's mind, but he/she may still maintain contact, loyalty, and/or involvement with the culture of origin as evidenced throughout existing theories of second-culture acquisition (Berry 1986; Gleason 1979; Gordon 1964; Ogbu and Matute-Bianchi 1986). As part of a bicultural's ongoing acculturation process, maintaining a healthy cultural identity will be important to ensure psychological well-being. As such, we classify it as a chronic goal that biculturals pursue as part of their bicultural experience (Bargh and Barndollar 1996).

Our framework addresses the role of cultural identity in bicultural consumer's response to cultural product cues. As a chronic goal, maintaining one's cultural identity is highly accessible for priming by situational cues (Chartrand and Bargh 2002). In particular, the means to pursue this goal can activate the goal and the motivation to pursue it (Kruglanski et al. 2002; Shah and Kruglanski 2003). Because purchase and usage of culturally-laden products (i.e., products representing the individual's original culture or the dominant culture identity) can serve the goal of identification with that culture, we posit that cultural products can serve as cues that trigger this cultural identification motive. This goal priming increases the individual's propensity to pursue products that advances the goal of identification with the culture of origin or the dominant culture.

We predict that cultural identification motive activation mediates the product cue culture-purchase behavior relationship. We also hypothesize that situational product cue characteristics will affect its likelihood of priming a cultural identification motive. Particularly, scarcity research suggests that an object's perceived scarcity increases the salience of its attributes (Folger 1992). Thus, we predict that perceived product scarcity increases the salience of product's associated culture and thus, scarcity moderates the product cultural-cultural identification motive activation relationship. Our paper contributes to bicultural research by moving beyond the realm of cognitive processes impacting judgment into the realm of motivational processes impacting behavior.

To ensure that differential effects exist between biculturals and monoculturals, we conducted a preliminary study focusing on the moderation of perceived scarcity on the product culture-purchase intention relationship. Because scarcity increases the salience of the culture symbolized by the product and its likelihood of activating a cultural identification motive, biculturals' purchase intentions should

be greater toward the scarce product cue versus the non-scarce product cue, but given biculturals' chronic cultural identity goal their intentions toward the scarce non-dominant culture (Hispanic) product should be greater than for the scarce dominant culture (American) product.

The stimuli were fictitious movie promotions: the movie title and plot theme was Hispanic ("*Los Hermanos Garcia*") or American ("*The Murphy Brothers*"). The movie premier was a select city limited engagement (scarce) or a nationwide (non-scarce). Purchase intention was operationalized as likelihood of seeing the movie and biculturalism was assessed with a single-item self-report measure. Manipulation checks were successful.

A 2 (Product: Hispanic v. American) x 2 (Scarcity: high v. low) x 2 (Participant: bicultural v. monocultural) between subjects factorial ANCOVA was conducted on purchase intentions. To eliminate potential extraneous influences psychological reactance and movie quality are covariates.

The product culture x scarcity x biculturalism interaction was only marginally significant ($F(2, 74)=2.78$, $p=.10$), perhaps due to the heterogeneity of the biculturals in our sample (e.g., African American, Portuguese, Hispanic, etc.). Biculturals are more likely to see the scarce Hispanic movie ($M=3.31$) than the scarce American movie ($M=2.04$) and more likely to see the non-scarce American movie ($M=2.46$) than the non-scarce Hispanic movie ($M=1.99$). Biculturals were more likely to see the scarce ($M=3.31$) than the non-scarce Hispanic movie ($M=1.99$). Monoculturals were more likely to see the scarce American movie ($M=2.48$) than the scarce Hispanic movie ($M=1.96$) and slightly more likely to see the scarce ($M=2.48$) versus non-scarce ($M=2.67$) American movie.

These results support our cultural identification motive activation account. Both biculturals and monoculturals reported greater purchase intentions toward scarce movies matching their cultural background than toward non-scarce movies matching their cultural background, supporting the idea that scarcity increases the salience of product culture and its likelihood of triggering a cultural identification motive resulting in greater purchase intention. More importantly, consistent with the culture identity activation hypothesis, biculturals had greater purchase intentions toward the non-dominant cultural product (i.e., Hispanic movie) than the dominant culture product (i.e., American movie) and monoculturals had greater purchase intentions only toward the dominant culture product than the non-dominant culture product, suggesting that differential effects for the cultural identification motive activation by the cultural product cues exist between bicultural and monocultural consumers.

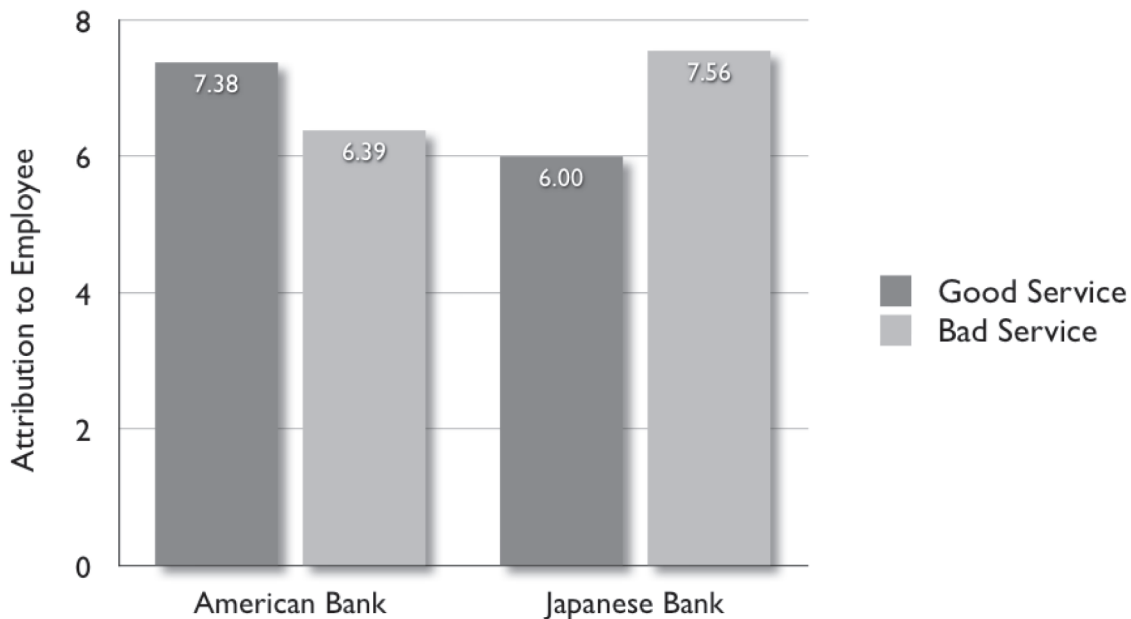
# Country-of-Origin Effects on Consumers' Attributions and Word-of-Mouth Communications about Services

Kachat Andrew Wong, University of Southern California, USA
Valerie Folkes, University of Southern California, USA

What do you think of when you hear about a person's bad experience with a Japanese bank, a French airline or a Turkish hotel chain, as opposed to an American counterpart? Research on country-of-origin (COO) effects suggests that consumers' inferences about the experience should differ depending on beliefs about the country (e.g., Leclerc, Schmitt, and Dubé 1994; Maheswaran 1994). Knowledge of a product's COO promotes category-based processing, which influences cognitive inferences about quality and performance (Hong and Wyer 1989, 1990). Whereas past research focuses on products, there is little research on service-related COO effects. Yet, consumers'

**FIGURE 1**

Attribution to Employee as a Function of COO Favorability and Service Quality, Experiment 1



inferences about services may differ in some important ways from inferences about products, depending particularly on stereotypes about individuals. Our research examines COO effects on consumers' attributions for service quality. Further, we relate those inferences to consumers' descriptions of a service encounter to shed light on COO effects on consumers' word-of-mouth communications.

We propose that the congruency between service quality (good vs. bad) and COO stereotypes (favorable vs. unfavorable) influences the types of causal attributions consumers make about a service encounter as well as how they describe those encounters to others. Stereotype-congruent scenarios lead to dispositional as opposed to situational attributions, which, in turn, reinforce existing COO beliefs. Drawing on the linguistic bias literature (e.g., Maass, Montalcini, and Biciotti 1998; Wigboldus, Semin, and Spears 2000), we further propose that such congruency leads to greater use of abstract language as opposed to concrete language when describing that encounter to others. .

