To our knowledge, this research presents the first experimental evidence of positive effects of consumer co-production on authenticity perceptions. A methodological contribution is also offered to research on consumer prosumption. The scenario manipulation in study 2 was too weak to produce any of the effects observed in study 1. This finding suggests that real participation is needed in future experiments on the effects of prosumption.

The Role of Attribute Importance in the Effect of Defaults on Choice: The Moderating Effect of Budget Range and Justification

Sehoon Park, Sogang University, Korea

Moon-Yong Kim, Korea Advanced Institute of Science and Technology, Korea

EXTENDED ABSTRACT

There are several product/service categories in which consumers have some control over the number, type, and configuration of options they select (Park, Jun, and MacInnis 2000). For instance, consumers are allowed to create their own consumable products by either starting with a basic product and adding desired components or starting with a fully loaded product and deleting undesired components (Levin, Schreiber, Lauriola, and Gaeth 2002; Park et al. 2000). That is, there are many everyday examples of additive (or upgrading) or subtractive (or downgrading) default designations for relatively less expensive nondurable products (e.g., pizzas) or more expensive products (e.g., PCs, automobiles): the default is the choice alternative a consumer automatically receives if he/she does not explicitly request otherwise (Brown and Krishna 2004, p. 530).

Much prior research concerning default effects has demonstrated that defaults can change the likelihood that a particular item is chosen (Brown and Krishna 2004; Johnson, Bellman, and Lohse 2002; Levin et al. 2002; Park et al. 2000). Especially loss aversion or an endowment-based account (cf. Kahneman, Knetsch, and Thaler 1991) offers a clear explanation for why the strength of the default may vary according to which alternative receives the default designation, and thus it predicts that high (i.e., more expensive) defaults will have a stronger effect on choice than will low (i.e., less expensive) defaults (see Brown and Krishna 2004).

Tversky and Kahneman's reference-dependent model (1991) suggests that loss aversion may vary systematically across attributes. Among some of the determinants of the differences in loss aversion, it was demonstrated that attribute importance is a strong predictor of loss aversion (Johnson, Gächter, and Herrmann 2006). Given that default effects are typically described as a manifestation of loss aversion, thus, we proposed that the effect of the ordinal position of defaults (low vs. high) on choice differs depending on the importance of attributes that constitute the defaults.

In addition, recent research has identified critical moderators that help define the boundaries of loss aversion (Ariely, Huber, and Wertenbroch 2005; Camerer 2005; Novemsky and Kahneman 2005a, 2005b). Although there may be several pathways through mechanisms that underlie loss aversion, we proposed that consumers' budget range and justification for choice differentially affect the dual mechanisms that vary the degree of loss aversion (i.e., changes in cognitive perspective and emotional attachment) as suggested by Ariely et al. (2005), and thus they serve to moderate the effect of defaults on choice. Finally, we suggested the role of attribute importance in the low- or high-default condition that varies the differential effect of two extrinsic, contextual factors (i.e., budget range and justification) on the dual mechanisms that underlie loss aversion, which would, in turn, influence the effect of defaults on choice.

We tested our hypotheses in a series of three studies. We selected automobiles as the product category for these studies. A set of 10 product attributes was selected, five of which were rated as important or less important. Eighty-eight undergraduate students at a large university participated in study 1. Under both no financial constraint (i.e., wide budget range) and no justification (i.e., participants not instructed to provide reasons for their choice) conditions, one factor (i.e., the ordinal position of defaults: low vs. high) was manipulated across two experimental cells. To manipulate the

ordinal position of defaults, we followed the same manipulation established by Park et al. (2000). In the context of product attributes choice decisions, the participants were asked to either add desired product attributes to a base model (i.e., low-default condition) or delete undesired product attributes from a fully loaded model (i.e., high-default condition). The participants for study 2 consisted of 89 undergraduate students at a large university. Under both financial constraint (i.e., narrow budget range) and no justification condition, the ordinal position of defaults (low vs. high) was manipulated across two experimental cells as in study 1. The control group was the 88 respondents in two experimental cells from study 1. In study 3, a 2 x 2 between subjects design was used in the justification condition: the ordinal position of defaults (low vs. high) and budget range (narrow vs. wide). A total of 173 undergraduate students at a large university were randomly assigned to one of the four experimental conditions. The control group was the 177 respondents in four experimental cells from studies 1 and 2.

In study 1, it was demonstrated that under no financial (budgetary) constraint, there arises a positive effect of default designation (low vs. high) on choice. And, the positive effect of default designation on choice was shown to increase in proportion to the importance of attributes that constitute the defaults. That is, the difference in consumer choice outcomes between low- and high-default conditions was observed to be larger when important (vs. less important) attributes are added to (deleted from) a low (high) default.

Study 2 demonstrated the moderating role of budget range in the effect of defaults on choice: As the range of budget narrows, it was shown that choice outcomes decrease more greatly among consumers in the high-default condition than among consumers in the low-default condition. Also, it was found that the moderating role of budget range in the effect of defaults on choice arises when important attributes are added to (deleted from) a low (high) default, whereas it does not have a significant moderating role in the effect of defaults on choice when less important attributes are added to (deleted from) a low (high) default.

In study 3, we examined the moderating role of justification in the effect of defaults on choice. It was shown that justification increases the difference in consumer choice outcomes between low- and high-default conditions under no financial constraints (i.e., under the wide budget range), unlike under the narrow budget range. Also, it was revealed that when less important (vs. important) attributes are added to (deleted from) a low (high) default, justification plays a moderating role in the effect of defaults on choice under the wide budget range, unlike under the narrow budget range.

Understanding the Role of Materialism in the Endowment Effect

Inge Lens, Katholieke Universiteit Leuven, Belgium
Mario Pandelaere, Katholieke Universiteit Leuven, Belgium

EXTENDED ABSTRACT

People generally demand more money to give up an object in their possession, than they are willing to pay to obtain this object (Thaler 1980). This asymmetry between willingness to pay and willingness to accept is referred to as the 'endowment effect' (Kahneman, Knetsch, and Thaler 1990; Thaler 1980). It is widely assumed that the reluctance to exchange possessions observed in the endowment effect, can be explained in terms of loss aversion (Kahneman et al. 1990). The theory of loss aversion suggests that the positive experience of gaining an object cannot compensate for the pain of giving up a possession. As a result people are inclined to value possessions more than (monetary) alternatives of similar objective value (Kahneman and Tversky 1979; Tversky and Kahneman 1991). However, the same loss appears not to be as aversive for everyone at any time. Previous research revealed a number of moderators of the endowment effect (e.g., Liberman et al. 1999; Lin et al. 2006; Loewenstein and Issacharoff 1994; Strahilevitz and Loewenstein 1998). This paper aims to extend this line of research by proposing materialism as an additional moderator.

People who strongly endorse material values consider the acquisition of possessions as a central life-occupation, bringing forth happiness and success (Richins and Dawson 1992). Given the attachment of materialists to their possessions, we propose that materialistic 'sellers' are more reluctant to exchange endowments for money than less materialistic sellers, resulting in higher minimum selling prices (hypothesis 1). Next, we assume that materialistic 'buyers' are more willing to spend money on an object they don't possess, relative to buyers low on materialism (hypothesis 2). Finally, we assume that the influence of materialism is more pronounced for sellers than for buyers, suggesting that the endowment effect increases with increasing materialism (hypothesis 3).

To test the hypothesis that materialism moderates the endowment effect, one hundred eighty-seven students participated in a first study. Half of them were endowed with a coffee mug (sellers), the other half were not (buyers). Buyers stated a maximum buying price for the mug, whereas sellers reported their minimum selling price. Materialistic values were assessed with the Material Values Scale (Richins and Dawson 1992). The results suggest that materialistic sellers demand higher minimum prices than less materialistic sellers. No relationship between buying prices and materialism is found. Hypotheses 1 and 3 are thus supported, hypothesis 2 is not. A second experiment with 68 male students replicates these findings with more valuable endowments (six technologically innovative gadgets, e.g., an optical, wireless computer mouse). Additionally, two alternative explanations are ruled out. The impact of materialistic values on selling prices cannot be attributed to a higher desirability of the gadgets for materialistic relative to less materialistic sellers or to differences in affect between more and less materialistic participants. In line with Terror Management Theory (e.g. Solomon, Greenberg and Pyszczynski 2004) and empirical evidence that reminding consumers of their own mortality induces or reinforces materialistic behavior (e.g. Mandel and Heine 1999; Kasser and Sheldon 2000), we predict in a third experiment that an increased endowment effect will be observed after a mortality salience induction and we assume that this increase will be stronger for materialistic consumers than for less materialistic consumers. In this experiment we first measured levels of materialism of two

hundred eighty-two participants. Subsequently, we instructed half of the participants to write a short essay about their own death (experimental condition with death-related thoughts). Participants in the control condition wrote about a more neutral topic: their favorite music or a visit to the dentist. After a number of unrelated tasks, half of the participants in each condition stated their maximum buying price for a small gadget, the other half of the participants indicated their minimum selling price. The data again support the assumption that chronic levels of materialism moderate the endowment effect. Furthermore, evidence is found for the predicted three-way interaction between endowment condition (buyer-seller), mortality salience condition (death-related thoughts-neutral thoughts) and materialism. It appears that reminding participants of their own mortality results in an increased endowment effect, at least to the extent they endorsed material values prior to the mortality salience induction. These findings again support hypotheses 1 and 3. Similar to the previous studies, no influence of materialism on stated buying prices is found.

In sum, in two correlational studies and one experimental study we found that materialists demand higher prices for their endowments, relative to less materialistic individuals. Materialism, however, has no predictable impact on buying prices. These implications of materialism in the occurrence of the endowment effect enhance our insight in this extensively documented phenomenon, and, in doing so, advance our understanding of the (economic) consequences and the nature of materialism. Materialism has previously been associated with a near-sighted consumption pattern (Dittmar 2005; Watson 2003) and high aspirations for possessions and wealth (Kasser and Ryan 1996; Kasser and Sheldon 2000). However, our data suggest that materialists don't necessarily want to have everything at any cost. On the other hand, the endorsement of material values seems to motivate people to demand higher prices for their goods, even when cheap or rather unattractive commodities are traded. So far, research on the effect of materialism on consumer behavior has mainly focused on spending tendencies and intentions of prospective buyers, whereas this paper shows that materialism might as well have important implications for the supply-side of market relations (e.g., in second-hand markets like eBay).

The current paper has demonstrated a robust relationship between materialism and the endowment effect. Although the current paper did not focus on any underlying mechanism, it is likely that materialistic consumers experience more loss aversion, resulting in higher selling prices and an increased endowment effect. Future research may assess the validity of this hypothesis

Inclusion versus Exclusion: The Effect of Perceived Uncertainty on Screening Strategies

Rajani Ganesh Pillai, North Dakota State University, USA

Xin He, University of Central Florida, USA

Raj Echambadi, University of Central Florida, USA

EXTENDED ABSTRACT

Screening refers to the process that governs the admission of options into the choice set (Beach 1990; 1993). Extant literature notes that screening strategies play an important role in consumer decision making (Beach 1990, 1993; Payne, Bettman, and Johnson 1993). For example, research shows that the type of screening strategy employed influences the composition of the consideration set (Levin, Huneke, and Jasper 2000; Yaniv and Schul 1997, 2000), and impacts the final choice and purchase likelihood as well (Chakravarti, Janiszewski, and Ulkumen 2006; Levin et al. 2002; Park, Jun, and MacInnis 2000).

Consumers typically use two types of strategies in screening: an exclusion strategy wherein alternatives not worthy of further consideration are eliminated, and an inclusion strategy wherein attractive alternatives are selected for additional evaluation (Yaniv and Schul 1997; 2000). While prior literature has predominantly focused on the consequences of the two screening strategies, such as the characteristics of the consideration set (Yaniv and Schul 1997, 2000) or final choice (Park, Jun, and MacInnis 2000; Shafir 1993), little attention has been devoted to the antecedents of screening strategies. We do so here. Specifically, we argue that perceived uncertainty has a systematic influence on the preference of screening strategies, such that consumers with high perceived uncertainty are more likely to adopt an exclusion strategy whereas those with low perceived uncertainty are more likely to employ an inclusion strategy.

Prior research shows that consumers frequently experience uncertainty in decision making, and such uncertainties arise from multiple sources: from not knowing the potential outcomes of the options, the individual's intrinsic preferences, or the attributes and decision rules that are relevant to the task at hand (Simonson 1989; Urbany, Dickson, and Wilkie 1989). The theoretical underpinnings of the proposed relationship between perceived uncertainty and screening strategy are drawn from the literatures on consumer learning (c.f. Alba and Hutchinson 1987; Johnson and Russo 1984) as well as probabilistic reasoning (c.f. Tversky and Kahneman 1974). Drawing from and building upon these two streams of literature, we suggest that consumers high in uncertainty are more likely to use exclusion screening strategies because exclusion is more likely to increase the perceived accuracy in decision making.

Empirical Studies

We test our theoretical hypotheses in two separate studies. In Experiment 1 ($n=126$), we demonstrate the effect of perceived uncertainty on screening strategies using a 2(uncertainty) \times 2 (task complexity) between-subjects design. We manipulated task complexity in order to rule out an alternate explanation. Uncertainty was manipulated by varying the clarity of preferences and familiarity with the product category (Urbany, Dickson, and Wilkie 1989) while task complexity was manipulated by varying the number of alternatives available to choose from (Payne, Bettman and Johnson 1993). Results indicated that participants who were highly uncertain were more likely to prefer exclusion screening strategy. We also examined the underlying psychological process through the mediation analysis of perceived accuracy. Results of the mediation analysis (Baron and Kenny 1986) indicate strong support for the mediating role of perceived accuracy of the screening strategy as

opposed to effort savings. Finally, in Study 2, we seek to demonstrate the external validity of our findings (Winer 1999) by analyzing the verbal protocols from the popular TV game show "Who Wants to be a Millionaire?" Verbal protocols from twenty-four shows were coded following Ericsson and Simon (1993) and analyzed using various (OLS, fixed effects regression, Logit, and mixed-Logit) models. Results corroborates our experimental findings—contestants high in uncertainty were more likely to adopt exclusion screening strategies whereas those contestants low in uncertainty were more inclined to employ inclusion strategies.

Discussion

This paper highlights the important role of perceived uncertainty in consumer decision making. It not only influences final choice but also the specific screening strategy used in prechoice screening. The consistent pattern of results using different methodologies (experiment and verbal protocol analysis), samples (students and adult contestants), decision contexts (apartment rental and TV game show), and models for analysis (OLS, fixed effects regression models, Logit, and mixed-Logit models) lend robustness to our findings. Further, we show that the preference of screening strategy is mainly driven by accuracy considerations rather than effort savings, a finding consistent with the idea that screening improves quality of decisions by preventing bad options from being considered for choice (Beach 1990, 1993). These findings have important implications in a wide variety of decision contexts like choosing among investment alternatives or medical procedures, where uncertainty is an inherent component of the decision process, and where the final choice carries not only lasting but often irrevocable consequences. We hope that future research will continue to examine inclusion and exclusion strategies and help consumers make informed decisions through a better understanding of the underlying screening process.

The Influence of Self-Regulatory Focus in the Effectiveness of Emotional Health Campaigns: It Is a Matter of Context Too...

Leen Adams, Ghent University, Belgium
Tineke Faseur, Ghent University, Belgium
Maggie Geuens, Ghent University, Belgium

EXTENDED ABSTRACT

In health campaigns, fear-relief appeals are often used. This kind of message usually first focuses on the risks of an unhealthy behavior (inducing fear) and next offers a solution (inducing relief) by offering behavioral recommendations (Hale and Dillard 1995). To contribute to the debate which appeals are most effective for which type of audience, we investigated the moderating impact of consumer's motives on the effectiveness of health communication.

According to the self-regulatory focus theory of Higgins (1997), there are two different motivational systems that regulate our behavior, namely (1) a promotion and (2) a prevention focus. These two foci have a significant impact on the type of goals that are pursued, the typical strategies that are used and specific emotional vulnerabilities. Regarding the latter, Higgins, Shah and Friedman (1997) found that promotion people are more prone to dejection-related emotions, such as sadness and cheerfulness, whereas prevention people are more sensitive to agitation-related emotions, such as fear and quiescence.

Studies building further on this theory have found that, in case of a match versus a mismatch between a stimulus and a recipient in terms of their regulatory focus, the stimulus is evaluated as more valuable, a principle referred to as regulatory relevancy (Higgins 2002; Pham and Higgins 2005). However, in consumer settings, compatible stimuli have been developed only in terms of verbal and objective information. Knowing that (a) affective considerations can be influential in consumer decisions in general (Pham 1998), and concerning health behaviors more specifically (Lawton, Conner, and Parker 2007), and that (b) a strong link between self-regulatory focus and specific emotional vulnerabilities exists (Higgins et al. 1997), we examined the validity of the regulatory relevancy principle further by matching the emotional tone of health messages to the chronic focus of the audience.

For this, we set up a between-subjects design in the context of the 'quit smoking' theme. Two factors were included, namely the chronic self-regulatory focus of the respondents (promotion vs. prevention) and the type of emotional tone of the antismoking campaigns (fear-relief vs. sadness-joy). Beforehand, a pretest with 28 student smokers showed that our campaigns elicited the intended emotions. The experiment was run via an online survey for university students and as such, data from 256 smokers were collected. We first measured the chronic focus (Lockwood et al., 2002) (after performing a median split on both measures, only predominant promotion and prevention respondents were retained) and initial intention to quit smoking and then randomly assigned respondents to one of the two antismoking ads. Afterwards, dependent variables (ad involvement, attitude towards the ad (Aad), and behavioral intentions) were measured. Finally, socio-demographic data were collected.

We found that, in case of affect-eliciting stimuli, a match versus a mismatch is more persuasive, and this for both foci. Specifically, promotion people rated the sadness-joy campaign as more relevant which led to a more favorable Aad, whereas for prevention people, the typical fear-relief format led to more involvement and a more favorable attitude.

This finding appears to be somewhat in contrast with the conclusions of Pham and Avnet (2004) in that prevention people can rely just as much on affect as promotion people. At the same time, we also used stimuli focusing on prevention-related emotions, which was not the case in their paper. In addition, in our setting, affect was probably highly relevant and served as a valid argument to all smokers, which could explain why here both foci relied on it (Pham 1998). However, this implies the necessity to take into account the role of the context in examining the impact of the chronic self-regulatory focus in processing emotional stimuli.

Considering interaction effects between traits and situational factors is an issue under investigation in different streams of literature (Rusting 1998). Overall, in previous research, the activation of related constructs has produced additive and stronger effects, but unstable results were obtained when activated constructs were opposing each other (Bargh et al. 1986).

Therefore, we examined the role of the chronic self-regulatory focus and of the type of context (in terms of perceived affect relevance (low versus high)) in the effectiveness of different emotional tones (dejection-cheerfulness versus agitation-quiescence) for sun protection campaigns via a between-subjects design. Again, a preceding pretest with 153 female respondents confirmed that the stimuli reflected the intended emotional tone. To run the experiment, we set up an online survey. Via two websites of a large media concern, we obtained data from 1386 women between the age of 24 and 38 years old. We first assessed existing tanning activities and then randomly assigned respondents to one of the health campaigns. A control group was also included. Questions about attitudes and behavioral intentions followed next. Perceived affect relevance was then measured (afterwards, we did a median split). Finally, the chronic self-regulatory focus and socio-demographics were measured as before.

We found that when promotion people considered affect to be more relevant in processing the ad, their chronic focus was more strongly activated and stronger emotion-congruence effects emerged. In particular, promotion people were more persuaded by the sun protection ads with a dejection-cheerfulness tone than by the ones with an agitation-quiescence tone. Prevention people are assumed to rely less on affect (Pham and Avnet 2004) and thus, we only expected the absence of emotion-congruence effects in a context where affect was considered to be little relevant. Although results were not in contrast to this hypothesis, we also did not expect them. Specifically, emotion-incongruence effects on relevancy measures emerged: prevention people evaluated the incongruent dejection-cheerfulness more favorably than the congruent agitation-quiescence appeals. Other types of processing, such as heuristic or motivated processing, could be responsible, but more validation is needed. In case of a highly affective context, we did not find emotion-congruence effects in prevention such as in promotion people. However, in a more ego-involving situation, reflected in a highly frequent use of sun beds, an emotion-congruency trend appeared, indicating that emotional appeals could be used as relevant information by prevention people, but only in situations where affective involvement is highly personal.

The Glass Is Both Half Full And Half Empty: The Strategic Use Of Mixed Counterfactual Thoughts

Christina I. Anthony, The University of Sydney, Australia
Elizabeth Cowley, The University of Sydney, Australia

EXTENDED ABSTRACT

Why is it that after experiencing inevitable losses, heavy gamblers continue to spend money on gambling? Consumers often engage in a variety of consumption behaviors that are not necessarily in their best interest, apparently paying little attention to previous experiences that yielded questionable outcomes. The decision to gamble again, for example, should be influenced at least in part by one's success on previous occasions. And evaluations of these experiences should, on average, discourage repeat behavior. The purpose of this research is to examine how mixed counterfactuals may contribute to our understanding of potentially dysfunctional consumer behaviors. More specifically, we investigate frequent gamblers dysfunctional use of mixed counterfactuals in order to justify a loss, and devalue a win.

Relevant Literature and Hypotheses

Counterfactual thinking is the process of imagining alternative outcomes that could have, but did not occur (Roese 1997). Theorists have categorized counterfactuals in terms of their directionality. Upward counterfactual thoughts (UCTs) involve the generation of better alternative outcome(s). Downward counterfactual thoughts (DCTs) involve the generation of worse alternative outcome(s) to reality. UCTs increase negative affect with our actual outcome, via a comparison to the better imagined alternative. DCTs increase positive affect with our actual outcome, via a comparison to the worse imagined alternative. An important determinant of the directionality of counterfactual thoughts is outcome valence. Research shows that people are more likely to spontaneously generate UCTs following failure, and DCTs following success (Gleicher et al. 1995; Grieve et al. 1999; Markman et al. 1993; Sanna, Chang, and Meier 2001). This can be explained in terms of the functional value of counterfactual thoughts.

Functional accounts assume that counterfactuals can beneficially serve people's goal states and motivations (Roese 1994; Roese and Olson 1995). UCTs generally serve a preparatory function, and DCTs generally serve an affective function (McMullen 1997; McMullen and Markman 2000; Roese and Hur 1997). Therefore, using UCTs following failure may be functional as the resulting negative affect helps one to learn from the past and avoid similar failures. On the other hand, generating DCTs following success may be functional as the resulting positive affect allows one to appreciate their success. Thus, we hypothesize that infrequent gamblers should show a significant difference in the direction of their counterfactual thoughts for a loss compared to a win (more UCTs for loss, more DCTs for win), further they should feel more disappointed with a loss relative to a win.

Whereas functional accounts are concerned with the beneficial role of counterfactual thinking in people's understanding of events, the dysfunctional perspective implicates the potentially adverse use of counterfactuals (Sherman and McConnell 1995). We propose that mixed counterfactuals (both UCT and DCT) may be generated in response to an outcome to justify continuing an activity. Frequent gamblers may use DCTs dysfunctionally to discount a loss and gloss over any problems signaled by their UCTs. Frequent gamblers may use UCTs dysfunctionally to devalue a win and dismiss their appreciation for an outcome which could have been worse as was signaled by their DCTs. In effect, we hypoth-

esize that mixed counterfactuals are strategically generated to counteract more spontaneous functional responses in order to justify replaying the game. Thus, we predict that frequent gamblers unlike infrequent gamblers, should generate mixed counterfactuals, and should not reveal any differences in their affective reaction to a loss relative to a win.

Method

One hundred and forty two gamblers played 300 games on a computer displaying a simulated poker machine game called Maid Marion. The design included one manipulated independent factor and one measured factor. The patterns of wins and losses in the games were pre-determined to manipulate the outcome of the experience (win, loss). A series of questions were asked to determine whether the participant was a frequent gambler. After the game ended, gamblers counterfactual thoughts and affective reactions were collected.

Results

We demonstrate that infrequent gamblers generated significantly more upward relative to downward counterfactuals for a loss, and more downward relative to upward counterfactuals for a win. Further, they were more disappointed (less pleased) with a loss, and more pleased (less disappointed) with a win. These results supported our predictions regarding a functional use of counterfactual thoughts which enable the infrequent gambler to learn from a loss and appreciate a win.

In contrast, we demonstrate that frequent gamblers generated mixed counterfactuals. Further, unlike infrequent gamblers, they did not reveal any significant differences in their disappointment with a loss relative to a win. These results supported our predictions regarding a potentially dysfunctional use of counterfactual thoughts which enable the frequent gambler to gloss over a loss and devalue a win, in order to justify replaying. Interestingly, our results suggest that mixed counterfactuals may have been generated sequentially, as evidenced by the additive/subtractive changes in frequent gamblers affective response. Further, our results suggest that frequent gamblers dysfunctional response may be mediated via their negative affect rather than their positive affect.

Discussion

This paper examined the potentially dysfunctional use of mixed counterfactuals in the context of gamblers evaluations of poker machine outcomes. Evidence of mixed counterfactuals and their dysfunctional influence on affect was demonstrated for frequent gamblers. In this paper, 'mixedness' was defined in terms of the direction of counterfactual thoughts; generating both UCT and DCT in response to an outcome. Interestingly, our results support the idea that mixedness stems from the direction of counterfactuals bearing an additive/subtractive influence on affect, rather than from dual modes of affective processing. However, future research should examine and compare the multiplicity of forms through which duality, or mixed counterfactuals may manifest.

Further, in this research we were not able to directly measure the sequential nature of dysfunctional counterfactuals, rather this was inferred from the pattern of affective response. However, this effect and other mixed counterfactual process mechanisms should

be empirically tested. While the context of investigation in this paper is limited to gambling, our findings provide a platform for research into the effects of mixed counterfactuals and their potentially dysfunctional effects. We conclude by acknowledging the possibility that in other situations, mixed counterfactuals may serve a functional purpose, this remains to be examined.

Self-positivity in Risk Judgments: The Role of Processing, Encoding, and Recall Biases

Parthasarathy Krishnamurthy, University of Houston, USA

Magdalena Cismaru, University of Regina, Canada

EXTENDED ABSTRACT

Self-positivity bias refers to the tendency of people to consider themselves as more fortunate than others. In the context of health judgments, this illusion of invulnerability can lead to poor choices and unfortunate consequences such as not getting medical attention in a timely manner or becoming obese. Therefore, examining the process may open up ways to manage such biases with important implications for designers of public policy campaigns advocating changes in behavior such as preventing obesity.

Although literature demonstrates self-positivity in a variety of contexts, including health, there are no empirically tested accounts of how self-positivity occurs. According to Chambers and Windschitl (2004), self-positivity might arise from biased retrieval of risk information. In the present research, we (a) present a first empirical test of biased retrieval of risk information, and (b) argue that self-positivity begins with biased encoding and biased processing of information. We report three studies examining self-positivity in encoding, processing and recall of risk information in the context of health estimates.

The principal goal of Study 1 was to assess biased retrieval of risk information. Students participated in 2 (target person) x 2 (order of elicitation) mixed design, with the target person manipulated within-subjects and the order of elicitation manipulated between-subjects. The design, measures, and procedure were based on Menon, Block, and Ramanathan (2002); Menon, Raghurir, and Schwarz (1995); and Raghurir and Menon (1998). Participants were exposed to a series of slides about Chronic Fatigue Syndrome (CFS) that described the condition, the symptoms, the severity, the difficulty of being diagnosed, and the people at risk. Participants then judged their own risk of developing CFS, the risk of an undergraduate student of developing CFS, and the risk-increasing and risk-decreasing factors that they used in providing the risk estimate for each target person (self and the average student). Results show that participants retrieved relatively more risk-increasing factors when the target person was the average person than when it was the self. Mediation analyses indicate that self–other differences in retrieval associated with risk-increasing and risk-decreasing factors mediate the effect of target person on risk estimates, consistent with Chambers and Windschitl’s proposed model (2004) and our expectations.

The goal of Study 2 was to assess whether self-positivity is observed even in the processing of risk-behaviors, and whether such biases lead to positivity in risk-judgments. The online study involved two target persons, self versus average student, administered in two phases separated by a 10-minute distraction task. In phase 1, all participants were exposed to a condensed version of the CFS presentation and then presented with a list of eight behaviors—four risk-increasing (i.e., “consuming a lot of sugar”) and four risk-decreasing (i.e., “eating plenty of fruits, vegetables, whole grains, and beans”) — in regard to one’s chance of developing CFS. Participants in the self-target person condition were instructed to think of these behaviors and to describe themselves performing them, one behavior at a time. Those in the other-target person condition were asked to think of the same behaviors and to describe an average student performing them. Following this, participants were asked to indicate how clearly they were able to visualize the target person (self or average student) engaging in each of those behaviors (imagery). A difference in the clarity of imagery was

employed as an indication of information processing. After about 10 minutes or so, in phase 2 of the study, participants generated risk estimates for their assigned phase 1 target. The results from Study 2 suggest that self-positivity is not limited to retrieval, as noted in the three-stage model of Chambers and Windschitl (2004), but extends to processing of information. The same risk-behavior when processed with respect to one’s self is visualized more readily if the behavior is risk-decreasing and less readily if the behavior is risk-increasing. Furthermore, the relative readiness to visualize risk-increasing behaviors (relative to risk-decreasing behaviors) significantly mediates the impact of the target person on risk-judgments.

The goal of Study 3 was to assess whether there are systematic biases in the encoding of risk information. Students participated in an online study with two target persons, self versus average student. They were exposed to a scenario that described oneself or an average student buying a lunch. They were then asked to evaluate the meal’s content of fiber, sugar, whole grains etc., and indicate the extent to which the lunch was healthful, likable, etc. The effect of target on encoding was examined by looking at whether the target person influenced the evaluation of the meal. Results indicate that the target person affects encoding of ingredients, therefore suggesting that self-positivity is not limited to retrieval and processing of information, but extends to encoding of information. In general, participants considered their meal to be lower in undesirable ingredients such as sugar, fat, or calories, and higher in desirable ingredients such as grains and beans in contrast to evaluating the same meal for an average student. These results help extend the Chambers and Windschitl’ model (2004) to include encoding biases as well as retrieval and processing biases documented in Study 1 and Study 2.

Although our findings extend our understanding of the mechanism behind self-positivity bias, identifying ways to manage self-positivity with important practical implications for designers of public policy campaigns remains to be investigated by future work. Specific research questions concern framing the information provided in a way to minimize encoding biases as well as processing biases and further retrieval biases when warranted.

Gender Identity Salience and Perceived Vulnerability to Breast Cancer

Steven Sweldens, RSM Erasmus University, The Netherlands

Stefano Puntoni, RSM Erasmus University, The Netherlands

Nader T. Tavassoli, London Business School, UK

EXTENDED ABSTRACT

Breast cancer is one of the world's leading causes of death and breast cancer awareness campaigns aim to increase women's risk awareness and promote early screening behavior. Health campaigns aimed at increasing women's breast cancer awareness often stress women's vulnerability to breast cancer using images and appeals related to the female sex and to femininity. Estimates of personal risk are constructed by individuals based on environmental cues and personal experience. In particular, personal risk perceptions are closely tied to individuals' sense of self due to the link between aspects of one's self-concept (e.g., lifestyle, age or gender) and actual risk. Despite the large body of literature devoted to understanding the psychological processes involved in the estimation of perceived vulnerability, the relationship between risk estimates and self-identity is still unclear.

This paper explored how inherent characteristics of a risk interact with self-identity salience to influence estimates of perceived vulnerability. In particular, we investigated how and under which conditions the salience of a certain identity trait (e.g., gender) can influence one's perceived susceptibility to risks associated with this trait (e.g., breast cancer). Two alternative theoretical accounts—cognitive accessibility and defense mechanisms—provide opposing predictions with regard to the direction of the influence of identity salience in perceived risk.

Cognitive accessibility predicts an increase in gender-related risk perception following an increase in gender salience. Contextual factors that increase the salience of a dimension of self-identity should increase the accessibility of knowledge structures associated with this dimension and result in higher likelihood estimates for risks that are associated to this activated dimension through the operation of judgmental heuristics. For example, increased (decreased) accessibility of AIDS-related information had a positive (negative) effect on associated risk perceptions (Raghubir and Menon 1998). The cognitive accessibility account therefore predicts that increased gender salience should increase estimates of gender-specific risks.

A different line of reasoning, based on defense mechanisms, leads to the opposite prediction for identity aspects that are central to the self. The sexual self is a central aspect of women's multifaceted self and a disease such as breast cancer is inextricably bound to women's perception of their gender identity. Under conditions of heightened gender identity salience, the thought of contracting breast cancer may be perceived as especially threatening. Consequently, defensive mechanisms—which are intimately related to ego threat—may occur in these conditions, leading to a minimization of subjective risk estimates. For example, participants who were made to believe they suffered from a fictitious enzyme deficiency evaluated this deficiency as less serious than controls (Jemmott, Ditto, and Croyle 1986) and personal relevance increases the likelihood that threatening health messages are defensively processed (Liberman and Chaiken 1992).

To summarize, two distinct accounts make opposing predictions regarding the effect of identity salience on identity-specific risk perception. Cognitive accessibility predicts that heightening women's gender identity increases perceived vulnerability to risks such as breast cancer. A motivational defense mechanism account predicts instead that when a central aspect of the self (e.g., women's

gender) is made more salient, threats (e.g., breast cancer) to this aspect are likely to trigger defensive mechanisms (e.g., risk minimization). Neither account predicts an effect of increased gender salience on gender-neutral risks.

We conducted a series of experiments with female participants to test these theories. Significant interactions and simple effects provide evidence for the defensive mechanism account and explored boundary conditions for the effect of identity salience on perceived risk. In experiment 1, 2, and 4 identity salience was manipulated using an essay writing task. Relative to a control condition, in the gender prime condition we observed a decrease in women's perceived risk of contracting breast cancer (experiments 1 and 4) whereas no effect was evident on risks without a link to gender identity. Behavioral implications were apparent in experiment 2, in which we found that gender priming leads to a decrease in donations to research on ovarian cancer treatment. Confirming the role of nonconscious defensive mechanisms, fear appraisal prior to the risk rating task muted the effect of gender identity salience on risk perceptions (experiment 4). In experiment 3 we used a more subtle gender priming task in which participants determined the gender of Dutch words. Establishing the importance of self-identity, perceived breast cancer vulnerability was lower when women were primed with their own gender, but not with the general category of gender.

These experiments contribute to literature on subjective risk estimates, defensive mechanisms and cognitive priming. Moreover, the results have implications for the design of health campaigns. Breast cancer awareness campaigns almost inevitably stress womanhood or women's sense of gender identity and along with it the relative importance of this identity aspect for their self-concept. Our findings indicate that an increase in gender identity salience can trigger defensive mechanisms of risk minimization, thus potentially attenuating or even reversing a campaign's intended consequences. The results of the experiments provide a number of suggestions on how to reduce the likelihood of defensive mechanisms interfering with the intended aim of health campaigns.

Measuring Internet Product Purchase Risk

Brent L S Coker, University of Melbourne, Australia

EXTENDED ABSTRACT

Despite general agreement amongst researchers that risk is an important phenomenon influencing online consumer decision making, there has been little consistency in the way risk has been defined and measured. Although the nature of online risk has been well defined, a psychometrically robust scale to measure this risk has yet been developed.

Internet Product Purchase Risk (IPPR) is defined as "the degree of uncertainty an individual perceives towards purchasing a product on the Internet". Perceptions of risk are activated during product evaluation and transaction stages of purchase decision making (Howard, 1973).

Evaluation Judgment Risk (EJR) is activated from an assessment of how easy or difficult a product is to evaluate online. It is defined as the degree of uncertainty aroused from an individual's belief in their ability to make an accurate judgment of product quality on the Internet. Given that some products are comprised of more experiential type attributes than others, EJR is influenced to a large extent by the physical characteristics of a product (Swaminathan, 2003). However, because consumers differ in which attributes are considered important when evaluating a product, EJR also differs between people for the same product (Alba et al., 1997; Klein, 1998).

Internet Security Risk (ISP) is an evaluation of how insecure the Internet is for shopping, and is defined as the degree of uncertainty and mistrust aroused from thoughts about providing personal and financial information over the Internet. An individual with low ISP is likely to have more confidence in their ability to shop on the Internet than an individual with high ISP. Low ISP consumers are characterized by a positive self-evaluation of their Internet shopping ability, displaying more robustness against contradictory cues and perceived inhibiting factors in their Internet shopping behavior than those who are risk averse (Eagly & Chaiken, 1993).

The Internet product purchase risk (IPPR) scale was developed and tested in four studies. In the first study (n=100) a preliminary pool of items was generated with evidence of content validity. In the second study (n=600) the IPPR scale was purified using principal axis factor analysis. In the third study (n=600) evidence of criterion-related, known-group, nomological, and discriminant validity was demonstrated. In the fourth study (n=184), the moderating effect of IPPR on trust-purchase intentions was empirically examined.

The IPPR scale was found to be internally consistent, exhibiting high criterion-related, known-group, and discriminant validity. Evidence of content validity was shown during initial selection of the items, and when open-ended questions of risk were matched to IPPR scores by expert judges (Zaichkowsky, 1985). The comparison of IPPR scores to open ended questions by expert judges also tested the criterion-related validity of the scale. The IPPR scale was also shown to have known-groups validity by demonstrating how those who were frequent online shoppers had higher IPPR than infrequent shoppers. Evidence of nomological validity was demonstrated by showing how IPPR was affected by perceived behavioral control, and correlated to intentions to purchase online. The metric invariance between item scores when measuring four products differing in experiential attributes suggested the items were robust in terms of interpretation.

Two main findings were found in the development. First, IPPR was found to have a quadratic relationship with experience purchasing from the product category. The results showed that although the frequency of purchase initially reduced IPPR, levels of IPPR actually increased for those who had purchased more than 6 times from the product category in the past 12 months. The second main finding was that IPPR was found to moderate a trust-purchase incompatibility tendency, with risk averse participants trusting a different seller than the one they preferred to purchase from. The results from the fourth study suggest that negative framing may be used to enhance trust for those with high perceptions of Internet purchase risk.

We conclude that IPPR plays an important role in influencing consumers' decisions to adopt the Internet for purchase, and suggest the scale is likely to be useful for academics seeking to further our understanding of online consumer related phenomena.

APPENDIX 1

The Internet Product Purchase Risk Scale

Internet Product Purchase Risk (IPPR) Scale

—for measuring the degree of uncertainty
towards purchasing a product on the Internet

Buying a _____ on the Internet is...
(Insert name of product)

Unpredictable	_____	Predictable
Safe	_____	Risky*
Uninformative	_____	Informative
Reliable	_____	Unreliable*
Untrustworthy	_____	Trustworthy
Secure	_____	Not Secure*
Not Credible	_____	Credible
Clear	_____	Unclear*
Uncertain	_____	Certain
Responsible	_____	Irresponsible*

Instructions:

1. Write the name of the product to judged at the top
2. Write a cross (x) in one of the intervals for each word pair
3. Work quickly, but carefully, through the list. Do not pause

Examples:

_____X_____	_____X_____
Neutral	Slightly
_____X_____	_____X_____
Quite	Extremely

Scoring:

1. Reverse score items marked with an asterisk (*)
2. Total the scores from each word pair (from 1 on the left to 7 on the right)
3. Scores range from 11 (extremely low perceived risk) to 70 (extremely high perceived risk)

Flow in Consumer Research: A Novel Approach

Jan Drengner, Chemnitz University of Technology, Germany
Manuela Sachse, Chemnitz University of Technology, Germany
Pia Furchheim, Chemnitz University of Technology, Germany

EXTENDED ABSTRACT

Since the seminal article by Hoffman and Novak (1996) flow has gained more attention in consumer research. Reviewing the literature, there have been several attempts to develop a conceptualization of flow, whereby the following characteristics seem to make up the core of the construct: action-awareness merging (1), loss of self-consciousness (2), transformation of time (3), sense of control (4), clear goals (5), unambiguous and seamless feedback (6), challenge-skill balance (7), concentration on task at hand (8), and autotelic experience (9).

However, our examination shows disparity between the different conceptualizations. First, there is no overall agreement on the use of the flow characteristics. Some researchers (Chen, Wigand, and Nilan 2000; Jackson and Eklund 2002; Stavrou et al. 2007) take all of the above mentioned characteristics into consideration. Alternatively, others confine themselves to selected characteristics and/or use additional ones (Huang 2006; Novak, Hoffman, and Yung 2000; Shin 2006). Second, there is often no discussion whether these characteristics are formative or reflective dimensions, or even if they might be seen as antecedents or consequences of flow. Only a few researchers (Drengner, Gaus, and Jahn 2008; Sánchez-Franco 2006; Sánchez-Franco and Roldán 2005; Shin 2006; Siekpe 2005) discuss the nature of the dimensions (reflective vs. formative) intentionally.

Generally, both problems seem to be based on the fact that flow has often been defined with special focus on the respective subject of investigation. Therefore, we develop a new and universal conceptualization and test it empirically.

With the help of some decision rules by Jarvis, MacKenzie, and Podsakoff (2003), we classified the characteristics 1 to 4 and 8 as reflective dimensions and the characteristics 5 to 7 as antecedents. Since it is neither an antecedent nor a formative dimension or a manifestation of flow, we see characteristic 9 rather as a consequence of the flow experience. Hence, we excluded this characteristic from our 3 empirical studies.

In study 1, subjects were 618 online-game players (81 female, 537 male; 23.0 mean age). Study 2 contained 1,556 soccer World Cup viewers (742 female, 854 male; 25.7 mean age). The sample of study 3 consisted of 120 attendees of soccer World Cup public viewing points (48 female, 72 male; 23.6 mean age). We assessed the antecedents and dimensions, each with 3 items following the Flow Scales by Jackson and Eklund (2002).

In all three studies, there was no differentiation between respondents who experienced flow and those who did not with respect to their perceived control. These findings can be corroborated by the theory of planned behavior (Ajzen 1991), stating that perceived control is a precondition for behavioral intention and behavior. Following this idea, control would lead to the behavior, which might result in a flow experience. Hence, we exclude characteristic 4 from further analyses.

The remaining characteristics were evaluated by two different second-order models in study 1 with the help of CFA. Model 1, which draws upon the mostly used perspective (e.g., Chen et al. 2000; Csikszentmihalyi 1975; Jackson and Eklund 2002; Stavrou et al. 2007), incorporates all characteristics (1 to 3, 5 to 8) as dimensions. Model 2 distinguishes the characteristics between dimensions (1 to 3, 8) and antecedents (5 to 7) of flow according to

our suggested conceptualization. The fit values (χ^2 , RMSEA, SRMR, NNFI, CFI, PNFI, CVI), the loadings of the characteristics as well as their explained variance attest superiority to model 2.

Given the need for generalizability we retested model 2 in study 2 and 3 with different subjects of investigation. Again, the empirical findings support our conceptualization with 4 reflective dimensions (1 to 3, 8). Therefore, we suggest the following flow definition: Flow is a holistic experience, explaining the state in which the acting individual experiences a loss of self-consciousness, loses all sense of time while being highly concentrated and having the impression of his or her consciousness and action merging. This definition provides first directions towards a universal conceptualization of flow, which is applicable in various fields of consumer research.

The Impact of Matching Between Emotion Types and Product Offerings on Evaluations

Kiwan Park, Seoul National University, Korea
Hakkyun Kim, Concordia University, Canada
Norbert Schwarz, University of Michigan, USA

EXTENDED ABSTRACT

In conceptualizing how affect plays an informational role, the valence of affect, such as positive or negative, has been of focal interest. Although the differential role of positive versus negative affect has been well documented as a mechanism accounting for people's different behaviors or decisions (depending on the valence of the affect), and has been proven useful for our understanding as to how human cognition and affect interplay, many questions are still unanswered. Will sad people behave in the same manner as angry people, assuming both are equally negative? Or, will excited consumers prefer a trip to an amusement park as much as consumers experiencing a peaceful mood, given the same degree of positivity? Actually, the significance of the specificity of emotions has been a bit neglected, in favor of the parsimony of research programs.

Inasmuch as the same positive or negative affect serving as an informative cue is context-dependent, distinct emotions within positive or negative mood can carry different informational values, depending on how well the context can be understood with the prevailing mood state. Since discrete emotions (of the same valence) are associated with their unique meanings respectively and are followed by different types of appraisal, or the accessibility of semantically congruent information that matches those emotional states (Lazarus 1991), it appears to be plausible that incidental emotions (beyond positive or negative valence) can influence how people incorporate discrete emotions in generating evaluative judgments. In fact, an exploration into the premise that discrete emotions have distinct effects on people's judgments has only begun recently.

For example, by adopting appraisal theories of emotion, Lerner and Keltner (2001) show that angry people express optimistic risk estimates and make risk-seeking choices while anxious people express pessimistic risk estimates and make risk-averse choices. Similarly, DeSteno et al. (2000) show that sad individuals believe that sad events are more likely to occur than angering events, whereas angry individuals believe that angering events are more likely to occur than sad events. These findings reflect the notion that sadness being experienced in the moment is used as input for coloring one's environment as a sad place and influences the likelihood of sad events occurring. In the same vein, momentary feelings of anger are used as a cue indicating one's environment as a place full of angering events, which then affects the likelihood of angering events occurring.

Following that it is the match with the current domain of concern, rather than the emotional valence or congruence in a general sense, that determines the information that is given processing priority, we reason that a match between felt emotion and the emotional appeal of a product will generate more favorable evaluations toward a product. This prediction is based on theorizing that consumers will better empathize with product claims when they are in the same emotional vein (e.g., feelings of excitement), which will lead them to believe that the product will surely give them the claimed benefits (e.g., adventure). Consequently, people are expected to find certain messages or product claims as more convincing or appealing in the matching versus the mismatching condition.

Two experiments were conducted to test the above hypotheses. Study 1 aimed to assess whether a match versus a mismatch

between emotional state and product appeals yields differences in evaluation by participants whose ambient emotions differ. To accomplish this goal, we employed a 2 (Emotion: excited vs. peaceful) \times 2 (Product: adventurous vs. serene) between-subjects design and measured participants' evaluations of a target object when the overtones associated with distinct emotions varied. The results from study 1 provided support for our hypothesis. More specifically, we found that people's evaluations toward travel products in the form of advertisements depend on a match versus a mismatch between an individual's emotional state and emotional appeals of a product. When the travel destination was described as a place full of adventurous offerings, people showed more favorable attitudes toward the destination under excitement than under serenity. Conversely, when the same destination was depicted as a place full of serene offerings, people showed more favorable attitudes toward the destination when people felt peaceful than when they felt excited.

In a follow-up study, we further investigated the mechanism underlying the emotion congruency bias observed in study 1. In evaluating a product built on emotional benefits, people may (implicitly) ask themselves "how would I feel if..." and can get a direct answer from their current emotional state. Specifically, when there exists a match, people may increase their likelihood estimates of a matching emotional benefit, as people tend to infer how they would feel from how they are feeling in the moment. On the other hand, when there exists a mismatch, what people infer from their current emotion can actually play a disturbing role, in that their current emotion blocks people's imagery regarding the proposed product's emotional benefits. Thus, it is predicted that the positive impact of a match (vs. a mismatch) will influence people's evaluations via enhanced estimates of the occurrence of product benefits. The results from study 2 confirmed this premise. Specifically, by using structural equation models, we showed that individuals experiencing a specific emotion are more likely to believe events associated with their emotions prevail in their environment: as a consequence, they make more positive evaluations of products whose nature is more consistent with their emotional states, as those products are expected to reflect corresponding emotions that are promised from their consumption. Thus, study 2 replicates the results of study 1 and further determines the underlying process that explains the emotion congruency bias for positive discrete emotions.

Taken together, these findings add to the emergence of emotion specificity and fluency effects as factors affecting consumer judgments. In addition, the managerial implications from the current research can be important, in that that firms have an opportunity to make use of mood to their advantage by employing tactics in advertisements and interpersonal sales designed to enhance consumers' emotional states, in combination with positioning decisions.

The Effect of Experiential Analogies on Consumer Perceptions and Attitudes

Miranda R. Goode, University of Western Ontario, Canada

Darren W. Dahl, University of British Columbia, Canada

C. Page Moreau, University of Colorado, USA

EXTENDED ABSTRACT

Microsoft has compared playing the Xbox 360 to participating in a city-wide water balloon fight and Alfa Romeo has compared driving a sports car to a first kiss. These are prime examples of experiential analogies. By comparing a product to a familiar but disparate experience, these analogical comparisons have the power to shift consumer focus from objective information, such as functionality and performance, to the evaluative, emotional and multi-sensory information associated with the product experience. This shift in focus highlights the importance of base preference (i.e., a consumer's liking for the comparison experience) as an important influence on analogical persuasiveness. This shift in focus also highlights the power of an analogy to tap into the emotional knowledge that individuals have gained from their own experiences. Surprisingly, previous research has focused almost exclusively on analogies designed to transfer objective knowledge in the context of strategic and functional oriented comparisons (Gregan-Paxton 2001; Gregan-Paxton and Moreau 2003; Hoeffler 2003; Roehm and Sternthal 2001). In doing so, not only has the consumer's ability to transfer unique, personally-experienced emotional information been ignored, but the effect of prior preferences on an analogy's persuasiveness has not been investigated. Addressing these gaps and building on previous speculation on the role of emotions in analogical thinking (Thagard and Shelley 2001), our research defines and isolates the effects of base preference, emotional knowledge, and experienced emotion on consumer attitudes.

When processing an experiential analogy, it is anticipated that consumers will access their knowledge of the base experience and any knowledge they might have of the target product experience. With the Alfa Romeo Spider ad, individuals would think about what happened and the emotions experienced during a first kiss. Any similarities between what takes place during a first kiss and what an individual knows or thinks driving the sports car might entail would be cognitively identified. Finally, based on these identified similarities, emotional inferences (i.e., predictions about the emotions that would be experienced during target product use) would be generated. We predict that whether or not the generation of emotional inferences will have a positive or negative effect on target attitudes will depend on the favorability of the base preference (i.e., how much the base experience is liked). This moderating hypothesis implies that target attitudes will be more positive when preference for the base experience is favorable and a high number of emotional inferences are generated. When preference for the base experience is less favorable and a high number of emotional inferences are generated, we would expect target attitudes to be more negative. Note that the current investigation focuses on the more common use of experiential analogies to positively influence consumer attitudes.

Three studies were designed to test our theorizing. This was done using three different analogies across several base and target categories, thus contributing to the generalizability of our effects. Across all three studies, we also compared the persuasiveness of an experiential analogy to more general emotion-oriented appeals. This provided us with additional insight on the contributors to analogical persuasiveness and the ability to make substantive recommendations for whom experiential analogies may be more persuasive.

Study 1 involved direct measures of base preference and emotional inferences to test the main moderating prediction. Participants were randomly assigned to view either an experiential analogy ad or an emotional appeal control ad. The findings were consistent with expectations and suggest that experiential analogies cue the transfer of emotional knowledge from the base experience to the target product. The effect of emotional inferences on target attitudes was moderated by base preference. The more participants liked the base experience and the more emotional inferences they generated then the more favourable were consumer attitudes. The analogy ad was also liked significantly more than the emotional appeal ad.

Study 2 was designed to provide additional evidence for the main moderating prediction and for the cognitive nature of the emotional knowledge transfer process. This was done by manipulating participants' ability to generate emotional inferences through cognitive load. Measures of experienced emotion were included in this study and in study 3 to further show that emotional knowledge transfer is cognitive and has an effect on product attitudes independent from experienced emotion. In study 3, the soundness construct (which captures the extent to which the base and target share deeper underlying similarities) was introduced to further demonstrate that base preference moderates the effect of emotional knowledge transfer on target attitudes. Across studies 2 and 3, we found evidence that the processing of experiential analogies results in the generation of emotional reactions which also predict consumer attitudes. Importantly, accounting for experienced emotion did not reduce the significant effect of base preference and emotional inferences on consumer attitudes. This suggests that experienced emotion and emotional knowledge transfer, a more cognitive process, may be viewed as having complementary effects on the persuasiveness of an experiential analogy.

The contribution of this research is three-fold. First, analogy researchers have highlighted the need to move beyond the identification of factors that affect analogy comprehension to identify the factors that affect an analogy's persuasiveness (Perrott, Gentner, and Bodenhausen 2005). Addressing this, we establish base preference as an important influence on an analogy's persuasiveness. This research is the first to examine how preference for a disparate base is integrated into a target product evaluation. Second, we demonstrate that product attitudes can be significantly influenced by directing people to consider their own subjective experience as a basis for understanding the emotions that may be experienced when using a new product. We find evidence that this involves the cognitive consideration of emotions, which we have labeled emotional knowledge transfer. This is perhaps surprising and of central interest to marketing practitioners, since we show that the persuasiveness of an experiential analogy is not limited to emotional reactions. Finally, on a broader level, our research provides the first known empirical investigation of analogies involving experiential comparisons, thus establishing their value in persuasion.

Evaluative Conditioning 2.0: Direct and Indirect Attachment of Affect to Brands

Steven Sweldens, RSM Erasmus University, The Netherlands

Stijn van Osselaer, RSM Erasmus University, The Netherlands

Chris Janiszewski, University of Florida, USA¹

EXTENDED ABSTRACT

When initially neutral stimuli such as new brands co-occur repeatedly with positively valenced stimuli (such as beautiful pictures, nice music, celebrity-endorsers etc.), we observe that as a result the brand becomes more positively evaluated itself. This repeated-pairings procedure is referred to as “evaluative conditioning” in the literature (for a review, see De Houwer et al. 2001). According to the established theory by De Houwer et al., positive affect only becomes *indirectly* attached to the brand. The brand becomes more positively evaluated through mediating memory links to the affective stimuli it co-occurred with in the past. Thus, after a sufficient number of co-occurrences, the brand starts to evoke (un)conscious memories to the affective stimulus it co-occurred with in the past. Positive affect experienced towards the brand is caused by the triggering of such memories. In this article, we introduce a new theory, in which we show that—only in specific circumstances—affect can also become *directly* attached to the brand. In this case, it is the brand itself that acquires the positive affect, without the necessity for further intermediating memories to the affective stimuli.

We show when direct versus indirect affect transfer occurs, which is critically dependent on the way the brands and affective stimuli are presented together. We also show that direct transfer of affect (compared to indirect affect transfer) results in much more stable brand attitudes which are uniquely resistant to retroactive interference from new learning (e.g., advertising clutter) and uniquely resistant to post-conditioning devaluations of the affective stimuli (e.g., celebrity endorsers falling from grace).

We identified two properties of conditioning procedures that determine whether affect becomes directly or indirectly attached to the brand. First, the time gap between the presentations of brand and affective stimulus should be zero for direct affect transfer to be possible. This matches on the distinction between a *sequential conditioning* procedure and a *simultaneous conditioning* procedure.

Second, we manipulated whether the brand was repeatedly paired with the same affective stimulus (*same pairings* condition) versus always with different affective stimuli (*different pairings* condition). In a *same pairings* conditioning procedure, it becomes more likely that the brand will evoke (un)conscious memories to the affective stimulus in the future, hence indirect affect transfer is promoted. However, in a *different pairings* conditioning procedure, there’s no such establishment of a strong link between a brand and a certain affective stimulus, making it unlikely that one will be recalled upon future presentation of the brand. Therefore, different pairings inhibit the indirect transfer of affect.

Combining these deductions, we conclude that in a sequential same pairings conditioning procedure, only indirect affect transfer will occur. In a simultaneous different pairings conditioning procedure, only direct affect transfer will occur. In a simultaneous same

pairings conditioning procedure, both types of evaluative learning can occur. In a sequential different pairings conditioning procedure however, evaluative learning should be inhibited because it is not conducive of indirect (due to the different pairings), nor direct (due to the sequential presentation) affect transfer.

We set up a first experiment to test the hypothesis that a sequential different pairings conditioning procedure should lead to less transfer of affect than other procedures.

Experiment 1

Fifty-seven students at a large Southeastern university participated in this experiment in exchange for course credits. We employed a 2 (simultaneous vs. sequential conditioning) x 2 (same vs. different pairings) x 2 (attitudes towards positively vs. neutrally conditioned brands) mixed design with the first two factors manipulated between subjects and the latter manipulated within subjects. We used pictures of unknown Belgian beers as brands and positive and neutral pictures from the International Affective Pictures System as the affective stimuli.

Confirming our prediction, evaluative conditioning was strongly significant in all conditioning procedures, except in a sequential different pairings condition.

Experiment 2

We directly tested the indirect versus direct nature of the attitude changes caused by evaluative conditioning by investigating what happens when the valence of an affective stimulus suddenly changes after the conditioning phase. On the one hand, when affect transfer is indirect, a brand derives its valence by (un)consciously retrieving the associated affective stimuli. Therefore, the brand’s valence will be tied to the affective stimuli’s valence and a devaluation of the affective stimuli will cause a devaluation of the brand. On the other hand, when affect becomes directly attached to the brand, it is of no further consequence what happens to the affective stimuli that were previously paired with the brand.

Ninety-seven students at a large Southeastern university participated. The design of the study was a mixed 2 (sequential vs. simultaneous conditioning) x 2 (same vs. different pairings) x 3 (attitudes towards normally positively conditioned, positively conditioned with a posteriori devaluated affective stimuli, and neutrally conditioned brands). The first two factors were manipulated between subjects, the latter one within subjects.

In accordance with our theory, we found that a devaluation of the affective stimuli negatively impacts the affect towards the brand in a sequential same pairings condition, in a simultaneous same pairings condition, but not in the simultaneous different pairings condition. As in experiment 1, no affect transfer occurred with a sequential different pairings condition.

Discussion

In an unreported third experiment we also found that attitudes generated by a simultaneous different pairings procedure (leading to direct affect transfer) are much more stable and hence not sensitive to forgetting induced by other learning tasks after conditioning, whereas attitudes generated by a sequential same pairings procedure (leading to indirect affect transfer) are very vulnerable to forgetting of the associations induced by new learning tasks.

¹Support from the Department of Marketing Management at the Rotterdam School of Management, the Marketing Department at the Warrington College of Business Administration, the Erasmus Research Institute of Management and the Trust Fund Erasmus University Rotterdam is gratefully acknowledged. This paper is based on the first author’s dissertation.

It can be concluded that achieving direct transfer of affect carries distinctive advantages for the brand. First, it shields the brand from devaluation of associated affective stimuli (such as celebrity endorsers falling from grace). Second, it's much more stable with regard to interference by subsequent learning as in advertising clutter situations.

How and When Alpha-Numeric Brand Names Affect Consumer Preferences

Kunter Gunasti, Pennsylvania State University, USA
William T. Ross, Jr., Pennsylvania State University, USA

EXTENDED ABSTRACT

“... An alpha-numeric brand name is defined as a name that contains one or more numbers either in digit form (e.g., “5”) or in written form (e.g., “five”). This means that alpha-numeric brand names include referential or non-sense mixtures of letters and digits (e.g., WD-40), mixtures of words and digits (e.g., Formula 409), or any of the preceding where the figure is written out in word form...” (Pavia and Costa, 1993, 85).

There are millions of registered and unregistered alpha-numeric trademarks in use (US Patent and Trademark Office 2006). The increase in the market segmentation; spread of technology; difficulty of finding and implementing new brand names; decrease in product life cycles; and the tendency to stretch a favorable brand name to new products have led marketers to use alpha-numeric brands (see Boyd 1985 for a review). Even highly successful non-alpha-numeric brands like Lincoln and Acura have recently switched to alpha-numeric brands that dominate the automotive industry.

Some alpha-numeric brands make it fairly simple to draw inferences about the product. For instance, the BMW 3.20 refers to a 2 liter engine volume for the 3 series cars, and you can easily tell that the 3.28 is a relatively better product due to its larger engine (2.8 liters). Correspondingly, Audi A8 and A6 indicate larger size and higher luxury levels than A4 and A3. However, it is not always so easy to understand alpha-numeric brand names. Mercedes has over ten letter classes resulting in a rather complicated set of some forty alpha-numeric brand names and not many people know the difference between an S550 and an E550 car. Sometimes alpha-numeric brands are not consistent with the consumers’ intuitions. For example, contrary to intuition, Nokia 6110 is inferior to Nokia 6102 and average consumer has no idea what 6110 really refers to.

Most past studies on alpha-numeric brands have focused on the perception of the brands and how consumers associate them with different product categories. In their benchmark study, Pavia and Costa (1993) investigated how consumers react to the magnitude of the numbers and the symbolisms of the letter combinations used in alpha-numeric brands. Authors found that the numeric portions of the brands play a vital role in the perception of the product generation, whereas the letters usually help consumers identify the product type. In parallel, Ang (1997) investigated the effects of phonetics, lucky numbers and letters on consumers’ processing of alpha-numeric brand names and showed that various linguistic properties of the brands affect consumers’ general opinions of the products.

While past research has provided us with important insights about the perception of the alpha-numeric brands, the effects of these brands on consumers’ choices have not been explored. It is well-known that the brand name is the foundation of a brand’s image and it has a vital role on customers’ purchase decisions in the marketplace (Kohli and LaBahn 1997). On the other hand, despite their widespread use in numerous industries, we know very little about how alpha-numeric brands actually affect the choice outcomes. Our research contributes to literature by extending on past studies and identifying the systematic effects of alpha-numeric brand names on consumers’ preferences under different circumstances. Building on previous findings, we demonstrate how and when alpha-numeric brand names can improve or reduce the

accuracy of consumer choices. We consider situations, when there is complete or incomplete attribute information and explore the different cognitive processes through which alpha-numeric brands have an effect on consumers who have different levels of need for cognition.

This research reveals that alpha-numeric brands have a systematic effect on product choices. We show that given an identical choice set, labeling a product option with a higher or lower alpha-numeric brand (X-100 vs. X-200) increases or decreases its choice share. We also consider the situations when choice options are missing important attributes and reveal that under missing information, alpha-numeric brands can still affect (potentially mislead) consumer choices. We further examine the different cognitive processes through which alpha-numeric brands affect consumers with low and high need for cognition (Cacciopo and Petty 1982). Our findings indicate that consumers with low need for cognition use a simple brand name heuristics and make their decisions based on the assumption that alpha-numeric brands with higher numeric portions correspond to more advanced products. On the other hand, those with high need for cognition process alpha-numeric brands more deeply trying to infer brand-attribute correlations and understand the relations among the brand names and attribute values.

Besides its contribution to different streams of literatures such as branding, missing information and inference making, our research has important managerial and practical implications. The fact that product familiarity did not prevent the effects of alpha-numeric brands on choices highlights the serious implications of our research for marketers and consumers. Our results further show that consumers’ choices can be fairly easily manipulated by marketers in real life purchases. If sales people strategically expose their customers to various product options with alphanumeric brands they may maximize the possibility that consumers will make a choice based on alphanumeric brand names.

Broadening Perceptions of Familiar Brands

Robert Jewell, Kent State University, USA
Christina Saenger, Kent State University, USA

EXTENDED ABSTRACT

When changes in the market reveal the need for a well-defined brand to broaden its consumer perceptions, such attempts are often met with resistance. Perceptions of well-defined brands are typically strongly held, inhibiting the ability of a brand to broaden perceptions when faced with changes in the market, such as shifts in consumer preferences or flat revenues. This research examines how a well-defined brand can encourage the assimilation of discrepant information into the brand meaning via comparative advertising. We propose that the comparison brand acts as a referent, facilitating the development of associations between the advertised brand and new attribute information. Further, we argue that the characteristics associated with the comparison brand will moderate the ability of a brand to expand its meaning via comparative advertising.

It is generally accepted that brands are stored as concept nodes and are defined based on linkages to category-relevant attributes (Nedungadi 1990). To broaden perceptions of a brand, links to new attributes must be established. One way to establish these links is to make salient relevant context cues (Meyers-Levy and Tybout 1997); when context cues become accessible, the evaluation of an item is not only derived from the characteristics of the item, but also from the interaction of the characteristics of the item and the context in which the item is evaluated (Meyer and Johnson 1995). Thus, employing a context cue or referent should facilitate consumers' interpretation of the extent to which a brand is associated with new attributes; however, a brand-attribute link will be rejected for a brand attempting to associate with a product-class category that is inconsistent with existing brand linkages. Well-defined brands are constrained by strong associations to existing product-type attributes; the association of new information is likely to be resisted due to the high level of discrepancy between the new information and the existing associations. Combining new information with a contextual cue that dissociates the brand from, but still ties to membership in, its existing product type, should result in relative acceptance of the new attribute information.

Comparative advertising is often used in marketing to make a context cue salient. The comparison brand serves as a reference point by which the new claim of the advertised brand is, in part, judged. When selecting a comparison brand, a competitor may be chosen from either the brand's current product-type category, or from the product-type category of the new attribute information. When comparing a brand to a competitor in its existing product class category, the advertisement communicates points of distinction of the brand from that competitive group (i.e., a dissociative strategy). When comparing a brand to a competitor in the product-type category of the new attribute information, points of similarity between the brands are emphasized (i.e., an associative strategy).

When communicating the link between a brand and a new attribute from a different product-type category with a noncomparative advertisement, we expect the highly discrepant attribute information to be rejected due to its inconsistency with current perceptions of the brand (cf. Meyers-Levy and Sternthal 1993); the development of the link would be met with resistance. In a dissociative comparative advertisement, however, we expect that the reference point increases the likelihood that the link will be developed between the brand and the new attribute information because the comparison brand has links to the current product-type

category, providing a schema-consistent reference point that makes the link between the advertised brand and new attribute seem less discrepant. In an associative comparative advertisement, this tempering of the new claim is not expected. The associative reference point should amplify the discrepancy between the advertised brand and the new attribute information because the advertised brand would be compared to two referents from a different product-type category: both the attribute and the competitor from the new product-type category.

We hypothesized that a dissociative comparative advertising strategy would be more effective in broadening perceptions of a well-defined brand than both an associative strategy and a noncomparative strategy, and that there would be no difference between the associative and noncomparative strategies. Further, we hypothesized that an associative strategy would result in evaluations that are more consistent with the current product-type category than would a dissociative or noncomparative strategy. Results of our first study confirmed that the use of a reference point facilitates the broadening of the meaning of a brand, and that the nature of the reference point (dissociative or associative) matters. Further, results of the associative strategy showed that associative comparative advertising strengthens the association to the existing product-type category.

While the dissociative comparative advertising strategy proved successful in our first study, it may have a significant weakness. Repeated encoding of dissociative information may strengthen the linkages of the advertised brand to the existing product-type category due to repeated activation of the schema-consistent reference point as the comparison brand. Thus, we proposed that a comparative advertising approach combining both dissociative and associative strategies will be successful, over time, in pushing the brand away from the existing product-type category and pulling the brand toward the new product-type category. We hypothesized that this combination approach would be more effective than a purely-dissociative approach, and that the dissociative approach would be perceived as more consistent with current product-type category attributes than the combination strategy. Results confirmed that context cues from multiple product-type categories were more effective in broadening perceptions, and that multiple exposures to context cues from the current product-type category reinforce the existing meaning of a brand.

The present paper contributes to the comparative advertising literature by demonstrating how comparative advertising can be used to broaden perceptions of a well-defined, existing brand. Previous research on comparative advertising has focused on the effects of a comparison brand on perceptions of new or unfamiliar brands, where the process of assimilation is fairly straightforward. This paper examines the impact of existing linkages on the acceptance of new information and provides a framework through which a well-defined brand may broaden the way it is defined in the marketplace.

Whence Brand Evaluations? Investigating the Relevance of Personal and Extrapersonal Associations in Brand Attitudes

Sandor Czellar, HEC Paris, France
Benjamin Voyer, HEC Paris, France
Alexandre Schwob, HEC Paris, France
David Luna, Baruch College, USA

EXTENDED ABSTRACT

A recent conceptualization of attitude structure in social psychology proposes that individuals may have in their memories different types of salient associations about an object, each type with a different role in personal attitude formation (Olson and Fazio 2004). According to this conceptualization, some of these salient associations, called *personal associations*, contribute directly to the formation of personal attitudes about the object. However, other associations, called *extrapersonal associations*, may be accessible in memory, but because individuals may not necessarily endorse them, these associations do not contribute directly to the formation of personal attitudes about the object. Those extrapersonal associations may be based on a variety of sources, including cultural knowledge, social influence or media information (Karpinski and Hilton 2001).

As this new typology bears potentially important implications for attitude conceptualization and measurement, it has promptly generated considerable research interest. Thus, experiments across several attitude domains highlight the importance of the personal-extrapersonal distinction for a better understanding of the associations affecting the outcomes of different attitude measures (De Houwer, Custers, and De Clercq 2006; Han, Olson, and Fazio 2006; Olson and Fazio 2004). The purpose of the present research is to investigate the validity and boundary conditions of Olson and Fazio's (2004) framework in a consumer attitude domain—brand evaluations. We present three studies on different car brands that are globally supportive of the new typology.

Study 1 suggests the presence of extrapersonal associations for all brands investigated, by showing that some highly accessible brand associations indeed do contribute to global attitudes about those brands, but others do not. In particular, we found that, for each of the car brands used in the study, at least one of the thoughts among the first five reported by the respondents did not correlate significantly with the overall attitude toward the brand.

Study 2 shows that an individual difference, consumer expertise with the category, impacts the accessibility of personal associations in a brand evaluation context. An important difference with respect to Study 1 is that, instead of using thought protocols, Study 2 assessed the personal-extrapersonal nature of associations with an implicit procedure by implementing the Implicit Association Test. We administered two different versions of the Implicit Association Test (IAT): the traditional IAT (Greenwald, McGhee, and Schwartz 1998) and the personalized IAT (Olson and Fazio 2004). The traditional IAT, according to Olson and Fazio (2004), is potentially affected by extrapersonal associations that are accessible at the time of categorizing the target object. Olson and Fazio (2004) devised a "personalized" version of the IAT that should be affected by personal associations to a greater extent than the traditional IAT. Our study found that increasing levels of category expertise lead to a greater correspondence of IAT measures with explicit attitude measures in the personalized (but not in the traditional) IAT.

Study 3 further highlights the value of the new typology for consumer research by showing that it can meaningfully explain changes in brand knowledge structures in a persuasion context. As in Study 2, we find that individuals with different levels of expertise

use knowledge in different ways when they report their brand evaluations. Further, this study finds that personal associations (those used in the construction of brand evaluations) are made accessible by either strong or weak messages, depending on whether individuals are experts or novices, respectively.

Taken together, our three studies provide strong support for the value of Olson and Fazio's (2004) framework and provide a better understanding of the nature of the brand associations that form consumer brand attitudes. We conclude the paper with a discussion of the theoretical implications of our results with respect to recent research on the personal-extrapersonal distinction between associations. For instance, our results contribute to our knowledge on attitude structure and provide valuable results for current conceptualizations of attitude processes (Fabrigar, MacDonald, and Wegener 2005). Recently, Gawronski and Bodenhausen (2006, 2007) advanced a distinction between two kinds of evaluative processes: associative and propositional. Associative processes are claimed to provide the basis for primitive affective reactions in evaluative judgments, while propositional processes involve thoughtful assessments of the validity of evaluative statements. Gawronski and Bodenhausen (2006) argue that the personal-extrapersonal distinction is likely to operate at the propositional level but less so at an associative level. Indeed, the explicit attitude measures used in our three studies likely implied some level of propositional reasoning and thus support this view. However, our second study using different variants of the Implicit Association Test corroborates recent findings in other research (Olson and Fazio 2004; Han et al. 2006) suggesting that the distinction between personal and extrapersonal information may, in some domains at least, also operate at a low-thought, associational level. Our findings suggest that attitudes for long-standing, established brands are likely to be part of such domains. However, the new typology may not apply to, for example, freshly formed attitudes toward new brands. Further research is certainly warranted to investigate which consumption domains are more or less likely to entail the relevance of the personal-extrapersonal distinction at both associative and propositional levels.

Encounters of Accidental Tourists: Maintaining Boundaries through Food Consumption

Fleura Bardhi, Northeastern University, UK

Anders Bengtsson, Suffolk University, USA

Jacob Ostberg, Stockholm University, Sweden

EXTENDED ABSTRACT

The study attempts to provide an understanding of the ways that tourists relate to local and home food and the role that these relationships play in personal management of tourist experiences. Tourism involve boundary crossing and may generate a sense of fragmentation and discontinuity. Tourist traveling may even threaten our familiar sense of who we are. Thus, tourists do not only engage in adventurous explorations, but also in boundary maintenance practices (Belk 1997). Acculturation studies have pointed at several such practices and have emphasized the role of possessions and rituals in boundary maintenance practices during long term mobility. However, research that examines the ways that tourists manage their experiences abroad is lacking. Further, mobile consumers behave conservatively when it comes to food consumption and foods tastes are among the most resistant practices during acculturation. Considering the relationship between food, identity, and home, we intend to provide an explanation and perspective on such tourist food experiences. Food consumption is fundamental for human life and we take the perspective that food is never just about eating and eating is never just a biological process (Rozin 1999; Watson and Caldwell 2005). In this paper, we examine how food becomes a cultural resource for consumers that are temporarily away from their everyday life contexts.

One of the reasons that tourists feel distressed when being faced with the local food at the tourist destinations is that “food consumption simultaneously asserts the oneness of the ones eating the same and the otherness of whoever eats differently” (Fischler 1988: 275; Mintz and Du Bois 2002). Food consumption is not only about defining oneself towards or from various groups, it is also about being unique, which is a fundamental aspect of our sense of self-identity (Giddens 1991). On this more individual level food consumption is central since any human is constructed, biologically, psychologically and socially by the food he or she chooses to incorporate. When the self is threatened by the abundance of unfamiliar cultural cues at the tourist destination, food becomes an anchor that reminds the tourist of who they really are.

Food plays a salient role during boundary crossing and maintenance also because it is an essential and portable part of the materiality of home (Miller 2001), and as such can be used to recreate an experience of home and a sense of stability when away (Petridou 2001). Additionally, food tastes reflect socialization processes that work directly on the body and these embodied tastes tend to be enduring and difficult to transform (Allen 2004). Prior research has shown that mobile consumers resist changes in such embodied food preferences and long for the cultural environments similar to their home country (Thompson and Tambyah 1999). Thus, we expect that tourists may cope with cultural and existential alienation through maintenance of these embodied food preferences to recreate a sense of home in the body and abroad.

The empirical data for this study consists of accounts of 29 middle-class American consumers’ experiences of food consumption during a trip to China that lasted for 10 days. This particular context (i.e. first time tourists to a culture that is distinctly different from their native culture) was deemed appropriate for understanding the a) consumer alienation experiences as tourists; and b) the existential role of food as a coping mechanism. Data collection took place during and after the trip. Informants were instructed to keep

a personal journal of their food encounters during their trip. When they returned to United States, we used their personal journals as the backbone for one-to-one in-depth interviews that lasted from 30 to 90 minutes with each of them. The interviews evolved around their overall tourist experience in China, their experiences with Chinese foods and other types of foods they selected to consume. An interpretative and semiotic perspective was followed in analyzing and interpreting the data.

Informants make sense of their tourist experiences and consumption of food through continuous categorization and interpretation of the host and home food cultures illustrated in the paper by a model inspired by Greimas’ semiotic square. We find that the category Chinese Food creates considerable discomfort whereas the remaining three categories of the semiotic square (Domestic, Non-Chinese, and Non-Domestic food) represent positive food encounters because these enable informants to cope with experiences of alienation. Consistent with prior work, we find that the mass tourist typically lacks the local cultural capital to make sense of the experience abroad and makes little effort do so (Hannerz 1990). Thus, food encounters with the Other challenge tourist as competent consumers, decision makers, and alienate them from the local Other. Tourists attempt to grapple with these negative experiences by creating a symbolic distance towards the Other through food categorizations and judgments. Further, we find that negative judgments that informants made about the local Chinese food were extended to the judgments about the social Other.

Another important finding in the study is the fact that cultural and food regimes continue to play a salient role in making sense of daily consumption experiences. We find that they become even more salient during boundary crossing situations (such as tourism) when the home culture is symbolically threatened (Swidler 1986). Our informants resisted local foods and practices and strived to sustain the home-based cultural interpretation framework and practices. Consumers may not be as open to food experimentation as it is often suggested in the food consumption literature. This research shows that the familiar ways of eating food are still strongly connected to the consumers’ sense of self as embodied practices (Allen 2004). This leads us to wonder whether the suggested condition of gastroanomy is exaggerated (Warde 1997) and traditional food-ways continue to structure our eating in the same way as before.

Additionally, globalization processes and food transnationals have created in some way a reassuring standardized servicescape for tourists that enable them to experience “home” abroad through patronization of these predictable, safe, and familiar spaces and tastes. We find that while informants reject transnational fast foods at home, they embrace it with longing and satisfaction abroad. For many informants search and consumption of non-Chinese food became a symbolic project of finding and experiencing a sense of home and normality. They expressed greater satisfaction with non-Chinese food that was also transferred to quality and customer satisfaction evaluations with the overall servicescape. Further, we find that iconic authenticity (Grayson and Martinec 2004) with the ‘home food’ was sufficient for tourists to reduce cultural and personal anxieties and feel comfortable, at home abroad.

Living with Uncertainty: The Impact of Terrorism

Krittinee Nuttavuthisit, Chulalongkorn University, Thailand

EXTENDED ABSTRACT

Terrorism has become a global event that creates a continuous effect on not only killing and destruction but also on significant changes in people's behavior. Nevertheless, in consumer research there have been few studies on the impact of terrorism on consumer behaviors. Possibly this is because of limited access to the victims of terrorism and affected locations. Literatures in related areas include studies of uncertainty, coping strategies, and terror management. The major findings are that when people feel uncertain about what will happen, they try to regain a sense of control which helps to reduce the stress of uncertainty. However, prior research mainly specified control over situation while the circumstance of terrorism is inexplicable and out of control.

This research explores the effects of the ongoing terrorist violence in the southern provinces of Thailand. It aims to address the theoretical gap in studying how people cope with their experiencing uncertainty when they feel victimized and powerless under the uncontrollable situation. Moreover, this study reflects recent terror management research which has emphasized cultural-specific responses (Rindfleisch and Burroughs 2004).

Thailand is considered a peaceful country with Buddhism as the dominant religion. Thai Muslims are mostly concentrated in the southern provinces of Thailand, particularly in Narathiwat, Yala and Pattani. With their different lifestyle, some Thai Muslims feel estranged from the rest of the country and, together with the chronic concerns of poverty, underdevelopment and discrimination by some abusive officials, these problems led to the insurgency led by Muslim separatists. In the beginning the targets of the terrorist attacks were government officials but now include all kinds of people, ranging from Buddhist monks to school teachers, Muslim farmers and innocent children. The reason for these attacks is unclear and no group has claimed responsibility for these events. The daily random attacks have resulted in sustained uncertainty and dramatic changes to the lifestyles of residents and their families.

Uncertainty is a dynamic state of discomfort, a situation that exists when people feel that they cannot predict what will happen. Uncertainty has long been recognized as a critical issue and different means of managing uncertainty have been identified in various fields of studies. Pavia and Mason (2004) emphasized the experience of uncertainty and coping strategies as a rich field for consumer research. Generally, the specified coping strategies can be categorized into two basic concepts, avoiding suspected causes of uncertainty and seeking what brings stability and a sense of future. The two major coping strategies may appear antithetical but they are linked by the common goal of regaining a sense of control.

This research study began early in 2005 with respondents including residents of the three southern provinces, soldiers stationed in the region and their families. Eight long interviews and two focus group interviews, one with soldiers and another with their wives, were conducted. Due to the upsurge in violence field visits were not possible, and interviews with residents in the troubled areas were carried out when they visited Bangkok. Verbatim transcripts were interpreted by means of a hermeneutical process (Thompson, Locander, and Pollio 1989).

The research data illustrates that, in accordance with the previous theory of uncertainty management, people try to avoid suspected causes of uncertainty and seek what provides a sense of stability. The means to address their fear, worry and tension are reflected in their consumptions of time, place, faith and social

affiliations which also suggest the unique responses to managing uncertainty depending on the context and cultural values. In this case, rather than avoiding the suspected causes of uncertainty (i.e., dangerous areas, or 'ghostly terrorists' which are impossible to identify), local residents instead attempt to adjust their own routines or lifestyles. Although theories of uncertainty management emphasize increased flexibility in creating alternatives (Lazarus and Folkman 1984; Courtney, Kirkland and Viguerie 1999), this study found that people prefer the familiar even when this is unsafe to encounter the odds of daily attacks at anytime. In seeking what brings stability or sense of future, they relied on faith or miracles rather than performing concrete preventive acts within the community or with the authorities. They trust that fate will bring a natural end to these events over which they feel they have little or no control.

To some people, these coping behaviors may appear gullible, insubstantial or short-sighted, but they serve the purpose, as specified in previous theory, of enabling people to regain a sense of control which helps to reduce the stress of uncertainty. However, a difference must be noted here as the sense of control in this study is rather control over self rather than the situation. Based on the notion that uncertain events cause the sense of uncertainty, prior research suggested that constructing a new normalcy can enable individuals to restore order and envision a sense of future (Becker 1997; Pavia and Mason 2004). Creating a new normalcy in which individuals can *explain the situation*, i.e., what has happened and what will happen, enables them to choose the way to live their lives (Weitz 1989). However, the findings of this research illustrate that people rather try to *recognize the situation* and adjust the self (e.g., lifestyle and beliefs) to handle the experience of uncertainty. Instead of constructing a new normalcy they familiarize themselves with the uncertain events and, in this way, they can also gain the sense of control, but over self rather than the situation. The focus is on dealing with the present rather than unveiling the past or the future. Uncertainty is rooted in the individual's perception of the outcome or meaning of a situation (Penrod 2007). Hence, whether it is managing the situation or managing the self should also induce changes in an individual's perceptions of the circumstances. This study proposes extension of the theory regarding management of uncertainty to incorporate coping mechanisms from the perspective of self. It also endorses the view that cultural differences (i.e. belief in fate occurring by law of karma in Buddhism or by god's will in Islam) significantly influence how individuals respond to uncertainty.

Cultures of Unruly Bricolage: 'Debadging' and the Cultural Logic of Resistance

Douglas Brownlie, University of Stirling, Scotland

Paul Hewer, University of Strathclyde, Scotland

EXTENDED ABSTRACT

Abstract

Arnould and Thompson note that the "marketplace has become a pre-eminent source of mythic and symbolic resources through which [people] construct narratives of identity" (2005: 871). Not only do consumers "actively rework and transform symbolic meanings" (ibid: 871), but in everyday practices they use "marketplace cultures [to] define their symbolic boundaries through an ongoing opposition to dominant lifestyle norms and mainstream consumer sensibilities (ibid: 874). The paper examines identity work done with cherished possessions, in this case cars. By means of a netnography we focus on everyday practices where consumers rework brand identity towards their local identity projects.

Introduction

A rich stream of research has explored consumers' resistance to commodity culture and brands (Arnould & Thompson, 2004; Holt, 2001, 2002; Dobscha, 1998; Fournier, 1998; Schor, 1998). Research has thus focused upon the anti-brand movement (Fischer, 2001), lovers of the natural world (Dobscha, 1998), downshiftees (Schor, 1998), to the voluntary simplicity movement (Murray, 2002) or the burning man movement (Kozinets, 2002b). Murray (2002) draws our attention to how such consumers, who are often cynical of commodity culture, seek to construct their sense of who they are, through what he terms their 'salient negations' to commodity culture. We reveal how consumer subcultures are engaged in forms of guerrilla warfare to affirm, maintain and consolidate their group identity through their appropriations of marketing brands.

Conceptualisation

In their recent synthesising overview of consumer culture theory, Arnould and Thomson discuss the constitutive and productive aspects of consumption, noting that the "marketplace has become a pre-eminent source of mythic and symbolic resources through which [people] construct narratives of identity" (2005: 871). They remind us that not only do "consumers actively rework and transform symbolic meanings" (ibid: 871), but that through a variety of everyday practices they also use "marketplace cultures [to] define their symbolic boundaries through an ongoing opposition to dominant lifestyle norms and mainstream consumer sensibilities (ibid: 874). In this paper we construct a line of argument based on those thematic observations, exploring in particular the identity work that is done by consumers through modifying cherished possessions, in this case cars. We focus, paradoxically perhaps, on the site of everyday practices by means of which consumers de-badge, or perhaps, re-badge their vehicles, or otherwise rework its brand identity, in pursuit of local identity projects.

Methodology

In our quest to understand the consumer practices and tactics of 'debadging' we drew inspiration from the netnographic work of Kozinets (2001, 2002a). We started by 'lurking' at a number of web forums devoted to car cultures. These included amongst others: MBWorld Discussion forum, otherwise known as the forum for Mercedes-Benz enthusiasts; VWvortex forum, otherwise known as the Volkswagen enthusiast website; Mini2.com, otherwise known

as 'fuel for your mini obsession'; Hondacivicforum.com; and 7thGenCivic.Com. Most of the forums advertise themselves in much the same way that the Honda Civic forum does: "as a discussion forum & one stop resource for all Honda Civic related discussions, with forum topics including Honda Civic vehicle maintenance, tech help with car repairs, and performance upgrades."

Findings

The findings are organised under three key themes: first to unravel what we mean by the practice of debadging; second to theorize the consumer as a designer; and third, to explore the forms of exchange, and affiliation exhibited by car enthusiasts. For instance, we find that design at the everyday level is about finding solutions to identity tasks and overcoming contradictions through bricolage. For many the changes made through de-badging their vehicles focus upon the achievement of a particular look, where the reclamation of de-signing is intended to achieve a degree of anonymity, but also a form of cultural capital in itself in which such practices were engineered to speak to those who understand, and exclude others for their lack of aesthetic and technical knowledge and appreciation. The informants display a sophisticated understanding and appreciation of the state of things and are restless in their pursuit to change the things that matter in their lives.

Conclusions

The analytical focus of the paper is directed towards a virtual community of car enthusiasts and a series of online reports of consumer bricolage in the empirical setting of car modification. This opens a window on a variety of everyday practices that characterize how consumers actively use cars and other resources of popular culture in creative ways as symbolic resources for constructing and sustaining social identity. Also illuminated are ways in which arenas of anti-consumption are invested with particular meanings that are grounded within practices of daily life. Through analysing forms of reportage naturally occurring in those online sites, textual data is generated about consumption practices that can be read as constitutive of forms of consumer resistance. Theorising resistance through de Certeau's (1984) lens of everyday practice brings analysis to 'grounded aesthetics' (Willis, 1990) as a potential arena in which practices of consumer resistance are played out. Over an eight-month period an internet-based methodology generated observations of online posting activity on five different internet newsgroups attracting those with an interest in the highly particular pursuit of car modification. Participants used those web-forums not only to share information and insights, but to give individual and collective voice to enthusiasms towards car modification and customization as a way of improving vehicle aesthetic appeal. The term 'grounded aesthetics' (Willis, 1990) is used to describe 'articulations' (Kozinets, 2001, p. 70) between practices of everyday life and the creativity that consumers bring to their 're-appropriation of the product-system' (de Certeau 1984, p xxiv). For some informants the practice of debadging is a tactic to improve the look of the vehicle; for others it expresses a more radical practice that feeds-off desires to be free of what is seen as the thinly concealed calculation and manipulation of visible brand livery. Findings show that, as Denzin (2001) observes, "grounded aesthetics function both as vehicles and sites of resistance" (ibid, p.

328). The paper concludes that the discussion threads of the studied web-forums offer access to the interplay of discursive resources in circulation among interest-based collectives; and that they can usefully be understood as arenas for following how the discursive resource-base is nurtured, sustained and transformed through various interpellations, including the rehearsal of anti-consumption rhetoric and sentiment. But rather than being anxious or defensive about such forms of unruly re-appropriation, we advise that businesses, especially designers and consumer researchers, would benefit from following the discussion occurring on such sites—for this speaks of fragments of cultural change that, should it gather impetus, will circulate more widely within contexts of consumption.

Consumer Mourning and Coping with the Loss of Strategic Rituals: The Case of Marshall Field & Co.

Cele C. Otnes, The University of Illinois at Urbana-Champaign, USA
Behice Ece Ilhan, The University of Illinois at Urbana-Champaign, USA
Jenny Yang, The University of Illinois at Urbana-Champaign, USA
Nicole Tami, The University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

It is a well-supported assertion in the social sciences and in consumer behavior that rituals provide structure and meaning to people's lives (e.g., Driver, 1991; Rook 1985). Furthermore, through commitments of time, energy and money, consumers demonstrate their attachment not only to consumer-generated rituals such as family holidays, but also to "strategic rituals"—repeated, dramatic events engineered by retailers and marketers in order to achieve key customer and profit objectives. Although current research on consumer/retailer relationships examines the importance of retail aesthetics and the ways retailers enhance brand meaning (e.g., Sherry 1998; Sherry, et al, 2004; Thompson and Arsel, 2004), our understanding of the benefits consumers accrue from such relationships remains underdeveloped. In this paper, we focus on the how consumers mourn and cope with the loss of strategic rituals offered by a retailer. By focusing on the loss of these strategic rituals, we illuminate the specific benefits consumers glean from them, and the ways consumers cope with aspects of ritual loss.

Our interest in the topic was spurred by the outpouring of negative emotions accompanying the announcement that the landmark Chicago-based department store chain Marshall Field & Co. (hereafter, "Field's") would be rebranded as Macy's as of September, 2006. The significance of Field's as a venue for its own strategic rituals was well-documented in media accounts and on web blogs. In addition, Field's was highly significant as a pioneering retailer in the United States, and offered many "firsts"—such as the first restaurant in a retail store, the first delivery, the first return/exchange policies, and one of the first stores to recognize the importance of the aesthetic experience of shopping (as evidenced by its Tiffany windows, fountain and large staff devoted to store display). We employed an interpretive approach, beginning with a few preliminary depth interviews with friends and acquaintances who confirmed that they were mourning the loss of Field's. We then placed an ad on a Midwest university bulletin board, asking for volunteers to discuss their thoughts and feelings on the renaming of the store. Informants include key players involved in maintaining websites dedicated to the memory and/or resurrection of Field's, such as *fieldsfanchicago.com* and *darrid.com*. Our fifteen informants (one was interviewed twice) were all middle- or upper-middle class in their 20s-50s, and were primarily white females. However, three were African-American females and two were men. Three of the four research team members, all women between their 20s and 40s, conducted the interviews. We conducted the first few in pairs to facilitate discussion among the research team of emergent issues, with the last half being conducted by single researchers. Transcripts of these interviews yielded over 125 pages of single-spaced text.

Three of the four team members participated in the analysis, reading and re-reading the data and focusing our research questions to those we believed could best help us understand the ritual mourning and coping we observed. These questions are: 1) What cherished rituals did Field's create or co-create with consumers? 2) What benefits of these rituals do consumers miss the most? 3) How do consumers cope with the loss of these strategic rituals? The

authors negotiated the interpretation of these questions and discussed the most salient issues to include in this paper, as well as other issues to pursue as our interviews continue. Our findings reveal that Field's created or co-created at least six strategic rituals for consumers: selection of focal ritual artifacts (such as the first pair of high heels, prom dresses, and wedding gowns), enhancement of the Christmas ritual, customized shopping experiences, sources of iconic brands/gifts, inclusion on a tour of Chicago, and bargain shopping. Furthermore, consumers elicited five key benefits from these strategic rituals at Field's. Specifically, the source provided a venue for aspirational but democratic consumption, a source of aesthetic pleasure, a source of civic pride given the importance of Field's and the Fields family to Chicago, a locus for family traditions, and the quintessential shopping experience through the offering of unique, high-quality merchandise, unparalleled customer service and even a highly desirable work environment complete with rituals designed to enhance employees' work experiences. Further, in coping with the loss of Field's, consumers exhibit both avoidant and accepting behavioral coping strategies. Avoidant strategies include venting their unhappiness over the loss of Field's, rejecting Macy's and other alternatives to the strategic rituals Field's had created, and distancing themselves physically and cognitively from the memories of Field's. Active coping strategies include accepting the loss, but also engaging in more active civic-oriented strategies such as staging protests outside the store and boycotting Macy's. Our paper reveals that consumers do find strategic rituals supported or co-created by retailers as meaningful experiences in their lives, and when the opportunities for these rituals disappear, must mourn and cope with these losses.