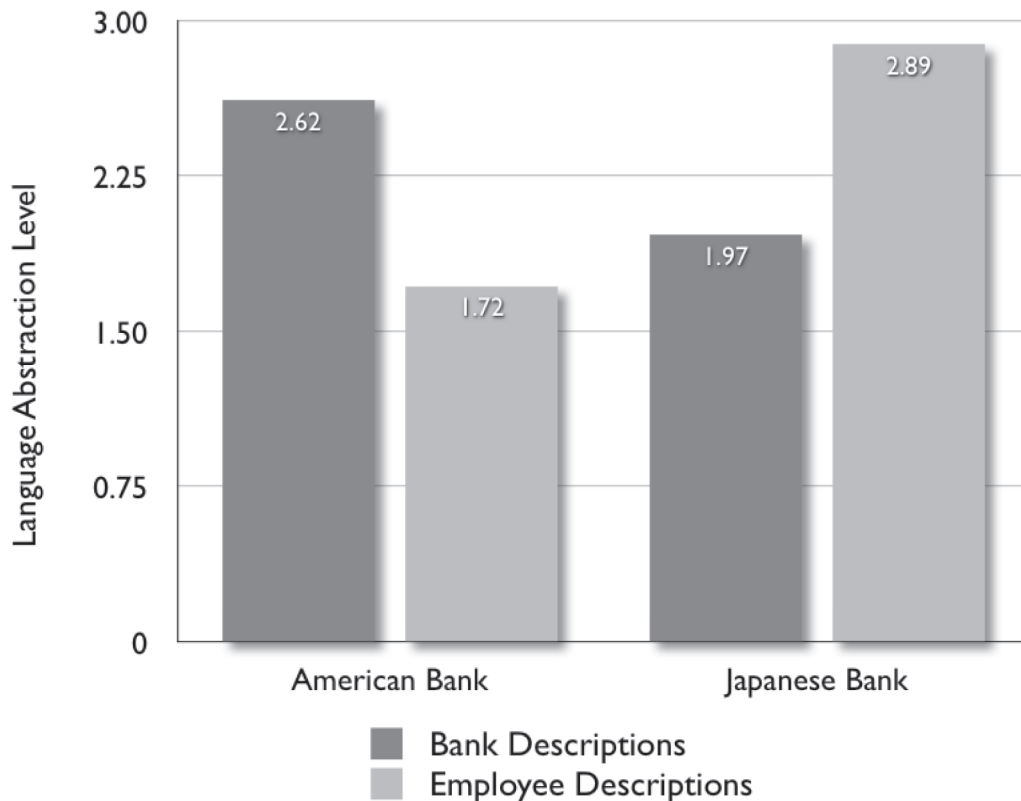
The linguistic bias model has shown a tendency to describe expectancy-consistent information at a higher level of abstraction than inconsistent information. The definition and operationalization of language abstraction are based on the linguistic category model (Semin and Fiedler 1988), which categorizes words into different levels of abstractness. At the most concrete, verbal descriptions maintain an immediate reference to concrete behavioral events. At the most abstract, descriptions maintain an abstract reference to a person's psychological properties (i.e., their traits and dispositions). For example, a service episode can be described in concrete terms ("it takes the server 5 minutes to get the bill") as well as in abstract terms ("the server is slow and forgetful!"). Testimonials that differ in abstraction level may prompt recipients of that information to differ in their conclusions about and use of the information. We hypothesize that COO stereotype-congruent scenario will be encoded abstractly whereas incongruent scenario will be described concretely. We conducted two experiments to examine COO effects on evaluations, attributions and linguistic biases.

In study 1, 80 undergraduate students were randomly assigned to conditions in a 2 (COO: USA vs. Japan) x 2 (quality: positive vs. negative) between-subjects design. Participants were given brief background information about a fictitious bank, which was based in either USA or Japan. Separate pretests confirmed that USA was a favorable whereas Japan was a less favorably COO for banking services. Participants then listened to a recording of a telephone conversation between a customer and a bank representative. The service encounter rolls were enacted by two Caucasian voice-talents who remained constant throughout all conditions. Service quality was manipulated via the manner in which the employee handled the caller's complaint. In the good service condition, the way the employee handled the problem was polite and empathetic, whereas in the poor service condition, she was rude and unconcerned. After listening to the recording, participants received a questionnaire asking for evaluations of service quality and causal attributions for the outcome (e.g., causality attributable to the bank versus to the employee).

Causal attributions ratings were submitted to a 2 (COO) x 2 (quality) ANOVA. The expected 2-way interaction ($F(1, 76)=9.83$, $p=.002$) emerged such that the positive service was more likely to be attributed to the employee's traits in the American bank compared to the Japanese bank ($M_{USA}=7.38$ vs. $M_{Japan}=6.00$; $t(76)=2.26$, $p=.03$). Conversely, the negative service was *less* likely to be attributed to the employee in the American bank compared to the Japanese bank ($M_{USA}=6.39$ vs. $M_{Japan}=7.56$; $t(76) =-2.19$, $p=.03$). The results suggest that when the service was congruent with the COO stereotypes, consumers are inclined to make dispositional inferences and attribute the cause to the intrinsic traits of the agent (Reeder et al. 2004). An activated COO stereotype on the firm level should have triggered a corresponding stereotype about individuals.

We conducted another study ($N=68$) to further explore the COO effects on consumers' communication. The procedure and manipulations were the same as in study 1. In addition, participants provided a verbal description of the service encounter immediately

**FIGURE 2**
Language Abstraction Level as a Function of COO Favorability and Types of Description, Experiment 2



after they listened to the recording. Their open-ended responses were classified as to whether they were bank or employee-specific and then coded on the basis of the linguistic category model (Semin and Fielder 1988). The mean levels of abstraction were computed for the bank and employee-specific descriptions respectively, ranging from 1 (the most concrete) to 4 (the most abstract). A 2 (COO) x 2 (types of description) ANOVA revealed a significant interaction ($F(1, 64)=8.15$, $p<.006$). Whereas the average abstraction level of the bank-specific descriptions was not statistically different between the American and Japanese bank ($M_{USA}=2.62$ vs. $M_{Japan}=1.97$; $p=.12$), employee-specific descriptions exhibited a significant difference in abstraction level ($M_{USA}=1.72$ vs. $M_{Japan}=2.89$; $t(64) =-3.22$, $p=.002$). The descriptions associated with the Japanese bank's employee were high in abstraction, implying a stable, dispositional attribution to the employee. The positive correlation between the abstraction levels of employee-specific description and employee attribution ($r=.24$, $p=.05$) provides converging evidence to support the effects of attributions on linguistic biases.

In conclusion, consumers evaluate service quality through the tinted glass of COO stereotypes. When the outcome is congruent with existing beliefs, they tend to make a stronger dispositional attribution and describe the encounter more abstractly than when the outcome is incongruent. Future research should explore how the match/mismatch between the ethnicity of employee and COO moderates the effects. An important implication of this research is that the biased use of language by communicators may prompt recipients to make stronger dispositional attributions. Additional research should investigate the role of biased use of language in stereotype maintenance and dissemination in consumer's networks.

# Role of Incongruity and 'Aha' Effect in Positive Affect Experienced from Visual Metaphors

Praggyan Mohanty, University of Missouri, USA

A recent ad for Microsoft Office showed a female standing in an office setting with the head of a dinosaur. The ad copy read as "Microsoft Office has evolved have you?" This is an example of a visual metaphor, a type of rhetorical figure that is used extensively in advertising and communication(Phillips 2003). A *visual metaphor* makes an analogical comparison between two terms, by stating that one term is figuratively like the other term, even though the two are literally different (Stern 1990). The visual of a dinosaur's head on a female's body is incongruous, it does not make sense at a literal level. This incongruity in the visual attracts attention and one is drawn towards reconciling the incongruity. Only at a figurative level, can one interpret that the ad is suggesting that the female is "outdated, anachronous" and needs to upgrade to newer versions of Microsoft Office. The incongruity in the visual makes the ad stimulating (McQuarrie and Mick 1996; McQuarrie and Mick 1999; Peracchio and Meyers-Levy 1994), elicits some level of exploratory behavior(Berlyne 1960) and subsequent resolution of incongruity with meaningful perceived comprehension yields what is termed in semiotics literature as 'pleasure of the text' (Barthes 1986). 'Pleasure of the text' is conceptualized as the positive affect that the viewer experiences due to the viewer's subsequent perceived comprehension of an initially incomprehensible text.

We embark on a journey to address two unanswered questions in advertising and marketing literature: (i) What is the nature of relationship between incongruity in visual metaphors and affect? (ii) What is the mechanism by which incongruity in visual metaphors leads to positive affect? First, the relationship between incongruity in visual metaphors and positive affect has not been examined empirically in the marketing literature. Research has demonstrated the "figures effect" i.e. rhetorical figures versus literal expressions have a significant positive effect on attitude-toward-the-ad (McQuarrie and Mick 1999; Mothersbaugh et al. 2002). But we are still uninformed about the effect of different levels of incongruity in rhetorical figures (visual metaphors in our study) on ad evaluations. Second, the process by which incongruity in visual metaphors leads to positive affect though has attracted theoretical discussions; it still has not been empirically examined.