The Construction of Value in Attention Economies

Ashlee Humphreys, Northwestern University, USA

Robert V. Kozinets, York University, Canada

EXTENDED ABSTRACT

In this paper, we view YouTube through the lens of the “attention economy” and use it as a site to further develop our understanding of the hierarchical processes of attention consumption and the construction of value within attention economies. Originally developed by Herbert Simon, the concept of an attention economy comes from considering the many effects implied by an abundance of information. As Simon (1971) says, “[w]hat information consumes is rather obvious: it consumes the attention of its recipients. Hence a wealth of information creates a poverty of attention and a need to allocate that attention efficiently among the overabundance of information sources that might consume it” (p. 41). Although Simon perceptively notes that attention becomes a resource and therefore comes to have value, he does not elaborate the process by which attention becomes transformed into something valuable. More recently, popular management writers have built off of Pine and Gilmore’s (1999) idea of an “experience economy” to argue that this experience economy is underlain by an interest-driven “attention economy” (Davenport and Beck 2001). A number of authors take the attention economy principle to speculative lengths, predicting that, one day, “attention transactions” will replace financial transactions (Franck 1999; Goldhaber 1997). We take this speculation to pose several specific research questions. How do attention transactions occur on and through YouTube? How do the partners to an attention exchange form an idea of their role in this system of exchange? What roles are normatively available to them and how do they find a place within these roles? Further, how do these roles change over time?

Previous research has suggested that that people in an exchange network can vary in their roles as giver and receiver. However, when we consider attention economies we do not yet have a theory for how people assume an exchange role, how they conceive of these roles, or how these roles change over time, as the system evolves. Research on fan communities and fandom explores affective exchange both amongst fans and between fans and celebrities (Jenkins 1992; Kozinets 2001; O’Guinn 2000). On the one hand, fans actively interact with the objects of their admiration, contributing texts made from cultural materials (Lanier, Muñoz, and Schau 2006; Schau and Russell 2004) and forming social groups based on affiliation (Kozinets 2001). These characteristics of activity and involvement are particularly relevant to forming conceptions of an attention-based economy in an environment where interaction drives value and exchange. On the other hand, celebrities come to have value as a result of many of these fan activities and attentions. The precise nature of the relationship between fan feedback and celebrity value in attention economies, and particularly the fluidity of these concepts within electronically media, present a unique opportunity to develop a theory of the ways in which value is constructed through consumer/producer/fan/celebrity interaction, activity, and exchange.

To understand how people view themselves within attention exchange systems, we interviewed users of the YouTube network, an internet community where people exchange videos, post comments, and maintain personal profiles. Sixteen interviews were conducted in situ over the internet via private messages (Giesler 2006; Kozinets 2002). A netnography of site content, including analysis of videos produced by informants and those ‘favored’ by informants, was also conducted (Kozinets 2002). In addition to self-

reports from interviews, several observations—the number of videos watched represented the level of consumption, and the number of videos posted to the site represented the level of production—were used to indicate the users’ status as a consumer, producer, fan, and/or celebrity.

From this data, we find that in the attention exchange system, several ideal typical roles emerge from the ways in which people talk about their place in YouTube network, consumer, producer, fan, and celebrity. Although these ideal-typical roles—consumer, producer, fan, or celebrity—are not often fully-realized empirically, they orient consumer’s conception of their place within the system. These dialectically-formed roles are often mutually exclusive within one exchange. That is, if one person discursively takes the producer role as the provider of value, the other person in the exchange takes the consumer role as the user of value.

We can then model the process of value creation through attention exchange as a four stage movement between these identities along two dimensions, the affective dimension and the market dimension. On the affective dimension, people exchange affect—words of encouragement, notes on the video’s content, related thoughts or jokes. In general, the affective dimension represents attention being given to the producer of a video. Most often, the receivers of these comments are heralded as ‘celebrities,’ and the givers of the comments think of themselves ‘fans.’ Celebrities also give affect in return by sending messages to their fans or responding to posted comments. The market dimension represents the dimension on which content is exchanged. The ideal-typical producer actually makes the substantive components of the video and the ideal-typical consumer actually receives the content. In the case of YouTube, the material exchange is either the video itself or the verbal statements that make up the comments. As a result of this exchange process, four market identities with specific orientations arise: the productive celebrity, the fan-as-consumer, the fan-as-producer, and the produced celebrity. Each identity in the system is dialectically constructed through the process of exchange, the interaction between two parties in a given stage.

From the study of YouTube as an attention exchange system, we learn several things about identities within an exchange system. First, people construct their role in relation to the other people in the exchange in systematic ways. These identities change systematically both temporally within the exchange itself and between exchanges in the system. Second, value is created through the interaction of affect and material exchange. When videos are produced, they do not immediately have value. Value is bestowed by fan response, not only toward the producer, but by the interaction of fans. Affect alone, however, does not produce value; this affect must be directed toward some product or some person that comes to represent value itself. Vital to this celebrity value are two elements—commonness and uniqueness—that fans work to collectively monitor and maintain these. Third, by studying this ‘sharing’ system, we gain insight into the factors that motivate people to share and to reciprocate. The exchange of comments, as “currency” repays sharers for their work and motivates them to produce again. User comments form a more reified indicator of value when they are used as metrics for measuring celebrity/producer value. In this sense, they truly are the capital on which this non-monetary exchange system functions.

Are Consumers Intuitively Bayesian? The Role of Consumer Metacognition

Dipayan (Dip) Biswas, Bentley College, USA
Guangzhi (Terry) Zhao, University of Kansas, USA
Donald Lehmann, Columbia University, USA
Dhruv Grewal, Babson College, USA

EXTENDED ABSTRACT

To reduce the uncertainty of product purchase decisions, consumers frequently resort to product rating information provided by third-party rating agents. Such rating agents and rating information are ubiquitous in the marketplace, ranging from stock rating by financial institutions, movie rating by film critics, product rating by consumer reports, product safety rating by government agencies to product ratings posted online in blogs by individual consumers (Jadad and Gagliardi 1998).

This paper attempts to examine how consumers might process such information about product rating and source accuracy, how their judgment updating might be influenced by the data format, and whether their updated judgments would be consistent with a normative Bayesian framework. Prior research reports contradictory results regarding how consumers will update their judgments when processing sequential numerical data. While the Bayesian belief updating theory is perhaps the most widely used theoretical framework to examine how people are likely to update their beliefs based on sequential information (Diaconis and Zabell 1982), researchers have reported mixed empirical findings regarding the extent to which human judgments are consistent with Bayesian predictions. Some studies (e.g., Kahneman and Tversky 1972) came to the conclusion that people are not at all Bayesian. In contrast, another line of research (e.g., Gigerenzer and Hoffrage 1995), using an evolutionary psychology perspective found that under certain conditions (e.g., frequency data), people can be intuitively Bayesian. Yet a third line of research approached a middle-ground, and suggested that people do update their beliefs in a fashion that are directionally consistent with Bayesian predictions, but the extent to which people update their beliefs are conservative in comparison to the predictions by Bayes' theorem (see e.g., Edwards 1968; Rust et al. 1999). We attempt to resolve this apparent inconsistency in prior findings by examining the role of difficulty of computation of the numerical data in consumer belief updating. We ask the question: Would consumers update their beliefs with each piece of sequential numerical information, and will the final updated judgments/beliefs be consistent with a normative Bayesian model, or follow a different pattern of updating? More specifically, using a model based on consumer metacognition (e.g., Gollweitzer and Schaal 1998), we identify conditions under which participants will update their beliefs to an extent that is consistent with Bayesian theory, as well as conditions under which they will update their beliefs in a way deviating from Bayes' theorem. We propose that when the numerical information is easy to compute mathematically (e.g., for percentage format), consumer judgments are likely to be conservative than the Bayesian predictions, since an averaging rule will be applied. For difficult-to-compute frequency data (e.g., *Consumer Reports* has been correct 121 out of 173 times in its ratings), consumer judgments are likely to be in line with the Bayesian prediction. Our proposition might seem to be somewhat counterintuitive because Bayes' theorem is a normative model, while we are proposing that consumers are likely to have judgments consistent with Bayesian predictions when the numbers are difficult to compute mathematically and require extra cognitive capability. We provide the underlying theoretical causes for this

counterintuitive pattern of results, and in the process, hope to resolve some of the inconsistency in prior findings.

As mentioned earlier, we use a consumer metacognition framework to examine processing of difficult-to-compute data (e.g., frequency data) versus easy-to-compute data (e.g., percentage data). "Metacognition" refers to a person's knowledge about their own cognitive processes and/or abilities, and the consequent regulation of the cognitive processes (Garafalo and Lester 1985; Gollweitzer and Schaal 1998). Metacognition theory would predict that a consumer would utilize the optimal amount of cognitive resources to process any mathematical information (Garafalo and Lester 1985). This implies that a consumer would regulate their cognitive processing in the most efficient manner.

Therefore, applying the averaging algorithm for the processing of numerical data would depend on the processing fluency involved in the task (Schwarz 2004). One key distinction between easy-to-compute percentage versus difficult-to-compute frequency data is that sequential data presented in the former format is relatively easier to compute mathematically (Dehaene 1992, 2001; Waters et al. 2006; Sloman 1996). In other words, it is relatively easier to apply the averaging algorithm in the case of percentage data than it is for frequency data.

Hence, when evaluating a sequence of percentage data, consumers are likely to average out the information. In contrast, with the computational difficulty of applying the averaging algorithm in the case of frequency data, consumers are likely to apply a different type of algorithm. Specifically, we propose that for frequency data, with the difficulty of applying the averaging algorithm, consumers would have very little incentive to allocate cognitive resources to such an algorithmic task. Instead, consumers are likely to form an overall impression or hypothesis of the given information (e.g., Product B is better than Product A), and use subsequent sequential information to test that hypothesis.

In Study 1, we found support for our hypothesis that consumers would have greater degree of belief updating and judgments consistent with Bayesian predictions for difficult-to-compute frequency data than for easy-to-compute frequency or percentage data. Study 2 showed that highlighting data distinctiveness enhances belief updating for percentage data, but does not make a difference in the case of frequency data. Finally, Study 3 showed that the results of Study 1 hold when the data are presented in consistent frames, but not in alternate frames. That is, when the data are presented in consistent frames, participants have updated judgments consistent with Bayesian predictions. However, for data presented in alternate frames, updated judgments for frequency data get conservative than the Bayesian predictions, while for percentage data, judgments are conservative than Bayesian predictions irrespective of data presentation frame.

Translation Errors in the Aggregation of Consumer Recommendations

Boris Maciejovsky Massachusetts Institute of Technology, USA
David V. Budescu, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT:

An increasing number of consumers uses the internet rather than brick and mortar stores for their purchase decisions. One important difference between traditional stores and virtual marketplaces is that the latter do not allow consumers to inspect directly the physical properties of goods and commodities. This lack of immediate experience triggers uncertainty about the specific properties and the overall quality of the products. One way to reduce this uncertainty is to allow consumers to share their experiences in the form of reviews and recommendations. Indeed, many of the leading internet marketplaces (e.g., Amazon.com, EPinions.com) offer consumers the opportunity to publicize their experiences in the form of verbal statements and numerical ratings. Verbal statements usually are free-format short essays, whereas numerical ratings provide a complementary summary in the form of quantitative ratings.

These two different information formats, verbal and numerical, need to be integrated by consumers to adequately aggregate the available information. Prior research on the internal consistency of preferences suggests that such integration might often be less than optimal. One explanation for such preference reversals is based on the compatibility between stimulus and response. According to the compatibility hypothesis (Fitts and Seeger, 1953), "the weight of any input component is enhanced by its compatibility with the output" (Tversky, Sattath and Slovic, 1988, p. 376). We extend this line of research by studying compatibility effects in information aggregation across different information formats (verbal and numerical). We predict higher rates of preference reversals when the stimulus format (verbal or numerical) does not match the response format (verbal or numerical).

We used a two-stage design to test this conjecture. On stage 1, participants rated the attractiveness of 12 fictitious products. This allowed us to derive an individual ranking of the products. For each product, participants saw 10 recommendations that were presented either as brief verbal statements (e.g., "this product was excellent" or "this product was average"), or as numerical ratings on a 5-point scale (1 to 5 stars). The verbal statements were pre-tested, and rated by independent raters, to match the 5-point numerical scale. We also varied the variance (low or high) and the mean (low, intermediate, or high) of the recommendations. Each of the 12 products was described by a unique combination of the presentation mode, the variance, and the mean of the recommendations.

After a 10-minute filler task, subjects entered stage 2 of the experiment. They were shown pairs of the products as used on stage 1. For each product subjects saw the corresponding 10 recommendations. Subjects were asked to provide a summary evaluation of each of the two products. The evaluation was either in a matching or a non-matching format. For instance, if the products were accompanied by verbal recommendations, subjects in the matching-format condition were asked to provide a summary evaluation of the products in the form of verbal statements (they were shown 5 pre-tested verbal statements) and asked to summarize the product. The options ranged from "this product was very bad" to "this product was excellent." In the non-matching condition, subjects were asked to click on a 5-point rating scale (1 to 5 stars). After summarizing each of the two products, subjects had to pick their preferred one. Comparing the evaluations of the rankings derived from stage 1 and the choices of stage 2 allowed us to study the internal consistency of preferences for each individual.

In study 1 we employed a 2 (stimulus mode: verbal or numerical format) x 2 (response mode: matching or non-matching format) between-subjects design to study how preferences are affected by the compatibility of the provided information. Our results confirmed that preference reversals are significantly higher for non-matching formats as compared to matching formats. Preference reversals were particularly pronounced for high variance products. In study 2 we allowed participants to select the response mode, verbal or numerical, by themselves. The majority of subjects preferred the numerical response mode, even in cases in which the products were presented verbally. This led to an increase in preference reversals. This finding suggests that subjects did not anticipate the importance of compatibility between stimulus and response format on preference consistency. In all studies DMs showed the highest levels of preference inconsistencies for products with identical means but different standard deviations, suggesting that DMs have more trouble exhibiting consistent preferences for high variability options (and considerably less difficulty for options with mean differences).

Interactive Restructuring: Implications for Decision Processes and Outcomes

Nicholas Lurie, Georgia Institute of Technology, USA
Na Wen, Georgia Institute of Technology, USA
Doe Hyun Song, Georgia Institute of Technology, USA

EXTENDED ABSTRACT

Many online environments offer tools that allow consumers to interactively restructure decision environments. Examples include the ability to sort alternatives on different attributes and to eliminate alternatives from consideration. For example, when planning a trip on Expedia, a consumer can sort hotels by price if her goal is to find a low-priced hotel. Alternatively, when comparing hotels, Travelocity allows the consumer to eliminate those she does not like. In theory, such tools should help online consumers avoid information overload and make better decisions. However whether, and the conditions under which, such tools lead to better decisions is not well understood.

Although prior research in offline environments has shown that consumers sometimes restructure decision environments to facilitate the comparison of alternatives, it also suggests that restructuring is contingent on the effort involved (Coupey 1994). Given that the effort involved in restructuring offline environments is high, such restructuring should only occur when consumers are highly motivated. Relatedly, a large body of research has found support for Slovic's (1972) "concreteness principle," which proposes that consumers rarely restructure decision environments and instead make decisions consistent with the way in which information is presented (Bettman and Kakkar 1977; Bettman and Zins 1979; Jarvenpaa 1989; Kleinmuntz and Schkade 1993). Moreover, other research has shown that the extent to which consumers adapt their decision strategies depends on the effort and accuracy associated with using these alternative decision strategies within a given information environment (Payne, Bettman, and Johnson 1988, 1993).

By dramatically lowering the costs to consumers of restructuring information environments, interactive restructuring tools have important implications for decision processes and outcomes. The extent and conditions under which they enhance decision-making quality, however, is unclear. On the one hand, tools such as sorting and elimination may create a better match between the task and the decision environment, which should reduce information overload, improve decision quality and/or reduce decision effort (Hoch and Schkade 1996; Lurie 2004). In addition, previous research suggests that restructuring leads to more compensatory decision making by freeing up cognitive resources (Coupey 1994); this suggests that the availability of tools that lower the cost of restructuring information should lead to more compensatory processing. In particular, consumers using restructuring tools may be more likely to consider multiple factors than those without access to such tools. At the same time, there is a reason to believe that the availability of interactive restructuring tools may actually be detrimental to decision quality in some information environments. For example, to the extent that sorting leads to heuristic decision processes, such tools may lead to lower quality choices in environments in which attributes are negatively correlated (Bettman et al. 1993).

We propose that the availability of restructuring tools is likely to lead to two types of adaptive behavior (Payne et al. 1993). First, to the extent that interactive restructuring tools serve as substitutes for cognitive effort, decision makers will be adaptive in their use of these tools. For example, decision makers should be more likely to use such tools in difficult choice environments—such as those in which attributes are negatively correlated. Second, decision makers

should adapt to the environments created by using such tools. For example, they should be more likely to process by attribute after using sorting tools that order alternatives by a given attribute.

To address these issues, two experiments were conducted that manipulated the availability of interactive restructuring tools as well as the correlation among product attributes. Study 1 compared decision quality in the presence versus absence of sorting tools for choice sets characterized by positively or negatively correlated attributes. Study 2 extended Study 1 by examining the impact of providing elimination as well as sorting tools to consumers. In addition, Study 2 used process-tracing techniques to examine how the availability of interactive restructuring tools affects decision processes as well as outcomes.

Results from both studies show that the availability of sorting tools increases choice accuracy in positively correlated environments but not in negatively correlated environments. In support of the idea that consumers are adaptive in their use of such tools, consumers sort more when product attributes are negatively correlated than when attributes are positively correlated. However, they are no more likely to use elimination tools. In support of the idea that consumers adapt to the restructured environments that they themselves create, the availability of sorting tools increases time per acquisition and selectivity in negatively correlated environments. Moreover, a significant 3-way interaction was found between attribute correlation, sorting tools, and elimination tools. When product attributes are negatively correlated, the availability of sorting tools lowers choice quality when elimination tools are not available but increases choice quality when elimination tools are available. When attributes are positively correlated, the ability to sort improves decision quality regardless of the availability of elimination tools.

Good from Far but Far from Good: The Effects of Visual Fluency on Impressions of Package Design

Ulrich R. Orth, Christian-Albrechts-Universität Kiel, Germany
Keven Malkewitz, Oregon State University, USA

EXTENDED ABSTRACT

Consumers often make initial judgments about brands based solely on the brand's packages, and the accuracy of these impressions influences brand selection and evaluation. This paper examines the accuracy of meaning (brand personality and quality impressions) derived from package design (Bloch 1995). More specifically, we examine three areas where there are gaps in our knowledge concerning the effect of package design on impressions, the areas of consensual accuracy, spatial accuracy, and individual differences in spatial accuracy.

The first area concerns the consensual accuracy of brand impressions which are derived from the design of packages. Brand managers, designers, consumers and other stakeholders have a vested interest in having consumers form similar impressions from their packaging. This provides a consistency in impressions, allowing managers to more accurately convey information, and allowing consumers to receive more accurate knowledge. The second area concerns spatial accuracy. Many situations exist where consumers see marketing stimuli from more than one distance. For example, a billboard viewed from a distance may result in different impressions than the same billboard viewed from up close, and a wine bottle in a retail store might evoke one set of brand impressions from a distance, and yet another set of impressions when held in the hand. A third area where we have little knowledge is the influence of interpersonal differences on impressions formed from packages, specifically brand and quality impressions. Individuals who are highly involved in a product category, or those whom have a great deal of acumen in the design of packages, may process package information differently than those who are less involved or those who have less design acumen.

We designed and conducted two studies to examine these three gaps in our knowledge, specifically 1) consensual accuracy, 2) spatial accuracy, and 3) the affect of individual differences in involvement and design acumen on spatial accuracy. In our first study, we examine fifty examples from five different types of holistic package designs identified in prior research (massive, contrasting, natural, delicate, and non-descript packages, Orth and Malkewitz 2008), and we examine the influence of the five package designs on brand personality (Aaker 1997) and quality impressions. We find that the five designs significantly differ in their ability to generate the consistent impressions needed for consensual accuracy. Natural and delicate designs had more consensual accuracy, and massive, contrasting, and delicate designs had less. These differences are thought to be due to difference in the perceptual fluency of the stimuli (Janiszewski 1993; Reber, Winkielman, and Schwarz 1998)

Study 2 was conducted to examine the spatial accuracy of the five types of package designs, the situation where a package is viewed from more than one distance, as if approaching a package on a shelf in a retail environment. Subjects were shown smaller and larger package images, and the difference in brand and quality impressions was examined. Consumer also provided additional information on their level of involvement with their level of involvement in the category (Zaichkowsky 1985) and their design acumen (Bloch, Brunel, and Arnold 2003). Changes in brand personality (independent of design) were found for "exciting" brand personality impressions (packages rated more exciting for

the smaller "seen at a distance" packages), while ruggedness, competence, and sophistication brand impressions were stronger for the larger "seen up close" packages. Quality ratings were also higher for larger "seen up close" packages.

The influence of the five holistic package designs was also significant, Massive and contrasting designs had significantly greater changes in personality and quality impressions, while changes in the natural and delicate designs were not as great. There was little change in non-descript designs. Additionally, there were several situations where there were differential impressions of brand personality due to package design. For example, massive designs gave the impression of being more sophisticated when viewed from a distance, while delicate designs gave the impression of being more sophisticated when viewed up close.

We also found that being more involved in the product category, or having more design acumen, resulted in a decreased spatial accuracy of these individuals. The addition of more information to the process of evaluating packages results in significant differences in the brand personality evaluations.

The implications of this research are of interest for all brand and package stakeholders. We provide evidence that package design has an influence on the consensual accuracy of the brand and quality impressions formed by consumers, that certain package designs are more (or less) consistent in the impressions that they generate when viewed at different distances, and we show that consumers high in involvement and design acumen form package impressions that are different from those with less involvement or less acumen. This evidence suggests that brand managers should more closely examine their packages to insure consumers form consistent impressions from their packages (consensual accuracy), to insure consumers form consistent impressions regardless of viewing distance (spatial accuracy), and to insure that their packages are appropriate for consumers differing in levels of acumen and involvement.

When Good Looks Kill: An Examination of Consumer Response to Visually Attractive Product Design

Rishtee Kumar Batra, Boston University, USA

Frederic Brunel, Boston University, USA

Sucharita Chandran, Boston University, USA

EXTENDED ABSTRACT

In a time when companies are able to match each other on dimensions of quality and price, superior design is seen as a key to winning customers. In the past several years the issue of design and its role as a strategic tool for marketplace success has been pursued by manufacturers of consumer goods from small appliances to automobiles. But while design has been an area of growing concern, it remains unclear whether superior design should be a goal sought after by all. The present paper examines the effect of visually attractive design upon consumers' perceptions of quality and argues that under certain circumstances, firms benefit from investing in superior visual design while in other circumstances companies might be adversely impacted in pursuit of highly attractive visual design. We develop and empirically test a model of visual information processing based on theories assimilation-contrast and implicit personality. It is shown that a U-shaped relationship exists between visual attractiveness and perceived performance but that this relationship is moderated by both brand information and access to processing capabilities. By understanding the boundary conditions and mechanisms involved in this process of performance-related trait inference, we can begin to outline implications for when and how to use a product's visual design as a competitive tool.

At the root of this model lies Helson's (1964) adaptation-level theory. Person perception research from social psychology has already demonstrated that individuals maintain adaptation levels of acceptance around cues such as physical attractiveness of others. Whether or not the person's attractiveness falls within a latitude of acceptance, people are either shown to assimilate information to a "what is beautiful is good" stereotype or to make a contrasting judgment. In the present study, this finding is extended to the domain of product design and consumers are similarly thought to have a latitude of acceptance around a product's visual attractiveness. In the case that processing capabilities are unconstrained, individuals first consider the extent to which the product being evaluated falls within an acceptable range of attractiveness. Depending on whether or not they deem the product to fall within this range, different beliefs are drawn upon.

In Study 1, we demonstrate that depending on the level of attractiveness—either within or beyond one's latitude of acceptance—individuals draw upon different belief structures. We show that in absence of other information, when a product's level of attractiveness is low or moderate, consumers draw upon a "what is beautiful is good" structure such that more attractive products are rated as being of higher quality than less attractive products. However, when a product's level of attractiveness exceeds a threshold, consumers draw upon a "too good to be true" belief structure such that highly attractive products are rated as being of lower quality than moderately attractive products. But when consumers have access to external information, such as brand reputation of the manufacturer, they adjust their initial judgments to accommodate this information. In the high brand reputation condition, evaluations of products at all three levels of attractiveness are enhanced, resulting in suppression of the "too good to be true" belief. However, in the poor brand reputation condition the belief remains in tact.

While in Study 1 we show that individuals process visual information in a cognitive manner under conditions of unconstrained processing ability, the same is not true under conditions of low processing ability. In Study 2, when individuals are faced with limited processing capabilities they engage in perceptual processing of visual information based on an affect-transfer process. In absence of other information, regardless of whether or not a product falls within latitude of acceptance, consumers process visual information through a process of affect transfer such that more attractive products are preferred to less attractive products. Thus, perceived performance is thought to increase monotonically with increased attractiveness and brand information is not shown to interact with product attractiveness.

The findings of this research hold interesting implications for product designers and brand managers in helping assess when investment in a product's visual design is beneficial and when this investment might backfire. Although the present paper makes progress toward outlining visual design and positioning guidelines for managers, there are still questions that might be pursued by future researchers. For example, the model described in this paper accounts for the possibility that product category might moderate the impact of attractiveness upon perceptions of quality found in high processing capability conditions. Different product categories (e.g. primarily functional products versus primarily hedonic products) are thought to have different latitudes of acceptance around what is considered acceptable in terms of attractiveness and might have different belief structures associated with each level of attractiveness.

Do We Judge a Book by its Cover and a Product by its Package? How Affective Expectations are Contrasted and Assimilated into the Consumption Experience

Sharon Horsky, Bar Ilan University, Israel
Heather Honea, San Diego State University, USA

EXTENDED ABSTRACT

Marketing actions can serve to activate expectancies that impact consumption experiences and product efficacy. For instance, Shiv et. al. (2005) show that consumption of the exact same product differently impacts performance when the product is purchased at a discount versus at regular price. They confirm that the impact of consumer perception on performance is mediated by expectations.

When consumers do not have prior knowledge of a product's qualities, a product's visual aesthetic is a marketing action that serves to set consumers expectations. Attractive visual aesthetics generate favorable responses and impact product expectations (Postrel 2003). We propose that attractiveness generates *affective expectations* (beliefs about the pleasure or positivity associated with a consumption experience). In the case of hedonic products, where the benefit of the product is primarily determined by the affect experienced during consumption, affective expectations driven by product packaging may be contrasted to or assimilated into actual consumption beliefs and experiences.

An initial product survey validates the relationship between attractive aesthetics and product expectations. Then three experimental studies test propositions regarding the relationship between expectations set by packaging and consumer perceptions. The studies investigate the effect packaging aesthetics have on actual consumer beliefs and consumption evaluations and examine whether these effects carry through to purchase intentions. To create a context for contrast and assimilative effects, product quality and consumer affective expectations were varied across conditions.

Intuition might suggest that a more appealing packaging would increase consumers' product evaluations, purchase intentions, and beliefs. We show that this is not always the case. A contrast effect was found in the case of high quality product. The high quality product was evaluated more positively when it was paired with a package that was not particularly beautiful. This was due to surprise that was elicited from the incongruence between an individual's affective expectations generated by context and the actual product experience.

Study 1 was conducted to examine the relationship between hedonic product aesthetics and consumer expectations. Five hundred individuals were shown two inch pictures of 44 different hedonic product packages. Brand name was intentionally obscured but the product package was visible in terms of design and color. Participants rated the product on six semantic differential scales anchored by 1 and 7. The scales were Ugly-Pretty, Boring-Exciting, Unattractive-Attractive, Lame-Cool, Unsophisticated-Sophisticated, Unstylish-Stylish. Finally, participants rated their affective expectations of the product on a scale anchored by very low=1 and very high=5. Highly correlated semantic measures were combined. The Pretty and Attractive measures were combined to form a Beauty indicator ($r=0.862$). Cool and Exciting were combined to form a Coolness indicator ($r=0.813$). Sophisticated and Stylish were combined to form a Style indicator ($r=0.851$). Regressing these three indicators on expectation shows that they explain over 70% of the variance in participants' affective expectations for a product.

Having established the relationship between aesthetics and expectations we investigated the effects of aesthetics on the accep-

tance of non-verifiable highly positive credence claims. Study 2 employed a 2x2 between-subjects experimental design with product package (high vs. low attractive) and product quality (high vs. low) as experimental factors was utilized. Packaging aesthetics interacted with product quality to influence belief in credence claims and purchase intentions. When the context for a low quality product is an attractive package, consumers are marginally more likely to accept credence claims. When the context for a high quality product is aesthetically low, consumers are marginally more likely to accept credence claims. Study 2 indicates that expectations are set based on packaging and product quality interacts with expectations. However, affective expectations from the packages were not perfectly contrasted or assimilated into consumer beliefs regarding credence claims. Perhaps credence claims, although positively valenced were not sufficiently affective in nature, therefore contrast or assimilation with affective expectations was imperfect.

We expect that hedonic product experiences are more affective in nature. This leads to specific predictions regarding the interaction between affective expectations and hedonic product experience.

Proposition A: All that Glitters is Gold Effect. Beautiful aesthetics, such as attractive packaging, increase initial positive response to a product. This positive response positively biases hedonic product experiences.

Proposition B: Frogs can be Princes Effect. Lack of aesthetics, such as plain packaging, does not increase initial positive response to a product. When hedonic product experience exceeds expectations generated by the low level product aesthetics, the resulting positive response biases hedonic product experiences.

Study 3 was conducted to determine the implications of packaging on perceptions of verifiable product attributes by examining actual product experience and purchase intentions. A 2x2 between-subjects experimental design with product package (high vs. low attractive) and product quality (high vs. low) as experimental factors was utilized. As predicted packaging aesthetics interacted with actual product quality to influence taste evaluations and purchase intentions. We find that a highly attractive package pattern positively biases taste evaluation in the low product quality case (assimilation)—providing evidence of the *All that Glitters is Gold Effect*. Purchase intentions appear to follow a similar pattern, with increased intention to purchase with low quality product when presented in the context of a highly attractive vs. low attractive package. The contrast bias was not significant with the high quality product in the low attractive package, though the means are directionally consistent with the *Frogs can be Princes Effect*.

Study 4 was conducted to further examine the unique impact low aesthetics and a high quality product to determine whether a contrast effect occurs. Participants' post-taste responses were measured to assess whether feeling surprise played a role in their perceptions and intentions. A between-subjects experimental design was employed, with product package (high vs. low attractive) and identical very high quality product in both packages. We find that if the packaging signal does not generate a positive response

700 / Do We Judge a Book by its Cover and a Product by its Package?

because of its low aesthetic appearance, then the individual is delighted when she experiences a high quality product. This surprise increases evaluation. Purchase intention follows a similar pattern. Apparently, when an individual kisses a frog that turns out to be a prince, her subsequent assessment is more positive than it would have been if she had expected to be kissing a prince initially. However, this *Frogs can be Princes Effect* appears to come into play only in the case of very high quality product. It seems that a product must be pretty “charming” to be contrasted to the low aesthetics of its package.

Bilingualism and the Emotional Intensity of Advertising Language

Stefano Puntoni, Erasmus University, The Netherlands
Bart de Langhe, Erasmus University, The Netherlands
Stijn van Osselaer, Erasmus University, The Netherlands

EXTENDED ABSTRACT

Regardless of their cultural heritage and native language, consumers around the world are routinely addressed by large numbers of marketing messages in a foreign language, mostly English. Calls for an increased focus on the consequences of globalization for consumers (e.g., Johar, Maheswaran, and Peracchio 2006) emphasize the need to improve current understanding of how the globalization of advertising language influences consumer response to marketing communications. In particular, no previous research has examined the emotional consequences of the use of a foreign language in commercial messages. This issue is important because generating emotional experiences around a brand is an important goal of brand communication and it is currently unclear what the emotional consequences of the globalization of advertising language are. Extending recent literature on the emotions of bilinguals (e.g., Pavlenko 2005), we propose a language-specific episodic trace theory of language emotionality to explain how the emotionality of marketing messages is influenced by the language used.

Following Hintzman's influential Minerva 2 model (Hintzman 1986, 1988), we argue that each experience is stored as an array of elements. At the time of retrieval, presenting one or more elements of such an experience activates memory traces of experiences that contain that or those elements. Activation of an experience makes therefore the other elements of that experience that were not in the probe accessible. Although Minerva 2 was not designed to deal with linguistic issues or emotions, a multiple-trace view may be applicable to emotional appraisals of advertising in one's first (L1) or second (L2) language. It seems possible that consumers' episodic memory traces include not only the direct, external perceptual elements of an experience, but also the emotions that were felt during an episode. In addition, it seems natural that the sights and sounds of words or series of words perceived during an episode would be stored as elements of the episodic trace as well. This would imply that if a word or series of words is encountered later, it functions as a probe for the multi-trace memory of experiences. Thus, advertising copy or slogans in L1 or L2 may function as memory probes which lead to the activation, and feeling, of emotions experienced before in same-language contexts. Assuming that emotional *echo content* is a positive function of the number of activated emotional traces (e.g., Hintzman 1986), this would imply that the perceived emotionality of marketing messages depends on the number of experiences in which the words of that message, in that language, have been encountered previously. In the context of the globalization of advertising language, it is reasonable to assume that the number of events experienced by consumers in concomitance with an L1 language context outnumbers that of events experienced in an L2 language context. L1 marketing communication should in general therefore trigger stronger emotional responses than L2 marketing communication. We assessed the language-specific trace theory of language emotionality in a number of studies.

In Study 1, Dutch-English-French trilinguals were addressed in English and rated a series of Dutch and French advertising slogans on emotionality and originality. Half of participants were L1 speakers of French and half were instead L1 speakers of Dutch.

We observed a two-way interaction between language and type of appraisal such that L1 slogans were rated as more emotional than L2 slogans, with no difference between L1 and L2 slogans in perceived originality. The two-way interaction, moreover, was not qualified by a three-way interaction with population: the emotional advantage of L1 was in fact exactly the same for Dutch and French native speakers.

In Study 2, nonnative speakers of English from a variety of countries rated the emotionality of single English words after having copied the word either in English or in their native language. Participants for whom the native language translation had been made more accessible rated the English words as more emotional. In this experimental paradigm all participants rated the same stimuli, ruling out a comprehension account for the effect of language on emotionality.

In Study 3, we provided direct evidence for the role of the context of language use for the effect of language on emotionality obtained in the previous studies. A set of L1/L2 word pairs was selected based on a pretest to differentiate between pairs that had been predominantly encountered in L1 versus L2 language contexts. Participants in the main study (Dutch native speakers who were fluent in English) then rated the emotionality of both L1 and L2 words from each pair. We observed a crossover interaction between language and language context. For concepts encountered predominantly in L1 language contexts we replicated the emotional advantage of L1 found in previous experiments but for concepts encountered predominantly in L2 language contexts we observed a reversal of this effect: in this case L2 words were rated as more emotional than L1 words.

In Study 4, we replicated the emotional advantage of L1 using ads featuring congruent visual information. Moreover, we manipulated the language of the rating scales. Participants reported more extreme ratings of emotional intensity when performing the task using L2 than L1 rating scales. This reversal of the effect of language across the two stimulus elements (ads and rating scales) is consistent with the stronger emotional intensity of L1 by showing that language shifts the perceived intensity of the anchoring points of semantic differentials. That is, the emotionality scale anchors are perceived as less extreme in L2, leading to more extreme ratings of stimuli on the L2 scale.

This article is the first to focus on the consequences of language for the perceived emotionality of marketing messages and, from a broader point of view, the first to adopt a psycholinguistic perspective on the emotional consequences of the process of globalization for consumers. Bilingualism is a growing area in consumer research (e.g., Luna and Peracchio 2001) and the article adds a new dimension to this body of literature.

The Role of Brand Personality and Consumer Attachment Style in Strengthening Brand Relationships

Vanitha Swaminathan, University of Pittsburgh, USA

Karen Stille, University of Pittsburgh, USA

Rohini Ahluwalia, University of Minnesota, USA

EXTENDED ABSTRACT

Background. That brands have personalities or human characteristics is now well established in the literature; as is the idea that brand personality is a vehicle of consumer self-expression and can be instrumental in helping consumers express different aspects of their self (Aaker 1997). Humanizing a brand empowers it to play a more central role in the consumer's life: potentially enabling the consumer to project an aspect of their self which might be desirable for relationships they seek (Aaker 1997); or possibly even give them a sense of comfort at having found a brand that "fits" with their self-concept (Aaker 1999). In order to harness the potential of brand personality, it is important from both a managerial and a theoretical point, to understand the underlying mechanisms invoked under different circumstances, and identify moderators that provide more specific insights into which brand personality traits are going to matter to consumers. We adopt an attachment theory (Bowlby 1980) perspective to provide a richer understanding of the role of brand personality in influencing consequential branding outcomes such as brand attachment and purchase likelihood, especially under marketplace settings where consumers are not explicitly directed to pay attention to the brand's personality.

Predictions. Attachment theory has identified two dimensions of attachment style based on the individuals' view of self and view of others, i.e., anxiety and avoidance respectively, which are expected to influence the type of relationships they engage in and their potential for forming attachments in the interpersonal domain (Bartholomew and Horowitz 1991; Bartz and Lydon 2004). We propose that a consumer's attachment style (based on these two dimensions) will moderate the effect of brand personality on crucial outcomes such as brand attachment and purchase likelihood.

Method. Through a series of three experiments, our research demonstrates that consumers' attachment styles are likely to moderate the impact of brand personality on marketplace outcomes. We examine these hypotheses across three studies. The first study examines the extent to which consumers' attachment styles moderate the role of brand personality in predicting their existing brand attachments for favorite clothing brands. In Study 2 and 3, the key variables of attachment style and brand personality are manipulated (instead of measured), to provide a cleaner test of the hypotheses. Generalizability of the pattern of effects obtained with favorite brands in the first study is extended to the context of brand extensions (study 2) and new product introductions (study 3). The last two studies also attempt to provide process related insights (study 2) as well as identify boundary conditions for the effects obtained (study 3).

Results. Our research reveals that consumers who have an anxious attachment style are more likely to be influenced by a brand's personality than those who are less anxious about relationships. For the anxious types, when the brand is associated with a personality trait which the consumer considers important or relevant for maintaining relationships with others, brand attachment and purchase likelihood are enhanced. In this regard, our research reveals that high anxiety types who tend to avoid relationships are likely to be influenced by exciting brands; whereas high anxiety individuals who are low on relationship avoidance are attracted to sincere brands. In contrast, consumers who do not have an anxious

attachment style, tend not to be influenced to the same extent by the brand's personality, demonstrating similar brand outcomes (attachment as well as purchase likelihood) for sincere and exciting brands. Importantly, this pattern of effects is replicated whether attachment style is measured or manipulated; across different product categories (clothing, shoes, and clocks); for well known favorite brands to new and unfamiliar brands; for outcomes varying from brand attachment to purchase likelihood. Further, these results appear to be more important in the context of publicly consumed goods rather than for privately consumed goods.

Conclusions. As such, our research points out to an interesting but counterintuitive finding: brand personality can be most useful for forging consumer-brand connections in a domain where past literature in the interpersonal relationship context suggests brand attachments are most unlikely (e.g., the high anxiety high avoidance consumers). Interestingly, brand personality might hold the key to forming relationships with and enhancing purchase likelihood of these consumers. Specifically, although high anxiety and high avoidance type of individuals (fearfuls) have been shown to demonstrate the lowest levels of attachment potential in past literature (e.g., Bartholomew and Horowitz 1991), the use of an exciting brand personality led them to exhibit brand attachment levels similar to low anxiety low avoidance (secure) individuals, associated with highest attachment potential in the interpersonal domain. Furthermore, it appears these relationships are formed with a view to projecting one's image as more desirable. Hence, this relationship potential is most likely for products which tend to be consumed publicly.

Our research sheds light on the processes underlying these effects. We contrast the mediating role of self-brand relevance and self-brand similarity. We find that self-brand relevance offers a better account of the processes by which individuals use brand personality in an instrumental way to building brand attachments.

Implications. At this point, it is important to note that several potential roles of brand personality have been discussed in the literature, ranging from a match with the consumer's self-concept to impression management via brand personality with the goal of developing positive relationships (Aaker 1999). Our research suggests that consumer attachment styles might be more likely to invoke the impression management type of mechanisms, serving as a tool to enhance one's attractiveness as a relationship partner.

By illuminating the important role of attachment styles, this research may serve to encourage scholars to re-think some of the fundamental notions of the universality of brand personality traits and their meaningfulness across groups of consumers differentiated based on attachment styles. This research contributes to the literature by demonstrating the important role of consumers' view of self and view of others, which, developed during infancy, influences how consumers seek brands with personality traits that are self-relevant or important. Brand personalities help consumers derive symbolic meaning from their relationships with brands. Sincere brand personality traits, for instance, are meaningful to consumers who seek relationships (less avoidant), but who have a highly anxious view of self. Exciting brands also symbolic meaning and are particularly meaningful to those anxious individuals who are focused on self-reliance.

The Impact of Employee Behavior on Brand Personality Impressions: The Moderating Effect of Pseudorelevant Information

Daniel Wentzel, University of St. Gallen, Switzerland
Sven Henkel, University of St. Gallen, Switzerland

EXTENDED ABSTRACT

Sales employees frequently disclose personal information to consumers in order to gain their trust and to improve the course of an interaction (Crosby, Evans, and Cowles 1990). A salesperson at an Apple store, for instance, may tell a customer who is looking to buy an iPod that she owns a particular model herself and uses it when she goes running on the weekends. The information that is disclosed on such occasions may be irrelevant for the final outcome of the interaction and for judging whether the salesperson has successfully performed her prescribed role. Information of this kind, however, may be indicative of the salesperson's general character, for which reason such pieces of rich, nondiagnostic information are referred to as "pseudorelevant" information (Hilton and Fein 1989). Even though the disclosure of pseudorelevant information should be a common occurrence in many sales interactions, there are no studies that have investigated how such information influences brand personality impressions. In this research, we propose that pseudorelevant information affects the extent to which consumers update their existing brand personality impressions after interacting with an employee whose behavior is consistent or inconsistent with these impressions.

To develop our predictions, we draw on studies that have been conducted in the area of stereotyping theory. The disclosure of pseudorelevant information during a sales interaction may determine how typical the employee is considered to be. This, in turn, can affect the extent to which the employee's behavior is generalized to the brand personality. When an employee does not disclose any pseudorelevant information, customers are likely to stereotype the employee and should regard him or her as a typical representative of the brand (Matta and Folkes 2005). When, however, pseudorelevant information has been disclosed, consumers may dissociate the employee from the brand and should consider the employee as a relatively unique, less typical member of the brand. This process is referred to as "fencing off" or subtyping (Kunda and Oleson 1995; Yzerbyt, Coull, and Rocher 1999). Stereotyping and subtyping processes should also determine to what extent an employee affects brand personality impressions. Because people produce less generalization from atypical than from typical group members (Rothbart and Lewis 1988), consumers' brand personality impressions should not be affected as strongly by the employee's behavior when they have received pseudorelevant information during the interaction. Two studies were conducted to test this prediction.

In the first study, participants read a scenario that depicted an interaction between a customer and an employee of a fictitious biking brand. In these scenarios, the employee's behavior was either consistent or inconsistent with the brand's personality. In addition, the amount of pseudorelevant information was varied through a conversation that took place between the customer and the employee. The results showed a significant interaction between the consistency of the employee's behavior and the disclosure of pseudorelevant information. When participants did not receive pseudorelevant information, their brand personality impressions were strongly influenced by the employee's behavior. That is, consistent behavior strengthened brand personality impressions, whereas inconsistent behavior weakened them. When participants received pseudorelevant information, however, they subtyped the

employee. As a consequence, they transferred the employee's behavior to a lesser extent to the brand.

The second study extended these findings and showed that the impact of pseudorelevant information is moderated by accuracy motivation. More specifically, the second study manipulated the availability of pseudorelevant information and the degree to which participants were motivated to form an accurate impression of the employee. The analyses revealed a significant interaction between these two variables. When accuracy motivation was high, brand personality impressions were less strongly affected by the employee's behavior if participants had received pseudorelevant information. When accuracy motivation was low, however, brand personality impressions did not differ as a function of the information that had been disclosed. These results show that pseudorelevant information can block generalization because consumers are motivated to arrive at an accurate impression of the employee they are interacting with.

These results have implications for the literature on self-disclosure by showing that disclosing personal information can affect the extent to which consumers generalize an employee's behavior. This may entail positive as well as negative implications. On the one hand, the brand is not harmed as badly when the employee's behavior is inconsistent with the brand personality; on the other hand, the brand does not benefit as strongly when the behavior is consistent. Furthermore, our findings also contribute to research on the formation and updating of brand personality impressions (Aaker, Fournier, and Brasel 2004; Johar, Sengupta, and Aaker 2005). Earlier studies have suggested that personality traits come to be associated with a brand in a direct way by the company's employees. Our results indicate that the strength of this association depends on the information that consumers possess about an employee and their accuracy motivation. In fact, without knowing how the employee is perceived, it may be impossible to predict how brand personality impressions are affected by an employee's behavior.

Happy Now or Overall? The Measurement of Local versus Global Well-Being

Stacy L. Wood, University of South Carolina, USA

Adam W. Craig, University of South Carolina, USA

EXTENDED ABSTRACT

The diversity of measures used in recent research illustrates that many researchers take different approaches to measuring happiness. While many of these approaches are logical given specific research questions, a lack of discussion about inherent measurement differences slows the progress we make in knowledge building because it keeps us from knowing how to compare results from disparate measures or, worse, leads us to make inappropriate comparisons between results. In this research, we assess the potential for measurement differences to arise from the respondent's own interpretation of what the researcher means when s/he asks "How happy are you?"

Here, we investigate two common interpretations of happiness that may be equally normatively appropriate for respondents, and yet, may be conceptually distinct (i.e., rely on inputs that do not perfectly overlap). These two interpretations originate in differences in temporal orientation—happiness that is perceived as an enduring or overarching assessment and happiness that is perceived as immediate and transitory pleasure (Kahneman and Krueger (2007)). We use the terms, *global* and *local*, to describe these two interpretations. Many cultures understand happiness as two related but distinct concepts—the temporary enjoyment of positive affect (local happiness) and a more static disposition suggestive of positive life choices and satisfaction (global happiness). Individuals may understand this difference as "Am I feeling happy right now?" versus "Am I happy overall?" Importantly, we propose that very similar response items may prompt either interpretation. In other words, people may understand the simple direction to "rate your happiness" as an injunction to report on their current short-term pleasure or the degree to which they have good lives. In this work, we investigate (1) the methodological and conceptual implications of these two interpretations, (2) how measurement vehicles may prompt one versus the other, (3) how the assessments may rely on different inputs and, (4) how the assessments may be differentially correlated with common well-being measures.

In this research, we present five studies that demonstrate consistent differences in the evaluation of happiness and provide process evidence that differences are due to one's temporally-oriented interpretation of happiness. This evidence offers behavioral researchers a better understanding of what existing (and future) findings from happiness and well-being studies may be validly compared.

Because the word "happiness" is used in common parlance to capture both global and local interpretations of happiness, we suggest that respondents are impacted by the nature of the item or the context in which the item is asked in determining whether they should respond in terms of their long-standing global well-being or their more changeable short-term enjoyment. In order to investigate this, we consider the influence of three context factors that may influence local/global interpretations: (1) the existence of local/global primes, (2) the temporal context of other items, and (3) the item language itself. Finally, we consider the process of temporal orientation through which these influences impact happiness ratings.

Our empirical data suggest that respondents use surprisingly subtle cues in happiness measures to determine whether they are being asked how happy they are now or how happy they are in general and that this distinction leads to consistent differences in

reported happiness. Study 1 examines whether priming respondents with the concept of "local" versus "global" can influence their subsequent report of happiness. Respondents report lower happiness when primed with a local cue than those who are primed with a global cue. Study 2 is to replicate the priming effect found in study 1 and to additionally test the influence of item wording on reported happiness (Wierzbicka 2004). We observe lower reported happiness with the use of the word "pleased" versus the word "happy." Additionally, in replicating the main effect found in study 1, we observe lower reported happiness (with either wording) in the Local Prime condition. Study 3 tests the effect of survey context on local versus global interpretations of assessed happiness and finds that manipulating the type of survey questions that surround the item measuring happiness (e.g., local items such as "hungry" versus global items such as "stingy") prompts respondents to interpret happiness as local and to report lower happiness ratings than global contexts. Study 4 replicates the context effect (H3) found in study 3 and additionally examines process evidence (cognitive responses that capture inputs) that differences in responses may be due to differences in the respondents' local (immediate/situational) or global (enduring/static) inputs to the rating. Finally, Study 5 examines process evidence that differences in correlations to life satisfaction may be due to differences in the respondents' local or global interpretation. When participants responded to a cognitive response task after evaluating their happiness, those in the local context condition expressed more immediate reasons for their evaluation (e.g. "It's sunny today," or "I had a good breakfast") and those in the global context condition expressed more static reasons (e.g. "I have a good family," or "I like my job").

In conclusion, cues that signal a local (happy now) interpretation lead to lower ratings of happiness in lab settings than do global (happy overall) interpretations. Cues can consist of unintentional priming, context, or wording differences in the scale/item. Local interpretation leads respondents to consider more immediate short-term inputs (e.g., good day, not hungry) and global interpretation leads respondents to consider more long-term inputs (e.g., family, career) when assessing their happiness.

Reducing the Spoiler Effect in Experiential Consumption

Alex S.L. Tsang, Hong Kong Baptist University, China

Dengfeng Yan, Hong Kong University of Science and Technology, China

EXTENDED ABSTRACT

A spoiler is a summary or description of a narrative product (e.g., comic book, movie, novel, TV drama), in which a dramatic “twist”, such as the identity of the murderer in a detective story, is revealed. The spoiler effect denotes a phenomenon that a consumer’s interest in consuming a particular narrative is reduced after exposure to a spoiler. We identify the psychological process underlying the spoiler effect, from an affective forecasting and focusing illusion perspective. Following the same logic, we further suggest a method for marketers to neutralize this effect.

Spoilers are a common phenomenon with narratives. When consumers consult external information sources, the source may intentionally or unintentionally leak information about the plot. Spoiler exposure creates a satiation effect (Redden, 2008) and an explanation effect (Wilson, Centerbar, Kermer, and Gilbert, 2005) that hinder favorable affective forecasting. As a result, intention to consume the narrative is reduced. In this research, we propose a psychological mechanism that underlies the spoiler effect and accounts for the satiation and explanation effects. We hypothesize that affective forecasting mediates the relationship between spoiler exposure and consumption intention of a narrative. Specifically, exposure to a spoiler produces an unfavorable forecasted affect, in turn reducing consumers’ consumption intention (H1).

Study 1 was designed to test H1. Participants were provided with a scenario saying that a friend phoned the participant and revealed (spoiled version) or did not reveal (non-spoiled version) the identity of the murderer of a movie that the participant was planning to see; then, forecasted affects and narrative consumption intention were measured.

We adopted Baron and Kenny’s (1986) three-step procedure to test the main and mediating effects, the first step shows that spoiler exposure was significantly related to movie-seeing intention in a negative way. The second step shows that spoiler exposure significantly affected excitement and surprise negatively. Step three shows that, when both spoiler exposure and the two forecasted affects were regressed on narrative-consumption intention, only surprise, but not excitement, was significant in explaining narrative-consumption intention. However, spoiler exposure was still significant in the model, but its β was significantly reduced. The results suggest only a partial mediation effect between spoiler exposure and narrative-seeing intention. H1 is partially supported. We suspect this outcome is caused by the usage of a “generic” scenario without explicitly providing the plot of the movie making it difficult for participants to forecast their affects. Thus, Study 2 reassesses the mediating effect by using a hypothetical movie synopsis.

Spoilers are commonly spread by WOM; however, marketers can still limit their negative impact. We argue that the spoiler effect is caused by a cognitive bias called focusing illusion, which denotes assigning a heavier weight to an attended attribute than to other unattended attributes in predicting the affect produced by a particular object (Kahneman, Krueger, Schkade, Schwarz, and Stone, 2006). A spoiler draws consumers’ attention to a twist in a plot, thus they will rely heavily on the plot to forecast their affective responses for consuming the narrative. However, a leaked plot creates a satiation or explanation effect that reduces the forecasted enjoyment. Eventually, consumers’ interest in consuming the narrative is reduced.

According to this proposed mechanism, a feasible way to debias focusing illusion is to move consumers’ attention ways from the focal attribute. When other experience attributes (e.g., audiovisual effects) are made more salient at the time consumers forecast their affects, the plot’s influence will be reduced. Hence, we hypothesize that spoilers do not significantly reduce consumers’ narrative consumption intention if other experience attributes are made salient when they forecast their affect (H2).

Study 2 used a 2 (ad theme: plot focused / experience focused) x 2 (spoiler exposure: yes / no) between subjects factorial design. We designed an ad slogan emphasizing outstanding audiovisual performance instead of the unpredictable plot, so some other experiential attributes are made salient when consumers forecast their affects. They then read a movie excerpt, which contained or did not contain a spoiler. Eighty students and teachers participated in this study.

In order to test the debiasing mechanism; we split the sample according to which ad slogan the participants read. We then adopted Baron and Kenny’s procedure to test the mediating effect. For the sample that was exposed to the experiential-attribute-focused slogan ($n=38$), the first step failed. Spoiler exposure does not produce a lower movie-seeing intention.

For the sample that was exposed to the plot-focused slogan ($n=42$), the first step shows that spoiler exposure significantly affects movie-seeing intention in a negative way. Step two was also successful. It shows that spoiler exposure significantly affects only two (happy and surprise) affects in a negative way. Surprise is consistently significant in both Study 1 and 2. If a participant was first exposed to a plot-focused slogan, spoiler exposure significantly reduced their forecasted happiness and forecasted surprise. Step three shows that, when both spoiler exposure and the two forecasted affects were regressed on movie-seeing intention, both happiness (at $p=.05$) and surprise (at $p=.10$) fulfill the mediating requirement by being significant in the model. At the same time, spoiler exposure becomes no longer significant after the mediator enters the model. The results suggest that forecasted affects can fully mediate the effect of spoiler exposure on the intention to purchase narratives. These results not only support H2 but also provide some evidence supporting H1.

In this paper, we introduce affective forecasting as a mediator and empirically test how it mediates spoiler exposure to reduce consumers’ narrative consumption intention. We further postulate that focusing illusion biases affective forecasting and suggest a feasible way for marketers to defocus it. Our experimental results show that the negative impact of spoilers can be controlled. These findings are particularly valuable to practitioners. They provide guidance for promotional message formulation if narrative marketers do not want consumers’ patronage interest to be hampered by spoilers.

Geographic Differences in the Consumption of Hedonic Products: What the Weather Tells the Marketer!

Wenbin Sun, University of Mississippi, USA
Rahul Govind, University of Mississippi, USA
Nitika Garg, University of Mississippi, USA

EXTENDED ABSTRACT

Research has substantiated the association between weather and unrelated consumer behaviors. It has linked changes in states of weather to helping behavior (Cunningham 1979), consumer satisfaction (Mittal, Kamakura, and Govind 2004), consumer choice (Fergus 1999), retail sales (Starr-McCluer 2000), and stock returns (Hirshleifer and Shumway 2003) amongst others. In most of the studies in this stream, positive weather (e.g. presence of sunshine) has been linked to positive outcome (e.g. more helping behavior) and vice versa. The underlying assumption in all these studies examining the link between weather and consumption is that affect mediates this relationship. That is, weather manipulates affect which in turn influences behavior.

Recently, researchers have started focusing on the relation between weather and a specific type of consumer behavior—hedonic consumption. Weather has been found to affect aggregate consumption differences across countries for products such as alcohol, and coffee (Parker and Tavassoli 2000); purchase of lottery tickets (Bruyneel et al. 2005); and individual level consumption differences for variety of hedonic goods such as tobacco, food products (chocolate, cookies), and even choice of gift cards for stores varying in their degree of hedonicity (Govind, Garg, and Mittal 2008). In addition to demonstrating the relation between weather and hedonic consumption, Govind et al. (2008) also establish weather-induced affect as the driving force behind the weather-consumption relationship.

Given that hedonic consumption is vulnerable to contextual factors like advertising (Wansink and Ray 1996), packaging (Wansink 1996), and affect (Garg, Wansink, and Inman 2007); and that social marketing is concerned with increasing consumer and societal welfare by controlling (negative) hedonic consumption, it will be insightful to understand the role of weather, an exogenous factor, on consumption and the regional variations in the relationship. Thus, the current research will not only seek to replicate the weather-hedonic consumption association established by prior research but also, extend the literature by examining geographical variations in that relationship. Specifically, the current research will seek to answer questions such as, “will the impact of changes in amount of sunlight on hedonic consumption be the same in the east coast (which displays huge annual differences in temperature) as compared to the west coast (which displays less variance)?” This is important from the perspective of policy makers who spend millions of dollars in resources to manage and curb hedonic consumption.

The analysis utilizes secondary data from the entire continental United States on the consumption of two negative hedonic products, tobacco and alcohol consumption. Weather data consisted of twenty weather variables from The National Oceanic and Atmospheric Administration. In line with the prior literature, negative weather conditions are characterized by lower temperatures, reduced sunlight and increased precipitation. In addition to these factors, we include several unstudied factors such as danger due to hail, tornado and wind. We suspect that an increase in these weather risk factors will also increase hedonic consumption. In addition to the weather variables, we also include socio-economic and demo-

graphic factors since prior research has found these variables to have an effect on the consumption of products such as alcohol and tobacco.

We first conduct a factor analysis on the twenty weather variables to reduce the impact of multi-collinearity and to make the subsequent predictions more actionable. The resulting three factors are labeled as, (1) The Temperature Based Factor (2) The Weather-Risk Based Factor and (3) The Precipitation Based Factor. An Ordinary Least Squares (OLS) analysis was then conducted to establish the effect of weather (i.e. the three weather based factors) on hedonic consumption (alcohol and tobacco consumption) across the entire United States with each zip-code acting as a single data point. This analysis controlled for the effects of socio-economic and demographic variables such as income and age, which have been known to impact the consumption of the two hedonic goods. Following this, we explored regional patterns in the effect of weather on hedonic consumption by using Geographically Weighted Regression (GWR). This technique has some important advantages for our current research. For example, the assumption of OLS that the effect of weather on hedonic consumption is homogeneous across the country is not strictly reasonable. GWR addresses this problem by providing one set of coefficients for each zip code area, taking their special characteristics into consideration.

In addition to showing a significant association between weather factors and hedonic consumption, we find evidence of the space varying nature of the relationship across the US. Specifically, as the weather factors deteriorate, consumers become more likely to increase their consumption of tobacco and alcohol. Furthermore, in our analysis of regional patterns in the weather effects on consumption for these negative, hedonic products, we find that regions in the continental United States exhibit distinct spatial patterns in terms of their susceptibility to negative consumption with changes in weather. For example, the effect of changes in temperature on the consumption of alcohol is higher in the North-Eastern United States as compared to the Southern United States.

Although these regional patterns might differ based on the hedonic product being considered, it is clear that they vary significantly with shifts in weather conditions and that policy/ marketing initiatives designed to influence consumption of such products should adequately account for these patterns. Thus, stakeholders can utilize our findings to implement concrete policies based on the specific needs of the regions and consumers’ propensity to succumb to inclement weather factors. Such focused effort can result in enhancing the effectiveness of these initiatives from both, the monetary and the social welfare aspects.

The Effects of Time on Customer Revenge and Avoidance: An Examination in Online Public Complaining Contexts

Yany Gregoire, Washington State University, USA

Jeffrey Radighieri, Washington State University, USA

EXTENDED ABSTRACT

The potential for customers to get even with service firms after a service failure has grown exponentially with the advent of the Internet. As highlighted by Ward and Ostrom (2006), disgruntled customers can develop their own anti-corporation websites to denounce firms' misbehaviors. Based on a review of consumer advocacy websites (Yahoo! 2007), "homemade" anti-corporation websites represent only the tip of the iceberg of *online public complaining*, a phenomenon broadly defined as the act of using the Internet to publicly complain about a firm (cf. Singh 1988). A vast array of online third-party organizations now offers preformatted platforms that customers can use with even more convenience and at virtually no cost. As a general purpose, this study examines the phenomenon of public complaining made via online third-party organizations.

Online public complaining is intimately related to the notion of *customer revenge*, defined as the actions taken by a customer to cause harm to a firm for the damages it has caused (Bechwati and Morrin 2003). Given its managerial and financial implications (Luo 2006), research on customer revenge has recently gained in popularity (Bechwati and Morrin 2003 and 2007; Grégoire and Fisher 2006 and 2008).

Although progress has been made concerning our comprehension of customer revenge, a simple but important question still remains: How does customer revenge evolve over time? Does it grow stronger, or does it fade away? Managers should have a special interest in this question, because they need to know whether "online retaliators" will naturally reduce their vengeful activities over time, or persist in their efforts.

Our research here fills this gap by examining the effects of time on customer revenge. Moreover, we extend the revenge literature by incorporating another dimension reflecting a lack of forgiveness, *avoidance*. In this study, we suggest that customers fail to forgive as long as they stay motivated (a) to seek revenge against the firm, and (b) to avoid any form of interaction with the firm (cf., McCullough and colleagues 1998; 2007). Overall, we posit that time has differentiated effects on revenge versus avoidance.

Our hypotheses are tested with a longitudinal field study that was performed in collaboration with two established online third-party organizations over a two-month period. The study involves a series of four questionnaires that were administered at a regular interval of two weeks (cf., McCullough, Root and Bono 2007). Our sampling frame was composed of customers who made an online complaint at *consumeraffairs.com* (CA) or initiated a blog on *rip-off-report.com* (RR) in the 10 days preceding the first questionnaire. Initially, the sampling frames were composed of 1,434 and 952 individuals for CA and RR, respectively, for an overall sampling frame of 2,386. After the first wave, 431 participants completed the first survey, with 247 and 184 participants for RR and CA, respectively. For wave 1, the overall response rate was of 18.1%—17.2% and 19.3% for CA and RR, respectively. The number of respondents decreased by 131 between waves 1 and 2, by 85 between waves 2 and 3, and by 43 between waves 3 and 4. Overall, 172 respondents completed the four phases of the survey, with 111 and 61 respondents for CA and RR, respectively.

The central question of this research has both theoretical and managerial implications, and it can be formulated as follows: Do customers forgive firms over time? Our results suggest that customers have difficulties forgiving firms after a service failure that led to an online public complaining (see Figure 1). While customers lose their desire for revenge over time, which is perhaps satisfied after their online actions, their desire for avoidance *increases* over time, showing that they hold grudges. Overall, our results show little evidence that time would help the restoration of a relationship as it was before the service failure episode.

Despite an unforgiving tendency, the decrease of a desire for revenge over time constitutes encouraging news for managers. Let us remember that a desire for revenge is found to be associated with online public complaining for help-seeking in this research, and that this desire was found to be an important driver leading to harmful behaviors such as negative word-of-mouth, and vindictive complaining in previous research (Bonifield and Cole 2007). Compared to the results reported in the case of intimate relationships (McCullough, Bono, and Root 2007), the desire for revenge experienced by customers seems less sustainable. Overall, managers can find some comfort in these findings. The use of revenge is very demanding for customers in terms of time and emotional energy, and maintaining this response seems unproductive and unnecessarily costly. Note that these findings provide an explanation about the disappearance and lack of maintenance of many anti-corporation websites, after a given period of time (Ward and Ostrom 2006).

Although the consequences of a desire for avoidance are arguably less spectacular than those of revenge, they also come with costs that should not be underestimated by managers. In light of the influential work on lifetime customer value, the definite loss of a customer patronage can have non-negligible long-term financial repercussions (Luo 2007), especially in the case of strong-relationship customers. In addition, the service paradox literature has highlighted the importance of the recovery process through which a firm has the ability to create a renewed sense of loyalty (Maxham and Netemeyer 2002). Based on this paradox, customers' definite withdrawal from the recovery process may constitute the loss of a firm's last chance to restore a valuable relationship.

The Persuasiveness of Stylistic Properties: The Moderating Role of Ideal-self vs. Ought-self

Jing Zhang, University of Wisconsin-Milwaukee, USA
Xiaojing Yang, University of Wisconsin-Milwaukee, USA
Laura Peracchio, University of Wisconsin-Milwaukee, USA

EXTENDED ABSTRACT

Stylistic properties refer to a variety of factors that impact the manner in which visual material is displayed (Peracchio and Meyers-Levy 2005). Studies have suggested that visual images often convey semantically meaningful concepts that impact consumer judgments via their stylistic properties (Messaris 1997). Take camera angle for example, when a product is depicted with a low, upward-looking camera angle, viewers tend to associate the product with potency and powerfulness. This interpretation was found to influence viewers' brand evaluations (Peracchio and Meyers-Levy 2005).

Despite a steady increase in the study of stylistic properties, little research has examined the effect of self-concept in determining the interpretation as well as the persuasion outcome of these stylistic properties. This research issue is important to address given that self-concept has been found to play intriguing roles in explaining various consumer behaviors, ranging from the persuasiveness of ad messages, to consumers' brand extension evaluations, and to memory and recall (e.g., Ng and Houston 2006). In this paper, we study a particular self-concept, ideal-self vs. ought-self, and examine whether and how it moderates the effect of camera angle on product attitudes.

Ideal-self refers to whom people want themselves to be and is closely related to people's hopes, wishes, and aspirations. Ought-self refers to whom people think they should be and is closely related to people's obligations, duties, and responsibilities. These two selves are associated with distinct motivations (promotion- vs. prevention- focused) and distinct self-regulatory systems (approach vs. prevention strategies) (Higgins 1998). And they have shown to affect the type of information (affective vs. substantive) consumers rely on to form judgment (Pham and Avnet 2004).

We propose that the persuasiveness of camera angle is moderated by the type of self (i.e., ideal vs. ought) that is activated at the exposure to ads. Specifically, when an upward-looking (low) angle is used, consumers whose ought-self is activated would form more favorable brand evaluations than consumers whose ideal-self is activated. This is because consumers with ought-self focus on avoiding loss to achieve their goals and tend to make conservative choices (Liberman et al. 1999), they are more likely to be bound by the hierarchy relationship and to yield to powerful figures. A product shot from a low, upward-looking angle is more likely to make those consumers feel positively about products. Conversely, when a downward-looking (high) angle is used to promote a brand, consumers whose ideal-self is activated would form more favorable brand evaluations than consumers whose ought-self is activated. This is because consumers with ideal-self are less likely to be bound by status-quo interpretations of the stylistic properties and tend to interpret a downward-looking angle favorably.

Study 1, a 2 (self manipulation: ideal-self vs. ought-self) x 2 (camera angle: downward-looking vs. upward-looking) between-subjects design, was conducted to test the prediction. A target ad for a cereal brand was used as a stimulus. The ad featured a large box of the cereal photographed from either one of these camera angles. Participants completed a series of seeming unrelated studies: 1) complete the exercise that is pertinent to manipulation of self (Pham and Avnet 2004); 2) complete the manipulation check items; and 3) review the ad, list their thoughts, and rate their product attitudes.

The manipulation of self was deemed satisfactory. A 2x2 ANOVA yielded a significant two-way Self x Camera Angle effect on product evaluations. Contrast analyses confirmed our expectations.

Study 2 was designed to examine the boundary conditions under which the Self x Camera Angle effect emerges. We argue that although the meaning of the visual stylistic properties is subtle, these properties could serve like central arguments by conveying diagnostic information. We therefore expect that the 2-way interaction effect will emerge only under high motivation of processing. To test this hypothesis, a 2 (self manipulation: ideal-self vs. ought-self) x 2 (camera angle: downward-looking vs. upward-looking) x 2 (processing motivation: high vs. low) between-subjects design was employed. Results confirmed our hypotheses.

To summarize, we find that when a high, downward-looking camera angle is utilized to photograph a product, consumers reported more favorable brand evaluations and thoughts when their ideal-self is temporarily accessible. Conversely, when a low, upward-looking camera angle is utilized, consumers reported more favorable brand evaluations and thoughts when their ought-self is temporarily accessible. In addition, these effects occurred under the high motivation of information processing. Taken together, these results contribute to the visual processing literature by showing the effect of self-concept on the interpretation of the meaning imparted by one stylistic property-camera angle. This project also contributes to the self-concept literature by revealing the power of self in yet another dimension of persuasion efforts-the visual aspect of persuasive messages.

Promotion Framing Effects on Consumers' Perceptions of Customized Pricing

Fei Lee Weisstein, University of Illinois at Urbana-Champaign, USA

Kent B. Monroe, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

The Internet provides online retailers an opportunity to tailor product prices depending on consumers' individual characteristics. While modeling research suggests that there are positive benefits (Elmaghraby and Keskinocak 2003), behavioral research seems to discourage e-tailers to practice customized pricing since researchers have identified negative effects on consumers' perceived fairness, trust, and (re)purchase intentions (Garbarino and Lee 2003; Grewal, Hardesty, and Iyer 2004; Haws and Bearden 2006). The different conclusions from research raise a question: if it is practiced, can consumers' negative reactions be minimized? Recently, it was shown that price framing may reduce consumers' negative reactions (Lee and Monroe 2008). However, will price framing tactics influence consumers' perceptions similarly for high-priced versus low-priced products? Would perceived differences across product-price levels affect perceived price fairness and its outcomes? In this paper, we extend previous research by examining whether price framing can mitigate consumers' negative perceptions of customized pricing for both high-priced and low-priced products and further investigate the causal relationship of perceived fairness outcomes.

Research has shown that different price presentations affect consumers' evaluations of a deal offer (Krishna et al. 2002). That is, various promotions of the same magnitude framed differently may be perceived differently in terms of gains versus reduced losses (Diamond and Campbell 1989). Compared to a transaction with no framing, price promotions (e.g., discounts or gift rewards) may introduce a positive perception of differences. Therefore, consumers' negative perceptions of customized pricing could be reduced by making prices for apparently similar transactions less or not comparable. We predict that a price framing will induce higher consumers' perceived transaction dissimilarity. The more consumers perceive the transactions to be dissimilar; the lower will be their perceptions of price unfairness. Perceived price fairness may further positively influence perceived value, trust, and purchase satisfaction, and consequently have a positive impact on repurchase intentions. Pricing research suggests that consumers are often inaccurate when performing mental arithmetic calculations (Estelami 2003). Consumers may use simplifying heuristics rather than engage in more difficult mental arithmetic when integrating pieces of product information to form an overall judgment. We hypothesized that a discount framed in dollars (percentage) will be more effective for a high-priced (low-priced) product, and vice versa in reducing consumers' negative perceptions. Nevertheless, consumers perceive nonmonetary promotions differently than monetary promotions with the same nominal value. Consumers tend to segregate the benefits and perceive them as gaining something extra (Campbell and Diamond 1990). For example, a free gift with purchase promotions can lead to inferences about the value of the gift. Consumers tend to attach higher value to the same gift if it is given by a higher-priced brand name and vice versa (Raghubir, 2004). Thus, we predict that using free gift for a high-priced product may be effective in reducing consumers' negative perceptions of customized pricing since the free gift can enhance the transactional value of the purchase (Monroe 2003).

Studies 1 and 2 involved both discount framing (dollar off versus percentage off) and reward framing (free cash coupon versus free gift) for a high-priced desktop PC versus a low-priced movie DVD in a between-subjects factorial design. Participants first read

a short scenario asking them to consider buying a HP desktop PC (or a movie DVD) on the Internet. The manipulation of price presentation format was introduced via a web page with the product image, name and model number, price, and product description. All participants were presented the same desktop PC (DVD) web page with the same product but with a different promotion presentation framing format. Participants were randomly assigned to either the control or one of the four framing conditions (\$ off, % off, cash coupon, or a free gift). In the control group, participants were simply presented with the same product at the final price without any framing manipulations. The final computer (DVD) price for all participants was the same amount, \$599.00 (\$19.99). After all participants rated their willingness to buy, they were told that a friend had bought the same computer (DVD) from the same online store for a lower price, \$499.00 (\$16.99). Finally, participants evaluated the dependent measures of perceived fairness, perceived value, purchase satisfaction, perceived transaction dissimilarity, trust, and repurchase intentions. Open-ended thoughts data were collected to investigate participants' responses towards promotion framing, transaction dissimilarity compared to their friends, and overall purchase experiences.

The conceptual model of the underlying transaction dissimilarity mechanism was assessed using latent variable structural equation modeling in AMOS and showed a good fit. Our findings confirmed the proposition that the degree of transaction similarity is highly related to perceptions of price unfairness (Xia et al. 2004). Our findings further show that as perceived fairness increased, consumers perceived a higher value, purchase satisfaction, and trust. Consumers' repurchase intentions were mainly driven by trust (i.e., mediator of price fairness on repurchase intentions) in the high-priced product category while it was driven by both trust and perceived value in the low-priced product category. Contradictory to previous literature and our prediction, surprisingly, our results reveal that percentage off and free gift framing are more effective than dollar off and cash coupon framing in reducing consumers' negative perceptions of customized pricing not only for low-priced but also high-priced products. Both free gift and percentage off are in different units from the initial list price (monetary unit). The non-dollar promotion format also will produce a dissimilarity effect such that consumers, when comparing with other people's purchases, will perceive their own purchases differently. Additional comparisons between these two framings reveals that free gift framing in the high-priced product category and percentage off in the low-priced category yields the best results in enhancing consumers' perceptions. Overall, the findings suggest that promotion framing tactics influences consumers' reactions of customized pricing differently across different product-price levels. Consumers' perceived transaction dissimilarity is an important antecedent of perceived price fairness. We demonstrate that different promotion framing tactics can effectively mitigate consumers' negative perceptions of customized pricing.

Effects of a Scarcity Message on Product Judgments: Role of Cognitive Load and Mediating Processes

Junsang Yeo, Dongguk University, Korea
Jongwon Park, Korea University, Korea

EXTENDED ABSTRACT

The literature on the scarcity of objects has shown a generally positive effect of the scarcity in forming preferences and behaviors in diverse contexts (See Lynn 1991 for a review). Yet, the research on the effect of a scarcity message in marketing communication context (e.g., advertising) is relatively limited and provides mixed results. The present research intended to examine the effect of a scarcity message in a persuasive marketing communication and the processes that underlie the effect. While doing so, we also identified moderating conditions for the effect that have not previously been reported.

Consumers often hear a company announcing a plan for limited production of special products for a special occasion or encounter a retailer announcing the limited number of items remaining in stock. As such, consumers are frequently exposed to information about the scarcity of a product or service. A scarcity claim in a persuasive marketing context is likely to elicit positive thoughts about the product such as enhanced quality and exclusiveness. Yet, the claim can also provoke a second, negative thought, i.e., suspicion about marketers' manipulative intent (i.e., persuasive attempt). To this extent, the effect of a scarcity message is largely dependent on whether the second thought is actively generated.

Based on the research on dispositional attribution (Gilbert and Malone 1995; Trope and Gaunt 1999) and persuasion knowledge (e.g., Ahluwalia and Burnkrant 2004; Campbell and Kirmani 2000), we expect that generating the second thought (suspicion about the persuasive intent) and acting on it is relatively an effortful and controlled process, and thus requires considerable amount of cognitive resources. Consequently, it is hypothesized that a scarcity message in marketing communication can produce a positive impact on consumer evaluations only in a situation in which the cognitive resource is limited so that inference processes regarding the marketer's manipulative intent in using the message are unlikely to operate. When the cognitive resource is available, inferences about the manipulative intent are likely to occur, which in turn reduce or eliminate any positive consequence of the scarcity message.

These expectations were examined and confirmed in two experiments. In experiment 1, participants received a promotion pamphlet for a MP3 player that contained either a scarcity or a non-scarcity message. In addition, the cognitive resource was manipulated (high vs. low) by providing a cognitively distracting vs. non-distracting secondary task (i.e., memorizing an 8-digit vs. 2-digit number) at the time participants process the target message. A significant two-way interaction of cognitive resource and message type on evaluations indicated that the scarcity message, compared to the non-scarcity message, led to more favorable evaluations of the target product only when the cognitive resource was distracted. In addition, an analysis of participants' perceptions about persuasive attempts also yielded a significant 2-way interaction effect, indicating that indeed participants who received a scarcity message were more suspicious about the marketers' manipulative intent under no distraction conditions than under high distraction conditions, whereas the suspicion level in the latter conditions were comparable to the level in the non-scarcity message conditions.

Experiment 2 replicated findings from experiment 1 and in addition, examined the two alternative possibilities regarding the

processes underlying the effect of the distraction task. The first, "discounting-inhibition" hypothesis posits that a distraction task inhibits discounting processes on target evaluations based on perceptions of the marketer's manipulative intent. The second, "activation-inhibition" hypothesis posits that the distraction task inhibits activation of persuasion knowledge per se from memory that is relevant to process the scarcity message. To examine these alternative possibilities, the persuasion knowledge was either primed or not before participants received the target information. Results showed that the effect of the cognitive distraction on the effectiveness of the scarcity message relative to the non-scarcity message was evidenced only when the persuasion knowledge was not primed. This supports the "activation-inhibition" hypothesis, suggesting that the effect of the distraction task was due to its influence on activation of persuasion knowledge rather than its influence on discounting process based on perceptions of the manipulative intent.

The Effect of Creative Mindset on Consumer Information Processing

Xiaojing Yang, University of Wisconsin-Milwaukee, USA
Torsten Ringberg, University of Wisconsin-Milwaukee, USA
Huifang Mao, University of Central Florida, USA
Laura Peracchio, University of Wisconsin-Milwaukee, USA

EXTENDED ABSTRACT

Framing of persuasive messages becomes an important topic for researchers and managers alike in recent years (Lee and Aaker 2004; Wheeler, Petty and Bizer 2005). However, there are disagreements in the literature regarding the effectiveness of message framing. Many researchers (Edwards 1990; Lee and Aaker 2004; Wheeler, Petty and Bizer 2005) maintained that messages framed in a way that is consistent with consumers' natural mode of processing (as determined by their personality, processing motivation etc.) are more appealing ("matching effect" of persuasion). By contrast, some other researchers found the reverse to be true ("mismatching effect" of persuasion). That is, sometimes consumers are more susceptible to messages that are framed in a way that is inconsistent with their natural mode of processing (Aaker and Williams 1998; Millar and Millar 1990). We posit that consumers' mindset at the time of processing messages will determine the effectiveness of message framing. Specifically, we expect that a creativity mindset could reverse the commonly observed "matching effect" of persuasion.

Existing literature reveals that when there is a match between the framing of the message and consumers' personality schemata, consumers are likely to feel comfortable when processing incoming messages because these messages are consistent with how they naturally think about issues. This has been described as "processing fluency (Lee and Aaker 2004)" and "processing readiness (Thompson and Hamilton 2005)." This subjective experience of processing fluency could in turn influence subsequent evaluations. Thus, more positive evaluations are formed. By contrast, when the framing of the message is inconsistent with how they naturally process information, consumers are likely to feel frustrated and thus negative evaluations about the issue will result. Another explanation for this "matching effect" is elaboration-based. For instance, Wheeler, Petty and Bizer (2005) found that if the message framing is compatible with one's self-schemata, consumers will scrutinize the message more carefully.

We posit that this "matching effect" is likely to occur when consumers are in their "normal/natural" processing mode, without some sort of internal or external disruptions. Prior research (Sassenberg and Moskowitz 2005) has demonstrated that priming people with "thoughtfulness" mindset can trigger their common associations with the target issue. In these circumstances, consumers automatically relate the messages in a way that is consistent with how they "naturally" process information. Under this logic, when there is a mismatch between the two (i.e. message framing and how consumers naturally think), consumers will find the message more difficult to process and thus form less favorable evaluations. Thus, mismatching appeals would be ineffective.

We expect the reverse to be true when consumers are in a creativity mindset. By definition, being "creative" implies that consumers should stay away from common solutions to an issue, and avoid activation of typical associations related to the issue at hand. Once primed to think "creatively", we posit that this activated mindset will affect consumers' subsequent information processing activities—we expect that consumers will prefer something different and novel from how they naturally process information. Since mismatching appeals are framed in a way that is inconsistent with how consumers naturally think about the issue, consumers may be

attracted to these novel and different appeals (Aaker and Williams 1998). Thus, we expect consumers should be more likely to elaborate on these "novel" messages, which ultimately affect their evaluations of the brand.

We examined this hypothesis across two studies in the context of mental construal (i.e., abstract vs. concrete thinking; see Trope and Liberman 2003). In both studies, we asked respondents to view an ad with different level of abstraction (abstract claim vs. concrete claim). We expect and found that when inducted with creativity mindset, abstract thinkers should find concrete (vs. abstract) ad claims more appealing, while concrete thinkers should be more susceptible to abstract (vs. concrete) ad claims, revealing a "mismatching" pattern. By contrast, when primed with thoughtfulness, abstract thinkers should find abstract (vs. concrete) ad claims more appealing, while concrete thinkers should be more susceptible to concrete (vs. abstract) ad claims, showing support for a "matching pattern."

Together, the results of study 1 and 2 indicate that consumers' mindset at the time of information processing is an important predictor of the "matching" or "mismatching" effect of persuasion. In line with conventional wisdom, when primed with thoughtfulness, consumers' common processing mode is reinforced and thus a "matching" effect of persuasion is observed. Specifically, respondents find messages that are consistent with their natural way of processing, as dictated by such factors as their personality, motivation or processing goals etc., more persuasive. By contrast, when we primed creativity, we found a "mismatching" effect of persuasion. That is, respondents are more susceptible to incoming messages that are inconsistent with their natural way of thinking.

Intention-Behavior Consistency: The Effect of Time Perspective

Muge Capar, Georgia Tech, USA

Koert van Ittersum, Georgia Tech, USA

EXTENDED ABSTRACT

Predicting future behavior is one of the central research topics in marketing and consumer research. Most of the theories developed to predict behavior, such as the theory of reasoned action (Fishbein and Ajzen 1975), the theory of planned behavior (Ajzen 1985, 1991), the model of interpersonal behavior (Triandis 1980), the theory of goal setting (Locke and Latham 1990), and the social-cognitive theory (Bandura 1977, 1998) propose that intention is the key predictor of behavior. Although intentions help predict behavior, there is often a substantial gap between people's intentions and their subsequent behavior—an intention-behavior inconsistency, meaning that people behave inconsistently with their intentions. To improve our understanding of the origin of this intention-behavior inconsistency, this research focuses on one of the key differences between intention and behavior: time. There is always a time interval between the formation or measurement of intentions and the performance of behavior. Despite the central role of time in the intention-behavior relationship, research that focuses on time-related aspects is scarce. Research has studied the effects of temporal distance and the characteristics of behavior (or the object of behavior) on people's decisions regarding future behaviors. In terms of intention-behavior relationship, in addition to the importance of temporal distance between intention and behavior, it is also important how the person approaches time. In order to fill this gap, we examine the effect of people's time perspective—a personality construct that reflects people's approach to past, present, and future—on the intention-behavior consistency. It is important to understand how this personality characteristic affects self-prediction of behavior in order to control for and correct errors in self-prediction so that more accurate and confident results can be obtained. Based on Zimbardo and Boyd's (1999) time perspective factors, we examine the effect of future, present-fatalistic, and present-hedonistic time perspectives on intention-behavior relationship in the concept of new product adoption. We hypothesize on the effect of these factors both on stated intentions, and intention-behavior consistency. We also hypothesize on the moderating role of attitude on these effects.

In order to test our hypotheses, we conducted an experiment with student subjects, in which we asked them their intention to pick up a stainless steel mug in a given time period in the near future, as well as measured their time perspective using Zimbardo Time Perspective Inventory. In the second part of the experiment we kept track of the participants that picked up or did not pick up the mug. To test the effects of these variables on stated intentions, we used logistic regression analysis with self reported behavioral intention as the dependent variable. Participants' attitudes towards the mug, the three time perspectives—present-hedonistic, future, and present-fatalistic, and the interactions between their attitude and the three time perspectives, were included as independent variables. To test the effects of the same variables on intention-behavior consistency, we again used logistic regression analysis with the intention-behavior consistency (0=inconsistent, 1=consistent) as the dependent variable. Those who followed through on their intentions (self-reported intention=yes; behavior is performed; self-reported intention=no; behavior is not performed) were classified as consistent, while those who did not follow through on their intentions (self-report intention=yes; behavior is not performed; self reported intention=no; behavior is performed) were classified as inconsis-

tent. Participants' attitudes, their time perspectives, and the interaction terms were included as independent variables.

We find that present-hedonism positively influences self-reported intentions, and this positive effect is strengthened by consumers' attitudes towards the mug. While we do not find a main effect for present-fatalism, we do find that the effect of present-fatalism on self-reported intentions is moderated by consumers' attitudes towards the mug. More specifically, consumers' attitudes towards the mug strengthen the negative influence of present-fatalism on self-reported intentions. We also find that people with high future time perspective are more conservative in stating their intentions and have a tendency to state lower intentions than individuals with a low future time perspective.

In line with their desire to achieve future goals, we find that more future-oriented individuals display a higher intention-behavior consistency. On the other hand, more present-oriented individuals tend to display a lower intention-behavior consistency. A strong orientation toward present pleasure, with little concern for future consequences, causes more present-hedonistic people to overstate their intentions, as a result of which they display a lower intention-behavior consistency. More present-fatalistic people display a lower intention-behavior consistency because of their hopeless attitude towards the future, which causes them to either overstate or understate their intentions. Furthermore, consumers' attitudes towards the mug moderate the effect of present-fatalism on the intention-behavior consistency—the more favorable consumers' attitudes, the weaker the relationship between present-fatalism and the intention-behavior relationship.

On Believing Our Imagination: The Role of Mental Imagery in Belief Generation and Resilience

Massimiliano Ostinelli, McGill University, Canada
Ulf Böckenholt, McGill University, Canada

EXTENDED ABSTRACT

Theoretical evidence suggests the existence of a deliberate and an implicit route to believing. Deliberate beliefs are purposively held through a validating frame (e.g., explicit argumentation or source credibility), whereas implicit beliefs are derived from spontaneous and nonconscious inferences generated by perceptual-like experiences (Sperber, 1997). This distinction is akin to the one discussed by Gilbert and colleagues (e.g., Gilbert, Krull, & Malone, 1990) concerning the Cartesian approach—which suggests that people mentally represent ideas and then decide whether to accept them as true or false—and the Spinozan approach—which suggests that, once encoded, ideas are automatically endorsed as true and deliberation is needed to discard them.

Drawing on this literature, we propose that imagery-provoking messages (e.g., narrative, imagery instructions) induce both deliberate beliefs—due to the strength of the arguments and/or the credibility of the source—and implicit beliefs—due to the experience of mental images generated by the message—, whereas abstract messages (e.g., product ratings, abstract messages) induce only deliberate beliefs. For example, an abstract consumer review stating that “dialing with this cell phone is a tiring, error-filled process” might be believed only deliberately (e.g., I trust the reviewer, therefore I believe that the phone is bad), whereas an imagery-provoking one, such as “the buttons of this cell phone are too small so our fingers are always pushing the wrong button” can, in addition to deliberate beliefs, lead to the generation of implicit beliefs due to the experience of mental images (e.g., a person experiencing difficulty while dialing a phone number).

Moreover, we propose that beliefs derived by abstract messages, being held deliberately, should be relatively easy to discard. Once the credibility or the arguments of the message has been questioned, there is no reason to purposely maintain these beliefs. However, implicit beliefs generated by mental images should be less affected by deliberate attempts to discard the content of the message. That is, once generated, the mental images of a product will affect product evaluation even when the message has been discounted as unreliable.

The advantage of imagery-provoking messages, however, holds to the extent that consumers are able and motivated to generate mental images. Therefore, factors undermining an individual’s willingness (or ability) to imagine might reduce the resilience of beliefs induced by imagery-provoking messages. One of these factors might be represented by consumers’ expectations about the credibility of a message. Being suspicious about the trustworthiness of a message should reduce consumers’ willingness to imagine product-related behaviors (e.g., why should I imagine something that is not true?). For this reason, the resilience of beliefs generated by imagery-provoking messages should be lower when discrediting cues (e.g. information about the credibility of the message) are provided before, rather than after, the encoding of the message.

Three studies were conducted to test our propositions. In Study 1, respondents judged imagery-provoking product claims as more believable than abstract ones, despite the fact that they were told that there was no “objective” reason to infer the believability of the product claims. Interestingly, almost 60% of the variability

in claim believability was accounted for by the average imaginability rating of product claims. Study 2 examined how product evaluation was affected by mental imagery generated by a message that was afterwards declared either credible or non-credible. Results showed that source credibility had a stronger effect on product evaluation among participants reporting low mental imagery than among those reporting high mental imagery. This finding suggests that respondents who reported high mental imagery kept holding positive beliefs about the product despite knowing that the message was unreliable. In Study 3, participants evaluated a restaurant after being presented with two contradictory reviews presented either in an imagery-provoking (i.e., narrative) or an abstract manner (i.e., product ratings). Results showed that impressions formed by imagery product reviews were more resilient to subsequent challenges than those formed by abstract ones. Study 3 also suggested that the resilience of imagery-provoking messages was lower when the contradictory review was provided before, rather than after, the encoding of the message.

By suggesting that imagery-provoking messages induce beliefs that are more resilient than those generated by abstract ones, this work contributes to the literature on beliefs generation and correction (e.g., Gilbert & Ebert, 2002; Gilbert, Gill, & Wilson, 2002; Johar & Simmons, 2000; Schul & Burnstein, 1985; Schul & Mazursky, 1990). Our findings have significant implications for marketing practice given that people often imagine consumption-related behaviors (e.g., MacInnis & Price, 1987; Petrova & Cialdini, 2007; Shiv & Huber, 2000) to form product impressions that might need to be adjusted or even discounted. Our results apply not only to the case of mental images prompted by messages that are later found to be unreliable, but also to cases in which consumers need to integrate contradictory evidence presented either in an imagery-provoking or abstract format (e.g., imagery-provoking ads vs. consumer reports).

The Effects of Imagery, False Memory and Experience on Attitude Confidence

Priyali Rajagopal, Southern Methodist University, USA
Nicole Montgomery, College of William and Mary, USA

EXTENDED ABSTRACT

Two key variables that have been little considered in the marketing literature on imagery are the creation of false memories and attitude strength. A false memory may consist of a mistaken belief that a fictitious event occurred (e.g., being lost in a mall as a child) or a distortion of an event that actually did occur (e.g., meeting Bugs Bunny at Disneyland instead of Mickey Mouse). Recent research in psychology (e.g. Mazzoni and Memon 2003) has suggested that imagery can lead to the development of false memories. Thus, imagery can make respondents incorrectly believe that an event was actually experienced by them.

Based on this stream of research, we suggest that if false memories are implanted through imagery, these false memories may exhibit some effects that are similar to genuine product experience. Past research in marketing has demonstrated that product experience leads to stronger attitudes as compared to attitudes that are based on indirect product experience such as exposure to advertising (e.g., Regan and Fazio 1977). If imagery results in a mistaken belief that consumers have direct experience with a product (i.e., false memory), then it follows that imagery and experience may have equivalent effects on attitude strength. Therefore, we propose that attitudes based on imagery-evoking information will be stronger than attitudes based on information that is not imagery-evoking due to the creation of false product experience memories following exposure to a high-imagery advertising message.

Study 1

Design: 2 (image-provoking ability of the ten ads: high-imagery vs. low-imagery) x 10 (different products) mixed design, with imagery as the between-subjects factor and the different products as the within-subjects factor with 100 undergraduate students.

Procedure: Respondents were given a series of 10 print advertisements and given 45 seconds to view each ad. One week following the presentation of the ads, respondents were asked to complete an online survey containing the dependent measures.

Dependent measures

False memory. We used two different measures of false memory. The first measure was a product usage memory measure wherein, participants were provided with a list of fifty brands, amongst which were the ten target brands contained in the series of ads. Respondents were asked to select all of the brands that they believe they had used at least once. For the second measure, five brands (two target brands and three filler brands from the list) were each presented to respondents with a series of three statements (“I have purchased this product,” “I have seen this product in local grocery stores,” “I have heard about this product from friends or family members”) and respondents were asked to select all statements that apply.

Attitude and attitude strength. Attitude was measured through the use of a four-item, seven-point scale (bad-good, negative-positive, unfavorable-favorable and undesirable-desirable). Attitude strength was measured using a three-item, seven-point scale (“how strongly do you hold the opinion about ___?”, “how confident are you in your opinion of ___?” and “how certain are you in your opinion of ___?”)

Results

There were no differences in self-reported involvement between any of the experimental conditions (all p -values $>.1$). There was no effect of imagery on attitudes towards the two target brands ($M_{\text{High Imagery}}=5.21$, $M_{\text{Low Imagery}}=5.02$, $F(1, 73)=0.75$, $p>.1$).