We propose a *process model* to empirically examine the effect of different levels of incongruity of visual metaphors on affect. We define, *incongruity in a visual metaphor* as the degree to which there is the lack of structural and semantic correspondence between the source and target elements in the visual metaphor in the presented context and the pre-existing knowledge structures associated with source and target elements in the given context. There are two routes that account for the effect of incongruity of visual metaphors on affective evaluations. One is the *perceptual route* and other is the *comprehension route*. *Perceptual route* is the direct effect of the incongruous stimuli on affect. On the other hand, *comprehension route* is the effect of incongruity of visual metaphor on affect mediated by comprehension. The *perceptual route* can be understood in terms of *arousal boost* concept and *comprehension route* can be understood in terms of *arousal jag* concept introduced by Berlyn (1971; 1960) in context of collative variables. The two routes can be reconciled to understand the overall effect of incongruity in an ad on advertising evaluations. We propose a non-linear relationship between incongruity in a visual metaphor and affect. This argument is informed by theoretical paradigms proposed by Berlyn (1971; 1960) and the schema incongruity theory (Fiske and Taylor 1991; Mandler 1982). The perceived comprehension and perceived certainty of comprehension play a crucial role in the intensity of affect experienced from the metaphor.

*H1*: Incongruity in visual metaphors will have a non-linear relationship with affect. Moderate level of incongruity versus low level of incongruity in a visual metaphor should lead to a greater level of positive affect. Also, moderate level of incongruity versus high level of incongruity in a visual metaphor should lead to a greater level of positive affect

A mediatory process of interest in this process model is the 'aha experience'. The 'aha experience' is a transition from a state of incomprehension to that of comprehension of the stimulus. The 'aha experience' therefore is an outcome of the combination of *arousal boost* caused by perceptual route and *arousal jag* caused by the comprehension route. 'Aha' is experienced in case of visual metaphors because the incongruity is meaningful or metaphorical comprehension resolves the incongruity. We propose that incongruity in a visual metaphor will have a non-monotonic relationship with the 'aha experience'. That is moderate level of incongruity should lead to maximum intensity of 'aha'. It is the 'aha experience' that leads to the 'pleasure of the text'. *Pleasure of the text* is the positive affect that a viewer experiences due to the viewer's perceived successful comprehension of an initially incomprehensible text. 'Pleasure of the text' is like the thrill one experiences from cracking a puzzle (Peracchio and Meyers-Levy 1994). The stronger the 'aha experience', the greater should be the 'pleasure of the text'.

*H2*: Incongruity in a visual metaphor will have a non-linear relationship with the 'aha experience'

*H3*: The 'aha experience' will mediate the relationship between incongruity of visual metaphor and pleasure experienced from a visual metaphor

*H4*: The 'aha experience' will have a linear relationship with pleasure experienced from a visual metaphor

We hope to make the following contributions to research, both in the area of rhetorical figures and interplay of emotions and cognitions. We propose to empirically examine the relationship of incongruity in visual metaphors and affect. Our study will throw light on the process by which incongruity in a visual metaphor leads to positive affect. In attempting to study the 'aha experience', we intend to introduce a relevant mediator to advertising studies. Also, we hope to make a contribution by presenting a method of operationalizing incongruity in visual metaphors. All of the above are gaps in the current marketing literature. Given the preponderance of visual metaphors in advertising, our research would make a managerially as well as academically relevant contribution.

# The "Kick Him While He's Down" Effect: Consumers' Responses to Unfortunate Leaders when Judging Corporate Crime

Morgan K. Ward, University of Texas, USA
Julie R. Irwin, University of Texas, USA

In an era in which corporate crime is an increasingly common occurrence, the issue of how a company that has committed a crime should approach its media relations and PR is both relevant and important to practice. Companies that are found guilty of corporate crimes risk erosion of brand equity, consumer boycotts and other forms of consumer punishment. However, consumers' judgments about and subsequent actions towards a criminal company are often influenced by information beyond the simple facts of the case. In two studies, we investigate how people's perceptions of a company's leader influences their feelings and judgments (e.g. anger at, forgiveness for) and purchase decisions.

One of the moral tenants guiding legal judgments of guilt is that "all individuals are to be judged by the purposeful actions they commit and *not* by the random events that befall them". (legal requirement of "mens rea"). In practical terms, a man should not be judged negatively for being unlucky (e.g. getting cancer).

However, there are many examples in which a person's unfortunate circumstances partially "excuse" him of wrongdoing in the eyes of others. Companies leverage this idea and often act in accordance with their lay theory that highlighting the misfortune of their leader may create consumer empathy and lessen consumers' punitive actions in response to the company's crime. A recent example of this occurred when the felony charges of spying on employees were dropped against the CEO of Hewlett-Packard, after news of her advanced ovarian cancer was released to the public. MSNBC reported that "authorities said [her] battle with cancer was at least partly responsible for their decision to drop the case against her."

Though it is intuitive, that featuring the misfortunes or bad luck of a leader will garner consumer sympathy, the inference-making literature predicts the opposite. Research on the Imminent Justice Hypothesis (Piaget 1965, Fein & Stein 1977) and the Just World hypothesis indicates that people harbor the (irrational) belief that "a fault will automatically bring about its own punishment" (Piaget 1965). In other words, if an individual commits a criminal act, he will inevitably receive just retribution. Using this rationale, people may be *less* sympathetic to criminal CEOs who have suffered misfortune and rather than empathizing, conclude that they have "gotten what they deserve." Moreover, recent research on children's' judgments of unlucky vs. lucky people (Olson et al. manuscript) indicates that children have a natural preference for lucky over unlucky people and often discriminate against people deemed less lucky.

In two studies, we examine whether highlighting the misfortunes of a CEO creates empathy and forgiveness for a company embroiled in a corporate crime, *or* if highlighting the "unluckiness" of the CEO simply causes people to like the CEO and take punitive actions, or conversely, take pity and purchase more. In a 2 (CEO Luck: Unlucky vs. Control) x 2 (Crime Severity: High vs. Low Crime) design, we test how the luck of the CEO influences people's judgments of the crime, the company and the CEO.

In study 1 we presented participants with a hypothetical crime scenario in which a company underpays its workforce (minor crime scenario) or underpays, harasses and abuses it workforce (severe crime scenario). We crossed the severity of the crime with the luck of the CEO. In both conditions we described the CEO's background (e.g. age, number of children, past positions); in the Unlucky condition we added that the CEO's wife had recently been killed in a hit and run accident. The results supports corporate intuition that people are

more willing to forgive a company for corporate crimes if the company is headed by an Unlucky vs. Control CEO when the crime is small but less forgiving for large crimes.

In Study 2, we further investigate how consumers differentially respond to Unlucky CEO vs. Control CEO in low vs. high crime scenarios. We presented participants with a hypothetical the high vs. low crime scenarios described above in the form of a newspaper. The articles describe the crime of a hypothetical cell phone company (MobiFon). In the Unlucky condition the article also explains that the CEO has recently been diagnosed with cancer.

After reading about the article, participants filled out a conjoint study indicating their preference ratings of cell phones from MobiFon (vs. another hypothetical cell phone company called Connex). We varied the phones on the attributes of brand, price and styling. We then collected participants' attitudes about the crimes, CEO and the company. We find that in low crime conditions, participants indicate they are not very angry at the CEO, are more willing to forgive the MobiFon brand and are more likely to purchase a product from MobiFon if the CEO has cancer than if he has no health problems. These results confirm corporate intuition of consumer empathy and forgiveness. However contrary to this corporate lay theory, in high crime conditions (where participants indicate feeling more angry and less forgiving), they display a "kick him while he's down effect". Specifically, they indicate that they are much *less* willing to purchase a product from MobiFon if the CEO is diagnosed with cancer than if he has no health problems.

Our results expose several contextual and individual factors that contribute to consumers' responses to Unlucky leaders. The results corroborate the notion that people are influenced by CEO's personal attributes and misfortunes when making judgments about a company after a corporate crime has been committed. Moreover, it appears that while people are motivated to make decisions based on the direct actions of a CEO in the corporate crime, they ultimately allow non-diagnostic factors to influence their decision. Finally, the results confirm that companies' lay theory that revealing the misfortunes of their leaders is a good tactic in mitigating consumer anger at the company after a crime has been committed in small crimes but when the crime is more egregious, this may ultimately undermine the company's attempt to reinvigorate business.

# Examining the Effects of Narrators' Accents When Informational Programming Has Verbal and Visual Cues

Juliana Renovato, San José State University, USA
Therese A. Louie, San José State University, USA
Erica Melissa Medina, San José State University, USA
Cynthia A. Enriquez, San José State University, USA
Janalee Velasquez, San José State University, USA

Imagine that an overseas documentary has a narrator who speaks like a North American national news anchor. For added authenticity, the show's producers added a second reporter whose native language influences heavily his or her English-speaking accent. This research examines how accents influence viewers' evaluations of informational programming.

Research findings suggest that the responses to accents depend in part on the listeners' contexts (Fuertes, Potere, and Ramirez 2002). Although accents can draw favorable attention in entertainment programming, they have had less positive effects on informational materials. The distinction may be due to a greater need for comprehension in learning, than in leisurely, environments. Gill (1994) asked American students to listen to tape recordings of male teachers who spoke with one of three accents. Instructor perceptions were more favorable when he had a North American—rather than a British or a Malaysian—accent. Participants' level of understanding and degree of recall also were highest with the North American speech.

Building upon past research, this study more directly analyzed the link in Gill's (1994) work between the evaluation of the speaker and the degree to which participants felt they could understand him. Somewhat surprisingly, the connection between evaluations and perceived comprehension has not been a primary focus in studies showing deleterious accent effects. Also, unlike the studies noted above, this work provides information in visual, as well as in auditory, form.

An actor skilled in accents provided the narration for a documentary-style program about a Latino celebration called a "Quinceañera." Pretests revealed that he could convincingly speak with both a North American accent and with speech that reflected native fluency in Spanish. Thirty-seven undergraduates were randomly assigned to view the video with the North American ($n=16$) or with the Spanish-language influenced speech. The unseen actor's voice described parts of the ceremony simultaneously shown on tape.

An initial set of analyses examined if findings of accent derogation (e.g., Gill 1994) were replicated. When not accounting for the audience members' perceived ability to understand the narrator, the participants preferred the video with the North American accent rather than the Spanish-influenced accent upon noting (a) the video's informational value ($t(35)=2.39$, $p<.03$), (b) the narrator's knowledge of the video topic ($t(35)=2.15$, $p<.04$), (c) the ease of understanding the narrator's voice ($t(35)=6.60$, $p<.001$), and (d) the total number of open-ended recalled items ($t(35)=3.83$, $p<.002$).

Then, a second round of analyses was conducted to determine if the significant effects were due to participants' perceived comprehension of the narrator. When examining the data using "ease of understanding" his voice as a covariate, the differences between the accent conditions are not significant ($p$s>.10) for all variables but the mean total recalled items ($F(1, 36)=7.11$, $p<.02$).

Hence, in informational programs with both visual and aural stimuli, a preference for non-accented voices could be due largely to the perceived ability to understand the presented style of speech. Of course, comprehending a non-native speaker depends largely upon the strength of—and upon listeners' familiarity with—his or her accent. Depending upon those factors, according to this research, there may be drawbacks to the practice of adding narrators with foreign accents to increase cultural programs' authenticity. Rather than enhancing credibility, the narrator's foreign accent reduced his perceived knowledge of the program topic.

It is important to note that the five-minute video used in this research did not give audience members much time to adapt to the speaker. Longer exposure to the accents might facilitate comprehension. Advertising legend David Ogilvy used this strategy, noting, "I am particularly nervous about the impact of my English accent… I therefore open with axioms which nobody can question. By the time the audience grows accustomed to my accent, I launch into more controversial judgments" (Ogilvy 1964).

Researchers can investigate factors affecting the "ease of understanding" variable influential in this study. Aside from the ability to comprehend heavily accented words, there are a number of framing issues that influence listeners. Work on "fluency" suggests that messages that are subjectively difficult to decipher produce compromised choices (Novemsky, Dhar, Schwarz, and Simonson 2007). Even if an individual's speech is understandable, the presence of an accent may prime listeners to anticipate comprehension difficulty, which subsequently could lower their evaluations (Rubin and Smith 1990). In addition, prior associations with accents might affect fluency, as might the ability to watch the narrators' expressions and body language.

The program topic may shape viewers' responses. If individuals presenting material related to their home countries appear biased (Ryu, Park and Feick 2006), it might decrease listeners' attention. Also, while cultural content may make a narrator appear more ethnic, it is possible that programming prompting expectations for a mainstream voice reduce or eliminate perceptions of foreign accents (Rubin and Smith 1990). Research can further investigate how message content frames audience members' evaluations.

Media technology continues to expose audiences to speakers around the world. It is hoped that this research sheds insights into the perceptions of accents when segments and shows have informational content.

# The Lifestyle Consumer Confidence Index: Detecting the Undercurrents and Dynamics of Consumer Confidence

Michael Merz, University of Hawai'I, USA
Qimei, Chen, University of Hawai'I, USA

Businesses, private investors, and public policy makers have long noticed that anticipating future consumer spending and saving behavior is key in today's marketplace (Georgoff and Murdick 1986; Kotler 1994; Lawson, Todd, and Boshoff 2001; Lilien and Kotler 1983). For example, anticipating consumers' future expenditures can help managers assess the general mood of the market and plan their marketing activities accordingly. Furthermore, private investors can benefit from such information to assess the right moment to make great investments. More importantly, such information can give public policy makers early warnings about whether the economy is moving towards recovery and growth or recession.

While early predictions of consumer consumption behavior solely focused on objective, economic variables—such as income, interest rate, and inflation rate—Katona (1951, 1960) suggested that consumer expenditures do not only depend on consumers' ability to buy but also on their willingness to buy, and thus on more subjective, psychological factors. This notion has become known as the theory of psychological or behavioral economics (Curtin 1982; Katona 1974). It has stimulated the development of many indexes, which have in common the goal to measure consumer confidence, or sentiment, as an indication of the future course of the national economy (Curtin 1982; Linden 1982; Roper 1982).

Prior research has focused on comparing the predictive value of different consumer confidence indexes (Batchelor and Dua 1998; Eppright, Arguea, Huth 1998; Huth, Eppright, and Taube 1994) and on explaining variance in such measurements (Garner 1981; Vuchelen 2004). A similar research stream has developed in marketing (Barksdale and Darden 1972; Barksdale, Darden, and Perreault 1976; Barksdale and Perreault 1980; Gaski and Etzel 1986) and assessed consumer confidence towards marketing in the international marketplace (Chan, Yau, and Chan 1990; Wee and Chan 1989).

While these prior research streams have led to interesting and helpful findings, several limitations (such as measurement items, methodology, and applicability) of existing consumer confidence/sentiment indexes are yet to be addressed (Didow, Perreault, and Williamson 1983; Weiss 2003). In particular, it has been argued that psychographic or lifestyle variables are needed to help explain the undercurrents, that is, the variation in consumer confidence across the population (Lawson, Todd, and Boshoff 2001) and that the dynamics of consumer confidence—and thus the movement in optimistic and pessimistic directions over time—need to be understood further (De Boef and Kellstedt 2004; Garner 1981).

The purpose of this article is to develop an index that facilitates our understanding of the consumer confidence construct and that helps capture its undercurrents and dynamics. Specifically, we aim at (1) developing a *lifestyle consumer confidence index (LSCCI)*, (2) applying this new index to demonstrate the importance for public policy makers to conduct cross-sectional analyses to understand the *undercurrents*,

that is, the current composition of consumer confidence, and (3) revealing the significance for public policy makers to conduct longitudinal analyses to detect the *dynamics* of consumer confidence over time.

To develop our index that projects consumers' perceived confidence, a secondary data analysis was undertaken. Factor analysis revealed that the total LSCCI can be divided into two sub-indexes: one sub-index that measures consumers' present confidence (our Present Lifestyle Consumer Confidence Index; PLSCCI) and another sub-index that measures consumers' future confidence (our Future Lifestyle Consumer Confidence Index; FLSCCI).

For our analyses, we calculated consumers' confidence from 1997 until 2001, based on the data available from the DDB Needham Life Style Study. By doing so, we obtained several interesting and important preliminary results in respect to our cross-sectional, micro-level as well as our longitudinal analyses. These findings have important implications especially for public policy makers. Overall, we demonstrate that the regular screening of cross-sectional consumer confidence helps identify the undercurrents, that is, the momentum that takes place below the aggregated surface of the overall consumer confidence. As such, the segmenting variables as well as the problematic groups within a particular variable that constitute potential threats to the local economy can be identified. Further, to perform a regular screening over time helps chart the dynamics of those undercurrents. As such, consumer segments showing negative or highly fluctuating trends over time can be identified and addressed to avoid potential recessions, and instead strengthened to prompt economic recovery or stability. Hence, our proposed LSCCI helps discover challenging segments that (1) are low in consumer confidence in a particular year, (2) show a continuously decreasing level of consumer confidence, and (3) are very unstable over time. By discovering such challenging segments, public policy makers will be able to form preventive policy and are, to a certain extent, able to direct the local economy into the desired direction.