Attitude strength. There was a significant main effect of imagery on attitude strength towards the two target brands ($F(1, 73)=6.36$, $p<.05$). Respondents exposed to the high-imagery ads reported stronger attitudes ($M=6.01$) than respondents exposed to the low-imagery ads ($M=5.06$). Thus, H1 was supported.

Product Usage Memory. There was a significant main effect of imagery ($F(1, 73)=5.26$, $p<.05$) such that respondents that were exposed to the high-imagery ads selected more targets from the list on average ($M=2.50$) than respondents that were exposed to the series of low-imagery ads ($M=1.69$). Thus, H2 was supported.

Second memory measure. Respondents that read the high-imagery ads selected more false memory statements on average for each of the target brands ($M=1.14$) than respondents that read the low-imagery ads ($M=0.61$, ($F(1, 73)=13.20$, $p<.05$), supporting H2. There was not a significant difference between the two conditions in terms of the number of false memory statements selected for the filler brands ($p >.05$).

Mediation analysis. To test whether false memory mediated the effect of imagery on attitude strength, we conducted analyses in line with the procedure outlined in Baron and Kenny (1986). The following three relationships were established: (1): Imagery predicts attitude strength ($\beta=.28$, $p<.05$) (2): Imagery predicts false memory ($\beta=.39$, $p<.05$) and (3): When imagery and false memory are included as predictor variables, only false memory significantly predicts attitude strength ($\beta=.25$, $p<.05$) and imagery is reduced to non-significance ($\beta=.19$, $p>.1$). These results suggest that false memory fully mediates the effect of imagery on attitude strength.

Study 2

Design: 2 (direct product experience: yes vs. no) x 2 (imagery: high vs. low) between-subjects design with 113 undergraduate students.

Procedure: Respondents were exposed to the same set of 10 ads used in study 1 and were given 45 seconds to read each ad. Respondents in the no-experience condition then moved on to another study. Respondents in the experience conditions were informed that they would be given one of the advertised products to taste. The target product used in the study was Orville Redenbacher’s Blue Corn popcorn. Respondents were given half of a cup of popcorn to taste. Since the target brand was a fictitious brand, we used ACTII popcorn for the taste experience. One week after the experiment, respondents were contacted by e-mail and instructed to complete a survey online

Dependent measures: We measured false memory, attitude and attitude strength for the Orville Redenbacher popcorn using the same measures as in study 1.

Results

False memory. Planned contrasts revealed that in the no-experience conditions, there was a significant effect of imagery on false memory such that respondents that read the high imagery ads selected a significantly higher mean number of statements in the false memory measure ($M=.91$) than respondents that read the low

imagery ads ($M=4.6$, $t=1.97$, $p=.05$). In the product experience conditions, as expected, there was no effect of imagery on false memory. There were no main or interactive effects of experience and imagery on the false memory for any of the filler brands and none of the planned contrasts were significant (all p -values $>.1$). Thus, as expected, the false memory creation was specific to the target brand alone.

The two experience conditions did not differ significantly on any of the dependent variables (all p 's $>.1$) including attitude strength (supporting H3a), and hence we averaged the two experience conditions and conducted planned contrasts to test H3.

Attitude strength. In line with expectations, we found that the experience conditions elicited significantly higher attitude strength than the low imagery alone condition ($M_{\text{Experience}}=6.1$, $M_{\text{Low Imagery}}=4.41$, $t=3.59$, $p<.01$), supporting H3d. The high imagery-no experience condition also elicited significantly higher attitude strength than the low imagery-no experience condition ($M_{\text{High Imagery}}=5.40$, $M_{\text{Low Imagery}}=4.41$, $t=2.08$, $p<.05$), supporting H3b. The experience and high imagery alone conditions were not significantly different ($t=1.60$, $p>.1$), supporting H3c.

Attitude. In line with expectations, we found that attitudes towards the target brand were significantly higher in the experience conditions ($M=4.93$) as compared to the high imagery-no experience ($M=4.39$, $t=2.13$, $p<.05$) and the low imagery-no experience conditions ($M=4.31$, $t=2.22$, $p<.05$). There were no differences between the high imagery and low imagery no experience conditions ($p>.1$).

Our research contributes to the literatures in imagery, product experience, and false memory. We extend the effects of imagery to include attitude strength, a variable that has not been previously considered in the imagery literature. Contrary to much of the previous research on product experience, we find that experience only results in stronger attitudes than an ad if the ad is pallid; an extremely vivid ad leads to equivalently strong attitudes as experience. Further, we find that the effect of imagery on attitude strength persists for as long as one week, suggesting that the effect is strong. In addition to contributing to research on imagery, we extend the false memory literature by considering the effects of false memory on attitudes and attitude strength.

Mental Simulation and the Evaluation of New Products: The Affective and Cognitive Dimensions of Process- Versus Outcome-Focused Thoughts

Min Zhao, University of Toronto, Canada
Steve Hoeffler, Vanderbilt University, USA
Gal Zauberaman, University of Pennsylvania, USA

EXTENDED ABSTRACT

Really new products (RNPs) allow consumers to do something they have not been able to do before. In this research we identify a key difference between RNPs and INPs regarding the natural mental representation that is formed when consumers consider the product: a focus on the process of using the product versus a focus on the end benefits provided by the product. More importantly, we proceed to address the question of how process- and outcome-focused visualization can be applied to INP and RNP to enhance evaluations. Further, we explore the efficacy of each type of mental simulation to enhance evaluation under each specific information processing mode (i.e. cognitive and affective) for RNPs.

Natural Mental Representations

According to Hoeffler (2003), consumers have less knowledge and greater performance uncertainty for RNPs than for INPs. Recent work (Wood and Lynch 2001) showed that high prior knowledge leads to learning complacency and lower motivation for information processing. This suggests consumers may not consider all aspects of INPs due to lower motivation, while they may have a higher motivation to learn different aspects of RNPs (i.e. both product benefits and the adoption and usage process). In addition, past research suggests that consumers focus more on the benefits for products with low complexity, but could consider both benefits and learning cost for products with high complexity (Mukherjee and Hoyer 2001). Thus we predict that:

H1: While consumers will focus more attention on the benefits than the process of using a product for INPs, they will focus equally on both aspects when evaluating RNPs.

Process- versus Outcome-Focused Mental Simulation

Research in psychology has identified two distinct types of mental simulation: process simulation that is focused on the process of reaching a goal versus outcome simulation that is focused on the desirable outcome of achieving the goal (Taylor et al. 1998). Multiple studies show that process simulation is more effective than outcome simulation in facilitating goal attainment (e.g., Taylor et al. 1998) or behavioral intentions (Escalas and Luce 2003, 2004). However, recent work in the context of preference over time (Zhao, Hoeffler and Zauberaman 2007) has demonstrated that each type of simulation is more effective when it augments the mental representation of an event that is naturally neglected. Based on consumers' natural focus of INP and RNP, and the complementary role of mental simulation in terms of activating the naturally less accessible considerations, we suggest that:

H2: While process simulation increases evaluations more than outcome simulation for INPs, the effect of process and outcome simulation will not differ for RNPs.

Impact on RNPs: Cognitive vs. Affective Processing Mode

To explore the potential effect of mental simulation on the evaluation of RNP, we reviewed the mental simulation literature

and argue that the existing literature in mental simulation has either confounded process and outcome simulation with cognitive and affective components (i.e. process simulation with a cognitive focus vs. outcome simulation with an affective focus (Taylor et al. 1998)), or incorporated both cognitive and affective components into process and outcome simulation (Escalas and Luce 2003, 2004). Our approach here is to tease apart the cognitive and affective processing focus and investigate the unique effect of process and outcome simulation on the evaluation of RNPs under each type of processing. We predict that:

H3: When evaluating RNPs under a cognitive focused processing mode, outcome simulation leads to higher product evaluations than process simulation; whereas the reversal is true under an affective focused mode.

Experiments and Findings

In experiment 1, we asked participants to read a mock ad for an INP (ThinkPad) or a RNP (AudioPC) and indicate how much they thought about the process of using the product and how much they thought about the end benefits of using the product. The results showed that participants naturally made more thoughts about the end benefits than about the process of using the product for INP. However, they indicated similar amount of thoughts about both aspects for RNP. H1 was confirmed.

In experiment 2, we examined the role of classic process and outcome simulation (i.e. combined focus on both the cognitive and affective components) on the evaluation of new products. We asked participants to practice either a process-oriented (i.e. visualizing the steps of using the product) or outcome-oriented (i.e. visualizing the benefits of using the product) mental visualization task after they read the ad. The results showed that for INPs, process simulation indeed led to higher product evaluation because it activated the naturally ignored thoughts regarding the process of using the product. However, for RNPs which naturally evoked thoughts about both the product benefits and the process of using, the effect of process and outcome simulation on product evaluation did not differ. This supported H2.

In study 3, we tested the specific effect of process and outcome simulation on the evaluation of RNP by teasing apart the effect of cognitive vs. affective processing mode. Participants performed either a process-focused or outcome-focused visualization task that emphasized either the cognitive or affective components. The results indicated that under a cognitive processing mode, outcome simulation increased product evaluation more, whereas under an affective mode, process simulation was more effective than the opposite type of simulation. This provided support for H3. In addition, we found a partial mediating role of performance uncertainty on this pattern.

Conclusion

Our research centers on the role of mental representations in new product evaluation. Our findings provide better understanding to this important and complex question by showing the differential effects of process and outcome simulations, and by showing the role of affective and cognitive considerations in the different effective-

ness of these two types of simulations. We further identified performance uncertainty as a mediator. We believe that our research provides some answers to the open questions about new product preference development, and well as open questions about the exact nature of different types of mental simulations and their effectiveness.

Visual Inferences and Advertising Spending in Political Marketing

Michael Lewis, Washington University in St. Louis, USA

JoAndrea Hoegg, University of British Columbia, Canada

EXTENDED ABSTRACT

This paper explores how advertising spending and candidate appearance influence Congressional electoral outcomes. Our analyses reveal that campaign spending and visual inferences about candidate personality traits significantly predict vote share, but these factors have asymmetric effects across the major parties.

Introduction

Political campaign managers are increasingly utilizing marketing tools, and spending on political advertising is growing rapidly (Teinowitz 2004), yet political campaigns have received little attention within marketing. Our research considers the role of two marketing variables in political campaigns: product appearance, (i.e. the physical appearance of the candidate) and advertising spending strategies. In particular we explore how the role of party brand image and incumbency moderate the influence of these factors in political campaigns.

Background

Candidate Appearance and Impression Formation

Almost all products are subject to visual inferences that arise out of initial exposure when reactions can result in an established attitude before other information is considered. For political candidates, where visual contact with the candidate is often solely through short news clips or advertisements, personality inferences based on brief visual exposure may be critical. Research has demonstrated how personality inferences based on photographs of political candidates can influence elections (Todorov et al. 2005). Todorov et al. had study participants make relative personality judgments of U.S. Senate and Congressional candidates based solely on their photographs. Results indicated that the appearance of competence was highly predictive of electoral success.

The results of Todorov et al. (2005) are striking but may be incomplete. Because political parties function like brands in that they strive to develop distinct positions, such stereotypes likely differ across party. Thus, the visual qualities that mean success for a Republican may differ from those that mean success for a Democrat. We investigate this possibility.

Advertising Spending

We also consider the role of advertising spending. A consistent finding in prior research on campaign spending is that while challenger spending is found to influence vote shares, spending by incumbents usually has a statistically insignificant effect. The main explanation is that much like an early market entrant, incumbents start with advantages in awareness, which impacts the marginal effects of advertising investments. In contrast, challengers often start from a point of relative anonymity, so marginal spending has a greater effect. We examine this effect and also consider whether asymmetries exist across political party.

Finally we explore effects of advertising tone to see whether the effectiveness of negative advertising is altered as a function of incumbency and political party. As the later entrant into the market, challengers may gain relatively more by employing negative ads that highlight familiar deficiencies in their competitors because they enable alignable comparisons. On the other hand, negative advertising by incumbents that emphasizes the risk of switching to the challenger may be relatively more effective. Party affiliation may also have an effect. Given that political parties have estab-

lished brand images and distinct positions, negative advertising may be differentially effective for Democratic versus Republican candidates.

Data

We obtained personality judgments based on candidate photographs for 112 congressional races from 2000 and 2002. Participants were presented with photographs of the two main candidates side by side, labeled "Candidate A" and "Candidate B" (picture position counterbalanced). Participants provided relative ratings on four personality trait questions (competence, intelligence, likeability, and trustworthiness), each on a seven-point scale from "Candidate A looks much more [intelligent]" to "Candidate B looks much more [intelligent]."

Advertising tone data was obtained from the University of Wisconsin's Political Science Department, which has compiled a database containing information on elections in the top 75 media markets in 2000 and the top 100 markets in 2002.¹ The database includes information on whether campaign ads were primarily positive or negative in tone, as well as estimated costs for each airing. We use the estimated costs and tone judgments to calculate the percentage of negative advertising used by each candidate. In addition, we use campaign fundraising and spending statistics from the Federal Election Commission.

Results

We first conduct an analysis of only the visual inference data for Democrats and Republicans. As predicted, the results suggest that the various visual assessments operate differently for the two parties. Republicans benefit from being perceived (visually) as more competent and trustworthy. Appearing more likeable or more intelligent has negative effects. The pattern is strikingly reversed for Democrats.

In the second stage of the analysis we examine the relationships between candidate spending, advertising tone and vote shares. Consistent with results in the political science literature, we find spending for challengers has a significant positive impact but for incumbents has a negligible effect. We also find that spending on negative advertising by Republican challengers is found to be significantly more effective than for Democratic challengers.

As a final step we use the personality inferences data and the spending data in a combined model. We find that spending levels and candidate appearance both significantly influence election results. Including the spending variables and the visual effects in a single model provides an opportunity to quantify the value of inferred personality traits. For example, a Republican incumbent gains the same benefit in vote share from a competence appearance

¹The data were obtained from a project of the Wisconsin Advertising Project, under Professor Kenneth Goldstein and Joel Rivlin of the University of Wisconsin-Madison, and includes media tracking data from the Campaign Media Analysis Group in Washington, D.C. The Wisconsin Advertising Project was sponsored by a grant from The Pew Charitable Trusts. The opinions expressed in this article are those of the authors and do not necessarily reflect the views of the Wisconsin Advertising Project, Professor Goldstein, Joel Rivlin, or The Pew Charitable Trusts.

advantage of .1 as from shifting from a spending ratio (incumbent spending to total spending) of .5 to .56. If the Democratic challenger is spending the average of \$450,000 this represents an incremental investment of approximately \$115,000.

Discussion

Our research extends previous work in political marketing by examining how party brand image moderates the effectiveness of certain marketing variables in political campaigns. We show that visual inferences of candidate personalities have asymmetric effects on elections across the parties. We also extend research on the effectiveness of negative advertising by showing that effectiveness varies by party and incumbency. Future research is needed to understand the drivers of these asymmetries.

Mellowing Skeptical Consumers: An Examination of Sponsorship Linked Advertising

Sarah J. Kelly, University of Queensland, Australia
T. Bettina Cornwell, University of Michigan, USA
Leonard V. Coote, University of Queensland, Australia

EXTENDED ABSTRACT

The current research examines a communication form, namely sponsorship-linked advertising, having arisen since Friestad and Wright (1994) developed their persuasion knowledge framework. Sponsorship, defined as "...investing in causes and/or events to support overall corporate objectives and/or marketing objectives" (Cornwell 1995 p.15) has developed into a mainstream communications approach in the last two decades. Sponsorship-linked advertising has emerged as a way to leverage sponsorship relationships. It is also often misappropriated by event ambushers and thus has an interestingly complex relationship with the potential development of skepticism.

Cognitive psychology theory is used to propose a model of consumer response to sponsorship-linked advertising, in terms of underlying information processing dynamics. The theoretical model used is novel in that it incorporates skepticism and attributed advertiser motives as important resistance mechanisms to persuasion. The results obtained from experimental research support the existence of widespread consumer skepticism toward advertising generally, and a propensity for consumers to infer attributions on advertiser motive depending upon contextual cues both within and ancillary to ads. Moreover, differential processing of sponsorship-linked advertising is confirmed, such that sponsorship-linked advertising is associated with more favorable cognitive outcomes, including more positive thoughts, less ad skepticism and more favorable attributions. Results support existing conceptualizations of consumer skepticism which suggest that it may be transitory, depending upon contextual cues. This study contributes to sponsorship research by offering empirical evidence of favorable consumer response to sponsorship-linked advertising, suggesting that it is a viable leveraging tool. Moreover, consumer behavior research is advanced, with the study gaining insight into the complex relationship between persuasion attempts and skepticism. Interestingly, results imply that consumers may actually derive enjoyment, or at least feel less skepticism when viewing sponsorship linked ads as compared to non sponsorship linked ads.

Consumers' Response to Advocacy Advertising: A Process Model of Consumer Skepticism, Empathic Response, and Prosocial Behavior

Robert Madrigal, University of Oregon, USA
Johnny Chen, University of Oregon, USA
Monica LaBarge, University of Montana, USA
Namika Sagara, University of Oregon, USA

EXTENDED ABSTRACT

Advocacy ads are often produced by organizations wishing to promote a particular position on an issue. These ads typically feature a call to action such as asking consumers to write letters to public officials, donate money, protest, volunteer, or boycott a company's products. Advocacy ads are expected to be most effective when they create an emotional response in consumers that is premised on feelings of empathy for the affected parties. We build on Escalas and Stern (2003) by exploring in greater detail the process associated with empathic response. We contend that consumers' empathic emotional reactions will reflect a mixture of discrete emotions that directly predict related to a set of active coping behaviors aimed at attenuating the stressful situation. Implicit in the hypothesized model is the ability of empathy to mediate the influence of sympathy on each emotion. We also expect that each emotion will mediate the direct effect of empathy on active coping.

We propose a hierarchical model in which consumers' skepticism (ad credibility and inferences of manipulative intent) toward an advocacy ad influences their empathic response (i.e., sympathy and empathy) toward the affected parties featured in the ad which then, in turn, predicts specific empathic emotions (anger, hope, worry, and guilt). Both are considered antecedent to empathic response because if it is unlikely that viewers will have sympathetic feelings to an ad if they believe the ad is not credible and/or if they consider it to be manipulative (Cotte, Coulter, and Moore 2005).

Two studies examine an empathic hierarchy and subsequent coping responses. In study 1, blame (people vs. oil company) and self-blame (moderate vs. high) were manipulated to elicit empathic responses. Structural equation modeling was used to assess the fit of the proposed model to the data. The hierarchical model provided an excellent fit to the data ($\chi^2=38.82$, $df=34$, $p=.26$; $RMSEA=.022$; $SRMR=.04$; $CFI=.99$). Two alternative models were examined. The first was identical to our final model except that the positions of empathy and sympathy were reversed. The model tests for the possibility that reactions to the ad affect feelings of empathy initially and that this then predicts sympathy which, in turn, influences the discrete emotions. The resulting model provided a very poor fit to the data ($\chi^2=147.61$, $df=34$, $p<.001$; $RMSEA=.12$; $SRMR=.093$; $CFI=.90$). We also considered the sequence reported by Bagozzi and Moore (1994) having each discrete emotion (hope, worry, guilt, and anger) related directly to empathy, and empathy predicting active coping. This sequencing resulted in a poor fitting model ($\chi^2=69.45$, $df=24$, $p<.001$; $RMSEA=.095$; $SRMR=.11$; $CFI=.93$).

The primary purpose of the study 2 was to replicate the findings in study 1 using a different set of stimuli. In study 2, appeal type (emotional vs. cognitive) and peer advocacy (single vs. group) were manipulated. First, the ad either made an emotional or cognitive appeal. People may be moved to action due to the effects of either appeal type, yet little is known about how these approaches are likely to influence consumers' empathic responses. Second, past research has shown that people are more likely to help a victim represented as a single person than a group (Kogut and Ritov 2005; Slovic 2007), but nothing is known about a single versus multiple

endorsers of an issue. In addition, we examined two related concepts thought to influence empathic responses. First, respondent sex was included as a predictor in study 2 as prior research has assumed that women show greater empathy than men (Argo, Zhu, and Dahl 2008). Second, humanitarianism-egalitarianism (HE) was also considered as a predictor. HE is concerned with the "ideals of equality, social justice, the concern for others' well-being" (Katz and Hass 1988, 894) and is thought to contribute to people's coping behavior and feelings.

The overall structural configuration of the model in study 2 was consistent with study 1 except that two additional latent variables (HE and Gender) had been introduced and allowed to load across all endogenous variables. The resulting model provided excellent fit to the data ($\chi^2=581.40$, $df=205$, $p<.001$; $RMSEA=.038$; $SRMR=.069$; $CFI=.99$) and also replicated our initial findings and lend support to our proposed model that describes the underlying relationship between consumer skepticism, feelings, and coping behaviors.

The current research expands our knowledge of the processes underlying consumers' empathic response to advertising and its consequences. We focused on advocacy advertising because of its reliance on connecting emotionally with consumers. Results indicate that respondents' skepticism toward an ad directly affects their empathic response which, in turn, gives rise to a set of discrete empathic emotions that each individually predict specific actions aimed at coping with the situation. Our results support the temporal sequence outlined by Escalas and Stern (2003). Consistent with their view, we found that a model specifying a direct effect from sympathy to empathy outperformed one in which those effects were reversed. Moreover, significant indirect effects of sympathy on each emotion through empathy were found. Our results also indicate that the influence of empathy on active coping is mediated by each of the empathic emotions. Finally, we also contribute to the research on empathy by providing an alternative to the variable sequencing reported by Bagozzi and Moore (1994). In contrast to their hypothesized ordering, we found that our model predicting an empathy→emotion→coping sequence provided a better fit to the data than their emotion→empathy→coping hierarchy.

Consumer Expectations and the Automatic Shifting of Standards in Brand Evaluations

Claudiu Dimofte, Georgetown University, USA

Johny Johansson, Georgetown University, USA

EXTENDED ABSTRACT

Biernat, Manis, and Nelson (1991) developed a schematic model of a “shifting standards effect” to explain the process by which prior, schema-based expectations can influence the word-based ratings elicited from respondents. Their SSE model proposes that recourse to commonly used stereotypes will change the meaning of subjective scales for respondents and thus shift their evaluative scores. This shift will not occur for objective scales. Biernat et al. (1991) empirically tested the model in the context of judgments about the financial success of several profiled men and women. When actual dollar figures for annual income were used as scale units, the resulting target ratings reflected the judges’ more objective knowledge (i.e., factual beliefs) confirming the stereotype that males earn more than females. However, when word-based scales were used (anchored by *financially very unsuccessful* and *financially very successful*), judges differentially adjusted the meanings of the anchors for the two genders, rating the same profiled women as more successful than the same men. The subjective scales effectively reversed the well-known income stereotype (Biernat et al., 1991). Briefly put, we seem to relax our evaluative standards for stimuli associated with lower expectations, and in the process “cut them some slack.”

In applying the SSE model to marketing research, we are testing whether marketing scales evaluating consumer response to brands might also exhibit the biases described by Biernat et al. (1991). This is an important issue, as at the core of consumer marketing lies the intent to differentiate the company or its brands from similar offerings in the marketplace on one or more evaluative dimensions. Applying the propositions of the Shifting Standards Model to the case of numerical and word-based brand ratings, we should be able to trace the shifting effect of brand expectations on consumer response.

Our starting point is the notion that when two brands evoke differing expectations of performance on some dimension, the observed differences in performance evaluations on that dimension may depend on the type of scale employed (i.e., numerical or word-based). Thus, product quality expectations for Japanese and U.S. electronics brands will likely favor the former, such that, compared to U.S. brands, Japanese brands are expected to be of higher quality. If the SSE model is correct, we should find instances when numerical judgments reveal this expectation, whereas more subjective, word-based judgments do not. Thus, under a scenario where consumers expect brand A to be superior to brand B, the following should occur:

H1: The use of subjective judgment standards (inherent to word-based measures) will automatically shift consumers’ reported evaluations in accordance with prior brand expectations. Given the posited scenario, brand A will be judged as superior to brand B on a numerical scale, but this difference will be attenuated in word-based units.

The next hypothesis involves the precise explanatory account and proposed automatic nature of the hypothesized shift. We propose that the shifting standards effect derives from an internally generated, implicit anchor (i.e., the associated expectation). Further, when word-based scales are used to elicit the ratings, individuals engage in an unconscious corrective process that leads to

attenuation of expectation-based differences. If true, this automatic component of the SSE could be captured by measures of implicit cognition. Formally put, using the same “A superior to B” scenario:

H2: Consumers will show weaker automatic associations with favorable attributes for brand B than for brand A. However, this difference will be less pronounced after responding to word-based rating scales than after responding to numerical rating scales.

Our results suggest that a common but unconscious consumer cognitive response to brand information may significantly impact the measured differentiation. Whereas more objective, numerical scores would indicate a sustainable differentiation between two brands along a particular dimension, more subjective, word-based responses may in fact show the very same brands to be virtually indistinguishable. This anomalous inconsistency was shown to originate in consumers’ use of different evaluative standards for high and low expectations brands. In word-based judgments, evaluative standards are automatically more relaxed for the brand associated with lower expectations, allowing it to match its competitor’s advantage. Study 1 established the effect in the context of expectations related to brand extension fit. Studies 2a and 2b uncovered the automatic nature of the shift by actually measuring the automatic adjustment of standards (i.e., comparative anchors) for word-based scales both directly and indirectly. Finally, study 3 eliminated the shifting effect by bringing this cognitive heuristic into individuals’ awareness.

We also presented results that suggested a way to prevent consumers from making these automatic adjustments. By framing the word-based scales explicitly against respondents’ expectations, we showed that it is possible to prevent the unconscious shift and to obtain the same ratings as for the numerical scales. In a sense, this manipulation and objective scales in general appear to induce what cognitive psychology terms a confirmation bias, whereas subjective scales avoid this bias and instead induce another—the SSE.

EXTENDED ABSTRACT

The purpose of this paper is to develop a revised and more psychometrically sound version of the Maximization Scale (Schwartz et al. 2002) that would enhance the use of the scale among behavioral researchers across several of the social science disciplines. The research presented in this paper is based on an analysis of both pre-existing datasets and new data. The pre-existing data consist of 12 pre-existing datasets, representing a total of over 5,800 respondents, were obtained from several authors, across several disciplines, in both the U.S. and overseas, who have used the Maximization Scale in their research. The new data were collected in three studies: (1) a questionnaire administered to academic researchers (n=8) regarding the content validity of the Maximization Scale; (2) a survey among a general population sample (n=40) regarding readability of the individual scale items; and (3) an experiment in the domain of financial decision making among a sample of adult participants (n=176) that tested both the new and original versions of the scale.

In this paper we conduct four sets of analyses. In *Analysis 1* we examine 10 pre-existing datasets containing the Maximization Scale in order to confirm the factor structure of the scale, assess its internal consistency and dimensional purity, and reduce the number of items. Based on these analyses we conclude that some of the scale's psychometric properties are unsatisfactory. In *Analysis 2* we employ both pre-existing data (10 datasets) and new data (n=48) in order to develop revised versions of the Maximization Scale (9-item, 6-item, and 3-item versions). In the process of revising the Maximization Scale, we follow a set of rules and procedures consistent with past work (Richins 2004; Smith, McCarthy, and Anderson 2000; Stanton et al. 2002), which rely on internal, external, and judgmental criteria. Next, we evaluate the discriminant and nomological validity of the newly developed revised scales by relating them to existing constructs—anticipated regret (Schwartz et al. 2002), subjective happiness (Lyubomirsky and Lepper 1997), satisfaction with life (Diener et al. 1985), and optimism (Scheier, Carver, and Bridges 1994). In *Analysis 3* we cross-validate the three shorter versions of the scale employing 12 pre-existing datasets. We use both internal and external criteria in order to confirm their dimensionality, reliability and validity. Finally, in *Analysis 4* (n=176) we experimentally examine the revised scales' predictive validity and look into the relationship between consumers' maximizing tendencies, as measured by the revised Maximization scales, and their information processing and

choices in an investment decision context. In this study we also measure several additional traits that are expected to be related to maximization to see whether maximization can predict consumers' decision-making beyond these other related variables. We measure regret, happiness, satisfaction with life, and optimism, mentioned above, as well as depression (Cole et al. 2004), perfectionism (Hewitt and Flett 1990), and need for cognition (Cacioppo and Petty 1982).

Based on results from our analyses of reliability, predictive, and nomological validity, and model fit, we conclude that the revised 6-item Maximization Scale exhibits superior psychometric properties as compared to the other versions of the scale we tested, namely, the original 13-item scale and the 9-item, and 3-item scales. The 6-item scale possesses good internal consistency and superior model fit as compared to the other two scale versions. Furthermore, it possesses good validity: its nomological net is similar to that of the original 13-item scale and its validity correlations, i.e. correlations with related traits, are more consistent with our predictions and past literature than those of both the 9-item scale and the original scale. The 6-item scale's predictive validity, as indicated by its capacity to distinguish between the decision-making processes of maximizers and satisficers in an investment decision making context, was also superior to that of the other two scale versions.

In this paper we also define and examine the three dimensions of maximization and conclude that the scale consists of three sub-dimensions—'high standards', 'alternative search', and 'decision difficulty', which converge on a higher-order latent construct. In our analysis we examine not only consumers' summed maximization scores, but also their scores on the three scale sub-dimensions. Our results suggest that the three dimensions of maximization might be differentially predictive of various consumer traits and behaviors. Therefore, we recommend that future researchers examine not only consumers' maximization scores but also their sub-dimension scores.

Past research has found a clear tendency for maximizers to report being significantly less happy, less satisfied with life and with their choices, and more depressed than satisficers (Iyengar, Wells, and Schwartz 2006; Schwartz et al. 2002). Our results build on these findings and suggest that the real problem with maximizing is not having high standards (as this dimension was not correlated with depression, satisfaction with life, or happiness), but rather, having high standards in a world of limitless alternatives, which demands extensive search and creates decision difficulty. It seems that the source of maximizers' psychological trouble is the need to search extensively and make difficult decisions, and not their tendency to set high standards for themselves.

The present research contributes to the existing literature on maximization in several important ways. First, we reduce the Maximization Scale length by more than half (from thirteen to six items), while improving its psychometric properties. There is growing interest in the maximization construct on behalf of researchers in areas such as social psychology, positive psychology,

¹The authors gratefully acknowledge support for this research provided by a generous grant from the FINRA (formerly NASD) Investor Education Foundation (#2005-08). The authors would like to thank Tilottama Chowdhury, Samuel M.Y. Ho, Matt Wallaert, Rachael E. Wells, and the authors of the original Maximization scale—Barry Schwartz, Andrew Ward, John Monterosso, Sonja Lyubomirsky, Katherine White, and Darrin R. Lehman for generously providing their datasets for the analysis in this paper.

and consumer psychology. The shorter revised Maximization Scale proposed in this paper will provide these researchers with a measure of the construct that is brief, yet reliable and valid. Second, we show that the revised 6-item scale possesses very high predictive validity, since it was uniquely capable of differentiating between the information processing and decision making patterns of maximizers vs. satisficers in an investment decision-making situation, after controlling for several other related constructs. Third, we assess the Maximization Scale's dimensionality, and define and examine the three scale sub-dimensions. Our results suggest that the three dimensions are related to different traits, and researchers should examine people's scores on the three maximization sub-dimensions in addition to their summed maximization scores.

Having a shorter, yet more valid and reliable instrument with which to measure people's tendency to maximize should enhance research efforts examining how consumers' tendencies to maximize or satisfice during the choice process affect their decisions and choices and ultimately their happiness and well-being.

Deception at a Distance: How and When Does Temporal Distance Affect Persuasion Knowledge Activation?

Ryan Rahinel, University of Minnesota, USA
Norman O'Reilly, Laurentian University, Canada

EXTENDED ABSTRACT

Friestad and Wright (1994) theorize that consumers acquire persuasion knowledge over the lifespan. Such knowledge structure contains beliefs about the ways by which marketers and other persuasion agents attempt to persuade consumers and how consumers cope with these persuasion attempts. Researchers have theorized that when a consumer perceives a marketing agent to be appealing to psychological factors that the consumer believes to mediate persuasiveness (e.g., attention, emotion), the agent is perceived to be engaging in persuasive activities and the current (and, to some extent, future) encounters are evaluated by the consumer in this light (Friestad & Wright, 1994). At this point the consumer engages in one or more coping strategies to deal with the persuasion attempt (Kirmani & Campbell, 2004) and the consumers' persuasion knowledge is said to be activated. This entire process of persuasion knowledge activation has often been shown to result in decreased evaluations of the stimuli, product, brand, and even future messages by the brand (Main, Dahl, & Darke, 2007; Kirmani & Zhu, 2007; Wei, Fischer, & Main, 2006; Campbell & Kirmani, 2000). This research builds on previous work in persuasion knowledge by focusing on situations in which consumers are engaged in non-imminent (i.e., temporally distant) purchase decisions and where message cues vary in terms of the product feature mentioned in the persuasive message.

Conceptually, we draw on the work in Construal Level Theory (CLT) to arrive at our hypotheses. CLT argues that when events or objects are temporally distant, physically far, less like ourselves, or less probable, we tend to think about (and therefore describe) them in terms of their more abstract, stable, and general features (Trope, Liberman, & Wakslak, 2007). In other words, we form a high-level construal of the subject. Conversely, when events or objects are imminent, physically closer, more like ourselves, or more probable, CLT argues that we tend to think about and describe them in terms of their detailed, less stable, and peripheral features (Trope et al, 2007). That is, we engage in low-level construal. One implication of this is that we tend to focus on the primary features of a product when the purchase decision is temporally distant, but on the secondary features when the purchase decision is imminent (Trope & Liberman, 2000). Based on this, we arrived at three hypotheses. H1 suggests that a temporally distant purchase decision will lead to significantly higher persuasion knowledge activation and perceived ad deceptiveness than a temporally proximal purchase decision, but only when the product feature mentioned in the persuasive message cue is a primary feature. When the product feature mentioned in the persuasive message cue is a secondary feature, no differences will be present. H2a followed by suggesting that a temporally distant purchase decision will lead to significantly lower product and brand evaluations than a temporally proximal purchase decision, but only when the product feature mentioned in the persuasive message cue is a primary feature. When the product feature mentioned in the persuasive message cue is a secondary feature, no differences in product and brand evaluations will be present. Further, H2b suggests that the negative relationship between the temporal distance/product feature interaction effect and brand attitude will be mediated by persuasion knowledge activation.

We conducted a 2 (product feature mentioned: primary or secondary) X 2 (temporal distance: proximal vs. distant) experiment using 167 undergraduate students who were randomly assigned to treatments. The first page of the instrument package was a scenario in which subjects were told to imagine either that they would like to buy a digital camera *today* (temporally proximal) or *one year from now* (temporally distant), just before they leave to go on vacation to Europe. In both conditions, subjects were then asked to imagine browsing through a magazine *today*, and while doing this, encountering the advertisement on the following page of the package. The one-page print advertisement was for a new digital camera manufactured by a fictional brand named Eylum. The second claim in the advertisement was highly deceptive in reporting either that the studies conducted by Eylum found that the LCD screen used by the Eylum e2000 was of higher quality than the LCD screen used by Canon (secondary feature condition) or studies conducted by Eylum found that the lens used by the Eylum e2000 is of higher quality than the lens used by Canon (primary feature condition).

Controlling for factors such as depth of processing and previous individual differences in importance of lenses vs. LCD screens, we find full support for H1 and H2a, and partial support for H2b. With regard to H1, there was a significant interaction effect on both persuasion knowledge thoughts (measured by coding thoughts of suspicion) ($p < .04$) and perceived ad deceptiveness (measured as three likert items: truthfulness, believability, and non-deceptiveness) ($p < .05$). Most importantly, while there were no differences between respondents in the secondary feature conditions, temporally distant subjects reported more persuasion knowledge thoughts and more perceived ad deceptiveness than temporally proximal subjects (Persuasion Knowledge Thoughts: $p < .01$; Perceived Ad Deceptiveness: $p < .02$). Consistent with H2a, we found no main effects but significant interaction effects on product quality (measured as five likert items: quality, reliability, performance, stylishness, and produces sharper pictures) and brand evaluations (measured as three likert items: likeable, appealing, favourable) (both $ps < .02$). Again, while there were no differences between the secondary feature treatments, we found differences between the primary feature treatments for both measures (both $ps < .02$). For H2b, we attempted two mediation analyses first using persuasion knowledge thoughts as the mediating variable and then using perceived ad deceptiveness as the mediating variable. Results showed that only perceived deceptiveness moderated the relationship between the temporal distance/product feature interaction and brand attitudes, providing evidence that the mediating role of persuasion knowledge operates via an automatic process.

Physiological Arousal Mediates the Persuasive Impact of Positive Peripheral Cues in Threatening Communication

Zhenfeng Ma, University of Ontario Institute of Technology, Canada
Laurette Dubé, McGill University, Canada

EXTENDED ABSTRACT

Threat-related communication, such as health communication, is often processed in stressful contexts. For recipients under stress due to perceived threat, a desirable objective of health communication is to increase recipients' self-efficacy beliefs. We review a psychophysiological perspective of stress and the excitation transfer theory to propose how physiological arousal, above and beyond affect, can mediate the impact of positive peripheral cues (PPC) in threatening communication on recipients' self-efficacy beliefs.

Hypotheses

Research from various domains suggests that stress is a psychophysiological process that concurrently involves psychological (e.g. negative affect) and physiological responses (Ursin and Eriksen 2004; Ledoux 1995). Physiological responses include autonomic response such as increased skin conductance, and endocrine response such as increased salivary cortisol. Because the various psychological and physiological components of stress are mediated by relatively distinct neural pathways, they may each uniquely predict consumer behavior or attitude under stress.

Based on the framework of mediation analysis proposed by Kraemer et al. (2002), we propose that physiological arousal meet the essential criteria as the mediator of the persuasive impact of PPC. Specifically, physiological arousal can 1) occur during the communication exposure and be influenced by communication cues; 2) have a direct or interactive effect on the persuasive outcome. Research has shown that for individuals under stress, positive stimuli can alleviate psychological distress and physiological arousal (Fredrickson and Levenson 1998; Berk et al. 1989). For such individuals, PPC may function as safety signals which convey the presence of safety or the absence of threat, thereby leading to improved psychophysiological wellbeing. It can be expected that for recipients under stress due to perceived health threat, PPC in threatening communication can decrease physiological arousal and negative affect. However, such stress-buffering impact of PPC may be negligible for recipients in normal contexts, as the safety-signal value for these individuals will be minimal. We thus hypothesize:

H1: Relative to threatening communication featuring no positive peripheral pictures, threatening communication featuring positive peripheral pictures reduces psychological distress and physiological arousal among recipients who have undergone prior stress due to perceived threat, but not among recipients in normal contexts.

We further posit that physiological arousal, in addition to affect, may have unique impact on persuasion. The excitation transfer theory (Zillmann 1971) argued that physiological arousal resulting from a prior nontrivial event decays relatively slowly and often remains operative after the individual has physically withdrawn from the stimulus. Because people generally do not distinguish between the portions of arousal that are due to prior stimuli and those caused by present stimulation, they may misattribute their residual arousal from prior episodes to an attitude object that is

immediately present. In the context of health communication, when the communication is presented without PPC, recipients may misattribute their lingering arousal to their low self-efficacy beliefs ("I must feel bad because I lack confidence in the information."). On the contrary, when the communication is presented with PPC, the negative misattribution may be attenuated due to mitigated psychological distress and physiological arousal. It is even possible that the recipients may misattribute their improved psychophysiological wellbeing to their enhanced self-efficacy. Thus, for recipients who have undergone a prior threat, PPC in threatening communication may mitigate the negative impact of residual physiological arousal on self-efficacy beliefs, or may even transform arousal and distress from a negative impact into a positive influence on persuasion. Thus we hypothesize:

H2: Positive peripheral pictures in threat-related communication mitigate or reverse the negative impact of psychological distress and physiological arousal on self-efficacy beliefs among recipients who have experienced prior stress.

Methods

We tested the research hypotheses through an experimental study of a 2 (stressful vs. non-stressful contexts) by 2 (cue-present vs. cue-absent communication) between-subject design. Eighty healthy women (mean age=58 ± 7.8) from the local community participated in this study. We first manipulated prior stress via a mental imagery task pertaining either to a high- or low-threat scenario, and then asked participants to browse a consumer health information website that either used PPC or did not use PPC. Physiological responses (skin conductance, heart rate variability and salivary cortisol) and affect during both the mental imagery and web-browsing tasks were recorded. Self-efficacy beliefs were measured after the web-browsing task as an index of persuasive outcome.

Results and Discussion

The stressful imagery task induced higher autonomic and endocrine responses, as well as high negative affect relative to the non-stressful task. Thus the stress manipulation was successful. A series of ANCOVAs showed that the PPC-present website decreased psychological distress and physiological arousal, but increased positive affect among participants who had undergone a prior threat, but not among those in the non-stressful condition. Thus H1 was supported.

Based on Kraemer colleagues' (2002) framework for mediation and moderation, our analysis showed that for participants who had gone through the stressful imagery task, PPC mitigated the negative impact of psychological distress and autonomic responses on self-efficacy beliefs. Further, for those participants, PPC turned physiological responses from a negative impact into a positive influence on self-efficacy beliefs. Further, the physiological pathway to persuasion was more evident in the stressful versus normal context. Overall, for participants who had undergone health threat, PPC enhanced persuasion by either mitigating or reversing the negative impact of psychological distress and physiological arousal on self-efficacy beliefs. Thus H2 was supported.

This study provided initial evidence that communication cues can interact with both affect and physiological arousal to determine the persuasive outcome. The physiological arousal revealed an important mechanism that can not be captured by self-reported affect. Future research can examine the impact of physiological processes on consumer behavior and decision making in a variety of different settings.

EXTENDED ABSTRACT

Substantial research has investigated individual differences in consumer information processing, such as gender (Meyers-Levy and Maheswaran 1991), involvement (Petty, Cacioppo, and Schumann 1983), and cultural orientation (Aaker and Maheswaran 1997). For example, males' information processing is more likely to be influenced by overall message themes or schemas whereas females' processing involves detailed elaboration of message content (Meyers-Levy and Maheswaran 1991). Few studies, if any, have examined the influence of optimism on consumer information processing in response to advertising.

For the past two decades, optimism has been investigated extensively in the areas of social, personality, and clinical psychology. Most of the previous research in psychology examined how optimists and pessimists process information and cope with a variety of situations that they face in their daily life, including chronic illness and major life transitions (Aspinwall, Richter, and Hoffman 2001). Optimism has gained increasing attention and been applied in consumer contexts. In the consumer finance area, previous research has examined how optimism influences consumers' financial behavior, such as consumers' investment in individual stocks, savings behavior, and economic decision-making, (Puri and Robinson 2007). Moreover, studies found that optimism is negatively related to maximization. That is, more optimistic consumers feel worse off as their options increase (Schwartz, Ward, Monterosso, and Lyubomirsky 2002). In marketing, research indicated that optimism has significant and unique influence on consumer shopping behavior (Kahle, Shoham, Rose, Smith, and Batra 2003). However, little has been known about how optimism impacts consumers processing ad information.

In addition to replicating the findings in the previous research that optimists and pessimists adopt different information processing styles in consumer contexts, the purpose of this research is to investigate the impact of optimism on brand attitudes in response to advertising. According to Craik and Lockhart's (1972) levels of processing theory, we propose that message relevance would determine the information processing styles that optimists/pessimists adopt. Moreover, the processes underlying the effects are examined.

Two experiments were designed to examine the moderating role of optimism on consumer information processing. The first experiment investigated the relationship between dispositional optimism and consumers' responses to advertising information, and further explored the effects that underlie this process. The second experiment provided a conceptual replication of experiment 1 by manipulating situational optimism and replicated the findings observed in experiment 1.

In experiment 1, two versions of ad message relevance (high and low) and two versions of ad format (comparative and noncomparative) were manipulated. We hypothesized that when the ad message is low in relevance and presented in a noncomparative format, optimists evaluate the advertised brand more favorably than pessimists. In contrast, when the ad message is low in relevance and presented in a comparative format, pessimists evaluate the advertised brand more favorably than optimists. We hypothesized a different pattern of when the ad message was highly relevant. In

high relevant ad message conditions, pessimists were expected to evaluate the advertised brand more favorably than optimists when the ad format is noncomparative while optimists evaluated the advertised brand more favorably than pessimists when the ad format is comparative. The results were consistent with our predictions. Examination of thought measures provided additional support for the hypotheses.

Experiment 2 replicated findings in experiment 1. In addition, optimism was manipulated with two social situational scenarios instead of being measured as we did in experiment 1. Most of our predictions were supported. Examination of thought measures also provided additional support for the predictions.

Taken together, these two studies support most of our proposed theorizing about how optimism and message relevance affect consumers' brand attitudes in response to comparative advertising. This research suggests that optimists use global information processing whereas pessimists use local information processing when the ad message is low in relevance. Different processing modes were used when the ad message is highly relevant. When messages are highly relevant, optimists adopt rational information processing styles while pessimists adopt experiential information processing styles. This research demonstrated that optimists and pessimists have different levels of focus when processing irrelevant and relevant ad information. The results illustrate the underlying process of how optimists and pessimists process ad information.

From a managerial standpoint, this research has implications for advertising efforts. Specifically, when advertisers adopt comparative advertising, they should take the individual difference variable, optimism, into considerations. This research also enhances our understanding of how different processing styles of optimists and pessimists impact their brand attitudes in response to comparative advertising.

Relational versus Group Collectivism and Optimal Distinctiveness in a Consumption Context

Robert Kreuzbauer, University of Illinois at Urbana-Champaign, USA

Shengdong Lin, Sun Yat-Sen University, China

Chi-Yue Chiu, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

Across various research in cross-cultural consumer psychology as well as social psychology the probably most widely used framework to study differences how people feel, think and behave in different cultures is the individualism–collectivism distinction. However, the individualism–collectivism distinction has recently been conceptually and methodologically criticized from various researchers (see Brewer & Chen, 2007). In order to reduce these shortcomings Brewer & Chen (2007) have introduced a new theoretical framework conceptualization of individual, relational and collective selves. They protect individualism as a reliable and useful construct for the study of cross-cultural differences of various aspects, however within collectivism they make a distinction between relational (*relational collectivism*), and collective levels (*group collectivism*) of self-definition which embody two distinct forms of self-representation. Relational collectivism refers to aspects where the self is defined in terms of connections and role relationships to significant others whereas group collectivism occurs when the social self is defined as a depersonalized social category.

Although in every society people must be able to satisfy both individual and collective needs, that is, no culture, group or society is per se ‘individualistic’ or ‘collectivistic’. This view is also consistent with optimal distinctiveness theory (ODT; Brewer, 1991) which asserts that individuals desire to attain an optimal balance of connectedness and distinctiveness *within* and *between* social groups and situations. The goal of this article is to demonstrate that consumers from Western cultures use different strategies to satisfy their need for connectedness or belongingness (i.e. the collective need) than consumer from East Asian cultures. The main prediction of ODT is that social identity is driven by two basic social needs, the need for assimilation or connectedness with a group and the need for distinctiveness, that is, perceiving oneself as a unique and independent individual. These two motives are in constant opposition with each other; when there is too much of one motive, the other must increase in order to counterbalance it and vice versa. Whereas distinctiveness or uniqueness is a common element that most companies try to achieve with their brand images and which has also been extensively researched since in consumer science, ODT so far has only received little attention. This is insofar surprising as several of the most successful commercials and brand provide a balanced image between both distinctiveness and belongingness. A well known example would be the Apple brand which on the one hand provides distinctiveness from Microsoft, but on the other hand creates a feeling of being connected to a group of highly creative and freaky consumers.

Extending these thoughts we believe that consumers from different cultures are also likely to choose different strategies to achieve optimal distinctiveness. Consistent with the framework of relational and group collectivism, it seems plausible that when activating the need for belongingness Westerners tend to satisfy this need through group collectivism whereas Easterners rather focus on relational collectivism.

To test this hypothesis, we conducted two experimental studies where subjects from one US and one Chinese university had to evaluate consumption scenarios that asked subjects to personalize products such as cell phones, laptops, back bags etc. Each scenario contained three choice options: With option one, subjects could

personalize the respective product by putting a picture or symbol on the product that expresses their personality. Option two and three offered them to express their personality by putting a picture or symbol on the product that shows either their family or their university. The first study was designed to compare the responses between the different ethnic sample types (European Americans, Asian Americans and Chinese). In the second study we tested how the subjects’ responses might differ when their need for distinctiveness or belongingness is manipulated through a deceived feedback procedure (one group was informed that their personal values would substantially differ from those of their colleagues (to activate need for belongingness), the other group was informed that their personal values were very similar to those of their colleagues (to activate distinctiveness need)).

Consistent with our hypotheses, we found that Chinese subjects preferred the relational over group collectivism choice option, that is, they would rather personalize their products with a picture or symbol from their family than from their university, whereas European American subjects showed the opposite preference. However, in both studies we could not find any significant differences between Asian Americans and other ethnic subject types and we did also not find any significant cross-cultural differences regarding the individualism choice option (i.e. whether they want to personalize the product with their own picture). Here further research is needed in order to get a better understanding of these findings. In study two, we again found evidence for the fact that Chinese show a clear preference towards the relational collectivism option. In addition to that, this study revealed that Chinese consumers change their choice behavior when their need for belongingness is activated. That is, when Chinese subjects have been brought into a situation of overly distinctiveness and therefore into an increased need for belongingness (in accordance with ODT) their preference shifts towards the relational choice option. This manipulation did not have any significant effect on their preference towards the group collectivism choice option (i.e. personalize the product with a University symbol).

The contribution of this article is twofold. First, it provides a first empirical proof of the recently suggested framework (Brewer & Chen, 2007) of relational and group collectivism in a consumption context. This shows that Westerners achieve collectivism rather through group collectivism whereas Easterners prefer to rely on relational collectivism. The second contribution is the extension of this approach towards optimal distinctiveness theory, that is, when their need for belongingness is activated, Easterners achieve an optimal level of distinctiveness through relational collectivism, whereas Westerners tend to be rather ambivalent between the two collectivism choice options. This research therefore contributes to a better understanding of the collectivism concept in cross-cultural consumption.

“Accept a Gift or Reject it? That is Not A Simple Question”: A Cross-Cultural Study of Gift Acceptance and the Mediating Role of Feelings of Appreciation and Indebtedness

Hao Shen, The Chinese University of Hong Kong, China

Fang Wan, University of Manitoba, Canada

Robert S. Wyer, Jr., Hong Kong University of Science & Technology, China

EXTENDED ABSTRACT

People often share a consumption experience with others. For example, they have dinner with friends at a restaurant or share a taxi ride. After doing so, one of the parties might offer to pay the bill. What factors determine whether the others accept the offer or insist on paying their share?

The present research investigated cultural differences in reactions to a gift or favor and, therefore, the likelihood that it is accepted or refused. In conceptualizing these differences, we assumed that people typically have both positive and negative reactions to a gift. That is, they normally have feelings of appreciation but also feel obligated to reciprocate. The likelihood of accepting a gift may depend on whether the feelings of appreciation for the gift outweigh the negative feelings of indebtedness that are likely to result from its acceptance. To this extent, cultural differences in the likelihood of accepting a gift may be the result of differences in the relative magnitude of these anticipated affective reactions. Asians, for example, are more inclined than North Americans to be concerned with the social norm of reciprocity (Hofstede 1980; Singelis 1994). Consequently, they may anticipate feeling more indebted if they receive a gift and less inclined to accept it.

Experiments 1 and 2 confirmed the existence of a cultural difference in the likelihood of accepting a gift in two different consumption situations. In Experiment 1, Hong Kong and Canadian participants imagined a scenario in which they shared at taxi with a friend and the friend offered to pay the fare. We found that Hong Kong participants were less willing to accept this offer than Canadians were. Experiment 2 replicated the results of the first experiment using a different scenario. In addition, we found that Asians were not only less likely than Canadians to accept a gift, but also expect others to be less willing to accept a gift from them.

Experiment 3 provided further evidence of this difference and confirmed our assumptions underlying it. In particular, Asians were more likely than North Americans to attribute the offer of a gift to ulterior motives and, as a result, were less appreciative. At the same time, Asians anticipated feeling relatively more indebted if they accepted the gift.

The first three experiments confirmed the general cultural difference between Asians' and North Americans' willingness to accept a gift and the feelings of appreciation and indebtedness that underlie this difference. However, the magnitude of these reactions can depend on a number of situational factors that influence perceptions of the gift-giver's motives. Experiment 4 investigated how cultural different in gift acceptance was moderated by the age of gift giver.

In experiment 4, Hong Kong and Canadian participants imagined being offered a gift from either a student who had just entered the university or a senior who was about to graduate. Upperclassmen were assumed to have higher social status in the eyes of Hong Kong participants than in the eyes of Canadians. We therefore expected that Hong Kong participants would report feeling less indebted if they received a gift from a senior than if they received a gift from a first year student, whereas this difference would be less evident among Canadian participants. To this extent, the effect of the gift-giver's age on acceptance of the gift should be greater

among Hong Kong participants. The result of experiment 4 was consistent with this assumption.

Individuals who are concerned about being indebted are likely to keep track of the benefits they give and receive (Fong 2006). Thus, they feel disinclined to accept favors from a person that are greater than those they have given to the person in the past. (Cialdini 2001; Greenberg 1980). If this is so, and if Asians are more sensitive than North Americans to feelings of indebtedness, differences in the relative magnitude of the benefits they give and receive may have a relatively greater impact on their gift acceptance. Experiment 5 investigated this possibility by looking at actual gift acceptance behavior.

In experiment 5, the experiment was conducted at the student center of a Canadian university. The center was frequented by Chinese students from mainland China because it hosted courses in English as a second language. Students were randomly approached and asked to complete either a long (10-minute) or short (1-minute) survey. After doing so, participants were offered candy bars as a gift, being urged to take as many as they wished. We expected that Chinese participants would base the number of candies they selected on their perception of the benefit they had provided the experimenter (that is, the length of the questionnaire they had completed), and would avoid taking candy that would make them feel indebted. Thus, they were expected to take fewer candies if they had completed a short questionnaire than if they had completed a long one. In contrast, we expected North Americans to be less concerned about feeling indebted and that the amount of candy they took would be less dependent on the length of the questionnaire they had completed. These assumptions were confirmed by the data of experiment 5.

The studies we have reported provide one of the first demonstrations of a cultural difference in gift acceptance. Moreover, they provide insight into the reason why this difference occurs.

Ptolemy vs. Copernicus: Self-Construal and Social Consumption

Sarah G. Moore, Duke University, USA
Gavan J. Fitzsimons, Duke University, USA

EXTENDED ABSTRACT

Copernicus was the first astronomer to suggest that the Sun, not the Earth, was the center of the universe. Despite initial controversy, his theory prevailed, displacing the Earth from its central location. On a non-cosmic level, the self-construal literature demonstrates that individuals differ in how they define themselves relative to others in their social universes. Interdependent individuals, whom we refer to as Copernican, define themselves in terms of relationships, such that their sense of self includes others in their social world (Markus and Kitayama 1991). Independent individuals, following Ptolemy, define themselves as autonomous, such that the center of an independent individual's universe is himself.

While past research has examined individual consumer decisions in great detail (Bettman, Luce, and Payne 1998), the study of social consumption contexts where consumers observe and respond to others' choices (Ariely and Levav 2000) or make choices for others (Botti, Iyengar, and Orfali 2008; Pöhlmann, Carranza, Hannover, and Iyengar 2007) has been relatively neglected, despite its ubiquity in everyday life. Little work has focused on how individuals respond to others' choices independent of their own, how individuals respond to making choices for others, or how well they perform this task. We investigate how individuals respond to others' choices and how they make choices for others, and propose that self-construal (Singelis 1994) is a fundamental moderator of how individuals react and behave in social consumption contexts.

Interdependent individuals are sensitive to others even when making self-choices and are comfortable having others choose for them (Pöhlmann et al. 2007), and thus should be sensitive to others' needs and preferences whether observing, predicting, or making choices on behalf of others. Conversely, independent individuals should display a Ptolemaic view of social consumption that leads to a self-focus and a concomitant neglect of others whether observing, predicting, or making choices for others. These two points of view lead to a paradox: while interdependents are well calibrated about what others would do and make better choices for others, they do so at an emotional cost. In social consumption, self-construal creates a double-edged sword that balances sensitivity for others with protecting the self. In four studies, we consider how self-construal influences observation, prediction, and choice in social consumption.

In Study 1, we examine how individuals respond to observing others' choice outcomes independent of their own. Using a restaurant scenario, we find that independent individuals respond more strongly to personal service failures (not getting what they ordered) than to the same service failure experienced by a friend, in terms of dissatisfaction and negative emotion. Interdependent individuals do not distinguish between self and other service failures, and respond equally negatively whether they or their friend had a poor choice outcome.

Study 2 considers how well independent versus interdependent individuals predict what others would do in different decision contexts. Consistent with Study 1, we find that independent individuals' predictions about others' actions are biased by their self-focus. Independents predict that their friends will ask their advice more often than they would ask a friend's advice; this is particularly pronounced in difficult choice situations. Interdependent individuals show no such bias. Similarly, independents, unlike

interdependents, fail to recognize that others will respond as strongly as they will to a negative outcome, and underestimate others' emotional responses in addition to mispredicting their choices.

Studies 3 and 4 examine active choice on behalf of others. In Study 3, we evaluate how closely individuals adhere to their friend's preferences and investigate a moderator that impacts adherence. We find that independent individuals default to ignoring their friend's preferences and choose a friend's preferred option less often than interdependents. However, when their freedoms are threatened by a recommendation against their friend's favorite option, independents do choose this option—but do so in order to re-assert their freedom. Interdependents default to choosing a friend's favorite option, but move away from the choice upon receiving a recommendation against the friend's option because they are unwilling to inflict potentially negative outcomes on their friend. Corroborating these results, independents who receive no recommendation are quite happy, while individuals in the other conditions experience more negative emotion—independents because their freedom was threatened, interdependents because they feel responsible for choosing for others.

Finally, in Study 4, we allow individuals to decide whether they want to choose for others and investigate a moderator of willingness to choose. We use closeness as a proxy for self-construal: individuals who feel less (more) close to others should mirror independents (interdependents). Consistent with a Ptolemaic self-focus, non-close individuals are most likely to choose for others, and feel more satisfied and happier with their choices. However, when the stakes are high (when there are serious health consequences for making a choice), nobody is willing to choose for others. When the stakes are high enough, even independent individuals feel responsibility for choosing on behalf of others, close or distant.

In the context of social consumption, then, is it better to have a self-focused (Ptolemaic) or an other-focused (Copernican) point of view? While the Copernican point of view is probably best if one wishes to avoid being excommunicated by one's friends, it is the more emotionally difficult path to follow. Interdependent (Copernican) individuals are better calibrated about how others would make decisions, and make decisions that are closer to others' preferences. However, these other-focused individuals also respond more negatively if others come to grief in their choices, and suffer more negative emotional reactions when they choose for others.

'Fit for Charity': The Moderating Role of Private Self-Focus in the Persuasiveness of Regulatory Fit

Marieke L. Fransen, University of Amsterdam, The Netherlands

Bob M. Fennis, Utrecht University, The Netherlands

Kathleen D. Vohs, University of Minnesota, USA

Ad Th. H. Pruyn, University of Twente, The Netherlands

EXTENDED ABSTRACT

In a world full of societal problems such as hunger, homelessness, illiteracy, and diseases, the need for charity support cannot be exaggerated. Many individuals already engage in volunteering and donate money to charity (Giving USA foundation 2007), but fundraisers have to keep up and continue advocating for more attention, effort, and donations to support their cause. Previous research on the determinants of charitable behavior has primarily focused on either demographic and individual characteristics of the volunteers and donors (e.g., Matsuba, Hart, Atkins 2007), or on the persuasive techniques that are used by charities to convince people to help (e.g., Cialdini and Goldstein 2004). However, what happens when these two components meet? Is a charity appeal more persuasive when its motives and values are framed in congruence with the (potential) volunteer's motivating strategies? The present research proposes that the interaction between either individual or situational differences in regulatory focus on the one hand (Higgins 1997) and the framing of a persuasive message on the other, can influence whether and to what extent people are willing to involve in charitable behavior. In addition, it is expected that these regulatory fit effects on charitable behavior are stronger for individuals with a high private self-focus because these individuals are especially affected by external information that is optionally relevant for the self (Hull et al. 2002). It is argued that private self-focus increases the activation of self-knowledge making it easier to process information that fits with this activated self-knowledge (i.e., regulatory focus).

Regulatory Focus Theory (Higgins 1997) states that there are two distinct mechanisms to regulate judgments and behavior, labeled promotion and prevention focus. When individuals are concerned with their ideal self, they adopt a promotion focus. This focus involves an eager strategy in the pursuit of hopes, wishes, and aspirations. On the other hand, when individuals are concerned with their ought self, they adopt a prevention focus which entails vigilant strategies to fulfill duties, obligations, and responsibilities. Individuals experience regulatory fit when they use goal pursuit strategies that match their (current) focus orientation, which in turn increases the perceived value of their behavior. Previous research on regulatory fit in the domain of advertising has demonstrated that individuals show more persuasion when an advertisement is framed in line with individuals' current orientation focus than when an advertisement mismatches with individuals' regulatory focus (e.g., Aaker and Lee 2006; Cesario, Grant, and Higgins 2004). In recent studies, the effects of regulatory fit on product evaluations and other types of outcome measures have been explained by the process of 'processing fluency': the experienced ease of processing or recalling information (e.g., Labroo and Lee 2006; Lee and Aaker 2004). These studies show that information that fits with one's regulatory focus is processed more easily than information that does not fit, and is therefore evaluated more positively. Extending on the processing fluency account for regulatory fit effects one could argue that regulatory fit effects are stronger for individuals with a high private self-focus. This is based on work by Hull and colleagues on the relation between private self-focus and information processing (Hull and Levy 1979; Hull et al. 2002). They propose

that a state of high private self-focus (i.e., attentiveness to one's inner state, personal history or any other aspect of oneself) primarily relates to the encoding of information in terms of its self-relevance. They argue that private self-focus has an effect on behavior by enhancing sensitivity and responsivity to aspects of the environment that are (potentially) relevant to the self. High private self-focus is proposed to facilitate processing of external information in self-relevant terms. More specifically, a state of high private self-focus enhances processing of self-relevant stimuli by activating knowledge about the self (Geller and Shaver 1976). We propose that especially information that already fits with stored self-knowledge (i.e., information that fits with current regulatory focus) will be easily related to the self by consumers high in private self-focus. This implies that charity appeals framed in promotion terms are easily perceived as self-relevant to consumers with a promotion focus, and charity appeals framed in prevention terms are easily perceived as self-relevant to consumers with a prevention focus. Hence, we expect that individuals high in private self-focus (as opposed to low in private self-focus) experience greater processing fluency when they accept information that fits with stored or activated self-knowledge. The misattribution of processing fluency is subsequently expected to positively influence attitudes and actual behavior.

In a series of three studies, in which participants were presented with charity information that either matched or mismatched their regulatory (promotion or prevention) focus, we tested our hypothesis that consumers engage in greater charity support when there is fit than when fit is absent. Moreover, we expected that the effects of regulatory fit are stronger for consumers with a high (as opposed to low) private self-focus. As predicted, the results demonstrated that consumers with a promotion focus donate more money to charity (studies 1a and 1b), and have a more positive attitude towards the charity (study 2) when the charity describes its goals in eager terms (aimed at attaining positive outcomes; promotion frame) than when vigilant terms (aimed at preventing negative outcomes; prevention frame) are used. The opposite was found for consumers with a prevention focus. Moreover, we found evidence for the moderating role of private self-focus. The three studies revealed that the aforementioned regulatory fit effects were stronger for individuals with a high (as opposed to low) private self-focus. Furthermore, the results demonstrated that processing fluency is the underlying mechanism accounting for the role of private self-focus (study 2).

Charities could take advantage of this knowledge by framing their message in congruence with receivers' (current) regulatory mechanism to make consumers experience fit. Moreover, this strategy would be especially fruitful when consumers are focused on their private selves because the present results show that particularly high private self-focused consumers donate more to charity when they experience fit. The focus on oneself may thus result in enhanced motivation to help others rather than -what might be intuitively expected- to merely serve the self. Hence, when advocating for charity it might be advantageous to remind consumers of themselves before asking to support another cause. In this way consumers can relate the charity information more easily to them-

selves, especially when this information is framed in congruence with consumers' individual regulation strategies.

The “I” of the Beholder: The Impacts of Gender Differences and Self-Referencing on Charity Advertising

Chun-Tuan Chang, National Sun Yat-sen University, Taiwan
Yu-Kang Lee, National Sun Yat-sen University, Taiwan

EXTENDED ABSTRACT

With decreasing governmental support for social services, requests for charitable donations have become more frequent over the past decade. How to maximize the responses among public contributors is an important arena in the marketing of non-profit organizations (NPOs) especially when the fund-raising competitions among NPOs are fierce. To date, research that has attempted to better elucidate the relationship between charity promotion and donation behavior has focused largely on cognitive mechanisms to increase compliance rates of donation solicitation. The researched mechanisms include foot-in-the-door techniques, visual aids, and request size. Less attention is directed toward examining how to frame charity messages effectively.

Charitable donations can be promoted through altruistic-value framed messages (e.g., “As a caring person, you are going to do something good to others in need”) or egoistic-value framed ones (e.g., “As a successful person, you are going to do something good to protect your future”) with the same goal (i.e., donation behavior promotion). Framing messages with these two main motives (altruistic and egoistic) for helping can be different between men and women. This article contributes to this evolving stream of research by applying framing concepts in promoting charitable campaigns to demonstrate that message framing might not be equally persuasive in all conditions, and could be moderated by two variables in social psychology: gender role and self-referencing. Gender roles can be an important determinant of reactions to charitable appeals that indicate donations either helps oneself (i.e., egoistic advantages) or someone else (i.e., altruistic benefits). How individuals process information by relating to the self-concept, is also relevant for charity advertising research. The current research tests the idea that responses to charitable appeals could be influenced by gender differences, and examines whether charitable information differently framed in a message would modify the effects of gender differences. How should advertisers frame a message for promoting a charitable donation? Should they frame the donation message as egoistic or altruistic appeals? Will self-referencing affect responses to egoistic versus altruistic appeals? Are the impacts of gender differences and self-referencing additive or multiplicative in influencing consumer attitudes toward donation promotion and inducing compliance with a request?

Influences of self-referencing in the relation between gender differences and charity framing appeal on advertising effectiveness were explored in a 2 (gender: female vs. male) X 2 (charity framing appeal: egoistic vs. altruistic) X 2 (self-referencing: low vs. high) factorial design. Self-referencing was manipulated through the nature of a NPO. The experiment was conducted through the Internet. Potential participants received an email invitation to participate in the study through a highlighted hyperlink to instantly access the designed website. Respondents were informed to evaluate a poster that would be launched for a forthcoming charitable campaign regarding the importance of making personal donations. They were then randomly exposed to one of the four treatment versions by viewing a designed poster. Finally, respondents continued to complete a questionnaire containing post-manipulation measures and manipulation checks, and clicked the “submit” button.

After successful manipulation checks, a series of analysis of variance were conducted to examine proposed hypotheses. The

results support the general proposal that advertising effectiveness depends on complicated interrelationships among gender differences, charity framing appeal, and self-referencing. Specifically, the altruistic appeal results in more favorable intention than the egoistic appeal for the female audience, with the results reverses for the male counterparts. This lends qualified support to the phenomenon of *value congruity* (Brunel and Nelson, 2000; Supphellen and Nelson, 2001) in a charitable communication context. Contradictory to conventional wisdom (e.g., Block, 2005; Meyers-Levy and Peracchio, 1996; Shavitt and Brock, 1986, high self-referencing is not found to be always prevailing. The results further suggest that compared with women, men are more likely to be influenced by self-referencing. Self-referencing has a multiplicative impact on consumer attitudes toward donation promotion and behavioral intention when gender differences are considered.

Most importantly, we find that the interaction effect of gender differences and charity framing appeal can be attributed to and are moderated by different degrees of self-referencing. When the values delivered in the ad are accessible and easily activated by self-referencing techniques and match well with message claims, women are expected to resonate with altruistic claims that label them as caring because of socialization forces that encourage women to focus on others’ welfare, and men are expected to resonate with egoistic claims that label themselves as successful because of the traditional male role. It appears that if the charity framing appeal fits the social role of audience member, it should motivate that person to behave in an appeal-consistent manner. As such, self-referencing can be an explicit form of conveying values in terms of gender differences if they match with the social nature of the audience member. The results reflect previous studies in that when activated values are self-relevant, assimilation effects may occur in line with gender expectations (Aaker and Williams, 1998; Nelson et al., 2006). However, our research challenges these views and shows that the effects of value congruity do not always have a positive impact. In fact, the opposite could occur in the absence of self-referencing. When self-referencing is low, the congruence between gender and charity framing appeal may cause a boomerang effect on advertising persuasion of charity message. This is true for both women and men encountering a donation solicitation by a NPO which is perceived as a charity providing low self-referencing needs. The altruistic appeal becomes more effective to men, but the egoistic appeal is more effective to women. It could be due to that people rely on the heuristic cue in information processing when self-referencing is low. The framing appeal depicting the opposite traditional gender social role could catch more attention in serving a heuristic cue.

This study provides important insights into social psychological influences of gender differences and self-referencing that occur when charitable donation messages are pitched to the public. How an individual being socially perceived, and how he/she perceives a NPO would determine the effectiveness of two major framing appeals. Different types of NPOs should employ appropriate framing appeals, depending on the audience member’s gender. When individuals perceive a NPO as having a higher level of self-referencing, the effects of the “I” of the beholder (i.e., congruence between the gender and the message theme) may facilitate advertising

persuasion. Conversely, when facing a NPO with a lower level of self-referencing, the “I” may be determined by how a charity message is framed (egoistic vs. altruistic). In short, incongruity between the gender and message theme lead to higher advertising effectiveness.

Social Value Orientation as a Moral Intuition: Decision-Making in the Dictator Game

Gert Cornelissen, Universitat Pompeu Fabra, Spain
Siegfried Dewitte, Katholieke Universiteit Leuven, Belgium
Luk Warlop, Katholieke Universiteit Leuven, Belgium

EXTENDED ABSTRACT

The types of consumer decisions studied by social marketers often have a social dilemma-type structure. They involve a conflict, either between pursuing the collective interest (e.g., avoiding environmental degradation by buying eco-friendly laundry detergent or by using public transport rather than one's own car) and one's personal interest (e.g., buying a cheaper non eco-friendly laundry detergent or the comfort and flexibility of taking one's own car), or between one's delayed self-interest (e.g., eating a healthy salad and a piece of fruit as a snack) and one's immediate self-interest (e.g., eating a pizza, and a chocolate mousse for desert). We studied the decision-making process in such situations in which self-interest conflicts with the collective interest. Based on the findings, we propose some public policy recommendations for the promotion of social desirable, or social responsible consumer behaviors.

In this context of social dilemmas, *social value orientation* (SVO) is a heavily studied concept (e.g., Van Lange et al., 1998; e.g., Mark Van Vugt et al., 1995). It categorizes people according to preferred patterns of outcomes between the self and others in interdependence situations. Commonly used categorizations distinguish people who are cooperators, individualists, or competitors. Cooperators (or pro-socials) prefer to maximize group outcomes and equality in outcomes. Individualists and competitors (or pro-selfs) prefer to maximize personal outcomes. Van Lange, De Bruin, Otten, and Joireman (1997b) argued that these tendencies develop during our lifetime through experiences with interdependence situations. The analogy with moral intuitions, which, according to Haidt (2001), are automatically activated moral judgments that develop through social and cultural interactions, made us expect that these social value orientations may be automatically activated preferences for pursuing the public interest versus pursuing the self-interest.

This idea contrasts with the commonly held believe that pursuing the self-interest is an automatically activated goal (van den Bos et al., 2006), and that engaging in pro-social (consumer) behavior requires some kind of cognitive operation. We hypothesized that this would be true for pro-selfs, but not for pro-socials. On the other hand, we expected that if decisions would be based on a more elaborated thinking process, pursuing the self-interest would be a salient motive for all people. We attribute this to the fact that behaving selfishly has become a social norm in our society (Miller, 1999) and that private costs and benefits are more salient than public costs and benefits (Rothschild, 1979; Warlop et al., 2003) when thinking about outcome distributions.

A series of four studies, in which Dictator Games were played as a simulation for decision making in real life social dilemmas (like consumers' conflicts between pursuing collective or private interests), supported these hypotheses. In a Dictator Game two participants are paired. One of them receives an amount of money and is instructed to divide the money between himself and his partner. The size of a dictator's "donation" is a measure for cooperation level, or the degree to which one is motivated to pursue the collective interest. We showed that decisions to pursue the collective interest are the result of a two-step process. In an initial, automatic and intuitive step, participants anchored their donations according to their social value orientations. We elicited such intuitive decisions using a distraction manipulation, which existed of asking half of our

participants to remember a 7-digit number. Pro-socials intuitively tended to support the collective interest to a larger degree than pro-selfs. In a second step, in which dictators think more elaborately about the decision at hand, both pro-socials and pro-selfs tended to benefit their immediate self-interest.

Additionally, we showed that the automatic effect of social value orientations is partly due to a differential perception of the closeness of one's relationship with the interaction partner. Pro-socials chronically feel "closer" to anonymous other people than pro-selfs. This is, at least partly, the reason for their intuitive tendency to value collective interests. Interestingly, we also showed it is possible to influence such perceptions and the resulting automatic decisions. By making people feel "closer" to their interaction partner, donation sizes increase if the decision is made automatically, but not when it is contemplated more elaborately.

The present results may offer new perspectives on the way social marketing strategies may reach their objectives of promoting behavior that benefits the collective interest (like consumer decisions supporting environmentally friendly products, fair trade or items produced in circumstances in which human rights are not violated) or individual's long-term self interest (e.g., eating healthy, abstaining from smoking or consuming illegal drugs). They suggest that techniques, which activate people's pro-environmental, ethical, or health values, while preventing them from contemplating extensively on a current decision, could be efficient tools to achieve these goals. Obviously, being able to activate such values implies that these values need to develop first, and in this respect traditional social marketing techniques based on argumentation and education are indispensable. Based on our results we propose, however, that the motivation to contemplate should be minimized on the moment actual decisions are made, since a thinking process tends to result in people pursuing their immediate self-interest.

The Pervasive Effect of Aesthetics on Choice: Evidence from a Field Study

Jan R. Landwehr, University of St. Gallen, Switzerland

Aparna A. Labroo, University of Chicago, USA

Andreas Herrmann, University of St. Gallen, Switzerland

EXTENDED ABSTRACT

When it comes to purchasing expensive consumer durables, most people believe the choices they make result from thoughtful contemplation. For example, few people are likely to respond that they bought a car because the design was pleasing and familiar. However, a century of research on mere exposure effects suggests the intriguing possibility that visual design features and, in particular, the ease with which they are processed might play a powerful role in everyday decision processes. Research indicates that because important and personally relevant products are familiar and come to mind easily, people implicitly associate ease and familiarity with importance and personal relevance. As a consequence, archetypical designs, which are easier to process and more familiar, also seem more important, self-relevant, and likeable. These ease of processing effects are significantly stronger for visually complex than for simple designs because people might become aware of the ease of processing simple stimuli and correct their evaluations; if the design seems too familiar it might even feel boring.

While laboratory studies provide robust evidence of this phenomenon, its effect size in a high-involvement real world context with real financial implications (e.g., a car purchase) is unclear. The current investigation systematically examines this issue.

To investigate the impact of design features on sales in an important, real-life setting, we obtained six months (January 2007–June 2007) of officially recorded car sales data from the German Federal Transport Authority. Two objective design aspects were considered for each car: archetypicality and complexity. In accordance with the laboratory findings, we expected that archetypicality would increase sales of visually complex, but not of simple, cars. That is, complex cars would benefit from the ease of processing their design features and appeal most when they are archetypical, whereas for simple designs the ease of processing archetypical features would be non-informative.

Objective design archetypicality. A professional frontal photograph was taken of each car under standardized conditions controlling for stylistic aspects. Using morphing software from research done on human facial appeal, a morph was created. An archetype similarity score calculated by summing the Euclidian difference of each of 50 feature points of a car from the averaged position of the corresponding feature in the morphed (archetypical) car was created. A higher score indicated that a particular car was more archetypical and presumably easier to process.

Objective design complexity. Based on perception research which proposes that a computer algorithm for compression of an image file can measure picture complexity because it removes redundancies, ZIP algorithm was selected as an objective measure of design complexity.

Validating objective measures with subjective ratings. To confirm the two objective measures depict the proper constructs, 564 U.S. consumers rated the cars for typicality and complexity of design. As we expected, Euclidian (objective) archetype similarity significantly correlated with subjective archetype similarity ($r=0.46$, $p<0.02$) but not with subjective visual complexity ($r=-0.29$, $p>0.15$). Similarly, ZIP (objective) complexity significantly correlated with subjective complexity ratings ($r=0.56$, $p<0.01$) but not with subjective archetype similarity ($r=-0.35$, $p>0.09$). Furthermore, Euclidian

similarity and ZIP complexity were unrelated ($r=0.05$, $p>0.81$), suggesting that our measures capture conceptually distinct constructs and are suitable independent predictors. Only 15.1% of all of the images were recognized correctly, indicating the designs were difficult to identify and ratings unlikely to be biased by established associations. The results were not altered by removing ratings of images that were recognized.

Sales by objective archetypicality and complexity. To control for the correlative nature of our sales data, we included retail price, advertisement spending, technological sophistication, brand preferences, and time since market launch for each car in the analysis. Importantly, *none* of these controls was significantly correlated with either objective measure. The predicted pattern of results emerged: a positive effect of archetypicality ($\beta=0.35$, $p=0.049$), a positive effect of complexity ($\beta=0.28$, $p=0.031$), and an interaction between these two factors ($\beta=0.43$, $p=0.026$). With respect to the control variables, we observed substantial effects of retail price ($\beta=-0.29$, $p=0.023$) and brand preference ($\beta=0.62$, $p<0.001$), but the other three variables did not influence sales ($P \geq 0.30$). The model including design and control variables explained 87% of sales variance, and design factors alone explained 42% of sales variance. Because of this high level of explained variance, it is likely all important variables are included in the model. Additional analysis based on MM estimation which iteratively readjusts and reduces the weights of possible outliers to find the optimal solution with unbiased estimates yielded the same results.

Sales predictions with subjective measures. As additional evidence, we used the subjective ratings of archetypicality and complexity collected from U.S. consumers to predict German car sales. We observed a positive effect of increased archetypicality ($\beta=3.47$, $p=0.015$) and increased complexity ($\beta=3.60$, $p=0.01$) and the interaction term ($\beta=3.55$, $p=0.032$), thus replicating the effects observed with the objective scores. Including the five control variables did not alter the results, nor did *excluding* the 15.1% ratings of designs that were recognized; the three terms remained significant, with the model explaining 74% of sales variance.

General discussion. Our investigation provides evidence in a real market setting of the extent to which visual design features affect a purchase people presumably contemplate a great deal. The effect, observed on six months of car sales, is independent of retail price, technological sophistication, brand associations, advertising, time in the market, and replicates for both compact and executive cars. We observed it with subjective measures that controlled for brand recognition, suggesting it occurs outside conscious recognition, and with objective measures applying equal weight to the visual features of all cars.

Critics might suggest cars “rationally” best also have the best-liked designs. However, it is unclear why “rational” features correlate with “archetypicality” or “visually complex” cars, or how some manufacturers intuit the importance of such features for design of some but not all of their brands. Others might suggest two sets of consumers exist in the market, some who value design and others who value descriptive features, and design-valuing consumers somehow buy archetypical, visually complex cars. However, this implies that “rational” consumers are randomly and equally spread across remaining three conditions suggesting they are unable to distinguish a better car.

First Is Best: First Exposure Effects in Aesthetic Judgments

Mario Pandelaere, Ghent University, Belgium
Kobe Millet, Catholic University Leuven, Belgium
Bram Van den Bergh, Catholic University Leuven, Belgium

EXTENDED ABSTRACT

People differ from each other in their likes and dislikes. For example, a mother may disagree with her son's assessment that Madonna's version of *American Pie* is better than Don McLean's. Individual differences in number of exposures to the two versions of *American Pie* (e.g., the mother has been exposed more often to Don McLean and the son has heard Madonna more frequently) may explain the mother-son disagreement. Indeed, the more frequently people are exposed to a stimulus, the more they tend to like that stimulus (i.e., mere exposure, Zajonc 1968). Nevertheless, even when the mother and her son are equally familiar with the two versions of *American Pie*, we conjecture that the mother-son disagreement would persist if differences in order of exposure exist. More specifically, we hypothesize that a first encountered aesthetic stimulus tends to be preferred over related stimuli that are encountered later. The hypothesized *first exposure effect* differs from the mere exposure effect, because it refers to attitudinal effects of *first*, rather than *repeated*, exposure.

Bruine de Bruin and Keren (2003) argue that in sequential rating formats, items may be compared to earlier items. The analysis of Bruine de Bruin and Keren (2003) may apply only to situations where people process the different items analytically. In many situations, however, people may be less inclined to process analytically, but rather process stimuli in a less effortful, holistic fashion. We believe this may be the case in everyday consumption of aesthetic works. In those situations, we propose that a first encountered stimulus may be liked more than later encountered ones.

Our first real-life, correlational study (The music study) demonstrates that the appreciation of a song version not only depends on its familiarity (i.e., a mere exposure effect), but also on the order in which it has been encountered. In particular, a first encountered version of a song is appreciated more than a later encountered version. In a subsequent experiment (the song study), participants were exposed to different versions of the song *Boom Boom*. They preferred the version they heard first over the version they heard second. In the Landscape studies, participants were exposed to pictures of landscapes and the corresponding mirror-reversed pictures. Again, participants liked the picture they saw first more than the corresponding mirror-reversed picture they saw later. Moreover, the preference for the picture they saw first did not depend entirely on the correct identification of the picture they had seen first. Finally, in the Pollock study, participants were exposed to different orientations of abstract paintings. They appreciated the first orientation more than any subsequent orientation they were exposed to. This lower appreciation for subsequent orientations was not due to boredom.

Numerous studies suggest that earlier events and items are processed differently than later ones, either quantitatively (e.g., earlier items receive more attention) or qualitatively (e.g., earlier items bias the processing of later items). Although these studies demonstrate that the *cognitive* processing of first presented items may be different from later presented items, they do not imply *attitudinal* effects of first exposure. Nevertheless, across modalities (visual and auditory), across stimuli (music, abstract art and photographs) and across rating procedures (absolute evaluations and relative preferences), we demonstrated that a first encountered

stimulus tends to be liked better than later encountered similar ones.

The type of processing may determine whether a first exposure effect is observed. In the contestant studies, jurors may be more inclined to think analytically about the contestants' performances. As such, features may be detected that allow comparison processes to focus on unique features. In the current studies, in contrast, the items probably were processed holistically, i.e. as a whole without trying to analyze the stimuli into features. Possibly, items appear more similar when people process stimuli holistically than when they process stimuli more analytically. Hence, any effect of type of processing on the first exposure effect may be mediated by perceived item similarity.

If the first exposure effect on aesthetic judgments is due to the type of processing, similar first exposure effects may be obtained for non-aesthetic products as well. As such, current findings may extend research on the pioneering advantage (i.e. preference for a brand that enters a market first over follower brands, Carpenter and Nakamoto, 1989) because several studies indicate a cognitive basis for the pioneering advantage (Kardes and Kalyanaram 1992). The present studies found higher evaluations for items that are encountered first than for items encountered later without the necessity of recognizing the first items as having encountered first. This suggests that higher evaluations of pioneering brands may even be obtained when a brand is not recognized as a pioneer.

The effect of exposure on attitudes is epitomized by the mere exposure effect: people develop a preference for initially neutral objects as they are *more* exposed to it. The current paper demonstrates that people's preferences are not only shaped by repeated exposure or by exposure duration (Bornstein 1989), but also by first exposure. Future studies need to address the mechanism involved in the current findings. For now, however, it appears that aesthetic judgments may reveal strong primacy effects.

Resolving Aesthetic Incongruity

Vanessa M. Patrick, University of Georgia, USA

Henrik Hagtvædt, University of Georgia, USA

EXTENDED ABSTRACT

The current research proposes a theoretical framework to explain the phenomenon of Aesthetic Incongruity Resolution (AIR). We empirically investigate the affective and behavioral consequences of the aesthetic incongruity that often arises in everyday consumption. With a set of four experiments, we investigate the consequences of a mismatch (aesthetic incongruity) between a product and the existing *consumption environment*. Consumers' existing possessions constitute their consumption environment, and what the specific consumption environment is thus depends on the new acquisition and the purpose it is meant to fulfill. For instance, the existing wardrobe may be the consumption environment for a new shirt, while the living room and all the furniture and decorations therein may be the consumption environment for a new rug. Thus, the consumption environment is defined as the set of pre-existing possessions amongst which the new acquisition will be introduced and utilized.

The current research demonstrates that aesthetic incongruity between an acquired product and its consumption environment may result in a consumer's decision to either return the product or to spend more on additional purchases. This decision is moderated by product appeal. Specifically, for a product high in aesthetic appeal, incongruity results in feelings of frustration due to the lack of fit, while for a product low in aesthetic appeal, incongruity results in regret for having made the purchase. We demonstrate that feelings of frustration motivate additional purchases to accommodate the product within one's consumption environment while feelings of regret are more likely to result in product returns.

In study 1, photographs of lamps were pretested to be high versus low in aesthetic appeal. Two photographs were selected and were rated equally in terms of incongruity with the picture of a room in which the lamp was to be placed. Participants were randomly assigned to one of two experimental conditions and asked to imagine that they had purchased the lamp (high vs. low appeal) for their living room (i.e., the room in the photograph), and they completed a questionnaire based on this scenario. Results revealed that participants in the high appeal condition experienced significantly more frustration than regret resulting from the incongruity, while those in the low appeal condition experienced significantly more regret than frustration. Further, the high appeal products were more likely to lead to additional purchases, while the low appeal products were more likely to be returned.

In study 2, participants read a scenario in which they purchased a shirt (high appeal vs. low appeal) that either fit well or not at all well with the rest of their wardrobe. Results revealed that when the product was high in appeal, participants were more frustrated by the lack of fit than they were regretful, but when the product was low in appeal, participants were more regretful than they were frustrated. For the high (low) appeal product, participants were more likely to make additional purchases (return the product) as a result of poor fit. Mediation analysis demonstrates that the difference score of frustration minus regret mediates the effect of appeal on the decision to buy more versus return the product. Interestingly, participants reported satisfaction with the high appeal product regardless of incongruity, indicating that the desire to accommodate the product itself resulted in the feelings of frustration and motivated the purchase of additional items in the low fit condition.

In study 3, participants read a scenario in which they bought curtains for decorative purposes (consummatory goal) or blinds to shade the room from the sun (instrumental goal), with high or low aesthetic appeal, that did not fit with the rest of the things in the bedroom. Results replicated the results from the previous studies, regardless of consumption goal. In other words, when the product was high (low) in appeal, participants were more frustrated (regretful) by the lack of fit than they were regretful (frustrated), and they were more likely to make additional purchases (return the product). Again, mediation analysis demonstrates that the difference score of frustration minus regret mediates the effect of aesthetic appeal on the decision to buy more versus return.

Study 4 was designed to illustrate a key managerial implication of the current research, namely that for high appeal products, the option to buy additional items to accommodate the product within the consumption environment (versus the option to return the product) results in greater satisfaction and more repeat purchases. Participants were told that a consumer had purchased a high (low) appeal rug that did not fit with the rest of the things in her living room. They then read a dialogue between the consumer and a sales clerk from the store in which the consumer explains her predicament. In one condition, the sales clerk gives the consumer the options of returning the rug to the store or mailing it back to the store, and in the other condition the sales clerk gives the consumer the options of returning the rug to the store or being shown additional items to purchase that would complement the rug and make it fit in the living room. Results revealed that in the high appeal condition, participants rated the sales clerk as friendlier and more competent, and they were more likely to buy again from the store in the future, when they were offered the option to buy more. However, this was not the case for the low appeal product.

Thus, this research does not only provide insights into the affective and behavioral responses to aesthetic incongruity between new purchases and the existing product environment. It also provides managerial guidance in terms of how to resolve instances of aesthetic incongruity, leading to increased customer satisfaction and future repeat purchases.

Unexpected Benefits of Being Less Rather Than More Similar: The Influence of Consumer Mindset and Brand Presence on Copycat Evaluation

Femke van Horen, Tilburg University, The Netherlands

Rik Pieters, Tilburg University, The Netherlands

Diederik A. Stapel, Tilburg University, The Netherlands

EXTENDED ABSTRACT

Suppose you are in a Wal-Mart supermarket and want to buy peanut butter. The Wal-Mart private label peanut butter is located next to the incumbent Skippy brand on the shelf. The Wal-Mart peanut butter has the same light-blue lid, an identical blue label with red lettering and the jar is of similar material and size. How would you evaluate the Wal-Mart peanut butter? Previous copycatting research would predict that the Wal-Mart private label is evaluated more positively the higher its similarity with the Skippy peanut butter is (Kapferer 1996; Loken, Ross and Hilke 1986; Warlop and Alba 2004). That is the general idea in the marketing literature is that increased similarity with the incumbent uniformly improves the evaluation of the copycat. We argue, instead, that in addition to similarity, copycat evaluation depends critically on the physical arrangement of the brands at the point-of-purchase and on the specific mindset that is activated in consumers while evaluating brands.

To date, remarkably little is known about how, in addition to the sheer degree of similarity, characteristics of the shopping situation, such as the physical arrangements in the supermarket and the consumers' mindset, influence the evaluation of copycats. Moreover, because the focus in theory and practice has traditionally been on highly similar, more blatant copycats (Zaichkowsky 2006), the effects of more subtle degrees of copycatting are largely unknown. That is, whereas blatant forms of copycatting are fairly straightforward to detect and taken to court, subtle forms of copycatting appear abundant and are more difficult to detect, but—as we expect—may ironically benefit more from the incumbent's equity.

Social cognition theory (Sherif and Hovland 1961) and research in marketing (Herr 1989) has shown that contrast effects may occur when information about a product or brand is used as a comparison standard. Then, judgments about the brand will be displaced away from these comparison standards. Moreover, recent theories (Stapel and Suls 2004) suggest that the consumers' mindsets critically determine whether or not such comparison standards will be employed. Building on these ideas, the present research posits and shows that copycat evaluation is critically dependent on the i) consumer mindset (judge–consumer) and ii) brand presence (incumbent present–absent), as these prompt copycat-incumbent comparisons. Thus, when the Skippy peanut butter is in physical proximity when evaluating the Wal-Mart copycat, the latter might actually be evaluated less positively, as the incumbent brand is more likely to be used as a comparison standard, resulting in comparative contrast. In addition, when people are in a judgmental frame of mind (judge mindset) instead of an experiential frame of mind (consumer mindset) the Wal-Mart private label might be evaluated less positively as well. In a judge mindset, people are more inclined to critically appraise and gauge the copycat in terms of the acceptability of its trade dress tactics. In order to judge the copycat, a distinct representation of the incumbent brand will become accessible, which will be used as a comparison standard. This will result in a contrastive judgment, i.e., a devaluation of the copycat. We predict, however, that even when comparison is

instigated, contrast will only occur for highly similar, but not for moderately similar copycats, because information needs to be similar and extreme, rather than moderate, for comparison to result in contrast (Stapel, Koomen and Van der Pligt, 1997). Empirical support for these predictions would imply that contrary to common belief, lower similarity, subtle copycats can be as damaging as or even more damaging than higher similarity, blatant copycats.

Three studies tested the hypothesis that evaluation of copycats is dependent on the degree of similarity, but also, and critically, on the consumer's mindset and brand presence. In these studies the degree of similarity between a supermarket private label and an incumbent brand was systematically varied. Study 1 tested the prediction that the evaluation of degrees of copycat similarity is affected by the activated mindset. In the context of the introduction of a new olive oil, participants were asked to imagine either that they were considering to buy (consumer mindset) or that they were determining the acceptability of (judge mindset) an olive oil with a particular brand name. Next, they evaluated 25 brand names that differed in degree of similarity to the incumbent brand (no, low, moderate, high and extreme). The results showed, in support of the hypothesis, that when a consumer mindset was activated, highly similar copycats were preferred over less similar copycats. However, when a judge mindset was activated, highly similar copycats were liked less. Study 2 tested, in addition to similarity and consumer mindset, the influence of brand presence on copycat evaluation. Six brand names from Study 1 were selected with low and high similarity to an incumbent brand. Again either a consumer or a judge mindset condition was activated. And for half of the participants within each condition the incumbent brand name was present on the screen while they were evaluating each of the six brand names. The results of Study 2 replicated the results of Study 1 when the incumbent brand name was not present. However, when the incumbent brand name was present the results completely reversed: participants in the consumer mindset liked highly similar copycats less. In fact, when the incumbent brand name was present, participants in a consumer mindset evaluated the high similarity copycat as negative, as did participants in the judge mindset. Study 3 tested whether degree of copycat similarity and evaluation are, as our theory would predict, curvilinearly instead of linearly related, when the incumbent brand is present. In this study, brand packages instead of brand names were used respectively with low, moderate or high degree of copycat-incumbent similarity. In support of our predictions, the moderate similarity copycat was evaluated more positively than the low and high similarity copycat, when the incumbent brand was present.