# Parenting, Peer Influence, and Role Model on Compulsive Buying Tendencies of Early Adolescent Consumers

Chuanlan Liu, Louisiana State University, USA
Robert Laird, University of New Orleans, USA

Researchers have proposed to take different approaches to investigate the phenomenon of compulsive consumption (d'Astous, Maltais, & Roberge, 1990; DeSarbo & Edwards, 1996; Hassay & Smith, 1996; Roberts & Pirog Iii, 2004). d'Astous, Maltais and Roberge (1990) argued that a generalized urge to buy characterized all consumers at different levels and probably at different times, and therefore compulsive buying tendency may be a continuum with one end specifying normal buyers and the other specifying compulsive buyers. Compulsive buyers are at the extreme of the urge to buy continuum all the time. However, the research to date focused only on the most extreme form of compulsive buying and neglected to recognize individuals who have not yet reached full-blown addiction (DeSarbo & Edwards, 1996).

DeSarbo and Edwards (1996) argued that compulsive buying is related to different forms of drives and degrees of urge to buy and therefore compulsive buyers are heterogeneous groups. However, previous research adopted a uniform dichotomous compulsive treatment of buying behavior and thus leaves open the key issue of whether individuals classified as compulsive buyers have different internal or external drives. In fact, recent research suggested that consumer researchers should pay attention to the purposive element of compulsive behavior and to consider that compulsive buying may be viewed as a logical outcome for people who have personal goals rather than just being caused by psychological tension (e.g., Roberts & Pirog Iii, 2004).

Compulsive buying is not only linked to individual psychological traits such as dependence, denial, and depression but also linked to circumstantial factors such as avoidance coping, and family influences such as divorce (Roberts, Manolis, & Tanner, 2006). However, there is insufficient research related to exploring circumstantial and family related factors on compulsive buying behavior.

This research focused on compulsive buying tendencies of early adolescent consumers. Although common depictions of adolescence as a time of "storm and stress" appear to be exaggerations, adolescence is a period of great transition both for individuals and their families (Arnett, 1999; Hamburg, 1985, 1974). The transition from childhood to adolescence brings with it a new set of issues and concerns for childrens as children try to establish an identity separate from parents during this transitional development stage (Gecas & Seff, 1990) and for parents (Pasley & Gecas, 1984; Small, Eastman, & Cornelius, 1988) as parents approach mid-life, and the parent-child relationship becomes more egalitarian (Baumrind, 1991; Steinberg & Steinberg; 1994). This group of consumers provides rich potentials for us to

understand more on compulsive buying. For instance, this group of consumers enables us to investigate compulsive buying at the early/ light stage and to identify different types of motivations for compulsive buying other than psychological tension.

For early adolescents the personal goal to establish an identity separate from parents or others may be a more salient drive to develop compulsive buying tendencies than reducing psychological tensions. Previous research found that peers' influence on teenagers' identity establishment is reflected through impacted teenagers' consumption (Mangleburg, Doney, & Bristol, 2004). For instance, peer groups are voluntary in nature and are not directly responsible for monitoring teens' actions, but peers may provide an early forum in which teens can try out various aspects of the social self. In terms of buying and consumption, studies have shown that communication with peers positively affects teens' social motivation for consumption, materialistic values, and tendency to use peer preferences in making a product choice. Therefore, we propose that peer influence has significant impact on compulsive buying tendencies.

Another factor having significant impact on identity establishment may be role modeling. A role model for an adolescent can be anyone with whom the individual comes into contact, either directly or indirectly, who potentially can influence the adolescent's decision or behaviors (Bandura, 1986). Parents are the "assigned" role modes for adolescent. However, most adolescents choose their own "vicarious" role models which can be television and movie stars, athletes, or even best friends, as opposed to the role models of parents. Role models may influence adolescents on adopting their own set of self-image, lifestyle, and consumption pattern, and therefore have influence on adolescents' compulsive buying tendencies. Furthermore, parenting factors (e.g., parental solicitation, spending supervision) in this transitional stage may have significant influence on compulsive buying tendencies of early adolescent consumers. Specifically, parental solicitation may reduce adolescents' psychological tension. However, parents' over solicitation may create some psychological tension for adolescents and hence increase their compulsive buying tendencies. Supervision of spending helps adolescents to control spending, however, it may increase adolescents' desire to be independent from parents and therefore, increase the degree of urge to buy.

The primary objectives of this exploratory study were to (1) estimate the incidence of compulsive buying in an early adolescent population, (2) investigate the impact of parenting factors (parental solicitation, spending supervision), role model, and peer influence on compulsive buying of pre-teens.

Data from the Baton Rouge Families and Teens Project (BRFTP) were used to test the hypothesized research model. The BRFTP sample includes 133 parent-child dyads that were recruited at the end of grade 6. The sample is 45% female and 64% of the adolescents live in a two-parent home. 42% of the adolescent are White, non-Hispanic, 48% are African-American, and .8% are Hispanic. Measures were derived from questionnaires administered verbally to the adolescents during a summer visit to each family's home.

Because of the present study's focus on adolescents, the 11-item adolescent Compulsive Buying Scale developed by d'Astous et al. (1990) was used. Higher scores on the Likert-type items were associated with higher levels of compulsive buying. The measure of role model influence was adopted from Martin and Bush's research (Martin & Bush, 2000). The scale of susceptibility to normative peer influence was adopted from Mangleburg et al (2004). Two monitoring processes described and tested by Stattin and Kerr (2000) were used with slight modifications of the items to make them appropriate to early adolescents. Parental solicitation as measured with 5 items and supervision of spending were measure with 6 items.

Factor analysis on compulsive buying tendencies found that this construct was multidimensional. Three dimensions were identified: *(a) urge to buy, (b) lack of impulse control, and (c) post purchase guilt*. Path analysis results revealed significant and positive paths from urge to buy to lack of impulsive control, and to post purchase guilt, paths from susceptibility to normative peer influence to the three dimensions of compulsive buying tendencies, paths from role models to susceptibility to normative peer influence, and urge to buy, and a path from supervision of spending to lack of impulsive control. The paths from parental solicitation to the three dimensions of compulsive buying tendencies were not significant. However, there was a significant negative path from parental solicitation to susceptibility to normative peer influence. Results show that early adolescents' compulsive buying tendencies are mainly influenced by peer and role mode. Influence of parenting is mediated by peer influence. These findings indicate that compulsive buying tendencies may be developed by the early adolescent stage. At early stage of compulsive buying tendency, purposive element such as identity establishment may be a more salient factor than psychological tension on moving this tendency toward the extreme point of the compulsive buying continuum.

## Consumer Inferences about Hybrid Goods and Services from Pricing and Innovation

Nita Umashankar, University of Texas, Austin, USA
Raji Srinivasan, University of Texas, Austin, USA

As services become a key source of differentiation, a growing number of new products exhibit the inclusion of both goods and service components. Assuming that firms operate under budget constraints, the decision to introduce new services versus new goods for hybrid products becomes a key strategic variable. Three studies examine how consumers balance their desires for goods versus service innovation in hybrid products and under what conditions these preferences shift. Findings reveal that consumers prefer the locus of innovation to reside on the goods component and this preference is strengthened by positioning the hybrid as a physical product. However, designing for customization and social networking shifts preferences towards innovation of the services component. Further, pricing the two components differentially produces asymmetric effects of perceived benefits for each element of the hybrid. The results suggest that firms can design and price the goods and services components uniquely to maximize overall profitability.

## The Good, the Bad, and the Red: Does "Giving" through Buying Replace Direct Giving?

Aner Tal, Duke University, USA
Paul Bloom, Duke University, USA

Product Red is just the latest in an ongoing procession of charitable promotions led by for-profit companies. Naturally, such activities are highly publicized and integrated with companies' promotional activities, which leads some to doubt the altruistic intentions of the companies involved (Fry et al., 1982; Varadarajan & Menon, 1988) or even assume utilitarian motives for company donations (Strahilevitz & Myers, 1998; Bloom & Novelli, 1981).

Of course, whether or not the reasons for corporate donations are pragmatic, a dollar is a dollar, and donations stand to increase public well-being regardless of what motivated them. Further, common sense would lead one to assume that corporate donations increase the social salience of donations, potentially increasing donations overall. But what if corporate charitability leads people to feel that by buying charity-tied products they have "done their job" and need not contribute more? Could giving through buying actually *replaces* direct giving?

The possible substitution of direct charitable donation by "donation" through buying is especially pertinent in one particular kind of cause-related marketing: the donation of a percentage of sales or profit to charity (POS). Here, it is the *consumer* rather than the *company* who is directly responsible for the donation. Through buying a $20 Product Red sweater, the consumer might feel that they have given to charity and thus satisfy the "need" to give. The result might be a reduction in the overall sum transferred to charity, since psychologically the person feels they "gave" $20, while in fact they have only given the 5% of the price that is transferred to charity. Thus, a donation of $4 (5% of $20) feels greater than it actually is, and might substitute what would have been a greater direct donation (see Olsen et al., 2003).

The current paper explores the potential effect of projects such as "Red" on subsequent contributions. In two studies, we demonstrate the basic "Red" effect: charitable giving through a "percentage of sales" (POS) leads to a reduction in subsequent giving. Followups are planned to explore boundary conditions. Additional studies will further explore the mechanisms underlying the phenomenon: The "Red" effect could be due to (a) an overvaluation of sums donated through POS and/or (b) a satisfaction of the motives that would otherwise lead to donation behavior.

*Study 1*. Participants in this study (*N*=132) engaged in simulated online shopping on Amazon.com. Each participant was asked to imagine they had a gift certificate for Amazon.com, and continued to browse Amazon and list items that they would like to buy using the certificate. In one condition (control), no further instructions were given. In the other condition (POS), participants were informed that on the same day "Amazon has a special promotion where they give X% of their sales proceeds to United Way" (including gift certificate sales).[6]

Following the shopping task, participants were told that Amazon was also receiving donations for the Red Cross, and asked how much if anything they would want to donate. After some demographic questions, participants were also asked if they would want to donate books to the library for a local charity sale occurring around the time of the studies. A sub-sample (n=87) of participants were asked about willingness to donate to a local homeless shelter following a fire, another real event that occurred at the time of the studies.

*Results and Discussion*. Mean donations to Red Cross were lower for the POS condition (*M*=$7.08) than for the no POS condition (*M*=$11.39). In other words, participants contributed less to charity if they had previously purchased items proceeds from which were donated to charity. Note that the difference between the two conditions ($4.31) far surpasses the maximum proceeds donated through purchase (average $1.82). Thus, a POS promotion similar to Product Red resulted in reductions in overall levels of charitable donations.

---

[6]While these conditions were the same for the entire sample, the study was conducted in three different waves. For the first (n=37), the gift certificate was for $70 and the percent given for charity was 3%. For the second (n=50), the gift certificate and percent given were $50 and 2% accordingly. For the third (n=45), the certificate was also for $50 but the percent given was 5%. Since there were no significant interactions for date-wave and condition we collapse observations across waves, distinguishing only between percent-of-sales donation (Red) and no donation conditions.

Since the results contained outliers, the data was transformed using a log transformation. An ANOVA model controlling for self-perceived charitability found a significant effect of condition on donation ($F(1, 122)=3.96$, $p=.05$).

Further support for the hypothesis that donation through buying would reduce subsequent charitable behavior was found through examination of the other DVs, though results here were directional but not significant. POS participants were less likely to want to contribute books (17.5%) than control participants (27%). Similarly, only 14% of POS participants expressed willingness to donate food cans to the local shelter, versus 36.4% in the control condition.

*Study 2.* The study aimed to replicate study 1 with a few alterations. First, a different merchant and shopping medium was used (catalog shopping for J Crew). Second, the subsequent, post-shopping trip donation opportunity was separated from the shopping trip by presenting it as an unrelated event occurring later on the same day. Third, another control condition was added where participants could donate directly during the transaction as part of their shopping trip (n=34). The certificate sum participants could spend in this task was greater than before ($200), and the percent donated was 5% for half the participants in the Red condition (n=16), and 10% for the other half (n=16). Due to shortage in participants only 13 participants were assigned to the original control condition, though condition assignment was random. Total sample consisted of 79 participants.

New measures were added as well. First, we measured the amount of money participants spent in the trip. This served to ensure participants indeed chose items and it also permitted a more precise evaluation of POS donations. Second, several attitude measures were taken regarding the retailer, the charity collaborating with the retailer, and POS and direct donation as charity raising efforts. Attitudes for each object were gathered using three 7-point semantic differential scales (Good-bad, warm-cold, like-dislike).

*Results and discussion.* Replicating the results of study 1, participants in POS conditions donated less (M=$10.83) than participants in either control condition (M=$14.45).[7] There was no significant difference between the two control conditions (p>.1), which suggests the reduction in donations following Red donation wasn't merely due to the fact that in POS conditions participants had already donated whereas in the control condition they had not. Participants evidently donated less in POS than in either direct donation or no donation in all conditions, though these findings require replication.

The study also contributes in revealing potential boundary conditions on the Red effect: when the percent of sales given was high enough (10%), donations thorough the Red promotion ensured there was no reduction in overall donations over control. Further, the higher POS ensured no loss to the non-profit due to lower donations than in a parallel direct-donation situation. Donation in the shopping trip itself through either POS or direct donation was higher in direct donation ($13.89) than in the 5% POS condition ($9.07), but lower than the amount given to charity in the 10% POS condition ($16.81). In both cases donations come at the expense of the retailer, but might lead to higher sales given shopping that is not restricted to a particular sum as it was in our experimental task.

Attitudes towards the retailer did not differ between Red and control conditions. Attitude towards the non-profit for which donations were raised was directionally, though not significantly, lower in the Red condition ($\Delta=.27$ on a 7 point scale, p=.19). Attitude towards POS as a way of raising donations, however, was significantly lower in the POS condition: 5.13 vs. 4.34; $F(1, 77)=6.59$, p=.01. This suggests participants supported percent of sales donation in principle, but not when actually subjected to it, though further study is needed to ensure the robustness of this finding.

*Proposed studies.* The Red effect might be driven by an overestimation of donations given through POS promotions. People might bias their perception of the amount donated in the direction of the full sum of the purchase, rather than calculating the actual sum given to charity (Olsen et al., 2003). Since people might thus replace direct donation with a lesser indirect donation this might lead to an overall reduction in subsequent donations. This could be examined by asking for people's estimation of the amount donated through POS.

An additional psychological factor that might lead to decreased donations following "buying donations" is a satisfaction of people's selfish motivations for helping behavior (Harbaugh et al., 1998; Manner et al., 2002). If people are motivated to donate for reasons such as self-esteem (Crocker et al., 2003) or mood management (Cialdini et al., 1973; Bauman et al., 1981), satisfaction of these motives through the (lower) POS donation might lead to subsequent lower direct contribution. Further studies could explore this mechanism by manipulating selfish motivation to help (e.g., mood) and observing the impact on the Red effect.

# Think Fast, Feel Good? Thought Speed Enhances Mood and Product Trial

Brittany Duff, University of Minnesota, USA
Ronald J. Faber, University of Minnesota, USA

The impact of emotions in advertising is generally examined by manipulating message content (e.g. fear appeal, humor) or imposed through context (neutral ad appearing in an uplifting program). Less common, but perhaps equally important, is the creation of emotion through the use of medium features of ads such as zooms, edits and cuts (Lang 1990). Recently, Pronin and Wegner (2006) found that simply speeding up the time in which people were given to read a series of statements aloud induced positive mood. In addition to increasing positive mood, this effect of fast thinking was found to also increase feelings of energy. This work suggests that speed of presentation can affect both arousal and valence.

Prior research with media messages has tended to focus just on the impact of these features on the arousal dimension of emotion and its impact on attention and information processing. Features, such as number of cuts in a commercial have been found to elicit orienting responses and increased arousal (Lang 1990). Moving images have been found to increase arousal over still images (Lang, Dhillon and Dong 1995). Research on the speed of animated banner ads has found that fast animation increases attention and elicits increased physiological arousal. In turn, this may increase resources for information processing (Fox et al 2004, Sundar and Kalyanaram 2004).

Pronin and Wegner's work, however, suggests that that animation speed might not only influence arousal and recall, but also alters the valence of feelings. This is similar to theories such as perceptual fluency, where faster processing elicits more positive mood (Winkielman, et al 2003), or clinical cases such as manic episodes which are characterized by 'racing thoughts' along with elated mood. If faster speeds in banner animation do indeed create more positive feelings, this positive mood may influence brand evaluations.

However, some research shows that arousal may not always cause positive emotions. For example, arousal can serve to enhance judgments of an ambiguous ad in the direction of one's prior (positive/negative) mood (Gorn, Pham and Sin 2001). If this is the case, animation speed may not influence brand attitudes. However, it may still influence brand trial through the effect of arousal alone. Here, arousal may serve to tax self-regulatory resources and provide fewer resources to control subsequent desire (e.g. Vohs and Faber 2007).

To better understand the role of animation speed in banner ads can play, an experiment was conducted using a method similar to that employed by Pronin and Wegner. Because their message statements were highly valenced (positive or negative) it is difficult to dissociate induced mood from speed of thought. In order to overcome this problem, and to make the task more applicable to advertising, informational banner ads were used.

Eight banner ads, each with approximately 40 words and a visual brand logo, were put into a PowerPoint slideshow format. The ads were adapted from existing ads, with brands that were largely unfamiliar to the participants. The PowerPoint was programmed to progress at a speed of 40ms per letter in the fast condition (with an additional 400ms between slides) and at 160 ms per letter in the slow condition (with an additional 1,600 ms between slides). These speeds match those used by Pronin and Wegner and pretesting showed people correctly perceived the pace as fast or slow.