These results demonstrate that in addition to the degree of similarity, the evaluation of copycats is influenced by characteristics of the shopping situation, such as the physical arrangements in the supermarket and the consumers' mindsets, as these aspects are likely to instigate explicit comparisons between copycat and incumbent brand. We showed that under circumstances that are conducive to explicit comparisons, moderately similar copycats are in fact liked more than highly similar copycats. This reveals the unexpected benefits of being subtly similar for copycats, and the

potential harm for the equity of incumbent brands that focus on combating the blatant copycats, whilst letting the subtle ones go by undetected.

Contrast or Assimilation As a Result of Upward Social Comparison with Idealized Images: The Role of Mode of Exposure and Priming

EXTENDED ABSTRACT

The popular use of highly attractive women in advertising has received some support from consumer research in terms its positive impacts on product evaluation, ad evaluation and purchase intention (Belch et al. 1987; Kang and Herr 2006). However, this line of research is increasingly challenged by the mounting research evidence that exposure to idealized images in advertising media elicits upward social comparison, resulting in negative mood (e.g., Stice and Shaw 1994), decreased body satisfaction (see review Groesz et al. 2002), decreased self-assessed attractiveness (e.g., Smeesters and Mandel 2006) and even increased problematic eating patterns (e.g., Harrison 2000) among young women. At the same time, other researchers have documented that idealized images of female models can enhance women's body satisfaction and self esteem (e.g., Myers and Biocca 1992; Mills et al. 2002; Henderson-King et al. 2001). Our understanding of the processes and boundary conditions of positive and negative effects of idealized images on women's self perceptions has an important marketing implication: if the idealized images in advertising are detrimental to women's body and self esteem, how can products and brands endorsed by idealized female images be successfully marketed at and received by female consumers (Bower 2001)? Therefore, consumer researchers need to re-scrutinize the impact of idealized images on young women and resolve previous research discrepancies.

The task of this research is to examine the boundary conditions of positive and negative impacts of idealized images on young women. Whereas most research attention has been devoted to the negative effects of idealized images on self evaluations among young women (see review, Groesz et al. 2002), we are interested in examining the mechanism and processes that gives rise to other observations that exposure to idealized images can enhance self perceptions (e.g., Henderson-King et al. 2001; Meyers and Biocca 1992). Employing the framework of social comparison theory, we propose that social comparison process can take place via either an implicit or an explicit route. An implicit social comparison, when taking place automatically, or outside viewers' awareness, can lower viewers' self-perception and body satisfaction and lead to a *contrast effect*. However, when taking place within the scope of viewers' attention and awareness, an *explicit social comparison* will allow viewers' to engage in conscious efforts to boost their own self-esteem through counter-argument. Such an explicit social comparison, therefore, will lead to more positive self-perceptions and enhanced body satisfaction, resulting in an *assimilation effect*. We tested these propositions with three experiments.

The first experiment explored the role of mode of exposure to idealized images in triggering differential social comparison processes. To induce either implicit or explicit social comparison, participants were asked to engage in one of two tasks while being exposed to idealized images. Participants in the implicit social comparison group were led to believe that they were participating in a study that examined peoples' natural intuition about the types of sunglasses that are most suitable for different face shapes. In contrast, participants in the explicit social comparison group were asked to rate the attractiveness of each of the women. In line with our predictions, participants in the implicit social comparison group

reported lower evaluations of their weight related body traits compared to participants in the explicit social comparison group.

To further explore this finding, our goal of Experiment 2 was to examine whether participants' evaluations of their weight related body traits could be modified by inducing either a positive or negative interpretive frame. We expected that altering the interpretive frame would not influence the participants in the explicit social comparison group since they would be able to shield themselves from the impact of the interpretive frame by being consciously aware of, therefore combating the negative impact of threatening upward social comparison. In contrast, we expected that the participants in the implicit social comparison group would be influenced by the interpretive frame, leading to a contrast effect when the interpretive frame is positive, and an attenuated contrast effect when the interpretive frame is negative. In line with our expectations, we found that participants in the explicit social comparison group were unaffected by the interpretive frame. However, participants in the implicit social comparison group were affected by the interpretive frame: their self-perception was more negative when the content of the priming task biases them to interpret characteristics of the idealized females positively than when the priming task encourages a more negative interpretive frame. Thus, our results suggest that after explicit exposure to idealized female images, participants are able to insulate themselves from the negative impact of these idealized female images, whereas after implicit exposure participants are not able to shield themselves from negative impact of these female images, but are influenced by inducing either a positive or negative interpretive frame.

To account for the differences found for the participants in the explicit and implicit social comparison groups in Experiments 1 and 2 we speculated that participants in explicit social comparison are more aware of the upward social comparison process and tend to engage in counter-arguments to insulate themselves from the negative impact of exposure to a highly attractive comparison target. However, engaging in ego-protective strategies during the explicit social comparison process is cognitively demanding, therefore, such explicit social comparison processes requires more cognitive resources than social comparison processes that are implicit. To test this notion, our third experiment was conducted to mainly examine the role of the availability of cognitive resources in modulating the impact of exposure to idealized female images on participants' self-evaluations. Supporting our predictions, participants found the sunglasses task more cognitively demanding, which, consequently, meant that they had fewer cognitive resources available to engage in conscious strategies and counter-arguments that would help in protecting them from the negative consequences of exposure to idealized female images.

Altogether, these three experiments contribute to our understanding of the impact of social comparison processes on self evaluations. Surprisingly, our results indicate that participants were best equipped to deal with exposure to idealized images when this exposure was explicit. Thus, rather counterintuitively, we have found that women may be most susceptible to the negative consequences of exposure to idealized female images precisely when they are not focusing on their level of attractiveness.

The Role of Social Comparison for Maximizers and Satisficers: Wanting the Best or Wanting to Be the Best

Kimberlee Weaver, Virginia Tech, USA
Norbert Schwarz, University of Michigan, USA
Keenan Cottone, University of Michigan, USA
Kimberly Daniloski, Virginia Tech, USA

EXTENDED ABSTRACT

The distinction between maximizing, attempting to examine every option before determining which choice is best, and satisficing, choosing the first option one comes across that meets a threshold of acceptability, was first posited by Herbert Simon in the 1950s. More recent work on the topic has led to the conceptualization of a maximization individual differences scale (Schwartz et al., 2002) as well as assessments of the impact of maximization behaviors on both objective and subjective outcomes (Schwartz et al., 2002; Iyengar, Wells, & Schwartz, 2006; Parker, Bruine de Bruin, & Fischhoff, 2007). The current paper seeks to further this literature by addressing a question that previous work has left open—the underlying motivation behind maximizing versus satisficing behavior.

Research on maximization behaviors has revealed that they tend to be highly correlated with a reliance on social comparison information (Parker, Bruine de Bruin, & Fischhoff, 2007). As Schwartz et al. (2002) point out, “whereas ‘good enough’ usually is judged in absolute terms, ‘the best possible’ may...require social comparison” (p. 1184). While social comparison can certainly be a useful, and even necessary, way to gain information about what choice is best, there is an alternate explanation for maximizers’ reliance on it. Instead of seeking social comparison information in an effort to discover the best choice in an objective sense, it is possible that maximizers are seeking social comparison information to ensure they are the best in a relative sense. In other words, instead of being motivated to *find* the absolute best, maximizers may be motivated to *be* the best in a social rivalry. The current studies seek to parse apart these two motivational possibilities by explicitly pitting them against each other in a series of experiments.

Across three studies, maximizers and satisficers were given a series of two hypothetical versions of the world (an absolute choice and a positional choice) and were asked which one they would prefer (adapted from Solnick & Hemenway, 1998). For example:

- You make \$60,000 per year and nearly all of your co-workers make \$80,000 (absolute).
- You make \$50,000 per year and nearly all of your co-workers make \$30,000 (positional).

In the first option, subjects have a higher yearly income than in the second option (an absolute best), but they are making less than those around them. In the second option, though subjects have a lower income in an absolute sense, they are making more than those around them (a positional best). Results from Study 1 showed, across a wide range of scenarios, that maximizers are more willing than satisficers to sacrifice objective superiority in order to be the best relative to others.

Studies 2 and 3 presented respondents with absolute or positional choices while also manipulating the public visibility of the choice outcome. If maximizers place more weight on social comparison as a way to determine what *is* the best, then the social visibility of the outcome should be irrelevant and they should choose the same option in public as in private. In contrast, if maximizers place more weight on social comparison for positional

standing, then they should be more likely to choose positionally when others will know about the decision outcome, but may instead choose to maximize objective quality when the outcome is private.

Confirming predictions, Study 2 showed a significant *Visibility X Maximization Score* interaction, $\chi^2(1)=4.66$, $p<.05$. Overall, maximizers were more likely to choose the positional option when the outcome of the choice was publicly visible than when it was private and known only to the decision maker, while satisficers’ choices were unaffected by the visibility manipulation. Study 3 replicated this finding with products that were either naturally publicly visible (e.g., sunglasses, car, cell phone) or naturally private (e.g., pajamas, ice maker, mattress).

The results from these three studies suggest that the motivations of maximizers are multi-faceted. While maximizers tend to make more positional choices than satisficers when their choices are publicly visible, this effect is not found when the outcome of the choice is private and known only to the decision maker. Future research should examine the individual factors of the maximization scale to ascertain whether there are “types” of maximizers who are more or less susceptible to the effects of public visibility. Overall, the current studies add complexity to the current literature on maximizing and decision making. Rather than focusing on the “best” option, three studies indicate that the motivation behind maximization behaviors can change across contexts. When social rivalry is salient, maximizers appear to be motivated to be the best in a relative sense. When social rivalry is not salient, maximizers appear to be motivated to choose the best an objective sense of the word.

When Will People Tell You Something You Do Not Know?

Lei Huang, Dalhousie University, Canada

Sema Barlas, McGill University, Canada¹

EXTENDED ABSTRACT

Word-of-mouth (WOM) is considered to be an important source of information for individual decisions based on a widely held assumption that other people can bring diverse perspectives to the individual's decision process (Heath and Gonzalez 1995). For any given decision problem, individuals may hold unique knowledge that may be acquired through personal experiences as well as common knowledge that may be obtained from mass media. According to Grecian norms of conversations (Grice 1975) and information theory (Shannon 1964), people should exchange unique information in order to maximize the informational content of available information for decisions. Also, at the deliberate level, people agree to these prescriptions and ascertain that it is the unique information that should be exchanged in interpersonal communications. However, extant empirical research demonstrated that "what people talk about" in actual conversations is not always what is the most informative for decisions. For instance, overwhelming evidence has been accumulated in the literature demonstrating that conversations are dominated by the information that members hold in common before discussions, the information that is consistent with members' pre-existing preferences (Stasser and Titus 1985, 1987), and the information that is extreme or negative. In addition, Huang and Barlas (2006) demonstrated that people exchange emotional and recreational information more often than cognitive and utilitarian information in WOM in order to establish social connections.

This paper investigates the exchange of unique information in WOM depending on the nature of this information (e.g., whether it is emotional or cognitive). Note that bias for emotional information in WOM reported by Huang and Barlas (2006) might be observed because emotional information (e.g., consumption experiences) is often uniquely held by participants. If this is the case, one would expect that the bias for emotional information should diminish when emotional information is commonly held by WOM participants. However, causal observation suggests that bias for emotional information is amplified when it is shared knowledge among individuals. For instance, most political conversations revolve around emotional topics (e.g., the gay marriage issue in the 2004 U.S. elections). Candidates' positions on issues that spur emotions among the voters are widely communicated by the mass media, and therefore, are likely to be common information among voters, whereas cognitive information (e.g., foreign aid) is likely to be the unique knowledge held by individual voters since it is often not publicized. Also, much literature suggests that people try to validate the messengers as well as the messages by talking about the commonly shared information (Stasser and Titus 1985) in order to validate that their partners are similar to them with respect to interests. Indeed, talking about common topics establishes social connections among participants in the same way sharing of emotional information. Thus, this paper aims to tease out the effects of information types (emotional versus cognitive) and the distribution

of information among communicators (common versus unique) on the sampling of information for conversations and choices. We hypothesize that common information is exchanged more often than unique information in conversations; however, people demonstrate strong preference for common emotional information, but exchange unique information socially when it is emotional.

We used a political decision-making task where participants chose between two candidates for the Student President position after discussing candidates' profiles. Participants exchanged information with two other individuals before deciding to cast their vote. 120 participants (64 females) were recruited from undergraduate business courses as groups working on a class project together. Some groups were self-selected friends and others were formed by the course instructor choosing randomly among acquaintances. The 40 three-person groups were equally divided into two WOM conditions: common-cognitive-unique-emotional (briefed as common-cognitive) or common-emotional-unique-cognitive (briefed as common-emotional) condition. A control condition of 99 volunteered participants performed the same tasks as did the WOM participants except for exchanging information with others.

In the common-cognitive condition, the profile descriptions of electoral candidates included the same cognitive information across members, but emotional information was unique to the profile each member received. In contrast, identical emotional information was included in the profiles of all members in the common-emotional condition while each member received unique cognitive information. All participants were explicitly informed that their information was not complete before the discussion. All conversations were audio-taped for further content analysis.

Our results support the widely accepted conclusion in the literature that common information (mean=0.58) is exchanged more often than unique information (mean=0.42) in conversations. However, our results also suggest that unique emotional information (mean=0.61) that would facilitate interpersonal connections is, indeed, shared with others more often than common cognitive information (mean=0.39), but still less than common emotional information (mean=0.77). Thus one major contribution of this paper is the finding that emotional information enjoys a sampling advantage in WOM; this bias is inflated when emotional information is also commonly held by the members prior to conversations (e.g., as in online user groups). That is, the nature of the information plays a more significant role in conversations than the distribution of information among individuals. Additionally, these biases in information sampling lead to similar biases in the influence of information on decisions. There was a strong preference for the candidate who was favorable on the basis of common emotional information. By contrast, preference for the candidate who was favorable on the basis of cognitive information was not strong because participants exchanged the unique emotional information in conversations. The biases reported above were more pronounced when members in the group were similar with respect to the importance of emotional and cognitive attributes in their decisions. However, neither gender nor social ties (friends versus acquaintance) had significant impact.

Most existing research in the political marketing focuses on the impact of information valence on voting behavior. Differing from previous research, results from our study suggest that the nature of the information has considerable impact on conversations about candidates as well as on the votes and the size of this impact

varies depending on the distribution of information among communicators. By focusing on the affective versus cognitive nature of information, our paper thus opens a new direction for future research to discover what other aspects of information determines the dynamics of voters' WOM behavior and their subsequent ballots. In conclusion, our findings suggest that WOM participants herd into commonly known emotional-options more often than individuals making the same choices privately. Also, it appears that, although cognitive information may inform one person, the emotional information engage many individuals.

What Do People Talk About in Word-of-Mouth Communications?

Sema Barlas, McGill University, Canada
Lei Huang, Dalhousie University, Canada¹

EXTENDED ABSTRACT

Consumers perceive Word-of-Mouth information (WOM) as more credible than marketer-originated information (Bickart and Schindler 2001). Consequently, extant research focused on the antecedents and outcomes of WOM, and the question of what information consumers exchange with others (depending on “why”, “about what”, and “to whom” they are talking) has not received much research attention. It has been commonly assumed that people engage in WOM to improve quality of decisions, and thus, exchange diagnostic information to reduce their uncertainty with respect to offerings (Herr, Kardes and Kim 1991). Recent research indicates that people also engage in WOM to establish social connections (Sassenberg 2002). This paper aims to demonstrate that the social bonding goal increases the value of engaging marketing information in WOM. In our context, information is considered as socially engaging whenever it spurs shared emotions among communicators (e.g., funny or interesting information). More importantly, we also demonstrate that social-bonding efforts in WOM depend on “to whom” (e.g., friends vs. acquaintances) and “about what” people could talk (e.g., nature of marketing information).

According to our theoretical framework, people make trade-offs between different communication goals, depending on the characteristics of available topics and relationships among the communicators. Availability of highly engaging topics stimulates the social-bonding goal, and availability of relatively significant incentives resulting from attending to informative topics, facilitates the uncertainty reduction goal. Similarly, establishing social bonds via talking about engaging marketing information might be more prevalent among people with weak social-ties than among people with strong-social ties, especially when the given information is not about product benefits, and thus, does not trigger conversations about intimate consumption experiences (e.g., a funny joke in an advertisement). That is, impersonal marketing information might be a good conversation topic among strangers who lack other common topics. Lastly, we assume that goals influence selection of particular topics for conversations; therefore, observed bias for engaging information in social settings is an indication of the social bonding goal. More specifically, we predict that:

- H1: Engaging information becomes significantly more valuable when it is consumed socially than when it is consumed individually.
- H2: Acquaintances that are in need of social connections are more likely to promote the social bonding goal via engaging conversations about marketing information than other goals.
- H3: The choice of engaging option increases over time during the WOM episode and conversations at early stages of a WOM episode exert disproportional influence on later choices.

We applied an experimental paradigm in which participants were asked to choose between furniture and personal ads for proofreading to earn between \$5 and \$9, depending on the number of misspelled words they could identify over ten trials. Furniture and personal ads had, respectively, seven and three misspelled words. The task required participants to make a tradeoff between engaging conversations with others and their individual earning/savings as in consumer choice between discount ads and humorous ads. Furthermore, although participants were told in advance that furniture ads had more spelling mistakes and that personal ads were more interesting, they did not know the exact number of spelling errors; nor did they know how much more interesting personal ads were relative to furniture ads. Finally, there were two independent conditions in the study: subjects made their choices either privately or together with three other participants, in which case they could talk about the ads. All participants distributed 100 points between the spelling-error rate and the content to reflect the importance of these attributes in their choice of ads at the end of the study and indicated the number of people they were friends with in their group. All conversations were audio-taped for further content analysis.

Data support our predictions ($p < .05$). In general, engaging information became significantly more valuable when it was consumed socially than when it was consumed individually (H1) and the advantage of engaging information in social setting increased in conversations with weak ties (H2). More specifically, the importance of the content in making choices was significantly larger in the WOM condition than in the individual condition, suggesting that WOM participants intentionally shifted their goals in the direction of the social bonding goal. The intentional shift was larger for acquaintances than for friends. Also, WOM participants talked about the most relevant information for decisions, the spelling-error rate/money, only 23% of the time despite the fact that the importance of the spelling-error rate in making their choices was 42%. Note that the importance of money in the individual condition was 68%. That is, WOM groups deliberately switched their interest or preferences in favor of content, but they conversed about money even less than what would be expected given the intentional shifts in goals. In contrast to the conversations about money, intentional shifts determined the frequency of conversations about personal ads to a great extent; participants talked about personal advertisements 60% of the time and the importance of the content was 58% (32% for individuals); however, conversations systematically diverged from the intentional shifts in goals depending on the social ties. In particular, exclusively-acquaintance (mean=0.74) and exclusively-friend (mean=0.66) groups talked about the personal advertisements significantly more than the mixed groups (mean=0.56) did. Also, exclusively-friends groups talked about personal advertisements less than they intended to whereas exclusively-acquaintance groups talked about personal advertisements more than they intended to. Furthermore, WOM participants chose personal ads more than they intended to, compared with individuals. While the individual goal determined the initial choices, later choices were governed by the goal of the group and the nature of the conversations during the early stages of communications (H3).

Overall, our results suggest that WOM participants herd into engaging options disproportionately more with conversations over time in comparison to the individual decision-makers. Further-

more, acquaintances choose the engaging option more than friends especially at the beginning of the WOM episode. However, the influence of social ties on the herding behavior at later stages of WOM is absorbed by the group level intentional shifts in goals and conversations. Interestingly, biased sampling of information in conversations and its effect on choices diminishes in diverse groups.

Too Much to Take In? The Role of Advertising Variables, Emotions and Visual Attention in Consumer Learning for Really New Products

Stephanie Feiereisen, Aston Business School, UK

Veronica Wong, Aston Business School, UK

Amanda J. Broderick, Coventry Business School, UK

EXTENDED ABSTRACT

“Learning is not attained by chance; it must be sought for with ardor and attended to with diligence” (Eugene S. Wilson)

RNPs create new product categories or at least significantly expand existing ones, and can lead to major shifts in market shares (Lehmann, 1994). For instance, Personal Digital Assistants (PDAs) qualified as RNPs at the time of launch. RNPs are a priority for most companies as, without the success of such novel products, market shares ultimately drop off (Hoeffler, 2003). The difficulty for consumers to comprehend the nature of a RNP using their existing cognitive knowledge structures can be a significant barrier to the success of the product, due to their highly innovative nature. Past research has shown that two learning processes may help consumers understand RNPs: analogical learning (Roehm and Sternthal, 2001) and mental simulation (Dahl and Hoeffler, 2004). However, existing studies have typically examined responses to advertising for RNPs conveyed using words. As decision-making research has shown that visualization tools can make product concepts more accessible (Lurie and Mason, 2007), we seek to add to the extant literature by determining whether advertising strategies rendered by pictorials may be more effective. We also argue that emotional influence is likely to be greatest during the early stages of product learning (Wood and Moreau, 2006). Therefore, acknowledging the role of emotions should contribute to a better understanding of consumer learning for RNPs. Furthermore, the use of an unbiased physiological measure of visual attention may decrease the uncertainty involved when investigating consumer learning processes by offering a ‘window to the mind’ (Pieters, Wedel and Zhang, 2007).

The present research extends the literature on consumer responses to RNPs by exploring a) advertising variables that can be manipulated to enhance consumer comprehension of the product (learning strategy and presentation format), b) the extent to which an emotion (i.e. discouragement) acts as a mediator between the advertising variables and product comprehension and c) the explanatory role of visual attention in learning processes for RNPs.

The knowledge transfer paradigm identifies an analogy as the comparison between a “base” and a “target” which share relations but lack common attributes (Gentner, 1989). Mental simulation is defined as the nonverbal representation of perceptual information and sensory experiences in memory (Baddeley, 1986). Analogies and mental simulation have been proved useful to deal with uncertain environments (Hoeffler, 2003) and therefore should help consumers learn about RNPs. However, the academic interest for analogies and mental simulations has largely been confined to the use of words. Research in visual syntax indicates that one of the main properties of visual communication is its lack of explicit means to identify how images relate to each other (Messaris, 1997). Two types of inferences may be drawn from a claim: strong and weak implicatures (Sperber and Wilson, 1986). Strong implicatures call for one interpretation which varies little across individuals whereas weak implicatures yield a wider range of inferences. Using analogies or mental simulations conveyed by images should trigger weak implicatures (Messaris, 1997), hence a risk that consumers lack guidance to merge the RNP with their existing usage patterns.

Contrarily, the explicitness of verbal syntax may help respondents to vicariously experience the consequences of product use (Walker and Olson, 1997). Thus, we posit that both mental simulation and analogical learning strategies are more likely to increase product comprehension when conveyed by words rather than by pictures.

Moreover, drawing on the E3 model of emotional influence (Wood and Moreau, 2006), we argue that the difficulties involved in learning about complex new products will trigger strong emotional responses such as discouragement, which in turn will affect product comprehension. We hypothesize that an increase in discouragement will mediate the effects of presentation format and learning strategy on product comprehension.

We also intend to demonstrate how visual attention can contribute to our understanding of the links between conceptual and perceptual analyses when learning for a RNP. We use the physiology of reading literature (Rayner, 1998), and the inverse inference model (Feng, 2003) with the aim to discriminate the state of higher-order cognitive processing from observed patterns of eye movements. We hypothesize that when the message is conveyed with words attention increments to the advertising message will reflect an increase in product comprehension, whereas when the message is conveyed with pictures an increase in attention will indicate confusion.

A total of eight hundred fifty three respondents participated in Study 1. The design was a 3 within-subjects (learning strategy: mental simulation vs. analogy vs. no analogy/ no mental simulation) x 2 between-subjects (presentation format: words vs. pictures) X 3 between-subjects (product: Digipen vs. Video glasses vs. Intelligent Oven). Each participant was thus exposed to three adverts. Study 1 provides us with two important results. First, as expected, both analogies and mental simulations enhance product comprehension to a greater extent when conveyed using words than using pictures. An analysis per product reveals that the video glasses are a notable exception, which suggests that the combination of mental simulation and pictures may actually facilitate comprehension for RNPs of a more hedonic nature. Second, discouragement partially mediates the effects of presentation format and learning strategy on product comprehension.

Study 2 measures individuals’ visual attention to adverts for RNPs using an eye-tracking technique. The results suggest that when the message is conveyed using words, an increase in attention to the message reflects enhanced comprehension for the RNP. However, when the message is conveyed using pictures, an increase in attention reflects confusion towards the nature of the product. This study adds evidence to a growing body of literature which shows that eye movements reflect higher order cognitive processes (Pieters, Wedel and Zhang, 2007). Our research also demonstrates that the link between attention and comprehension is not always straightforward as an increase in attention may actually reflect confusion as opposed to comprehension.

Enough is Enough! Or Is It? Factors that Impact Switching Intentions In Extended Service Transactions

Keith S. Coulter, Clark University, USA

EXTENDED ABSTRACT

Research has documented that customers leave corporations and service providers for a variety of reasons (Bolton 1998). Keveaney (1995) found that core service failures and service-encounter failures were the two most common “determinant incidents” that cause customers to terminate service relationships. In the case of extended service transactions (which typically occur over a period of hours, days, or even weeks), a critical determinant incident may continue over a prolonged period of time, or the service transaction may continue after the critical incident has occurred. Thus, even though a determinant incident has led the customer to decide to terminate the service relationship, the decision to terminate the relationship may later be revoked, depending upon the service provider’s reaction(s) to the core service failure.

We posit that that a negative incident such as an extended service *delay* may be perceived as a core service failure that can culminate in service dissolution (Edvardsson and Roos 2001; Roos, Edvardsson, and Gustafsson 2004). Employee response to that service failure (i.e., service recovery efforts) may or may not serve to overturn the decision to terminate the service relationship (Hess, Ganesan, and Klein 2003). Because the extended service encounter is on-going, the customer/provider relationship may reach a point where even satisfactory recovery efforts may not be sufficient to prevent the customer from seeking dissolution. Thus we propose that (H1): As the length of the core service delay increases, satisfactory recovery efforts will be less likely to negate subsequent switching intentions.

In addition, because a core service failure (delay) that occurs early in an extended service transaction gives the firm and its employees more *opportunity* to respond, we expect that:

(H2): As the core service delay occurs later within an extended service transaction, satisfactory recovery efforts will be less likely to negate subsequent switching intentions.

Various factors may impact whether a specific service failure recovery attempt is likely to be judged as “satisfactory.” These factors may be classified in terms of four recovery attributes—compensation, response speed, apology, and initiation (Smith, Bolton and Wagner 1999; Smith and Bolton 2002). Because in the case of extended service encounters the consumer is frequently unable to exit the transaction before its scheduled conclusion, and because customer-initiated complaints are likely to be less necessary due to the fact that front-line personnel have a greater period of time over which to recognize the service failure, we expect that (H3): response time and initiation will be less important than compensation or an apology in driving customer satisfaction.

Customers assume lower service provider inputs for controllable compared with uncontrollable failures, and they therefore expect greater recovery efforts by the service provider in order to restore equity to the exchange (Hess, Ganesan, and Klein 2003). In the case of extended service transactions, however, there may come a point where controllability of the situation becomes a moot point, and *no* amount of recovery effort is likely to lead to customer satisfaction. Thus we expect that: (H4) as the length of the core service delay increases, controllability will be less likely to have a positive impact on satisfactory recovery efforts.

Airline passengers (n= 451) who had experienced “significant” travel delays during the period from September 2006 to June

2007 filled out an on-line survey that provided retrospective accounts of their experience at different points in time. Customer satisfaction with the recovery effort as well as the four satisfaction antecedents were assessed with measures consistent with prior research (Bitner and Hubber 1994; Taylor 1994; Smith, Bolton, and Wagner 1999). Length of service delay was estimated for five different time periods: a) prior to arriving at the airport, b) prior to boarding the flight, c) after boarding the flight but prior to takeoff, d) in-flight prior to landing, and e) after landing but prior to gate arrival. The length of delay measure was formed by summing across categories; the time of delay variable was formed by selecting the category with the greatest number of minutes. Changes in switching intention were assessed by comparing intentions at the time period of greatest delay to those at the time of questionnaire item completion.

Of our total sample of 451 passengers, 91% (n= 410) expressed a greater intention to stay with their present service provider at time period two ($M=5.12$) than at time period one ($M=2.63$). Because the tendency to negate switching behavior was defined as a *positive* change in intentions, only those subjects who indicated this positive change (n= 410) were included in further analyses. We first examined the impact of satisfactory recovery efforts on (negated) switching intentions utilizing OLS regression. The overall regression equation as well as the satisfaction independent variable was significant. We next examined the impact of the five independent variables on satisfaction. Again the overall regression equation (as well as all independent variables) was significant. The magnitude of the beta coefficients suggested that compensation and apology have a greater impact on satisfaction than response speed or initiation; thus H3 was supported.

We then employed hierarchical regression to examine our remaining hypotheses. The procedure involved constructing regression models that included main effect terms for all independent variables, as well as product terms representing each moderator effect. After calculating models containing only the main effects of the independent variables, each product term (i.e., moderator effect) was entered individually. The key test was whether the product term accounted for a significant amount of incremental variance, and whether the sign of the interaction terms was in the predicted (negative) direction. Results supported H1 and H2, but H4 was not supported. Overall, the two significant interaction terms accounted for nearly 9% incremental variance. We also replicated our H1-H2 results utilizing only that subset of subjects whose intentions changed by +5 or greater.

Overall, our results provide insights into those factors that impact the relationships between length of core service failure, time of core service failure, and satisfaction with service recovery efforts. These interrelationships are shown to impact customers’ decisions to dissolve a service relationship.

A Typology of Consumer Territorial Rudeness

Merlyn A. Griffiths, University of North Carolina-Greensboro, USA

Mary C. Gilly, University of California-Irvine, USA

EXTENDED ABSTRACT

Commercial and services settings are evolving in functional provisions for customers, serving as a place to conduct business, study, hangout, cyber connection, reading room, mental rejuvenation space, etc. The expectation is that consumers will linger and mingle and have a positive interactional experience. However, although the invitation to socialize with unknown others is encouraged by the myriad of offerings, layout, physical features and ambience, consumers often do not socialize. In fact, as a norm in the setting, social interaction seems frowned upon and may be even considered against proper etiquette in these settings (McGrath 2006). Instead of socializing, some consumers in these settings behave territorially over the space they occupy. Some consumers who have had territorial encounters with another customer within these linger and mingle places become morally outraged, as they perceive another's territorial actions as being rude. What is unclear is what aspects of territoriality do consumers perceive to be rude?

Researchers have empirically shown that consumer-to-consumer interaction frequently do occur in service environments with great frequency, and can impact evaluation of the overall experience, satisfaction, repatronage and loyalty (Bitner et al., 1990; McGrath and Otnes 1995). However the concept of territorial rudeness as a component of consumer-to-consumer interaction in service environments has been less explored. To categorize a person's behavior as rude is to make definitive judgments that the person's communicative actions are intentional displays of contempt and lack of respect (Tracy and Tracy 1998). Along this line rudeness can be considered as discourteous behavior, which is in opposition of normal, rational practice of social life; polite, face-attentive interaction (Goffman 1955). According to Thomas (1965) "rude behavior is the kind of behavior which hurts people's feelings and causes them offence...it must give offence or be intended to offend, or be generally judged offensive" (p. 403). Rudeness therefore can be defined as "insensitive or disrespectful behavior enacted by a person that displays a lack of regard for others" (Porath and Erez 2007, p. 1181). We employ qualitative methods to develop a typology of consumer territorial rudeness.

Understanding Territoriality

Territorial behavior is defined as "a self/other boundary-regulation mechanism that involves personalization of or marking of a place or object and communication that it is 'owned' by a person or group. Personalization and ownership are designed to regulate social interaction and to help satisfy various social and physical motives. Defense responses may sometimes occur when territorial boundaries are violated" (Altman 1975, p. 107). Thus, territoriality involves three distinct behavioral dimensions; marking, encroachment and defense.

Marking: Territorial markers serve as a mechanism to dissuade or delay others from invading space already spoken for (Shaffer and Sadowski 1975; Sommer and Becker 1969). Markers also serve preventative and regulatory functions (Altman 1975). They regulate the level of social interaction, and offer individuals or group the choice to not engage others or allow them into claimed space.

Encroachment: When these self-relevant spaces are invaded, the response is likely to be commensurate in intensity with the loss of control. Lyman and Scott (1967) distinguished three forms of territorial encroachment: *violation*, *invasion*, and *contamination*.

The term *intrusion* which refers to someone who uses and claims the space of another group or person was introduced by Goffman (1971) to encapsulate both violation and invasion.

Defense: The most common defensive behaviors are verbal responses like arguments and discussions. Other defensive behaviors can include gestures, facial expressions and body posture changes (Altman 1975). Knapp (1978) identified two types of territorial defenses: *prevention defenses* and *reaction defenses*.

Methods

Since the existing literature revealed little in terms of research on consumer territorial rudeness, qualitative methods of depth interviews and a territoriality thematic apperception test were chosen to allow for full exploration, clarification and development of the concept of territorial rudeness (see Strauss and Corbin 1998; Murstein 1963; Morgan 2002). Data were analyzed using the thematic analytic technique (Brun and Clark 2006; Boyatzis 1998).

Findings

We determined territorial rudeness is context, situational and individual characteristic dependent. With this in mind, we define *territorial rudeness* as territorial actions (including ignoring a person and language) and demeanor (including personality characteristics and attitude) that is interpreted by others in the setting as ill-mannered or discourteous to customers, the place or the owners. The results indicate that consumers perceive lingering, disregard for others in the usage of space, and intrusion to be rude.

The Sprinter Effect: When Involvement and Self-Control Fail to Overcome Ego-Depletion

Danit Ein-Gar, Tel-Aviv University, Israel

Yael Steinhart, University of Haifa, Israel

EXTENDED ABSTRACT

Recent studies have explored the mechanisms that can help individuals overcome a depleted state. These studies pointed to several mechanisms such as increasing glucose levels in the blood, introducing humor, raising situational involvement, and personality dimensions such as chronic self-control. The current research focuses on exploring what happens when two of the above mechanisms interact together in depleting states. More specifically, we focus on the joint effect of situational involvement and chronic self-control on performance under depleted states. The literature has demonstrated the separate effects of each factor in dealing with ego-depletion. Thus, the separate effect of enhancing situational involvement helped overcome an ego-depleted state and similarly having high dispositional self-control decreased the likelihood of spending money even under depleted states.

However, little attention was given to what happens when the two take place simultaneously, as most often occurs in real life. The current research posits that although self-control and involvement separately may lead to the same pattern of behavior, when joined together they cause a turnover effect resulting in less controlled behavior under depleted states.

Individuals with high self-control and high involvement have a greater need to perform well in an ego-depleting task compared to individuals who have little involvement or low levels of self-control. Consequently, these high self-controlled and high involved consumers allocate extended resources in order to perform well in an ego-depleting task. When faced with a series of such tasks, however, this extended effort may leave them with fewer available resources for subsequent tasks. In other words, these extremely motivated consumers over exhaust their resources up to the point of no recovery. Therefore, when faced with the next self-regulating task, even their high motivation will fail to help them perform well. In contrast, consumers who are less motivated are expected to invest fewer resources in a demanding task, so they suffer less from ego-depletion. As a result, when they encounter a subsequent task, they will be able to perform relatively well because they have not expended all their resources on the former demanding task.

Study 1 tested participants' performance in an ego-depleting task and then their performance in recognizing "jumbled-up" known brand-names. Under the depleting condition, high self-controlled, high involved participants performed well in the ego depletion task in comparison to less motivated participants. However, the same high self-controlled, high involved participants had fewer resources available for the following task, and therefore, performed worse in the brand recognizing task. That is, after being depleted, extremely motivated participants recognized fewer brand names compared to those with lower levels of motivation.

Study 2 was conducted in a grocery store with shoppers. Both involvement and ego-depletion were activated before participants entered the store, and the resulting effects on shoppers' impulsive buying behaviors were measured as they were leaving the store. As hypothesized, under a depleted state, involved shoppers with high self-control were more likely to engage in impulsive buying than other, less involved or less self-controlled shoppers.

It is, however, an over generalization to claim that very involved, very self-controlled consumers are always prone to reach the ego-depletion low-point-of- no-recovery and consequently act less rationally or perform poorly in subsequent tasks. Hence, we

postulate that a state of mind metaphorically resembling a "marathon" runner's mindset will cause the opposite effect. When a runner is about to run a short sprint without being informed in advance that there will be a number of sprints, she may put all her efforts into the first sprint and then will be left with no available resources for the following ones. However, if the same runner was informed that she were running a marathon consisting of a number of runs one after the other, she would probably manage her efforts differently, reserving some strength for the last runs.

Accordingly, in the last study (Study 3) we wish to show that informing consumers about the number of tasks they are expected to perform and giving them a general description of the tasks, (without indicating anything about the need for self-control) will allow them to activate a resources conservation strategy and consequently to avoid the burnout. In this case, when highly involved, high self-controlled consumers know in advance that they are about to conduct multiple consumption tasks, they enter a "marathon" state of mind. They try not to expend all their efforts on the first task; they try not to exhaust themselves so that they ensure they have enough resources to perform well in later tasks as well.

In Study 3, we repeated the procedures used in Study 1 with two exceptions; First, participants were informed about the total number of tasks at the outset. Informing participants about the outline of the tasks was expected to make the difference between a "sprint" mindset and a "marathon" mindset. Second, after the depleting task, participants read a hypothetical consumption scenario and indicated their probability of buying impulsively different grocery products.

As expected, the results of this study altered the results of studies 1 and 2 and show that when planning ahead, the sprinter effect is diminished. In the ego-depleting condition, high involved participants with high self-control were less willing to buy impulsively grocery products than participants with lower motivation levels.

At What Stage of Process Does Depletion Hurt the Most?

Darlene Walsh, Concordia University, Canada
Antonia Mantonakis, Brock University, Canada

EXTENDED ABSTRACT

Researchers have offered many different theoretical models to better understand self-regulation. One such model is the ego-depletion model, whereby the self has a limited reserve of some resource, that is analogous to strength or energy, which is used whenever the self actively regulates, changes, or overrides responses. According to this model, when an individual engages in an initial task that requires self-regulation, they do not have the resources available to exert self-regulation on a subsequent, unrelated task also requiring self-regulation (e.g., Baumeister, Bratslavsky, Muraven and Tice 1998; Baumeister, Heatherton and Tice, 1994; Muraven and Baumeister, 2000; Baumeister, Sparks, Stillman and Vohs 2008).

Many researchers interested in self-regulation and consumer behaviour have examined various applications of this model, and have observed that depletion results in more passive, uncompromising, and affective consumer decision making (Baumeister et al. 2008). However, the goal of our research is to obtain a better understanding of the mechanism underlying the ego-depletion model. Specifically, we investigate whether there is a point within a self-regulation task that the effects of depletion are most detrimental. Our research question is, are the effects of depletion more evident at initial stages of a self-regulation task (i.e., when getting started on the task) or does depletion impede performance consistently throughout the entire self-regulation process? To answer this question, we designed and conducted two experiments described below.

In experiment 1, we created a self-regulation task that captures the process of learning a basic skill and assessed participants' ability to learn this task while they were depleted or not (Baumeister and Showers 1986). The self-regulation task required that the participants type out six-letter strings using only the index finger of their dominant hand. To assess the point that depletion influences performance, we recorded both the time it took participants to initiate a response (i.e., the time it took to type the first letter of the string) and the time it took participants to complete the response once it was initiated (i.e., the time it took to type the remaining letters of the string). We term these two components of the behavior *response initiation* and *response completion*, respectively. We manipulated depletion using self-presentation (see Baumeister and Showers 1986), such that participants in the depletion condition completed the task while the experimenter stood directly to the left of them, which induced self-attention, and as a result, self-presentation concerns (e.g., Baumeister and Steinhilber 1984). Participants in the no depletion condition were not watched.

We found that participants were slower to initiate the response on the self-regulation task when they were depleted than when they were not depleted. However, once depleted and non-depleted participants had initiated the task, they required the same amount of time for response completion. These results suggest that depletion influences an individuals' capacity to initiate the appropriate self-regulation response, but does not influence the self-regulation process once it has begun. Said differently, we found that depletion influences *response initiation*, but not *response completion*.

In experiment 2, we tested whether the detrimental influence of depletion caused primarily by a slowing of response initiation can be attenuated as participants learn the self-regulatory task. Assuming that performance can be described as either a controlled

process, which is typically described as slow and effortful, or as an automatic process, which is usually described as fast and effortless, it is likely that controlled processes are dominant early in learning but give way to automatic processes later in learning (Shiffrin and Schneider 1977; Shiffrin and Schneider 1984). In other words, once a task is well-learned, the negative influences of depletion might have less of an impact on performance. Thus, the primary purpose of experiment 2 was to test whether the effect of depletion on response initiation dissipates as a task becomes well-learned. To do this, we used the same self-regulation task and depletion manipulation that we used in experiment 1, but extended the number of trials of learning, making the task relatively well-learned.

We replicated the results of experiment 1, showing that it is the *initiation* component of responding that is influenced by depletion, not the response *completion* component. In addition, we found that as experience in this self-regulation task grows (i.e., as the task becomes habitual) the effect of depletion on response initiation was reduced.

Forgetting Without Inhibition: A Resource Depletion Account of Retrieval-Induced Forgetting

Andrea Hughes, University of the Fraser Valley, Canada
Antonia Mantonakis, Brock University, Canada

EXTENDED ABSTRACT

The construct of inhibition has long been part of language, both in daily life as well as in scientific theorizing. From an experimental psychology perspective, the term inhibition has two primary functions: to explain basic neuronal behavior within the central nervous system, and to account for a variety of *deficits* in both cognitive and social phenomena (Aron 2007). It is the latter function that is the focus of this paper. The goal of the present research was to examine the utility of the concept of inhibition within the domain of memory and we use the retrieval induced forgetting paradigm—a paradigm which has been paramount in the development of the cognitive inhibition account—as a tool to demonstrate the limitations of the notion of inhibition as a psychological construct. In the case of the retrieval-induced forgetting effect, which is the observation that retrieval of some items in memory impairs other items in memory (Anderson, Bjork and Bjork 1994), we suggest a mechanism involving resource depletion (Muraven and Baumeister 2000; Vohs and Heatherton 2000).

The resource depletion mechanism takes into account both a person's capacity limitations (Baddeley 1996) and the strategies used to perform a memory task. According to the resource depletion view, the self has a limited reserve of a resource that is deployed whenever the self actively regulates, changes, or overrides a response (Baumeister and Heatherton 1996). Resource depletion is observed by some deficit in task performance; when participants must engage in some sort of self-regulatory task, performance on a subsequent task is inferior compared to a baseline for which no such regulatory task has been engaged in (Vohs and Heatherton 2000).

The resource depletion view does not suggest overarching deficits in motivation or ability, as depletion occurs only in tasks that require active control of the self. Depletion occurs when a person engages in more complex, but not simple, cognitive tasks, suggesting that, when depletion occurs, performance on subsequent, but also resource-laden, cognitive tasks declines (Schmeichel, Vohs and Baumeister 2003).

In light of the findings in the literature on self regulation, we questioned whether retrieval practice involves a form of self-regulation. That is, retrieval practice requires the individual to control responses on some task. Therefore, performance on the subsequent task (final recall) is inferior compared to a baseline for which no retrieval practice has taken place; failure to remember during final recall seems to not be due to inhibition, but rather, to the depletion of the resource needed to be successful during retrieval practice and again in the final recall test.

We first replicated the basic retrieval-induced forgetting effect (experiment 1) using the standard procedures which employ a 30 second recall opportunity. We posited that during the initial task—the retrieval practice session—one must actively practice some items from some categories, which depletes resources. In consequence, given that the final test requires the same set of resources as those required for the retrieval practice, and given that it is easier to report the practiced items; unpracticed items are not reported on the final test. We reasoned that allowing more time on the final test may provide an unconstrained context that allows report of all items. According to the resource depletion view, allowing participants more time to recall may provide a better context for which

participants can use whatever is left over from their self-regulatory resources. Thus, experiment 2 was virtually identical in procedure to that of experiment 1 with the exception of the amount of time given to recall each category on the final test. We observed no retrieval-induced forgetting, providing evidence to support the hypothesis that the forgetting effect is, at least in part, determined by the demands of the recall task.

The aim of experiment 3 was to investigate resource depletion in an alternate way. We manipulated recall order on the final recall test. A resource depletion account would suggest that there should be greater decrements in recall for whatever is retrieved second, which is what we observed. An inhibition account would argue that “retrieval induced forgetting” should be observed regardless of output order.

A resource depletion account would predict that the self begins with a limited stock of any given resource, which is consumed when one engages in cognitive activity. This consumption results in decrements in performance on subsequent tasks that require the same resource. As long as the same resource is required in the second task as the first, decrements should be observed. An inhibition account instead makes specific predictions about when inhibition should occur at the taxonomic level. For example, there cannot be inhibition across categories: repeated practice in retrieving some members of a class should impair retrieval of other member of that class, not members of other classes (Anderson, et al 1994; Alba and Chattopadhyay 1986).

Based on this assumption, in experiment 4 we carried out a between-subjects manipulation which varied the number of categories used. Based on the findings of our previous experiments, we predicted that the amount of retrieval-induced forgetting will decrease as the number of categories decreases. Such a finding would further call into question the need for the mechanism of inhibition. That is, if the forgetting effect is attenuated by reducing the number of categories, there can not be a role for inhibition, as inhibition occurs within a particular category. However a finding that the forgetting effect is attenuated by reducing the number of categories would provide additional support of a resource depletion account. That is because, by reducing the number of categories, the resource required for retrieval practice is depleted to a lesser extent than with more categories. As such, reducing the number of categories should lead to a lower likelihood of performance decrements. Comparing the decrement in recall for the 8-category group to the same means of the 6-category group, there was a reliable decrease in retrieval induced forgetting for the 6-category group. This result provides compelling support for the resource depletion account of retrieval induced forgetting.

“The Name Remains the Same for Fans”–Why Fans Oppose Naming Right Sponsorships

David M. Woisetschlaeger, University of Dortmund, Germany

Vanessa J. Haselhoff, University of Dortmund, Germany

EXTENDED ABSTRACT

The selling of a stadium's naming right is one very common type of sponsorship. For example, 14 out of 18 German soccer stadiums have sold their stadium's name in the last 15 years. Although financially highly profitable for a club, naming right sponsorships are not without risk. Clark, Cornwell, and Pruitt talk of “high controversy surrounding sponsorship deals” (Clark, Cornwell, and Pruitt 2002, p.17). Greenberg and Gray (1996) as well as Crompton and Howard (2003) refer to some examples of public opposition to stadiums' name selling. While the fit between sponsor and sponsee is empirically examined as a success factor of sponsorship (e.g. Simmons and Becker-Olsen 2006, Speed and Thompson 2000), little knowledge exists to guide the management of such companies that are in the particular situation of a low fit or even reactance of consumers. The present article contributes to the literature by examining the determinants and consequences of sponsorship fit using a qualitative and a quantitative study.

To gain a first idea of possible reactance motives of soccer fans, we followed an explorative approach by conducting in-depth interviews with 22 fans of Borussia Dortmund. The popular German soccer club sold the stadium's naming right to a local insurance company which was followed by negative reactions of its fans. To uncover the fans' deeper motives, the laddering-technique was applied (Gutman 1982, Reynolds and Gutman 1988). In summary, several aspects seem to influence the naming right-reactance. These include the fans' sense of tradition and their regional identification, their fan identity, and their attitude towards commercialization. Other aspects compromise the sponsor's regional identity as well as the perceived benefit of the sponsorship for the soccer club. A central factor was the perceived fit between the sponsor and the sponsee.

The second study aims to quantify the directions and strengths of effects that the attitudes identified in study 1 have on the evaluation of the sponsorship. More precisely, in accordance with findings from existing literature we propose that the perceived fit between sponsor and sponsee is crucial for the evaluation of the brand (club) image and intentions toward the brand (club), i.e. positive word-of-mouth. From a theoretical point of view, a miss-fit perceived by the consumer is equivalent to incongruence between sponsor and sponsee. Such incongruence causes psychological tensions in the consumer's mind and forces to reestablish congruence (Festinger 1957, Heider 1946 and 1958, Osgood and Tannenbaum 1955). Hence, a perceived miss-fit should be related to a more negative evaluation of the sponsor and the sponsee.

Due to the crucial role of fit for the success of the sponsor partnership, it is important to assess the effects of possible determinants of fit. The aspects derived from study 1 are used to develop theoretical explanations for possible effects on the perceived sponsor-sponsee fit. First, the degree to which fans identify themselves with the soccer club could be negatively related to the perceived fit. Consumers classify themselves and other consumers as being an in-group member or as being a member of the out-group (Carlson 2005). We propose that fans that identify themselves strongly with their soccer club are more likely to treat a sponsor as an intruder. Taking the same rationale, we propose that regional connectedness and tradition consciousness contribute to consciousness of kind and consequently increase the likelihood that the sponsor is not accepted as in-group member. Moreover, a negative attitude towards

commercialization in general is likely to have a negative influence on sponsorship-fit. Finally, two positive aspects were mentioned in study 1 that could contribute to a positive perception of sponsor-sponsee fit: perceived benefits of the partnership and perceived regional identification of the sponsor.

To test the hypotheses, data was collected via an online survey. A total of 524 respondents participated, who are mostly male (93.2%), young ($m=24$ years), and highly involved fans showing a strong identification with their soccer club Borussia Dortmund. We measured attitude-related variables with multi-item scales. The dependent variables (brand image and word-of-mouth intention) are operationalized for the club (sponsee) and the sponsor. Three items are used to measure the brand/club image. Word-of-mouth intention is measured by four items adopted from existing literature again for the sponsor and the sponsee (e.g. Algesheimer, Dholakia, and Herrmann 2005). The evaluation of the sponsor-sponsee fit is included as a mediating construct (Simmons and Becker-Olsen 2006). As determinants of sponsor-sponsee fit, scales for attitude toward commercialization (Lee, Sandler, and Shani 1997), and fan identification (Algesheimer, Dholakia, and Herrmann 2005) were adopted from existing literature. Based on the findings of study 1, the fans' sense of tradition and their regional identification, and the sponsor's regional identification as well as the perceived benefit of the sponsorship for the soccer club were measured by multi-items scales developed by the authors.

Structural equation modeling was used to estimate the parameters of the structural model. Goodness-of-fit statistics indicate the overall acceptability of the structural model. The proposed positive relationship of fit and the dependent constructs brand (club) image, and brand (club) WOM intention is only valid for the sponsoring brand. The negative fit is attributed to the sponsor, while the sponsee's image remains unaffected. Furthermore, the perceived benefits for the club have the strongest positive impact on fit. The regional identification of the sponsor is another important positive determinant. The degree of regional connectedness and the attitude toward commercialization have a negative influence on fit. No significant influence is found for fan identification and tradition consciousness. A total of 63.6 % of the variance of fit is captured by the determinants above.

Results of the two studies demonstrate that negative effects of sponsorships are especially relevant for the sponsoring company since both brand image and WOM-intention are affected negatively. Some attitudes that affect the sponsor-sponsee fit like attitude toward commercialization and regional connectedness seem to be difficult to influence. The good news is that the strongest determinants of the sponsor-sponsee fit are at least potentially manageable by the sponsor: through communication of the benefits of the partnership, and by communicating the regional identification of the sponsor.

Why Thematization?

A. Fuat Firat, The University of Texas-Pan American, USA
Ebru Ulusoy, The University of Texas-Pan American, USA

EXTENDED ABSTRACT

Thematization, a flourishing phenomenon, has attracted attention by scholars who observe contemporary culture. Many scholars observe thematization as a recent trend and make a distinction between themed spaces and the rest of the world. We argue that thematization is not a recent phenomenon and that the distinction made between environments considered themed and not themed is one of perspective, not present in the nature of the phenomenon. We investigate the reasons why a distinction is favored in popular culture and why interest in thematization has increased lately to propose an extension to explanations that concentrate on theming as a profitable business in contemporary culture. Our exploration of the history and conceptualization of thematization, indicates that the main force underlying the increased interest in thematization is cultural rather than economic.

Past conceptualization of thematization basically evolve around elements that constitute themed environments, such as social control, entertainment, fantasy, decentralization and privatization, and the spectacle (Gottdiener 1995, Ritzer 1999). In order to provide a direct definition without a prejudgment of its separation from the everyday, we define thematization as the patterning of space, activity or event to symbolize experiences and/or senses from a special or a specific past, present, or future place, activity or event as currently imagined.

Two themes are common to many of the theses regarding thematization (Gottdiener 2001; Sorkin 1992; Baudrillard 1996; Davis 1999; Beardsworth and Bryman 1999; Ritzer 1999): (1) thematization is driven by corporations and (2) contemporary consumers are accomplices in the theming of the world.

For corporations, competing for consumers who pay greater attention to the symbolic and the spectacle (Debord 1983), thematization is a sophisticated marketing technique (Gottdiener 2001) that serves economic interests by transforming the mundane to attractive, thus rendering it marketable. Humanistic values and enchanted forms in theme production are also means that help thematization serve the economic interests of corporations. Corporations institutionally create themes to imply social action and caring for the ecosystem.

Recent themed environments impact on all human senses by utilizing a multidimensional system of signs. They are, thus, are attractive to contemporary consumers who need multidimensionality in spaces and experiences (Featherstone 1990). Consumers who visit themed environments enjoy and appreciate them if they find experiences of meaning and substance (Firat 2001), and as their needs for emotional, symbolic, and spiritual relief through encounters with public space, nature, democracy, and other cultures are fulfilled (Gottdiener 2001). Theming also provides securities sought in modernity, such as physical safety and hygiene (Beardsworth and Bryman 1999). Themed places introduce alternative visions of what people seek and become a new source of cultural capital (Hannigan 1998).

The most telling explanation for consumer interest in themed environments is the growth of a postmodern cultural sensibility where people develop a tacit understanding of the futility of making a distinction between the 'real' and the 'fantasy', everyday spaces and themed spaces. Thus, we find consumers ready to experience the thematic without reservations.

Consequently, the special interest in distinguishing certain spaces as themed and others as not themed tends to be an aberration of contemporary culture and a consequence of modernity that is maintained and reinforced by the emerging postmodern cultural sensibility where alternative modes of being and living are sought, and commitment to or the belief in the possibility of constructing one ideal order has waned. Recognizing this quest for difference and multiplicity, the corporations find production of 'themed' environments as a panacea to their cultural bane, their guilt in having constructed a disenchanting modern order, as at the same time they profit from offering such environments to consumers. Furthermore, maintaining the illusory distinction of the 'themed' versus 'everyday', 'fantasy' versus the 'real', absolves them from being blamed as the culprit in humanity's disenchantment. In this absolution, they are aided by the members of the middle class who also tacitly recognize their complicity in having passively accepted and gone along with the lives that modern corporations created, at the same time they also seem aware of the illusory distinctions so maintained.

Representing the 'themed environment' as an economic strategy to develop market offerings, scholars have also inadvertently aided corporate interests. It is important, therefore, to deconstruct the current theses about thematization and provide insights that may further humanity's quest in building meaningful and substantive lives.

When reality is perceived as constructed and thematic, people afford greater power to reconstruct it as can be imagined. When reality is perceived as 'out there', people feel resigned to what they have inherited. As the illusory nature of the distinction between where people live everyday and where they go to have fun is articulated, the consciousness is gained that maintaining the distinction and organizing lives accordingly is not only limiting humanity's potentials to build more habitable worlds, but that it also perpetuates certain interests and a human condition that humanity can better do without.

Product Bundles and the Compositional Nature of Contextual Information

Dan Rice, University of Florida, USA
Alan Cooke, University of Florida, USA

EXTENDED ABSTRACT

With all of the attention that examinations of bundle evaluations have garnered in the literature, it is surprising that no research has investigated how consumers process contextual information when the context, target, or both are composed of bundles. The evaluation of individual product offers has been shown to be sensitive to dominance (Huber, Payne and Puto 1982), attribute tradeoffs (Simonson and Tversky 1992), tradeoff extremity (Simonson and Tversky 1992), attribute range and spacing (Cooke and Mellers 1998; Mellers and Cooke 1994; Parducci 1965), timing of product presentation (Wedell, Parducci and Geiselman 1987), and the extremity of the contextual products (Herr 1989), to name a few. Despite these results, little research has investigated how contextual information is processed when the target or contextual offers consist of product bundles. Here, contextual information is available not only in the distributions of each product category, but also in the joint distributions of attributes across different bundles containing these products. This compositional information may also serve as a context relative to which bundles are evaluated.

The primary goal of this research is to demonstrate that consumers are sensitive to how single contextual products are combined into bundles when evaluating target stimuli. To avoid confusion, we refer to this previously unexplored compositional contextual information as "bundle context," and the context created by single products as "single product context." After demonstrating the existence of bundle context effects, we further examine the process by which consumers account for the bundle context and explore moderators of the effects. We propose that the influence of bundle context is due to effortful comparisons between the bundle and the surrounding context, and the relative difficulty of these comparisons moderates the effects of the context. Three experiments provide evidence to support our hypotheses.

Our first experiment used a constant set of eight individual products that were pretested for attractiveness. The four moderately attractive products were combined into high and low attractiveness target bundles. Bundle context was manipulated by differentially combining the remaining four contextual products in different conditions. In the wide bundle contexts, the two most attractive products were bundled together in one contextual bundle and the two least attractive products were bundled together in the other. This created a wide range of overall attractiveness at the bundle level. In the narrow bundle context, the most attractive contextual item was paired with the least attractive contextual item and the second most attractive item with the second least attractive, forming a relatively narrow range of overall bundle attractiveness with the same individual products.

The results of experiment 1 show that bundle context influences the way consumers perceive contextual stimuli even when single product context is held constant. Target bundles appeared more similar in the wide context, where contextual bundles had widely disparate overall evaluations, than in the narrow context, where contextual bundles were more similar in overall evaluation. If consumers were only sensitive to single product context or were insensitive to context effects, the evaluations of the target bundles should have been constant across all conditions.

The results also revealed that bundle attractiveness was significantly less than the most attractive product it contained in all but the wide context, high context bundle comparison. This might be

due to a ceiling effect of the two best products combined together in one bundle. This pattern of results is inconsistent with an additive model, even one allowing for extreme subadditivity. However, it is consistent with a number of alternative combination processes including both averaging and anchoring and adjustment processes.

A second experiment investigated whether the effects could be attributed to response language effects in the judgment process. The results of experiment 2 provide evidence that bundle choice reversals are possible and consumers are sensitive to the aggregate levels of attributes within the bundles of the contextual set even when the individual products in the set are held constant. From a theoretical standpoint, the choice reversal between target bundles is important because it shows that bundle context effects are a representational phenomenon that cannot be explained away by response language effects or single product context. That is, we obtain choice reversals between target bundles in a constant product set where the attribute levels only change at the bundle level. From a managerial perspective, the findings are important because they show that it is possible to create choice reversals between bundles simply by rearranging the products surrounding those bundles without adding new products to the set.

The third experiment investigates the process by which consumers account for the extra compositional information of how the individual products are paired in bundles (i.e. the bundle context). The results of experiment 3 indicate that bundle context effects are due to effortful contextual comparisons between bundles in the set. Participants found the bundle context information useful and tried to extract the information, but they were influenced more by the more attractive product in the bundle when under load.

Recognition analyses provide evidence that the attractiveness of the product influences recognition of the product. The analyses also show that the effect of attractiveness on recognition is greater under load. We interpret these results as an indication that the more attractive products were processed more deeply, creating better memory for those products (Craik and Lockhart 1972). This is consistent with consumers anchoring on the more attractive product and adjusting for the less attractive products in bundle evaluations (Yadav 1994).

The Impact of Anticipated Follower Entry on Consumer Acceptance of Pioneer Brands

Zhenfeng Ma, University of Ontario Institute of Technology, Canada

Ying Jiang, University of Ontario Institute of Technology, Canada

EXTENDED ABSTRACT

Existing research on pioneering advantage has implicitly treated followers as a threat to the pioneers (Shankar, Carpenter and Krishnamurthi 1998; Golder and Tellis 1993). However, Carpenter and Nakamoto (1989) suggest that the market entry by late movers may actually increase consumers' preference for the leaders, especially when the late movers' products are not sufficiently differentiated (i.e. 'me-too' followers). In this study, we propose that the impact of the anticipated market entry by 'me-too' followers on the pioneer brands depend on the innovation newness and network externalities of the products. We show that the me-too followers' market entry announcements increased consumers' acceptance of the pioneer of really new products but not incrementally new products. We also demonstrate that for the pioneers of really new products, the positive impact of anticipated follower entry is more evident when the products exhibit high (versus low) indirect network externalities.

The Moderating Effect of Innovation Newness

Consumers usually perceive higher risks in buying really new products (RNPs) (Ram and Sheth 1989). Based on the research on category learning, we propose that the anticipated market entry by me-too followers may increase the conceptual clarity of the RNP category, thereby reducing consumers' uncertainty about the pioneer brand. Specifically, for a RNP category, me-too followers serve as category exemplars to increase the perceptual and conceptual salience of the RNP as a distinct product category. The increased conceptual clarity about the category can in turn reduce consumers' uncertainty and enhance consumers' acceptance of the pioneer. Moreover, the market entry by followers may be perceived as endorsement of the technologies used by the pioneer of a RNP, which increases consumers' confidence in the pioneer. In contrast, followers' entry may decrease consumers' acceptance of the pioneer of an incrementally new product (INP), because when the innovation newness of the product is low, the perceptual dominance of the pioneer is low, and it is easy for late comers to design products that deliver better performance than the pioneer brand. We thus hypothesize:

H1: Anticipated follower entry increases consumers' purchase intention toward the pioneer of a really new product, but decrease consumers' purchase intention toward the pioneer of an incrementally new product.

H2: The effect of anticipated follower entry on consumers' purchase intention toward the pioneer brand of a really new product is mediated by consumers' perceived risks.

The Moderating Effect of Indirect Network Externalities

Indirect network externalities (INE) exist when a customer's utility for a product increases as the number of complementary products increases (Srinivasan, Lilien and Rangaswamy 2004). Consumers often adopt a "wait-and-see" attitude toward pioneer brands with high INE, because they cannot obtain the full benefits of such products until there are sufficient complementary products. We posit that for the pioneer of a RNP with high INE, followers' market entry increases consumers' anticipated availability of the complementary products, thereby increasing the expected utility of the products. However, the impact of follower entry on the pioneer

of low-INE will be minimal, for the link between anticipated availability of complementary products and the perceived utility is weak for such products (Farrell and Saloner 1986). We thus hypothesize:

H3: Anticipated follower entry is more effective in increasing consumers' purchase intention toward the pioneer of really new products that exhibit high versus low indirect network externalities.

Study 1

Research hypotheses were examined by two experimental studies. The purpose of Study 1 is to examine the effect of anticipated follower entry on consumers' purchase intention towards the pioneer brand of a RNP versus an INP, and the underlying psychological mechanism of such an effect. One hundred and forty-five undergraduate students (94 males and 53 females) participated in this study. The study was a 2 x 2 design with anticipated follower entry (with- vs. without-follower) and innovation newness (RNP vs. INP) as the between-subjects conditions.

Anticipated follower entry and product type were manipulated by a purported news report about a new TV. In the RNP conditions, the product was described as a TV which can display vivid 3D images without the need for special glasses. In the INP conditions, the product was a LCD TV which outperforms existing models in several key attributes. In the with-follower entry conditions, the news report stated that the major competitors of the pioneer brand have announced plans to introduce their own LCD (3D) TVs based on technologies similar to those of the pioneer. In the without-follower entry conditions, the news report stated that the pioneer brand is the only LCD (or 3D) TV of its kind in the market and will remain as the sole player in the foreseeable future.

Consistent with H1, anticipated follower entry increased consumers' purchase intention toward the pioneer brand of a RNP, but had decreased consumers' purchase intention toward the pioneer of an INP. Consistent with H2, the effect of anticipated follower entry on purchase intention toward the pioneer brand of a RNP was mediated by perceived risk, especially by perceived financial risk.

Study 2

Study 2 tests the impact of anticipated follower entry and indirect network externalities on consumer acceptance of the pioneer brands. The study used a 2 (high vs. low INE) x 2 (with vs. without anticipated followers) between-subject design. Seventy-two undergraduate students (48 males and 24 females) participated in this study. INE and follower conditions were both manipulated by a news report about a 3D TV. In the low NE condition, the news report claimed that the TV either require (high INE) or did not require (low INE) any specially formatted TV programs or DVDs to show the 3D images. The anticipated follower condition was manipulated in the same way as in Study 1.

Consistent with H3, anticipated follower entry increased consumers' purchase intention toward the pioneer of high-INE products to a larger extent than toward the pioneer of a low-INE product.

Discussion

Previous research on pioneering advantage has focused on situations where the pioneer's best strategy is to create and defend

a market position that minimizes competition. In this study we found that the positive impact of the me-too follower's entry on the pioneer is contingent on the innovation newness and network externalities of the product. Thus, marketing managers need to take into account these specific product characteristics when formulating competitive strategies.

How to Overcome Customers' Adoption Barriers?

Sabine Kuester, University of Mannheim, Germany

Silke Hess, University of Mannheim, Germany

EXTENDED ABSTRACT

Customers' resistance to innovations turns out to be a significant managerial problem as it is a major cause of new product failure. Resistance refers to a negative outcome of new product evaluation and is evoked by several adoption barriers, which inhibit the intention to adopt the innovation. Prior research has focused on functional adoption barriers such as innovations' perceived risk or expected value and has identified marketing instruments to overcome these barriers (Bearden and Shimp 1982; Ziamou and Ratneshwar 2003). Other studies in a new product context point to the need to target customers' cognitive barriers that refer to the complexity associated with the evaluation of innovations and lead to an unfavorable judgment (Moreau, Lehmann, and Markman 2001; Ozanne Brucks, and Grewal 1992; Peracchio and Tybout 1996). Therefore, in this research, we identify marketing communication instruments that decrease perceived complexity of new products and reduce customers' difficulties in evaluating innovations. In doing so, we also account for innovation-specific and customer-specific factors that may moderate the effects of these instruments on customers' adoption barriers.

In our study, cognitive barriers signify situations when the innovation is difficult to evaluate and to categorize into existing schemas. In this regard, cognitive barriers refer to the complexity associated with innovations and are the potential cause of resistance. Communicating that the new product belongs to an existing category may help customers to better understand and evaluate the innovation. In line with prior studies, we propose that providing a categorization cue in the presentation of a new product will reduce perceived complexity and in turn decrease innovation resistance (Gregan-Paxton and Moreau 2003; Moreau, Markman, and Lehmann 2001).

Furthermore, it is expected that innovation-specific and customer-specific factors moderate the effect of a categorization cue on perceived complexity. Prior research shows that the degree of newness perceived by customers is a crucial factor in the evaluation of new products (Veryzer 1998). Besides fundamental differences between more radical or incremental new products, consumer behavior research of new product evaluation shows that the relationship of judgment making and newness of information is not linear (Meyers-Levy and Tybout 1989; Ozanne et al. 1992). Therefore, following Robertson's (1971) continuum model of innovations, characterizing innovations as continuous, dynamically continuous, and discontinuous, we propose a U-shaped moderating effect of product newness on the relationship between categorization cue and complexity.

Since the objective of this study is to analyze the emergence of adoption barriers within a new product evaluation process, we regard customers' involvement and need for cognition as relevant moderating variables. Involvement leads to more extensive processing of new information. Consequently, we expect that a categorization cue will be more effective in a high involvement situation. Similarly, we hypothesize that individuals' willingness to make a cognitive effort is a prerequisite for the effectiveness of a categorization cue. Hence, we propose that individuals showing high need for cognition will be more engaged in using a provided categorization cue for new product evaluation.

Furthermore, we assume that experts are more competent than novices in evaluating new products of a particular category, since experts possess more distinct category knowledge. Yet, empirical

research provides an interaction effect between expertise and incongruity in such a way that experts and novices respond differently to a match or mismatch of new information (Sujan 1985). Therefore, we hypothesize a three-way-interaction between the impact of the categorization cue, expertise, and product radicalness.

In our experiment members of an online panel evaluated a continuous, a dynamically continuous, and a discontinuous product innovation. Overall, results support our hypotheses. Presenting new products with a categorization cue significantly decreases customers' perceived complexity and consequently innovation resistance. We also observed a significant interaction effect of categorization cue and product radicalness. As expected, this interaction effect was best described by an U-shaped curve. In this respect, the categorization cue is less effective for dynamically continuous new products as they are more incongruent to the induced category than incremental ones. To categorize dynamically continuous new products individuals need a larger amount of information, hence, the provided categorization cue is not sufficient and cannot resolve the discrepancy. In case of discontinuous innovations, individuals tend to analyze information more analytically and can use the categorization cue to reorganize cognitive structures. Besides, we found a moderating effect of customers' need for cognition and conclude that the effectiveness of a categorization cue requires the willingness to engage in cognitive processes. In line with our proposition, the impact of the categorization cue was larger in high involvement situations, although the interaction effect was not significant. Furthermore, the effect of the categorization cue on complexity was smaller for experts when evaluating an incremental new product. However, when evaluating a radical new product, this effect was larger for experts. We conclude that experts are more competent to categorize congruent information within their field of expertise.

We derive implications for innovation management and recommend managers to assist customers in evaluating and categorizing new products. Our research suggests that by providing a categorization cue innovation resistance can be prevented, and thus, new product failure avoided. Furthermore, when designing marketing communication instruments for new product launch, managers have to carefully consider the impact of innovation-specific and customer-related factors. In particular, our empirical results point to the need for customer-specific launch tactics such as a new product communication campaign that targets either experts or novices.

Measuring Salesperson Orientation of Consumers

Jeffrey S. Larson, Brigham Young University, USA

Sterling A. Bone, Brigham Young University, USA

EXTENDED ABSTRACT

Research on customer-salesperson relationships and sales performance has been plentiful (Churchill et al. 1985; Franke and Park 2006). This research can be divided into two major categories: 1) research that focuses on the properties of specific customer-salesperson relationships and the effects of those properties, and 2) research on enduring salesperson characteristics and their consequences.

More recently, researchers have begun to focus on the role of the consumer in the salesperson-customer interaction (Kirmani and Campbell 2004). Much of this study has grown from the acknowledgement of the Persuasion Knowledge Model of consumer behavior (Friestad and Wright 1994). This recent consumer-focused literature parallels the first category of the salesperson-focused stream of literature—an assessment of situation-specific consumer behavior in the sales process. We develop the Salesperson Orientation of Consumers (SOC) Scale to aid researchers and practitioners alike in understanding the many enduring consumer characteristics that affect the consumer-salesperson interaction.

We define the Salesperson Orientation of Consumers (SOC) as the enduring disposition of a consumer to engage in particular salesperson-related thoughts and behaviors across a variety of marketplace encounters with salespeople. Previous research on consumer behavior regarding salespeople has focused on how this behavior changes as a result of the properties of a particular interaction. By developing the SOC scale, we hope to identify and measure the salesperson-related behaviors that are determined more by consumer traits than the interaction.

To develop the Salesperson Orientation of Consumers (SOC) scale, we followed the procedures for creating and validating scales developed by Churchill (1979). First, an initial set of items were drafted. The original list of potential scale items came from several sources. A literature review on consumer-salesperson interaction turned up a 13-item scale from Goff, Bellenger and Stojack (1994) which measured consumers' orientation toward automobile salespeople. We adapted their scale items to address general salesperson orientation, rather than car-salesperson-specific orientation.

A second source of preliminary scale items came from a two-stage brainstorming process. In the first stage, we hypothesized various factors that consumers could use to describe their feelings and orientations toward salespeople, including factors from the literature and some of our own hypothesis. After brainstorming these factors with ourselves and by informal consultation with various colleagues, we generated several items to measure each of these factors. We then removed redundant measures, which resulted in a pool of 35 items.

Scale Purification: Study 1

The 35-item scale was administered to three different samples. The data from all three studies were subjected to separate exploratory factor analyses with a varimax rotation. In all three studies, the results suggested a four-factor structure with similar loadings across the 35 items. Individual scale items that either 1) did not load strongly on any of the four dimensions or 2) did not load consistently across all three studies were dropped. This left the 18 items below. Items 1-5, 6-10, 11-15, and 16-18 loaded on factors 1, 2, 3, and 4, respectively.

1. When a salesperson is helping me, I usually take his/her advice.
2. I value the opinion of salespeople.
3. I feel more comfortable buying something when a salesperson has recommended it to me.
4. I want salespeople to help me make decisions.
5. I trust the information I get from salespeople.
6. I feel some obligation to please salespeople.
7. I sometimes wonder if a salesperson thinks better of me as a result of my buying something.
8. I sometimes wonder if a salesperson thinks ill of me when I don't purchase anything.
9. I am sometimes afraid that a salesperson will think I'm cheap if I don't buy something.
10. When I decline to buy something, I feel bad for the salesperson.
11. I avoid stores with a lot of salespeople.
12. When shopping, I would rather make the decision on my own before talking to any salespeople.
13. I wish salesclerks only answered questions instead of trying to convince you to buy something.
14. I feel more comfortable entering a store where I know salespeople will not approach me.
15. I wish I could forever avoid having to talk to a salesperson.
16. I am a person who is easily convinced by salespeople.
17. I could be talked into a purchase by a persuasive salesperson.
18. For reasons I don't fully understand, pushy salespeople are often successful in getting a sale from me.

Factor Structure: Study 2

To test the new 18-item scale, 532 undergraduates completed the scale in exchange for extra credit in a marketing course. The data were then submitted to the same factor analysis with varimax rotation as previously performed to check that the factor loadings concurred with the data collected from the 35-item scale. The resulting factor structure aligned precisely with the one predicted. The data were also subjected to a confirmatory factor analysis in Lisrel 8.8, which confirmed the four-factor structure on all measures.

Interpretation of Factors

Information Seeking. Previous research has made much of the function of salespeople as experts aiding consumers to make better decisions (Wernerfelt 1994). Of course, consumers are likely to differ in their beliefs about salesperson motivations. The first factor in the SOC scale captures the consumer tendency to seek and value the information provided by salespeople.

Self Presentation. Personal interaction with a salesperson is one type of social interaction. In social interactions with salespeople, consumers are likely to vary in their concern for the impression they give to the salesperson (Lennox and Wolfe 1984). The second factor of the SOC scale measures this concern.

Avoidance. Previous research has shown that consumer heterogeneity in tolerance for salesperson interaction can lead to a differentiated retail equilibrium (Chu, Gerstner and Hess 1995).

The existence of this third SOC subscale provides some empirical evidence in support of their model specification. Consumers vary in the extent to which they seek to avoid salesperson interaction.

Convinceability. Despite universal contempt for high pressure selling tactics, salespeople continue to use them. Asch's conformity experiments and Milgram's fake-shock experiments illustrate the powerful effect of social pressure (Asch 1952; Milgram 1974). It should come as no surprise then that salespeople can often use social pressure to extract sales from not-entirely-willing consumers. Of course, consumers vary in the extent to which such sales tactics work on them. This fourth and final SOC subscale measures the extent to which consumers are influenced by salespeople.

Predictive Validity: Study 4

In study 4, participants responded to a number of vignettes about marketplace behavior relating to salespeople. Due to space limitations, we cannot present the results here, but the full working paper is available from the authors.

Does the Patient Really Act Like a Supermarket Shopper? A Semiotic Typology of Patients' Attitudes and Expectations towards the Health-Care System and the Consumption of Medicines

Isabelle Chalamon, Groupe ESC Dijon Bourgogne, France

Benoit Heilbrunn, ESCP EAP, France

Ines Chouk, IUT Cergy-Pontoise, France

EXTENDED ABSTRACT

What do patients expect of the health-care system? How can we explain the diversity of these expectations and how can we classify them? The purpose of this paper is to answer these questions by proposing a general typology of patients' attitudes and expectations towards the health-care system and medicines consumption.

In the health-care sector, the patient occupies a more and more central place. Increasingly active in health-care decision making (Shaffer and Sherrell 1995; Charles, Gafni, and Whelan 1999; Stevenson, Barry, Britten, Barber, and Bradley 2000), the patient is often treated as a "participant actor", as a "patient-expert" (Barbot 2002; Fox, Ward, and O'Rourke 1999), or as a "consumer" of medicine and health-care. He (or she)'s involved in his/her own diagnosis and treatment, (Herzlich and Pierret 1984) and is actively in search of information (Riskier 1996; Wagner, Hu, and Hibbard 2001). The patient, as a final user of the health care system, is thus emerging as an increasingly pivotal research object.

The existing literature presents many typologies such as patients' preferences for various attributes of the doctor-patient relationship (Vick and Scott 1998), patients' participation in healthcare decision-making (Flynn, Smith, and Vanness 2006), patient's behaviours in health-care services (Shaffer and Sherrell 1995) and of patients' satisfaction (Singh 1990). Two main limits of these approaches can be identified. Firstly, these typologies focus only on one dimension of the relationship between patients and the health-care system. A more global approach is required in order to really understand patients' preferences and expectations with respect to the health-care system and medicines consumption. Secondly, these typologies are based on "fixed" positions: each patient of the sample is "classified" in one cluster. But the points of view expressed are largely dependant on situational variables. We need to identify "virtual positions" and, based on these positions, built situational "scenarios". In this context, our research objective is to develop a general conceptual framework to understand and classify patients' expectations towards the health-care system and medicines consumption. Furthermore, from a managerial point of view, there is no clear market "segmentation" of patients behaviours in this sector. Thus, the aim of our research, is to propose a relevant "segmentation tool" in the health-care context. It will provide professionals in this sector with a global vision of the final consumer's expectations. Based on this segmentation, improvements in service quality and patients' global satisfaction could be made. Indeed, the proposed classification will help doctors and institutional organizations to better understand patients' expectations and hence to meet their preferences more accurately. Moreover, based on this typology, pharmaceutical firms and actors in the field of health-care could provide a better positioning of their offers and develop more adapted communication strategies.

In order to develop a typology based on virtual positions, we carried out a semiotic analysis (Greimas 1983; Greimas and Courtès 1983) of patient's representations and expectations of the health-care system and medicines consumption, on the base of 38 semi-

structured interviews. Four types of values expressed by patients were identified: the functional, the existential, the critical and the hedonistic values. The "functional" patient has a problem/solution logic and a functional approach towards health-care. On the other hand, the "existential patient" values health-care in a more global way: his definition of good health is more than just "not to be ill". This kind of patient trusts the system greatly and has a social approach to medicine: he feels that dialogue is a part of treatment and his choice may be influenced by peers or professional advice. The "critical patient" has a consumerist approach towards medicine. He is in a logic of comparison and budget-optimisation. Hedonistic valorisation is the negation of practical values. For this type of patient, health-care is a kind of "game" in which only the ludical dimension of the service is considered. Based on these values, a quantitative study was carried out in order to identify a typology of patients: data were collected on 200 patients. We identified four patient profiles: Hedonist, Functional, Optimizer, and Skeptic.

This study has two main contributions. First, this research underlines the interest of a structural semiotic approach to study the behaviour of health-care consumers. This approach provides an analytic tool to understand the variety of patients' attitudes and behaviours regarding health, health-care and medicines consumption. From a theoretical point of view, we can conclude that patients may be studied as consumers, and that medicine and health-care services are evaluated and valorised in the same way as other products or services. Second, this study provides a segmentation of patient behaviours. Based on patients' values, a typology of four patient profiles was proposed: hedonists, functionals, skeptics and optimizers. Based on the real-world heterogeneity of health-care consumers, our analysis should permit the development of a more targeted approach for each patient-type, and indeed a more global, uniform, yet accurately partitioned communication strategy. Depending on the cluster characteristics, different communication strategies should be adopted. For example, for skeptics, communication should be concentrated on the benevolence of the pharmacist/doctor. Optimizers, on the contrary, are more interested in cheaper products. Functionals are sensitive to the promptness of service, and hedonists to the benefits of the products on their welfare. Given the specificity of the context (France) and the size of our sample, additional research should be realized to determine the extent to which the results can be generalized.

Intersectionality: Insights for Consumer Research

Ahir Gopaldas, York University, Canada

Ajnesh Prasad, York University, Canada

David Woodard, Ontario Ministry of the Attorney General, Canada

EXTENDED ABSTRACT

Intersectionality is a research paradigm that considers how multiple social systems (such as race, class, gender, education, marital status, sexuality, religion, nationality, immigration status, disability, etcetera) co-determine the experience of human life (Collins 1986, 1990; Crenshaw 1989, 1991). Over the past decade, numerous, diverse, and even conflicting definitions, methods, and applications of intersectionality have preoccupied social theorists and paradoxically popularized the paradigm across the social sciences (Davis 2008). In this article, we conduct a multidisciplinary review of literature on intersectionality to chart a brief history, distinguish it from prior perspectives, organize its various meanings, and delineate McCall's (2005) tri-partite classification of (*anticategorical*, *intracategorical*, and *intercategorical*) methodological approaches to intersectional research. Next, we consider the general intellectual utility of intersectionality across the social sciences and specific implications for important topics in three consumer research paradigms. We believe this line of inquiry is important for a number of reasons:

Proliferation. The intersectionality paradigm is gaining currency in theory, education, and practice. It has been hailed as the "most important contribution that women's studies has made so far" (McCall 2005: p.1771). Major social science journals now expect intersectional approaches, while race-, class-, and gender-only studies can be seen as "theoretically misguided, politically irrelevant, or simply fantastical" and are thus often rejected (Davis 2008: p.68). Intersectionality is now also taught in introductory undergraduate and graduate courses (Ritzer 2007). Collins' (1990) foundational text on intersectionality (*Black Feminist Thought*) has been discussed and applied widely across the social sciences (its citation count currently exceeds 3000), and in 2008, Collins became the 100th President of the *American Sociological Association*. Finally, though theory is several steps ahead of practice (Verloo 2006), legal awareness of intersectionality is slowly reformulating governance policies in domains such as affirmative action, human rights advocacy, and social work.

Conceptual confusion. Despite its "spectacular success," Davis (2008: p.67) notes that intersectionality remains a confusing concept because it suffers from "ambiguity" and "incompleteness" (p.76). Hence, in this article, we aim to clarify the meanings of intersectionality by contrasting intersectional and non-intersectional approaches to social research and disentangling the paradigm's ontological, axiological, epistemological, and methodological facets.

Methodological complexity. Acknowledging the intersectional nature of social systems challenges researchers to account for an incredible amount of phenomenological complexity. However, the task of intersectional research is itself also a complex endeavor requiring careful methodological considerations to make it comprehensible. McCall (2005) offers the most extensive review of methodological approaches to date. We build on her tripartite classification of approaches to develop a comparative framework that elaborates on the distinctive features of each approach.

Transferable utility. Thus far, intersectionality has been applied to a limited number of substantive topics. We argue that intersectionality can be applied to any systematic study of differ-

ence, among or within social systems, in economic, cognitive, social, or cultural processes, in quantitative or qualitative research.

Transformative Consumer Research (TCR). TCR (Mick 2006) is an emerging paradigm that emphasizes the public policy goal of achieving consumer welfare in an otherwise theoretical discipline of consumer research. To further bridge the transformative-theoretical divide, we discuss how intersectionality is particularly well suited to address the theoretical concern of consumer vulnerability, a top TCR priority.

Consumer Psychology. Diversity is an important but significantly overlooked domain of consumer psychology (Williams, Lee, and Henderson 2008). We suggest how future diversity research can be attuned to the intersectional nature of social categories without losing sight of consumer psychologists' current methodological competencies (i.e. experimental and quantitative methods).

Consumer Culture Theory (CCT). The CCT paradigm (Arnould and Thompson 2005) has already begun to tacitly appropriate intersectional ways of thinking, especially studies of the *sociohistorical patterning* of consumption. In this article, we discuss less apparent implications for studies on *identity interpellation*.

The meanings of intersectionality. A multidisciplinary review of the current literature on intersectionality generates a plethora of nuanced meanings. Intersectionality has been described as a social phenomenon, a theoretical perspective, a set of normative guidelines, and a set of methodological practices. To encompass this wide array of meanings, we describe intersectionality as a paradigm and attempt to disentangle its ontological, axiological, epistemological, and methodological facets. The foundational ontological proposition of the intersectionality paradigm is that identity categories (*American, European, Black, White, Poor, Working-class, Middle-class, Professional, Men, Women, Illiterate, Educated, Single, Married, Divorced*, etcetera) are integrated in subjects (e.g. *White Professional Men*) and collude to produce unique social experiences, which cannot be adequately accounted for by the sum of essences (e.g. *White-ness, Professional-ness, Masculinity*) or the interaction effects at the level of systems (e.g. race, class, gender). However, the intersectionality paradigm does *not* make a universal statement about the extent or manner in which systems of categories are integrated *but* contends that this question be left open to empirical investigation in context. The paradigm's purpose is to highlight the prospect of partial to extensive integration of systems and to prescribe concepts and methods to investigate the extent and manner of such integration. In addition, the intersectionality paradigm also posits that the nature of being for any social subject is always multi-categorical, sometimes multi-level, internally heterogeneous, dynamic, crosscutting, and context-specific. In axiological terms, the paradigm is a two-fold political project to (1) reveal the matrix of privilege/oppression and (2) amplify the lived experience of marginalized individuals. For example, McCall (2001) empirically demonstrates the intersectional roles of race, class, gender, and context in producing wage inequality. The remainder of this article uses McCall's (2005) tri-partite classification of (*anticategorical*, *intracategorical*, and *intercategorical*) intersectional approaches to social research to organize a discussion of methodology. While all methodological approaches share the

paradigm's ontological and axiological facets, they diverge on epistemological counts. We hope our discussion highlights the theoretical potency of the intersectionality paradigm and draws more research attention to the dynamic interplay of social systems.

Sequencing Promotion and Prevention Features: The Moderating Role of Regulatory Focus

Subimal Chatterjee, Binghamton University, USA
Ashwin Vinod Malshe, Binghamton University, USA
Timothy B. Heath, Miami University, USA

EXTENDED ABSTRACT

Consider a recent advertisement for Crest Pro-Health toothpaste highlighting seven brand benefits: preventing cavities, preventing tartar, whitening teeth, freshening breath, preventing sensitivity, preventing gingivitis, and preventing plaque (<http://www.crest.com/prohealth/>). Since the brand lists more prevention features (i.e., information focusing on avoiding negative outcomes) than promotion features (i.e., information focusing on achieving positive outcomes; Aaker and Lee, 2001), it is likely to appeal more to prevention-focused consumers as opposed to promotion-focused consumers (Higgins 1997). However, the advertisement also uses a mixed sequence to present the information (alternating between prevention and promotion features) instead of blocking them (presenting all prevention features before all promotion features, or vice versa). We claim that a mixed sequence might appear less organized than a blocked sequence, a sense of disorganization that could increase the perception that the brand offers more variety (Kahn and Wansink 2004). Moreover, should the enhanced variety perception give the impression that the toothpaste is a change from the status-quo, the mixed sequence should appeal more to promotion-focused as opposed to prevention-focused consumers (Chernev 2004). This is because the desire for change fits better with the advancement goals of promotion-focused consumers than the security and safety goals of prevention-focused consumers.

In Study 1, sixty undergraduate students (26 females), from a large university in the northeast, read that the makers of a new brand of toothpaste, positioned on two promotion features (fresh breath and white teeth) and two prevention features (plaque buildup and tooth cavity), were investigating three different methods of ordering the features in their advertisements. The mixed sequence alternated between the promotion and prevention features. The two blocked sequences put the two promotion features either first, or last. We asked participants which sequence maximized the perception that the brand offers a variety of features. Thereafter, the participants completed the Regulatory Focus Questionnaire (RFQ; Higgins et al. 2001) that contained six promotion items (e.g., *I feel like I have been successful in making progress toward being successful in my life*) and five prevention items (e.g., *Not being careful enough has gotten me into trouble at times*; reverse scaled). Seventy percent of our participants (42/60) reported that the mixed sequence maximized feature variety ($z=3.10, p<.01$). We classified each participant as either promotion-focused (average promotion score-average prevention score >0) or prevention-focused (difference score <0 ; see Higgins et al. 2001) and examined the feature variety perceptions of the two groups. Seventy-one percent (21/41) of the promotion-focused participants thought that the mixed sequence offered more variety (than the two other blocked sequences), and 68% (13/19) of the prevention focused participants thought likewise.

In Study 2, we tested whether a mixed presentation of promotion and prevention features led to superior brand evaluation relative to a blocked presentation of the same features, and whether the favorable assessment was stronger among promotion as opposed to prevention-focused consumers. One-hundred-eighteen undergraduate students (77 females) participated in the study. We randomly assigned the participants into one of two regulatory focus conditions. Following the procedure outlined by Higgins and others (1994), we asked participants in the promotion-focused (preven-

tion-focused) conditions to write a brief essay about their hopes and aspirations (duties and obligations), at present as well as five years from now. After participants had completed their essays, we directed them to a different task where they read that a toothpaste manufacturer was conducting a market survey to find out what consumers thought about the four different features of their brand. The selected features were identical to Study 1. To mimic a sequence, we presented the four features, one page at a time. The mixed sequences alternated between a promotion feature and a prevention feature or between a prevention feature and a promotion feature. The blocked sequences presented all the promotion features first or last. After reading about each feature, the participants evaluated the feature on two 7-point scales (very attractive/very unattractive, very important/very unimportant), and then turned the page to read about the next feature. After the participants had read and evaluated all four features, they evaluated the brand on a 100-point (Best/Worst) scale (see Escalas 2007, for a similar scale).

The attractiveness/importance ratings of the features were sufficiently correlated ($\alpha=0.75$) to merit creating a composite weight measure for the promotion and prevention features. We modeled brand evaluation as a function of all main and interaction effects of regulatory focus (prevention, promotion) sequence (mixed, blocked), prevention-feature weights, and promotion-feature weights. We controlled for gender (males, females), and the felt intensity of the prime (the number of words written by the participants in their essays) by treating these as covariates in the model. On the average, the brand received higher evaluation when the features were mixed ($M=89.19$) than blocked ($M=80.37$; $F(1, 98)=4.99, p<.05$). The sequence main effect was qualified by regulatory focus ($F(1, 98)=5.33, p<.05$). Promotion-focused participants gave higher brand evaluation when the features were mixed ($M=90.93$) than blocked ($M=78.50$; $F(1, 98)=7.99, p<.01$). The prevention-focused participants gave marginally higher brand evaluation when the features were mixed ($M=87.83$) than blocked ($M=82.39$), but the difference was not statistically significant.

Our results hold both theoretical and practical significance. From a theory perspective, to the best of our knowledge this is the first attempt to connect the concept of regulatory focus to information sequencing, and therefore adds to previous research on self-regulation in different contexts (Brockner et al. 2002, Chernev 2004, Liberman et al. 1999). From a managerial perspective, given that marketers often cannot customize their appeals to the promotion-focused and prevention-focused target segments (e.g., one Crest Pro-Health advertisement targeted to both promotion-focused and prevention-focused segments), it would make sense to include both promotion as well as prevention appeals in their communications. However, to get the maximum impact out of such mixed advertisements, our results show that marketers would need to use a mixed (alternating) feature sequence.

Consumer Response to Harmful Products with Cause-Related Marketing: Influences of Product-Cause Fit and Product Type

Chun-Tuan Chang, National Sun Yat-sen University, Taiwan

EXTENDED ABSTRACT

Partnering charitable causes with products has become a common practice for many marketing programs, referred to strategically cause-related marketing (CRM). CRM is one major philanthropic activity for a corporation to donate money to a charity each time a consumer makes a purchase. Sharing the business ethics and value of “paying back to society”, CRM has become popularly adopted by industries or companies which have brought about many of environmental problems (e.g., water and air pollution, land degradation, and chemical contamination, and transport) because of the manufactured products or production process.