Participants filled out a pretest which included a baseline mood scale (PANAS; Watson, Clark, and Tellegen 1988) as well as some filler tasks. They were then shown to a room and told that they would be participating in an advertising study. Participants were instructed view and read out loud the content of the banner ads. They were told that this would be recorded to ensure that they had actually read all the information. Though this decreases external validity, this was necessary in order to ensure that the banners were being completely read at the speed shown. After going through a practice ad, they viewed the 8 ads in succession and then filled out a questionnaire which assessed their perceived speed of thoughts, feelings of energy and mood state. When that packet was completed, they were given a second packet with a previously unseen print ad and asked to complete additional questions related to this ad. This was done because work in arousal (e.g. excitation transfer) and mood has shown that it is transient and more likely to attach itself to objects and judgments apart from the cause. Thus it was believed possible that arousal from the fast animation would not influence the banner ads themselves, but would instead affect a subsequent message.

Participants in the fast condition rated their subjective feeling of thought speed significantly higher than those in the slow condition (t(54)=-5.02, p<.001). A significantly heightened sense of energy was also found in the fast group (t(53)=-2.21, p<.05). Interestingly, mood was significantly higher in the fast group for both positive mood (t(53)=-1.81, p<.05) and negative mood (t(53)=-3.27, p<.005). For ad evaluation there was no effect of speed of banners on attitude toward the subsequent ad (t(51)=-1.35, p>1), however those in the fast condition were significantly more likely to indicate that they would try the product (t(51)=1.91, p<.05).

As would be expected from a generalized arousal effect, those in the fast banner group reported a significantly higher sense of energy. Additionally, positive mood states showed an increase after viewing the fast banner ads relative to the slow condition. Interestingly, negative moods also increased more after viewing the fast banner ads. This contradicts the findings of Pronin and Wegner who only found an increased positive mood for their fast condition. Speed of presentation did not impact attitude toward the subsequent ad. In spite of a lack of difference between the groups in ad attitude, those in the fast group were more likely to say they would try the product. This finding is in line with work on self-regulation and impulsivity showing that cognitive, behavioral and attentional tasks that reduce self-regulatory resources all lead to an increase in impulse buying (Vohs and Faber 2007). The impact of arousal from fast banner ads may have similarly increased the likelihood of trial in response to a subsequent ad.

# It Tastes Better Conscious: The Role of Attention in Hedonic Consumption Experience

Aner Tal, Duke University, USA

Imagine it's Thursday evening and you're enjoying dinner along with NBC's comedy night. The show is great and you're laughing and enjoying yourself. At the same time, though, are you enjoying your food? Would you enjoy your food more were you paying attention to eating rather than to the TV?

Surprising findings in recent consumer behavior research suggests that people might enjoy hedonic stimuli more when distracted. In two papers Shiv & Nowlis (2004; Nowlis & Shiv, 2005) demonstrated that consumers chose one of two options more and evaluated an option more highly after trying it under distraction than under no distraction. In Shiv & Nowlis' general procedure, participants tasted a food sample under high or low cognitive load, and subsequently evaluated the sampled item or chose between the item and an alternative. Participants consistently displayed enhanced preference for items tasted under distraction.

Shiv & Nowlis claimed this effect occurred due to the dynamics of two additive and independent elements of evaluation: affective and informational. Under the authors' assumption that the informational component is valenced lower than the affective component for hedonic items, a summation of the two should lead to reduced evaluation over a consideration of affect alone. Without distraction both elements add up to determine overall evaluation, whereas under distraction only the affective element effects evaluation. Thus, evaluation under distraction should be higher than evaluation under no distraction.

A vast literature in the psychology of pain perception, however, paints a different picture (for reviews see Cioffi, 1991; McCaul & Marlott, 1984). Under psychological models of pain perception, cognitive elements play an integral and interactive part with sense data in determining hedonic experience (e.g., Dar & Leventhal, 1993; Melzack & Wall, 1965). A similar role for conscious cognition and attention has been found in other domains, including consumer behavior (Lee. et al., 2006; Levin & Gaeth, 1988; Wood & Quinn, 2002). Under these conceptions attention is crucial to hedonic experience. Consequently, these models predict–and extensive research verifies– that distraction leads to a muting of hedonic experience.

How does one reconcile the conflicting results described above? We propose that memory processes, often neglected in both streams of research, might hold the answer. People's memory for hedonic episodes is often lacking, and is based on either selective recall for particular elements of the experience (Kahenman, 1999; Ariely & Zauberman, 2000), or on reconstructions based on beliefs and expectations rather than on actual recall (Novemsky & Ratner, 2003; Wilson & Gilbert, 2003). Thus, online judgments of experience might produce markedly different results then judgments following delay (Lee, 2002).

In Shiv & Nowlis' (2004; Nowlis & Shiv, 2005) studies, choice normally followed sampling after some delay. Consequently, participants under load (i.e., the distraction condition) might not have encoded their experience from working memory to long-term memory (e.g., Craik et al., 1996; Baddely & Craik, 1984). Thus, participants in the distraction condition might have based their evaluations or choices on *beliefs or expectations*, while participants in the no distraction condition might have based their evaluations or choices on *actual experience*. Thus, evaluations in the two conditions have different bases and are consequently rendered incomparable in regards to participants' actual hedonic experience (see Lynch & Srull, 1982; Lee, 2002). Further, the results obtained in Shiv and Nowlis' sampling studies make sense in light of the differential reliance on memory versus beliefs, since given the "high-quality chocolate" context of the experiments participants were likely to expect high quality from the sampled brand.

If these ideas are correct, a reversal of Shiv & Nowlis' results should be obtained given reliance on actual experience. This can be obtained by including an online evaluation, which will make the basis of evaluation for distraction and non distraction comparable. In sum:

H1a: Participants will prefer the tasted over the non-tasted items more with high (rather than low) distraction when evaluation is delayed.

H1b: Participants will prefer tasted over non-tasted items less with high (rather than low) distraction when evaluation occurs during tasting.

*Study 1*. The study closely paralleled previous studies of distraction and sampling. Participants (*N*=30) tasted chocolate and granola bars under high or low load (shopping list memorization), and subsequently indicated their preference between the tasted snack and a second, comparable alternative. In the online condition, participants indicated their preference during tasting, whereas in the delay condition participants indicated their preference after a minute's delay during which they recalled memorized lists. The design was a 2

(snack type: chocolate and granola-bar) X 2 (distraction: high or low load) X 2 (delay: delay or no delay) within-participants foldover design.

*Results and Discussion*. We ran an ANOVA model predicting choice from delay and distraction with snack-type as a covariate. No main effects or interactions were found for either snack-type or for the separately examined order of conditions (distraction, delay). There was no main effect of either distraction or delay ($p$>.2). The predicted pattern of delay and distraction was obtained, with the delay X distraction interaction significant at the .01 level ($F$(1, 52)=7.12).

When there was delay between sampling and preference indication, participants preferred the tasted snacks more under distraction (73.33%) than under no distraction (46.67%). The pattern was reversed when preferences measures were taken during sampling. Here, participants chose the sampled snacks more (80%) under no distraction than under high distraction (40%).

*Study 2*. Participants (N=87) tasted unidentified crackers under high and low distraction conditions similar to study 1. After tasting, participants received negative information about the crackers. This included a low consumer panel rating (4.6/10 points) and display of a cheap-looking cracker box (rated low in pretests) from which the crackers were ostensibly taken. Participants then rated the crackers on a scale of 1-7, anchored by "not at all tasty" and "very tasty", as well as rating the crackers on a 5-item evaluative measure taken from Shiv and Nowlis' studies.

Note that in this study all participants were essentially in a delay condition. Under our conceptualization, participants should weight the information they received (i.e., show lower evaluation) more under high, rather than low, distraction, reversing the normal delay/distraction pattern found in study 1 and in Shiv and Nowlis' research. This was indeed the case: participants evaluated crackers as less tasty on a 7-point scale under distraction (3.98) than they did under no distraction (4.67)-F(1,93)=6.09; $p$=.015. Similar results were obtained using the 5-item measures employed by Shiv and Nowlis ($p$=.05). Note that these results are the opposite of the prediction of Shiv and Nowlis' framework, where information should be weighted more highly under low, rather than high, distraction.

The next study planned will examine the moderating role of the intrinsic valence-level of the consumption experience using high and low (taste quality) rated snacks. Under the predictions of the current model, experience should weigh more heavily under low, rather than high, distraction.

# The Sins of the Father Shall Be Visited Upon the Sons: The Effect of Corporate Parent Affiliation on Consumers' Perceptions of Corporate Societal Marketing

Andrew E. Wilson, Florida State University, USA
Peter R. Darke, York University, Canada

## Abstract

This research investigates how affiliation with a corporate parent affects consumers' perception of corporate societal marketing (CSM). It also examines whether this effect is more pronounced when the affiliation is perceived to be hidden, and therefore in violation of the norm of openness. Lastly, the study examines whether any of the effects flow back to the parent company. Findings include that corporate parent affiliation does not necessarily lead to decreased evaluations of the niche marketer brands. However, when consumers see the affiliation as hidden, evaluations are negatively affected. Evidence suggests effects may depend on prior track record of parent firm.

## Conceptualization

Corporate societal marketing is an increasingly popular method of building brand equity (Hoeffler and Keller 2002). Some niche brands have been successfully built by firms appealing to socially concerned consumers. Several such firms have been acquired by larger firms. Examples of this phenomenon are reviewed and discussed. In each case, a large firm acquired a smaller firm and continued to operate the brand unchanged. This strategy seems to assume that consumers will continue to value the brand based upon its CSM characteristics. It is possible, however, that consumers devalue the brand upon learning of such an affiliation, especially if the parent brand is perceived to lack similar commitment to the cause. The purpose of this paper is to examine how consumers evaluate CSM based brands of a niche marketer affiliated with a larger firm.

The study is informed by three principle areas of theory: 1) corporate societal marketing, 2) the correspondence bias in attribution theory, and 3) fairness in marketing. The correspondence bias refers to the attributional bias in which people make judgments about others based upon their behavior, even in the presence of situational constraints that offer alternative explanations. Fein, Hilton, and Miller (1990) found that the presence of ulterior motives acts as an antidote to the correspondence bias. When behavior may be motivated by an ulterior motive, observers become suspicious, and are therefore less inclined to make attributions based on that behavior. In the present research, it is expected that upon learning of the affiliation, the ulterior motive of image management, or of the profit motive, will become accessible as a ulterior motive for the CSM activities, causing consumers to lower their evaluations of the firm and brand.

Fairness is an important component of exchange (Oliver and Swan 1989; Campbell 1999). Ashworth and Darke (2006) found that consumers' perceptions of fairness are affected by violations of prescriptive norms–such as openness–even when the outcomes of the exchange were perceived to be distributively fair. Consumers expect to be treated fairly in the marketplace, not only because of material concerns, but also as a matter of principle. In the present research, it is expected that consumers' perception of openness will affect their evaluation of the companies and their brands.

Corporate Societal Marketing (CSM) has been defined by Drumwright and Murphy (2001) as marketing initiatives that have at least one non-economic objective related to social welfare and use the resources of the company and/or one of its partners. There is evidence that consumers' evaluation of CSM efforts depend partly upon their perceptions of the marketers' motivations or intentions. It is expected that consumers will find it more credible that a niche focused firm is sincerely motivated by social objectives than is a larger, more diversified firm.

## Study 1

### Method

A total of 268 participants (131 males) with a mean age of 32, ranging from 18 to 80 participated. A mixed sample of students and non-students was sought to increase external validity. The study employed a three-group posttest-only randomized experimental design, and was conducted by means of an online website.

Participants viewed materials consisting of an abridged version of the niche brand website, and mocked up news stories ostensibly from an online business news service. Affiliation with a corporate parent was manipulated by exposing the participant to different levels of information about the affiliation in each of the three conditions (control, open, hidden). The effectiveness of the manipulation, as well as the intended interpretation of the other materials, were confirmed through checks.

Established scales were used to measure brand beliefs, attitude towards the brand, organizational associations, and brand sincerity. Reliability was shown through an assessment of Cronbach's alpha

### Major Findings

Repeated measure ANOVA was conducted for each of the dependent measures treating brand as a within-subject factor. In the norm of openness violation condition, the following effects were found: 1) brand beliefs of the parent brand (product effectiveness) are reduced, 2) attitude towards the niche brand were (marginally) reduced, 3) brand sincerity were reduced for the niche brand, and 4) organizational associations were reduced for both the parent and the niche brand. In the open condition there were no such effects.

Consumers' perceptions of a niche brand are not necessarily effected by knowledge of an affiliated with a corporate parent, even though the parent's behavior is at odds with the CSM values. When the social norm of openness is violated, however, the results are quite different. Openness is an important consideration for consumers when forming evaluations. Some evidence was found that these effects flow back to the parent company. This may be because a norm violation leads to distrust, which generalizes to the consumers' brand beliefs.

## Study 2

The objective of study two was to replicate the findings of the first study, while extending them by investigating whether the effects depended upon the prior social responsibility track record of the parent firm. Parent company track record was manipulated by the text of the news story.

*Method*

A total of 235 participants (125 females) with a mean age of 20, ranging from 18 to 29 participated.. The study was a 2(track record: good or bad) x 3(disclosure of affiliation: none, open, or hidden) and was conducted by means of an online website. Because the manipulations involved subtle differences in written language, non-native English speakers were eliminated from the sample, resulting in a useable sample of 207.

*Major Findings*

As in study one, repeated measure ANOVA's were performed, treating brand (parent or niche) as the within subject factor. It was found that when the parent company has a good track record, disclosure of the affiliation does not effect perceptions of parent brand sincerity. However, when the parent company's track record is poor, hidden disclosure lowers perceptions of parent brand sincerity. A similar pattern of effects were found for attitude towards the parent firm.

# Experts, Novices, and Non-consumption among Appalachian Trail Thru-hikers

Jon Littlefield, Berry College, USA

Robert A. Siudzinski, Skillshops, Inc., USA

We study consumer expertise among thru-hikers of the Appalachian Trail (AT). The AT, a 2,175 mi. trail that extends along the Appalachian mountain range from Georgia to Maine, is the site of a four- to six-month trek of 2,000 hikers annually. Consumption decisions in preparation for this trip are constrained by the ability to physically carry what is purchased. Also, the confined juxtaposition of novices and experts on this extended hike creates a site in which adaptive, situational learning takes place. We document this process and suggest a conceptualization of consumer expertise that extends beyond that seen in the consumer research literature.

An extensive literature exists in judgment and decision making that describes how experts and novices differ. For instance, Johnson and Russo (1984) found that consumers familiar with a product category had increased ability to code and organize new information related to that product category and limited their search activities for that category. Sujan (1985) found that experts and novices used different categorizing processes when faced with discrepant information in an advertisement. Experts in Maheswaran and Sternthall's (1990) study processed attribute information (as opposed to benefit information) more extensively than did novices and also found that detailed processing by experts was more evaluative in nature, while that done by novices tended to be more literal, suggesting that category knowledge influences not only the amount of processing done, but also the qualitative nature of that processing.

Alba and Hutchinson (1987) suggest that consumer knowledge is comprised of both product familiarity, which they define as "the number of product-related experiences that have been accumulated by the consumer," and expertise, defined as "the ability to perform product-related tasks successfully" (p 411). They suggest that the former leads to the latter and that expertise has five different dimensions: cognitive effort, cognitive structure, analysis, elaboration, and memory. Common to these studies is a paradigmatic focus on the psychological inputs into and moderators of the individual decision-making process. In contrast, we focus on the lived experiences of expert and novice hikers as they progress. We define an expert as "someone who has acquired domain-specific knowledge through experience and training" (Spence and Brucks 1997, p 233), and operationalize it as a hiker who has covered at least 2,000 miles on the AT, while a novice hiker has hiked at least 200 miles. Our focus is on the social interactions and the learning processes exhibited by expert and novice hikers, and specifically their gear- and equipment-related decision processes.

We used a focused ethnographic approach consistent with past research in the consumption literature (Arnould and Wallendorf 1994; Spiggle 1994). Data were collected using depth interviews with thru-hikers with variation sought on gender, age, hiking experience level, and degree of involvement in the AT thru-hiking community. Additional sources of data included informal discussions with thru-hikers, participating in the annual Trail Days gathering, and conducting of video-ethnographic interviews with hikers about their equipment. Lastly, we have both backpacked on the AT extensively since childhood. The data were analyzed hermeneutically (Thompson 1997)—initial categories were iteratively challenged and restructured as the study progressed and as themes emerged.

We find a conceptualization of expertise, distinct from that found in the judgment and decision-making literature that is characterized by Reflective Choice Adaptation (RCA). RCA consists, first, of self-reflection sited in both private (individual) and public (social) spheres. Public journaling allows experts to share the benefit of their experiences with both novices and other experts, and allows learning to be scaffolded through the discursive process of public feedback and evaluation. Adjustment to dynamic environmental conditions is the second characteristic of expertise. This ability to make choices within the contextually rich decision context, rather than dogmatically, allows the expert to adjust rapidly to changes in the environment. The final characteristic of expertise we found was that of adaptation. Adaptive expertise involves the marshalling of resources (in both cognition and equipment) in situ to adapt to the demands of a given situation, and includes the modification or creation of personalized technologies. Several experts we met along the trail carried shelters, clothing, or tools that they had made themselves because no product existed, or because the available tools failed to satisfy the hikers' needs.

We find that RCA more completely characterizes experts than do previous conceptualizations of expertise in the consumer research literature when the context examined is more social in nature, and we suggest that there might be applications to not only other recreational contexts, such as performance musicians and live-aboard sailors, but also other decision contexts such as purchase situations where the act of purchase is more social in nature.