Recent studies have begun to examine potential factors that might affect CRM effectiveness and how consumers respond to CRM initiatives. One important variable that has been identified to determine the success of CRM is the *fit* between a product and a cause. Although researchers agree that selecting the “right” cause is a key to a successful CRM strategy, little is known in terms of what constitutes a good fit and how the fit nature can moderate the CRM effectiveness. In the present study, two high-fit natures are explored: *consistent fit* (i.e., a cause and a product have consistent images or similar values) and *complementary fit* (i.e., a selected cause is used to improve the harmful image through a compensation act). This issue especially draws our attention in the circumstances that consumers already have inherent negative evaluations toward a product when they perceive it as harmful. The other factor investigated previously is product type. Hedonic products are motivated by the desire for sensual pleasure and utilitarian ones are provoked by a basic need. CRM is more likely to be effective in promoting hedonic products than utilitarian ones because of guilt feeling accompanied with the purchase. However, contingent effects of product type with harmful nature remains unexplored.

Using the context of harmful products, this research extends the concept of product-cause fit by exploring how consumer perceptions of fit nature affect attitudes toward the sponsoring company and behavioral intention in purchase situations with different product types (i.e., utilitarian or hedonic), and consequently determine whether product-cause fit and its nature are necessary criteria to influence CRM effectiveness. Hypotheses were drawn from attribution theory including non-common effects and argumentation versus discounting principle (Kelley, 1967; Kelley, 1973; Kelley and Michela, 1980). An experiment in a 3 (product-cause fit: consistent fit vs. complementary fit vs. low fit) X 2 (product type: utilitarian vs. hedonic) between-subjects design is developed to test the relative CRM effectiveness of advertisement messages to promote products that consumers perceive as harmful. Products containing plastic (including packaging) are used as harmful products. In order to eliminate the effects of product-selection bias, two products with different price levels were chosen for each type (hedonic vs. utilitarian) based on a pre-test. Therefore, 12 experimental versions were produced. Prior to the experiment, the treatment booklets were randomized. Participants were randomly assigned to one of the 12 conditions above.

After successful manipulation checks, a series of analysis of variance were conducted to examine proposed hypotheses. The main effect of fit was first examined to replicate previous results. Participants preferred the product with a high-fit cause to that with a low-fit cause. The research supports the common assertion that

“fit” is important for successful CRM programs (Gupta and Pirsch, 2006; Hamlin and Wilson, 2004; Lafferty, 2007; Pracejus and Olsen, 2004; Trimble and Rifon, 2006). Participants tend to accept a product with a cause more easily when the cause is perceived as a high fit with the product image than as a low fit. Using the harmful product contexts, the experimental results are also analogous with recent works that the hedonic products bundled with a charity incentive are more effective than the utilitarian ones (Strahilevitz, 1999; Strahilevitz and Myer, 1998). More importantly, the present study raises concerns over the comprehensive understanding of “fit” and how it works. With a high-fit cause, the assessment of “fit nature” between a product and a cause may be an important consumer heuristic. Three observations are noteworthy.

First, when promoting a utilitarian product, the consistent fit between a product and a cause is more effective than the complementary fit. The results echo what previous research (e.g., Campbell and Kirmani, 2000; Szykman, 2004; Yoon et al., 2006) suggests that perceptions of a company’s profit opportunities as obvious can lead to positive attitudes to the product bundled with a cause. Such perceptions of consistency could be the common node that would be activated in an individual’s associative networks. *Second*, compared with the consistent fit, the complementary fit between a product and a cause is more effective when the charity incentive is associated with hedonic products. The purchase of hedonic products that have negative consequences on the environment may lead to dispositional blame. There is a motivation to alleviate the blame. Discovering that the manufacturer donates part of the profit from sales to an environment cause is consistent with this motivation and leads to increased behavioral intention to buy this product. With the purchase of utilitarian products that are environmentally harmful, the dispositional blame is diluted by the situational attribution that it is necessary to buy the product. Learning that part of the profit will go towards improving the environment is less consistent to consumers’ goal. Behavioral intention to purchase thus becomes lower. *Third*, the influences of fit nature are stronger when the price of the harmful product is low. A possible reason could be that high price of the item may be associated with the downbeat impression that the company exploits the cause and that consumers would be better off making a direct contribution to the non-profit than purchasing products on CRM (Gupta and Pirsch, 2006). The effects of fit nature are thus reduced because of criticism of this exploitation.

This article has theoretical and practical contributions to CRM, consumer purchase decision-making, and societal marketing practice. It is important to go beyond simple demonstrations of the effects of fit, and to clarify *when* a cause-related promotion of a harmful product is likely to be observed, reversed, or eliminated because of fit nature. Investigating impacts of fit nature is an important marketing and public policy issue because both complementarity and consistency are commonly used as good-faith attempts to promote the charity incentive. However, they may not be equivalent with respect to their ability to enhance CRM effectiveness when different product types are considered. In practice, marketers hence stand to gain not only by choosing the appropriate fit strategy for their advertised products but also by taking the perceived product type of the offered bundles into consideration to optimize the effectiveness of cause-related campaigns.

The Category Label and Overall Similarity in Hybrid Products: Matches/Mismatches and Categorization Asymmetry in Consumer Preferences

Maria Saaksjarvi, Delft University of Technology, The Netherlands and HANKEN, Finland
Ewa Pulkkinen, HANKEN, Finland

EXTENDED ABSTRACT

Numerous studies show that consumers categorize a product based on its name, or based on its visual appearance to other products (i.e., its overall similarity) (e.g., Gregan-Paxton et al. 2005; Rips 1989). The relative dominance of the cues in categorization has been debated. A number of researchers claim superiority for the category label, stating that it is a more accurate cue for categorization, as a product's appearance does not necessarily reveal much of a product's purpose (Rips 1989; Yamauchi and Markman 2000). Others hold that overall similarity determines categorization to a much greater extent than the category label, as consumers are more susceptible to visual than verbal cues in categorizing new products (Gregan-Paxton et al. 2005; Rosch 1978). Although the category label and overall similarity have been widely studied, their conjoint effect is less known. Taking the approach of Yamauchi and Markman (2000) we define the category label and overall similarity on the level of mismatches and matches. The *category label* represents a product's category membership, whereas *overall similarity* refers to the degree of overlap a new product has to existing ones.

Our objective is to investigate the role of matches (and mismatches) of the category label and overall similarity in consumer preference for hybrid products. Hybrid products are products that combine two previously independent product categories into one product (Jain and Ziamou 1995). As compared to other products, they have multiple category labels, and overall similarity that links the product to multiple product categories. Considering that consumers categorize products in multiple ways, focusing on hybrid products allows us to examine how the way in which a product is categorized influences how consumers react to matches (mismatches) between overall similarity and the category label. By focusing on hybrid products, we extend on Yamauchi and Markman's study, which focused on a product with a single plausible category label with a single plausible category membership.

Studies that have addressed joint effects of *category labels and overall similarity* have received mixed results regarding their relative influences. Rips (1989) showed that similarity does not completely determine category membership, but neither does the category label alone. Rosch (1978) proposes that the effect of the category label is supportive to that of overall similarity, but cannot determine categorization by itself. Yamauchi and Markman (2000) propose that the conjoined influence of category labels and overall similarity primarily emerges from if they match or mismatch. In case of a mismatch, consumers follow the category label, presumably as it is more reliable and allows them to link the product to a taxonomic category.

The matches and mismatches in hybrid product can be linked to product categorization. Hybrid products can be interpreted using an asymmetrical or symmetrical categorization. If the categorization is *asymmetrical*, consumers use one of the product categories combined in the hybrid, reaching the interpretation that the product has one main category, and a single functionality (Costello and Keane 2000). In a *symmetrical* categorization, consumers use both of the product categories the hybrid product combines in classifying the product, thereby reaching the interpretation that the product has

two main categories and two functionalities (Goldvarg and Glucksberg 1998; Wisniewski 1997).

In two studies, we examine the influence of matches/mismatches of consumer preference for hybrid products. Study 1 was an eye-tracking study conducted using 25 students. The results showed that consumers paid more attention to overall similarity than the category label, but that the importance of the category label increased in the mismatch condition. Study 1 also showed (tentatively) that consumers who engage in asymmetrical categorization were positively (negatively) influenced by matches (mismatches) between overall similarity and the category label in assessing their preference for a hybrid product, whereas consumers who engage in symmetrical categorization are not likely to be influenced by matches (mismatches) between overall similarity and the category label in assessing their preference for a hybrid product.

Study 2 was a questionnaire (paper and pencil study) with 75 consumers. In study 2, we replicated the hypothesis concerning the influence of categorization strategy (asymmetrical vs. symmetrical) and found support for the notion that consumers engaging in asymmetrical (vs. symmetrical) categorizations are susceptible to matches (mismatches). We also extended the applicability of the match/mismatch hypothesis to product characteristics, and showed that consumers are influenced by matches (mismatches) between the category label and overall similarity when assessing a product's net benefits and complexity. A match between the category label and overall similarity resulted in more benefits and less perceived complexity for a new hybrid product. Further, by comparing the match/mismatch hypothesis to the individual effects of the category label and overall similarity, we show that matches/mismatches account for a larger number of consumer responses to new products than the individual effects of the category label or overall similarity.

Taken together, the results provide support for the match/mismatch hypothesis in assessing the importance of the category label and overall similarity in consumer preferences.

Examining Discourses of Gender and Consumption in the Media

Linda Tuncay, Loyola University Chicago, USA

Katherine Sredl, University of Illinois, USA

Marie-Agnès Parmentier, York University, Canada

Catherine Coleman, University of Illinois, USA

EXTENDED ABSTRACT

Gender identity is a fluid concept that has changed considerably over time, not only in its representation in media and its interpretation by consumers, but also in its conceptualization by researchers. Using hermeneutic analysis, a method used by prior consumer researchers, (e.g., Humphreys forthcoming; Coskuner 2006; Sherry 1995; Hirschman 1988), this paper explores gender and consumption discourses in popular media. Because gender is a relational and evolving construct, this study explores masculinity and femininity together to gain a holistic view of gender discourses in today's society. Specifically, the authors draw from two popular television shows, *Entourage* and *Sex and the City*, to illustrate how contemporary notions of femininity and masculinity are intertwined with consumption. The researchers found that the characters in both shows struggled with tensions between more traditional gender roles and the assumption of new, postmodern roles intimately associated with consumption (see, for example, Firat and Venkatesh 1995 for discussion on the assumption of postmodern roles). The nuances of these tensions are less frequently mentioned in popular media.

Three themes of masculinity emerged in *Entourage* that were both rooted in prior research as well as interwoven with more feminized notions of masculinity not extensively examined in previous inquiries. The first theme that emerged in the show was the Peter Pan ethos of childhood play and fun (Register 2001) and the Playboy lifestyle of self-indulgence and sexual conquests (Osgerby 2001). For the characters in *Entourage*, consumption is instrumental in enacting the masculine themes of the Peter Pan and Playboy lifestyles. At the same time, it is intertwined with traditionally feminized notions of gift giving and shopping. Second, the theme of buddydom, or the celebration of friendships with other men, was prevalent in *Entourage*. However, the characters' enactment of this relationship was more closely associated with a non-traditional family unit than with traditional notions of male bonding. While women are most often associated with communal goals, the portrayal of the *Entourage* "family" is reflective of broader shifts in the U.S. towards "non-traditional" households, including men living together beyond their college years (Lavigne 2004). Third, the consumption of "toys" has been demonstrated in prior research to be an important part of the enactment of masculinity (Fiske 1987) and is a central part of the male characters' lives in *Entourage*. But the quest for acquisition sometimes causes internal struggles for the characters when it conflicts with their desire to remain authentic. The motivation for authenticity has been demonstrated as a core theme of masculinity for Gen X men in prior research (Tuncay 2005). This struggle was particularly evident in the breadwinner, Vince, in a tension between his desire to take on "meaningful" acting parts in independent films and offers to act in commercialized, yet lucrative studio roles that would subsidize the characters' Hollywood consumption habits. Thus, in *Entourage*, several themes of masculinity emerged that resonated with prior research on gender and consumer behavior. However, the themes of this study were intertwined with conceptualizations of gender more traditionally associated with females, such as familial relationships, gift giving, shopping, and emphasis on physical appearance. While in the recent past, these behaviors have been associated with a seg-

ment of male consumers called "metrosexuals," such behaviors have now moved into the mainstream. Thus, it is evident that new forms of masculinity are emerging, and are represented in popular media.

Three themes of gender fluidity and consumption also emerged in *Sex and the City*. While some of these themes have been discussed in prior research, the show demonstrates anxieties about balancing traditional and changing notions of femininity and masculinity. First, tensions between strict traditional gender roles and gender fluidity are prevalent. Negotiations over gender roles are demonstrated in the character Miranda, who struggles with her non-conformity to traditional gender roles when, for example, she prioritizes her career as a corporate lawyer, purchases a home and is faced with housekeeping. This tension is further demonstrated in the second theme that explores the costs of freedom and independence. *Sex and the City* displayed notable violations of traditional gender roles; in particular, the narratives of Samantha Jones portray striking examples of female sexual freedom. In asserting her independence and power through professional accomplishment, financial independence, sex without ties and home ownership, she is also forced to face her vulnerabilities. Third, the characters of *Sex and the City* struggle with the quest for authenticity, both in their consumption and in their identities. Much like in *Entourage*, the theme of authenticity builds through various storylines in which consumption actions are developed as metaphors for broader themes of life. For example, for the women of *Sex and the City*, the Playboy Mansion epitomizes notions of fantasy—sexual freedom and an idealized and luxurious lifestyle, especially for Samantha. However, their visit to the mansion ultimately signifies a lack of authenticity and fails to maintain the positive connotations of fantasy.

This research demonstrates that the characters of both shows actively explore masculine and feminine roles, though not without anxiety, as they move through new and fluid identities of gender that often are enacted through consumption. Tensions between traditional masculinity and alternative masculinities have been examined by past researchers (see, for example, Holt and Thompson 2004; Otnes and McGrath 2001). But in *Entourage*, the characters find ways to reestablish and reinforce their masculinities as they create new roles. In *Sex and the City*, several themes of gender found in prior research also emerged. While the notion of juggling and independence has been discussed in prior research (e.g., Thompson 1996) and despite acclaim in the popular press about ground-breaking portrayals of contemporary women, it is evident that the characters of *Sex and the City* still struggle to negotiate the gains of feminism with more traditional feminine ideals, much like how the characters of *Entourage* balance traditional gender roles with new masculine ideals. The authors find that these themes are reflective of ideological gains and shifts exemplified in feminist agenda and that, to a greater extent, they question what happens when these gains have been made.

Video Games, Processing Fluency and Choice: Exploring Product Placement in New Media

Haiming Hang, Lancaster University, UK

Susan Auty, Lancaster University, UK

EXTENDED ABSTRACT

Only recently has the increasing use of product placements in video games attracted academic attention. Video games, unlike TV or films, increase interactivity and sensory immersion, which may increase players' involvement with the placed product (Schneider and Cornwell, 2005). However, up to now no research has examined this advantage in detail, especially with regard to children who are believed to be more vulnerable to commercials (e.g. Auty and Lewis, 2004).

Furthermore, all previous research exploring product placement effectiveness was done without any consideration of contextual influences. But in reality consumers are not exposed to brands without contexts. For example, some consumers might indulge in video games (and be exposed to the brand) to demonstrate their game skills while others might only play the video game at their friends' request. Recently research has found that advertising effectiveness could be moderated by its context, an area that is worthy of further exploration (e.g. Malaviya, 2007).

In order to fill the above gaps, three experiments were done to explore the underlying mechanism of product placement in video games in affecting children's choice and to see whether its effectiveness would be moderated by one contextual factor—children's regulatory fit/nonfit when playing the game. By doing so, this study extends previous product placement research on several fronts: it is the first research to explore with children whether there is a unique advantage in encouraging interactive engagement with brands in video games; secondly it tries to demonstrate that a contextual factor such as children's regulatory fit/nonfit can moderate product placement effectiveness. Furthermore, while all previous research documented positive affect in participants after exposure to brands in the media, this research explores a possible boundary condition of this effect.

The main purpose of Study 1 was to explore the effect of product placement when brands were used as background in the game. The experimental design was a 2 (exposed to product placement vs. not exposed) x 2 (visual stimuli test vs. auditory stimuli test) between subjects factorial design. Children (n=131) were invited to either play a branded game (7 Up logo was used as background) or play a no-brand game for a similar length. The results show that product placement had a significant effect on children's choice, although the effect disappeared when the modality of presentation was changed from a visual display to a verbal offer. Therefore, it appears that when there was no interaction with the brand, perceptual but not conceptual fluency led to the effectiveness of product placement.

Study 2 was conducted to see if there is a unique advantage of placing brands in interactive media. Children (n=97) were randomly placed into four conditions: 1) control group playing an unbranded tennis game; 2) perceptual group playing a football game where the teams displayed the Nike logo on their shirts; 3) a conceptual group where children listened to a tape asking them to guess the team sponsor (Nike, Coke or Toshiba) and then played the unbranded tennis game; 4) a conceptual-perceptual group where children listened to the tape, "guessed" the sponsor and then played the same branded game as Group 2. Half of each group was asked to make a stimulus-based choice for the brands while the other half was asked to write down the brand names without the stimuli being provided (Lee, 2002). In order to keep conscious recall separate

from unconscious fluency, children in both test modes were asked to exclude brands they had encountered in the game. The findings suggest that elaboration at the time of exposure led to conceptual priming. Prior exposure to the verbal stimulus of possible sponsors made children more likely to choose the brand in a written test (without cues) even though no child could recall being exposed to the brand. But there appeared to be no synergistic effects when children experienced both perceptual and conceptual fluency. It may be that perceptual fluency or conceptual fluency alone is sufficient to enhance the liking of a brand, and there are no additive effects on preference.

While previous research always reported a positive effect after exposure to product placement, Study 3 was done to see whether children's regulatory fit/nonfit when playing the game would moderate a placement's effectiveness. Children (n=100) were randomly allocated to the following four conditions: 1) a control group (playing a video game without any brand), 2) a test control group (playing a branded game only), 3) a regulatory fit group (playing a branded game while experiencing regulatory fit) and 4) a regulatory nonfit group (playing a branded game while experiencing regulatory nonfit). Children in both regulatory fit and nonfit conditions were asked to watch a TV ad about a cream preventing athlete's foot (a prevention focus) before playing the video game—FIFA 2002. Then when playing the video game, children who were allocated to the nonfit condition were told that the key strategy for playing the game was to score as many goals as possible (a promotion focus) while children who were allocated to the fit condition were told they needed to avoid letting the other team score (a prevention focus).

The results suggested that children in the regulatory fit condition were more likely to choose the brand in the game into their consideration set than children in the nonfit condition. Furthermore, children in the nonfit condition were also significantly less likely to choose the brand than children in the test control group (exposed to the brand only). Thus it appears that regulatory nonfit might block children from processing the stimulus even minimally.

In short, while previous research has attributed the effect of product placement to perceptual fluency, this study found that when the priming entailed a conceptual elaboration, such as being asked to choose a brand for players to wear—a common occurrence—children's subsequent choice of brand could be influenced even without perceptual fluency. However, its effect may be moderated by children's regulatory fit/nonfit when playing the game.

The Signaling Effects of Advertising and Distribution

Yaqin Shi, Hakuodo, Japan
Akinori Ono, Keio University, Japan

EXTENDED ABSTRACT

Research Objective

The “signaling effect” stands as one of the most important topics in studies of consumer behavior. Previous research has focused primarily on price-quality associations in the consumers’ cognitive processes (i.e., whether price has signaling effects on consumers’ perceptions regarding the quality of a product). Some studies have confirmed the signaling effects of price, whereas others claim that there is only weak relationship between perceived price and quality. Advertising and distribution, in combination with price and quality, represent the key components of a marketing mix, known as the 4Ps: price, product, promotion, and place. However, little signaling research has dealt with advertising and distribution as signals, and no studies have examined associations among price, quality, advertising, and distribution. Here, we propose a causal model to examine the signaling effects of advertising and distribution on the perception of price and quality.

Proposed Model

Our proposed model includes the main hypotheses underlying previous signaling research, namely, that perceived price has direct and negative effects on purchase intention, as well as indirect and positive signaling effects on purchase intention via mediation by perceived quality. We expand this model by adding the construct of “subjective norm.” This model is regarded as a variant of the Theory of Reasoned Action (TRA) insofar as it incorporates three determinants of purchase intention within the same general framework. Unlike the original TRA—and other purchase intention models proposed by signaling researchers—our model does not include attitude—and perceived value—because of evidence demonstrating direct links between belief and intention and also because of the difficulty in disentangling the direct effects of subjective norm on intention from the indirect effects as mediated by attitude. Finally, the signaling effects of perceived amounts of advertising and distribution on perceived price, quality, and subjective norm were introduced in this model.

The signaling effects of perceived amount of advertising on the perception of quality rest on the idea that honest sellers that provide high-quality products are more likely to expect repeat purchases compared to dishonest sellers that provide low-quality products. Moreover, heavy advertising may lead to inferences by consumers that these advertised products are more familiar to other consumers than unadvertised products, increasing the likelihood of the subjective norm. Consumers may also infer that well-advertised products are higher in price simply because the heavy advertising results in higher cost.

The presumed signaling effects of perceived amount of distribution on perceived quality rest on the idea that highly distributed products (i.e., products sold by many retailers and/or occupying more retail shelf space) are perceived as higher in quality because of some assumed link between product value and its prevalence. Moreover, consumers may infer that highly distributed products are popular and hold higher subjective norm. However, our model does not include the hypothesis that higher distribution causes the perception of higher prices because consumers have equally direct access to both price and distribution when they visit stores.

Methodology and Results

Our proposed model was tested empirically by distributing questionnaires to 263 university students. Consumer data of pertaining to a new released hard-disc-driven (HDD) portable music player/recorder (i.e., a competitor of iPod) were collected. For the structural equation modeling, we used multiple scales developed in previous signaling research.

Scaling and model estimation were conducted successfully, resulting in support for seven of nine hypotheses examined. It may have been that the hypothesis regarding the direct effect of perceived price on purchase intention was not supported because the respondents did not regard price as important when choosing high-tech HDD portable music players. The hypothesis regarding the signaling effect of perceived price on perceived quality and, therefore, indirect effect of perceived price on purchase intention, may have lacked support because the respondents may have preferred advertising and distribution to price as signals of quality.

Our results suggest that perceived amounts of both advertising and distribution might be stronger signals than perceived price. This finding is pertinent to the controversy concerning the weakness of the signaling effects of perceived price on perceived quality. Our results demonstrate that the signaling effects of the amount of advertising carry the greatest effect on the subjective norm, whereas those of price and distribution carry the greatest effects on perceived quality. We believe that these findings will fill an important void in the literature regarding the signaling effects in studies of consumer behavior.

FILM FESTIVAL

Summary

Russell Belk, York University, Canada

Marylouise Caldwell, University of Sydney, Australia

This was the seventh annual North American ACR Film Festival. Despite competition from the Latin American, European, and Asia-Pacific ACR Film Festivals that have also emerged in recent years, as well as at least three consumer research journals with special DVD issues, the quality and number of submissions just keep getting better. This year's submissions continue to represent a truly global interest in film, both in terms of topical focus and the geographic origin of the filmmakers. This is evident in this year's two prizes as well. The **Jurors' Award** went to Marta Rabikowska and Matthew Hawkins, University of East London, for their feature length film *Consumption, Belonging and Place*. The film shows how members of a multi-racial community located in South London negotiate their identities via a range of socially embedded consumption activities largely located in the local High Street. An earlier version of this film garnered a parallel prize at 2007 European ACR Conference. The prize carries a cash award from the Center for Consumer Culture (3C), Georgetown University, and the University of California, Irvine. The **People's Choice Award** went to Ebru Ulusoy and Handan Vicdan, University of Texas-Pan American, for their capsule-length entry: *Bodily Experiences of Second Life Consumers*. Their film provides preliminary evidence of how consumers experience their bodies as avatars in virtual worlds such as Second Life. Ebru Ulusoy has also become a repeat winner and this was her third film to win an ACR Award. Additional Film Festival submissions covered a variety of topics, including amongst others, the consummate loving relationships that some consumers have with their cars, the way Middle Eastern house design reflects Islamic gender power relations, the meaning of luxurious experiences to upper class Japanese consumers, and the methodological and representational challenges that researchers face when striving to produce academically sound films. For the time being these films are not available online. Those wishing to see or use one of the films are encouraged to contact the filmmakers.

PRESENTATIONS

"Can Buy Me Love"

John L. Lastovicka, Arizona State University, USA

Nancy J. Sirianni, Arizona State University, USA

Danny Kunz, Arizona State University, USA

The videography "Can Buy Me Love" portrays exhibitors of classic cars, muscle cars, and hotrods at public car shows in the Phoenix, Arizona metropolitan area. In contrast to Susan Fournier's work, these auto-enthusiasts reveal deeper and more intimate relationships with their possessions than previously reported in the consumer research literature. We show how these auto-enthusiast consumers have personified their automobiles as partners in—as what psychologist Robert Sternberg defines as—a consummate loving relationship. Consummate loving relationships exhibit three components, namely: passion, intimacy and commitment. Our videography contains a sampling of the behaviors, emotions and words of informants manifesting these three components with respect to their beloved cars.

"Can't Buy Me Love" also discusses the emotive benefits consumers receive from these relationships with their cars. We reveal that such relationships appear to fill an emotional void in their lives. Thus we conclude that the loving relationship that consumers have with their beloved possessions is asymmetric. Consumers invest their own time, energy, money and emotions into their possessions. In exchange, these beloved possessions help fill an emotional need for consumers. This is similar to what psychiatrists Donald Horton and Richard Wohl have characterized as the "para-relationships" that some television viewers have with media personalities.

The videography concludes by discussing what our insights offer marketers. First, we note that monogamy is not required in these loving relationships. Thus those who madly, truly, and deeply love one car have the opportunity to have more than one of these special cars in their garage. It was not uncommon for our informants to have more than one special car. Second, part of achieving intimacy with a loved possession means investing time, money, and effort into the loved possession. That means a host of complementary material possessions are often needed in support of the loved possession. We illustrate this point with the hundreds of dollars of potions, lotions and machines that informants can spend on keeping a dazzling mirror-like finish on the car's body. As the French philosopher Denis Diderot noted, consumers' possessions require other possessions. We believe this is especially true for consumers' most beloved possessions.

"This Day is to be Special: The Role of Exaggerated Contrast in an Indian Wedding"

Ekant Veer, University of Bath, UK

The role of sacred and profane objects has been well founded in consumer research for some time. Belk, Wallendorf, & Sherry's (1989) seminal paper underlines the pervasiveness of the sacred within modern consumer culture. This research takes a reflexive look at one particular aspect of the sacred and profane relationship; that is, the way in which the sacred is kept separate and detached from the profane as a means of maintaining the importance and power associated with the sacred.

By drawing on a reflexive stance to this research the film presents the results of one interpretation of an Indian wedding. Reflexivity in this case, allows for the researcher to engage with the research site, but also accept his or her own biases and theoretical dispositions (Joy et. al 2006). The results presented show how aural and visual cues are exaggerated to illustrate the importance of sacred events in the lives of Hindu Indians. Although this research focuses specifically on a North Indian Hindu wedding the results from the research offer explanations for the exaggeration of aural and visual cues in other contexts.

This research uses the artistic concept of *negative space* as an analogy for how the sacred is contrasted with the profane. White space, Negative space or Silence all refer to the role that pauses or emptiness play in promoting the focus of a particular subject (Murray 2005).

For example, in music, without the silence between notes the notes themselves lose meaning (Zakia 1993). One may not consciously be aware of the negative space that encompasses a piece, but without it the nature of the artistic creation is often muddled and lost in the composition (Brittain & Beittel 1960). It is when the difference between the negative and positive space is overly exaggerated that one can more clearly see the positive, but also the role that the negative plays in framing the subject itself.

This research shows how the contrast between the positive, in this case a wedding, and the negative, the everyday lives of the participants, is exaggerated to more clearly understand and appreciate the positive or sacred as being differentiated from the profane and everyday. Although all five Aristotelian senses are exaggerated in an Indian wedding this movie only focuses on the exaggerated contrast of aural and visual cues.

The methodology employed in the research was that of a videoethnographic study. The chosen context was a typical North Indian Hindu wedding held in December 2006. The research followed the marriage participants throughout the many different Hindu wedding rituals as well as interviewing family members to understand the cultural meanings associated with the various aspects of the wedding. In total, 14 hours of video tape was recorded focusing on the wedding itself. However, to understand the everyday lives of the participants the researcher continued to follow the couple before and after the wedding as they lived their lives away from the sacredness of the ceremonies. A further 11 hours of video was taken of non-wedding context. The final dataset comprised primarily of observational data and interviews with various people living in Delhi.

From the research it was seen that colour was the most prominently exaggerated visual cue used to differentiate the wedding from the negative space of the participants' everyday lives. Gold, red, orange and silver all play a prominent role in the observed ceremonies, but are rarely seen in such brilliance and concentration in everyday Delhi life. Clothing is also used as a means of contrast with *turbans* and finest *saris* worn especially for the ceremonies, but are rarely worn at other times. The central focus of the main wedding ceremony is the *Hawan* or holy fire that grows in intensity as the ceremony progresses. The combination of rhythmic chanting and growing flames offer an almost hypnotic aural and visual contrast from the often mundane nature of city life.

Aural cues are clearly contrasted in a number of ways. For example, when the groom approaches the bride on the wedding day he is led by a large band playing traditional and auspicious instruments such as the *Shehnai*. The sounds experienced by participants are in stark contrast to the soundscape of traffic and white noise that typify modern Delhi life.

Based on the research it is possible to see a number of areas where aural and visual cues are overly exaggerated to promote the importance of the sacred and positive and differentiate it from the negative space that the profane offers. This effect is also seen in many other contexts beyond the Hindu wedding ceremony, such as the prominence of Washington monument over the relatively flat landscape of Washington D.C.; the use of stained glass in Christian architecture and even the importance of a singular finger set aside for wedding rings in western culture. When mixed with the profane the sacred loses its efficaciousness (Durkheim 1915 [1928]); however, by exaggerating the difference between the sacred and profane the sacredness of the Hindu wedding is more easily recognised as such.

"Behind Closed Doors: Gendered Home Spaces in a Gulf Arab State"

Russell Belk, York University, Canada

Rana Sobh, University of Qatar, Qatar

In the United States misunderstandings of Middle Eastern women are particularly strong. As Read (2003) observes, "Cultural stereotypes of Arab-American women tend to collapse religion and ethnicity into synonymous components of culture, portraying them as veiled Islamic traditionalists" (p. 208). These misunderstandings are fueled by prejudice and are, if anything, stronger when it comes to Arab women in the Middle East rather than emigrants to the United States. While Western xenophobia and prejudices toward the Middle East and Islam have grown stronger since the September 11th attacks on the Twin Trade Towers, there is a long history of vilifying Arabs in Hollywood films (Shaheen 2001). These stereotypes of Arab women over a century of Hollywood films include those of the closeted, subservient, and oppressed wife, the exotic, scantily clad, and sexually seductive harem maiden, the fat, unattractive beast of burden, the shapeless, ululating bundle of black, and the mindless fanatical terrorist. Never do we see normal Arab women at home with their families, in the office or workplace, or occupying professional positions as professors, engineers, or doctors. In other words, rather than portray a common humanity, Middle Eastern women are depicted in the Western media as objects, villains, threats, and victims.

By focusing on the home and gendered spaces and objects within it, our research presents a more accurate, normal, and human face for Qatari women. In so-doing, we hope to help create greater understanding as well as contribute to research streams concerning home, identity, culture, consumption, and gender. We sought to know what goes on behind the closed doors of the Middle Eastern household. As a crossroads of the Middle East, Qatar offers a unique opportunity to understand what is unique as well as what is common in Middle Eastern and Western values involving women, privacy, identity, and the home.

The consumption of spaces and places within our homes is expressive of culture. Using observation and ethnographic depth interviews with 30 middleclass Qatari families, we hoped to understand the meanings of home spaces and artifacts in their lives. We find that the home and its spaces and objects are encoded differently by men and women, particularly in terms of notions of privacy. Historically, the idea of personal versus shared spaces within homes is a relatively new one. Tuan (1982) shows that it is only within the last few hundred years that notions of privacy and of separate public and private spaces within the home have emerged. Notions of private space are also encoded architecturally and intimacy within the nuclear family is a concept that has grown as the presence of extended families sharing the same home has diminished. As Rybcynski (1986) points out, it was highly unusual for someone in the sixteenth century to have his or her own room and it was another century before people had rooms where they could retreat from the public view. In the process of privatization of areas of the home, individual family members began to think of areas of the home as being their territories (Altman 1975). Even when a particular area like the bathroom must be shared with other family members, it is common to temporarily claim private space for hygienic, purifying, and beautification rituals, on either a scheduled or first-come/first-served basis (Kira 1970). All of these distinctions are expanded in the Arabian Gulf. When these spaces are encroached upon by others, there is a sense of violation of privacy and person. There is therefore an inclination to formally or informally designate spaces and boundaries defining personal space, spaces for close kin, and spaces where gender-segregated friends, neighbors, and strangers can meet within the home.

The Middle Eastern sense of what is totally private is more absolute, due largely to the moral concerns of Islam. Within Arab Muslim homes, there is a sharper distinction between men's and women's spaces as well as transitional spaces in moving from one to another. Compared to the West there is also a sharper distinction in these homes between public and private space, often with high exterior perimeter walls and inward facing rooms. Furthermore, there is a sense of private space that a Muslim woman carries with her as she goes from home to marketplace. As Cooper (2001) found for women in Niger, creating and decorating a room of their own was extremely important to their identities as well as their sense of social and economic status. Although some (e.g. Nageeb 2004) have called this enclaving of space a "neo-harem," reducing rather than increasing women's sense of space and of control over their lives, our informants find it liberating. While there are also gendered areas within Western households, we find sharper and more formally drawn boundaries within the present study in Qatar. The basis for these differences are cultural and do not arise from prescriptions within Islam, although there is disagreement on this point (Campo 1991; Nageeb 2004).

If clothing can be thought of as a second skin for the individual, home and personal possessions may be seen as a third skin defining who we are by forming a part of our extended self (Belk 1988). Wallendorf and Arnould (1988) found that Americans' favorite objects were more likely to be linked to personal memories, while those from Muslim Niger were more likely to mention objects linked to social status. They also found gender differences, with men in Niger more likely to cite the Quran and women more likely to cite silver jewelry as well as objects given to them by others. On the other hand, we found less difference, with favorite possessions within the home likely to be sentimental objects, especially for women in our study. The present video focuses more on home spaces and provides a context for further on-going examination of favorite possessions.

"Urban Archetypal Hedonistas"

Marylouise Caldwell, University of Sydney, Australia

Paul Henry, University of Sydney, Australia

A meta-analytic review of research into a market orientation suggests that successfully implementing a marketing orientation associates with higher revenue and profits (Kirca, Jayachandran and O'Bearden 2005). Yet academic literature provides limited guidance as to how this goal is practically achieved (For an exception see Gebhardt, Carpenter and Sherry 2007). One observed barrier is an inability by firm personnel to readily empathize with target consumers and understand their values, consumption priorities and lifestyles. In this film, we present representations of female consumer archetypes found to resonate strongly with marketing practitioners operating in markets for food, fun, fashion and furniture in Sydney Australia. The representations are the result of academic research, consultation with market researchers and empirical testing of the film on consumers and marketing professionals.

"Bodily Experiences of Second Life Consumers"

Ebru Ulusoy, The University of Texas-Pan American, USA

Handan Vicdan, The University of Texas-Pan American, USA

This video studies the meanings of the body concept in virtual worlds to provide an alternative perspective to the embodiment/disembodiment debate. We explore whether the body is present in virtual worlds, and if it is, how this presence takes place.

The concept of body has long been an interest for consumer researchers. The main focus of this interest evolved around the corporeal body, 1) as a means of self-presentation and socialization (Thompson and Hirschman 1995), and 2) as a project that modern consumers work on (Featherstone, Hepworth and Turner 1991; Schouten 1991). Thus, modern consumers treated their bodies as not an 'end' but a 'means' of conveying a desirable image to others. Moreover, with the emergence of new communication technologies, the focus of the debate among social scientists has become the presence of the body. Some argued that these technologies have enabled people to break out of the finitude of their embodiment and engage in disembodiment (Balsamo 2000; Stone 2000; Turkle 1995; Ward 2001). Others have contested the idea of the body becoming futile in virtual worlds, and advocated the essential role of embodiment in any human experience (Argyle and Shields 1996; Flichy 2007; Froy 2003; Hansen 2006; Mingers 2001). These perspectives in the literature have been briefly reviewed in the video.

The growing semiotic potential of the virtual worlds allows for visual representation of one's physical self through images such as avatars and photos, which brought another perspective to the embodiment/disembodiment debate. In this videography, we explore the symbolic and experiential construction of body through avatars, which can be defined as "graphic icons representing users through various forms" (Chung 2005, p.538), in a three-dimensional virtual world called Second Life (SL), where experiences are completely user created.

Experiencing the body in this symbolic realm brings us new inquiries concerning the meanings attached to the avatars by their creators, how these avatars are constructed and reconstructed, and how and what consumers experience through these virtual bodies.

For the purpose of this videography, we interviewed three people (Skyler, Jesse, Fred) in physical everyday life settings, such as their offices or a computer lab at a university. These interviewees were logged in SL during the interviews, and were able to share their avatar (re)construction processes and bodily experiences with us visually. In addition, we interviewed five people (Raven, Esme, Spiff, Ginny, Cecil) online in their SL settings. First, we asked informants to talk about their initial involvement in SL and their feelings when they first found out about SL. Then, we asked them to describe what an avatar means to them and how having an avatar influences their SL experiences. Then we asked them to talk about the processes of avatar creation and recreation and what influences them in these processes. The informants talked about the number of avatars they created, the reasons behind creating several avatars, and how they created and modified their avatar(s). Lastly, we asked them to talk about the characteristics of the avatar(s) they created and whether there are any similarities or differences when they compare the characteristics of their avatar(s) and their first life selves. In sum, the questions mainly focused on the feelings and motives concerning their lives in SL, the processes of the (re)creation of virtual bodies/avatars, the motives behind these processes, and the experiences with these avatars in SL.

Concerning the concept of body in virtual worlds, our findings from the inquiry of involvement in SL, “avatar” meanings, avatar (re)construction and avatar experiences basically reveal that the body concept is perceived and experienced differently in many ways when compared to its perceptions and experience in first life. In virtual worlds, the body concept is more a reflection of contemporary consumers’ desire to experiment with different identities, experiences, and modes of life independent and free of nature and any one particular way of being and living. Preoccupation with the body is an essential part of virtual lives. The (re)construction of symbolic corporeal selves reflects the transforming urge of a modern consumer from perceiving his/her body as less of a tool for communication with and impression to others to an experience itself, an end that s/he playfully engages in for its own sake. The body itself becomes the experience in SL, rather than solely being a communication or impression management medium as it is perceived in first life.

The video concludes that the presence of the body in virtual worlds becomes symbolic in nature and enables people to playfully engage in (re)constructing several bodily selves. Freed from the physical constraints, the body is experienced in the symbolic realm of the virtual worlds. Consumers reconcile their urge for physicality with the non-physicality of cyberspace in symbolic forms. We call this process as sym embodiment and our explorations in SL reveal that body is present in virtual worlds, yet not with its physical constraints but with its symbolic meanings.

“The Ties That Bind: Being Black, Buying, and Hope”

Linden Dalecki, Pittsburg State University, USA

Consumer culture involves a quest for meaning in life primarily through consumption. With our logo-laden clothing and shopping bags, we roam the shopping mall in search of an identity and in search of meaning in life.

—Russell Belk, 2006

Can individuals use consumer culture to transcend the internalized or habituated orientations that emanate from their socialization in class, gender, ethnicity, and other dimensions of social structuring?

—Arnould & Thompson, 2007

The Ties That Bind: Being Black, Buying, and Hope (2007), is an 8-minute consumer ethnography shot on miniDV that was commissioned by Burrell Advertising as part of the 2007 Proctor & Gamble Ethnic Marketing Conference. Burrell’s main interest was to get a “30,000 foot view” of African American

consumption patterns and attitudes. It is expected that a dialogue will be generated around the following theme: to what extent do the videography typologies proposed by Kozinets and Belk (2007) in the *Handbook of Qualitative Research Methods in Marketing* result in different sorts of consumer information? For example, *The Ties That Bind* videography utilizes (1) videotaped interviews and (2) observational videography, as well as (6) impressionistic forms. Given that the short has participants from a range of socioeconomic backgrounds with a range of views regarding African American consumption and representations in marketing, it is also expected that discussion will be generated on the subject of various distinct consumer sub-segments within the African American community. In particular, given what appeared to be a common interest for highly-education African Americans in “marketing which targets healthy eating and healthy living”—something which this sub-segment felt was particularly lacking in contemporary marketing—a discussion of emerging trends and solutions could be invaluable.

Other interesting themes expressed by participants included the notion that marketers will all too often “whitewash black culture and try to sell it back to the black community” as well as the notion that blacks are still being represented in a manner that stereotypes them (i.e. offensive character depictions in fried chicken commercials, offensive character depictions in stomach-medicine commercials, etc.), and the finally the idea that African Americans are sensitive to the difference between brands that “get them” and speak to them authentically, versus brands that are simply pandering.

Another relevant area touched on by the project is the notion of variations on “intergenerational brand loyalty”— on the one hand many professional African American participants mentioned wanting to distance themselves from brands to which their parents were loyal, but on the other many discuss “strange attachments” that are felt to particular products and/or brands. One of the more interesting examples was an executive woman whose mother was loyal to “regular Tide” and who wanted to distance herself from the brand, but then felt drawn to and eventually became loyal to a higher-end Tide line-extension.

“Binomial Structure in Luxury: Analyzing Overseas Trip Experiences of Japanese Well-to-dos”

Junko Kimura, Hosei University, Japan

Hiroshi Tanaka, Kato University, Japan

Introduction

What is luxury? What does luxury mean to consumers? This is the basic research question we would like to advance. So far we have been investigating the meaning of luxury, interviewing with people around the globe. Up until 2007, we interviewed mainly with ordinary people in New York and Tokyo, asking questions about their own properties which they think luxurious. Those properties were; plates of matrimonial gifts, collections of combs of her passed-away mother’s, her father-in-law’s curios, etc. We found that if the thing is to be her/his luxury, it has to have the following four characteristics: 1 Rarity, 2 Conspicuity, 3 Escape, and 4 Identity Reinforcement. This finding suggests that luxurious things mean not just gorgeous and deluxe appearances, but relevant and beneficial experiences to ordinary consumers. In the summer of 2007, we visited homes of Italian aristocrats in Florence, Italy. These aristocrats live in grand mansions which they inherited from their ancestors. We, however, found that for these ancestors the wealthy properties are not their luxury. Again, material abundance does not necessarily mean luxury.

This time our investigation turns from luxurious things to non-things, such as luxurious experiences. The reason is that during our interviews consumers frequently pointed out non-materialistic consumption are important part of their luxury. For example, one informant in New York told us bath a Japanese at her home is her luxury. Bath tub itself is a thing but its use and experience is her luxury. For this purpose in mind, we picked up wealthy people’s overseas trip as a typical example of non-materialistic luxurious consumption. Wealthy people frequently go overseas for traveling. For the Japanese rich people, overseas trip appears to be one of the few entertaining moments in life, as they are having busy city life and have strong needs to escape. They already own gorgeous houses and expensive branded fashions. Their abundant expenses go naturally to overseas trips. The question here is as follows: Why overseas trip is a luxury for wealthy consumers. What are they feeling while they are enjoying trips in foreign countries?

Methodology

This time we adopted a method what we call photo-confrontation narrative. We first asked informants to pick up ten photos which they feel of luxury during their overseas trip. Then we interviewed the informants in what way they felt luxury during the overseas trip. We tried to search deeper meanings of their luxury. The informants were Keiichi, Junko and Mr and Mrs Tadenuma. These three people all live in the most upscale districts in Tokyo area, such as Shoto at Shibuya.

Findings

Our utmost important finding is that luxurious experience of overseas trip arises from binomial concepts: two competing and contrastive concepts appeared simultaneously in their luxurious experience narratives.

Extra-ordinariness versus Ordinariness

Overseas trip is usually extraordinary experience for everyone. People visit foreign countries, walking down towns they never knew, eating exotic foods, and meeting people of different habits and cultures. Overseas trip is thought to be unusual experience. However, as we take a close look how people feel during overseas trip, “ordinary feelings” are strongly sought in overseas trips. These wealthy people are enjoying luxury assuming they live there. They enjoy themselves when the tourists act and behave as local people, eating local foods, walking local streets, looking at the scenery as if local people see the scenery.

Expectedness versus Unexpectedness

When we travel abroad, we usually make plans prior to visit, what to see, and what to eat. When we first visit Paris, many of us visit Eiffel tower. First time travelers expect to see what they have expected beforehand. However, unexpectedness is another thing they expect to experience. Expectedness and Unexpectedness is another dimension in rich people’s overseas trip experiences.

Separateness versus Connectedness

In overseas trip, each moment is a precious experience. People meet new and curious things in each moment. In this regards, overseas trip is a moment-by-moment experience. However, if the trip has to be luxurious, the experience has to have factors related to past experiences and memory. Past experience and memory have an important meaning for overseas travelers. To repeat the past experience adds more luxury to the present overseas trip.

Non-wastefulness of time versus Wastefulness of time

Time devoted to overseas trip is a valuable resource for everybody. They do not want to waste time during trips in foreign countries. They try to fully utilize the time while staying in overseas. However, wealthy people feel luxuriousness when they waste time. Wasting time is a luxury while they are spending time efficiently doing overseas trips. Not useful time spending is another way to feel luxuriousness.

Conclusion

Why is overseas trip luxury for wealthy consumers? It was found that overseas trip has binomial meaning structure. Binomial means contrasting, competing concepts appear during their overseas trip experiences and creates luxurious feelings. As business implications, manufacturers and service providers of luxurious products tend to believe that they have to provide something gorgeous and deluxe looking. We would like to suggest that luxury is created not just from gorgeous appearing things, but luxury is created from internal meaning structures of consumers. All in all, luxury is produced not just from one pillar of this two pillar diagram but also from another side of the diagram.

“Everything You Always Wanted to Know About the Pre-Party* (*But Were Afraid To Ask)”

Christoffer Dymling, Stockholm University, Sweden

Jonas Olofsson, Stockholm University, Sweden

Eric Ugglå, Stockholm University, Sweden

Jacob Ostberg, Stockholm University, Sweden

This videography focuses on a distinct social and cultural phenomenon in Sweden commonly known as the pre-party. This consumption phenomenon is familiar to virtually all Swedish youth from the age where people start familiarizing themselves with alcohol to the age where they have formed more or less stable relationships. There are some unique institutional characteristics that foster a milieu in which the pre-party is a necessary form for youth eager to engage in nightlife activities. First, the legal drinking age is 18 for drinking in a bar or at a restaurant and 20 if you wish to buy alcoholic beverages in the state-owned liquor store, Systembolaget. As most Swedish youngsters feel an urge to drink alcohol before the age of 18 they have to do so outside of bars or restaurants. A second institutional characteristic is the extremely high taxation on alcoholic beverages in Sweden; especially if you buy the beverages in a restaurant you have to pay more money than most youngsters can afford. Consequently the pre-party attendants save money by drinking cheap, often privately imported alcohol before going out. Previous studies on alcohol consumption has tended to emphasize the negative aspects of alcohol consumption and have, we would claim, disregarded potential positive aspects of social drinking (cf. Banister and Piacentini 2006). Reading previous studies on youth and drinking thus leaves one confused over the apparent popularity of this consumption activity; if drinking only leads to unwanted social encounters, is fueled by negative peer pressure, and has negative consequences for one's self and social identity, why is it such an enormously popular consumption activity?

To learn more about the consumption phenomena of the pre-party, ethnographic research methods, focus groups, and an Internet survey have been used to gather empirical material. This material has been analyzed using the framework of ritual consumption (Rook 1985; Wallendorf and Arnould 1991). The study thus illuminates and enhances the understanding of the symbolic aspects of the consumption culture phenomena. Findings suggest that the pre-party can be understood as a consumption ritual containing an artifact, an audience, performance roles, and script phases: the meet & greet, the synchronization, the intoxication, the critical phase, and the ending. The ritual becomes meaningful to its participants by providing security, community and a possibility to escape everyday life.

We have chosen to structure the videography as a fictional story rather than the conventional documentary style (Kozinets and Belk 2007). The reason is that we would like to push the boundaries of the video format and explore its potential for representing consumption phenomena in creative non-fiction style (Brown 2005; Sunderland 2007).

“Behind Closed Doors: Opportunity Identification Through Observational Research”

Cynthia Webster, Macquarie University, Australia

Richard Seymour, The University of Sydney, Australia

Kate Dallenbach, Victoria University, New Zealand

To thrive in today's competitive marketplace, businesses constantly need to search for opportunities to develop. Organisations frequently draw on consumers' experiences, creative thoughts and usage behaviours for inspiration. The rationale for using consumers for creative solutions is that different individuals have different experiences, abilities, beliefs and needs (Shane and Venkataraman 2000). Such differences lead to unique interpretations of existing functional capabilities, possible product transformations to develop new solutions and novel conjectures for applications in new product areas (Henderson and Cockburn 1994; Kirzner 1997; Zahra and Nielson 2002).

In his seminal work on innovation, von Hippel (1986, 1988, 2005) emphasises the importance of those outside the organisation, especially “lead users” in identifying opportunities for innovation. von Hippel argues that new product concepts generated through consumer discussions or within artificial environments, as in a laboratory or computer simulations, are limited as real usage situations typically are not encountered. Along with other consumer researchers, von Hippel (2001) advocates an observational approach to opportunity identification, focussing on the ways in which users in authentic, real world situations modify and interact with products and services (Griffin and Hauser 1993; Leonard-Barton 1995). With this in mind, the purpose of the short film “Behind Closed Doors” is to: 1) further our understanding of the ways in which consumers transform ordinary products to serve their everyday needs, and 2) broaden our appreciation of the role observational research and videography play in opportunity identification.

As videography is a precise way to vividly document the “lived realities of every day consumption” (Belk and Kozinets 2005, p.128), it is ideal for the purposes of opportunity identification. Within consumer research videographic methods are increasingly being used both to provide rich sources of data and as a dynamic format to present results. Not only does videography complement other methods by providing stimuli for support and analysis, it extends research because the recordings can be viewed repeatedly and analysed from multiple perspectives, stimulating further insights and adding another layer to the research. Videography also is consistent with von Hippel’s (1986, 1988, 2005) lead user approach to innovation in that recorded images of observed behaviour document the actual ways in which participants use objects within social environments. Observation of existent behaviours is important as studies show that what people say and what they do are two different things (Bernard, Killworth, Kronenfeld and Sailer 1984; Freeman and Webster 1994; Webster 1994). Moreover, some groups of individuals, such as children, do not have sophisticated verbal skills and as a result are unable to provide comprehensive explanations of their behaviours (Valkenburg and Buijzen 2005). Finally, the entrepreneurial research points out that people do not report innovative behaviours, in part, because they do not have full information and so do not realise what is unique (Shane 2000). Videography, therefore, is a valid technique to manage such difficulties.

In this film, results from trace analysis and usage behaviors are presented in five themes: “Fresh Ideas”, “Storage”, “Playing”, “Repairs” and “Food Combinations”. Results exemplify the distinctive ways in which mundane, household products are transformed through novel applications. In each category ordinary, everyday products are shown to have unusual applications. For example, in “Fresh Ideas” bull clips are used to preserve food items, yogurt is placed in the freezer, baking soda keeps the freezer and shoes smelling fresh and clothes are put on hangers before placing them on the clothesline. Under “Storage” the same type of plastic box is used to store shoes, videos and toys while metal stands are used in place of beside tables and bookcases. In “Playing” items such as stickers, yarn, bracelets and plastic string are used to decorate walls, windows, dresser drawers, musical instruments and toys. The social play of two children reveals multiple uses for a trampoline. Not only do the children jump, but they introduce soft toys to the jumping. Play is then extended with the toys to underneath the trampoline. Video boxes are used as blocks to build enclosures for a pretend zoo. With “Repairs” many items are not repaired, instead a quick fix occurs. Tape is used to hold the washing machine hose in place, Blu Tack keeps bathroom tiles on, ties fasten foam padding to the trampoline and frozen peas are used as an ice pack for a hurt arm. In “Food Combinations” the mother manually inserts corn into pasta tubes for her son, the young girl wraps a gelatine snake around a banana, she also modifies a biscuit into a form to be eaten with hommous. The social interaction between the two children is highlighted through the making of their ice-cream sundaes. They obviously are in a state of excitement showing off to one another adding unusual ingredients such as Milo (a chocolate milk powder) and various cake decorations while creating their masterpieces.

Understanding of innovation and innovative organisations is relatively limited (Salaman and Storey, 2002). Very low success rates of innovation suggest that ‘successful’ companies can expect around one third of their innovations will fail, yet it is not always clear why these new products fail (Cooper and Kleinschmidt, 1987; Poolton and Barclay, 1998). The challenge for practitioners and researchers alike is to develop methods that will lead to a ‘pipeline’ of potential project innovations that are consumer-driven, and ‘understood’ clearly within and across the innovating organisation. “Behind Closed Doors” highlights how naturalistic observations incorporated with videography are able to expose the creativity, problem solving, and variety seeking behaviors of one family. This research suggests alternative approaches for future research into opportunity identification, making use of observation and videography. Moreover, the current work emphasises that innovation and creativity require consideration of the relational rather than just self-seeking behaviours, needs or events.

"Consumption, Belonging and Place"

Marta Rabikowska, University of East London, UK

Matthew Hawkins, University of East London, UK

A documentary, *Consumption, Belonging, and Place* is part of a bigger project on the relationships between consumption, ethnicity and material reality in which video ethnography was applied as a main method, accompanied by interactive methods of communicating with the receiving community, such as local screenings, exhibitions, and internet blogging. The role of the marketplace and the distributions of social and cultural meanings in creating the community has been investigated in this film within the time span of one year: 2006-2007. The film was designed and executed to probe a methodological basis of research involving a voice of the researcher and her own experience in the community. In its current form the film represents the researcher's interpretation of the results from semi-structured interviews which were conducted among two groups of inhabitants of the community: the owners of businesses and the shoppers in the High Street. The street—the marketplace delineates spatio-material topography of the study but also serves as a symbolic representation of the socio-cultural practices of the local community. As in Nigel Thrift's theory of space in this research the street is "porous"—with no boundary to incoming memories, messages, or encounters, and with no stable landscape for communication (2002), though, as my ethnographic film shows, there will be plenty of attempts to make that space static and stable.

The film is an interpretative tool which shows that the street is made up of many kinds of stories and practices brought in to relation with one another through a continuous and largely involuntary process of encounters. The space of one street, however, emphasizes the 'materiality of thinking' (Carter 2004) which in this research is accepted as an epistemological foundation for consumption practices. Such practices are observed in relation to space and ethnicity which are themselves the products of interpretation of the consumption of the street and its facilities by different informants.

The film shows the researcher's own story of the place and other stories provided by the inhabitants of which none can become a dominant narrative. The interpretivist approach is articulated through a subjective process of editing combined with self-referential images which reveal the process of film-making and the researcher's personal engagement (Cohen 1994). Both a textual and meta-textual level in the film is to accentuate the awareness of a tension between representation and everyday life practices, including the practice of research too.

To acknowledge the mutual exchange between those levels, the self-reflective visual 'footnotes' were utilized in the film which come from the reality of the researcher and the production-team. This approach recognizes the interconnectedness of objects, texts, images and technologies in people's lives which are the object of an ethnographic research. This is to state that, unlike in Collier's traditional approach, in this film ethnography is regarded as an aspect of research and an aspect of representation as well, while the whole project represents the narrative-based communication story constructed by the researcher (Clifford 1986).

The recorded interviews indicate that most of the stories told by the informants find their opposite versions in other informants. This differs mostly across different ethnic groups using the same street but also across generations and lifestyles. Nonetheless, in the process of editing, those stories acquire another form which depends only on a researcher who interprets them from her own point of view.

ROUNDTABLE
Understanding and Improving Consumer Personal Finances

Chairs:

Lisa E. Bolton, The Pennsylvania State University, USA
Paul Bloom, Duke University, USA
Joel Cohen, University of Florida, USA

Participants:

David Glen Mick, University of Virginia, USA
Ron Paul Hill, Villanova University, USA
Kathleen D. Vohs, University of Minnesota, USA
Amar Cheema, Washington University, USA
John G. Lynch, Duke University, USA
Vanessa Perry, The George Washington University, USA
Gal Zauberman, University of Pennsylvania, USA
James Burroughs, University of Virginia, USA
Cynthia Cryder, Carnegie Mellon University, USA
Scott Rick, University of Pennsylvania, USA
Eldar Shafir, Princeton University, USA
Stephen Spiller, Duke University, USA

How do consumers make decisions about budgeting, spending, saving, investing, and borrowing? And what can be done to improve consumer personal finances? The recent sub-prime meltdown and related developments have focused attention on these important aspects of consumer behavior, yet research on consumer personal finances is scant. The objectives of this roundtable are 1) to encourage research on important issues related to consumer personal finances; 2) to bring together academic researchers and consumer organizations in order to identify issues of mutual interest; and 3) to improve consumer welfare through the development and dissemination of knowledge that improves personal financial decision-making among consumers. This roundtable will include participants from academia and industry, including the National Endowment for Financial Education and the Federal Reserve Bank, who are consumer advocates and sources of research funding.

ROUNDTABLE

Aesthetics and Consumption

Xiaoyan Deng, University of Pennsylvania, USA
Rishtee Kumar Batra, Boston University, USA

Aesthetics is increasingly becoming an important criterion by which consumers evaluate and differentiate between product offerings and make purchasing decisions. Recognizing this growing trend in the marketplace, a number of consumer researchers have begun focusing on this area of research. However, there exists no comprehensive, overarching, or integrative theoretical framework for aesthetics research in the consumption domain. Indeed, the concept of aesthetics is itself understood in diverse ways, and researchers variously equate it with, for instance, beauty, intrinsic interestingness, artistic appeal, pleasantness to the senses, or a combination of these and other concepts. It may therefore often be necessary for researchers in this area to specify how aesthetics is to be conceptualized in a given research project.

The topic of aesthetics tends to inspire interesting philosophical debate, as it also did during the roundtable, and different philosophical perspectives may help shape different research agendas. Notwithstanding these perspectives, it was noted that a general challenge for marketing scholars is to maintain a focus that is relevant for consumer behavior. Otherwise, aesthetics may become an esoteric topic for those of us with a special interest in the area, rather than the fertile and broadly influential area of research that it has the potential to be, based on the central role it plays in consumers' everyday evaluation and choice. Keeping this focus in mind, a number of issues brought up during the discussion are presented here in a brief, summary fashion.

Areas of Discussion

- Aspects of the aesthetic experience shaped both by universal influences stemming from our common evolutionary heritage and by individual differences stemming from culture and other sources.
- The aesthetic experience is often characterized as one that is enjoyed purely for its own sake, without regard to other, more practical considerations.
- Some argue that aesthetics is divorced from considerations of functionality, while others argue that the perception of a form-function relationship can help shape an aesthetic experience.
- Aesthetics as an all-consuming experience versus minor moments of pleasure.
- Emotions implicated in the experience of aesthetics.
- Is aesthetics a unique experience? If so, how?
- What is the relationship between aesthetics and hedonics?
- Aesthetic value. How does this translate to profit?
- Aesthetics as rich experience versus instant judgment, complexity versus fluency, cognition versus emotion. The race model: some aesthetic experiences may be instantaneous while others are elaborate and nuanced. What distinguishes these experiences?
- Aesthetics as a flow experience, leaving little cognitive capacity for reflection and analysis.
- Aesthetic schema, with innate and learned components.
- Aesthetics as a visual phenomenon, versus aesthetics incorporating all sensory perception. Perhaps the aesthetic schema is more fully developed for visual perception. This is also important for mass customization, where marketers must assume that consumers know what they like.

Contentious Areas

- Are concepts like the sublime relevant to consumer behavior research? Perhaps more mundane concepts tend to be more relevant for the majority of products, while the sublime can be relevant to other consumer experiences?
- According to Maslow, hedonic needs or higher order needs are taken care of only after functional needs have been met. Other evidence suggests that the need for aesthetics is present even when functional needs have not been adequately addressed.
- To which extent is aesthetics high culture or related with luxury, and to which extent is it more pervasive and found even in the most mundane consumption experiences?
- How immediately obvious should the managerial relevance be of research in aesthetics? What are, for instance, some issues related to trade dress, that is, the ownership by the firm of aesthetic presentation (look and feel)?
- Is there a good way to measure the aesthetic experience and to capture the rationale of the emotional choice?
- How does the work on aesthetics add to extant theory? We need to avoid conceptual replications. We need to establish different processes. Is aesthetics just another attribute?

One of the biggest challenges facing researchers in the domain of aesthetics is publishing in top journals. However, given the substantial and growing managerial importance of aesthetics, it seems reasonable that this area be given increasing attention in the marketing literature, as long as the theoretical contribution is also sufficient.

Perhaps interesting empirical effects without substantial theory should also be publishable on occasion, but this will not be sufficient to grow the topic of aesthetics as a viable and broadly influential area of research. Since research on aesthetics in marketing is still at a stage of infancy, it is likely to remain fragmented for some time to come. However, as the area matures over time a broader understanding of aesthetics is likely to emerge, as tends to be the natural progression for most areas of scientific inquiry. The current roundtable, where many researchers were not able to enter and partake in the discussion because the room was too full, clearly demonstrates that an increasing number of marketing scholars realize the importance of aesthetics as an area of research in marketing. Therefore, it seems realistic to hope that academic research in this area will eventually catch up with managerial practice and increase our general understanding of consumer behavior phenomena pertaining to aesthetics.

Since David Mick's rousing 2005 presidential address calling for more transformative consumer research (TCR), we have seen a flurry of activity and increased institutional support. For example, a special issue on TCR will be published in the *Journal of Consumer Research* in the Fall of 2008, the first TCR conference was held at Dartmouth in 2007 (and a second one is being planned for 2009 at Villanova University), and a Handbook of Transformative Consumer Research is currently underway.

The primary people involved in building the TCR community, such as the members of the TCR task force and TCR Board, have been senior researchers who are well established in their careers. While resources in the form of research grants have been distributed to support the research of young scholars, junior scholars have not been directly involved in the formal deliberations that have shaped the direction of TCR. Moreover, given the diversity of issues spanned by TCR, some emerging scholars have voiced a desire and need to network within the larger community of researchers studying social problems. The long term success of any program of research, of course, depends on the ability to attract, foster, and develop a cadre of new researchers.

HLM: Hierarchical Linear Models

Chair:

Dawn Iacobucci, Vanderbilt University, USA

Participants:

Gerri Henderson, Northwestern University, USA

Adam Duhachek, Indiana University, USA

Jim Oakley, University of North Carolina, USA

Steve Hoeffler, Vanderbilt University, USA

Steve Posavac, Vanderbilt University, USA

Simona Botti, London Business School, UK

Katherine A. Burson, University of Michigan, USA

Pankaj Aggarwal, University of Toronto, Canada

HLM, or Hierarchical Linear Models, is a technique that Org Behavior scholars are finding very useful, and that marketing might also use in certain applications. The models integrate data that represent different (usually only two) levels of analyses. For example, individuals might state certain purchase preferences, and groups (households, buying centers, departments) might express others, and it would be naïve to model one part of the data without considering the other.

This workshop will provide an introduction to HLM models. We'll talk about why these techniques are an improvement over naïve methods to approaching the multi-level problem. We'll also talk briefly about how these models compare to other linear models.

Syntax will be provided, and attendees guided through, both stand-alone HLM software and SAS's means of analyzing HLM data.

A roundtable was held at the 2007 ACR conference to discuss the issues and challenges with conducting consumer research in India and China. In our pre-conference discussions via an online group forum, and at the 2007 conference we identified and discussed some key issues and challenges and agreed upon the need to expand the discussion of the topic from India and China to include all transitional economies/emerging markets. This roundtable is thus a continuation and an expansion of the discussion started at the 2007 conference.

In order to facilitate pre-conference discussion, participants as well as forty researchers working on emerging markets that are a part of an online forum were asked to send in questions on topics relating to methodology, research and geographic area issues with conducting research in emerging markets. Since this roundtable is a part of an ongoing discussion started at ACR 2007 and to be continued at ACR–Asia Pacific, 2009, the discussion topics and questions identified were ones that could continue the discussion started last year. The discussion at this roundtable therefore centered on several key areas:

1. **Capturing Cultural Nuances:** Several respondents talked about the difficulty of capturing cultural and contextual nuances when conducting research in emerging markets. From practical issues such as finding good translators to finding a comfort level and understanding before starting research in these markets, participants discussed several complexities in emerging markets that require good research partners in these settings as well as a willingness on the part of the researcher to immerse themselves in the culture and understand the local context before collecting data. A participant from China talked about the diversity of the Chinese market and how consumer behavior changes from city to city within China based on the level of development in each city. This was echoed by researchers working in some other emerging markets such as India about tier I versus tier II or III cities and the urban-rural divide in most markets that makes generalization very difficult. A need and a platform to share these experiences among researchers working in these markets were felt to be useful.
2. **Data Collection Issues:** Several participants last year expressed a view that it is important for researchers to share our experiences with using various methodological tools in these markets. This year's discussion centered on using the right kind of research partners. Participants mentioned partnering with local universities as a way to get access to students and student assistants to help with data collection. Several participants shared issues with research partners and assistants not understanding exact research procedures and thus possibly affecting the quality of the data being collected. Again a need for a database to share experiences with other researchers who have worked in these markets before was agreed upon as being a very useful tool.
3. **Theoretical issues:** Last year we had discussed briefly the applicability of theories from developed markets being used in emerging ones. This year we extended this discussion by talking about the importance of recognizing context and its influence before

deciding on applying a particular theory in a new market. The idea that some theories are more amenable to cross-cultural application than others was discussed with the conclusion that researchers need to be very sensitive to the issue of context with theory translatability across cultures. Further, some participants discussed the need to clarify what their unit of analysis is when studying these markets. Is it the individual consumer or is it the market itself? Also, a researcher pointed out that the idea of multi-sited research with interpretive research which is typically not done by anthropologists is ideal for our field since there are topics within consumer research that lend themselves well to this type of work.

4. **Geographic Area Uniqueness & Challenges:** An important element of expanding the discussion from 2007 was to include work in geographical areas that do not have as much representation. For instance, what are some challenges with working in Latin America and Africa? A participant from Tunisia talked about the difficulty of connecting with researchers from other parts of the world. Since a majority of consumer research work is published in the United States and Europe, he talked about better accessibility to publishing outlets when working with these researchers. He talked about the need for more dialogue between researchers in other parts of the world and those based in the United States. Again, the usefulness of a database that would connect researchers working in various countries with each other was thought to be very useful.
5. **Miscellaneous issues (Publishing Outlets, IRB issues, research contacts for local firms):** Last year we talked about the difficulty sometimes of getting IRB approval due to various local level research collection methods not being agreeable to human subjects committees in several US universities. This time the discussion centered on finding solutions to these human subjects issues by talking to other researchers who had managed to clear this issue with their boards. Again the need for a dialogue among researchers was felt to be essential to find out about human subjects approval requirements in the countries where the research is being conducted as well as with getting approvals quickly in home countries. The other issue that researchers were interested in is was on how researchers might be able to contact local companies and managers in particular countries. Another issue discussed was the need to document and list some key publishing outlets for research on emerging markets. Given the changing nature of these markets, some topics may get outdated if these are under review for longer periods hence information on which outlets may be ideal was felt to be good information to share with other researchers.
6. **Database:** this year the main thread running through the discussions on the various topics listed above was the need to build a database and a community so that researchers could share their experiences on various aspects of conducting research in emerging markets. The database ideally would contain a list of research centers that fund research in emerging markets; a list of key contacts with firms/respondents in emerging markets; a list of potential journals to publish in and very key would be a list of researchers working in various emerging markets. Researchers' ability to post questions and receive responses from other researchers would add value given the need expressed by most researchers at the roundtable for a forum to discuss various issues. We currently have more than 50 ACR members that are a part of an existing online forum that was created last year. Ideas on where to site this database and how to structure it were discussed and these discussions will continue with participants to get consensus on the best way to structure this database/forum.

The next roundtable to continue this discussion will be held at ACR-Asia Pacific in India in January 2009. That discussion will involve a dialogue between researchers based in India working on consumer behavior issues and those based elsewhere that are interested in these issues.

In summary, the 2008 ACR-SF roundtable reinforced the idea that conducting consumer research in emerging markets is gaining tremendous interest among researchers as these markets expand rapidly. There are also various challenges to conducting research in these markets as discussed at this roundtable. Researchers working in these markets therefore strongly need a forum and a community to share their experiences on methodological tools and other issues to be able to be more efficient with conducting research in emerging markets.

ROUNDTABLE
Intro To Social Network Methods

Chair:

Dawn Iacobucci, Vanderbilt University, USA

Participants:

Gerri Henderson, Northwestern University, USA

Adam Duhachek, Indiana University, USA

Jim Oakley, University of North Carolina, USA

Steve Hoeffler, Vanderbilt University, USA

Steve Posavac, Vanderbilt University, USA

Simona Botti, London Business School, UK

Katherine A. Burson, University of Michigan, USA

Pankaj Aggarwal, University of Toronto, Canada

Networks are currently enjoying a great deal of popularity. Popular business press features regular articles speculating on how companies can make money off of the Facebook-and variant-like phenomena (cf., an entire special issue of *Forbes* last spring). Marketing has long acknowledged the importance of word-of-mouth, e.g., in diffusion models, and in recommendations for selections of service providers, yet only recently have they begun to embrace social network concepts. Further from acceptance still is the use of the social network analytical tools that might actually contribute to the understanding of network structures.

This workshop will provide an introduction to social network methods—the micro, actor-level indices, the meso, group-level methods, and the macro, network-level approaches. Attendees have probably heard of such concepts as centrality, and we'll see the many ways of computing it. Similarly, we'll look at techniques for identifying, cliques, structural equivalence, etc.

This overview will give attendees an appreciation of what social network methods are, e.g., as they read journal articles in which the techniques are used, or as they attend talks by their management colleagues. Perhaps some attendees will also be inspired to experiment with some social network aspect of their own research. To that end, we will also spend some time talking about how social network data are collected (not just modeled).

Martin Reimann, Stanford University, USA
Scott Rick, University of Pennsylvania, USA

This roundtable session sought to discuss recent approaches in the field of consumer neuroscience that aim at understanding the neural systems supporting and affecting marketing-relevant behavior. The session brought together researchers currently using neuroscientific methods to investigate questions related to marketing in order to 1) assess the current state of knowledge and 2) discuss directions for future research. The session began with a discussion of the marketing-relevant questions that have been investigated within consumer neuroscience, as well as decision neuroscience and neuroeconomics. This was followed by a discussion to elicit ideas about research future directions.

Generating eReferrals Using Incentives and Bribes: A Field Experiment Testing Various Incentives for online Referrals

Jan Ahrens, Golden Gate University, USA

Michal Ann Strahilevitz, Golden Gate University, USA

Abstract

This research examines several methods for generating company-initiated electronic referrals (eReferrals). A field experiment was conducted with 45,000 participants using different online referral techniques. We manipulated the incentive magnitude for senders and receivers. Dependent measures included the number of eReferral emails sent, the number of eReferrals made and the number of eReferrals that led to sales. Our results show that incentives to both the receiver and the sender lead to higher eReferral rates. We also identified an interaction where relatively higher incentives for the sender of the eReferral were most effective when the receiver of the eReferral also was offered an incentive, albeit a lower incentive.

Introduction

The trend toward consumers generating their own marketing messages is increasingly taking the power of attracting customers out of the hands of the marketers. Traditional referrals can be described as one consumer's promotion of goods or services to another consumer. Electronic referrals (eReferrals) are those referrals that occur online. Firms are making great efforts to respond to this new technology-enabled phenomenon. This has led many firms to invest in encouraging customer acquisition via electronic referrals. eReferrals offer marketers a way to acquire new customers from current customers, at a potentially higher quality and lower cost than advertising.

The research used a large-scale field experiment measuring actual eReferral, registration and purchase behavior. Participants in the study were customers of Ebates and the individuals to whom they referred. Ebates is a website offering services and discounts to online shoppers who purchase through their portal.

When financial incentives to both senders and receivers are offered, equity theory suggests the two parties will be affected by what they each receive. Intuitively we may think that the person making a recommendation cares only about what incentive is offered to him or her, however, equity theory suggests otherwise. In general, equity theory can be described as the proposition that individuals seek equity in what they give and what they receive (Walster, Berscheid & Walster 1973). So the sender may believe that the receiver should also receive an incentive for efforts made. Equity exists when both parties receive the same incentive, such as \$5 for the sender and \$5 for the receiver.

Inequity may be present when the perceived inputs of one person are in opposition to what that person perceives are the inputs of another person (Adams 1963). Or, stated another way, inequity may be present when the incentive levels to the two parties are of different magnitudes. For example, assuming equal effort, if the sender gets \$10 and the receiver gets \$5, there is positive inequity for the sender. That said, assuming equal effort, if the sender gets \$5 and the receiver gets \$10, there is negative inequity for the sender.

Field Experiment Measuring Actual eReferral Rates Under Different Incentive Conditions

The field experiment was conducted with 45,000 participants who were customers of Ebates. Ebates offers a percentage of cash back on purchases to its customers who can shop at over 900 popular online stores. Participants were randomly selected from Ebates' base of customers who had purchased goods through Ebates within the past twelve months and had not opted-out of email communication from the company. The study was a two-factor between-subject experiment, where the size of the financial incentives offered to the senders and receivers of the eReferrals were manipulated. Specifically, the two independent variables were 1) *Incentive magnitudes to senders of the eReferrals* (\$5, \$10, \$25, and \$50), and 2) *Incentive magnitudes to receivers of the eReferrals* (\$5, \$10, \$25, and \$50). There were a total of eight conditions, representing the different incentive combinations (the first incentive level is for the sender, the second is for the receiver): \$5/\$5, \$5/\$10, \$5/\$25, \$5/\$50, \$10/\$5, \$25/\$5, \$50/\$5, \$25/\$25. Participants were randomly assigned to one of the eight conditions.

The eReferral initiation process began by Ebates contacting 45,000 current customers via a "prospecting email" with one of eight financial incentive offer combinations in exchange for referring others. These members then chose to make eReferral invitation attempts to friends, relatives, acquaintances or other persons. Receivers of these eReferrals then had the opportunity to register contact information with Ebates and thus become new Ebates members. As indicated in the invitations, for both parties to earn the financial incentive offered, the new member must have made a purchase within the offer expiration period of three weeks. Once this step occurred, the new member's status changed to that of a buyer, and the promised incentives were rewarded to both parties.

There were three dependent variables in the field experiment: 1) the number of eReferral invitation emails sent in attempts of creating an eReferral ("invitation emails"), 2) the number of new Ebates members acquired through the eReferral efforts ("new members"), and 3) the number of those new members that converted to become buyers ("new buyers"). Of the 45,000 "prospecting emails" sent from Ebates, 37,601 were actually delivered (i.e. "good" email addresses).

A unique URL was included in each email to enable tracking by condition. The URL was tied to each unique sender who then received the promised incentive when a receiver became both a member and a buyer by both registering and then purchasing through Ebates. A total of 2,226 "invitation emails" were sent from Ebates' Senders. There were 810 "new members" who registered and then subsequently 391 "new buyers" who purchased during the three-week offer expiration period.

Results

We hypothesized that in equal financial offer combination eReferral situations (e.g. the same amount for each party such as \$5/\$5), the higher the total financial incentive offer combination for senders and receivers combined, the more eReferrals results would occur. All three dependent variables increased significantly between the group that received \$5 for both parties (\$5/\$5) compared to the group that received \$25 for both parties (\$25/\$25) as follows: 1) the rate of eReferral “invitation emails” sent out increased from 40.1 to 100.4 per thousand ($p < 0.0001$), 2) the rate of “new members” increased from 13.9 to 42.9 per thousand, ($p < 0.0001$), and 3) the rate of “new buyers” increased from 7.1 to 21.1 per thousand, ($p < 0.0001$).

In unequal financial offer combination eReferral situations (e.g. a different amount for each party such as \$5/\$10), we also hypothesized that the higher the total financial incentive offer combination for senders and receivers combined, the more eReferral results would occur. Groups in this analysis included \$5/\$10 and \$10/\$5 (\$15 total), \$5/\$25 and \$25/\$5 (\$30 total), \$5/\$50 and \$50/\$5 (\$55 total). Significant increases of all three dependent variables occurred as each total incentive level increased ($p < 0.0001$). As an example, the rate of eReferral “invitation emails” sent increased from 47.2 per thousand in the \$15 total group, to 59.5 in the \$30 group, to 71.3 in the \$55 group ($p < 0.0001$).

We also hypothesized that in cases with an unequal financial offer combination (e.g. \$10/\$5), those conditions with the sender receiving a higher financial offer than the receiver would yield higher eReferral rates than when the receiver’s incentive is higher. Subjects with offer conditions of \$5/\$10, \$5/\$25 and \$5/\$50 were combined into a ‘sender lower’ financial offer group, while subjects with offer conditions of \$10/\$5, \$25/\$5 and \$50/\$5 were combined into a ‘sender higher’. An ANOVA analysis was performed. The hypothesis was supported as eReferral results increased significantly from the “sender lower” to the “sender higher” groups. The rate of eReferral “invitation emails” sent increased from 48.1 to 68.8 per thousand ($p < 0.01$); the number of “new members” increased from 17.2 to 23.5 per thousand ($p < 0.05$); and the number of “new buyers” increased from 7.5 to 12.1 per thousand ($p < 0.05$).

When conditions within the unequal financial offer combination eReferral situations were isolated, those with the offer combinations of \$50/\$5 and \$25/\$5 showed significantly better measures in all three dependent variables than all three conditions in which the senders offer was lower (\$5/\$10, \$5/\$25 and \$5/\$50).

Conclusion

The results of this field experiment provide insight into consumer responsiveness to company-initiated eReferrals under different conditions. Not surprisingly, as the incentive to the referrer increased, so did the sender’s eReferral effort and success in referring others. eReferrals rates also correlated positively to higher incentive levels for receivers of the eReferral. There were significant increases in eReferrals as the offer incentives increased both to senders and receivers. However, the effect of the size of the incentive to the sender was stronger than the effect of the size of the incentive to the receiver. When incentives to senders and receivers were unequal in size, eReferral results were higher when the sender’s incentive was higher.

On a deeper level, the results suggest that mild positive inequity (i.e., inequity favoring the receiver of the offer) is tolerable, and in fact may motivate the highest level of effort (as measured by eReferral rates). Yet, too great a level of positive inequity may have a negative effect on motivation (as measured by eReferral rates). In short, the power of greed may only motivate consumers up to a point. At some maximum level of tolerance for positive inequity, our results suggest that consumers may be more motivated by offers that involve sharing rewards with others.

Preferences for Food with Nutrition and Health Claims in a Close-to-Realistic Choice Context

Jessica Aschemann, University of Kassel, Germany

Ulrich Hamm, University of Kassel, Germany

Abstract

In 2007, the EU introduced a regulation on nutrition and health claims on food products in response to the increasing importance of claims. However, to what extent and how European consumers react to claims remains an open question. This study analyses purchase behaviour in a close-to-realistic laboratory choice test. The results show that foods with nutrition and health claims are generally preferred. Determinants of choice are perception of healthiness of the product, extent of information search and credibility of the claim. Participants’ behaviour and statements indicate that the premise of designing a close-to-realistic choice context has been met.

Introduction

Health is an important motive for food choices and increasingly used as an argument in the communication strategies of food companies. In reaction to this trend, the EU commission developed the regulation (EC) No 1924/2006 on nutrition and health claims. Its aims are an EU-wide harmonisation in the handling of claims and consumers’ protection from misguidance with regard to the “healthiness” of products. However, research on European consumers’ reactions towards such claims on food is scarce so far, especially in a realistically designed decision context. This study, funded by the German Research Foundation, examines the influence that claims have on purchase decisions and the determinants of food choice in the presence of claims, using the choice-test method.

Methodology

A multi-measurement approach was developed combining a discrete choice-test in the laboratory with unobtrusive video-recording and a subsequent face-to-face-interview. The task was designed as realistically as possible, in reaction to the frequently expressed critique that previous studies on such claims might lack external validity (e.g. Keller et al. 1997; Garretson and Burton 2000; Van Trijp and van der Lans 2007), as well as consumer research (Liefeld 2000). We used three-dimensional, authentic products with brand names and inconspicuously added the claims with professionally designed adhesive stickers. The test persons were not forcefully exposed to the claims, were allowed a no-choice option (Dhar and Simonson 2003) and acted under budget constraints as well as increased relevance due to the non-hypothetical choice (Lusk and Schroeder 2004). Each of the 210 regular buyers of the products invited to the laboratory experiment was asked to imagine that they had strawberry-yoghurt, fruit-muesli and spaghetti on the shopping-list. They could choose one out of five alternatives each. The claims were present on two alternatives at a time (expected frequency of random choice of a product with claim therefore being 40%) and its appearance rotated between the brands in order to minimise the brand influence. Furthermore, the claim phrasing alternated between a nutrition claim, a health claim and a health risk reduction claim. We did not manipulate the products with further positive information in order to control for a mere-label-effect (Van Trijp and van der Lans 2007), because the authentic layout of the products already included other positive information (for example “with honey”, “deliciously creamy”, etc.).

Results

The sample size consisted of 630 cases, with the no-choice-option selected in 5% of all. 50.5% of the respondents were 45 years or older and 71.4% female. The proportion of choice for products with a claim was significantly different from the expected with 44.4% ($n=599$, $\chi^2=4.848^*$; with $p \leq .001=***$; $p \leq .05=*$). Hence, the subjects preferred the products with a claim, even though only 52.4% of the respondents stated that they had actually noticed the claim during the experiment and 38.7% said they had selected the habitually chosen brand. Additionally, the mean duration of information search for all three choice decisions was very short, 1.81 minutes only, and, on average, subjects touched 1.2 products per product category.

Binary logistic regression was applied for each of the three food categories in order to determine which of the independent variables contributed to the explanation of choice behaviour. Age, sex, credibility of the claim, knowing the nutrition-health-relationship and a positive attitude to functional food were insignificant influencing factors in all three models. Only perception of healthiness of the product with a claim had a significant and positive influence on choice for each food category. Choosing the habitual brand has a negative influence on choice of a product with a claim for pasta and yoghurt, scepticism towards texts on food packages has a positive influence for muesli but a negative for yoghurt and the fact that the claim is presented on the cheapest of the alternatives has a positive influence for pasta but a negative for yoghurt. Further variables are only significant for one of the food categories. All three models (yoghurt; muesli; pasta) are significant (Likelihood-Ratio Test: $\chi^2=76.511$; $df=11$; $p=.000$; : $\chi^2=22.224$; $df=11$; $p=.023$; $\chi^2=32.131$; $df=11$; $p=.001$) but differently satisfying (Nagelkerke $R^2=.464$; .168; .218).

Conclusions

The study shows that products with claims are preferred. We conclude that the probability of preference for a product with a claim is higher when the person regards the product alternative as relatively healthy and does not choose the habitually chosen brand. Which are the determinants of choice as well as the direction of its influence depends very much on the food category and, related to that, the content of the claim. We deduce from the participants' behaviour and statements that we might have been successful in meeting the premise of a realistically designed choice decision context. It can therefore be assumed that claims on food products increase the likelihood of purchase by consumers, even under the impact of the various influences at the point of sale.

Should I Keep or Should I Give: The Effects of Mortality Salience on Disposing

A. Selin Atalay, HEC School of Management, Paris, France
Meltem Türe, Bilkent University, Turkey

Reminders of human mortality, mortality salience (MS) are inevitable in consumers' everyday lives. Terror Management Research (TMT; Greenberg et al.1997), explains how individuals deal with MS. TMT has shown that MS induces excessive spending and greed (Kasser and Sheldon 2000), preference for high status products and increased expression of materialistic values (Arndt et al. 2004, Mandel and Heine 1999). We extend this research by investigating how consumers dispose their possessions after acquiring new ones.

When mortality is salient, individuals try to establish a sense of control by reinforcing their belief in a cultural worldview (CWV), and enhancing their self-esteem (Pyszczynski et al. 2003). Self-esteem which mitigates the effects of MS, is enhanced by being a valuable member of a valuable culture (Arndt et al. 2002). A CWV also helps reduce anxiety by providing literal, and symbolic immortality (Pyszczynski et al. 1998).

Disposing is an important consumption phenomenon. By disposing possessions, one can create, maintain or negotiate an identity (Belk 1988; Price et al. 2000), and can deal with aging and death (Marcoux 2001; Kates 2001; Price et al. 2000). As such, that it is important to understand how disposing shapes up under MS. The relationship between MS and disposition has not yet been investigated. Disposition of possessions may be both physical and psychological ‘therapy’ for consumers (Scwebke 2006) as it induces symbolic immortality, and presents a way to create a certain type of self. It helps an individual preserve a certain identity or construct and communicate a desired one (McAlexander 1991, Wallendorf and Young 1989).

From a TMT perspective we study how consumers dispose their possessions when mortality is salient. We hypothesize:

H1a: When mortality is salient individuals will dispose their possessions in ways that will help them create a sense of symbolic immortality.

H1b: When mortality is salient individuals will dispose their possessions in ways that will allow them to form a socially valued identity.

Study 1

Study 1, an experiment conducted with 41 undergraduates, tested how MS impacts disposing. MS was manipulated and its effect on disposing was measured.

Manipulation. In the MS condition, participants responded to two open-ended questions about death: 1) “Please briefly describe the emotions that the thought of your own death arouses in you.”; 2) “Jot down, as specifically as you can, what you think will happen to you as you physically die and once you are physically dead.” Participants in the control condition responded to a neutral topic: 1) “Please briefly describe the emotions that the thought of going to the dentist arouses in you.”; 2) “Jot down, as specifically as you can, what you think will happen to you the next time you get a painful procedure done at the dentist’s office.” Standard distracter tasks followed to ensure that MS was present at a non-conscious level (Greenberg et al. 1990; Harmon-Jones et al. 1997).

Disposing. After the manipulation, participants reviewed a scenario which asked them to imagine that their family gave them an upgraded version of their existing camera. Participants were asked to indicate what they would do with their existing camera.

Results. In the MS condition, 68% indicated they would give their camera to someone else, while in the control condition 33% indicated they would give their camera to someone else. The remaining 34% of the participants in the MS condition indicated they would keep their old camera, while 67% of participants in the control condition indicated they would keep their old camera.

A binary logistic regression, with disposition type as the dependent variable (choice of giving the old camera coded as 1) and MS as the independent variable, showed a significant effect of MS on disposition type ($b=1.5$, Wald $\chi^2=4.4$, $p<.05$) indicating individuals in the MS condition preferred to give their old cameras to someone else more than those participants in the control condition.

In explaining their motivations, the MS participants reported that they would give their camera to someone else to prevent waste, achieve symbolic immortality and because giving is the “*right thing to do*”. Individuals in the MS condition who chose to keep their camera reported an emotional connection with the item. Participants in the control condition who chose to keep their cameras did so because they might need the item. They stated that they they might give it to someone they knew, which allows them to still have access to it.

To make sure that the effect of MS on disposition choice was not driven by a mood induced by MS, the Positive Affect Negative Affect Schedule (Watson, Clark and Tellegen 1998) was administered. The ANOVAs on positive and negative affect indicated no differences ($p>.64$ and $p>.40$, respectively) between the experimental groups.

Personality measures; Self-esteem (Rosenberg 1965), Desirability of Control (Burger and Cooper 1979), and Materialism (Richins 1989) indicated no differences between the groups ($p>.32$, $p>.50$ and $p>.60$, respectively).

Discussion. As predicted, MS caused individuals to dispose their item in ways that provide them a socially accepted identity and symbolic immortality. MS induces a striving for symbolic immortality and self-esteem. Disposing literature suggests that giving away one’s belongings can help one achieve a desired identity and symbolic immortality. Hence, giving away possessions help individuals mitigate the effects of MS.

Future Studies

This work investigated the effects of the needs for self-esteem and symbolic immortality induced by MS on disposing. In the studies that follow it will be important to understand the effects of the other needs induced by MS on disposing namely; need for control and materialism.

General Discussion

MS is widely experienced, thus it is important to understand its effects on all phases of consumption. This research helps us understand how consumers evaluate their possessions and detach themselves from them under MS which in turn have implications for charitable donations, waste management, increasing recycling and sustainable consumption.

So, what will you do with your old item the next time you replace a possession?

Environmentally Friendly Consumption Preferences: Understanding the Impact of Consumption Routines

Tugba Orten, Izmir University of Economics, Turkey

Deniz Atik, Izmir University of Economics, Turkey

Since the 1970s, environmental issues have been increasingly studied by many marketing scholars. Especially in the early stage, majority of the studies attempted to identify environmentally concerned consumers (e.g., Murphy, Kangun, and Locander, 1978) under different names such as socially conscious consumers (e.g., Anderson and Cunningham, 1972; Brooker, 1976; Webster, 1975), voluntary simplifiers (e.g., Leonard-Barton, 1981; Shama, 1985), or green consumers (e.g., Diamantopoulos, Schlegelmilch, Sinkovics, and Bohlen, 2003). As it can be understood from these various denominations, these studies could not reach a common definition of who are the environmentally concerned consumers (Connolly, McDonagh, Polonsky, and Prothero, 2006). This may be because identifying who is a green consumer is not easy or not even possible. Consumers, regardless of the degree of their ecological consciousness, do not buy environmentally friendly products only on the basis of their ecological impacts (Henion, Gregory, and Clee, 1981). There may be many other reasons beyond the environmental aims motivating those purchasing decisions such as the health concerns of consumers for themselves or their families, economic constraints, quality issues, availability or pleasure (Connolly, McDonagh, Polonsky, and Prothero, 2006; Leonard-Barton, 1981).

Although after 1980s, the general focus of the studies has altered, investigating the underlying factors motivating proenvironmental behaviors like values, norms, beliefs, awareness, knowledge, concern and attitudes (e.g., Fransson and Garling, 1999; Garling, Fujii, Garling, and Jakobsson, 2003; Kim and Choi, 2005; Minton and Rose, 1997; Roberts and Bacon, 1997; Olander and Thøgersen, 2006; Osterhus, 1997; Thøgersen and Grunert-Beckmann, 1997), the results were again inconclusive in explaining why there is a weak relation

between these predictors and the actual behaviors (Kilbourne and Beckmann, 1998). Moreover, studies underlined that there are different proenvironmental behaviors which are affected by different factors, and even at different levels under different structural conditions (Guagnano, Stern, and Dietz, 1995; Poortinga, Steg, and Vlek, 2004; Roberts and Bacon, 1997; Olander and Thøgersen, 2006). For instance, Stern (2005) argued that personal variables (e.g., financial resources, literacy, social status, and behavior-specific knowledge and skills) are less likely to influence proenvironmental behavior when contextual factors (e.g., laws and regulations, financial incentives and penalties, and social pressure) are strong. The interrelationships of these personal and contextual variables might also vary depending on different types of environmentally significant behaviors such as green purchasing, recycling, or energy conservation behavior (Kim and Choi, 2005).

From a broader perspective, there are so many distinct green issues (Zimmer, Stafford, and Stafford, 1994) and for each one there are different types of proenvironmental behaviors that can be performed (Thøgersen and Grunert-Beckmann, 1997). For example, if one concerns for waste management, buying biodegradable, recyclable or reusable products and separating waste are some of the alternative behaviors that can be followed. To put it in another way, in such a case, a consumer may buy beverages with refillable bottles but not separate his/her kitchen waste or may continue to buy hair sprays which contribute to another environmental deterioration, air pollution. In such situation, the critical questions are: are we going to define that person as an environmentally conscious consumer or not? Or, is it satisfying to place that person in a category and make predictions about his/her environmentally benign behaviors depending on that category?

Beyond this ambiguity and its inconclusive results in promoting environmentally friendly behavior, this study aims to understand: Which kinds of proenvironmental consumptions are preferred, and what are the reasons behind those preferences? In accordance with this desire to understand rather than explain, an unstructured interviewing method was chosen to have "a greater breadth of data, given its qualitative nature" (Fontana and Frey, 2000, p.652). Consequently, open-ended, in-depth interviews were conducted with twelve respondents, performing different levels of environmentally friendly consumption behaviors. This diversity in green consumption degrees also contributes to the discovery of dominant green consumption choices, and enables us to develop a better understanding of the common motivators behind consumers' choices.

Preliminary results show that consumers mostly tend to express their environmental concerns by their green buying behaviors rather than reducing their current consumption amounts. The data also reveals that there are some preeminent green purchasing preferences among respondents such as buying energy saving light bulbs. Even though some of the participants who proclaimed that they were aware of some other possible environmentally friendly consumption choices like buying paper-packs, they stated that high mark-ups, lack of less damaging alternatives or the limited availability of reaching those alternatives were the main reasons for not buying them. However, the in-depth look at their consumption preferences indicates that the most prominent difference between the preferred consumption choices and the ones not preferred was the frequency of buying. This interesting result stimulates further research on understanding the impact of consumption routines on environmentally friendly consumption preferences.

From Saver Society to Consumer Society: The Case of the East European Consumer

Eleonora Axelova, York University, Canada

Russell Belk, York University, Canada

During the last nineteen years, the world has witnessed an important transition in Central and Eastern Europe, unprecedented in contemporary history—the move from a centrally planned to a market economy. In this short period of time, East European consumers have faced a new environment with changes in all spheres of their lives as well as an influx of new goods, services, media, and market institutions. The prior poor selection of products with shabby packaging, displayed in drab places with a lack of information was rapidly replaced by a wide choice of new products and brands from new countries-of-origin. These new goods came with attractive packaging, modern retailing, and clever and exciting advertising.

The East European consumer has now been amply exposed to marketing that is quite like that of the West. They have had enough time to become accustomed to the novelty of the market economy, but the communism of the past is not forgotten. Based on ethnographic participant observation and interviews in Bulgaria and Romania, we consider whether a market economy necessarily leads to a consumer society or whether some of the practices of earlier consumption patterns continue. At a macro level there is some evidence of nostalgia for communism seen in manifestations as diverse as the re-emergence of East German rock music, the Trabi automobile, and Cultural Revolution restaurants (Berdahl 1999; Yang 2003). But we are interested in the more micro-level and perhaps deeper imprints of communism on the Eastern European consumer. Just as those raised in the Great Depression often evidenced cautious consumption and parsimony for many years after the Depression (Cohen 2003), it is possible that East Europeans may show similar traces of their prior ingenuity in surviving communism (Drakuli? 1991). Although there is some consumer research on East European consumers after Communism (e.g. Axelova 2004 and 2005; ; Belk 1997; Coulter, Price, and Feick 2003; Ettenson 1993; Feick, Coulter, and Price 1995; Ger, Belk, and Lascu 1993; Lofman 1993; Shama 1992; Shultz, Belk, and Ger 1994; Witkowski 1993), there is little that explores the persistence of old consumption habits, such as those we discovered in Bulgaria and label the "Saver Society."

What is the "Saver Society"?

The Bulgarian proverb "Prepare for winter and if summer comes say : 'Welcome!'" shows the cautious character of the Bulgarian people. At the heart of the Saver Society is a notion of "Saving," while the heart of Consumer Society lies consuming and spending. Saving was necessary under communism where credit did not exist. To buy a major appliance or an automobile, could take years of savings and patience. Thrift was necessary in daily life to allow any savings. Consumers were also frugal in using things. An old nylon stocking could become a fan belt, bottles for cooking oil or beer were returned to the store to be refilled. Vegetables, rabbits, and chickens were raised for food where possible. Sharing with relatives was another means of making do. Nothing went to waste. But besides thrift, there was also a cultural value placed on modesty. Another Bulgarian proverb says "Modesty makes the person beautiful, impertinence makes him ugly." When everyone was poor during the communist years it was also dangerous to stand out through even a small amount of conspicuous consumption. But savings patterns were no doubt easier in a time of scarcity and income parity when there were no stores full of attractive merchandise, glittering advertising, and nouveau riche consumers displaying alternative consumption models. So what has happened since 1989?

After defining the Saver Society and its characteristics, we describe how each characteristic has been transformed in light of the changes since communism. The initial conditions for the emergence of a Consumer Society in Eastern Europe now exist. These conditions include an attractive array of goods including Western brand names, media and tourists displaying the external world, plus feelings of deservingness (Belk, 1997) among local consumers, many of whom believe that after years of thrift and modesty, they have been earned the right to a better life.

Another change in Eastern Europe after 1989 has been new social stratification. Disparities that have arisen in income and class have provided new incentives for displaying wealth. Emphasis for many has shifted from hiding signs of wealth so as not to provoke others' envy, to openly displaying wealth and inviting envy.

Two extremes reactions toward Consumer Society in Eastern Europe have emerged. One is the case of the privileged consumers with high incomes and more cosmopolitan lifestyles. They can travel abroad, buy expensive foreign brands, and acquire a knowledge of lifestyle trends elsewhere. They have easy access to the consumer credit and the Internet. These favoured consumers are already part of the Consumer Society.

The other extreme is the low income, often older, consumer. These consumers buy local brands and have difficulty obtaining credit. They do not belong to the Consumer Society. They, of necessity, remain part of the Saver Society. But between these two extremes we find others who remain a part of the Saver Society by choice. They continue to buy cheap, reuse what they can, display thrift and modesty in consumption, share with relatives, and avoid credit.

Conclusion and Discussion: The Broader Notion of the Saver Society.

Should we regard the group of voluntary members of the Saver Society in Bulgaria as a fossil of another time that will disappear with the next generation of children raised in a growing Consumer Society? It is possible, but we don't think that this will be the case. There are lingering lessons of childhood and culture just as there are lingering lessons of communism. Besides the voluntary members of Saver Societies there are many poor within rich countries who are also more likely to be Savers. Hill and Stamey's (1990) work with American homeless, Stack's (1974) work with residents of an impoverished housing development, and Chin's (2001) work with poor black children all find instances of Saver Societies alongside Consumer Societies. We believe that our knowledge of both will be advanced by examining the coexistence of such vastly different consumption orientations.

Feedback Effects and Evaluation Process of Health-related Perceived Risk and Health Behavior: A Conceptual Model and an Empirical Test

Yi Zhang, University of Manchester, UK
Zheng Yin, University of Manchester, UK
Jikyeong Kang, University of Manchester, UK
David Baxter, National Health Service, UK

Abstract

Many theories have identified perceived risk as a predictor of behavior. However, contradicting findings from empirical studies have caused researchers to question the role of perceived risk.

This study aims to explore the internal mechanism behind the inconsistencies and to provide further insights. Based on an empirical study concerning the use of condoms, we propose a two-stage dynamic model, involving a process of "evaluation" of an initial action and a construct of "feedback effect" of perceived risk.

Our model will aid researchers and practitioners in social medicine and marketing in achieving a better understanding of health prevention behaviors.

Introduction

Perceived risk has been an interesting research topic for more than four decades. Bauer (1960) first coined the concept of perceived risk in the marketing area. Since then, numerous studies have been conducted to define, measure, and model perceived risk in the context of consumer behavior. Perceived risk has also been applied in various areas, including the food industry (Eiser, Miles, and Frewer 2002), e-commerce (Liebermann and Stashevsky 2002), banking (Gorton 2004), and health services (Kreuter and Strecher 1995). Many studies have illustrated the significant relationship between consumers' health behaviors and their perceived risk, and, indeed, the importance of perceived risk has been widely recognized.

Perceived Risk and Health Preventive Behavior

Perceived risk, as an important element of various health behavior models, has a strong relationship with health behavior or the intention of health behavior (Lindan et al. 1991). Many recent studies, however, state that perceived risk does not have a significant relationship with behavior and has little predictive power in health behavior models (Brewer et al. 2007; Leventhal, Kelly, and Leventhal 1999), such as the Health Belief Model, and the Theory of Reasoned Action. These contradicting findings have led several researchers to conduct meta-analyses in order to bring a more holistic picture of the importance of perceived risk and the relationship between health-related perceived risk and behavior (Brewer et al. 2007; Floyd 2000; e.g., Harrison, Mullen, and Green 1992). Those studies, however, failed to provide a clear explanation of inconsistent findings. Thus, the main purpose of this study is to provide a better understanding of the relationship between perceived risk and consumers' health-related behavior.

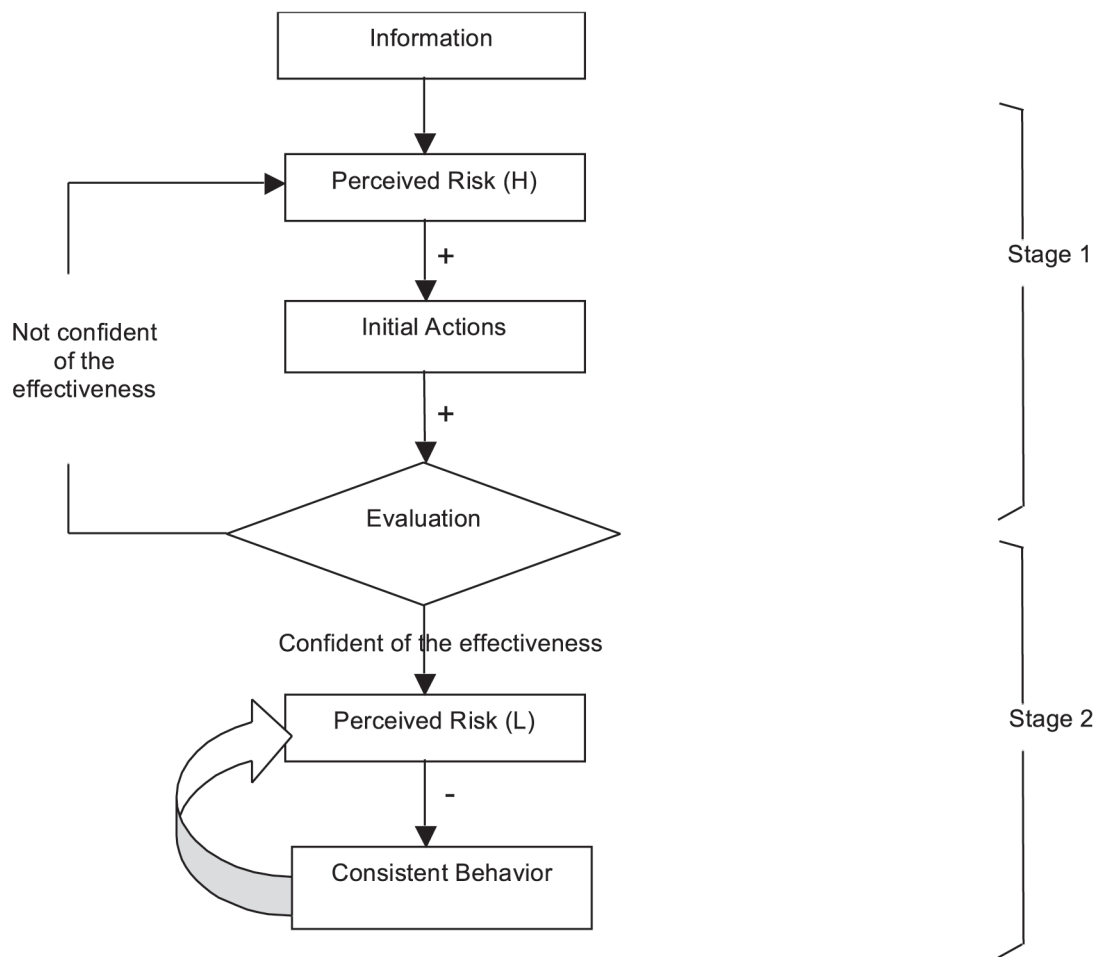

Brewer et al. (2004) attempt to explain the inconsistencies by proposing a reappraisal hypothesis, which provides a semi-dynamic structure explaining the inconsistencies. Their study clearly illustrates a relation between preventive health behavior and perceived risk using a longitudinal method. Nevertheless, Brewer et al.'s study did not observe the inconsistencies directly and failed to provide necessary background information of participants by assuming that all other factors are constant. More importantly, a vital "evaluation process" was not illustrated in their study, which explains the decision process during the formation of perceived risk and consistent health behavior.

In our study, health-related perceived risk and behavior are not considered in a static model, which naturally neglects the fact that either perceived risk or behavior can be changed or interrelated in a dynamic way with the progression of time. Instead, we propose a two-stage dynamic model to provide a possible explanation of the inconsistencies found in past studies. In addition, a new construct of "feedback effect" between perceived risk and behavior has been defined and explained.

Proposed Model

The model shown in Figure 1 illustrates the formation of consistent preventive behavior and the mechanism of feedback effect. We hypothesize that the contradicting findings from previous empirical studies are partially due to the fact that participants are at various stages

FIGURE 1
Proposed Model

of perceived health risk. At the beginning stage, people obtain information from various sources which can improve the knowledge of a particular hazard or disease. They tend to have a high level of perceived risk after obtaining such information or having enough knowledge on a particular hazard. Based on previous behavioral models, a high level of perceived risk will lead people to engage in preventive behavior, which is then demonstrated in the second stage of the model. After an initial action, an evaluation process which determines the perceived effectiveness of the preventive behavior is carried out. When a person finds the preventive behavior cannot provide enough confidence, he/she stays at a high level of perceived risk. If a person believes that the preventive behavior can offer an effective protection against the particular risk, his/her perceived risk will be reduced and he/she will move to the 2nd stage which is stable.

In the 2nd stage, people have a low level of perceived risk and exhibit a consistent preventive behavior. Preventive behavior provides “feedbacks”, which establish people’s confidence and further reduce the perceived risk. On the other hand, a low level of perceived risk negatively related with a preventive behavior increases people’s willingness to continue engaging in further preventive behaviors.

Study Design

In order to test the proposed model, we conducted a survey research based on a high-risk population in Manchester, UK. Participants were Female Commercial Sex Workers (FCSWs) who had a high risk of catching Sexually Transmitted Infections (STIs). We gained access to our participants by collaborating with a local organization, MASH (Manchester Action on Street Health) which provides sexual health services to FCSWs. Structured interviews were conducted to measure the perceived risks involved. The preventive behavior used in this study is a consistent use of condoms.

Data Collection

FCSWs’ responses to the statement “I am at risk of being infected with HIV/AIDS” were recorded, and the reasons for their perceived risk status were also asked, using a four-point Likert-type scale. Higher scores represent a perception of greater risks. After participants evaluated their risks, they were asked to briefly explain the reasons. In addition, participants’ knowledge of STIs, the years of working as FCSWs.

Results

Using the qualitative data, we observed that the perceived risk and the stages of FCSWs are significantly correlated ($\chi^2(1)=107.76$, $p<.001$). FCSWs' working-years also played an important role; the longer the participants had worked in the industry, the more likely they entered into the later stage in which they tend to use condoms consistently and with low perceived risks ($\chi^2(1)=3.75$, $p<.05$). Knowledge of STIs, the indicator of the information obtained by FCSWs, also affected which stage participants were at. When FCSWs obtained better knowledge on STIs, they were normally in stage 2 of the proposed model ($\chi^2(1)=5.20$, $p<.05$).

Summary and Contributions

Our study, which focuses on health-related perceived risk and behavior, filled a gap and explained the reasons why perceived risk has little predictive impact in many empirical studies. Feedback effects and the evaluation process, as proposed in our model, explain the interaction between perceived risk and health preventive behavior. Social marketers will benefit from our research whilst providing health preventive campaigns.

The Values and Lifestyles of Prior Mature Chinese Consumers

Lien-Ti Bei, National Chengchi University, Taiwan
 Chih-Ping Wang, National Chengchi University, Taiwan
 Hung-Miao Lin, Chinatrust Commercial Bank, Taiwan

Aging is a major issue in most developed and developing countries. The fact that the baby-boomer generation is approaching retirement age has attracted the attentions of governments in the areas of health care, social security, and retirement plan issues. In Italy, Germany, France, and North Europe, aging people occupy 15% of each nation's population. This enormous amount of consumers will also form a large senior market in ten years. Since they will have time after retirement and better health and financial conditions than the depression generation, the potential of this market cannot be ignored. Therefore, the consumption habits, values, and lifestyles of senior consumers have become an emergent issue for marketing researchers and practitioners (Gibler, Lumpkin, and Moschis, 1997; Moschins, Lee, and Mathur, 1997).

Gibler et al. (1997) referred to consumers aged 60 and above as "mature consumers." The present study follows this notion and refers to consumers who are approaching retirement as "prior mature consumers." The cohort of consumers, the 45 to 65 age group, is the ideal target for the study of the future senior market.

After closing its door for more than 50 years, China market has opened to the world and gained worldwide attention. Its prior mature population is around 150 million people. Therefore, this study targets on prior mature Chinese consumers. The purpose of this study is not only to explore the consumption habits, values, and lifestyles of consumers in this booming market but also to reveal the endurance and influences of traditional Chinese culture and Confucian values on consumer behavior when faced with the influences of western culture.

This cohort of Chinese consumers was educated with traditional Confucianism; they have experienced and admired the western modern life and materialism in their adulthood; and they gradually accept the concept of individualism. The conflicting value systems provide the best research targets to illustrate the durations and influences of various consumption values on purchase behaviors and

patterns. Four metropolitan cities, Beijing, Shanghai, Guangzhou, and Taipei, were selected due to their economic and political representative status. In January and February 2006, 2075 respondents, 511 to 527 in each city, at the age of 45 to 65 were face-to-face surveyed via a demographic quota sampling procedure.

Other than demographic and consumption items, the questionnaire includes 133 Likert-type 6-point items on values and lifestyles. These items were designed for eight categories of values and concepts: concern about health, financial attitudes, gender issues, career and retirement plans, social relationships, attitude toward aging, consumption values, and other life perspectives. The result of factor analysis extracted 25 important factors. Under the control of age, gender, and work status, the 25 value and lifestyle factors of respondents among the four cities were compared by general linear models. The main findings are:

- 1) *Health concern and financial attitude*: In the industrial city Guangzhou, prior mature consumers care about their own health condition less and retain fewer traditional Chinese values, such as “limiting expenses within the income boundary and avoiding borrowing money.” They are also more willing to invest through professional financial assistance than consumers in other cities.
- 2) *Consumption value*: In the most internationalized city, Shanghai, consumers prefer products endorsed by celebrities and enjoy the “taste of life” most.
- 3) *Career and retirement*: In a city where the economy is booming, such as Shanghai and Beijing, prior mature consumers worry about retirement less; while in a city with a slight recession, such as Taipei, prior mature consumers sense that “retiring means not having money” and tend to keep working after age 65.
- 4) *Social relationships*: Living in the political center, consumers in Beijing, unsurprisingly, care about all kinds of social issues most.
- 5) *Attitude toward aging*: prior mature consumers in Taipei are more accepting of aging. It can be explained by the traditional Confucian value of respecting the elderly that people in Taipei hold.

In general, family values, respect for seniors, and compliance with authority in traditional Confucianism are still obvious in the value systems of Chinese prior mature consumers. The results suggest these values are more enduring than others. On the other hand, traditional Chinese values regarding gender issues, conservative consumption rules, and desirable social behavior are influenced by western values more. Also, reflecting the economic prospects, in a city where consumers enjoy economic growth, future mature consumers tend to focus on enjoying the western-style life more and rapidly moving toward individualism. Our results suggest that marketers may emphasize the better and more enjoyable life provided by western imported brands; meanwhile, they should also emphasize how the product can contribute to the whole family or is acceptable to the society when targeting these prior mature consumers at present or in the future.

Intergenerational Study on the Effects of Attachment Style on Eating Behaviors

Aida Faber, McGill University, Canada
 Laurette Dube, McGill University, Canada
 Sophie Belanger, L’Oreal Canada, Canada

The family as a collective enterprise is central to consumer behavior, in particular in domains that pertain to lifestyle choice¹. In today’s world of plenty, individuals within families face many challenges and find it hard at times to maintain healthy diets and exercise patterns^{2,3} as indicated by soaring obesity rates due to over-consumption and lack of exercise⁴. Yet, little research has attempted to combine the most recent theoretical developments in health and consumer psychology with others from family and parental processes. Such a combination would allow for a more sophisticated understanding of lifestyle decisions that may guide parents and children toward a better balance between health and the many other factors that drive choice and behavior. In this paper, we combine recent psychology research on self-regulation with that of attachment style to examine from an intergenerational perspective the effect of attachment styles on eating behavior in a large sample of child-parent dyads.

Research background

Attachment deals with regulatory functions and consequences of maintaining proximity to others⁵. According to attachment theory, children are born with a “repertoire of behaviors (attachment behaviors) aimed at seeking and maintaining proximity to supportive others (attachment figures)”⁵. In the face of threat or when inner resources are depleted, cognitive representations of attachment figures are automatically activated, thus increasing the person’s confidence that there is protection available and facilitating self-regulation^{5,6}. There are individual differences in attachment styles. When significant others are available in times of need, a sense of secure attachment is developed. On the other hand, when significant others are unavailable or unresponsive to one’s needs, distress and a sense of insecurity are omnipresent.

Secure attachment styles are linked with effective coping skills, constructive ways of dealing with stress and conflict, and healthier interpersonal relationships^{7,8}. On the other hand, insecure attachment styles are linked with eating disorders, trouble sleeping, and feeling of ineffectiveness and helplessness^{7,9}. Interestingly, these differences in coping styles between securely and insecurely attached individuals can be linked to differences in self-regulation focuses that have recently received robust evidence in health and consumer

psychology research. Self-regulation refers to the ability of setting and striving for goals in the face of ongoing challenges^{2,10} and is widely applied to healthy lifestyles behaviors² because people seem to give in to temptation and not follow through with their long-term goals^{11,12}.

Hence, attachment security can be said to be associated with healthier lifestyles, i.e., engaging in health promotion behaviors and avoiding risky behaviors, and attachment insecurity with unhealthier lifestyles, i.e., engaging in risky behaviors and avoiding health promotion behaviors⁷. As a result, the objective of this paper is to study attachment styles and their link to food knowledge and consumption. Thus, in this study, we hypothesize that more secure attachment styles in parents and children will be linked with knowing more fruits and vegetables (F&V, hereafter) and having healthier diets. Because there are reliable gender differences in dealing with distress, with males coping in a non-rational manner by trying to distract themselves^{13,14}, we furthermore hypothesize that attachment security will have a beneficial role for them in that securely attached males will know more F&V and have better diets. Finally, the mediation effects of parental attachment on their children's food knowledge and consumption will be tested.

Method

Design and procedures

To test the above hypotheses, only the pre-intervention questionnaires of a web nutrition intervention aiming to increase children's F&V consumption were analyzed. In total 238 children (157 girls and 79 boys; $M_{\text{age}}=10.15$ years; $M_{\text{BMI}}=21.42$) and 210 parents (37 males and 183 females; $M_{\text{age}}=41.05$ years; $M_{\text{BMI}}=25.48$) completed the questionnaire. Although the 12-step parent/child web intervention took place at home, children between 8 and 12 years old were recruited from 28 French primary schools in a major Canadian city.

Measures

Attachment was measured using an adapted scale from Bowlby¹⁵ from insecurely to securely attached (Cronbach's alpha parents=.890, children=.855). F&V knowledge was assessed by asking participants whether or not they knew 31 fruits (fruit knowledge) and 39 vegetables (vegetable knowledge). F&V consumption was assessed by calculating the average fruit, vegetable and F&V intake of all the previously known F&Vs. High caloric food and snack (HCF and HCS, hereafter) consumption was calculated as the average number of times participants ate respectively eight specific HCFs, i.e., hot dogs, and six specific HCSs, i.e., cookies, during a day.

Results

For children, results showed that more securely attached children knew more fruits. There were also two significant interaction effects, in that vegetable and F&V knowledge was the same for girls regardless of their level of attachment whereas it was higher for more vs. less securely attached boys. Furthermore, there was an interaction effect for vegetable consumption in children, in that average vegetable consumption for girls remained the same regardless of their level of attachment whereas for boys, the more secure the attachment the higher the vegetable consumption. Attachment levels did not significantly predict fruit and fruit and vegetable consumption. Lastly, the more securely attached the children, the less HCF and HCS they consumed.

For parents, results showed that more securely attached parents, as measured in relation to their own parents, knew more vegetables and F&V. For fruits and vegetables separately, consumption was the same for women regardless of their attachment levels but was higher for more vs. less securely attached men. For F&V, HCF and HCS consumption, a more secure attachment was linked to higher F&V consumption and lower HCF and HCS consumption.

Mediation analyses showed that parents' attachment mediated the children's relationship between attachment and fruit, vegetable, and F&V knowledge, and HCS consumption but only partially mediated HCF consumption.

Conclusion and Discussion

In conclusion, this study shows that attachment, a variable closely linked with self-regulation focus, is an important predictor of healthy eating habits, not only for children but also for parents. Most importantly, through their own attachment styles, parents influence the role of their children's attachment in predicting healthy eating, which further confirms the pervasive influence of attachment in the every day consumption choices of two generations.

The Role of Consumption in the Organization of Urban Space: The Case of Neo-Bohemia

Yesim Ozalp, York University, Canada
 Russell W. Belk, York University, Canada

“Though locals will tell you that West Queen Street West extends all the way down to Gladstone Street, where the oh-so-hip Gladstone Hotel opened in late 2006, walking any farther than the intersection of Ossington and Queen Street West is an exercise in diminishing returns— with appliance stores more numerous than trendy cafes. This part of this street, it seems, is still waiting for its own renaissance.” (New York Times, September 02, 2007)

Although Consumer Culture theoretic scholars have studied issues of class (Allen 2002; Henry 2005; Holt 1998), gender (Holt and Thompson 2004) and ethnicity (Crockett and Wallendorf 2004) in the socio-historic patterning of consumption (Arnould and Thompson 2005), urban life and urban space, where consumption is structured by and structures these socio-historic forces, have been left in the background (an exception is a study of gentrification by Ilkucan and Sandikci 2005). Consequently, our understanding of both low involvement everyday consumption choices and practices and high involvement consumption choices (e.g., buying a house) has been isolated from the dynamics of urban life and urban space, including the strategies used by actors in the consumption scene to create or to contest value and their struggles over symbolic and social spaces where value is created. This study follows a Bourdieudian tradition in order to understand acts of legitimization, performative consumption, value dynamics and cultural politics of consumption. We focus on conversion of capital and strategies and struggles in the field that enable and/or impede this conversion, different from other Bourdieudian studies in CCT which have focused on the concepts of capital (Bernthal, Crockett, and Rose 2005; Holt 1998) and habitus (Allen 2002; Henry 2005).

Within the limits of this research, we present a very specific type of neighborhood, often referred to as neo-bohemia. According to (Lloyd 2006), neo-bohemia is the current shelter of the post-modern creative class (Florida 2002), the *Bobos* (Brooks 2000) and the hipsters (Leland 2004). The most important aspect of both modern bohemia and post-modern neo-bohemia is the non-stable relationship between the mainstream, the market and the commercial on one hand and the alternative, creative and cultural on the other. Tensions in this non-stable relationship are constantly played out in urban life and urban space through both daily mundane consumption activities and momentous consumption choices such as buying a loft.

In order to understand the relations between consumption and the organization of neo-bohemian urban space, we selected the Queen Street West neighborhood in Toronto as our context. It was gentrified by the artists who moved out of an increasingly elite Yorkville neighborhood starting in the 1970s (Caulfield 1994) and now has the highest concentration of art galleries in Toronto. In addition to art galleries, the part declared as the Business Improvement Area (BIA) is occupied by new fashionable stores, restaurants and clubs, loft buildings and new commercial developments. Although the neo-bohemian trend has existed in the neighborhood, it has recently become “hot” after two companies announced and sold their loft developments in the area.

Our investigation of Queen Street West is an ongoing multi-method study. Our data include ethnographic observations conducted since early 2007. In addition, we have conducted interviews with neighborhood residents and art gallery owners. We have also collected two types of archival material: promotional material and media texts. Promotional material includes sales brochures and a bi-weekly publication promoting new condominium developments in Toronto. In addition to advertisements, the publication also has articles on condominium lifestyles, real estate trends, and decor. The media text, comprised of articles from Toronto newspapers and Canadian magazines, addresses not only the changes in the neighborhood, but also the lifestyle promoted by these new developments.

Our analysis addresses how consumption organizes and is organized by urban space, and our current findings involve themes of acts of legitimization, performative consumption, value dynamics and the cultural politics of consumption. Despite a backlash, the acts of legitimization provide a central strategy followed by the developers and which they seek to transfer to their customers. Developers depict the bohemian and hipster lifestyle as being among the “amenities” of their high-rise “lofts” in order to attract the “new urbanites” and invite them to be part of this “scene”. One of these developments has even used the word bohemian in its name, although it has generated negative reactions among the Queen West art community. It also has staged community events such as fashion shows, which was only open to an exclusive crowd of designers and loft buyers. Another developer has purchased art products from local galleries with the intent of

benefiting both galleries and their development. This created controversy among art galleries and some refused to sell. Central to all these acts is an attempt to convert economic capital into commodified and reified cultural capital, since position-taking and legitimacy in this field requires both forms of capital.

An important characteristic of these acts of legitimization involves performative consumption. The new buyers are asked to be part of this neo-bohemian lifestyle through their “consumption performances”. This performative lifestyle, as our opening quote depicts, became central to the value dynamics in the neighborhood. Our interviewees suggest that recently opened shops in the neighborhood were mostly one-of-a-kind design stores and boutique shops selling non-mainstream clothing and decorating, replacing hardware stores and even some art galleries. Even the daily activity of having lunch has been affected by such value dynamics, and one of our informants maintains that she can no longer find a good place to lunch within her budget.

This example brings us to our final theme, the cultural politics of consumption. We find mechanisms of both inclusion and exclusion in this urban space and show how consumption plays a key role in this. We also problematize the relationship between these new developments and the neighborhood, to show how the exclusionary mechanisms can also impede the capital conversion process, since it diminishes and alters available resources. Through these four themes we build an understanding of the mutual effects of changing neighborhood, consumption lifestyles, and public and private meanings of community.

Empowered Consumers=Benevolent Consumers? The Effects of Priming Power on the Appeal of Socially Responsible Products

Swati Bhargava, New York University, USA

Amitav Chakravarti, New York University, USA

Cause related marketing or marketing of products that have social cause attached with them seems to be a good way to respond to consumer expectations of social initiatives and this has led to the popularity of corporate social responsibility (CSR) initiatives to influence consumers and differentiate product offerings. There is a general assumption that consumers will reward firms for their support of social programs and this has led many firms to adopt social causes (Levy, 1999). Till date research in cause-related marketing domain has looked at consumer's response to these endeavors based on the fit between cause and company (Barone et al., 2007), consumer's perceptions of company's motivation (Dacin & Brown, 1997, Barone et al., 2000), consumer attitudes toward such firms (Berger, Cunningham, and Kozinets, 1996; Ross, Stutts, and Patterson 1990-91), and its products. However, the impact of power on consumer benevolence has largely gone unexamined.

Potentially, there are two very distinct, and opposing, possibilities associated with elevated power. On the one hand, “power” has been associated with corrupting people and exerting negative influence (Kipnis, 1972; Fiske, 1992). On the other hand, power can also elicit social responsibility goals that increase the salience of others in decision-making (Chen et al., 2001). The latter goals elicit behavior that enhances and reflects attentiveness and responsiveness to others' needs. We hypothesize that enhancing the salience of social responsibility goals for consumers by empowering them can enhance the relative importance of consumers in the process of buying socially responsible products. This should lead to increased purchase likelihood for products that support pro social endeavors. We introduce the construct of “power” as a variable that can influence the way message for a socially responsible product is perceived and

processed. Support for why power would lead to socially responsible behavior is derived from Keltner et al. (2003) theorizing on the effects of elevated power. The authors in this paper posit that elevated power activates the behavioral approach system (BAS), which regulates behavior associated with rewards (e.g., Carver & White, 1994; Sutton & Davidson, 2000). This is because increased power is correlated with increased resources, which in the consumption or consumer behavior context are the monetary resources available to spend on products. Powerful individuals are also aware of the abundance of social resources such as esteem and praise that are available in their environment. This has message framing implications for promotion of a cause-related product. Thus, such a message, by eliciting high power for prospective consumer can also elicit the realization of control of not only the ability to make a difference but also the realization of positive social rewards from the environment by enacting in a responsible way. This should enhance approach tendencies for socially responsible products. Across our studies we find evidence for positive influence of power on consumer responsiveness towards products that promote social causes.

In Study 1, we exposed participants to GAP (RED) advertisements. The computer based study presented the advertisement as a banner ad that is usually seen on various websites. The two conditions that participants were exposed to differed on power dimension. In one frame the tagline read “We Can Make a Difference. You can help” (original GAP commercial). This frame was meant to put the corporation i.e. GAP in position of power to make a difference in lives of people suffering from AIDS. The other frame was the consumer empowering frame where the tagline read, “You Can Make a Difference. We can help.” (manipulated commercial). In each condition, participants reported the extent to which they felt powerful relative to the corporation. In addition they indicated their liking and purchase likelihood of the product in the two conditions. We expected the consumers to feel empowered in the condition where the tagline put the onus of helping needy on them and respond favorably towards the product. Our results were consistent with our hypothesis. However, there was no difference in the appeal of the tagline across two conditions.

In the second study we replicated the effect using a rather unknown European brand “Mobistar”. This was done in order to take care of the potential confounding effect of liking and familiarity with the GAP brand. We get much robust effects in this study. The consumer empowering frame is certainly the preferred frame for consumers as they report feeling more power in this frame. This is evident in the significantly enhanced purchase likelihood in the consumer empowered frame. Further, we see the enhanced appeal of the tagline and enhanced overall opinion for the brand in the message that places consumers in the position of power. Participants also report liking the product better.

In sum we find that the construct of power can be used in consumption domain to influence evaluations of products that promote a social cause. This work shows that empowering message frames have the ability to influence consumer behavior in a way that it leads to win-win situation for all involved. The results presented here also have a number of important managerial implications. It provides marketers a unique opportunity to frame messages for cause-related marketing so as to garner maximum support for a cause. Typically, it is assumed that only those who are in position of power by virtue of their abundant resources such as financially sound individuals have the power to pursue social responsibility goals and make a difference in improving others' lives. This work shows by priming power, social responsibility goals can be evoked in any individual and their response for cause-related marketing can be much enhanced.

The Effects of Drug and Supplement Marketing on a Healthy Lifestyle

Amit Bhattacharjee, University of Pennsylvania, USA

Lisa Bolton, Pennsylvania State University, USA

Americus Reed II, University of Pennsylvania, USA

Obesity has been declared a public health epidemic in the United States, and food marketing has been implicated as one important factor in its pervasiveness (Seiders and Petty, 2004; Wadden, Brownell, and Foster, 2002). While high-fat eating remains attractive to many Americans, an assortment of weight management and fat-fighting products (both drugs and supplements) have proliferated. Indeed, in 2006, advertising expenditures ballooned to \$4.8 billion for the pharmaceutical industry and \$981 million in the supplement industry (Langreth and Herper, 2006; Brandweek, 2007). Though such fat-fighting remedies appeal to many consumers, recent research suggests that there may be unintended consequences that actually undermine consumers' intentions to engage in a healthy lifestyle. Hence marketing of such remedies may unwittingly exacerbate risky decision making and reduce, rather than improve, consumer welfare.

Bolton, Cohen, and Bloom (2006) found that problem status (or the relative attractiveness of the problem domain) moderates the effects of remedy marketing messages on consumers. Specifically, remedy messages undermine risk avoidance and increase risky behavioral intentions, particularly for those consumers most at risk. Though this boomerang effect exists across several domains, Bolton, Reed, Volpp, and Armstrong (2008) recently extended this work, identifying the psychological mechanisms that drive this phenomenon in the health domain. Their results indicate that drug marketing boomerangs and sabotages healthy lifestyle intentions in consumers via two mechanisms. First, drug marketing reduces consumer perceptions of health risk and lessens the perceived importance of complementary health-protective behaviors. Thus, consumers are less motivated to engage in these healthy behaviors. Second, drugs are associated with poor health, reducing consumers' perceptions of their own health and their self-efficacy, and thereby diminishing their perceived ability to engage in complementary behaviors (Bolton et al., 2008). Lacking both motivation and perceived ability to undertake health-supportive behaviors, consumers are unlikely to do so, leading to less healthy lifestyle intentions and a reduction in consumer welfare. Interestingly, this pattern does not hold for supplements: unlike drugs, supplements are not associated with poor health, and suggest by their very name that they are meant to be used as part of an overall health-protective regimen. Notably, Bolton et al.'s (2008) results also indicate that the drug marketing boomerang may be neutralized with a corrective intervention that addresses both motivation and ability to engage in health-protective behaviors in concert.

Building on prior research, we present a series of five studies conducted across samples of university students and field samples of adults from a daycare center and members of a fitness club. These studies seek to further investigate the boomerang phenomenon and its robustness in a substantive domain. We extend past research to address a problem of particular concern to society—the obesity epidemic—by focusing specifically on the effects of weight management drug marketing on healthy lifestyle behaviors in consumers. Results thus far can be summarized as follows: 1) Actual consumption of high-fat foods increases with mere exposure to weight management drug versus supplement remedy messages, particularly for those participants who are hungriest, and thus most attracted to the problem domain; 2) Healthy behavioral intentions decrease when participants imagine taking a weight management drug versus supplement, particularly for those participants who suffer from body image issues and have a problematic relationship with this domain of unhealthy behaviors; 3) As theorized, the boomerang effect of weight management drug marketing on healthy behavioral intentions is mediated by decreased motivation and a perceived decrease in ability to engage in health protective behaviors; 4) Evidence from two field samples of real consumers with a range of knowledge levels suggests that erroneous consumer beliefs about drugs and supplements underlie the boomerang effect of weight management drug marketing. While the boomerang is partially mitigated by more accurate knowledge, only the highest levels of knowledge (reflecting specialized training or expertise in drugs and supplements) are sufficient to eliminate it completely.

Overall, the present research builds on past research and contributes to the literature in several notable ways. First, past research has tended to investigate the boomerang phenomenon by examining behavioral intentions after imagined consumption of a remedy, and these results are replicated here in the domain of weight management. However, to our knowledge, the present research is the first to demonstrate the boomerang effect of drug marketing on actual behavior, and the first to demonstrate a boomerang arising from mere exposure to a drug marketing message. Second, the present research indicates that the boomerang effect can be influenced by both transient visceral factors (e.g., hunger) and relatively stable individual differences (e.g., body image) that alter the relative attractiveness of the problem domain. Taken together, these results provide evidence that while drug marketing can influence mindful, intended consumer behavior, it can also impact consumer behavior in relatively mindless eating contexts, highlighting the power and robustness of the boomerang phenomenon. Third, the present research provides evidence for the underlying role of consumer beliefs, suggesting that consumer activation of a drug-and-supplement-knowledge schema in response to weight management remedy marketing may account for the results in these contexts. Finally, the present research investigates the role of consumer knowledge underlying the boomerang phenomenon in field samples of real consumers. Only highly specialized training appears to mitigate the erroneous beliefs underlying the boomerang; otherwise, even well-educated consumers are susceptible, supporting the robustness of the phenomenon. In summary, the present research represents a call to action to develop efforts to mitigate the boomerang of drug remedy marketing for weight management, a domain crucial to the health and well-being of consumers.

The Impact of Product Review Writing on Attitude Formation

Stephen Xihao He, Georgia Tech, USA

Samuel Bond, Georgia Tech, USA

Abstract

Putting emotional experiences into words has been shown to evoke various health and psychological consequences. Extending these ideas, our research examines the impact of writing on the evaluation of consumption objects. We argue and demonstrate that under certain conditions, consumers' ratings of a product are systematically biased when they are first given the chance to write a product review. In an experiment using short films, the bias was obtained for two different review manipulations which focused on distinct properties of the viewing experience. Importantly, most participants did not believe that their evaluations were affected by the review-writing process, and the effect was not moderated by lay theories about its existence.

Introduction

Consumers frequently rely on the opinions of others to make their purchase decisions. Although many recent studies have explored the influence of reviews on audiences' attitude toward a product, little existing research has considered how the process of writing a review might influence the attitude of the reviewer. Our work addresses two primary questions. First, does writing a review systematically impact the evaluation of a target product (and if so, in what direction)? Second, to what degree are consumers aware that this influence may occur?

Writing helps people to think and reason about their experiences. The highly structured nature of language and syntax often leads to a "search for meaning" and enhanced understanding of an experience or attitude object (Singer, 2004). Numerous studies have demonstrated positive health and social outcomes of writing about intense emotional episodes (Bootzin, 1997; Frattaroli, 2006; Slatcher & Pennebaker, 2006). On the other hand, verbalizing an episode may impair memory for details (Lane & Schooler, 2004), and deliberating about one's attitudes may alter those attitudes (Millar & Tesser, 1986) or impair decision quality (Wilson & Schooler, 1991).

Our framework relies on a set of attitude models involving the construal of targets and standards (Feldman & Lynch, 1988; Schwarz, 1999). These models assume that contextual influences make certain information temporarily accessible (Higgins, 1996), and that the influence of accessible information on judgment occurs through the formation of different mental representations. Typically, the inclusion (exclusion) of information in one's representation of a target results in assimilation (contrast) effects on their evaluations of the target.

Applying these ideas to the consumer review process, we suggest that the act of writing about a consumption experience makes certain details of the experience more salient and accessible. Importantly, we predict based on theories of memory and cognition that content of reviews is going to be biased by the overall valence of the experience. Consequently, because information retrieved and analyzed during the writing task will be deemed diagnostic, it will be included in one's mental representation of the experience, triggering assimilation effects. An implication of this proposal is that consumer "ratings" may depend on whether or not they are preceded by a review (e.g., ratings of a generally favorable product will be higher following a review.)

Hypothesis 1: Writing a product review prior to assigning a rating will systematically alter evaluations of the product.

Review instructions vary dramatically across different consumer forums (e.g., *Amazon.com* vs. *epinions.com*). Therefore, we consider two different types of review, *self-focused* and *target-focused* (described below). Self-relevant information is likely to be salient even without writing; however, target-focused reviews should make accessible facets of the experience that would otherwise go unnoticed, enhancing the influence of the writing task.

Hypothesis 2: The effect of review writing on evaluations will be stronger for reviews that are target-focused rather than self-focused.

Abundant research suggests that individuals are poor at introspecting into their mental processes (Nisbett & Wilson, 1977). Hence, if the review task does alter evaluations, it is unlikely that consumers will be aware of the existence (or direction) of the effect.

Hypothesis 3: Individuals will not be aware of the effect of reviews on their evaluations.

Design

The study was conducted in a university lab with 121 student participants. The target stimulus was a short movie clip (*George Lucas in Love*) that parodies the popular *Star Wars* franchise. After viewing the movie clip on a computer, participants were given different instructions according to condition. Participants in the *target-focused review* group answered a series of questions focusing on attributes of the clip: e.g., "Please comment on the PLOT of the movie clip"; participants in the *self-focused review* group answered a series of questions focusing on their own feelings and responses: e.g., "Please comment on HOW YOU FELT as you were watching the movie clip." Participants in the *control group* wrote for five minutes about events of the previous day. Next, all participants rated the movie on four 7-point attitude scales and one ten-star "movie evaluation" scale. They were then asked whether they believed that their ratings were

affected by the writing task, and (if so) in what direction. In addition, participants completed various demographic measures and follow-up questions (not discussed here).

Results and Conclusions

Participants were excluded from the analysis if they had seen the clip before, did not finish, or were not native English speakers, leaving a sample of 99 participants. A composite rating measure was formed by combining the standardized residuals of the four attitude questions and the ten-star scale. Univariate ANOVA on this measure revealed an overall effect of condition ($t=-2.29, p=.03$), indicating that review writing did in fact influence ratings. Ratings assigned by the control group ($M=-.280$) were significantly lower than those assigned by both the *target-focused* group ($M=.278, t=2.43, p=.02$) and the *self-focused* group ($M=.109, t=1.83, p=.07$), supporting Hypothesis 1. The difference in ratings of the two review groups was directionally consistent with Hypothesis 2 but not significant ($p>.4$).

Supporting Hypothesis 3, the data revealed a fundamental lack of awareness regarding the effect of review writing. The vast majority of participants in the review groups (44 out of 60) did not believe that writing affected their evaluations, yet the ratings of this subset were significantly higher than the control group ($F=5.18, p=.026$). Of the remaining 16 participants, most (11) suggested that the review process *negatively* influenced their evaluations; however, the ratings for these participants were also (directionally) higher than those of the control group. Overall, lay theories had no significant effect on ratings ($F=.06, ns$).

Further analysis revealed that the total number of words written was not significantly different across the treatment and control groups ($M=116.67$ vs. $130.13, ns$), suggesting that it was not writing in itself that enhanced attitudes. Coding conducted by an independent assistant confirmed that both target-focused and self-focused reviews were generally positive in valence ($M=5.71$ and 5.34 on a 7-pt scale). Interestingly, the correlation between review valence and ratings was directionally lower for the target-focus group than the self-focus group ($r=.71$ vs. $.91, ns$).

Overall, these initial results support our contention that the act of writing a review can influence consumers' evaluations of the products they consume. In following up this research, we plan to explore the robustness of this effect to consumption experiences which differ in product category, valence, intensity, etc. Also, we plan to isolate the underlying mechanism by varying features of the review process. For example, our construal approach suggests that when review instructions are obviously nondiagnostic, consumers may discount the review from their mental representation, resulting in contrast effects.

“My Fifty Pairs of Shoes are all Different!”: Exploring and Explaining Exorbitant Buying

Mousumi Bose, Louisiana State University, USA

Alvin C. Burns, Louisiana State University, USA

Judith Anne Garretson Folse, Louisiana State University, USA

“I like shopping but I am not a compulsive buyer. When I find something I want, I sleep it through and when I think I still want it, I head to buy ... I still have 73 pairs of shoes.”

Why do some of us have the fourteenth black shoe? Fifty pens? Thirty fishing rods? These questions have intrigued researchers studying buying behavior, and diverse explanations exist. While some motivations relate to compulsive buying (O’Guinn and Faber 1989), others involve impulsive buying (Rook 1987) and still others refer to conspicuous (Frank 2000) and status buying (O’Cass and McEwen 2004), excessive buying (Ridgway, Kukar-Kinney and Monroe 2006; Wu, Malhotra and van Ittersum 2006), collecting (Arnould, Zinkhan and Price 2004) and fixated buying (Schiffman and Kanuk 2007). However, there is a set of consumers who purchase recurrently, have an inventory far greater than that of a typical consumer and yet do not share the negative characteristics of the extreme buying mentioned

earlier. This set of consumers is termed 'exorbitant buyers' and little research exists to understand them (ACR Exorbitant Buying Roundtable 2007).

Only three inquiries of exorbitant buying exist that relate to shopping and ownership experience, and motivations of product purchase and their subsequent non-consumption (Danziger 2002, Trocchia and Janda 2002, and Strack, Werth and Deutsch 2006). These studies have identified buyer characteristics and motivations in non-consumption, but have failed to acknowledge the underlying intent of buying a great many products in certain categories. This exploratory study seeks to define and describe exorbitant buying and to understand the underlying processes, motivations and factors affecting it. A second goal of this study is to analyze and explain exorbitant buying using concept mapping, based on social representations theory (concept map formed by sense-making of the participants about their inventory of products, Moscovici 1981).

Characterizing Exorbitant Buying

Exorbitant buying may be defined as an extensive acquisition of products to augment one's inventory of goods (of a certain category such as shoes, tools and others), for which logical justification, defensible in the mind of the buyer, exists. Central to the phenomenon are the fine-grained, thin-slicing 'needs' for which an ever-expanding list of products that necessitate buying in a bid to stay prepared for any eventuality ("I need black, open-toed shoes just in case I am invited to the party"). Individuals observe minute distinctions in their inventory of products such that they "see uniqueness in each of their products" that form the basis of rationalizing their purchases.

"People may look at them and say, they're all blue... I wouldn't say that any of them are exactly alike. They all have sort of a unique character in my mind, something different about them."

With a highly developed consumption vocabulary, these individuals are "picky" in their buying behavior; purchasing only items that fit their preference criteria. Detailed understanding of the nature of the phenomenon emerged from in-depth interviews conducted with students and non-student subjects; analysis of the former is presented here.

Methodology

Twenty exorbitant buyers were interviewed. During each interview, informants shared self-taken photographs of the products they buy exorbitantly for themselves. Questions related to the types of inventory that participants possessed, the reasons for such an inventory, and the process and outcomes of shopping (to understand inventory acquisition and consequences). Interviews were tape-recorded, transcribed and analyzed using an open coding process. A total of 38 themes emerged from these data. Next, *QDA Miner* was used to develop the concept map.

To elicit the structure of social representations, analysis of similarity (Flament 1986) was used with the assumption that the more themes are used together; the closer they are in the social representation. Inter-attribute similarity coefficients defined relationships among the themes; while a nearest neighbor algorithm identified the important relationships (Kruskal 1956). Next, core and periphery analysis of the social representation was conducted (Abric 2001). Core elements represent themes that constitute the essence of the representation. Coreness (Borgatti and Everett 1999), salience and sum similarity (Pawlowski, Kaganer and Carter 2007) were used to determine the core/peripheral concepts (map to be supplied at presentation).

Results: Dominant themes of Exorbitant Buying

- More articulated 'needs' per product category and average or more products per articulated need
 - Owing to refined preferences with the ability to differentiate products based on minute, exacting differences (of looks, styles and purposes).
 - Because of the perfectionist nature (pickiness in buying and consumption)
 - Ever-expanding list of needs to be acquired.
 - Look for variety in trends and styles to fit their needs.
- High level of self-control in shopping; with no purchases made if the products do not fit certain preference criteria.
- An extensive consumption vocabulary, with detailed knowledge about products in a particular product category.
- Products are consequential to 'staying prepared' and 'in control' in response to current or anticipated events.
- Switch brands; not brand loyal as products are bought to fulfill particular needs rather than be used for display.
- An 'insider-outsider' phenomenon in which the buyer (insider) rationalizes the purchase and may not consider the purchase excessive while the observer (outsider) deems it superfluous.
- Constant, deliberate and purposive search for a perfect purchase; short span of attention in terms of post-purchase consumption and a likelihood to "move on" to the next product; high attachment for the product rather than the process.
- No pronounced feelings of regret or guilt on the part of the buyer; low levels of financial stress as a result of buying unlike other extreme buying forms.

Conclusion

While commonly observed, exorbitant buying has had virtually no research attention. This study is the first attempt towards explaining consumer's rationalization of their inventory of products. The social representation approach helped identify that though shopping tends to be a positive emotional experience, the choice of items of the ever-increasing inventory tends to be based on analytic justification, defensible in the mind of the consumer.

Confused, Frustrated, and Angry: Consumer Responses to Promotional Messages in Online Service Transactions

S. Adam Brasel, Boston College, USA

Promotional nesting in online services, such as offering music downloads when purchasing concert tickets, is increasingly commonplace. In a goal-driven service transaction, consumers cannot simply avoid unwanted promotional messages as they are unsure of the promotional content's goal-relevance. An online study shows that nested promotions confuse and frustrate web novices, who are unsure if promotion participation is necessary to continue the central service transaction. Experts find nested promotions frustrating when they are on the same page as service content; promotions on separate (interstitial) pages elicit anger. While immediate compliance with promotions appears high, actual consumer follow-through expectations are very low.

Empty Pockets Full Stomachs: How Money Cues Induce People to Hoard Calories

Barbara Briers, HEC Paris, France

Sandra Laporte, HEC Paris, France

Abstract

Building on the security function of both money and food, we show in 5 studies that monetary cues can induce people to hoard calories as a means of securing their resources. In study 1 we test the main effect of money cues on food (caloric) preferences. In study 2 and 3 we illustrate the moderating effects of a resource manipulation (study 2) and individual differences in the security-worry meaning of money (study 3). Study 2 also reveals that calorie underestimation is mediating the effect of monetary stimuli on food preferences. Finally, in study 4, a general reward explanation is ruled out.

According to standard economics, money can be considered a conditioned reinforcer that gains its motivational property only because of its repetitive association with unconditioned reinforcers, such as food (e.g., Camerer, Loewenstein, and Prelec 2005). In psychological terminology, this tool theory about money (Lea and Webley 2006) corresponds to the security meaning of money (Rose and Orr 2007; Yamauchi and Templer 1982): money is considered to be instrumental; money is viewed as a means to obtain biologically relevant incentives. For most of humankind's history, however, food was the most relevant biological incentive (Diamond 1997), the ultimate form of resource security (Fieldhouse 1995). Building on the security function of both money and food, it seems reasonable then, to suggest that money as a conditioned reinforcer, is in particular 'conditioned' to food, and probably more to food than to other 'unrelated' rewards.

In behavioral studies there is a growing body of research supporting a close relationship between money and food. Nelson and Morrison (2005) found that men who feel either poor or hungry prefer heavier women than men who feel rich or satiated. This idea is

consistent with the finding that in cultures with scarce resources, heavier women are preferred to slim women (e.g., Pettijohn and Jungeberg 2004; Symons 1979). Most relevant to the current research, however, are the findings of Briers et al. (2006). Briers and colleagues showed that cues signaling scarcity in one domain (e.g., food) motivated people to acquire or maintain resources in the other domain (e.g., money). In a similar vein, we propose that exposure to money cues motivates people to eat more, that is, to hoard caloric resources. We will argue that the effect of money cues on food consumption is driven by the need to secure one's resources.

We present five studies that tested this hypothesis. In *study 1a*, after inducing fantasies about winning the lottery (see Briers et al. 2006), participants had to rank 6 dishes according to their preference. After exposure to a high monetary cue, the most caloric dish 'hamburger & fries' was rated significantly better than after exposure to a low monetary cue. In *study 1b*, we incorporated caloric estimation as a subtle measure of people's desire for 'calories', since it has been proven that the more you value a good, the lower you estimate its availability (Dai, Wertenbroch, and Brendl 2008). After inducing fantasies about winning the lottery (Briers et al. 2006), participants exposed to high money cues estimated the caloric content of regular strawberry yoghurt (125 grams) significantly lower than participants exposed to low money cues. In *study 2*, it is shown that monetary satiation (e.g., Nelson & Morrison 2005) eliminates the effect of money primes on need for calories. In a 2 (money vs. fish screensavers; see Vohs, Mead, and Goode 2006) X 2 (monetary satiation vs. control) between subjects design, participants primed with money on average chose a larger brownie and again underestimated the caloric content, but only when they were not satiated with money. Additionally, study 2 revealed that calorie underestimation is mediating the effect of monetary stimuli on food preferences. In *study 3*, we showed more directly that people hoard calories (i.e., resources) as a means of protection or security from an uncertain future. For this, we relied on the moderating role of an individual difference in the meaning attached to money (Rose and Orr 2007). For people with a low tendency to worry about money, monetary satiation versus deprivation (e.g., Nelson & Morrison 2005), had no effect on the estimation of the fattening content of a brownie; For people with a high tendency to worry about money, monetary satiation compared to deprivation, significantly increased the estimation of the fattening content of a brownie (and thus decreased its value; Dai et al. 2008). Finally, in *study 4*, a general reward explanation is ruled out. We show (1) that monetary cues affect food related choices, but have no influence on non-food items, and (2) that participants' sensitivity for reward is not moderating this effect.

In sum, five studies show how monetary cues can induce an internal need to consume more (caloric) food. The emerging evidence that monetary rewards and food rewards share a brain region (e.g., Breiter et al. 2001; O'Doherty et al. 2002) raises the question of the extent to which this region is involved in the processing of all kinds of rewards (Montague and Berns 2002; Wilson and Daly 2004). In case of the latter, appetite for money should give rise to an even higher caloric need among individuals with a sensitive reward system, compared to people with an insensitive reward system. However, unlike other studies testing this idea of a general reward system (e.g., Van den Bergh, Dewitte, and Warlop 2008; Wadhwa, Shiv, and Nowlis 2008), in our studies no moderation with sensitivity for reward could be proven. Besides the alternative reward explanation, we also rule out an alternative mood explanation.

The demonstrated effect of different money manipulations on an internal need for calories may help explain why poor people are especially vulnerable to overeating and have ill health as a result. The prevalence of obesity has increased substantially since 1970 (Keith et al. 2006). In industrialized countries such as the United States (Drewnowsky and Specter 2004), as well as in developing countries (James 2004), obesity is usually associated with poverty. Although the Big Two (*reduced physical activity* and *specific food marketing practices*) might be (partly) responsible for the difference in obesity rates between the rich and the poor, so far, no attempts have been made to investigate whether poor people actually have a stronger need (at the individual level) to consume more (caloric) food than rich people. Perhaps in our material world, the attraction to money is so powerful that people who, relatively speaking, fail in their quest for (more) money, tend to substitute their lack of money by consuming more calories than is healthy.

Explaining Obesity: An Inquiry into the Lives of the Obese

Jeff B. Murray, University of Arkansas, USA

Myla Bui, University of Arkansas, USA

Amy Stokes, University of Arkansas, USA

The United Nations' World Health Organization (WHO) has declared obesity to be the fourth major disease of the new century, alongside AIDS, cancer, and heart disease (2000). In 2003, Dr. Julie Gerberding, the director of The Centers for Disease Control and Prevention (CDC), argued that the health impact of obesity may be worse than the influenza epidemic of the early twentieth century or the black plague of the Middle Ages (Johnson 2005). For consumer researchers, the phenomenon has become a symbol of over-consumption and it is in this sense that it represents the dysfunctions of our consumer culture. This article reflects critically on the social construction of cultural discourses and therefore contributes to the critical tradition in consumer research (Murray and Ozanne 1991; Murray, Ozanne, and Shapiro 1994).

Conceptualization

The dominant paradigm in obesity research assumes that obesity is a serious preventable *disease* and is therefore part of the domain of epidemiology. By conceptualizing the topic in this way, researchers place the phenomenon in the context of the medical model. The organization of this paradigm is based on two guiding assumptions: the body as a machine metaphor and the energy imbalance thesis. Focusing on the environment completes the epidemiological triangle.

Although the medical model has taught us a lot about obesity as a risk factor, it has turned our attention away from the day-to-day experiences of obese consumers. Developing a more empathetic understanding of obesity shifts inquiry from medical discourses to social and cultural ones; this involves reclaiming the obesity topic from the study of physiology and developing it in terms of a body politics. The phrase "body politics" suggests a critical orientation directed to an institutionalized system of values and practices that discriminate against individuals that deviate from cultural standards. This article is directed by two research questions: How do obese consumers understand and conceptualize their corporeal experiences? How can an understanding of the experience of obese consumers be used with other perspectives in developing new explanations for obesity?

Our explanation for the rise in obesity rates involves three macro level perspectives: evolutionary, historical, and cultural. These are combined with the micro level perspective based on the hermeneutic analyses of our case studies. By beginning with the most macro (i.e., evolutionary) and ending with the micro (i.e., interpretive), we draw attention to the connections creating a *meso* level explanation. It is this meso level explanation that takes into account the consumer's day-to-day experience. Weight gain cannot be disentangled from the stories of consumers.

Method

Textual data were generated by means of existential-phenomenological interviews (Thompson, Locander, and Pollio 1989). The sample included nine females and five males. Nine of the 14 informants were married and their ages ranged from 25 to 62 with a mean age of 41. The BMI of all informants was over 30. Informants were from a variety of locations in the United States. Interviews were unstructured, focusing on narrative and context when discussing issues related to eating and weight.

Key Findings

Significant social and cultural events such as the Great Depression and World War II were found to have influenced many of our informants' attitudes toward diet and food. The *clean-your-plate* mentality is one of the consequences of this cultural socialization. In an era of abundance and fast food, this waste-not sensibility was patterned in the life stories of our informants as a contributing factor, passed down from previous generations, to their obesity.

Another key theme that emerges from the context of experience is the negative consequence of dramatic lifestyle changes. Divorce, physical injury, and the significant time constraints caused by attending school and working long hours were found to be common triggers of weight gain. Exhaustion, over-consumption, and eventual obesity, was the result of family circumstances, health issues, and scheduling conflicts that cannot be understood outside of a body politics.

The medical model, combined with media representations, fuels a fat prejudice and a cultural fat phobia, which makes it difficult to negotiate a fat identity. This phobia, combined with a struggle with weight, contributed to the poor self-esteem and anxiety experienced by our informants. Ironically, comfort food was the widespread coping mechanism used by many to regulate these negative emotions. Emotional eating was found to be a destructive spiral throughout our interviews: feeling anxiety over body image caused them to reach for comfort food to feel better, which led to weight gain and ultimately increased anxiety.

A large number of obese consumers see their bodies as both a subject and an object. The subject of the body involves the perception of the world through one's body. The objectified body is the body as perceived by the world; this is the socially constructed body. Many of the informants fragmented their bodies and described particular parts. It is the tension created by thinking that the world perceives a part of the body as inferior that makes it so difficult to negotiate a fat identity. The constant monitoring and regulation necessary to approximate the cultural ideal is challenging and requires cultural and economic capital; access to these resources is critical to having control over one's body project, yet is not accounted for when interpreting obesity using medical discourses.

By reintroducing, and working to combine experience with other historical and cultural perspectives, it is possible to construct an explanation for obesity that has additional implications beyond those provided by the medical model. Implications that respect personhood and take into account the importance of self-concept and self-esteem. As we continue to investigate this complexity, we need to include narrative and embrace a body politics. We need to construct explanations that are multilayered, bridging macro and micro perspectives, and we need to liberate consumers from repressive cultural discourses. This is the hope and vision of transformative consumer research. This article takes a small step toward this vision by bringing the voice of the obese to the conversation.

Technology Addiction: An Exploratory Study of the Negative Impact of Technology on Consumer Welfare

Monica A. Hodis, Southern Illinois University, USA
Gordon C. Bruner II, Southern Illinois University, USA

Abstract

The purpose of this article is to bring the technology addiction (TA) discussion into the realm of consumer research and to sensitize researchers, policy makers and practitioners to the idea that TA poses a real threat to consumer welfare. The extant literature on consumer pathological use of various technologies is reviewed to support the necessity of adopting technology in general as a unit of analysis. Evidence from a qualitative study suggests that TA is a behavioral addiction and that the object of addiction is not the technology itself but rather the cumulative experience it affords.

Technology is one of the most important symbols of advancement and has been reshaping the fabric of society for generations. While normal use of technology will improve and enrich the consumer's life, overuse and abuse of technology can lead to addiction and have a long-lasting negative impact on consumer welfare. Yet, the adverse impact of technology on consumer welfare is a greatly under-researched area. The purpose of this article is to introduce technology addiction (TA) to consumer researchers as well as policy makers and practitioners so that it may begin to be viewed more seriously.

Consumer behaviorists with an interest in consumer welfare have only investigated deviant consumer behaviors such as compulsive buying, drug abuse, and eating disorders. TA and the adverse impact of technology on consumer welfare have remained largely untouched. However, mounting evidence suggests that TA is a serious problem and can no longer be ignored. Americans are starting to show serious signs of dependence to their cell phones (Licoppe and Heuritin 2001; Wikle 2001). College students spend increasing amounts of time playing online games, resulting in decreased academic performance, poorer interpersonal relationships, and increase in social anxiety (Chou, Condrón, Bellan 2005; Lo, Wang, and Fang 2005). Neuroscientists have recently discovered evidence indicating that video games have an addictive potential not much different from drug or gambling addiction (Singer 2005).

Based on the extant knowledge, TA is defined here as *a compulsive, unnecessary use of technology that interferes with the individual's life, as well as his/her mental and/or physical well being. It is a psychological addiction to the cumulative experience one derives from one's involvement with the technology.* As a process addiction, TA dulls and distorts the addicts' reality allowing them to escape dealing with their true feelings and interfering with normal functioning and information processing (Schaeff 1987). In their compulsive pursuit, tech addicts will neglect important aspects of their lives and will display symptoms of loneliness, depression, even isolation from friends and family. They will experience anxiety and withdrawal symptoms as well as craving when denied their habitual involvement with technology (Greenfield 1999).

Addiction is not as much a factor of the time spent or of the specific technology used, but of the activities performed and the purpose and outcome of the consumer's involvement with the technology. The use of technology for socio-affective regulation has a high chance of resulting in addiction, while using the same technology for information acquisition will most likely not result in addiction (Weiser 2001; Park 2005). Addiction is more likely to be severe when technology acts as a depressant to alleviate dissatisfaction by enabling individuals to escape from the negative aspects of their lives (Park 2005; Wan and Chiou 2006). On the other hand, the potential for addiction is also possible when technology is used as a stimulant, as a means of deriving excitement and entertainment.

A method of establishing whether TA is truly an addiction is to compare it against clinical criteria for other established addictions (Griffiths 1995). Qualitative evidence was gathered to determine if TA, as a behavioral addiction, exhibited the six core characteristics of addiction as identified by Griffiths (2000): salience, mood modification, tolerance, withdrawal, conflict and relapse. Focus group and in depth interviews with heavy users of technology were conducted in order to gain insights into the drivers of technology overuse and serve as a basis for a more extensive quantitative study. Previous research suggests that young, well educated individuals, college students in particular, are most likely to become addicted to technology (Kandell 1998; Hall and Parsons 2001). Given this, the participants in the focus group were college students attending a large, Midwestern U.S. university. The study used the interpretive research template recommended by Altheide and Johnson (1994).

The participants who exhibited the characteristics of addiction viewed technology as central to their lives. They often lost track of the increasing amount of time spent using it, indicating that a state of flow is one of the antecedents to addiction. Their compulsive use of technology was driven by the derived benefits, combined with a sense of necessity and duty to be "on call." One of the perceived benefits was the fact that it gives individuals a sense of control over their lives. Paradoxically, however, the large number of contact points often generated internal conflicts and made them feel like they were losing control over areas of their lives. Other perceived benefits were indicative of mood management (boredom, relaxation, escape) as well as a need for entertainment and arousal, supporting both the depressant and stimulant models of addiction.

An important insight gained was that consumers do not use different technologies in isolation but interchangeably and in conjunction. The focus is to achieve the desired goal, to gain the desired benefit, and consumers will use the technology they find most contextually appropriate out of those available at that time. It was evident that a study of consumer addiction to individual technologies would present an incomplete picture of reality. In order to truly understand the dysfunctional consumption of technology, it is urged that technology products (in general) be the unit of analysis. The direct and indirect insights gained into the behavior of tech addicts clearly suggest that the object of addiction is not the technology itself, but rather the cumulative experience that it enables, as suggested by Peele (1985). The findings also indicate that a major part of learning how to cope with the disadvantages of technology is knowing that they exist. This suggests that there might be a need for educating the public about the addictive potential of technology and how to cope with it to minimize that eventuality.

Based on the insights gained, future research should test a model of technology use and addiction on a larger population. Since abstinence is not a realistic option for TA, a model that accounts for the factors and stages responsible for the onset of addiction is essential in understanding and combating the negative effects of dysfunctional technology use on consumer welfare.

The Lived Experience of Consuming Violence

Hillary A. Leonard, University of Rhode Island, USA

Julianne Cabusas, University of Rhode Island, USA

Violence today is pervasive. The United States is currently in what might appear to be perpetual state of war. The threat of terrorism lurks behind many aspects of public life. Schools have become shooting grounds. In 2006 alone, more than 1.4 million violent crimes were reported to law enforcement agencies (Federal Bureau of Investigation, 2007). February 2008 marked the expansion of prison population of the United States to an all time high of one percent of the population (Liptak, 2008). All of this is part of what has been termed a culture of violence. As a consumer society, this culture of violence translates to consumption. We consume media accounts of the violence reported above. Eighty-nine percent of the top video games contain violent content and the majority of this violence is of a serious nature (Media Education Foundation, 2005). Music lyrics, particularly music consumed by teens and young adults are rife with violent messages. Roughly two thirds of Hollywood films are rated R (Media Education Foundation, 2005). Violent sports such as football, ultimate fight club and dog fighting enjoy widespread patronage. Despite the prevalence of the consumption of violence, marketing research has largely neglected the consumer side of consuming violence: why violence sells and what the consumption of violence means to consumers.

Violence and its consumption is not a new phenomenon. Violence has been explained as a fundamental feature of all societies (Denzin, 1984). Using violence for entertainment has a long tradition in many societies (Pinker, 2007) and (1973). Modern sensibilities have changed and despite its prevalence, much of the world today publicly condemns and tries to minimize many forms of violence (Pinker, 2007). Accordingly, much of the research on violent consumption considers the consequences and effects of consuming violence (Allen et al 1995, Bushman 1998, Bushman and Philips 2001, Felson 1996 (Grier, 2001)).

Researchers have found that viewing violent media primes aggression (Hogben 1998, Smith and Donnerstein 1998), increases hostile feelings (Anderson 1997, Bushman 1995) and serves as an antecedent of aggressive behavior (Anderson and Bushman 2002). Research also indicates that media influences perceptions of the consequences of violent actions (Potter and Smith 1999), and that certain personality traits are linked with favorable attitudes towards media violence (Bushman 1995, Aluja-Fabregat and Torrubia-Beltri 1998). While there is relative agreement that the consumption of violence is correlated to aggressive behavior there is substantial debate regarding its causal effects and the role of additional factors (Grier, 2001). (For a review of research on this topic see the FTC's Report, Marketing Violent Entertainment to Children, Appendix A, 2000) (Federal Trade Commission, 2000).

While it has been found that people voluntarily expose themselves to, and often search out, images of violence (Zuckerman and Little, 1986), research into the attraction of consuming violence has been understudied. Research suggests that violent video games appeal to adolescent males as safe environment to experiment with controversial emotions (Jansz 2005). In the context of hockey, researchers found that presence of violence correlates positively with higher attendance rates (Jones, Ferguson and Stewart 1993). According to Zillman (1998), it is not necessarily the violence that accounts for the attractions of violent entertainment; it is what violence means to its audience that determines whether it will be appealing or not.

To uncover participants' feelings and meanings surrounding the consumption of violence this study uses the projective technique of collage creation. Projective techniques are useful for studying concepts that may be difficult to articulate or are uncomfortable topics of discussion (Rook, 1988; Zaltman, 1996). Because enjoying the consumption of violence may not be perceived as socially desirable, the projective approach is well suited for this study. Seventy-three participants recruited from an undergraduate consumer behavior course, each created a collage of what it means to consume violence and how it makes them feel. No materials were provided so that participants were free to use any material they chose in their collages. In addition to the collage created, all participants provided a short narrative explanation of their collage. Together, the collage and the narrative formed the text for analysis.

While this research is only at very early stage, preliminary analysis suggests that consumers feel conflicted by their consumption of violence. The consumption of violence is confrontational. The prevalence and appeal of consuming violence makes consumers feel trapped, and overrun, alone and powerless to resist the temptation of violence. They desire protection and escape. Yet it may be precisely these feelings of helplessness that lead consumers to feel empowered by violence. They describe their experience of consuming violence of one of human strength. And because they are consuming rather than enacting the violence, it is not a physical battle but a mental one. Living the experience of violent consumption results in feelings of triumph, against the violence consumed and ironically, against the societal pressures to consume it.

Restoring Hope and Enhancing Self-Regulation

Chiu-chi Angela Chang, Shippensburg University, USA

The purpose of this research is to understand the relationship between hope and self-regulation. Specifically, the research question is: how are individuals able to keep on regulating themselves in situations where they are losing hope or having low confidence about

achieving their self-regulating goal? As an example, consider the situation where an individual sets a goal of losing weight and then devises a plan to achieve the goal by exercising regularly. However, a myriad of outside influences keeps the individual from exercising on regular basis. Consequently, this person becomes discouraged and starts to losing hope. Therefore, the inquiry is: how would this individual get back on track to adhere to the exercise plan again in order to reach the goal?

There are separate research lines in the marketing literature for the concepts of hope and self-regulation. MacInnis and de Mello (2005) define hope as “a positively valenced emotion evoked in response to an uncertain but possible goal-congruent outcome.” These authors suggest that hope interacts with such consumer variables as involvement and expectations, to affect outcome variables, including brand attitudes and satisfaction. On the other hand, the concept of self-regulation is defined in Hong and Lee (2008) as “the exercise of control over oneself to bring the self in line with a desirable outcome or goal.” The literature provides different theories to explain self-regulation, for example, self-regulatory resource availability (Vohs and Faber 2007), regulatory fit (Aaker and Lee 2006), and goal-directed behavioral intentions (Gollwitzer and Brandstatter 1997). The present research aims to synthesize these research areas and examine strategies to help consumers restore hope and enhance self-regulation.

MacInnis and de Mello (2005) indicate that “enhancement of hope may also increase a critical predictor of intentions to stop consumption: self-efficacy.” This research focuses on the role of self-efficacy in the relationship between hope and self-regulation, and proposes that a promotion (versus prevention) regulatory focus can more effectively enhance perceived self-efficacy and thus self-regulation when hope is threatened. Formally,

Proposition 1: When confidence about what one hopes for is threatened, priming respondents with a promotion (vs. prevention) regulatory focus would enhance their perception of self-efficacy.

Proposition 2: Self-efficacy is positively related to self-regulation.

Proposition 3: Self-efficacy mediates the relationship between regulatory focus and self-regulation.

The rationales for the above propositions are as follows. When people have low confidence about achieving their hoped-for goals, they may be engaged in motivating reasoning about products touted as problem solutions in order to restore their hope (de Mello, MacInnis, and Stewart 2007). The present research further suggests that in the context of self-regulation, people may also be engaged in the (biased) appraisal of self-efficacy as a way to restore hope. Given that low confidence in the hoped-for goal is likely associated with low perceived self-efficacy, a relevant issue is to boost the perception of self-efficacy. This research proposes that because a promotion focus is oriented toward ease of taking actions or the consideration of self efficacy (Keller 2006) making a promotion (vs. prevention) focus salient will help enhance or sensitize an awareness of self-efficacy. In addition, the idea of regulatory fit indicates the significance of pairing a promotion (prevention) focus with eagerness (vigilance) strategies in enhancing motivation and self-regulation (Hong and Lee 2008). In the current context, restoring hope is in line with pursuing eagerness strategies. Thus, a regulatory fit may be obtained when a promotion focus is primed in the context of restoring hope. Moreover, perceived self-efficacy has been found to positively influence self-regulation intentions (Bolton, Reed, Volpp, and Armstrong 2008; Milne, Sheeran, and Orbell 2000), which provides support to Proposition 2. This research additionally suggests that the mechanism through which a regulatory focus impacts self-regulation is by affecting self-efficacy (Proposition 3). Note that, even if the sense of self-efficacy is mildly inflated or distorted (i.e., confidence in one’s capabilities is overestimated), this bias is still deemed helpful in increasing the likelihood of accomplishing self-regulating goals (cf. Taylor and Brown 1994, p. 23).

In terms of methodology, in order to test the three propositions in this paper, it is recommended that a scenario similar to de Mello et al. (2007) be used, causing some respondents to lose hope in an endeavor (e.g., exercising). Then, respondents would be primed with a promotion (or a prevention) focus by writing about their hopes and aspirations (or duties and obligations), following the procedures in Freitas and Higgins (2002). Respondents would then rate themselves on self-efficacy using six semantic-differential scales (powerless-powerful, weak-strong, ineffectual-effective, dependent-independent, reliant-self-reliant, undisciplined-disciplined) (Bolton et al. 2008). Finally, respondents’ persistence in continuing their endeavor would be measured.

In conclusion, individuals are faced with self-regulation issues on a continual basis and are often overcome with failures. When consumers are losing confidence in achieving their hoped-for goals (i.e., when hope is threatened), the need to restore hope and enhance self-regulation is enormous. This research explicates the role of self-efficacy in connecting hope with self-regulation and explores the effect of priming a promotion or prevention regulatory focus in this context. It is the intention of this terse conceptual paper to stimulate a stream of research to benefit consumers’ pursuits of self-regulating goals, particularly when hope is threatened.

When Electronic Recommendation Agents Backfire: Negative Effects on Choice Satisfaction, Attitudes, and Purchase Intentions

Joseph Lajos, INSEAD, France

Amitava Chattopadhyay, INSEAD, Singapore

Kishore Sengupta, INSEAD, France

Abstract

Many websites provide electronic recommendation agents that ask users questions about individual factors and their preferences for product attributes, and then rate and rank order the available products. Previous research has hailed these agents as rescuing consumers from choice overload. However, we report the results of an experiment in which use of an electronic recommendation agent negatively impacted participants' choice satisfaction, attitudes, and purchase intentions over a period of between one and two weeks. The data support our hypothesis that use of an electronic recommendation agent leads consumers to overweight utilitarian product attributes and underweight hedonic product attributes in choice.

Online nutrition retailers offer consumers an enormous selection of highly nutritious foods, drinks, and dietary supplements. For a novice health and fitness enthusiast, deciding which of these categories of products are likely to be helpful, and then choosing individual products within those particular categories, can be confusing, even when only a few options are available. For example, when selecting a nutrition bar, consumers may consider a diverse array of product attributes, including Calories, fat content, fiber content, glycemic index, protein to carbohydrate ratio, protein quality, and vitamin and mineral content, among others. Typically, the product that is best for a given consumer will depend on a variety of individual factors, such as age, eating patterns, exercise frequency and intensity, gender, and strength and weight goals, among others.

This example illustrates how the increasing selection of products and product features available in the marketplace, and especially online, has increased the complexity of many purchase decisions. Since consumers do not want more choices per se, but rather the more customized options that expanded choice can bring (Pine, Peppers, and Rogers 2005), it follows that the attractiveness of the expanded choice set offered by internet retailers depends on the ability of consumers to sort through it efficiently (Alba et al. 1997).

Product recommendation websites assist consumers in making complex purchase decisions in diverse product categories. These websites provide electronic recommendation agents that first ask users questions about individual factors and their preferences for product attributes, and then rate and rank order available products on the basis of their responses. The goals of these agents include improving decision quality and increasing satisfaction (West et al. 1999).

Although previous research has extensively examined the influence of electronic recommendation agent use on decision quality (e.g., Haubl and Trifts 2000), far less research has examined effects on satisfaction. Furthermore, those papers that have examined satisfaction have primarily focused on satisfaction with the choice process (e.g., Bechwati and Xia 2003), rather than on satisfaction with the choice itself. However, choice satisfaction is important to marketers, since it has been shown to influence attitudes and purchase intentions (Oliver 1980).

In this paper, we examine how use of an electronic recommendation agent for nutrition bars impacts consumers' choice satisfaction, attitudes, and purchase intentions over a period of one to two weeks, the time frame in which repurchase decisions for nutrition bars are typically made.

We conducted an experiment within the nutrition bar product category. The experimental design had two between-subjects conditions (recommendation agent vs. control). People recruited outside a behavioral laboratory near a large, urban university were assigned to one of the conditions and asked to examine descriptions of eight brands of nutrition bars and to select one of these brands to sample at home. At the conclusion of the in-lab portion of the experiment, participants received a package containing five sample bars of the brand that they had selected. One week after the experimental session, participants received an email that contained a link to an online follow-up survey that assessed their satisfaction with the brand that they selected, as well as their attitudes, purchase intentions, and other relevant variables.

Based on our hypothesis that use of an electronic recommendation agent leads consumers to overweight utilitarian product attributes and underweight hedonic product attributes, we predicted that participants in the agent condition would be more likely to choose one of the four utilitarian brands compared to participants in the control condition. Furthermore, we predicted that the total amount of time that participants spent examining the brands would not differ between the two conditions, as a lack of difference would indicate that participants in the agent condition did not just blindly follow the recommendations provided to them. However, we predicted that participants who ultimately selected a utilitarian brand would spend more time examining the brands than would participants who ultimately selected a hedonic brand, since utilitarian choices typically result from more intensive processing than do hedonic choices (Shiv and Fedorikhin 1999). The data supported all of these predictions.

Based on our hypothesis that use of an electronic recommendation agent reduces consumers' long-term choice satisfaction, we predicted that participants in the agent condition would like the bars less than would participants in the control condition. Furthermore,

based on our hypothesis that use of an electronic recommendation agent leads consumers to overweight utilitarian product attributes and underweight hedonic product attributes in choice, we predicted that among participants in the agent condition, liking would be greater among those who chose a utilitarian brand than among those who chose a hedonic brand, whereas among participants in the control condition, liking would not differ between those who chose a utilitarian or hedonic brand. The data supported all of these predictions.

Finally, based on the hypothesis that use of an electronic recommendation agent negatively impacts consumers' attitudes, purchase intentions, and other relevant variables, we predicted that participants' ratings of the bars' taste, their likelihood of purchasing the chosen brand, and their likelihood of recommending the chosen brand to a friend would all be lower among participants in the agent condition than among those in the control condition. The data supported all of these predictions.

By showing that including a product in an electronic recommendation agent can have negative consequences, our results give a word of caution to managers. In particular, our results suggest that marketers who manage relatively utilitarian brands within product categories in which both relatively hedonic and relatively utilitarian brands are established should be especially cautious. Although agents might help increase short-term sales of such products by leading consumers to overweight utilitarian product attributes and underweight hedonic product attributes, this boost may come at the cost of long-run profitability.

Consumer Ethnic Identity: The Implications of Short Term Exposure to a Similar Culture

Helene Cherrier, Luiss University, Italy

Caroline Munoz, Fairleigh Dickinson University, USA

Natalie Wood, Saint Joseph's University, USA

The concept of ethnic identity is a popular yet perplexing subject among consumer researchers. Unlike the term race, the concept of ethnicity disregards generic heritage and focuses on one's sociocultural history. Broadly, consumer research considers two main aspects of ethnic identity. First, how can marketers use consumer ethnicity as a segmentation variable (Guilherme, Stanton, and Cheek 2003; Armstrong and Peretto Strata 2004). Second, how does cross-cultural experience impact cultural selves and ethnic identities (Askegaard, Arnould, and Kjeldgaard 2005). Within the second stream of research, acculturation theorists address the impact of cross-cultural adaptation, adjustment, integration, assimilation, and acculturation on cultural selves and ethnic identities (Penaloza 1994). For them, cultural identities are not fixed, but are deconstructed and reconstructed as consumers cross cultural boundaries. Ethnic identities are fluid identities that evolve through processes of acculturation.

Acculturation theorists provide undeniable insights concerning the development of consumer ethnic identities. However, most of their research assumes the idea of a dominant culture; a culture that contrasts with identifiable marginalized other cultures. For example, researchers on acculturation processes have considered dominant cultures such as the United States or the Danish culture and looked at marginalized ethnic groups such as the Mexicans (Penaloza 1994), the francophone Haitian and Haitian Creole (Oswald 1999) and Greenlandic immigrants (Askegaard et al. 2005). Focusing on conflicting or clashing cultures between a dominant and a dominated culture tends to simplify current multicultural environments and accelerated trans-cultural interactions. For example, in contexts such as London or Dubai, the distinction between a dominant and dominated culture blurs in the face of increasing multi-cultural incomers. Our research considers the acculturation process that individuals undergo when immigrating to a culture similar to that of their home country, leading us to ask the question:

RQ1: What impact, if any, does relocation to a similar culture exert on consumer ethnic identity?

In addition to focusing on clashing cultures, most studies on acculturation tend to consider cases of permanent or prolonged culture contact. In today's global arena, consumers can experience multiple and short term cross-cultural living arrangements. For example, individuals often travel abroad for work assignments and students are increasingly required to spend one semester abroad. This then raises the question:

RQ2: What, if any, impact does short term (maximum of six months) cultural contact exert on consumer ethnic identity?

This study considers consumer ethnic identity in the context of short-lived, cross-cultural experiences where home and host cultures are not distinctively dissimilar (i.e. comparable cultural and linguistic environment). We study the acculturation process of eight American exchange informants studying at a London university. The eight students selected for the study all originate from a strong trans-national consumer culture: the United States. The small sample size enabled us to acquire a deep understanding of the process through which each student experiences the modification, negotiation, or assimilation of ethnic identities. They all have been living in London for less than six months and intend to move back to their country of origin after one year abroad. One of the authors spent five months lecturing to the students. This enabled the author to observe the evolution of each American student in the host country. Beyond personal observations made by the instructor, a projective technique was used and analysed. The use of projective techniques enabled us to consider all aspects of consumer ethnic identities within the process of acculturation without influencing the informants (Lindzey 1961). Each student is asked to construct a collage that depicts "the life of a college student today." They are instructed to use any materials they desired and include any information that they deem relevant to the assignment. Furthermore, the respondents prepare a two to five page report which explains why they have included each image. They are also asked to explain the relative importance of their presented images. To further explore the potential cultural changes and how they are incorporated into their identities, the United States sample is benchmarked against ten students residing solely in the United States. For both analyses each researcher independently reviewed the collages and reports. Next, the independent analyses were shared and common themes were identified and agreed upon by all researchers.

Similarly to previous studies on long-term migrations, our findings support that consumer ethnic identities are fluid. After a six months exposure to a comparable consumer culture, our informants did not solely identify themselves with "American" symbols. They incorporated aspects of "trans-national consumer culture." At the same time, our study emphasizes that acculturation processes do not completely dissolve ethnic identities into "trans-national consumer culture," or a "global youth cultural segment" (Kjeldgaard and Askegaard 2006). On the contrary, the acculturation representing host and home global consumer cultures triggers its own resistance to global consumer culture.

The capacity of acculturation processes to simultaneously dissolve ethnic identities into global consumer culture and create its own resistance leads us to consider the concept of "symbolic ethnicities" rather than nation grounded ethnicities in consumer behavior studies. Symbolic ethnicities have little or no connection with actual ethnic communities (Alba 1990; Alba and Nee 2003). Through the acculturation process, consumer ethnic identities no longer represent countries of origin. Considering the concept of symbolic ethnic identity in consumer behavior research has important implications. First, the concept of symbolic ethnicity recognizes that the expansion of trans-cultural interactions generates similarities among consumers and at the same time evokes different associations according to the consumer's individual experience, both past and present. Second, the concept of symbolic ethnicity respects the multiplicity of singularities present in global consumer culture (Kjeldgaard and Askegaard 2006).

Black & White, or Only Shades of Gray? Exploring the Influence of Consumer Ambivalence on Female Contraceptive Choice and Usage

Piyush Sharma, The Hong Kong Polytechnic University, Hong Kong
 Cindy M. Y. Chung, Nanyang Technological University, Singapore
 M. Krishna Erramilli, Illinois Institute of Technology, USA
 Bharadhwaj Sivakumaran, Indian Institute of Technology, India

Good healthcare and effective health education are major issues today for most governments and healthcare organizations. One of the biggest challenges for health education is to raise world-wide contraception prevalence rates in order to improve female health and welfare. To this end, sex-education in schools was expected to alleviate the problem of teenage pregnancies rampant in many developed

countries on one hand and control the population growth in developing countries on the other (Erramilli et al. 2005). However, the results have been mixed so far.

Interestingly, the introduction of comprehensive sex education in American schools has coincided with an increase in teenage sex among girls from 29% in 1975 to 55% in 1990, increase in multiple partners from 14% in 1971 to 34% in 1988 and a 23% increase in teen pregnancies and deliveries from 1972 to 1990 (Hymowitz 2003). These problems have been attributed partly to the continued ambivalence about chastity, childbearing and working, with the American teens both liberated (sexually active) and yet not liberated enough (low contraceptive usage) at the same time (Gress-Wright 1993). In contrast, teenage pregnancy rates in Europe range from 0.4% in Netherlands to about 2% (90,000) in UK (Hollander 2004; Short 2004). In Asia, sex-education is largely information-based, focusing mainly on human reproduction and anatomy with little discussion about specific sexual practices (Smith et al. 2003).

Prior research shows that inconsistent contraceptive usage by females is an important direct cause of contraceptive failure leading to unwanted pregnancies and considerable physical and psychological discomfort (Fisher et al. 2005; Layte et al. 2007). Various factors are associated with the propensity to take contraceptive risks including an abortion history, dissatisfaction with current contraceptive method, low education, ambivalence towards getting pregnant, and a history of contraceptive risk taking (Snell and Wooldridge 2001). However, the issue of ambivalence towards different contraceptive methods has not been addressed adequately.

Recently there is an upsurge of interest in ambivalence in social psychology area (Nordgren et al. 2006). Ambivalence reflects the co-existence of positive and negative evaluations of an attitude object, and it is a different construct from 'indifference' or 'dissonance' (Nowlis et al. 2002). Prior research draws distinction between cognitive and affective ambivalence as well as psychological, social and cultural antecedents of ambivalence (Otnes et al. 1997). Empirical findings about the ability of ambivalent attitudes to predict behavior are mixed with some showing these attitudes as weaker and less predictive of behavior (Conner et al. 2003), and less resistant to persuasion (Armitage and Conner 2000). Others have found ambivalent attitudes to be more predictive of behavioral intentions (Jonas et al. 1997).

In this paper, we investigate the impact of ambivalence towards different contraceptive methods with female consumers in Singapore. We first review the extant literature in sex education, contraception, and ambivalence to develop a conceptual framework and several hypotheses about the influence of ambivalence on contraceptive usage behavior. Next we describe the findings from our qualitative study consisting of in-depth interviews with influencers such as doctors, nurses and male partners, and focus group discussion with female consumers, followed by a discussion of the results from a large scale survey-based study (N=1000).

Our results show that female consumers in general have ambivalent attitudes towards different contraceptive methods resulting in their inconsistent usage despite the risk of unwanted pregnancies. However, the influence of these ambivalent attitudes on the choice and usage of different contraceptive methods is moderated by the importance given to the opinion of different influencers. Specifically, female consumers have mixed attitude towards oral contraceptive pills because they are perceived to be highly effective but also potentially harmful in the long run because of their use of hormones. In contrast, withdrawal and rhythm are seen as less reliable but more natural contraceptive methods. Interestingly, condoms are the most popular contraceptive method because of their convenience but they are considered a hindrance to sexual pleasure.

Our results show that users of oral contraceptive pills continue to use them if they attached high importance to the opinions of their gynecologist. In contrast, females with mixed attitudes towards the relatively unsafe contraceptive methods such as withdrawal or rhythm methods continue to use these if they attach high importance to the opinion of their male partners. Finally, condoms seem to be most popular but their usage is still quite low because of the male partners' unwillingness to compromise on sexual pleasure. These findings provide valuable insights into the underlying reasons for inconsistent usage of contraceptives among females, which may have dire consequences for the physical and psychological health of female consumers. We discuss several implications of these findings for healthcare and consumer organizations. Finally, we discuss some limitations of our research and suggest some directions for future research.

A Role of Referring Website on Online Shopping Behavior

HoEun Chung, Purdue University, USA

JungKun Park, Purdue University, USA

Abstract

Despite several attempts have been made to understand online consumer behavior across from different situational settings, little is known of referring website's functionality on purchasing behavior. The purpose of the present study is two-folds. Firstly, the study defines different behavior patterns when consumers visit an online store through a referring website versus when consumers directly enter to an online store sans a referring website. Secondly, we investigated on the types of products (i.e. high-involvement product vs. low involvement product) purchased by access manner. Total number of 3,885 online consumers was used to conduct the study based on their detailed transaction activities.

As Internet penetrates everywhere, e-commerce has become a crucial axis in understanding contemporary consumer behavior. From rudimentary stage of e-commerce, researchers have been putting strenuous efforts to determine on deciding factors of online purchasing behavior from almost all the possible angles. However, not so much attention has been paid to how online consumer behaviors are affected contingent on the manners of access to online retail store.

The manners of online shoppers are largely divided into two venues; 1) access to an online store directly and 2) access to an online store by other website namely a referring website. In this paper, we examine different purchasing behavioral patterns when consumers access to an online retail store directly versus when they access to a site through a referring website. The present study is consisted of two parts. Firstly, we attempted to identify consumer behavioral patterns depending upon the access manner (i.e. direct access vs. indirect access via referring website). Secondly, we investigated on the types of products purchased by access manner.

The concept of referring website has been existed and perceived by consumers in e-commerce but not recognized yet. In its literal meaning, the word refer denotes "to direct or send for decision" (Merriam-Webster's Collegiate Dictionary, 1993). In this light, this present study defines a referring website as "a third-party website that directs consumer to an online retail store for a possible purchase decision." However, this is not to say on a narrow meaning of referring website taking a proactive role of recommendation by using recommending agents on a specific website but to include a broader indication of meaning of guiding consumers to another website by exposure of a brand or store name. If a consumer received some type of navigational cues by e-advertising means to be directed to an online retail store, it could be viewed that a website exerted a role of "referring".

Product information search phase has been identified as important in shopping context (Hodkinson et al. 2000; Haubl and Trifts, 2000). Janiszewski (1998) dichotomized consumer search patterns for shopping into two categories of goal-directed search and exploratory search. The characteristic of goal-directed search behavior is highlighted as having specific plans or specifications for purchase in mind. In contrast, exploratory search behavior is distinguished from goal-directed behavior in that it is undirected and stimulus-driven. Distinctive characteristics of each search type by various scholars can be recapitulated as follow; 1) Goal-directed search type consumers regard shopping as task-related work or problems to be solved; their behavior patterns are geared to complete transaction fast, being efficient but deliberate at the same time. Simply put, utilitarian perspective is taken by this type of consumers. 2) Exploratory search type or experiential search type consumers have a tendency to immerse themselves in browsing behavior itself or navigating sites randomly without a planned purchasing goal. They are considered to be less focused on promptness of completing a shopping behavior. This type of behavior has often been linked with hedonic motives (Sherry, 1990).

Based on the dual characteristics of consumer search types mentioned in the above, the following hypotheses were developed:

H1: A consumer who enters online store directly not through a referring website will display goal-directed search type behavior spending 1) less time in total duration 2) more time per page 3) high-purchase intention.

H2: A consumer who enters online store through a referring website will display exploratory search type behavior spending 1) more time in total duration 2) less time per pages 3) low-purchase intention.

Petty and Cacioppo (1981) proposed a notable framework of Elaboration Likelihood Model (ELM) to explain persuasion process of consumers. The model postulates the cognition process is identified as two major routes: (1) Central route and (2) Peripheral route. Central route instigates consumer to elaborate on product allowing more thoughts on attributes and therefore more likely to lead altered product beliefs and brand attitude to purchase intention. In contrast, peripheral route provokes consumer to less cogitate on product with shallow thoughts and to pay attention on non-product information. Based on ELM, we assume that consumers with direct access manner would more cogitate and more likely to display purchase intention on high-involvement product. In contrast, consumers with indirect access manner are expected to be less influenced by the length of time spend at the site and less relevant of product involvement level when purchasing a product.

H3: Purchasing behavior of a consumer who enters online store directly not through a referring website will be associated with product involvement level.

H4: purchasing behavior of a consumer who enters online store through a referring website will be less likely to be associated with product involvement level.

Dataset were drawn from the ComScore 2004 Disaggregate data set. Our dataset is consists of 3,885 users who visited Amazon.com and made purchase on random items between July 1, 2004 to December, 2004. Product categories were grouped as in either high-involvement product or low-involvement product according to its price range and in reference to the FCB Grid (1986, Berger). Independent variables included total duration time, number of pages viewed, duration per page, connection speed, basket total, total price, and the ratio of total price to basket total. In the present study, the price ratio of total price divided by basket total was contrived to measure purchase intention. We define the price ratio that approximates to 1 as having higher purchase intention (ex. 0.1= low purchase intention; 0.9= high purchase intention).

Independent sample t-tests were used to determine if any significant differences existed in 1) total duration 2) duration per page 3) the price ratio between consumers who directly logged on to Amazon.com and who were mediated to the site through other referring websites. T-test was conducted to test hypothesis1 and hypothesis2. The logit regression was performed to test hypothesis3 and hypothesis4. The value of the each product category was compared to the criterion for the involvement level (i.e. high-involvement).

As expected, in measuring total duration and in number of pages viewed, consumers with direct access manner stayed during less amount of time than consumers with indirect access manner with significance level less than .001. The price ratio was higher in direct access manner group than indirect access manner group with significance level less than .05. This implies direct access manner group had greater purchase intention than indirect access group. Hypothesis 1 and hypothesis 2 were supported.

None of independent variables were significant in indirect access manner group in terms of product-involvement level from logit regression analysis. In direct access group, number of pages viewed, time spent per page, and the price ratio showed significance level less than .05 and total price less than .001. Among consumer with direct access manner to the site, as number of pages viewed by consumers decreased, it was more likely that high-involvement product was purchased. As time spent per page increased, it was more likely that high-involvement product was purchased. For both of total price and price ratio, it was more likely that high-involvement product was purchased as each dollar amount was increased. Hypothesis3 and hypothesis 4 were supported.

Using Brands to Communicate Self: How Effective Are We?

Renu Emile, Auckland University of Technology, New Zealand

Margaret Craig-Lees, Auckland University of Technology, New Zealand

Ken Hyde, Auckland University of Technology, New Zealand

The notion that tangible objects and modes of behaving communicate the role and status of individuals within a society has a long history (Gardner & Levy, 1955; Levy, 1959; Simmel, 1904, 1950, 1957; Veblen, 1899). A characteristic of contemporary societies is the centrality of the self and the wide acceptance that individuals use brands and/or products to create, maintain and communicate aspects of their self. The use of brands and/or products in this way has been extensively studied by consumer researchers. Aspects examined include: matching product and brand characteristics with the self; investigating the use of products and brands to reflect gender, role, status and prestige, reference group membership, ethnicity within and across cultural boundaries (Belk, 1988, 2004; Elliott, 1994; Elliott & Wattanasuwan, 1998; Goffman, 1951; Hogg, 1998; Holt, 1997; Lamont & Molnar, 2001; Cracken, 1988; Thompson & Haytko, 1997; Chaplin & Roedder-John, 2005).

The studies are primarily unidirectional, in that they report how the individual thinks the brand works to support aspects of their self. The question of whether the communication is actually effective, that is, does the sent or communicated message match with the read message, has had minimal attention. Advertising related research, while proposing a dialectical relationship between advertising and the consumer (Mick & Buhl, 1992; Sherry, 1987), also suggests that the construction of product and brand meaning ultimately builds up through interpersonal communication among consumers (Elliott & Wattanasuwan, 1998; Ritson & Elliott, 1999). Yet, advertising research continues to focus on the solitary subject at the expense of a more social orientation, neglecting the significance, use and interpretation of advertising messages in reciprocal social interactions. This observation can be applied to product and brand use. More specifically-are the messages that an individual wishes to send via the use of products and brands understood by intended audiences?

Grubb and Hupp (1968) found consumers of a specific brand to have self concepts similar to those of other consumers of the same brand. Grubb & Stern (1971) also found that users of a specific brand perceived that other users of the same brand would have similar self-concepts i.e., be the same type of people. Both studies were limited to the matching of perceptions of selected brands between two

groups-consumers and their reference groups, rather than the matching of communicated messages by the self with messages received by audiences. Though these studies have examined shared perceptions, they are still unidirectional. Accepted wisdom is that consumers use brands and products to communicate aspects of the self. What is largely unknown is their degree of success. This study asks the question: *If young adults use brands to develop, maintain and communicate aspects of their self, what aspects of their self do they communicate and how successful are they?* To answer this question the study will address the following issues and tasks:

- Confirmation/disconfirmation of the premise that young adults use brands and products to construct and/or communicate aspects of their identity.
- Identifying the products and brands young adults use, the meanings constructed, and the ways in which they think the meanings associated with brands and products express aspects of their self-identity.
- Determining how the intended audiences interpret the identity that the brand and products are meant to communicate.

Identity development is a central facet of adolescence and self-brand connections begin in early adolescence (Moschis & Churchill, 1978; Chaplin & Roedder-John, 2005). GenY are highly brand conscious and are cognizant of the symbolic value of the brands they consume (Galician, 2004). They are also sophisticated consumers of entertainment media. Though parents do have an influence, superstar role models also wield significant influence and entertainment media is a key source of information about lifestyles and behaviours (Martin & Bush 2000; Lockwood & Kunda, 1997). This literature suggests that young adults will have developed use and interpretation skills-having developed shared meanings within their age cohorts.

The study intends to draw upon a loose collection of socially oriented perspectives of the self from within the marketing and consumer behaviour literature. In particular, it will draw upon Goffman's (1959) notion that the self is constantly engaged in performances, routinely playing specific roles within particular social interactions. The study will also take a consumer culture orientation that conceptualizes consumption as a mode of socio-cultural practice, and that which focuses not only on the economic, social and political dimensions of consumption, but also on the symbolic boundaries that structure personal and group identities (Arnould & Thompson, 2005). This study assumes a shared perception of reality, identifying with the Berger and Luckmann (1966) notion of social constructionism; that when people interact, they do so with the understanding that their respective perceptions of reality are related. A common thread in social constructionism is the force of language as a principal assumption and the need to identify shared constructions of meanings (Burr, 2003). The study draws upon phenomenological approaches to research design (Husserl, 1970; Schutz, 1962, 1964, 1967, 1970; Thompson, Locander & Pollio, 1989).

The study will employ the use of photography and semi-structured interviews and be conducted in two stages (Harper, 2000; Kjeldgaard, 2003, 2004; May, 2001; Noland, 2006, Quinney, 1995; Ziller, 1990). In the first stage, young adults (18-21) will be asked to photograph brands and products that they use to express self and asked to describe that self. In the second stage, collage boards of the photographs will be presented to other young adults and other age cohorts (not known to the first set of participants) who will be asked to describe the persona of the person in the pictures. Factors such as gender and actual physical appearance will be controlled for.

Consumer Animosity a Two-Way Street? A Story of Three Countries

Annie Peng Cui, West Virginia University, USA
 Theresa A. Wajda, Slippery Rock University, USA
 Micheal Y. Hu, Kent State University, USA

Much research has been done examining why consumers buy; less attention has been given to investigations of why consumers do not buy. Studies in consumer animosity, representing one of the latter streams, focus on what makes consumers shun products from certain countries in spite of high product quality. This study represents a first inquiry into the reciprocal nature of consumer animosity, as well as its impact on consumers’ willingness to purchase foreign products in a cross-country setting (i.e., the U.S., China and Japan).

The objective of this study is twofold. First of all, this study examines whether the construct of consumer animosity is reciprocal in nature. Most of the studies that addressed the topic of animosity (e.g., Klein, Ettenson and Morris 1998, Klein 2002, Kalliny and Lemaster 2005, Hong and Kang 2006, Russell and Russell 2006, Shoham et al. 2005, Hinck 2004) studied consumer animosity as a one-directional construct in a single-country setting. The present study represents a first attempt to examine consumer animosity as a two-way street, namely, consumers’ animosity attitude toward a foreign country should influence consumers from this foreign country and affect their purchase decisions as well. Studying consumer animosity in the U.S., China and Japan and its impact of on consumers’ willingness to buy foreign products, this study contributes to the literature by examining the dynamics of consumer animosity in a cross-country setting.

Secondly, this study investigates the relationship between consumer animosity, product evaluation, consumer ethnocentrism and consumers’ purchase intentions (i.e., willingness to buy). We want to extend the current literature on consumer animosity to examine if consumer animosity, product evaluation, consumer ethnocentrism and purchase intentions interact differently under different levels of animosity (e.g., high vs. low). Since consumers may hold different levels of animosity toward two different countries and toward the

products from those countries, another major contribution of this research is to examine the impact of various levels of consumer animosity on purchase intentions.

We tested two hypotheses in study 1: 1) Chinese consumers have a higher level of animosity toward Japan than toward the U.S., and prefer American products over Japanese products; 2) even when consumer animosity is low, as long as it is present, it has a negative impact on purchase intentions. We adopted Klein, Ettenson and Morris's (1998) multi-item animosity scale and asked 175 Chinese participants to indicate their evaluations of products from the U.S. and Japan, their animosity toward the two countries, consumer ethnocentrism, and willingness to buy products from these two countries. We found that Chinese participants had a higher level of animosity toward Japan than toward the U.S. ($\text{Animosity}_{\text{Japan}}=5.32$, $\text{Animosity}_{\text{U.S.}}=4.27$, $t=11.35$ $p=0.01$, on scales of 1-7, 1 indicates low level of animosity and 7 indicates high level of animosity). Furthermore, though participants evaluated the American products and the Japanese products as equal in quality, they were more willing to purchase American products rather than Japanese products. Regression analysis revealed that even when consumer animosity was relatively low (in the case of the U.S.), as long as it was present, it had a negative impact on consumer's purchase intentions (U.S. coefficient=-0.17, $p=0.01$). Our hypotheses were confirmed by this initial investigation.

In our next studies, we will examine American consumers' animosity toward China and Japan, and Japanese consumers' animosity toward China and the U.S., as well as their perceptions of products from these countries. We hypothesize that although consumer animosity tends to be reciprocal (the sources of animosity such as war, culture, and politics should have impact on both sides), consumers from two countries may have different levels of animosity toward each other due to different perceptions of these animosity sources.

This research moves beyond the current animosity literature to investigate the reciprocal nature of the construct in a cross-country setting, different levels of consumer animosity and its impact on purchase intentions among Chinese, American and Japanese consumers. Preliminary findings in one of the three countries supported our hypotheses. We intend to conduct further studies in all three countries to achieve a better understanding of the construct of consumer animosity and its impact on consumers' willingness to purchase foreign products.

Brand Personality Profiles: A Pick-A-Winner Study of Two Methods

Annie Peng Cui, West Virginia University, USA

Robert Jewell, Kent State University, USA

Jie Xin, Shandong University, China

Brand personality, a multi-dimensional construct, provides a holistic view of a brand that goes beyond merely describing brand attributes (Keller 2003). A brand's personality is an aggregate representation of the benefits, usage, user and relative marketplace imagery associated with a particular brand. Examining what human personality characteristics consumers often endow a brand with will lead to a better understanding of the consumers' perception of the brand.

Aaker (1997, p. 347) defined brand personality as the "set of human characteristics associated with a brand." The purpose of Aaker's (1997) research was to assess and describe the aggregate structure of brand personality across brands and product categories. Aaker (1997) selected 37 brands from the EquiTrend study (1992) that were rated high on salience and represented different profiles of brand personality. Using a lexical approach similar to the Big Five model of human personality in psychology, the author developed a 42-item measurement scale from the original set of 114 traits and identified five dimensions of brand personality: excitement, sincerity, competence, sophistication and ruggedness.

Aaker's (1997) work inspired a stream of brand personality measurement studies. Some researchers attempted to measure brand personality using the five-factor model assuming each brand should have the same five-dimensional personality (e.g. Kim 2000; Best 2005). Rojas-Mendez, Erenchun-Podlech, and Silva-Olave (2004) applied Aaker's scale to the study of one specific brand, Ford. Kim (2000) and Best (2005) suggested that a brand's personality can be measured by the 15 facets of the five dimensions, instead of the full set of the 42-item scale.

Another group of researchers (Cui, Albanese, Jewell and Hu, 2007) adopted Q methodology to assess the brand personality of a single brand. They believe that Q methodology is uniquely suited for measuring the personality of a single brand because it allows researchers to measure a subjective construct in a holistic way without reducing the construct to factors (Cui, Albanese, Jewell and Hu, 2007). The instrumental basis of Q methodology is the Q-sort technique (Brown, 1996), a comparative ranking task in which participants rank order a set of statements (i.e., 42 brand personality traits), under certain instructions. Subjects are instructed to express their perceptions of a certain subject matter by rank ordering the provided statements into a continuum of categories, ranging from extremely characteristic to extremely uncharacteristic. Each category has a fixed number of statements. The number of statements required in the two extreme categories is the smallest, and the number gradually increases toward the middle of the categories; the distribution of the number of statements across categories resembles a normal distribution. Participants have to make comparisons among the statements before putting them into each category; therefore, the decision of assigning each statement to a particular category is made relative to the placement of the other statements. The subjective perspective of the brand's personality is constantly referred to by the sorter during the sorting process. The data then will be analyzed using Q-factor analysis to uncover groups of opinion about the subject matter.

The intention of the present study is to compare and contrast the two methodologies and to examine, based on consumers' evaluations, which method generates a more accurate and appropriate brand personality profile for consumer products. This research has two studies. In the first study, the authors will generate two separate personality profiles of the same brand using Q-methodology and the traditional survey method (e.g., Aaker 1997). A group of consumers will be presented with the two profiles (in words) and be asked to indicate which profile more accurately describes the brand's personality in their mind. This is followed by open-ended questions asking them to explain how they make their decisions and why they think a specific profile accurately depicts the brand's personality. Both the qualitative and quantitative data will be incorporated in the data analysis to draw the conclusion. Study 2 differs from study 1 in how the brand personality

profiles are presented to the participants. Instead of using words to describe the two profiles, we will demonstrate the brand personality profiles by print ads. Accordingly, two print ads will be developed based on the two brand personality profiles. The ads will be pre-tested to ensure that they represent respective brand personality profiles. Another group of consumers will be presented with the two ads and be asked to answer the questions similar to those from study 1. The purpose of study 2 is 1) cross-validate the findings of study 1, and 2) illustrate the brand personality profiles in a more natural marketing setting (than description in words), namely, print advertising.

The literature of brand personality suggests two different profiling methods. The goal of this study is to identify which method generates a more accurate and appropriate brand personality profile of a single brand. The present study contributes to the literature as the first attempt to compare the two methods and demonstrate the pros and cons of each method using consumers' evaluations.

Service Value Chains to Support Knowledge-Based Personalized Recommendations

Sonja Wendel, Erasmus University Rotterdam, The Netherlands

Amber Ronteltap, Wageningen University, The Netherlands

Benedict G.C. Dellaert, Erasmus University Rotterdam, The Netherlands

Hans C.M. van Trijp, Wageningen University, The Netherlands

Sophisticated consumer and market information databases increasingly allow firms to provide consumers with personalized recommendations that can assist them in finding lower prices and better quality items in the marketplace (Xiao and Benbasat 2007). Most research pertaining to personalized recommendations to date has focused on the development of new methods to improve the quality of these product recommendations or analyzed how consumers make product choices when they use product recommendation systems (Ricci and Werthner 2006). Increasingly it is argued that it would be desirable if product recommendation systems were extended to also allow for more complex, knowledge-based recommendations in service domains such as health and personal finance (Felfernig et al. 2006). Such knowledge-based recommendations are likely to require the exchange of more complex, more fuzzy, and often more sensitive information between consumers and the supply chain (Punj and Moore 2007). Typically, also these recommendations would rely on a greater involvement of the consumer (in sharing detailed information), and of multiple partners in the service supply chain (to provide the necessary expertise to generate a recommendation) (Pralhad and Ramaswamy 2004). Thus, knowledge-based recommendations are expected to require a much more elaborate type of service value chain.

In the current study, we address the question how consumers evaluate such service value chains designed to create and deliver knowledge-based personalized recommendations. To do so, we conceptualize the underlying cost-benefit trade-offs that consumers make in evaluating knowledge-based personalized recommendation systems as being determined by a psychological contract in which consumers contribute personal information and effort in exchange for a more useful, tailored recommendation by the firm (Rousseau 1989, Zeithaml 1988). This overall structure provides the basis for two key contributions of our study.

First, since service value chains to support knowledge-based personalized recommendation systems require input from consumers at different stages of the value creation process our initial research objective is to investigate how consumers evaluate the fact that they need to actively participate in the recommendation generation process. We anticipate that service stages in which consumers maintain decision control and can choose the contributions they wish to make freely (e.g., in applying a recommendation in their own home) will be evaluated differently from stages in which consumers are more dependent on firms' input (e.g., when exchanging information with firms) (Namasivayam 2004). We expect that for stages in which little or no firm input is required, consumers will be overly optimistic about the quality, efficiency, and pleasure connected with their own contributions to the personalized recommendation systems (Metcalf 1998; Pelletier et al. 2001). In particular, we expect that consumers' perceptions of usefulness, ease of use, and enjoyment are influenced less by variations in these stages than by variations in other stages, during which consumers are more dependent on firms. At the same time we expect that this level of optimism will not hold for the consumers' evaluations of the privacy safety of their personal information. The reason is that even in service stages in which consumers can freely determine their own actions they will still depend on firms to safely handle their personal information.

Second, we address the impact of service channel task context on the benefit trade-offs that determine consumers' willingness to use a service value chain with knowledge-based personalized recommendations. Previous research shows that benefit trade-offs may vary depending on the task context in which consumers are introduced to a product or service (Wendel and Dellaert 2005). We anticipate that the service channel through which a personalized recommendation is introduced plays crucial role as a key contextual factor in determining consumers' cost-benefit trade-offs. In particular, we investigate how consumers' cost-benefit trade-offs may shift when they are introduced to the service value chain out of their own interest, compared to when they use the system because of service channel requirements (Novak, Hoffman, and Duhachek 2003).

We test our proposed conceptualization and hypotheses in the area of nutrition recommendations. Recently a number of health organizations (commercial and non-commercial) have begun to implement personalized nutrition recommendations that rely on both detailed consumer input and on sophisticated firm expertise, and that offer a very promising tool to assist consumers in their decision making (Brug, Oenema, and Campbell 2003; Kreuter et al. 1999). Data collection involved 204 respondents from a large, ongoing consumer panel in the Netherlands who responded to hypothetical scenarios of different nutrition recommendation value systems. Our findings provide support for the proposed conceptual model and hypotheses. The results also provide managerial guidance to firms and public health policymakers wishing to promote the use of personalized health recommendations by consumers, as well as to consumers, who may find that they overestimate their own ability (or underestimate the effort involved) to implement the recommendations provided by personalized health recommendation systems.

Gender Differences in the Cognitive Organization of Spending Attitudes

Leslie D. Dinauer, University of Maryland University College, USA

This applied study, part of a larger ongoing project, examined Galileo cognitive maps of shopping concepts in men and women in order to inform the design of more effective debt counseling messages.

To study Galileo cognitive maps, a space containing attitude concepts that are relevant to the target population must be generated and analyzed. Several pilot studies were conducted to determine an appropriate set of shopping-related concepts to occupy such a space. Then, the final study employed Galileo spatial plot analysis and structural equation modeling to test the hypotheses about gender differences between the maps. The participants in this phase of the project were undergraduate students at a large eastern university.

Three hypotheses were tested:

- H1: Men and women will possess different cognitive organizations of shopping-related concepts.
- H2: When an individual receives a persuasive message directed toward a single concept, the force of that message will cause attitude change that will be reflected by motion in linked concepts.
- H3: Gender will affect attitude change among linked concepts in a structure of shopping-related concepts.

So, the purpose of the study was two-fold: (1) to examine the effects of an inter-attitudinal structure upon attitude change for shopping-related concepts, and (2) to determine if gender affects such change. In order to induce attitude change, three persuasive messages differing only in their focal concept were employed. These focal concepts represented the categories of the first independent variable, Message target. The second independent variable was Gender. Finally, because there was a concern that some participants may have greater accessibility of the study's theorized concept relationships, Priming was added as a third independent variable.

The primary dependent variable of the study was attitude. Magnitude estimation was used to measure attitudes. Consistent with Galileo mapping theory, an attitude was represented by the distance between a concept and *things I like* whereas an analogous evaluative believe was represented by the distance between a concept and *good*. It was also necessary to create one new dependent variable that captured the movement of the concepts in the study that were not targeted by any message. The existence of non-targeted concepts allowed examination of the indirect effect of the target message on concepts merely associated with the target concept.

The Galileo computer program V56 calculated the adjusted geometric mean distances among the nine experimental concepts which resulted in 2 sets of distances, one for men and one for women. When the distances were plotted together, a multidimensional cognitive space resulted. The program then rotated each space to the same orientation and transformed it to a least-squares best fit so that the spaces would be similarly aligned and visual comparison could be made between them to detect the changes across experimental conditions. Additionally, structural equation modeling determined the causal relationships between the variables of interest.

The Galileo results showed that, overall, the women's cognitive space of shopping concepts was significantly smaller than the men's, which corresponds with a greater liking of the shopping concepts overall (recall that smaller distances=more liking, greater distances=less liking). This was further supported by the results of a 2 (Gender: male vs. female) x 2 (Priming: primed vs. unprimed) x 3 (Message Target: shopping vs. clothes vs. food) analysis of variance on attitude toward shopping which found, as expected, that women like the shopping concepts significantly more ($M=4.55$, $SD=.06$) than do men ($M=4.79$, $SD=.09$), $F(1, 177)=4.78$, $p<.05$, $\eta^2=.02$.

Also, shopping is more central to the concept “needs” and the concept “wants” in the women’s space. This might represent women’s understanding of shopping as having equivalent roles in both necessary and unnecessary-but-desirable consumption. Women appear to closely relate shopping with a wider range of buying activities than do men. For example, the Galileo plot shows that women identify shopping and clothes as much more closely related than men (a *t*-test on the distance between shopping and clothes confirms this observation: *t* [205]=1.99, *p*<.05). It appears as if men consider shopping a not-so-good, disliked activity that, paradoxically, is most closely related to the acquisition of wants. For men, it appears, pain equals gain.

The structural equation models determined the causal relationships that existed between the variables of interest. These models suggested that women’s attitudes about shopping seem to activate a chain reaction of evaluations toward clothes, then food, then needs, wants, gifts and luxuries. These results have tremendous implications for application in debt counseling and education: It’s not enough, for example, for counselors to suggest, “Buy only what you need” when needs and wants are only marginally distinguishable.

The findings further suggest that (1) messages can be designed that attempt to influence attitudes toward and beliefs about shopping and debt indirectly, through related concepts, and (2) messages used for debt counseling might be much more effective if they employed gender-specific strategies that address men’s and women’s different understandings of shopping and related concepts. Even the act of determining an individual’s specific shopping-related space and revealing the significant relationships to him or her (i.e., making the space accessible and salient) may increase the effectiveness of debt counseling by creating a new awareness of associations between attitudes that may previously have seemed irrelevant. This prediction will be tested in an upcoming study.

Under the Cover of Alcohol: The Impact of Alcohol Consumption and Preventive Media on Intentions to Engage in Deviant Behavior

Kivilcim Dogerlioglu-Demir, Washington State University, USA

Kristine Ehrich, Washington State University, USA

Darrel Muehling, Washington State University, USA

Previous research has established that alcohol impairs judgments and increases the likelihood of engaging in risky behaviors. It has been reported in the alcohol literature that alcohol consumption leads to increased rates of sexual assault and acquaintance rape (Champion, Foley, DuRant, Hensberry, Altman, Wolfson 2004).

As a part of social marketing efforts, the sponsors of warning ads use diverse message themes (such as fear appeals, social norm tactics and novel information) to attract attention and caution individuals against heavy drinking and its consequences (Kalsher, Clark and Wogalter 1993). Research on preventive media indicates mixed results: some studies suggest that when carefully designed, warning ads are influential (MacKinnon and Lapin 1998; Kalsher et al. 1993) while others posit that they are ineffective (Steele and Josephs 1990) and may even result in resistance to comply and/or counterproductive (boomerang) effects (Synder and Blood 1992).

Most of these works, however, ignore the impact of an individual’s subjective assessment of impairment (“perceived intoxication”) and the motivation behind such an assessment on these risky actions. We investigate whether the link between alcohol consumption and intention to engage in deviant acts results solely from alcohol’s pharmacological effects or from placebo effects as a consequence of the belief that alcohol has been consumed (Barthalow and Heinz 2006). Since individuals’ perceived extent of impairment is “a viable decision making component” (Nicholson, Wang, Collins, Airhihenbuwa, Mahoney and Maney 1992), we believe that “perceived intoxication” may be a better predictor of intentions. We suggest that “perceived intoxication” is a variable that mediates the relationship between alcohol consumption and sexually aggressive tendencies. In addition, we argue that there is an individual difference variable (Alcohol Expectancy-AE) that may help explain the tendency of individuals to overestimate their intoxication levels (MacAndrew and Edgerton 1969; Brown, Goldman, Inn and Anderson 1980). The beliefs that individuals hold about the effects of alcohol on their behavior, moods, and emotions are expected to moderate the relationship between alcohol consumption and perceived intoxication.

It has been suggested in the literature that a person’s desire to experience a product’s expected benefits increases the efficacy of placebo effects (Shiv, Ziv and Arieli 2005; Irmak and Fitzsimons 2005). In a similar vein, we suggest that AE is the main motivation behind one’s self reported high intoxication levels. When people believe alcohol has the power to make them stronger, sexier, more confident and immune to dangers (high AE), they report their perceived intoxication levels much higher. We argue that this may even hold for individuals who are administered a placebo drink. “Perceived Intoxication” derived from the AE trait will act as a “cover” or permission to consider exhibiting an ordinarily forbidden behavior (such as sexual aggression). We also introduce an important individual difference variable, Rape Myth Acceptance (RMA), to explain individuals’ tendencies to engage in sexually aggressive behaviors (Wells 2003) and violent acts (Burt 1980; Stephens and George 2004). More specifically, the tendency to support adversarial sexual beliefs, tolerate interpersonal violence and stereotype gender roles are expected to moderate the relationship between perceived intoxication and the likelihood to engage in sexual aggression. These myths act as “psychological neutralizers” that allow individuals to turn off social prohibitions (Burt 1980).

In our model, Alcohol Expectancy constitutes the motivational aspect behind higher reported intoxication levels whereas Rape Myth Acceptance determines one’s likelihood to be acceptant of sexual aggression towards women. We provide a framework to examine the processes underlying deviant behaviors that arise as a result of alcohol consumption. We believe that it is meaningful to study the effectiveness of warning ads only after considering this broader framework.

In a pilot study, 52 heterosexual male undergraduate students of legal drinking age were recruited. Participants were screened via an online survey conducted a month before the actual experiment, where Alcohol Expectancy (adopted from Brown et al. 1980) and Rape Myth Acceptance (adopted from Burt 1980) measures were collected. The experiment was conducted in a design similar to a drinking occasion where participants consumed four drinks. They were then asked to rate perceived intoxication levels (“how intoxicated do you feel?” scale is from -9 to 9, with 0 meaning “at the legal limit”), attitude towards the ad and intention to engage in sexual aggression. It

was a 3 (alcohol condition: alcohol; no alcohol; placebo) x 2 (ad condition: anti-sexual aggression ad; control -Pepsi ad) between subjects design. In the alcohol condition, participants were given drinks with high alcohol concentration (.80 g/kg ethanol), in the no alcohol condition, participants were to taste and spit out the alcohol and in the placebo condition, participants were made to believe that they were actually consuming alcohol by using a drink that tasted and smelled like alcohol (.04 g/kg ethanol). The blood alcohol levels of all participants were measured throughout the experimental session using a breathalyzer device.

Our results suggest that the alcohol manipulation worked. While individuals in both alcohol ($M=2.8$ $SD=4.4$) and placebo ($M=-2.0$ $SD=3.3$) conditions reported higher levels of perceived intoxication ($p>.05$), the no alcohol group ($M=-6.8$ $SD=2.8$) indicated significantly lower perceived intoxication levels ($p<.05$). The results of a Sobel test ($p<.05$) indicated that perceived intoxication is a mediator between alcohol consumption and sexual aggression intentions, suggesting that individuals' perceived extent of impairment is a key factor in explaining deviant behaviors. Moreover, RMA had a significant main effect on sexually aggressive intentions ($p<.05$) indicating that one's tendency to support adversarial sexual beliefs has a strong impact on behavioral tendencies. However, we were not able to show a moderation effect between RMA and perceived intoxication. We also failed to show an interaction effect between AE and alcohol consumption. We were not able to demonstrate a significant interaction between ad condition and perceived intoxication. However, the signs of these variables were in the expected direction. We believe these non-significant findings may be primarily a power issue. A follow-up study with more participants is planned.

With this study, we hope to fill a gap in the social marketing and transformative consumer research literatures by providing a more inclusive conceptual framework on the relationship between the influence of alcohol and deviant behaviors. Our expectation is that alcohol has differing consequences on individuals that cannot be solely explained by pharmacological effects. The proposed framework may help explain the effect of warning ads on individuals' proclivity to engage in socially undesirable behaviors.

The Commodification of Marriage: "Mail-Order Brides" in the Electronic Age

Kivilcim Dogerlioglu-Demir, Washington State University, USA

Patriya Tansuhaj, Washington State University, USA

The film opens with kaleidoscopic shots of beautiful women posing for the camera. A man flips through the pages of a catalog resembling a catalog shopping for clothing. Looking at the booklet closely, one realizes that he is looking at the pictures of attractive women. Carefully examining these images, he is searching for a wife to take home. This is the opening scene of the 2003 documentary, *In the name of love*, directed by Shannon O'Rourke. The documentary tracks a number of women who are signed up with marriage agencies in Russia and rich American men searching for brides. O'Rourke examines commercialization of modern love and romance by looking at the lives of these women and the processes involved in this modern matchmaking business.

There are approximately 200 mail-order bride agencies in the United States, with an estimate by the U.S. Citizenship and Immigration Services to be 4,000 to 6,000 American men finding wives through those agencies each year (www.uscis.gov). This multi-million-dollar mail-order bride industry continues to thrive rapidly at a global scale and scope, with mixed reports on whether marriages via this international match making arrangement result in positive outcomes or in domestic violence. This international marketing practice has long been unregulated until recently when the International Marriage Broker Regulation Act was signed into law in 2006. Although this Act aims at protecting women from potential abuses, it in effect legitimizes the industry, and the volume of transactions continues to rise. A closer look at the law also indicates a sexist language in such a statement as, "The *seller* must obtain the man's record from the National Sex Offenders Public Registry database." (www.govtrack.us) We believe that it is worthwhile investigating this phenomenon from the perspective of morality of market exchange (Prasad 1999).

Advances in electronic commerce and internet technology accelerate speed, scope and scale of the mail order bride transactions on a global scale. Although these services represent a truly global consumption phenomenon, the mail order bride issue has not received sufficient attention from consumer researchers. This study aims at providing a better understanding of the nature of the mail-order bride service, causes of "commodification of love" and its consequences on gender relations, family and marriage formations. In an era where foreign brides are being marketed on the internet resulting in growing commodification of marriage, there is a high potential for violating personal identity of women in this process (Hughes 2000).

There are two dominant perspectives in studying consumption patterns as symbolic expressions in consumer research: Personality/values lifestyle analysis suggests that lifestyles are behavioral expressions of personality traits, and object signification research that posits that consumption objects (goods, services and events) represent social categories. Holt (1997) proposes the third, post-structuralist approach. He argues that this method is more appropriate for explaining consumption patterns in advanced capitalist societies. Meanings are realized in relation to peoples, times, places and objects. Moreover, meanings accumulate. They are not disconnected from history. They are "symbolic chains" that are constantly constructed. These meanings are multiple resources from which social actors select and combine. Hence, meaning of any object is dependent on which linkages are made. Consumption of marriage, for example, however individual, always works with the existing societal frameworks. Our research relies on Holt's perspective to offer a more comprehensive explanation of this complex phenomenon of commodification of marriage in the free market world.

The content analysis of currently active mail order bride websites includes virtual images, electronic presentations of brides, and other information on product and service offerings. Our initial review shows that most of the marketing activities concentrate on attracting American men to their one-stop shopping electronic bridal search service. Subservient and traditional women are typically portrayed as "products" offered as choices for men. They are described with such adjectives or phrases as, *untainted by Western feminism, family-oriented, innocent, pure, and loyal to the husband*.

We then develop a multi-stage model representing the international match-making process. Searching stage is characterized by clients viewing hundreds of mail-order bride agencies' websites and deciding the way he wants to connect with those potential brides. Clients can either choose to buy addresses or catalogs and magazines from agencies. Based on the photo and figure information (weight, height, or age), men get to know a bit about their future brides. In this process, women typically receive only very limited information about the man, mostly from what he chooses to tell her in the letters or emails. In the virtual contact stage, upon obtaining addresses, the client can start to write to women. The duration of pen-pal relationships lasts differently from client to client. In the rendezvous stage, mail-order bride agencies become travel and tour agencies. After a brief contact period, the client decides whether to take the next step of meeting prospective brides in person. In the bringing-home stage, it is often not the bride but rather the groom who makes the decision.

Following introduction of the above multi-stage framework, we plan to seek a theoretical explanation for commodification of women. We will conduct an interpretive study, via in-depth interviews and additional content analyses of websites, to account for consumption patterns evident in the mail-order bride industry. Visits with both women and men would allow us to hear their stories, stereotypes, expectations, emotions and satisfaction (or lack thereof). Coupled with our content analysis of mail order bride websites, we then will use themes and terms generated from the qualitative research to determine patterns of perceptions of and motives for mail order bride service participation from both the *seller* and the *consumer* perspectives. We expect to develop a theoretical model and related propositions for future empirical research on this global consumption phenomenon of social and human significance.

An Investigation Into Individuals' Repeated Attempts at Behavior Change

Courtney Droms, Valdosta State University, USA

Recent research has shown that individuals make repeated attempts at behavior change prior to actually being successful. For example, typically individuals try to change their dieting behaviors on 4 to 5 occasions prior to actually being successful (Polivy and Herman 2002). Many of the dark side of consumer behavior areas identified by Mick (1996), such as smoking, drug use, shopping, and gambling, are behaviors that individuals try to change on a repeated basis. As consumer researchers, however, we do not have a clear understanding of how people interpret behavior change failures and persist in their efforts to change their behaviors after such failures.

In an effort to understand these behavior change attempts, this dissertation replicates and extends the Theory of Trying (Bagozzi and Warshaw 1990), to include feedback loops from the outcomes of behavior change attempts to attitudes towards trying to change again. The main objective of this research to address the question of how individuals interpret behavior change failure and persist post-failure. These feedback loops include several factors (i.e. attributions, self-esteem, and hope) to aid in understanding how an individual interprets behavior change outcomes and uses those interpretations as inputs into attitudes towards trying in the future.

Theoretical Model

The theoretical model is based on the model developed in the Theory of Trying (Bagozzi and Warshaw 1990). The theory of trying is employed in this context because it includes two variables that seem very relevant to repeated attempts at changing behaviors (i.e. the frequency and recency of prior attempts at changing behaviors). However, the model proposed by Bagozzi and Warshaw (1990) ends at trying to change behaviors. While the authors do suggest that the outcomes of these behavior change attempts feedback into attitudes, they do not explore the nature of the feedback. In order to explore the nature of the feedback from outcomes to attitudes, this paper employs three constructs—attributions for outcomes, self-esteem, and hope. Each of these factors will now be briefly discussed.

Attribution Theory. Weiner's (1974) theory of attributions posits that there are three dimensions to attributions—locus, stability, and controllability—that assist individuals in understanding the causes of their behaviors and behavioral outcomes. In the model, specific hypotheses, consistent with prior literature on attributions and the self-serving bias, have been developed that explicate how outcomes for success and failure are attributed along each dimension. These attributions also act as input to attitudes towards trying again and as such, hypotheses have been developed to examine several combinations of dimensions that will have the most impact on attitudes.

Self-Esteem. Self-esteem is defined as an individual's subjective appraisal of him or herself (Sedikides and Gregg 2003), which can be influenced by both goal achievement and goal failure (Crocker et al. 2003). As such, individuals in this study are expected to have lower levels of self-esteem post-failure rather than post-success at trying to change behaviors. Hypotheses were also developed and tested to capture the complexity of the interplay between self-esteem and attributions. Finally, an individual's self-esteem is also hypothesized to have a direct effect on that individual's attitudes towards trying to change in the future.

Hope. MacInnis and de Mello (2005) define hope as a positive emotion attached to a goal. There are three important dimensions to hope: goal congruency (i.e. the extent to which an environment is conducive to fulfilling a specific goal), certainty (i.e. the level of confidence an individual has in being able to achieve his or her goal), and importance of the goal. All three of these dimensions should be affected by the individual's success or failure at trying to change behaviors, such that failure at trying to change behaviors should lower an individual's level of hope. Hope is also hypothesized to affect the ways in which individuals understand and attribute the causes of their

behavior change outcomes. Finally, individuals with high levels of hope should have a more positive outlook on the possibilities present in the future, which should enable them to have more positive attitudes towards changing in the future.

Methodology

An internet survey of 363 people who are currently trying to diet was completed. Modifying the procedure employed by Bagozzi and Warshaw (1990), data was collected in two stages, one month apart. Participants were asked to complete a series of measures in the first stage designed to capture their attitudes and intentions to try, the frequency and recency of prior attempts at trying to change behavior, and their current levels of self-esteem and hope. At stage two, one month later, individuals completed a second survey including measures of trying, the outcome of trying, and attitudes towards trying again in the future. Participants will also complete measures capturing their attributions for the outcome of their attempts at behavior change, as well as their updated levels of self-esteem and hope.

Discussion

Overall, this research will enlighten the discussion of how people repeatedly change their health behaviors. The theoretical model extends the Theory of Trying (Bagozzi and Warshaw 1990) by presenting a framework for understanding the various factors affected by the success or failure of a goal and how those factors then feedback into the attitude system. By incorporating concepts such as attributions, self-esteem, and hope into the feedback loops, we introduce several factors that are important in the interpretation of behavior change failure as well as the persistence towards the goal post-failure. There are important implications for both marketing and public policy as a result of this study. From a consumer behavior perspective, this model should shed some light on the effects of goal failure on an individual's attitudes and behaviors. From a public policy perspective, this study could suggest ways in which social marketing campaigns, policy recommendations, and health interventions should be designed.

The Role of "Interpretive Communities" in the Interpretation of "Open Text" Advertisements

Natalia Yannopoulou, University of Warwick, UK
Richard Elliott, University of Bath, UK

There has been a noticeable shift in print advertisements from functional to symbolic approaches as the use of rhetorical style in magazine advertisements has grown progressively more complex and elaborated over time (O'Donohoe, 2001). Thus the interpretation of brands and marketing communication has become extremely challenging, mainly due to the plethora of available cultural meanings and interpretive perspectives in combination with the instability of social categories (Firat and Venkatesh, 1995; Holt, 2002; Kates, 2002). The aim of this paper is to examine print advertising interpretation by different 'interpretive communities', in order to empirically explore how audiences interpret 'open' advertisements.

Multiple Readings

Empirical studies have not only established the existence of multiple readings of advertisements (Elliott, Eccles and Hodgson, 1993, Elliott and Ritson, 1995, Mick and Buhl, 1992), but they have also suggested that ambiguity and complex, non-anchored rhetorical figures may increase elaboration, because the consumer must figure out the advertisement's message (McQuarrie and Mick, 1999; Mothersbaugh, Huhman and Franke, 2002; Warlaumont, 1995). Increased elaboration in turn may increase the memorability of the advertisement (Kardes, 1998). In addition, consumers' pleasure in solving the puzzle of a rhetorical figure can lead to increased attention (McQuarrie and Mick, 1996) and a positive attitude towards the advertisement (McQuarrie and Mick, 1992; Peracchio and Meyers-Levy, 1994).

Open and Closed Texts

Advertising is consumed in a society composed of a variety of groups with different, often conflicting interests, requiring its texts to be what Eco (1979) calls open'. By this he means texts that do not attempt to close off alternative meanings and restrict their focus to one, easily attainable meaning.

This does not, however, imply that reading is completely idiosyncratic. In contrast, reader-response theorists believe that reading is based on collective conventions and that groups of readers can share certain reading strategies, allowing for the possibility of grouping similar readings and shared responses (Scott, 1994a).

Interpretive Communities

One way of achieving this, is through the concept of ‘interpretive communities’, which was introduced by Fish (1980) and proposes that it is “Interpretive communities...that produce meanings...Interpretive communities are made up of those who share interpretive strategies...” (p. 14). Regarding advertising, interpretive communities have been envisioned as a cultural formation with a shared social and historical context that results in similar interpretations (Elliott and Ritson, 1997; Schroder, 1994). As a result, the current study examines interpretive communities based on gender and social class.

Gender and Interpretation of Advertising

Gender differences in meaning interpretation of advertisements has been previously reported by Mick and Politi (1989), and Stern (1992) where males and females interpreted advertising visuals in noticeably different ways. Also Elliott (1995) found considerable differences in the way males and females responded to overt sexuality in advertising.

Social Class and Interpretive Codes

Consumers of different social classes code reality, language, products and advertisements in different ways (Durgee, 1986). Research by Bernstein (1973) on social relationships and linguistic patterns among middle and working class London school children, found two code types, restricted codes and elaborated codes.

Their implications for consumer behavior and advertising interpretation suggest that lower class consumers may perceive products based on their implied meanings and rely on context for their evaluation. They may prefer advertisements that use literal and concrete language and convey an image of a gratifying world in which products fit functionally into the drive for a stable and secure life. On the other hand, middle and upper class consumers may be more attuned to subtle differences of design and style and prefer appeals to more distant benefits, through the use of more symbolic and abstract language (Durgee, 1986).

Research Questions & Method

More specifically, this study will aim to answer the following:

- How do males and females interpret open advertisements?
- How do working and middle class audiences interpret open advertisements?

A reader-response approach was adopted since it emphasizes the meanings that consumers draw from advertisements (McQuarrie and Mick, 1999; Mick and Politi, 1989; Scott 1994). We conducted 40 in-depth interviews in the U.K. with working and middle class participants within the age range of eighteen to sixty years old. Ten advertisements were selected from magazines, based on their open versus closed approach to meaning and on the product categories whose target groups’ correspond to the audience of the research. The concepts emerged were analyzed using the interpretive thematic analysis technique (Spiggle 1994).

Findings

Findings of the in-depth interviews indicate that people of different genders and from different social classes do interpret print advertisements in different ways. As a result and based on the different themes that emerged during the data analysis, we organised our initial findings in the following four propositions, where the first two propositions refer to the gender differences and the last two propositions refer to the social class observed differences.

Proposition I: Male participants approach the advertisement in a descriptive way.

When an advertisement was shown to a male participant, he would approach it by describing it as a picture, stating its figures and elements and by giving an interpretation based on the intended meaning by the advertiser. It can be therefore inferred that the primary concern for males is to state that they are smart enough to understand the advertisement and capable of reading between the lines.

Proposition II: Female participants approach the advertisement in an interpretive way.

On the other hand, when an advertisement was shown to a female participant, she would talk about the elements of the advertisement as they appealed to her and then try to reveal the advertiser’s intended meaning. This observation leads us to think that females are willing to talk about and share personal emotions and past experiences more openly and more quickly than males. Consequently, it seems that females want to appear as free thinkers who no matter what, have something to say.

Proposition III: Working class participants approach advertisements in an implicit way.

Participants from the working class found advertisements that use simple adjectives and descriptors more appealing to them and more appropriate to convey a message that stressed the inherent quality of the featured product. Hence, they approached advertisements in a context dependent way and seemed to be more interested in the implicit fit of the product with their total lifestyle.

Proposition IV: Middle class participants approach advertisements in an explicit way.

In contrast, participants from the middle class approached advertisements in an explicit way. They enjoyed talking about implied meanings and how these could be seen in different contexts.

Thus this study provides insights into how people interpret advertisements and explores through the use of reader-response theory, the symbolic meanings that are drawn by them when consuming an advertisement. These findings present implications for designing marketing communications, with regards to the search and formation of different strategies concerning positioning and brand relationships, towards more flexible, multidimensional tactics and ambiguous messages, in order to be successfully communicated to multiple target groups conceptualized as 'interpretive communities'.

Is Effective Product Placement in Movies?: A Cross-Cultural Study Between French and Spanish Consumers.

Jose Torrano, Technical University of Cartagena, Spain
Enrique Flores, Technical University of Cartagena, Spain

Abstract

Product placement (PP) has taken its place as a major promotional medium, especially these days when consumers have an increasing array of media choices and have the ability to switch in and out of various media as and when they chose too. Based on Dual Mediation Hypothesis Model (Mackenzie et al., 1986), we have analyses PP effectiveness within the international context, and we have compared the results obtained from samples of consumers (French and Spanish). This intercultural framework is justified for the increase of international operations of firms that sell their products and services to a higher number of markets, directed to consumers of different cultures and nationalities.

Conceptualization

Several recent studies have demonstrated that Product Placement (PP) as an advertising technique is more acceptable for viewers than conventional advertising and some of them have demonstrated its effectiveness as an advertising technique (McKecnie and Zou, 2003; Choi and Miracle, 2004). PP has been defined as “the paid inclusion of branded products or brand identifiers through audio and/or visual means, within mass media programming” (Karrh, 1998). The volume and sophistication of PP have grown impressively and rapidly, easily outpacing research efforts in the field (Tiwsakul et al, 2005).

The main contribution of this paper lies in show an effectiveness cross-cultural model in base on Dual Mediation Hypothesis Model DMH (Mackenzie et al, 1986) using French and Spanish consumers. We have chosen France and Spain because they are Western countries, both of them are Mediterranean and Hofstede (2001) indicates that this countries are very similar in his four dimensions (Power Distance Index, Individualism, Masculinity, and Uncertainty Avoidance Index).

The variables of the model: Thoughts about PP, .Attitudes towards PP, Thoughts about brand, Attitudes towards brand and Purchase Intention.

Choi and Miracle (2004) indicate that advertising effectiveness may be implemented by the attitude towards advertising, attitude towards brand and buyer’s intention; a relationship which is widely supported by literature (Mackenzie and Lutz, 1989; Babins and Burns, 1997). Our model, in base on DMH, considers that thoughts generated about Product Placement influence directly on attitude towards PP (Yoon et al., 1995):

H1: Independently of the country, the attitude towards PP will be more positive for consumers with more thoughts about PP than for those consumers with a less thoughts about PP.

With respect to the attitude towards the brand Petty and Cacioppo (1986), with regard to PP, when consumer is exposed to PP, one of the first reactions to that exposure tends to be to demonstrate those feelings evoked.

H2: Independently of the country, the attitude towards the brand is more positive for individuals with more favourable attitude towards PP than for individuals with less favourable attitude towards PP.

As Petty and Cacioppo (1996) indicate, there are a direct relationship between those thoughts about the brand and the attitude towards brand.

H3: Independently of the country, the attitude towards the brand will be more positive for individuals with greater thoughts about the brand than for individuals with fewer thoughts about the brand.

As Makenzie et al. (1986) established, attitude towards advertising influence on thoughts about brand.

H4: Independently of the country, thoughts about the brand will be more positive when the attitude towards PPL is more positive than when the attitude towards the PPL is less positive.

According with (Mackenzie et al., 1986) effectiveness of advertising, finally, is determinate for relationship between attitude towards brand and purchase intention.

H5: Independently of the country, the purchase intention is greater for individuals with a more favourable attitude toward the brand than for individuals with a less favourable attitude.

Method

Subjects: 409 (205 French and 204Spanish undergraduate students).

Design: A 2x2 all between subjects full factorial experiment designs. The independent factors: frequency of watching movies (high, low), and frequency of using the product (high, low). Them a marketing jury determined the movie (actor/actress, brands and film were not Spanish or French). Four groups of these students (1.camera-on set, 2.camera-creative, 3.computer-on set, and 4.computer-creative) watched ten minutes of the film each one, in the university theatre. Those students filled the questionnaire with Karrh’s (1998) Product Placement definition.

Major Findings

The results of the hypotheses:

- H1: [F (1,405)=16.058; p<0.1], so it is supported. The results [F(1,405)= 1.469; p=0.226] also indicate that there are no differences between French and Spanish consumers.
- H2: [F (1,405)=0.115; p= 0.735] make us reject this relationship and refuse this hypothesis. With respect to the possible differences between French and Spanish consumers, the analysis indicates that there are no significant differences [F(1,405)= 2.041; p= 0.154].
- H3: [F (1,405)=4.683; p<0.1] indicate that this relationship is significant. Regarding the existence of possible differences between French and Spanish consumers we have indicates that there are significant differences [F (1,405)=40.573; p<0.1].
- H4: [F(1,405)= 7.848; p<0.1], we accept hypothesis H4. The analysis indicates that there are no significant differences between French and Spanish consumers [F(1,405)= 0.152; p= 0.697].
- H5: [F (1,405)=58.586; p<0.1], it is a significant relationship, and there are significant differences between both groups of consumers [F(1,405)= 7.535; p< 0.1].

The results have demonstrated that we can conclude that we can use MDH model, made to advertising, to demonstrate the effectiveness of PP, but in our study, the relationships are as follow: thoughts about PP influences on attitude towards PP, attitude toward PP influences on thoughts about brand, thoughts about brand influences on attitude towards brand, and attitude towards brand influences on purchase intention.

With reference to cross-cultural aspect, the results show that there are not significant differences between French and Spanish consumers. These outcomes are very important for Marketers and firm that works in international markets. For our study Hofstede's model (2001) is a good predictor for cross-cultural studies.

Teenagers' Willingness to Share Personal Information with Marketers

Anu Sivaraman, University of Delaware, USA

Dan Freeman, University of Delaware, USA

Stewart Shapiro, University of Delaware, USA

Despite growing concerns, few empirical studies have examined how teenagers respond to marketers' information collection and use practices. The objective of this research is to understand how factors like materialistic values and dislike of marketing tactics may affect the extent to which teenagers are willing to share personal information with marketers. Consistent with study hypotheses, results from a representative sample of 709 U. S. teens indicate that the dislike of marketing tactics plays a moderating role in the positive relationship between materialism and willingness to share information. Self-esteem and susceptibility to peer influence also affect willingness to share personal information.

Why Do We Overbuy? Value from Engagement and the Shopping-consumption Discrepancy

Dilney Goncalves, INSEAD, France

The recent decades have witnessed an unprecedented increase in consumer discretionary income. The increased income allied with cheaper consumer goods shifted consumption from necessities to more hedonic products. With this trend, another phenomenon became more apparent and important: *overbuying*. Overbuying, or the act of purchasing an object and not consuming it, may have several causes. It may result from bad predictions about future and needs or from changes in taste. We propose another explanation, namely that engagement in the act of shopping temporarily increases the value of objects to shoppers.

We build on Higgins' theoretical framework on value from hedonic consequences and engagement. Higgins (2006) proposes that the value of an outcome depends not only on the hedonic consequences (pleasure or pain), but also on the strength of engagement in obtaining the outcome. According to this conceptualization, hedonic consequences contribute to value by determining the valence (positive or negative) and influencing its intensity. However, intensity is also determined by the strength of engagement. When people are strongly engaged in obtaining a certain outcome, its value becomes more extreme: negative outcomes become even more negative and positive outcomes become even more positive. To be engaged is "to be involved, occupied, and interested in something. Strong engagement is to concentrate on something, to be absorbed or engrossed with it." Differently from the valuation effect (Brendl, Markman, and Messner 2003), value from engagement is not caused by activation of goals. Instead, it comes from the way a goal is pursued and how the goal pursuit is experienced.

Four sources of engagement are described by Higgins: opposition to interfering forces, overcoming personal resistance, use of proper means, and regulatory fit. For the purposes of our study, the most relevant of these sources is opposition to interfering forces. The experience of motivational force increases with the presence of interfering forces as long as these forces are not strong enough as to make people abandon the goal altogether.

The contribution of this research is twofold: (1) we show that there is a discrepancy in value between shopping and consumption occasions and (2) we demonstrate that engagement increases WTP; Additionally we provide a novel way of manipulating engagement in an online shopping context. From a consumer welfare point-of-view, our research suggests that consumers should try to correct their estimates of enjoyment of a particular product, especially when the shopping environment is engaging. From a marketer's perspective our second experiment suggests a simple way of increasing engagement in online shopping, leading to greater valuation of products.

In the first experiment, we explored discrepancies in value between shopping and consumption. One hundred eleven participants were randomly assigned to one of four conditions. They were asked to report a recent purchase or to predict a future purchase. The design was a 2x2 between-subjects factorial. The first factor was reporting past experience or predicting a future experience. The second factor was focusing on the shopping occasion or the consumption occasion. The dependent variable was "when you think about the moment you bought (consumed) this product, how happy does it make you feel?"

An ANCOVA with days from actual (expected) purchase and price as covariates revealed only a significant effect of the time X focus interaction. Thinking about future consumption leads to greater happiness than thinking about past consumption ($M_{\text{future}}=7.12$; $M_{\text{past}}=6.33$; $p=0.032$). When thinking about shopping, subjects' happiness from past shopping did not differ significantly from future shopping ($M_{\text{past}}=6.85$; $M_{\text{future}}=6.48$; $p=0.19$). These results suggest that people make inaccurate predictions about consumption but relatively accurate predictions about shopping. Importantly, there seems to be a discrepancy between shopping and consumption: while shopping, people expect greater pleasure from products than they actually experience.

The second study was designed to test whether greater engagement leads to greater valuation of products and greater purchase likelihood. Participants were 158 members of the community of a large Brazilian university. They were recruited by email. As an incentive, they were entered in a lottery to win one MP3 player. The email contained a link to a webpage with the experiment. The first page introduced the research and the cover story that we were investigating how people evaluate and choose products online. Participants were randomly assigned to one of two conditions. They were asked to state their willingness to pay for three models of MP3 player and how much they liked each model. We also measured engagement using three items: how involved, how absorbed, and how focused on the task they were.

Engagement was manipulated by varying the effort in information search. Half the subjects (high-engagement) had to click on a link to access each product's attribute information whereas the other half (low-engagement) got all the attribute information with just one click. By making it more difficult to access product information, subjects in the high-engagement had to actively seek information. High-engagement subjects were required to click on each link at least once. On clicking, they saw a page with a picture and description of the MP3 player. The number of times subjects clicked on each link was recorded. In the low-engagement condition, subjects saw the same pictures of MP3 players, but all the features appeared on the same page in a table under the pictures. No action was required in this condition. The dependent variables were willingness-to-pay for and liking of each model.

Effort was found to increase engagement up to a certain point, after which more effort reduced engagement (inverted-U relationship). More importantly, we found that people who engage more in the process of product information search and comparison stated greater willingness-to-pay than do those who engage less in the process. This result supports our hypothesis that engaging in shopping increases value.

Although we have shown that engagement increases willingness-to-pay, a next study will be executed to examine whether this translates in greater purchase.

Advice from a Caterpillar: Mainstreaming Hookah Consumption Into American Pop Culture

Merlyn A. Griffiths, University of North Carolina-Greensboro, USA

Tracy R. Harmon, Syracuse University, USA

Hookah smoking is a less known entity for consumer behavior researchers. Research on consumers' smoking behaviors have been vast in the marketing area, and has offered compelling evidence of the negative effects of smoking. The majority of these studies have focused primarily on cigarette consumption and the effects of advertising messages, antismoking messages and placement in media, as well as the addictive effects on adolescents, teenagers and young adults (see Pechmann and Reibling 2006; Pechmann and Reibling 2000; Pechmann and Shih 1999; Pechmann and Ratneshwar 1994; Pechmann et al. 2003). However, no studies to date have focused on American consumers' adoption or practice of hookah smoking. Just what is the appeal of this practice, and to what might we attribute its epidemic-like spread in mainstream culture. We investigate this phenomenon and identify factors relating to consumer attitudes, beliefs and attributed meanings that are contributing to the proliferation of hookah smoking.

Employing qualitative methods, our findings point to a significant disconnect for consumers in their perceptions. We have found nostalgic emotional disconnections, and disconnection of the risks and consequences involved in hookah consumption relative to cigarette and cigar smoking. Hookah consumption is viewed as a positive pleasurable experience that fosters group bonding.

Who to Choose? Source Credibility and Attractiveness of Endorsers in the 2008 Presidential Primaries

Pamela Grimm, Kent State University, USA

Hyunjung Lee, Kent State University, USA

Neslihan Yilmaz, Kent State University, USA

Endorsements in politics are ubiquitous, especially in the run-up to a presidential election. Though both marketers and politicians try to influence consumer/voter behavior through endorsements, the endorsement process in politics is more complicated than in marketing for several reasons. First, in marketing the endorser is usually a celebrity or expert on the product category, is paid for his or

her endorsement and, typically, an endorsement is not made unless a relationship (usually contractual) exists between the firm and the endorser.

In politics, celebrity endorsements seem less important than endorsements from sources such as other politicians. Endorsements in politics are not paid, there are no contractual relationships and some endorsements are rejected by the candidate because they are viewed as liabilities rather than assets. This rejection of an endorsement is a phenomenon seldom seen outside of the political arena.

It is especially clear in the 2008 Presidential Primary that endorsements matter. The campaigns make a point of sharing news about positive endorsements and several candidates have found themselves in the position of either having to reject or explain endorsements from sources viewed as negative by some voters. Yet, despite this obvious importance, there is only a limited understanding of the relative importance of different types of endorsers or the factors that drive the importance of an endorser.

This research provides insight into four broad categories of endorsers. These categories are: politicians, newspapers, organizations representing interest groups (ex: labor and religious groups) and celebrities. Evidence of the importance of most of these types of endorsements is found primarily in the Political Science literature, though the popular press has also been weighing in on this question as well. Political endorsements (Schulte 2008; Thomas 2008; Tumulty 2008), newspaper endorsements (Cooper, 2007; Erikson 1976; Stengel 2008), interest group endorsements (Grossman & Helpman 1999; Maher 2008; McDermott 2006; Rapoport, Stone, & Abramowitz 1991), and celebrity endorsements (Celeb in chief 2007; Goodnight 2005; Jones & Carroll 2007; Payne, Hanlon, & Twomey III 2007; Weiskel 2005) have all been studied, though typically in isolation from other types of endorsements.

This paper examines and compares these different types of endorsers utilizing the Source Credibility and, in the case of celebrities, the Source Attractiveness models of endorser effects (Ohanian 1990). Application of these models in the context of political endorsements has not been done, though this application was suggested by Ohanian (1990). Using these models should provide greater insight into the mechanisms underlying endorsement effects in a political context.

Subjects in the research were undergraduate students from an Ohio public university who were given extra credit for participating in the research. The survey was administered online and was made available 36 hours before the March 2008 Primary in Ohio. The survey included items designed to gather information regarding party affiliation, primary candidate preferences, source credibility for each of the four categories of endorsers (politicians, newspapers, interest groups and celebrities) and attractiveness and importance of eight specific endorsers. Subjects rated two actual endorsers for each of the four categories of endorsers, for a total of eight endorsers. The eight specific endorsers rated by a subject depended on the subject's primary candidate preference. The items used for source credibility and attractiveness were those developed by Ohanian (1990). A single seven point item (with 1 as "not at all important" and 7 as "very important") was used to gauge the importance that a subject assigned to a given endorser.

Overall, 355 surveys were retained; 85 respondents were registered Republicans, 135 were Democrats and 40 were independent. The remaining subjects were not registered. The source credibility items were administered to all subjects, but the source attractiveness and importance items were only administered to those subjects who were registered to vote.

The ten items representing source credibility were averaged, as were the five items representing source attractiveness. The results demonstrate that, in general, consumers/voters evaluate the different endorsers in significantly different ways based on source credibility. Other politicians are viewed as most credible (mean=4.9 average on a seven point scale), followed by newspapers (4.3), interest groups (4.2) and celebrities (3.6) ($p < .001$).

The rank ordering produced by the Source Credibility items is mirrored in the importance ratings assigned to the specific celebrities in each category for each candidate. The average importance for politicians was 4.7; for newspapers 4.3; for interest groups 3.9 and for celebrities 2.9. Politicians are considered most credible and important and celebrities are considered least credible and important.

The Source Credibility scale can be further decomposed into two sub-factors: trustworthiness and expertise. A factor analysis of the scale items for each of the four categories of endorsers showed that the pattern of factor loadings followed the results of Ohanian except for celebrity endorsers. Means were computed on the two sub-factors for politicians, newspapers and interest groups. Results show significant differences between the three groups in terms of trustworthiness and expertise. Politicians are rated higher in terms of both expertise (5.42) and trustworthiness (4.39) than the other two groups, though the difference between politicians and interest groups, in terms of trustworthiness, is not significant. Newspapers are rated second in terms of expertise (4.49) but third, behind interest groups, in terms of trustworthiness (4.14). Interest groups are not significantly different from politicians in terms of trustworthiness (4.31) but are significantly lower than politicians and newspapers in terms of expertise (4.17).

Source attractiveness measures were collected for the two celebrities endorsing each of the four specific candidates. The average attractiveness measure was 4.11 across the eight celebrities included in the study. The relationship between attractiveness and the importance assigned the endorser was positive and significant ($r = .406$, $p < .001$).

This research demonstrates the value of utilizing the Source Credibility and Attractiveness framework in a political context. There are significant differences in how different types of endorsers are viewed in terms of credibility in general, and trustworthiness and expertise in particular. Further, credibility is mirrored in the importance assigned to endorsers by consumers. Celebrity attractiveness is also linked to the importance assigned to a celebrity's endorsement.

Yes, The Poor Can Be Taught To Save-Evidence From a Survey of IDA Program Participants

Caezilia Loibl, The Ohio State University, USA

Beth Red Bird, The Ohio State University, USA

Michal Grinstein-Weiss, The University of North Carolina at Chapel Hill, USA

Min Zhan, University of Illinois at Urbana-Champaign, USA

Abstract

The question whether multi-year, intensive financial literacy programs aimed at helping those with low incomes and few assets actually work out in the long-run has not yet been answered. The current study is the first to scrutinize the outcome of participation in the Individual Development Account program in order to fill this void. The findings of a mail survey suggest that those who completed the program are more likely to accumulate assets, continue saving, and establish investment accounts, compared to those leaving the program prematurely. The influence of self-control and future orientation on savings behavior is discussed.

Conceptualization

Though saving is important to many low-income families, it can appear to be an impossible task in the context of a day-to-day effort to make ends meet. A number of psychological factors hamper regular savings. The lower the income, the higher tends to be the rate of time preference due to the many unfulfilled needs, which, in turn, leads to a lower willingness to delay gratification and to consider future consequences of current financial choices. Procrastination and naivety about this tendency contribute to people's belief that they will save tomorrow even if they are not saving today. Loss aversion suggests that people weigh the reduction of disposable income due to savings deposits more heavily than an equivalent future gain in consumption provided by the accumulated wealth.

The Individual Development Account (IDA) program has been designed with these factors in mind to help participants overcome the barriers to regular savings. IDAs are tax-protected, matched savings accounts designed to help those with low incomes and few assets to buy a home, capitalize a business, or fund higher education (Schreiner and Sherraden 2007). The current study is the first (to the best of the investigators' knowledge) to study the long-term outcomes of IDA program participation in order to answer the question whether those who complete the program continue to save and accumulate assets.

Method

A survey was mailed to all 465 former participants of an IDA program provider in the Midwest using best survey practices. A total of 164 usable questionnaires were returned (response rate: 43%); of those, 126 were returned by program graduates and 38 by program dropouts. A weighting correction was applied to the data to account for non-responses using normalized inverses of modeled response probabilities (Lohr 1999). The questionnaire inquired about six psychological (self-mastery; future orientation; self-control; economic strain; finances since IDA program; finances in a year), four program-related (graduation, months passed since IDA program, months in the program, asset type), nine financial (own checking/ savings/ investment/ credit card/ fixed-payment/ mortgage account; household savings; credit card debt; decision authority), and nine basic demographic measures.

Major findings

Do IDA program graduates continue to save?

An OLS regression model was fit to the data using household savings as the dependent variable and the demographic, financial, program-specific, and psychological metrics as independent variables. Program graduation emerged as a highly significant predictor of household savings. Program graduation resulted in \$341 higher household savings. Consistent with previous studies, we find future orientation to increase household savings.

Do future orientation and self-control develop during program participation?

To further assess the role of program graduation in individuals' future orientation, an OLS regression model was fit to the data using future orientation as dependent variable and the demographic, financial, program-specific, remaining psychological metrics, and the interaction terms with program graduation as independent variables. The results showed that a set of important savings predictors seemed unaffected by program graduation. We find the relationship between future orientation and self-control to be most important here. This observation may point toward the notion of a certain similarity in these psychological dispositions among those entering the IDA program, regardless of outcomes. While program graduation helped develop self-control, it did not affect future orientation, which emerged as a main effect in predicting household savings.

In conclusion, we propose that successful IDA program completion creates financial dispositions and behavior that provide long-term benefits. The program graduation variable itself provided a good predictor of household savings. The strict program structure and intensive financial training over several years time, we suggest, might succeed in building the willpower needed to achieve savings goals independently, long after leaving the care of the IDA program.

Falling in Love with Brands: An Inductive Qualitative Exploration of Pathways to Emotional Attachment

Doug Grisaffe, University of Texas at Arlington, USA
Hieu Nguyen, California State University, Long Beach, USA

Introduction

Emotional attachment to brands (EAB) is a relatively new construct in the consumer behavior literature and little is known about the construct except a seminal scale development paper (Thomson, MacInnis and Park 2005—hereinafter referred to as TMP). The process through which EAB, as a basis of deep “brand relationships” (Park and MacInnis 2006), is developed remains far from well understood. The purpose of our paper is to explicate a set of *underlying psychological mechanisms* that consumers themselves cite as reasons for developing and exhibiting devoted EAB. Our paper contributes to the understanding of the EAB construct and expands the discoveries of TMP's work by presenting the pathways through which EAB is formed. We also address some issues that TMP point out as unanswered in their research.

Method

Given the relative infancy of this line of research, we intentionally designed our study to be inductive in nature. We asked 125 respondents to explain in their own words the reasons why they feel emotionally attached to brands that they listed. We then used a thematic content analytic approach to extract a set of data-reductive codes that capture and summarize the original responses. To interpret our findings, and to provide initial support for their validity, we bridge back to broader theoretical and empirical literature in consumer research. Eighteen frequently-mentioned themes emerged from our analysis which we grouped into four “pathways” reported below.

Findings*Pathway 1: Marketing Characteristics, Value, and Satisfaction*

Oliver (1989) proposes a research approach that has been extensively used in the satisfaction literature: the comparison standards paradigm. The paradigm suggests that consumers hold certain product standards prior to consumption, observe product performance, compare the actual performance with their standards, form confirmation/disconfirmation perceptions, combine these perceptions with standard levels, and form satisfaction judgments with the product. Many respondents in our study cited satisfaction with the focal brand as the main driver for their EAB. This satisfaction is derived from perceived values including pricing (better prices), product (superior product quality and design), promotion (corporate image and advertising/market communication activities), and distribution (product/service availability, physical facilities). We propose that the first pathway to EAB is through customer satisfaction with superior product and service values as reflected in marketing characteristics.

Pathway 2: Utilitarian and Hedonic Benefits-What the Brand Does for Me

Fournier (1998) suggests that in close consumer-brand relationships, consumers come to identify and be involved with many of the brands they regularly consume. One important reason why people form lasting brand relationships is that such behavior helps create their personal identity and construct their own self concept (Ball and Tasaki 1992; Belk 1988). Work by Park, Jaworski, and MacInnis (1986) and Keller (1993) shows that there are three general dimensions of brand identities: functional, symbolic, and experiential. Brand functional attributes represent the utilitarian function or benefits of the product. Our data show that oftentimes consumers tried different brands but only one brand would provide the most satisfying solution to their problem, which formed the foundation of their EAB. These brands can aid consumers in fulfilling either a self-oriented goal (internally driven, e.g. having younger looking skin, softer hair, stronger teeth) or a social-oriented goal (supporting consumers' identity and social/professional roles, e.g. expressing self identity). Enhancing consumers' role in and out of the home is another attribute that these brands often possess.

Pathway 3: Consumer Socialization and Intergenerational Influence

Brands can also serve a social purpose by reflecting social ties to one's family, community, or cultural group (Muniz and O'Guinn 2001). Since the family is typically a consumer's most significant reference group, one way in which these social ties may be formed is via intergenerational transfer (Moschis 1985, 1987). In our surveys, many consumers revealed that they became emotionally attached to brands that they grew up with and their parents never used other brands. Many respondents also reported EAB with brands that their parents used as a way to "honor" the family tradition. The "family tradition" theme is not only limited to high-involvement, expensive branded goods, our respondents also reported their attachment to brands of fast-moving consumer goods such as soft drinks, laundry detergent, mayonnaise, and cookies.

Pathway 4: Sentimentality and Emotional Memories

Our fourth pathway to EAB involves an especially personal and meaningful pairing between a brand and some situation(s), experience(s), place(s), and/or person/people. For example, a woman might recall the "ritual" of visiting her grandfather as a child, sitting on the front porch of his house, and sharing Coca-cola and a Snickers candy bar. Now as an adult, she often has Coca-cola and a Snickers bar, and it reminds her of her grandfather, his house, and their front porch talks. With Pathway 4, specific brands become powerfully connected to sentimental and emotionally-imbued memories involving some meaningful place, situation, experience and/or person. It is as if repeatedly returning to the brands invokes a commemorative re-experiencing of some favorable or even longed-for past. It should be noted that inter-generational transfer doesn't require sentimental/emotional memory. Transfer alone could involve a user of Tide simply saying her grandmother used it, her mother used it, and so she uses it too. Likewise, Sentimental and Emotion memory does not require inter-generational dynamics. Someone might say he drank Taster's Choice coffee with his first long-term girlfriend in college while they stayed up nights to study. He reflects back fondly on those times to this day when he buys Taster's Choice. Thus Pathway 4 can correlate with Pathway 3, but not necessarily.

Conclusion

We expand the understanding of the EAB construct, initiated by TMP, by showing the pathways through which consumers form their EAB. We were also successful in having respondents report on brands with extreme levels of emotional attachment. While TMP's results suggest that brands to which consumers are emotionally attached tend to be high involvement and symbolically or hedonically related, our results show that EAB is also evidenced in low involvement and functionally related product categories. This finding could be more formally tested by controlling brands within different product categories (e.g. low vs. high involvement, utilitarian vs. hedonic). Future research should also examine the strength of each pathway, as well as the relation between EAB and market leadership.

What We Will Feel Depends on Who We Are: Cross-Cultural Differences in Affective Forecasting of "Ego-focused" Versus "Other-focused" Emotions

Vanessa Patrick, University of Georgia, USA

Henrik Hagtvædt, University of Georgia, USA

Abstract

In this research we aim to demonstrate that cross-cultural differences exist in the way individuals construct future events and consequently predict specific emotions. Five hundred and sixty-two participants from USA and India completed one of ten different versions of a questionnaire that varied 1) the positivity of the future experience, 2) whether the future experience was an individual vs. a group experience, and 3) familiarity with the future experience. Open-ended analysis is designed to reveal cross-cultural differences in the way future events are constructed. Quantitative assessment is designed to reveal differences in the forecasted emotions associated with these events.

There never was in the world two opinions alike, no more than two hairs or two grains; the most universal quality is diversity.
-Michel de Montaigne (1533-1592)

Recent research in consumer behavior has begun to examine the role of emotions in a cross-cultural context (Aaker and Maheshwaran 1997; Aaker and Williams 1998; Aaker and Lee 2001; Williams and Aaker 2002). However, the role of cross-cultural differences in the forecasting of emotions is an area that remains uninvestigated in the extant literature and forms the focus of the current research.

Affective Forecasting: Prediction of Future Affective States

A vast array of consumption activity is based on how consumers predict they are likely to feel at a future point in time. The choice and decision to consume is often based on a prediction of the emotional consequences of the consumption experience.

Affective forecasting (Gilbert et al. 1998) deals with a person's prediction of a future affective state. Recent research has demonstrated that making accurate affective forecasts is difficult and susceptible to a variety of errors and biases (Gilbert et al. 1998; Loewenstein and Schkade 2000) leading to affective misforecasting (Patrick, MacInnis, and Park 2007). Indeed, people exhibit what has been referred to as "impact" bias (Gilbert et al. 1998), where people tend to overestimate what the duration of their affective states will be, and "intensity" bias (Buehler and McFarland 2001), where people tend to overestimate the intensity with which they will experience a particular affective state.

In this research, we contribute to the extant research in two ways: 1) we investigate these biases in a cross-cultural context, and 2) we demonstrate these biases with specific emotions, namely ego-focused versus other-focused emotions.

Cross-cultural Differences in Affective Forecasting of Emotions

Extant research has demonstrated that the recognition and experience of many emotions appear to be cross-culturally robust. There has been support for the universality of basic emotions (Osgood, May, and Miron 1975), specific emotions like anger, surprise, fear, and empathy (Matsumoto 1989), and the recognition of these emotional states (Ekman 1984). However, significant cross-cultural differences do exist. Indeed, Triandis (1993) demonstrated that cross-cultural differences in emotions were a result of systematic cultural variations in the concerns of individuals, which in turn arose from differences in self-construal.

Based on this notion, cross-cultural research on emotions focused on "ego-focused" and "other-focused" emotions, and examined "the degree to which specific emotions systematically vary in the extent to which they follow from, and also foster or reinforce, an independent versus interdependent self" (Markus and Kitayama, 1991, p. 235). Thus, one would expect that in individualistic cultures (e.g., the United States, Western Europe, and Canada) the personal and subjective part of one's emotional experience is dominant, and "ego-focused" emotions like happiness, pride, frustration, and anger are more salient. On the other hand, in collectivist cultures (e.g., India, China, and Japan) the interpersonal and inter-subjective aspects of one's emotional experience is dominant, and "other-focused" emotions like empathy, guilt, and shame are more salient.

One might therefore posit that in predicting one's future emotional state (affective forecasting) people from different cultures would be likely to focus on different emotional/affective states, take into consideration different factors while making the affective forecast, and exhibit different errors or biases in their affective forecasts. The current thinking on the process of affective forecasting is that predictions of future affective states are made by conjuring up images of the future situation and predicting emotional reactions based on reactions to these images (Gilbert et al 2002).

Based on this we can expect that in individualist cultures the prediction of future affective states and subsequent decision to consume will be based solely on one's own personal tastes and preferences (happiness, pleasure, pride) while in collectivist cultures this prediction will also take into account the interpersonal and inter-subjective aspects of this decision (social approval, guilt, empathy).

Empirical Investigation and Data Analysis

This study employed a survey-based method designed to discern the categories of emotions that are forecasted and the nature of the thoughts associated with making the forecast for a variety of future events.

Five hundred and sixty-two participants (from India and USA) completed one of ten different versions of a questionnaire that asked individuals to forecast future experiences that varied 1) the positivity of the experience (e.g., restaurant vs. dentist visit), 2) whether the experience was an individual versus a group experience (e.g., a first job vs. a wedding), and 3) the familiarity of the experience (e.g., a vacation vs. winning the lottery). After constructing and describing the future experience, participants reported the extent to which they predicted a set of emotions would occur. Prediction of general positive and negative emotions, as well as ego-focused and other-focused emotions, was assessed. In addition, we measured individual differences in optimism, future orientation, and ability to consider future consequences. We expect that these variables in conjunction with the affective forecasts will help us discern cultural differences in individuals' ability to construct their future.

The analysis of both the quantitative and the qualitative aspects of the data are underway and will be completed by ACR 2008. The qualitative analysis has required the development of an extensive coding scheme to analyze the open-ended data. A brief summary of the preliminary quantitative results are outlined below:

- Participants in the individualist culture (USA) predicted more "ego-focused" versus "other-focused" emotions compared to participants in the collectivist culture (India)
- Participants in the individualist culture (USA) are more polarized in their affective forecasts (demonstrate a stronger impact bias) than participants in the collectivist culture (India). In other words, participants from individualist cultures predict more intense positive emotions for positive events and more intense negative emotions for negative events compared to collectivist cultures
- Participants in the individualist culture (USA) are more confident of their future feelings than participants in the collectivist culture (India)

Contributions of this research:

From a theoretical perspective, this research contributes to the extant literature by 1) demonstrating cross-cultural differences in the way future events are constructed, 2) introducing cross-cultural differences as an important variable that influences prediction of future affective states, and 3) demonstrating affective misforecasting biases for specific emotions, namely ego-focused versus other-focused emotions.

The Effects of Negative Feelings Caused by Forced Exposure to Banner Ads on Advertising Responses

Jung Ok Jeon, Pukyong National University, Korea
 Hyun-Hee Park, Kyungpook National University, Korea
 Jin-Hwa Lee, Pusan National University, Korea
 Yoon-Ho Kim, Pukyong National University, Korea
 Hee-Young Han, Pukyong National University, Korea

Most exposures to advertisements in traditional media occur at the same level of forced or intrusive exposure conditions. Unlike traditional media, the internet advertising makes it possible for the audience to be exposed to advertisements at many different levels of forced exposure. Moreover, as presentation techniques of the web rapidly advanced and sophisticated, the advertisers can generate different levels of advertising conditions. Despite such unique characteristics of the internet advertising, there are little research regarding the negative impact of different levels of forced exposure conditions on consumers' feelings, as well as on ad processing including avoidance behavior.

This study examines the possibility that the intensity level of forced exposure in banner ads may affect consumer's negative feelings, ad avoidance, and ad attitude. Especially this study sheds light on the moderating roles of negative feelings and ad avoidance. Based on literature review, it was hypothesized that: (H1) level of forced exposure and involvement would cause differences in relationships among negative feelings, ad avoidance, and ad attitude; (H2) negative feelings would be positively related to ad avoidance; and (H3) ad avoidance would be negatively related to ad attitude.

For the experiment, 2(forced level: no-skip 5" vs no-skip 10") x 2(involvement: high vs low) factorial designs were used. A total of 161 undergraduate students in Korea participated in the experiment. To represent different experimental conditions, two different types of banner presentation formats were created. For each condition, a pop-up window containing banner ad appeared when subjects opened the designated website. For the measure, negative feelings consisted of 3 dimensions: annoyance, irritation, and embarrassment. And, ad avoidance consisted of 2 dimensions: cognitive avoidance and physical avoidance.

It was found that the level of forced exposure showed significant differences in relationships among negative feelings, ad avoidance, and ad attitude. And, among negative feelings, feelings of annoyance significantly induced both of cognitive avoidance and physical avoidance, while irritation induced cognitive avoidance only. Also, both of ad avoidance dimensions negatively affected ad attitude. With the implications of these findings, extensive suggestions for future research are provided.

Consumers, Companies and Virtual Social Worlds: A Qualitative Analysis of Second Life

Andreas M. Kaplan, ESCP-EAP European School of Management, France

Michael Haenlein, ESCP-EAP European School of Management, France

When a company wishes to receive press coverage these days, a fairly safe bet is to announce corporate activities within the online application "Second Life". Second Life (SL) is a three-dimensional virtual social world that opened to the public in 2003 and in which users can interact with others in real time using personalized avatars. SL residents can explore their environment, meet and speak with each other and buy a wide variety of virtual products. The currency in SL is the Linden Dollar, which can either be obtained by exchanging US\$ via the SL Exchange or by searching for a job for the avatar. More interestingly, Linden Dollars can also be re-exchanged into US\$, making it possible to earn Real Life (RL) money by selling virtual products and services within SL.

SL is part of a group of Internet applications that can be subsumed under the term "virtual social worlds" and which can be considered as specific forms of virtual hyperrealities. Hyperrealities are one of the five conditions of postmodernism (e.g. Firat, Sherry, and Venkatesh 1994; Firat and Venkatesh 1993; Venkatesh, Sherry, and Firat 1993) and have previously been discussed in consumer research in the context of tourist attractions (e.g. Grayson and Martinec 2004) and media products (e.g. Rose and Wood 2005). We hypothesize that virtual social worlds offer unique benefits compared to traditional hyperrealities in the areas of marketing research and advertising. With respect to marketing research, we refer to Kozinets (2002) and his concept of netnography within online communities. Regarding advertising, we draw on previous literature showing that product placements in online games (e.g. Lee and Faber 2007; Nelson 2002) and virtual worlds (e.g. Schlosser 2003, 2006) positively impact brand attitudes and purchase intentions. However, despite these potential business benefits, few researchers have until now investigated consumer behavior within virtual social worlds.

Our analysis of SL is based on a series of 29 qualitative in-depth interviews with SL residents which we summarize in one integrated conceptual framework (e.g. Spiggle 1994). In the center of this framework is the SL resident, who appears in form of an avatar that can be considered as the virtual representation of an associated RL user. Similar to the RL user, who maintains a RL social network and RL exchange relationships with RL companies, the SL resident interacts as part of a SL social network and consumes products and services provided by SL stores. Such stores can either be set up and run by other SL residents (SL resident-owned stores) or be the virtual representations of RL companies within SL (SL flagship stores). This SL experience is connected to RL in two different ways: First, there is a potential connection between the SL resident and RL company if the latter uses Second Life for functions such as marketing research or the distribution of RL products (virtual commerce). Second, there can a connection between the RL user and the SL flagship store, for example if brand exposure within SL impacts RL purchase decisions similar to the effect of traditional or banner advertising.

Based on our conversations, we identify four key motivations for using SL: the search for diversion, the desire to build personal relationships, the need to learn and the wish to earn money. The first three motivations are similar to the gratifications sought from traditional mass media consumption (e.g. McQuail, Blumler, and Brown 1972), while the last one appears to be specific to SL. In line with previous findings in the context of personal webpages (Schau and Gilly 2003) there is a close resemblance between their RL personality and their SL avatar for some users, while for others there tends to be a substantial difference. The key social reference group for SL residents is their virtual friends within SL, while their RL friends are often unaware of their SL usage. Regarding purchase behavior, we observe impulse as well as planned purchases. This implies that at least for some part of their purchases SL users "plan ahead" before buying specific items, which closely mirrors behavior that can be observed in RL settings. SL users generally expect that the products available in SL flagship stores closely mirror the ones offered by the company in RL. This does not, however, imply that such products cannot be mildly adapted to the specific conditions of SL. Our interviews provided mixed support for ideas raised in the business press (e.g. Enright 2007) that companies could use their SL flagship stores to improve RL brand awareness, mainly because respondents stated to only rarely visit such stores. However, the idea of considering SL flagship stores as an extension of traditional e-Commerce activities and use them to distribute RL products generally seems to evoke positive reactions among SL users. Especially categories such as music, computers and books were named as prime examples for this form of distribution.

Overall, our analysis shows that users do not consider SL as a mere computer game, but as an extension of their RL. At some point (most likely with increasing usage intensity or consumption frequency), SL users seem to start engaging in activities that span beyond the single usage occasion so that the planning horizon that underlies SL usage goes beyond the actual time spent within the virtual social world. Regarding the business potential of this new medium, we find mixed support regarding SL's ability to influence RL brand attitudes and purchase intent. Simply setting up a flagship store within the virtual world is unlikely to be a promising advertising strategy. Instead, companies may need to supplement their virtual SL presence by regular events in order to maintain its attractiveness and attract a sufficient number of SL users. However, SL flagship stores could be used for the distribution of RL products and potentially help to overcome some of the drawbacks still associated with electronic mass customization (Kaplan and Haenlein 2006) and e-Commerce in certain product categories, such as the lack of physical product contact in the context of fashion items (Keeney 1999).

Consumer Hope Scale: Development and Validation of Dispositional and Situational Measures

David Hardesty, University of Kentucky, USA

Blair Kidwell, University of Kentucky, USA

Jason Rowe, University of Kentucky, USA

Abstract

This research details the development and validation of measures to assess consumer hope. We develop both dispositional and situational measures to capture the three dimensions of hope; "to hope", "to have hope", and "to be hopeful." Results supported the scale's reliability and its discriminant and nomological validity. Our domain-specific dispositional consumer hope measure predicted consumer outcomes, such as subjective knowledge, better than domain-general alternatives. Furthermore, our context-specific situational consumer hope measure in the context of healthy food choice, predicted food-related outcomes such as impulsive eating, involvement toward food choices, and anticipated regret from making poor food choices, beyond alternatives.

Introduction

Recent work by MacInnis and colleagues (MacInnis and de Mello 2005; de Mello, MacInnis and Stewart 2007) has established the importance of hope in consumer research. Despite these contributions, an appropriate hope scale has yet to be developed and psychometrically assessed that can effectively distinguish hopeful from less hopeful consumers, and the important marketing outcomes that might result. Furthermore, researchers continue to pose questions for future research, such as, what is the role of hope in exchange relationships and how do consumers use hope to make decisions (de Mello, MacInnis and Stewart 2007). These questions have remained largely unanswered. Without the ability to recognize the hope of customers, and in turn, understand the ramifications of hopeful versus hopeless consumers, there remains a significant aspect of consumer behavior that is not only neglected and not well understood, but one that could provide meaningful prediction of important consumer outcomes.

In this research, we develop and validate two measures that assess related yet distinct aspects of consumer hope—dispositional and situational—that will allow researchers to extend our knowledge of consumer hope and further realize the important role hope plays in consumers achieving various outcomes such as purchase decisions, satisfaction, and subjective knowledge. With this knowledge of consumer hope, we may be better able to distinguish consumers who make the highest (and lowest) quality consumer decisions. In the next sections, we provide an overview of consumer hope, discuss dispositional and situational influences of hope, provide a three-dimension structure underlying consumer hope, and offer a rationale for how the consumer domain and the context of healthy eating provides specificity by which dispositional and situational hope measurement is needed.

Conceptualization

MacInnis and de Mello (2005) define hope as a positively valenced emotion evoked in response to an uncertain but possible goal-congruent outcome. Further, de Mello and MacInnis (2005) provide a three faceted conceptualization of the hope construct including "to hope", "to have hope", and "to be hopeful". The "to hope" facet is defined as "a positive emotion that varies as a function of the degree of yearning for a possible, goal-congruent, future outcome". The second facet, "to have hope", is viewed as "a positive emotion that arises when a goal-congruent future outcome is judged to be possible" while the final facet, "to be hopeful", is "a positive emotion that arises as a function of expectations regarding the likelihood of a possible future goal-congruent outcome".

We propose an overarching view of consumer hope in which it is divided into two basic categories—dispositional consumer hope (DCH) and situational consumer hope (SCH). We have developed two measures of consumer hope that tap into each of these levels of analysis. Dispositional consumer hope is a long-term, stable predisposition in individuals to view consumption experiences as either hopeful or hopeless. Our DCH scale is designed to be specific enough to capture the entire domain of consumer behavior, but more specific than domain-general measures of hope that capture less specificity of consumer outcomes.

Situational consumer hope is a relatively short-term affective reaction to a specific environmental stimulus. As opposed to DCH, which is longer lasting but more diffuse, SCH tends to have a clear cause or object and is more focused and intense. Our SCH scale, therefore, is designed to more precisely measure outcomes related to specific contexts, but less effectively assesses broader consumer outcomes.

Scaled Development Methodology

Taking into consideration the conceptualization of hope by MacInnis and de Mello (2005) and remaining consistent with the authors' theorizing, we treat the "to have hope" and "to be hopeful" dimensions as necessary elements for hope to exist. However, we focus our scale development on the "to hope" dimension as this is the dimension we believe is most relevant for consumer research. While we create measures for the "to have hope" and "to be hopeful" dimensions of consumer hope in order to ensure that hope exists, we focus most of our validation efforts on the "to hope" dimension.

We develop items tapping both dispositional and situational aspects of consumer hope. First, we use methodological procedures to generate and purify our initial pool of items. Next, we use data from study 1 to select items based on a battery of psychometric criteria. Then, study 2 data are subjected to confirmatory factor analysis to provide evidence regarding the unidimensionality, scale reliability, and discriminant validity of the dispositional and situational consumer hope measures. Data from both studies 1 and 2 are then analyzed to provide further evidence of discriminant validity and initial assessments of the nomological validity of the scales. Study 3 is currently underway to evaluate the predictive validity of the newly developed consumer hope scales and study 4 is planned for the purpose of providing evidence for construct validation of our two measures in a food choice context.

Major Findings

In study 1, evidence is provided that both dispositional and situational consumer hope discriminate from optimism, a global measure of state-based hope, a global measure of trait-based hope, and a global measure of hopelessness. In study 2, we first provide validation for the unidimensional structure of the consumer hope scales. We then show that the dispositional consumer hope measure predicts subjective knowledge and customer satisfaction better than an existing global hope scale and optimism and that the DCH scale is distinct from both the Herth Hope Scale (Herth 1991) and the Life Orientation Test (Scheier et al. 1994). Moreover, we show that the SCH measure using a healthy food context predicts involvement with food choices, anticipated regret from making bad food choices, and impulsive eating better than an existing global state-based measure and that the SCH scale is distinct from the Herth Hope Index (Herth 1992). The results of two additional studies are forthcoming. In study 3, the DCH and SCH measures will be assessed for predictive validity while in study 4; we aim to demonstrate the predictive ability of both scales in a consumer food choice context.

Product Meaning and Consumer Creativity

Kelly Herd, University of Colorado, USA
 Ethan Pew, University of Colorado, USA
 Caleb Warren, University of Colorado, USA

Abstract

Product meanings are negotiated by a variety of social actors in a particular historical context. In this study we use a series of long interviews to explore product meanings actively created by consumers. We find that consumers create meaning through irony, through use innovation, and by adopting abandoned products. Consumers are motivated to create meaning because consumer-created meanings

provide flexibility in constructing an identity, economic rewards, and intrinsic enjoyment. Leveraging creativity enables consumers to develop a space free from commoditized identities bartered in the marketplace.

Introduction

Consumer products are not merely commodities, but symbols consumers use to construct identities, strengthen relationships, and understand their social environment (Arnould and Thompson 2005; Hirschman and Holbrook 1982; Solomon 1983). Consumers interpret a product's meaning by associating the product with other cultural signs. These signs include its physical appearance, its intended purpose, the meanings established by manufacturers, and the personal identities and autobiographical memories linked to the product (Hirschman 1986; Hodder 2000; Mick 1986). To the extent that consumers can alter the signs associated with a product, they are able to create new product meanings.

Most product meanings are not created by individual consumers (McCracken 1986). More often meaning is shaped through a firm's branding efforts. For example, Wheaties is "The Breakfast of Champions," a meaning established through extensive athlete endorsements. Occasionally, however, consumers go beyond established interpretations to instill products with new meanings. For example, by converting Altoids tins into Buddhist shrines, HAM radios, or thumb pianos consumers cause the tins to become more than packaging for curiously strong mints.

There is growing interest in the role of consumer creativity as it relates to design (Moreau and Dahl 2005), product co-creation (Bendapudi and Leone 2003; Vargo and Lusch 2004) and innovation (Hirschman 1980). Yet limited research links creativity to the meaning creation process. Our study attempts to fill this gap by exploring the strategies and motivations that underlie consumer-created product meaning.

Method

The authors conducted depth interviews using a purposeful sample of six informants in the greater Denver area. Interviews followed methodological procedures outlined by McCracken (1988). Informants were asked a series of grand tour questions concerning their identity, sense of style, and methods of self-expression followed by more specific prompts.

We interpreted the interviews first by looking for emic meanings embedded in the text. We next searched for broader themes and categories emerging in the interviews, interpreting these in light of our pre-understanding shaped by the literature and our own experiences (Arnold and Fisher 1994).

Findings

Strategies

Our interviews revealed three partially overlapping strategies informants used to create product meaning: irony, use innovation, and adopting abandoned products.

Irony was achieved by using products with a dominant meaning in clever and unexpected ways. One informant described a bookcase built from bear traps welded to form supports for glass shelves. This one-of-a-kind piece contrasts sharp metal teeth with smooth glass playfully requiring the user to reach across powerful steel jaws to access books. Another informant described an outfit pairing a men's A-shirt, which she referred to as a "wife-beater," with a sequined shirt passed down from her grandmother. This combination created ironic tension by pairing the "wife-beater," a symbol of female submission in society generally associated with rural, working class men, with sparkle and flair, symbols more frequently tied to garishness and conspicuous fashion consumption.

Our informants relied on juxtaposed associations to create new meanings that abstract away from dominant interpretations. While the specific ironic meaning did not exist prior to the informants' creations, the formula of using tension to create meaning remains constant.

Informants also generated meaning by using products in ways not initially intended, a practice known as use innovation (Hirschman 1986). Given that a product's purpose largely determines its meaning, consumers create new meanings through new uses. Examples include a swim buoy used as a living room decoration and a lemon used as a cosmetic. A swim buoy means something very different when placed on a wall for aesthetic value than when placed on a ship deck for safety. Similarly, the interpretation of a lemon depends on its use.

A final way our informants created meaning was by adopting abandoned or cast-aside products. By adopting vintage clothing or obsolete electronics, and associating them with new people and new contexts, our informants created new meanings for these products.

Motivations

Informants reaped both intrinsic pleasure and economic benefits by creating product meanings. Informants described acts of meaning creation, such as turning a "scarf into a new window treatment," as an enjoyable way to spend free time. Informants who created meaning themselves avoided paying brand or fashion premiums and, in some cases, profited from reselling the fruit of their creation. One informant saved money by purchasing abandoned clothing at second-hand stores. Another profited directly by selling products infused with new meanings. Dan re-sold a generic \$70 table purchased at Target for several hundred dollars after converting it to a custom made "Michael Jordan table" incorporating images from "his entire career."

Informants also created product meanings as a vehicle for controlling their identity. As product meanings are often leveraged in a quest to construct a self-image (Belk 1988), meaning creation affords consumers greater autonomy in shaping their identity. Creating novel product meanings enables consumers to construct a unique identity uncontaminated by meanings associated with undesirable, mainstream trends or commercialization. One informant sidestepped undesirable, dominant cultural meanings by purchasing obscure or second hand goods and by altering or combining products in ironic ways.

Discussion

This study hopes to illuminate an overlooked source of product meaning: consumer creativity. Through irony, use innovation, or by adopting abandoned products consumers can alter the signs, associations, and contexts of a product to establish new meanings. Given that identity is heavily shaped by possessions, meaning creation may be an essential step in developing a space free from the commoditized identities bartered in the marketplace (Firat and Venkatesh 1995; Kozinets 2002).

While this study represents an initial step towards understanding consumer-created meaning, many questions remain. To what extent do created meanings draw from existing, shared cultural understandings (Thompson et al. 1994)? Also, what types of consumers are most likely to create product meanings? Meaning creation may be especially prevalent amongst influential consumers (Gladwell 1997), consumers high in need for uniqueness (Tian et al. 2001), and consumers with above average cultural capital (Holt 1998). By continuing to pursue our study we hope to initiate an informative and enriching line of research furthering our understanding of consumer-created product meaning.

The Effects of Spoke-Avatars' Personalities on Source Expertise, Trustworthiness, and Attractiveness in the 3D Virtual Environment

Seung-A Jin, Boston College, USA

Yongjun Sung, The University of Texas at Austin, USA

Background

Second Life is the fastest growing virtual environment and has received considerable attention from researchers and practitioners in the fields of marketing and consumer behavior. To date, about 6.5 million people have entered *Second Life*, and the impact of this technology is beginning to be felt by society (Bainbridge 2007).

E-commerce already thrives in this digital world—approximately \$1,199,460 was spent in one 24 hour period (*Second Life* 2007). One of the most distinguishing key features of *Second Life* is that users can navigate, interact, and view the world through their own customized avatar. Avatars are increasingly used as company representatives and persuasion agents on commercial Web sites and virtual environments (Holzwarth, Janiszewski, and Neumann 2006).

Theoretical Framework

The notion of inanimate objects, such as commercial brands, becoming associated with human characteristics has been given a considerable amount of attention in consumer research. This symbolic meaning that commercial brands acquire is often called *brand*

personality (Aaker 1997). For example, a brand can be described by characteristics such as gender, age, social class, and lifestyle as well as classic human personality traits such as rugged (e.g., Harley Davidson), trendy (e.g., Apple), and sophisticated (e.g., Mercedes Benz).

This study aims to examine the relationship between symbolic consumption and consumer choice and to develop an understanding of what factors influence brand marketing and e-commerce in *Second Life*. This study empirically tests the role of brand personalities in persuasion and in the decision making process of the consumer. More importantly, the experiment was conducted in the avatar-based 3D virtual environment *Second Life*.

Although anthropomorphic qualities are most commonly associated with living creatures, consumers can also imbue non-human entities such as avatars with human personality traits. As sales representatives do in real life, avatars interact with consumers and make the online shopping experience more interpersonal (Holzwarth et al. 2006). Therefore, avatar-based 3D virtual environments are a promising marketing communications channel for brand management—not only online, but also in the real world—because marketers can effectively communicate personalities and images of their brands. Avatars are virtual sources or endorsers that can be used as company representatives. Thus, a company or brand's credibility can be created by any direct or indirect brand contact that the consumer experiences with avatars in virtual environments.

The purpose of the present study is to investigate the consequences of spokes-avatars' personalities on source credibility. More specifically, it conceptually links two streams of research (brand personality and source credibility) and examines the impact of two of Aaker's (1997) brand personality dimensions (Sincerity and Excitement) on three key constructs of source credibility: expertise, trustworthiness, and attractiveness. After reviewing prior research on brand personality and source credibility (e.g., Aaker 1997; Ohanian 1990), we predict that sincere spoke-avatars are more likely to be perceived as having source expertise (H1) and trustworthiness (H2) than exciting spoke-avatars, whereas exciting spoke-avatars are more likely to be perceived as having source attractiveness (H3) than sincere spoke-avatars. Towards the end, we conducted an experiment in the avatar-based 3D virtual environment *Second Life*.

Method

The present experiment is a two-group comparison design. Participants were 82 college students (43 females, 39 males) recruited from communication courses at a university in Massachusetts. We designed two different versions (featuring either an exciting or sincere spokes-avatar) of a 5-minute promotional script. We designed and manipulated the exciting avatar to appear young, trendy, unique, and contemporary. The avatar introduced itself by saying, "hi there! welcome to our store in second life!" and, then promoted the brand with an exciting tone consistent with the avatar's personality. On the contrary, we designed the sincere avatar to look honest, friendly, and wholesome. The avatar introduced itself by saying, "Hello. Welcome to our store in Second Life," and then promoted the brand with a sincere tone consistent with the avatar's personality. Subjects were told that they would be in a clothing store where they would interact with a sales-avatar, who would then tell them about online shopping inside *Second Life* and introduce a new line of clothes that the company had recently released. They were then asked to listen to the spokes-avatar's promotional dialogue and interact with it.

Results

To test the proposed hypotheses, a series of t-tests were conducted. Consistent with the predictions, the results indicated that subjects who interacted with sincere spoke-avatars showed higher scores for source expertise ($\alpha = .92$, $M_{expert} = 5.51$) and trustworthiness ($\alpha = .93$, $M_{trust} = 4.94$) than those who interacted with exciting spoke-avatars ($M_{expertise} = 4.79$, $t = 3.02$, $p < .01$; $M_{trust} = 4.24$, $t = 2.83$, $p < .01$), thereby supporting H1 and H2. Further, as predicted, the results suggest that subjects who interacted with exciting spoke-avatars showed higher scores for source attractiveness ($\alpha = .78$, $M_{attract} = 3.84$) than those who interacted with sincere spoke-avatars ($M_{attract} = 3.32$, $t = -2.01$, $p < .05$), thereby supporting H3.

Discussion

Despite the growing interest in the concept of brand personality, work in this area has been fairly limited and has made little progress in empirically supporting the importance of brand personality. Most of the research has focused on its structure and scales, but very limited research has empirically examined the consequences of brand personality. To fill the gap in the literature and expand application of brand personality to more diverse contexts (i.e., virtual environment and characters), this study investigated the predictive roles of spoke-avatars' personalities on key dimensions of source credibility. Our findings suggest that spoke-avatars' personalities can enhance source credibility in terms of expertise, trustworthiness, and attractiveness. The results showed that sincere avatars increased perceived source expertise and trustworthiness. Further, exciting avatars increased perceived source attractiveness.

From a managerial perspective, the findings of this study provide strategic insight into spoke-avatars and associated personality selection decisions. Avatars can serve as endorsers, sales agents, store assistants, and even as brands in virtual environments. Marketers can easily and effectively create, design, and manipulate spokes-avatars' personalities to convey personalities and images of products and companies, thereby increasing the persuasiveness of brand communications.

Are All Referrals Created Equal? The Impact of Social Connections on Consumer Discounts

Bryan R. Johnson, The Pennsylvania State University, USA
William T. Ross, Jr., The Pennsylvania State University, USA

Conceptualization

Throughout history, social relationships have played a critical role in facilitating communication and cooperation among individuals. Given their importance in social interactions, relationships possess the ability to shape various aspects of human behavior, including those related to consumption. Due to the important influence of these ties, many consumers incorporate relationships, either directly or indirectly, into purchasing products and services (Beatty et al. 1996; DiMaggio and Louch 1998). Accordingly, the purpose of this paper is to investigate the extent to which consumers receive benefits based on their structural relationships with firms, by identifying the economic impact of the different types of links (referrals) used to make purchases. More specifically, this paper examines how a referrer's connection to a firm (i.e., business relationship, personal relationship, customer relationship, etc.) impacts the size of the discount received by the consumer being referred. Interestingly, the basic question of whether or not consumers receive benefits based on structural relationships, including which connections have the greatest impact, has not been examined in the marketing literature. Nevertheless, given the extent to which consumers are socially connected to one another, and to firms, addressing this question is important if scholars are to understand the social dimension of consumer behavior.

To highlight the impact of social structure on discounts received by consumers, we draw upon social capital theory, which posits that individuals obtain benefits or returns as a result of their social relationships with others (Portes 1998; Lin 2001). In general, social capital theory focuses on the resources ingrained in an individual's social relationships and how these resources benefit the individual. These resources are considered social because they can only be accessed through direct and indirect ties with others. Common forms of social resources include advice, information, and ideas. Ultimately, to possess social capital, an individual must have relationships with others; it is only through social interactions that social capital can exist and provide benefits to individuals (Coleman 1988; Portes 1998; Lin 2001).

Scholars have explored the impact of social capital in a variety of settings within the social sciences (e.g., Lin and Huang 2005; Mouw 2003; Ream 2005; Seidel, Polzer, and Stewart 2000; Smoldt 1998). Although somewhat less prevalent, marketing scholars have also contributed to research in this area by highlighting the impact of social ties on consumption (Frenzen and Davis 1990; Brown and Reingen 1987; Reingen and Kernan 1986). To further contribute to theory in this developing research area, we highlight the economic consequences of using social ties to connect to firms. In the remainder of this paper, we evaluate the impact of a referrer's relationship to a firm on the consumer's discount, using a combination of qualitative and quantitative data. As the first of several studies, the main contribution of this research is that it demonstrates the economic impact of connecting to firms through various types of associations.

Method & Findings

The research site used for this case study, Car Concepts (a pseudonym), is a small automotive business located in the Western United States, specializing in basic to high-end products and services. This site is particularly appropriate for the current study because it is associated with an industry in which customers tend to rely heavily upon others to locate and connect to firms. Data for the study were drawn from the firm's archival records and from multiple interviews with the business owner between October and November 2007. These initial data include information for 35 consumers and the individuals who referred them to the firm. Additional data are currently being collected as part of an ongoing case study with the company.

To determine the impact of the referrer's relationship to the firm on the customers' discounts, we estimated an ordinal logit model with *customer discount* as the dependent variable and *referrer connection type* as the independent variable. We included *job size* and *customer type* as control variables. The results indicate that customers receive significantly smaller discounts when connecting through unknown individuals, through businesses, and through the firm's previous customers, than through those the owner deems to be friends. Stated differently, the odds of receiving larger discounts are much higher among those connecting through the owner's friends than through all other types of linkages to the firm. Amazingly, the average discount for those connecting through the owner's friends is \$88, compared to \$31, \$12, and \$7 for those connecting through previous customers, businesses, and unknown individuals, respectively. Clearly, our data strongly suggest that all referrals are not created equal.

Based on the overwhelming impact of friendship referrals, we conducted additional analyses among those customers connecting through friends of the owner. We created a cognitive friendship network, using the owner's perception of the relationships that existed among those he identified as friends. To construct this cognitive network, we asked the owner to identify whether or not each of the friends in his ego network were friends with one another, as done in previous research (Kilduff and Krackhardt 1994; Krackhardt 1990). We then used these responses to map the relationships among the owner's friends.

With this cognitive network in place, we used UCINET 6 to estimate the centrality of the owner's friends in the network. Then, we performed a median split to allocate these individuals to one of two categories: *central* or *non-central*. To test the impact of referrer centrality in the friendship network on the size of discounts received by customers, we estimated an ordinary least squares regression model with *customer discount* as the dependent variable, *referrer centrality* as the independent variable, and *job size* and *customer type* as control variables.

As expected, we find that customers receive significantly higher discounts when connecting through central friends than through non-central friends. After controlling for job size and customer type, the difference in the total discount received by customers who connect through a central versus a non-central referrer is approximately \$107. Hence, while it is beneficial for consumers to connect to firms through friendship relationships, friends who are central in the friendship network tend to yield even greater benefits.

In summary, the main contribution of this research is that it demonstrates the economic impact of connecting to firms through various types of referral relationships. Our research not only confirms social capital theory's fundamental premise in the context of consumption, but it goes above and beyond the notion that individuals benefit from their social connections, by determining a dollar value associated

with the different types of relationships employed in transactions with the focal firm. Although our findings emerge from a particular context, the theoretical implications of this study have broad applicability for consumer research.

Understanding Why Temporally Myopic People Have More Credit Card Debt: Two Complementary Explanations

Jeremy Kees, Villanova University, USA
 Jeff Joireman, Washington State University, USA
 David Sprott, Washington State University, USA

Given the growing trend toward large credit card balances and confusion as to what types of information influence consumers' perceptions of credit card offers, it is important to examine predictors of credit card debt and how consumers process and utilize financial information on credit card offers. In the present paper, we focus on the role of one theoretically-relevant individual difference variable, the consideration of future consequences (CFC; Strathman et al. 1994). Individuals high in CFC are more likely to engage in a variety of personally-beneficial behaviors (for a review, see Joireman, Strathman, and Balliet 2006), and recent research has demonstrated that CFC can influence certain types of financial decisions (Joireman, Sprott, and Spangenberg 2005). While theory suggests a link between CFC and credit cards, no studies to date have not directly examined the relationship between CFC and actual credit card debt. We address this issue in the current research and also explore *why* CFC predicts credit card debt. In short, we focus on two possible explanations: first, CFC may predict compulsive buying which in turn predicts credit card debt; second, CFC may predict attraction to credit card offers, especially those promising immediate rewards (e.g., a \$50 gift card after one's first purchase). In what follows, we briefly review work on CFC and fiscal responsibility, develop our hypotheses, and report two studies testing these hypotheses. We discuss the implications of our findings for both theory and practice.

Study 1

In Study 2, 84 participants completed the diagnostic screener for compulsive buying (DSCB; Faber and O'Guinn 1992), the CFC scale (Strathman et al. 1994), and reported their credit card debt. Originally, the CFC scale was reported to have a single underlying factor (Strathman et al. 1994). Recent research, however, suggests that the scale may contain two subscales, one comprised of the future-oriented items, which we will call CFC-Future, the other comprised of the immediate-oriented items, which we will call CFC-Immediate (Petrocelli 2003).

As expected, the CFC-Immediate subscale correlated significantly (and positively) with credit card debt. Findings also show that all of the CFC scales predicted compulsive buying, and compulsive buying was positively correlated with credit card debt. The pattern of results suggested that compulsive buying might mediate the relationship between CFC-Immediate and credit card debt. To test this mediation model, we conducted a two-step regression analysis predicting credit card debt. On Step 1, we entered CFC-Immediate. On Step 2, we entered compulsive buying. For mediation to hold, CFC-I should predict compulsive buying (which it does; $\beta = .50, p < .001$), CFC-I should predict credit card debt (which it does; $\beta = .24, p < .05$), compulsive buying should predict credit card debt (which it does;

$\beta = .53, p < .001$). Consistent with a full mediation model, the relationship between CFC-I and credit card debt became non-significant ($\beta = .04, p = .74$) when compulsive buying was entered into the model (Baron & Kenny 1986). A Sobel (1982) test further confirmed that the reduction in the relationship between CFC-I and credit card debt was significant ($z = 3.63, p < .001$). In summary, findings offer support for H2-H3 and partial support for H1.

Study 2

The goal of Study 2 was to evaluate whether those concerned with the immediate consequences of their actions would be more attracted to credit card offers that promised immediate rewards but implied long-term losses (i.e., through an extremely high interest rate). In Study 2, 145 participants participated in a 2 (temporal frame) X 2 (CFC) between-subjects experiment. The temporal frame of the offer was manipulated by altering the terms of the credit card offer; future orientation was a measured variable. For the temporal frame manipulation, participants were randomly assigned to one of two conditions. Participants assigned to the “short term gain / long term loss” framing condition or a “short term loss / long term gain” condition. We held constant the monetary benefits of the two credit card offers. After reading the credit card offer, participants indicated how likely they would be to apply for the credit card.

The analysis using the CFC-Immediate scale revealed a marginally significant main effect of condition $F(1, 142) = 2.88, p = .09$, as well as a marginally significant interaction between CFC-Immediate and condition, $F(1, 142) = 2.77, p = .10$. Follow-up analyses were run within each level of CFC-Immediate and within each temporal framing condition. Among those low in CFC-I, there was a significant preference for the credit card with the lower interest rate (STLoss-LTGain), $t(70) = 2.56, p = .02$; in other words, they avoided the card with the short-term gain but a higher interest rate. However, among those high in CFC-I, there was no significant preference based on condition, $t(72) < 1$; they liked each card equally. Within the STGain-LTLoss condition, those high in CFC-I were significantly more likely to apply for the card than those low in CFC-I, $t(70) = 2.26, p = .03$. However, within the STLoss-LTGain condition, there was not a significant difference based on CFC-I, $t(72) < 1$.

Brief Discussion

Findings from two studies provide insight into how consumer differences (i.e., CFC, compulsive buying) and types of information provided within credit card advertisements (e.g., fees, interest rates, and rewards) can influence consumers' financial decisions. Results across two studies were largely supportive that CFC can predict credit card debt (Study 1) and can impact evaluations of credit card offers (Study 2). Results are consistent with conceptualization of the CFC construct and prior CFC research in that some consumers tend to do a better job recognizing actions or behaviors that might jeopardize their long-term well-being. In addition to extending work on CFC, the present work also contributes to a better understanding of compulsive buying behavior.

The Effects of Implicit Color Preference and Implicit Racial Preference on Implicit Attitude towards the Ad

Ioannis Kareklas, University of Connecticut, USA

Robin Coulter, University of Connecticut, USA

Choosing an appropriate spokesperson is a critical decision for advertisers, given the mounting evidence in the persuasion literature which suggests different sources delivering the same message produce varied outcomes among recipients (Whittler and Spira 2002). Spokespersons who are perceived to be more credible, attractive, and similar to recipients are typically more persuasive (for a review, see Eagly and Chaiken 1993). In the context of ethnicity, extant research (using explicit measures) suggests that consumers respond more favorably (generate more positive advertisement and brand evaluations) to persuasive messages delivered by spokespersons of similar race (for a review, see Whittler 1991).

An important caveat regarding earlier work in this domain is that the bulk of this research has employed explicit (i.e., self-report) measures, which may suffer from response biases because the topic of race is socially sensitive, and explicit measures allow participants to consciously control their responses (Ashburn-Nardo, Knowles, and Monteith 2003; Brunel, Tietje, and Greenwald 2004). More recent work has employed implicit measures such as the Implicit Association Test (IAT; Greenwald, McGhee, and Schwartz 1998) to circumvent such response biases. Findings suggest that both Black and White participants exhibit an automatic “pro-White” preference when asked to sort Black versus White racial stimuli (Banaji, Greenwald, and Rosier 1997; Nosek, Banaji, and Greenwald 2002).

Additionally, research on the neural basis of social group processing has found that indirect measures of race evaluation correlate with functional magnetic resonance imaging (fMRI)-assessed activation of the amygdala (Phelps et al. 2000). Given that the amygdala is known to be involved in responding to threatening and to novel stimuli, and since research has shown that both Black and White participants demonstrate greater amygdala activity to unknown Black faces than to unknown White faces, Lieberman et al. (2005) posit that amygdala activity associated with race-related processing may be a manifestation of “culturally learned negative associations regarding African-American individuals.” This explanation is consistent with System Justification Theory (SJT; Jost and Banaji 1994), which has previously been used to explain why Black participants exhibit a lack of ingroup preference in implicit racial evaluations (e.g., Brunel et al. 2004).

SJT posits that people are motivated to believe in a just world, and that a history of discrimination can lead even minorities to internalize negative attitudes toward their own groups as a means of justifying the status quo (Rudman, Feinberg, and Fairchild 2002). Jost and Banaji (1994) emphasize that such attitudes and the motive to sustain them are likely to be nonconscious, which explains why this phenomenon may not be picked up by self-report measures, but can be unearthed by implicit measures (Rudman, Feinberg, and Fairchild 2002).

Within the advertising context, Brunel et al. (2004) using the IAT found that White participants exhibited a significant implicit preference for ads that featured a White (vs. Black) spokesperson, but no significant explicit preference, whereas Black participants exhibited a significant explicit preference for Black spokespersons but no significant implicit preference between Black and White spokespersons. These findings underscore the importance of utilizing implicit measures to assess the effectiveness of advertisements that feature spokespersons that are of a similar (vs. different) race than the target audience.

Research suggests that another variable that may impact consumers' evaluations of African-American and White-American spokespersons is their implicit color preference for the color white as compared to the color black. Specifically, in the United States and many other countries, the cultural associations related to the color white are more positive, whereas the associations with the color black are more negative (Smith-McLallen et al. 2006). Williams, Tucker, and Dunham (1971) note that the color white has been used in religion, literature, and the mass media as a symbol of "goodness," while the color black has been used as a symbol of "badness." Similarly, Longshore (1979) observes that white is used to connote decency and purity, while black is used to connote evil and disgrace.

The purpose of this paper is to develop a theoretical model of the effects of implicit racial preference (IRP) and implicit color preference (ICP) on consumers' implicit attitude towards the ad (IAad). The aforementioned literature suggests that consumers' advertising evaluations are likely to be impacted by their implicit racial preference and their implicit color preference. Thus, we posit the following:

- H1: Regardless of race, participants will exhibit an implicit racial preference for stimuli illustrating White-American (vs. African-American) faces.
- H2: Regardless of race, participants will exhibit an implicit preference for advertisements featuring White-American (vs. African-American) spokespersons.
- H3: Implicit racial preference will have a direct and positive effect on participants' implicit advertising evaluations, such that participants who implicitly prefer White-American (African-American) faces will also implicitly prefer ads that feature White-American (African-American) spokespersons.
- H4: Regardless of race, participants will exhibit an implicit color preference for the color white as compared to the color black.
- H5: Implicit color preference will have a direct and positive effect on participants' implicit racial preference, such that participants who implicitly prefer the color white (black) will also implicitly prefer White-American (African-American) faces.
- H6: Implicit color preference will have a direct and positive effect on participants' implicit advertising evaluations, such that participants who implicitly prefer the color white (black) will also implicitly prefer ads that feature White-American (African-American) spokespersons.
- H7: Implicit racial preference will partially mediate the effect of implicit color preference on participants' implicit advertising evaluations, such that controlling for participants' implicit racial preference will reduce the effect of their implicit color preference on their implicit advertising evaluations.

We propose testing our hypotheses using three IAT procedures: an implicit color preference IAT, an implicit racial preference IAT, and an implicit attitude toward the ad IAT. Equal samples of Black and White participants will be recruited. As a consequence of our research, we will be able to provide insights about the respective individual and joint effects of implicit color preference and implicit racial preference on attitudes toward advertisements featuring White or Black spokespersons, as well as provide guidance related to the development of ads that feature Black or White spokespersons targeting Black or White consumers.

Integral Affect and Attitude Strength in a Health Communications Context

Monica LaBarge, University of Montana, USA

An ongoing goal of practitioners and academics interested in health communications has been to improve their effectiveness (Keller and Lehmann, 2008). Research on the message effectiveness of health communications has largely focused on two major types of influences: 1) message characteristics such as positive versus negative framing, vividness, presentation of statistics, argument strength, and source effects; and 2) individual difference variables such as race, gender, need-for-cognition, regulatory focus, and involvement (Keller & Lehmann working paper). A variable that has been explored on a relatively limited basis in comparison to these other factors is the role of affect, and integral affect in particular, in influencing attitudes to health communications.

This is in spite of the contention by researchers that integral affect should be a relatively important influence in the context of health-related attitudes and decisions because of the very personal and potentially serious consequences associated with health behaviors (Slovic et al. 2005, Luce 2005). Research directed towards improving the effectiveness of health communications has explored the influence of affect in two primary ways. The majority of research on affect in this area has examined how antecedent mood states influence individuals' responses to health communications (Keller et al. 2003). A second stream of research has explored how the emotional presentation of information, such as the use of fear appeals or the vividness of the message (Keller 1999, Rothman and Salovey 1997), influence subsequent reactions to and perceptions of the message. With respect to information processing, Schwarz and Clore (1996) suggest that the role of affect can be framed in terms of two general streams: 1) an experiential approach that postulates an informational role of subjective experiences, including moods, emotions, bodily sensations, and cognitive experiences; and 2) a cognitive approach, which explores the impact of affective states on the content of thoughts rather than on the actual experience of thinking. Within the first stream, relatively little research has been directed towards improving our understanding of the hardwired, automatic (also called "somatic") processes that reflect affect. Within the somatic processes, the influence of affect includes not only emotion states stimulated by bodily processes, but also includes affect triggered by features of a stimulus that in turn activate schematic structures linked through conditioning to particular emotional responses (Pham 2004). The affect that is stimulated within an individual in response to an object or message can be termed integral affect. It is this internally-generated affect that is of interest in the current research.

The current research examines two research streams with respect to the role they each assign to integral affect in the processes of attitude formation. The first stream of research, based on the Elaboration Likelihood Model, has found that processing dominated by affect produces relatively weak attitudes compared to more cognitive processing. The second stream of research, based on the affect heuristic and two-systems theory, has determined that integral affective responses may be particularly important in situations where the decision to be made is extremely important and personally-relevant, or when the information presented is very complex and unfamiliar, as is frequently the case in the context of health-related choices (Slovic et al. 2005). Given these conflicting perspectives and a lack of empirical research that specifically investigates the strength of affectively-based attitudes, there appears to be a need for further exploration of how integral affective responses influence important persuasion-related variables such as attitude formation and attitude strength.

A series of laboratory experiments conducted with undergraduates at a major public university explored differences in affectively- and cognitively-based attitudes developed in response to health-related advertising. These differences were examined in measures of intention to engage in the advocated behavior; two measures of attitude strength (persistence and resistance), and three measures of attitude: overall attitude, and the affective and cognitive components of attitude.¹ Affectively-based attitudes were shown across studies to be stronger than cognitively-based attitudes for the measures of overall attitude and the cognitive component of attitude. The affective attitude component did not change significantly over time or in response to an attack, regardless of whether the attitude was initially formed based on affect or cognition. This suggests that the affective component of attitude is particularly stable when compared to overall attitudes and the cognitive component of attitude. In general, intentions to seek out information about or engage in the behavior advocated by the ad were more favorable for individuals in the affectively-based attitude condition. Together these results can be interpreted as supporting the contention of this research that affectively-based attitudes are more persistent over time and resistant to change and that intentions will be more favorable among individuals who hold affectively- than cognitively-based attitudes.

An additional methodological contribution of this research was to test a promising but relatively unproved experimental method for strengthening affectively-based attitudes (Peters and Slovic 2007). Elaboration tasks intended to strengthen the cognitive basis of an attitude, such as thought listings, have been well-validated (Petty et al. 1995), but few options have existed for similar strengthening of an affectively-based attitude. The goal of the silent feeling elaboration task employed in this study was to reduce disruption of affective processes underlying affectively-based attitudes, thus allowing for the maintenance of the affective basis of the attitude. Preliminary

¹This separation of attitude into three components is consistent with Crites et al. (1994), Fabrigar and Petty (1999), Verplanken et al (1998), and Peters et al. (forthcoming), and the methodology used to measure and analyze these components was also consistent with these authors.

results show that the silent feeling task was successful in strengthening affectively-based attitudes, facilitating accurate comparison of the persistence of affectively- and cognitively-based attitudes.

Blurring the Boundaries between Real and Virtual: Consumption Experiences and the Self Concept in the Virtual World

Ereni Markos, University of Massachusetts, Amherst, USA
 Lauren Labrecque, University of Massachusetts, Amherst, USA

Introduction

Millions of people currently have accounts in virtual worlds such as Second Life (SL). Members of these online communities customize avatars that can mimic real world activities such as shopping, socializing at a bar, going to the beach, driving a car, engaging in an intimate relationship as well as countless of other endeavors. In a commercial website, avatars enhance a shopping experience by serving as guides, conversation partners, and personal shopping assistants (Holzwarth, Janiszewski, & Neumann, 2006). In a virtual setting the key element is the user and as such users design virtual representations of themselves, to function and interact with other avatars in order to keep this world alive.

Virtual worlds are revolutionizing the online experience by extending the Web from a two dimensional platform to a three dimensional one. These platforms are growing in size and number at an exponential rate, creating an increased interest among businesses and the marketing community (Carr 2007; Kirkpatrick 2007; Stein 2006; Reena and Aili 2006). Interestingly, past research has shown that marketers see benefits in studying online communities as a tool in understanding consumption behavior (Kozinets 1999, 2002; Bromberg 1996; Muniz and O'Guinn 2001; Armstrong and Hagel 1996).

Our study focuses on one of the most rapidly growing virtual worlds, Second Life. The purpose of this paper is to better understand what drives virtual consumption and how these experiences play out in the virtual world and influence consumption in the real world. Further, drawing on the self concept theory we explore the implications in a virtual setting. We begin our investigation by conducting an exploratory study to learn more about SL and its residents. In our second study (ongoing), we create a survey instrument and collect data from residents in Second Life both inside and outside of the virtual world.

Methodology

In study 1 we explore SL by use of qualitative research methods. We employ a combination of structured and dialogic interviews coupled with participant observation to capture meaningful information. Research within virtual worlds is a relatively new area where 'there is no established precedent as to how to collect data' (Ward 1999). Research suggests that an efficient manner to gather data and conduct research in a virtual community is through using participant observations (Kozinets 2002; Reid 1995) and informal interviews (Turkle 1996).

In order to perform Study 1 we created two separate SL accounts (one for each author) and designed our unique avatars. Prior to interviewing, we spent time familiarizing ourselves with the landscape, etiquette, and functionality of SL. Throughout the research period,

we established relationships with many residents, were invited into their SL homes and were introduced to their SL community and friends. Our exploration in SL spanned a one month period, consisting of daily visits and interviews. Research was performed throughout the day to accommodate SL's 24 hour global access. The overall approach was to enter SL, go to stores or locations where there were other avatars, engage in unstructured dialogs, record conversations and capture moments with photos. Our conversations were conducted through a text based instant messaging interface, however after our initial research VOIP was added as an option and will be used in subsequent studies. Photo elicitation served as another means of collecting data in our study. During conversations with residents we captured our interactions by using the photo feature enabled in the SL interface. Notably there is a built in option that enables this function, therefore most residents are aware of this and most were welcoming. Finally, we disclosed that we were conducting research and received verbal consent to use residents' comments.

Preliminary findings

Our initial findings suggest that in SL one can live out desires and seemingly unattainable dreams. Extant research shows that desires and fulfillment of fantasies serve as the impetus for many consumption activities (Belk, Ger, and Askegaard 2003). Virtual worlds are ripe with occasions to engage in behavior to fulfill these types of longings. For instance, we frequented an island where residents shared a love for Greece and her culture. This island mirrors a traditional Greek island with blue and white buildings, turquoise water, Greek music and activities particular to this culture. Even though we are thousands of miles away from Greece we felt as if we were on a sun-drenched island on the Mediterranean Sea. Regardless of the backdrop people can purchase villas, motorcycles, convertible cars, appliances, accessories, clothes and luxury services similar to the real world but at a minuscule price.

Exploring different facets of oneself is within reach and an exciting feature of virtual worlds (Turkle 1995). Applying Belk's (1988) concept of the extended self, virtual possessions can "symbolically extend the self", which he states "allows us to do things which we would otherwise be incapable" (Belk 1988 p.145). Whether it's an avatars form, a sports car, a villa, or an island, these possessions allow users to explore different facets of their identity. The ability to customize an avatar allows one to explore ethnicity, gender and other aspects of self. One resident elaborated on the freedom SL allows to explore gender and race. Even though he is a man in RL he tried out the role of woman. He also spoke about changing his racial identity and his ability to be more social on SL. Since SL is a computer mediated environment people are seemingly less inhibited and more inclined to experiment outside societal norms and possibilities.

Our findings show that people embrace the opportunity to explore their creativity and support the notion that in SL dreams become reality and consumption based daydreams that are otherwise unfeasible are attainable (Molesworth 2006). A user can experience what it feels like to fly, cross gender boundaries or even live out a non-human existence (many users create avatars that take on the form of an animal, alien or other creatures). Ultimately, anything is possible in a virtual world.

In our follow-up study (Study 2), which is still on-going, we conduct survey research of Second Life residents, using a participant panel. This second data collection will be used to gain a better understanding of how virtual worlds can be used to explore the self and how this ties into both virtual and real life consumption.

Theoretical Foundation of Brand Personality for Postmodern Branding Dynamics: A Critical Review and Research Agenda

Eun-Jung Lee, Kent State University, USA

Abstract

This article attempts to contribute to a solid theoretical base for postmodern branding dynamics with a mediation of a popular market-oriented branding concept: *brand personality*. While re-illuminating market-oriented functions and common misconceptions about brand personality and discussing the limitation of its prevailing theoretical approach, a new and expansive conceptual ground has been suggested for brand personality upon *the theory of consumption symbolism*, a rising sub-stream in the consumer research literature, which speculates upon the meaning production and consumption in the postmodern marketplace. Based on its marketing-homegrown and interdisciplinary perspectives, some new research agendas have been suggested for the future academic approaches for deepening the academic understandings of the dynamics of brand personality and of the postmodern branding.

1. Conceptual Foundation

1.1 Brand personality in postmodern branding dynamics

Meanings of products play a critical role in contemporary consumers' choices. In the postmodern marketplace, commercial goods often perform as social identity markers, as well as carriers of functional qualities (McCracken, 1986). With a myriad of diverse meanings and symbols floating in the marketplace, consumers need heuristics for their decision-making regarding such non-utilitarian product—and brand—attributions. Marketers and managers need to make their branding activities compatible with their customers' interests (e.g., Solomon, 2003), and they require a systematic and organization-wide management for non-utilitarian facets of a brand. Brand personality has been devised and gradually elaborated upon to fulfill some of those needs in a more structured manner.

Brand personality, generally referring to the human characteristics associated with a brand (e.g., Aaker, 1997), is a branding concept that explains a facet of branding dynamics (e.g., Batra et al., 1993; Carr, 1996; Kapferer, 1998; Upshaw, 1995; Keller, 2001; 2003) which is about (some) non-utilitarian brand attributions (e.g., Keller, 1993). Brand personality is the core of postmodern branding dynamics, which fulfills a multi-faceted function in consumer-organization as well as within-organization communications (Davis, 2000; Aaker & Joachimsthaler, 2000; Silverstein & Fiske, 2005). Brand personality serves as an effective consumer-organization communication tool. It allows an organization to identify consumers' brand perceptions—even the hidden ones—by its projection techniques with (human) metaphor (Dent-Read & Szokolszky, 1993; Zalthman, 1997). Marketers can then use consumers' perceptions to make their marketing strategies become more focused on consumers. It also provides a useful research method for consumer studies. On the other hand, brand personality serves as an organization-wide guide for brand meaning communication. It helps marketers communicate brand meaning which otherwise might not be easy to understand and/or share (among marketers). By adding robust, descriptive, and realistic explanations for core yet abstract brand identity, brand personality makes the brand meaning understandable and contemporary (Aaker & Joachimsthaler, 2000).

The most unique and useful brand personality function comes from a synergy of these two functions above. As a result, it helps marketers to actualize market-oriented and consumer-empowered brand management, which are the most critical in postmodern branding dynamics (Simonson, 2003; Wathieu et al., 2002).

1.2 Trait-based theoretical approach: Limitation

There have been great amounts of practitioners' efforts expended in identifying "what brand personality is" and "how it works." The prevailing research stream has been based on the trait-theory of psychology. Almost every brand personality study has adopted the trait theory (recently more focusing on the five factor theory) that was originally devised for human personality in psychology (e.g., Aaker, 1997; Carprara et al., 2001; Sung & Tinkham, 2005).

Having contributed to gaining fundamental understanding into brand personality and boosting academic interests in the subject, however, the trait-based brand personality approaches have been questioned for their incomplete explanation of the whole dynamics of brand personality (Sweeney & Brandon, 2006). For example, the trait-based approach has been examined for its critical limitation in explaining some core functions of brand personality, such as identifying brands with their symbolic attributions within the same product category (e.g., Romaniuk et al., 2003; Austin et al., 2003). As such, brand personality lacks a complete theoretical understanding about its unique functioning, and there has been a conceptual discrepancy between the theoretical and empirical developments of brand personality (Azoulay & Kapferer, 2003).

This limitation is caused partly by the intrinsic limitations of traits (e.g., Pervin, 2003; Braun-LaTour et al., 2007), but moreover, it is mainly due to some common misconceptions amongst academics. Previously, academics contended that brand and human personality share the same conceptual framework as well as scales—which is not true. Brand and human personalities are not analogous—brand personality is beyond the lexical scope of human personality (Sung & Tinkham, 2005). As a marketing-homegrown concept, brand personality demands a marketing-homegrown theory (Rook, 2006)—which the prevailing theories are not.

2. The theory of consumption symbolism: A market-oriented approach

2.1 Suggesting a new theoretical base: The theory of consumption symbolism

This article suggests a new and expansive theoretical base for brand personality—the theory of consumption symbolism, which is a marketing-homegrown research stream with an interdisciplinary academic basis. With all the diverse approaches and terms, scholars have consistently pursued the same goal—to identify and tabulate symbols beneath the surface of consumer goods (e.g., Arnould & Thompson, 2005; Belk, 1988; Hirschman & Holbrook, 1992; Holt, 1997; 2004; Kate, 2002; Mick, 1986). The theory of consumption symbolism refers to a rising research sub-stream in the marketing literature, which aims at identifying the mechanisms of meaning of consumption in the contemporary marketplace and its relation with consumer behavior. To address the market-oriented research topics, the theory of

consumption symbolism has its roots in diverse basic disciplines such as philosophy, psychology, anthropology, economics, and sociology.

2.2 Application to brand personality studies

In-depth understanding of brand personality and its market-oriented mechanisms can be pursued within the theoretical base of the theory of consumption symbolism. This article presents two major new concepts that are required for the new brand personality studies to actualize market-oriented approaches. With the base of the theory, studies about brand personality can be expected to gain a market-oriented (i.e., context-oriented and consumer-oriented) perspective.

Context-oriented. According to the theory of consumption symbolism, the meaning of brand is established by consumers by being projected the everyday life stories of the consumers, which are inevitably contextual. The meanings of products should be understood and decoded based on “contextual” understandings that are essential in addressing consumption symbolism (Holt, 1997; Kates, 2002)—as should brand personality. However, the previous trait-based approaches considered brand personality with regard to customers’ demands for “traits,” which are inner-related and psychiatric characteristics of a human—therefore it is not apparently related to consumer behaviors in the marketplace. Therefore, the conceptual references of brand personality studies should be interdisciplinary, instead of single-disciplinary (e.g., psychology).

Consumer-oriented. Furthermore, studies about brand personality should maintain consumer-oriented perspectives. According to the theory, meaning of products should be understood from consumers’ perspectives, not from others, since the meaning is generated and interpreted by consumers themselves. What has been largely missed in the trait-based approach is that, with few exceptions, they have tried to build a conceptual framework for brand personality by referring other concepts in other areas. Brand personality is not a concept that has adopted other concepts and theories (e.g., traits) from different disciplinary (e.g., psychology), but rather it is a concept that is developed by customers within a marketplace (e.g., Upshaw, 1995). The consumer-oriented approach can also be actualized with the experimental consumer research methods suggested by scholars in the theory of consumption symbolism, such as hermeneutics (e.g., Thompson, 1997) or narrative approach (e.g., Bruan-LaTour et al., 2007).

3. Discussion and Research agenda

3.1 A new conceptual framework with a multi-method approach

To start up new theoretical approaches for brand personality, brand personality needs a new conceptual framework from the new theoretical base. To be useful in the marketplace, the new conceptual framework should be able to explain the meaning and symbols that are projected to brands (with human metaphor) by the majority of consumers. Based on its common definitions (e.g., Aaker, 1997), the conceptual boundary of brand personality can literally have all the human characteristics that consumers associate with a brand—traits and personality are only part of them. To investigate this, it may require a fundamental literature review regarding a basic question: what the human characteristics are—and this can be narrowed down into actual structural components, based on consumers’ perception about brand personality. This requires exploratory qualitative studies with a ground theory (e.g., Charmaz, 2006).

3.2 A systematic approach on non-utilitarian brand management

On many occasions, management skills regarding brand meaning have largely been left unidentified. Only a few celebrated gurus can figure them out on the basis of their intuitions and instincts. With the elaborated conceptual framework of brand personality, it is expected to reveal and explain some essential functions of brand personality (e.g., non-utilitarian differentiation points among brands) in a more structured manner—which gives useful insight for practitioners as well as academicians.

Useful brand personality measurements can also be identified based on the framework, but it requires in-depth understandings about the social and cultural contexts surrounding the marketplace. Some structural components of brand personality would be highly contextual, and others (e.g., traits) not. Eventually, this also brings us to the idea of multi-level in the structural components of brand personality (e.g., those that are more stable and essential and others that are more contextual).

Moreover, practically useful brand personality measurements should be different according to diverse contexts, and it also derives to studies about cultural difference which can give useful inspiration for global marketing.

3.3 Decoding brand meanings with the mediation of brand personality

Finally, brand personality can be a mediator for understanding brand meanings and the dynamics of postmodern branding. There have been a great contribution for brand meaning with a provocative approaches (e.g., Aaker & Joachimsthaler, 2000), theoretical explanations about brand meaning and the non-utilitarian characteristics of brands are still in its infancy stage, and the developments have mostly been accomplished only in practical marketing circles. With a well-developed conceptual framework of brand personality, some aspects of the non-functional attributions of brands, or of the brand meaning, or the consumption symbolism, can be decoded.

Endorser Influence on Product Judgment and Choice: A Comparative Study of Children and Their Parents

Aron M. Levin, Northern Kentucky University, USA

Irwin P. Levin, University of Iowa, USA

In this paper we will describe the next phase in our longitudinal study of the development of decision-making competence in children (National Science Foundation Grant No. SES07-21103). Whereas earlier phases focused on general decision-making style and riskiness of choice in games of chance, the current research focuses on an important class of real-world judgments and choices, namely the development of product preferences.

There is growing concern about how manufacturers of food products capitalize on the undue influence of favorite cartoon characters as "virtual persons" promoting unhealthy (e.g., sugar-laden) products. Specifically, we focus on the role of endorser influence as a peripheral cue affecting consumer judgments and decisions. Previous research on the general topic of endorser influence has been conducted within the context of Petty and Cacioppo's (1986) Elaboration Likelihood Model which distinguishes between central and peripheral routes to persuasion and considers "need for cognition" as a key individual difference variable. The bulk of this work has been done with adult consumers. We extend this work to children.

As in the earlier phases, the key to this research is developing tasks and measures suitable for both children and adults. In the present case, these developments required the following: 1) selecting both healthy and unhealthy food products used by children and adults; 2)

collecting normative data to identify favorite cartoon characters as “celebrity endorsers” for the target child group; 3) constructing a children’s version of the Need for Cognition (NFC) scale; 4) using each child’s parent as a “yoked control.”

Research Design

A 2x2x2 factorial design was used to generate 8 unique stimuli (product descriptions) for each child and parent. The factors were whether or not the product’s brand name was familiar, whether or not the product could be classified as “healthy,” and whether or not the product description included a well-known endorser. Each participant received each of the 8 combinations, constructed such that no person received the same brand name or endorser more than once.

Hypotheses

Based on prior research with adults (Homer, & Kahle, 1990; Petty, Cacioppo, & Schumann, 1983), the following hypotheses (H) are provided for parents’ data. In addition, a new research question (Q) will be addressed.

- H1. Endorser effects should be greater for those scoring low on NFC than for those scoring high.
- H2. Endorser effects should be less for known brand names than for unknown brand names.
- Q1. How are endorser effects moderated by whether the product falls into the “healthy” or “unhealthy” category?

Based on prior research showing that children of the targeted age are less responsive to risk level in their decisions (Levin, et al., 2007) and that they strongly identify with their favorite cartoon characters (Chapman, et al., 2006), the following hypotheses and question deal with comparisons between children and adults:

- H3. Children will weight endorser more and health benefits less than adults in their product ratings.
- H4. As with adults, the endorser effect will be moderated by need for cognition and brand name familiarity.
- Q2. Across child-parent pairs, will endorser effects be correlated such that parents who are most susceptible to endorser influence will have children who are similarly inclined?

Method

In the initial phase of the study of decision-making competence, 37 children age 5-7 and 43 children age 8-11, and their parents were administered a risky decision-making task especially designed to determine how riskiness of choice varies in response to contingencies that make risky choices advantageous or disadvantageous in the long run. For the new phase approximately 50 pairs of 7-8 year-old children and their accompanying parent are being recruited through the Child Research Participant Registry of a large midwestern university. Because some of these same children had participated in the initial phase, we will have background material on many of them.

Based on our pilot work, the following “endorsers” were selected for the children: Sponge Bob, Shrek, Scooby-Do, and The Incredibles. Their images were affixed to photos of the product package. Based on published norms of celebrity popularity, the following were selected as adult endorsers: Tiger Wood, Jay Leno, Katherine Heigl, and Adam Sandler. A photo of the endorser and a statement of endorsement appeared next to the photo of the product.

“Healthy” products were breakfast cereals and yogurts; unhealthy products were potato chips and sweet tarts. Within each product category the brand name was either well known or fictitious (ex. Yoplait vs. Emmi Yogurt). Each of the eight product depictions appeared as a separate laminated colored sheet. Participants are asked to rate each one on likeability, desirability and purchase intent. Standard Likert scales are used for adults; previously used frowning/smiling face scales are used for children.

Adult and child versions of the NFC scale are shown in the appendix. The adult version is the 18-item scale developed by Cacioppo, Petty, and Kao (1984). The child version retains 13 of these items in slightly modified form for each parent to rate her child.

Results and Discussion

The current results will add to our existing data which show that: 1) The decision-making style of young children age 5-7 closely adheres to that of their parents but diverges as they get older (8-11). 2) Younger children’s choices are less affected by risk level than are older children’s or adults’. 3) Children make riskier choices than their parents but their riskiness is moderated by dispositional traits such as “urgency”.

We expect data collection and analysis for the new phase to be completed by the beginning of the summer. Among the more important results we are expecting are that children will be more susceptible to endorser effects than adults, that the effects in children will be less subject to the moderating influences of brand familiarity and healthiness, but that there will be a relationship between child and parent susceptibility. Such results will advance our understanding of children as consumers and will provide guidelines for identifying the profile of children especially susceptible to adverse advertising influences.

The Intersubjectivity of Family Consumption: Intra-family Consumer Identity and the Family Scape

Jeppe Trolle Linnet, University of Southern Denmark, Denmark

This paper is based on ongoing ethnographic fieldwork among four Danish middle-class families in Copenhagen. It is a phenomenological account of how consumption constitutes the intersubjectivity of family life, interpreting a detailed case of one family's car ownership and purchase. This family used to drive a Volvo that long-term ownership had sacralized and de commodified (McCracken 1986; Belk, Wallendorf et al. 1989). The purchase of a new Ford marks a sea change in their constellation of individual identities, family identity and brand meanings. I use the phenomenological concept of intersubjectivity as a lens through which I analyze this process (Schutz 1970; Jackson 1996, 1998), and suggest two concepts for the analysis of family consumption: *Intra-family consumer identity* and *family scape*.

The paper contributes to uncovering the dynamics of consumer identity projects, and how the structures and normative views of society influence consumption (Arnould and Thompson 2005), as well as collective, long-term, narratively embedded forms of consumption rather than individual, isolated acts (Fournier 1998; Muniz Jr. and O'Guinn 2001).

I consider ways that the different family members exert individual agency as they negotiate their way towards a purchase decision balancing individual desires and collective needs. However, the paper is not focused on the modeling of collective decision-making and individual influences that has been a major preoccupation of family consumption research. Rather, the paper contributes to current research that aims to conceptualize the participatory roles of consumption objects and activities in fluid, multi-layered processes of family identity enactment (Epp and Price 2008), adding to this research a focus on intra-family negotiations and inter-family processes of identity construction through consumption.

I find the term *intersubjectivity of consumption* suggestive for describing the ongoing give and take of intra-family consumer relations, and how family consumption becomes meaningful in the context of a wider social network of families who evaluate each other's consumption practices and identities. To this end I present a detailed analysis of how family members both contest and resonate with each other's consumer desires and preferences. I emphasize that even in the "sacred" sphere of home and family life, access to which consumers often deny market messages (Coupland, Iacobucci et al. 2005), family members know each other *as consumers*. Each family member has a set of desires, preferences and values whereby other family members know him or her. I suggest the concept of *intra-family consumer identity*: An individual set of dispositions—changing over time—for certain practices of consumption, ownership and disposition that present our fellow family members with a window upon our needs, desires, values and fears, and thus a potential for collective or dyadic bonding and empathy, but also challenge them with potential transgressions and dominations of their lifeworld. In families as in wider consumer society, having desires is seen as a positive human trait, but can also as a potential disposition towards excess that collide with the surrounding social world (Belk, Ger et al. 2003). I outline a family-specific dynamic of mutual social knowledge about each other's everyday consumption patterns and desires, in which empathy and conflict coexist as intersubjective fundamentals of family consumption.

The concept of intra-family consumer identity allows for my observation that family members draw different meanings from the same consumption objects, but also that they are aware of the meanings perceived by their fellow family members. I argue that in order to conceptualize more fully family consumption, we must consider intra-familial diversity of interpretation, as well as conflicts. The temporal perspective is also important: in being less voluntary and fluid than brand communities, and involving long-term (even multi-generational; Price, Arnould et al. 2000) interactions across a wide range of consumption categories, the dynamics of family consumption differ from other consumption communities.

The last aspect to this analysis is how family consumption connects to society and social networks. The normativities and classifications of wider society impinge on family consumption in several ways documented by this paper: The moralized opposition between consumer restraint and excess, or between thrift and "the treat" (Miller 1998), repeat themselves in a fractal-like manner at each level from *inter-family* social distinctions to the gendered interactions of *intra-family* consumer identities, and at the individual level in the ongoing moral self-reflexivity of the individual consumer. Intra- and inter-familial consumer identities thus mirror the discourses and ideologies of the marketplace (Kozinets 2008).

Another structuring force influencing family consumption, which has also been suggested by other family consumption researchers, is the "familial gaze" of families observing and critically evaluating each other lifestyle (Epp and Price 2008). My paper shows the existence of a heavily moralized model for how a family ought to consume, one which sanctifies authenticity and hard earned rewards (such as home cooking or physically demanding family trips to the Norwegian mountains) while denigrating convenience (take away food or package tours to Tenerife). And just like the gaze of "absent others" is internalized and present in how people organize their material home (Miller 2002), the intra-family consumer identities simultaneously face inward towards the family sphere, as they are actualized in interaction with other family members, and outward towards the symbolic, libidinous and moral structures of the consumer culture, which they both resist and draw upon.

I suggest the concept of the *family scape* to denote this complex of meanings that structure family consumption, while also being appropriated by the family in its ongoing construction of identity. This scape is a general cultural model, transmitted partly through marketing, of what a family is and is not, and what being a family means in consumption terms. In several variations, the concept of the scape has shown its potential for consumer research and social science in theorizing how overarching structural codes and commonalities shape and constrict local communities, groups and individuals, who are thereby also empowered with a means for communicating identity and exercising agency (Billig 1995; Wilk 1995; Kjeldgaard and Askegaard 2006)

The Role of Voice Design Features in Effective Self-Service Technologies

Jiayun Wu, The University of Arizona, USA
Sherry L. Lotz, The University of Arizona, USA

Abstract

This study aims to advance the understanding of effective self-service technologies (SSTs) in an ever increasing technology-mediated environment. The study hypothesizes a positive relationship between the voice design features (i.e., ease of voice) and customers' voice intention. This relationship is also mediated by customers' interface evaluation of SSTs. The study also evaluates how customers' likelihood of successful voice outcome moderates the relationship between customers' interface evaluation and voice intention. Hypotheses are proposed to be tested by using a computer-based online shopping experiment and a questionnaire given to college students.

Justification and Purpose

Self-service technologies (SSTs)—defined by Meuter, Ostrom, Roundtree, and Bitner (2000, p. 50) as "technological interfaces that enable customers to produce a service independent of direct service employee involvement"—are increasing in prevalence and becoming an important component of marketing (Zhu, Nakata and Sivakumar 2007). SSTs provide various services including monetary transactions, e.g., retail purchases; customer services such as hotel check out; and self-help, e.g., distance learning. These services benefit retail organizations and customers alike. Retailers are drawn to SSTs by their promise of greater cost efficiency, enhanced service quality, and their appeal to new customers when compared to in-person services (Parasuraman and Grewal 2000). Customer benefits include increased convenience, increased perceived control, money and time savings, and product/service customization (Robertson and Shaw 2005).

Given these benefits, customers in technology-mediated shopping environments value considerably the features of the technological interfaces, viz., the core components of SSTs (e.g., Alba et al. 1997; Zeithaml, Parasuraman and Malhotra 2002). Past research on SSTs and e-services provide some evidence for the positive impact of design features. For instance, Zhu, Nakata, and Sivakumar (2007) show how combined interface characteristics (i.e., comparative information and interactivity) and their interactions with individual traits influence SST effectiveness. However, researchers still know little about SST voice design features from the perspective of customers.

The purpose of this study is to address the existing literature's knowledge gap regarding the factors that may lead to greater SST effectiveness. More specifically, it investigates the relationships between SST voice design features, customers' interface evaluation of SSTs, and SST customers' voice intention. It also examines whether and how customers' perceived likelihood of successful voice outcome influences the relationship between customers' interface evaluation and voice intention.

Theoretical Framework and Hypotheses

As SSTs prevail and increase within marketing (Zhu, Nakata and Sivakumar 2007), researchers and practitioners recognize the need to understand the effectiveness of SSTs. This study focuses on one design element of the SST interface, viz., voice, which has received only limited systematic research regarding its relationship to SST effectiveness. Using SSTs, an organization can provide efficient and effective interface features to facilitate and encourage customer voice.

This study includes four constructs in its theoretical framework. These include SST voice design features (i.e., ease of voice), customers' interface evaluation of SSTs, customers' voice intention, and customers' perceived likelihood of successful voice outcome. The literature defines ease of voice as customers' perceptions of the effort or trouble required to lodge a complaint with the service organization (Robertson and Shaw 2005). This study defines customers' voice intention as the customers' aim or intention to direct complaints to the service organization through various means. Interface evaluation refers to the judgments or attitudes about an SST based on customers' experience with it (Zhu, Nakata and Sivakumar 2007). This study defines likelihood of successful voice outcome as the customer's perception of the level of positive outcome resulting from a service organization's efforts to remedy a service problem. The definition of likelihood of successful voice outcome is a modification of the definition for likelihood of success of the voice, which refers to customers' perceptions of the service organization's willingness to remedy service problems without "hassle" (Hirschman 1970). Two major reasons underlie this modification. First, Hirschman's definition does not account for various scenarios within a more complicated picture. For example, customers might perceive a service organization's willingness to remedy service problems as very high, but success-of-voice likelihood could be low (due to factors such as a service organization's incapacity to remedy service problems to the degree it desires). Second, the experience customers gain from directing complaints to a specific service organization in addition to customers' previous experience with other organizations and/or technologies, may significantly influence their perceived likelihood of successful voice outcome. For instance, research has demonstrated that previous non-store experience may help predict customers' intention to adopt interactive electronic formats (Eastlick 1996) and to also shop electronically (Shim and Drake 1990).

The study proposes the following four hypotheses:

H1: Customers' perceived ease of voice of SST voice design features will relate positively to customers' voice intention.

H2: Customers' perceived ease of voice of SST voice design features will relate positively to customers' interface evaluation.

H3: Customers' positive SST interface evaluation will relate positively to customers' voice intention.

H4: Customers' perceived likelihood of successful voice outcome will moderate the relationship between customers' interface evaluation of SST and their voice intention.

Methodology

This study will utilize a combined methodological approach consisting of focus-group interviews, a computer-based online shopping experiment, and self-administered questionnaires to evaluate voice design features in the SST environment. First, focus-group interviews, comprised of a sample of 15 college students, will identify: 1) a typical product that they have commonly purchased via a website, 2) typical SST voice design features that are considered to be easy, and 3) typical factors that may influence customers' perception of likelihood of successful voice outcome. Fifteen college students will complete the focus-group interviews in approximately 40 to 60 minutes on average. Next, this study will develop and test a computer-based experiment that simulates the self-service process that occurs with online shopping. The experiment will allow participants to respond to and evaluate the SST based on their actual interaction with the technology rather than through a hypothetical scenario. Interacting directly with the technology will enable participants to develop a sense of the level of ease of voice and the likelihood of successful voice outcome in the study's SST environment, and to thereby assess the technology in a more realistic and practical fashion. Prior to using the website for the final online shopping experiment, the website will be pre-tested using 15 college students from the same university to ensure that the website is both feasible and realistic. Fifteen students will complete the website pre-test in approximately 25 to 40 minutes on average.

Finally, participants will be asked to complete the questionnaire and to provide individual demographic information to be used in the data analysis phase of the study.

Is it Always Good to Feel in Control? Effects of Mortality Salience and Health Locus of Control on Health Behaviors

Adriana Samper, Duke University, USA
 Mary Frances Luce, Duke University, USA
 Devavrat Purohit, Duke University, USA

According to Terror Management Theory (TMT), individuals invest in their worldviews to assuage the fear aroused by a reminder of their mortality when death is made salient (Greenberg, Solomon & Pyszczynski, 1997; Shehryar & Hunt, 2005). These worldviews act as anxiety buffers by creating order and meaning, by providing standards of value, and by offering symbolic death transcendence to those who strive to meet these standards (Greenberg et al., 1997). Research has suggested that reminders of one's mortality increase the need to believe that others share one's worldview, leading to inflated estimates of consensus of one's opinions (Pyszczynski, Wicklund et al., 1996). Communications to consumers regarding health behavior often take place in settings where the threat of death may be salient (e.g., in a physician's office, as part of negatively emotion-laden appeals). Hence, we believe it is important to investigate the implications of TMT for consumer health behaviors.

Past research has examined the role of TMT on worldview and its influence on attitudes and behavior in a health context (e.g., Goldenberg, 2005; Shehryar and Hunt 2005). To date, however, research has yet to examine how the worldview of *perception of control over one's health* affects actions and thoughts surrounding disease risk and prevention, particularly in the context of a contagious disease. We utilize the construct of Health Locus of Control (Wallston, Wallston, Kaplan & Maides, 1976; Wallston & Wallston, 1981) to measure perceived control over health. On this scale, "health internals" believe that one's health is largely a result of his or her own behavior. At the other end of the dimension, health externals have generalized expectancies that the factors that determine their health are largely uncontrollable (i.e., external factors such as luck, fate, chance or powerful others). In this research, we add to the relatively small literature on worldview, perceptions of control and contagion to examine how mortality salience affects behaviors and perceptions of risk in a fatal and contagious disease context.

Previous research on Health Locus of Control (HLC) suggests that the feeling that one is in control of one's health leads to more adaptive health behaviors. A more internal HLC has been associated with certain preventive health behaviors (Norman, Bennett, Smith & Murphy, 1998), such as the ability to stop smoking (e.g., Kaplan & Cowles, 1978), and performance of exercise and dieting behaviors (Norman et al., 1998). In this research, we examine the effects of Health Locus of Control under mortality salience to see how health locus of control affects risk perceptions and behaviors. In particular, we examine how the drive to resolutely defend worldview will lead to inflated views of consensus of one's worldview under mortality salience. We suggest that under mortality salience, a more internal locus of control causes individuals to externalize their worldview of personal control over health onto others, leading to the notion that others are also at lower risk for disease. This in turn should lead to reduced unrealistic optimism (Weinstein, 1980) of not being infected with HIV as well as reduced future HIV prevention intentions. Hence, we hypothesize that the traditional relationship between HLC and health behavior will reverse in environments characterized by mortality salience.

In Study 1, participants were presented with the threat of HIV following a mortality salience (versus a dental pain) prime, and were asked to rate their own risk of being infected with HIV, the average other's risk of being infected with HIV, and their intentions to engage in future HIV-preventive behaviors. A moderated regression analysis on both unrealistic optimism (likelihood of having HIV-likelihood of the average other of having HIV) and prevention intentions (e.g., index of condom use, selectivity in sexual partners, etc.) revealed that a more internal health locus of control, while leading to greater unrealistic optimism and increased HIV prevention intentions at baseline (dental pain prime), becomes maladaptive and leads reduced unrealistic optimism and lower preventive intentions under mortality salience. We interpret these findings as reflecting a process whereby mortality salience leads to an increased perception of consensus of others' risks being similar to one's own, reducing the perceived population risk, and thus reducing overall HIV prevention intentions.

In order to test our proposed mechanism (i.e., that mortality salience causes individuals to externalize their worldview such that they see that others' estimates as their own), Study 2 manipulated the (self versus other) focus of the health message while again measuring health locus of control. Thus, this study directed participants to either take on a self-view, or an 'average other'-view (akin to the externalized worldview that we propose happens under mortality salience in Study 1) when reading the involving HIV information. In this sense, Study 2 allowed us to examine whether the mechanism of false consensus (encouraged by other focus) would cause more internal individuals to reduce their heightened unrealistic optimism of avoiding HIV infection and erode the preventive advantage of internals, as seen in Study 1. Again, a moderated regression analysis on unrealistic optimism and prevention intentions revealed that a more internal health locus of control, while leading to directionally greater unrealistic optimism and increased HIV prevention intentions with a self-focus, becomes maladaptive and leads reduced unrealistic optimism and lower preventive intentions with an other-focus.

This research has important implications for the communication of health messages, specifically those that convey death as a possible consequence. This type of message could potentially lead to increased risk-taking behaviors among those individuals who would normally engage in very protective, preventive behaviors, as evidenced by our initial study. Our research will help elucidate why certain health appeals may be more or less effective depending on the presence or absence mortality salience, and the degree of an individual's health locus of control.

Changing Behaviors toward Stigmatized Diseases

Linyun Yang, Duke University, USA
Mary Frances Luce, Duke University, USA

One of the major barriers to getting individuals with stigmatized diseases (i.e. STDs and psychiatric disorders) to seek treatment is the shame and distress caused by having to admit one has the disease. A large amount of research has documented the many consequences an individual must endure should he or she be associated with a stigmatized group. For example, Young et al. (2007) found that people not only view individuals suffering from STDs as being immoral in the sexual domain (e.g. being promiscuous, having premarital sex) but people also view these individuals as being immoral in nonsexual domains (e.g. lying, shoplifting). Being associated with a stigmatized group can be so debilitating that individuals are reluctant to seek treatment despite the obvious health and social benefits of doing so. For example, in the United States, approximately 60% of people with psychiatric disorders failed to receive any treatment within a one year period (Wang et al. 2005). This sample included both individuals with relatively minor disorders (e.g. adjustment disorders) and individuals with serious illnesses (e.g. schizophrenia), suggesting that even those who should have had the ability to seek help (i.e. those with minor disorders) decided not to do so.

Recent research from the stereotype literature suggests a method to directly address this stigma associated with the disease. The stereotypes associated with individuals suffering from stigmatized diseases often motivate others' negative expectations and prejudices (Corrigan 2004). Thus, one way to address stigma is by leveraging the finding that the way exemplars are categorized can change the evaluations (and hence the stereotypes) of groups they belong to (Bless et al. 2001; Kunda & Oleson 1995). More specifically, when positive exemplars are *included* in a group, the characteristics associated with the exemplar will be assimilated to the evaluations of the group. For example, when a favorable exemplar like Colin Powell is included in the group of Republicans, subsequent evaluations of the Republican Party become more positive (Stapel & Schwarz 1998). On the other hand, the *exclusion* of a favorable exemplar will lead to subsequently more negative evaluations of the group. This occurs because the exemplar is used as a standard of comparison, so the group as a whole appears worse off, leading to a contrast away from the positive attitudes toward the exemplar. Thus, we predict that inclusion of a positive exemplar will have beneficial effects for individuals with a negative stereotype regarding a particular patient group (e.g., the mentally ill).

We hypothesize that this is moderated by preexisting attitudes towards treatment. The degree to which negative stereotyping is a barrier to treatment, and hence the benefit of the inclusion mechanism, should be particularly strong for individuals who doubt the efficacy of mental health treatment. Specifically, inclusion of positive exemplars should be beneficial for individuals with preexisting negative attitudes toward treatment seeking. That is, inclusion of a positive exemplar should, by reducing negative group stereotypes, motivate these individuals to take steps towards treatment, even if these steps will involve (potentially prolonged) association with the stigmatized group. Conversely, when their views of those suffering from a stigmatized disease are altered, individuals with preexisting positive attitudes toward seeking treatment will likely react very differently. For individuals who are already highly inclined to seek treatment and readily believe in its effectiveness, making them view the group more positively (through inclusion) may *reduce* treatment seeking by undermining the perceived extremity or severity of the disease, in turn reducing motivation to use treatment to be rid of the disease and dissociate themselves from the stigmatized group.

In our experiment, we measure whether or not individuals express intentions to seek treatment if they experience symptoms of the mental disorder depression. Prior to participating in the formal experiment, participants completed the "Attitudes toward Seeking Professional Psychological Help Scale" (Mackenzie, Knox, Gekoski, & Macaulay 2004). During the formal experiment, participants read an article describing the symptoms of depression and were also introduced to a positive exemplar, Uma Thurman, who had suffered from depression in the past. Next, participants completed questions that lead them to either include or exclude Uma Thurman from the group of individuals suffering from depression (Bless & Wänke 2000). Following this task, participants read a scenario that described a situation in which they were experiencing symptoms of depression and then answered questions related to treatment seeking behavior. We find a 2-way interaction ($\beta = -0.51, p < .05$) between manipulated inclusion (versus exclusion) and measured attitudes where individuals with more negative attitudes toward mental health services are more likely to seek treatment when they *include* Uma Thurman compared to when they exclude her. However, individuals who have more positive attitudes toward mental health services display the opposite pattern

where they are more likely to seek treatment when they *exclude* Uma Thurman. Follow up research manipulating (rather than measuring) underlying beliefs regarding treatment and disease is underway.

These results indicate that efforts to increase treatment seeking for stigmatized diseases must address both the stigma associated with individuals suffering from the disease and also people's preexisting attitudes toward seeking such services. This suggests that public service campaigns featuring celebrities with stigmatized diseases can be detrimental to some while beneficial to others, depending on each individual's preexisting attitudes toward mental health services and also how the celebrities are categorized. As we gain a better understanding of how stigma serves as a barrier to getting tested and seeking treatment for stigmatized diseases, we will be able to develop and implement effective strategies for combating this obstacle and encourage individuals with stigmatized diseases to request help to improve their health.

Choosing Between American and Chinese Brands

Jingjing Ma, University of California, Los Angeles, USA

Shi (shir) Zhang, University of California, Los Angeles, USA

As the world's largest consumer market, China attracts many multinational corporations and foreign products and brands. The Chinese consumers' choices of these products and brands have changed in the past few years. For example, compared to Chinese products, American products used to have many competitive advantages, such as high quality and prestige. Due to recent surge of economic development and progress in technology and manufactory capabilities, more and more consumers in China begin to prefer domestic products to American products and in some situations they perceive Chinese products to be better choices than American products. Given that consumer choice decision making can be driven to a large extent by situational variables (e.g., psychological reactions to marketing activities), it is important, in terms of both consumer research theory and managerial significance, to investigate when and how Chinese consumers prefer products from American versus from their own country is important, and the role of brand plays in the decision making. This research aims to provide insights into Chinese consumers' psychology of decision making, relative to what we already know about Americans.

Theoretical background

Earlier research findings show that when choosing products such as clothes, cosmetics, and high-tech gadgets like cell phones and laptops, Chinese consumers usually prefer American brands, but when facing durable goods, TV sets, food etc, they prefer domestic brands. We note that those preferred American products are hedonic products, which seem to provide more utility on the dimension of experiential consumption, fun, pleasure, and excitement, whereas those preferred Chinese products are in general utilitarian products, primarily functional and instrumental.

Drawing from existing research, we suggest that the above observed behavior tendency in choice decision making can be moderated by decision contexts. For example, Bohm and Pfister (1996) show that asking participants to justify their choices can enhance their preferences for utilitarian products. Similarly, Bazerman, Tenbrunsel, and Wade-Benzoni (1998) find that making a choice can force consumers to choose what they should buy (vs. want to buy), so that they are more likely to buy utilitarian products. Furthermore, Dhar and Wertenbroch (2000) find that requiring subjects to list reasons for their choices can de-emphasize the hedonic focus relative to the utilitarian focus in subjects' product evaluations. Based on findings from this earlier research, we suggest that Chinese consumers should prefer utilitarian products more in with-justification condition than in without-justification condition, as providing reasons to justify decisions make consumers more likely focus on the utilitarian aspects of products and less likely on the hedonic dimension. Further, since Chinese consumers view western products to be more image driven, while Chinese products are pragmatic, Chinese consumers should prefer Chinese brands more in the justification condition than in the no justification condition, and versa vice for American brands.

Experiment and Result

One hundred and forty students were recruited from Peking University in Beijing, China. They were paid for their participation. Participants reported to an amphitheater and were assigned randomly to four conditions by receiving four kinds of questionnaires. The two independent variables are product category (hedonic and utilitarian) and justification (without-justification and with-justification). This constitutes a 2 (product category) * 2 (justification) between subjects design. The dependent variable is participants' choice between a Chinese brand product and an American brand product. In this experiment we find that in without-justification condition, Chinese consumers prefer American products regardless of hedonic or utilitarian; however, in with-justification condition, their preference varies across categories: in hedonic category, more participants prefer American products, but in utilitarian category, more participants prefer Chinese products.

Discussion

Much country of origin research points out that in developing countries consumers generally prefer products from developed countries to their own products. We find that this is not necessarily the case, depending on specific choice situations. In without-justification condition, Chinese consumers generally prefer American products regardless of product categories; but in with-justification condition, their preference varies across categories: they prefer American products in hedonic category but prefer Chinese products in utilitarian category. Although previous research finds that product types or levels of justification may influence consumers' preference, no research combines these two factors together to explore their interaction.

Some research finds that levels of justification may influence consumers' preference toward hedonic and utilitarian products. Specifically in without-justification condition consumers are likely to prefer hedonic products, but in with-justification their preference towards utilitarian products may increase. The focus of this previous research is on the influence of levels of justification on choice of products types (hedonic or utilitarian). In our research, we use the previous independent variable-levels of justification and dependent variable-product categories as two independent variables, and focus on their interaction effect on choice between American products and Chinese products. We find that not only does justification influence preference towards utilitarian versus hedonic products, it also changes the pattern of consumers' preference toward American versus Chinese products in hedonic and utilitarian categories.

Understanding Shopping Stress Using Perceived Risk and Cognitive Appraisal Theory: A Synthesis, Elaboration and Application

Elaine MacNeil, Cape Breton University, Canada
Peter MacIntyre, Cape Breton University, Canada

It is important to identify not only shopping stressors but to understand why some events are perceived as stressful if we are to provide sound advice to retailers and consumers to reduce the stress associated with shopping. Unfortunately, stress has been a neglected area of enquiry in the field of consumer behaviour. Our research into shopping stress uncovered two concepts, previously studied independently, that shed light on this area: perceived risk and cognitive appraisal theory (CAT). The overlap between these conceptual schemes is striking and their synthesis provides a potentially powerful theoretical tool with which to study shopping stress. In providing this synthesis we propose two extensions that further our understanding of stress: the role of emotion and optimal challenge. Finally, we apply the conceptualization, emerging from a grounded theory approach, in an iterative fashion to the study of men who tell us they hate shopping. Consistent with this year's conference theme of Port of Call, we wish to reflect on where we have been and suggest a new direction for where we might go.

Raymond Bauer introduced the concept of perceived risk at the 43rd conference of the AMA in 1960, the same year in which Magda Arnold (1960) introduced the concept of appraisal into the stress literature. Over the years, the two research traditions have grown up quite independently, risk taking primarily studied in the field of marketing and CAT research primarily studied in the domain of psychology. Yet the conceptual overlap is astonishing. We propose that the integration of these concepts is useful to understanding stress, in particular the *differences* among people not only in what shopping events they consider stressful but why these events are stressful.

In synthesizing the literature on these concepts we considered the following categories: definitions, processes, and consequences. According to Cox (1967) the amount of perceived risk involved in any behavioral act is assumed to be a function of (1) what is at stake and (2) the individual's subjective feeling of certainty that the consequences will be unfavorable (Cox 1967, p. 37). Similarly, in CAT Lazarus suggested that "we must consider our chances of mastering the transaction and having a positive outcome, what we have to do to attain the goal, and what price we must pay for success and failure" (Lazarus 1999, p. 71). Cognitive appraisal results in a subjective emotional experience that helps to orient a person to the relevance of an object or event. Both perceived risk and cognitive appraisal theories draw attention to how persons evaluate and cope with stressors. The definitions of perceived risk and cognitive appraisal both emphasize the subjectiveness of the experience and the interaction of person-specific and situational factors. Experiences such as risk and stress are not viewed as objective properties of situations, therefore reactions differ greatly person to person. Perceived risk and CAT also share similarities in terms of the way people define what is at stake, including the potential cost of wasted time (Roselius 1971), physical wellbeing, financial resources, and threats to self-esteem (Jacoby and Kaplan 1972). Decision making is perhaps the key outcome in both theories. Coping with stress is a function of resources available, including spending more time or money and accessing knowledgeable others for support. Both theories also highlight goals as motivational supports. Cox (1967) proposed that "...whereas certainty and consequences determine the amount of perceived risk, the nature of the perceived risk should be a function of the nature of the buying goals involved" (Cox 1967 p.38). Similarly, stress occurs as a function of the strength of one's goal commitment and the degree to which the goal is endangered (Lazarus 1999). Sujjan, Bettman and Verhallen (1999) identified the largest categories of stressors as choice-related

stressors (e.g., having too many options) and in-store ambient stressors (e.g., music). However the question of why these factors were perceived as stressors in the first place largely was ignored.

In considering the convergence of these two theories, we note that at least two elaborations are required. First, a greater emphasis is needed on the importance of emotion in studying perceived risk. According to Taylor (1974) "risk is often perceived to be painful in that it may produce anxiety" (Taylor 1974, p.54), yet the role emotion plays in perceived risk has generally been ignored (Chaudhuri 1997). In the second area for elaboration, we recommend greater emphasis on the concept of optimal challenge, and with it potentially positive emotional reactions to risk. Within CAT, emotions associated with challenges include eagerness, excitement and exhilaration. Perceived risk in the consumer behaviour literature focuses almost exclusively on the negative consequence associated with uncertainty. We suggest that both the positive and negative outcomes should be considered in assessing perceived risk (Dholakia 1997). The perceived risk literature highlights the importance of uncertainty as a source of stress, but we believe that both certainty and uncertainty might have positive or negative consequences. For example, uncertainty might be perceived as a welcome challenge to the recreational shopper; product certainty might predispose a reluctant shopper to frustration if unanticipated delays occur.

We used classical grounded theory to inform this perspective. We interviewed 35 men who said they hate shopping. Emerging from this rich data was a complex relationship between stress, ability, and behaviour that we propose is mediated by the men's level of certainty. For example, in the context of gift shopping, certainty of a negative outcome affected expenditure of effort, one man said:

No matter what you buy it's the wrong size or it's the wrong style or it's I don't need that. What the hell do you get?" I just end up getting something. If she doesn't like it she will return it.

Uncertainty also affected risk taking, with anticipated time loss outweighing the potential benefits of shopping, as in this excerpt:

I won't go to a store looking for things that might be there. It's too chancy. There might be nothing there or a special I don want. I've just wasted half an hour.

A focus on positive and negative consequences associated with challenges and uncertainty has the potential to increase our understanding of the differences between enjoyable and stressful shopping situations. By integrating the literature on cognitive appraisal theory and perceived risk, and elaborating on the notion of the emotional processes accompanying challenges and uncertainties, future research can address not only the question of what shopping events are perceived stressful but why they are stressful for one shopper and enjoyable challenges for another.

Forming Brand Personality: Company-Based vs. Consumer-Based Sources

Natalia Maehle, Norwegian School of Economics and Business Administration, Norway

Chunyan Xie, Stord/Haugesund University College, Norway

Magne Supphellen, Norwegian School of Economics and Business Administration, Norway

In the modern consumer society we buy products not only for what they can do but also for what they symbolize. Brands encapsulate social meaning, and that allows us to use them to acquire or reinforce our identities (Johar and Sirgy 1991). Therefore, brand personality (brand's human-like characteristics) becomes one of the essential features that we consider while choosing a brand.

Not surprisingly, brand personality concept has got a lot of attention in marketing literature. However, the primary focus of previous studies has been either on understanding the effects of brand personality or on measurement issues related to the construct (Aaker 1997; Azoulay and Kapferer 2003; Govers and Schoormans 2005). Although it is also important to understand how consumers form their perceptions of brand personality, there has been little research in this direction (Batra, Lehmann, and Singh 1993). Moreover, the existing literature considers mostly company-based sources of brand personality such as company's employees, company's director, brand's endorsers (McCracken 1989), product-related attributes, product category associations, brand name, symbol or logo, advertising style, price, and distribution channel (Batra et al. 1993). Little, if any, attention has been paid to the possible consumer-based sources.

Nevertheless, consumer's voice is becoming more and more influential so that companies cannot just ignore it. Consumer based sources are important for forming brand personality both before and after consumer purchases the brands. Before the purchase take place, word-of-mouth effect will be significant in shaping consumers' understanding of the brand personality proposed by the company through the marketing mix. The formation of numerous discussion groups and brand online communities extend and strengthen the word-of-mouth effect from close others to a much larger group of people connected through a virtual network (McWilliam 2000). Compared to the company based sources, word-of-mouth will be treated as a more reliable information sources by consumers (Keller 2007). After the purchase and consumption, consumers' first hand experiences with the brands will be critical for them to reject or reinforce the proposed brand personality.

Brand personality encompasses five different dimensions: Sincerity, Excitement, Competence, Sophistication, and Ruggedness (Aaker 1997). We expect that consumer-based sources can be relevant for forming at least some of them.

Thus, the purpose of the current study is to find out which sources are relevant for forming different dimensions of brand personality. A set of sixty six semi-structured interviews was conducted to address these issues. Every respondent got questions about two different dimensions of brand personality. So, we got between twenty-five and twenty-seven answers for each dimension.

We started the interviews by explaining the concept of brand personality and the chosen brand personality dimensions in particular. Then we asked respondents to name a couple of brands that they think score high on a particular dimension. Respondents also explained their reasons why they thought so. Finally, respondents were asked to look on the list of possible sources of brand personality and choose five of them which they think are especially relevant for a particular personality dimension. Our final list included thirteen company-based and four consumer-based sources such as *company's employees, company's managing director, endorser, typical brand user, product attributes, product category, brand name, brand logo, advertising style, price, retail stores, country of origin, company's moral values, own experience when using the product, on-line consumer community, word-of-mouth, and own value system /own opinions*.

Both consumer-based sources and company-based sources were found to be important for forming brand personality. But they contributed differently in different dimensions. The results show that consumer-based sources such as own experience, word-of-mouth, and own value system play an important role for forming Sincerity and Competence dimensions. According to the respondents, "when you experience the brand by your own you can see if the brand is competent or not... you can check it..." "...It overshadows what I hear from others". However, "rumours [word-of-mouth] tell how good they [the brand] are" and "rumours influence what I believe".

On the other hand, company-based sources such as advertising style, brand name, product attributes, and typical brand user are dominant for forming Sophistication and Ruggedness dimensions. "It is all about the brand and its image", mentions one of the respondents. As for Excitement, it is formed by a blend of consumer- and company-based sources (e.g. advertising style, product attributes, word-of-mouth, own experience, and brand logo).

Thus, consumer-based sources are highly relevant for Sincerity and Competence but at the same time do not almost have any effect on Sophistication and Ruggedness. One of the reasons could be that consumers cannot accurately assess many of the brand's features related to Competence and Sincerity (e.g. product quality, product performance, product lifetime, value-for-money) before they purchase the brand. These features are the experience qualities which cannot be determined before consumers try the brand themselves (Nelson 1974). At the same time, Sincerity and Competence are vital features for every brand; they represent a kind of hygiene factors (Herzberg 1974) that any brand should have. Consumers being risk averse do not trust only company-based sources when they judge these dimensions; they need to get the confirmation from more credible sources such as their own experience or word-of-mouth (Keller 2007).

Sophistication and Ruggedness are of symbolic and intangible nature. They correspond to intersubjective quality emphasizing accepted cultural norms, often in the form of symbols and images (Pirsig 1999). These features are difficult to judge just from the direct contact with a product itself, and they are mostly based on the images and symbols which companies provide in their promotional campaigns. Excitement is related to both what you feel or think while experiencing a brand (subjective quality) and product characteristics like special technical features or exciting appearance (objective quality). Therefore, both company- and consumer-sources are relevant.

Thus, the current study indicates which sources tend to be more relevant for forming each brand personality dimension. Moreover, we have found out that consumer-based sources are extremely relevant for some dimensions, especially for Sincerity and Competence. However, further research is necessary to get a better understanding of how consumers form their brand personality judgments.

Functional Regret: The Positive Effects of Regret on Learning from Negative Experiences

Noelle Nelson, University of Minnesota, USA

Selin Malkoc, Washington University, USA

Baba Shiv, Stanford University, USA

Popular wisdom encourages people to "Learn from experiences" while placing equal importance on not regretting anything. This implies that people can gain all the necessary information from their mistakes, without enduring any of the pain. Previous literature has focused mainly on the detrimental effects of regret. For example, Zeelenberg and Beattie (1997) found that participants who have lost money in a negotiation task perform badly (to the point of losing money) on a subsequent negotiation task.

Other related literature has shown that emotion, in general, can cause negative outcomes. Shiv, Loewenstein and Bechara (2005) showed that brain damaged patients who do not suffer negative emotional feedback after a financial loss end up making more money in the task. These patients were not swayed to a set of investments that had low-yield, but less risky, outcomes. In the current research, we take the evolutionary perspective that regret, as with any emotion, is functional. Therefore, we posit that regret (i.e., negative emotion) is a necessary condition for learning from negative experience.

Further, we make an important contribution by testing the effects of the emotional side of regret, while keeping cognitive feedback constant. Zeelenberg (1999) has noted that regret is made up of both cognitive and emotional components. To the best of our knowledge, no research has examined only the emotional component. Rather, comparisons have always been drawn between groups of people who have had negative cognitive feedback (experience regret) and groups of people who do not experience negative feedback. Our research draws conclusions on the effects of regret on learning from comparing people who feel more or less regret. Also, much research has shown the effects of anticipated regret, while we show that experienced regret can be beneficial.

The current research provides evidence that regret is helpful for learning from past mistakes. In addition, we show that this emotion-learning is domain dependent. That is, feeling regret does not result in a global state where people make better decisions. In fact, we posit that the negative emotion caused by regret will negatively affect decisions made outside the domain in which it was felt. However, subsequent decisions that are similar to the decisions that caused regret will benefit from regret. This results in our two hypotheses:

- H1: For participants who experience regret to a greater degree, subsequent decisions that are similar to the regretted decisions will be better than for participants who experienced regret to a lesser degree.
- H2: For participants who experience regret to a greater degree, subsequent decisions that are dissimilar to the regretted decisions will be worse than for participants who experienced regret to a lesser degree.

Our design results in two factors: felt-regret (high vs. low) and decision type (domain: similar vs. dissimilar). Regret was manipulated between subjects and decision type was measured within subjects. Undergraduates entered the lab and were seated in individual rooms. Past literature has shown that caffeine can heighten emotional arousal (see Sawyer, Julia and Turin 1982 for a review), so we manipulate the extent of felt-regret with caffeine. Participants were told that they'd be asked to drink and evaluate coffee. Half of the participants were given regular coffee (caffeinated) and half were given decaffeinated coffee.

Participants were then asked to evaluate pairs of products, and were given the chance to purchase the products with five endowed tokens. Three products (pencil, car decal and electronic game) were presented in increasing order of desirability (pre-tested), but participants believed the order was random and did not know when their last chance to "buy" a product would be. Therefore, most people purchased the second product (car decal) and were not able to buy the third product (electronic game). This resulted in our regret manipulation.

After the regret manipulation, participants were asked how much they would require to delay the arrival of a DVD they ordered by three or ten days. This delay measure measured impulsivity on a domain dissimilar decision (because shipping delays are quite different than decisions to buy small objects). Domain similar decisions were measured by taking willingness-to-pay measures on items similar to the regret manipulation items (e.g., keychain, game book, photo-frame). The key difference between the domain dissimilar (shipping delay) and domain similar (small objects) measures is that the shipping delay question is measuring impatience to receive an item, while the product measure is simply willingness-to-pay for an item.

Consistent with our conceptualization, we found in a repeated measures analysis that participants who had consumed caffeine (high felt-regret condition) were willing to pay less on similar items than participants who had decaf coffee (low felt-regret condition). This evidence is in line with hypothesis H1.

Consistent with hypothesis H2, participants who were in the high felt-regret condition did not perform as well when it came to decisions outside the learning domain as did the decaf participants. That is, when asked how much money they would need to delay the shipping of a DVD, participants who experienced greater regret required more money to delay the shipping by three or ten days.

Overall, we propose that regret is a necessary component for learning from mistakes and is, therefore, functional. We provide contributions to the literature by separating the effects of emotional regret from cognitive regret and by manipulating experienced regret (instead of anticipated). Further, regret learning is domain-specific and guides decision making in a directed way. Regret does not cause people to become more conservative with all decisions, but leads them to make better decisions after they have experienced regret in a certain domain.

Factors Affecting Response Accuracy in Virtual Worlds

Francesco Massara, IULM University, Italy

Thomas P. Novak, University of California, Riverside, USA

Virtual worlds are emerging online environments that are beginning to be leveraged as a platform for consumer and marketing research (Bloomfield 2007; Hemp 2006; Menti 2007; Novak 2007, 2008). We compare the accuracy of responses obtained in virtual worlds with responses collected from traditional web-based research. We hypothesize that under certain conditions, data collected within a virtual world environment will generate more accurate responses than surveys administered through traditional Web browsers. We focus on low elaboration recognition tasks involving visual and text-based stimuli, and on how consumer motivational and characteristics of virtual worlds moderate accuracy on these tasks.

As highly visual environments, imagery plays an important role in information processing in virtual worlds. Because of their visual nature, virtual worlds induce imagery rather than discursive processing (MacInnis and Price 1987). For example, interacting with virtual objects has been found to facilitate mental imagery, which in turn has a positive impact on behavioral intentions (Schlosser 2003). A visual rather than text stimulus is congruent with the context of a virtual world, and this will predispose respondents toward imagery processing, resulting in a more accurate processing of images than text in virtual worlds. Thus:

H1: Response accuracy is greater for a visual (text) stimulus in surveys administered in virtual worlds (traditional Web browsers).

Three features differentiate virtual worlds from traditional two-dimensional Web environments: sensory experience, social networking, and virtual economy. First, human-computer interaction in virtual worlds is driven by a highly visual technology that engenders a more deeply immersive sensory experience than in the incorporeal, largely text-based environment of the Web. Second, despite the fact that virtual worlds merely simulate the realism of physical places, the social interactions within them can be strikingly real (Grimmelmann 2004); Gorini et al. 2007; Bainbridge 2007; Chesney et al. 2007; Yee et al. 2007). Third, virtual worlds such as Second Life support internal economies with convertible currencies, intellectual property and free market exchange, resulting in increased realism and greater motivation to play (Ondrejka 2007).

These three features of virtual world relate to Yee's (2007) model of user motivations for playing in online games. Yee identifies three dominant dimensions: immersion (curiosity and escapism), social (behaving altruistically by helping others) and achievement (the desire to gain power and for the accumulation of wealth symbols and status).

Within virtual worlds, the level of user motivation along each of the three dimensions of immersion, social and achievement is expected to related to the user's response accuracy; we would further expect the relationship of user motivation to response accuracy to be stronger in virtual worlds than for studies fielded via traditional Web browsers. In addition, the salience of the three virtual world features of sensory experience, social networking and virtual economy would be expected to further moderate the relationship of motivation and response accuracy. Each of the three virtual world characteristics acts as moderators, each on a corresponding aspect of user motivation:

H2: The difference in the level of accuracy between consumers looking for high and low immersive sensory experience will be larger in virtual worlds compared to traditional Web-based research, and this difference will be further increased in the virtual world condition when sensory experience is more salient.

H3: The difference in the level of accuracy between consumers looking for high and low social networking opportunities will be larger in virtual worlds compared to traditional Web-based research, and this difference will be further increased in the virtual world condition when social networking is more salient.

H4: The difference in the level of accuracy between consumers looking for high and low achievement will be larger in virtual worlds compared to traditional Web-based research, and this difference will be further increased in the virtual world condition when the virtual economy is more salient.

These hypotheses will be tested in a series of four planned studies. Respondents will be randomly selected from a university panel of Second Life users, contacted via e-mail, and assigned to one of three survey context conditions: 1) In-world using survey fielded entirely in Second Life; 2) In-then-out-world (i.e., the respondent is sent into Second Life and their avatar remains in Second Life while the respondent is directed to a Web-based survey), and 3) Out-world using a Web-based survey.

In a first study, we compare response accuracy for visual vs. text stimuli in research studies administered in virtual worlds vs. via Web browsers. Dependent measures include objective statistics d' and β from a signal detection task (SDT). The SDT will be a memory exercise featuring three sets of stimuli (picture, text, picture and text). Signal strength will be manipulated by varying the degree to which stimuli in a set differ from each other. Three consumer motivations for using virtual worlds—immersion, social, and achievement, are tested as moderators of response accuracy.

The parameter d' indicates the strength of the signal relative to noise, and larger values of d' indicate greater sensitivity of the respondent in recognizing previous information. The parameter β captures whether the respondent's decision style in a memory task is liberal or conservative, meaning that the responder has a tendency to say "yes" or "no" (Tashchian, White and Pak 1988). Values of β less than 1 indicate a liberal decision style with a greater tendency to say "yes," while values of β greater than 1 indicate a conservative decision style with greater tendency to say "no." We expect that for image recall in a virtual world, d' will be higher and the response criterion will be stricter with $\beta > 1$, as compared to a traditional web setting.

In a series of three additional studies, we manipulate the salience of the three aforementioned characteristics of virtual worlds—sensory experience, social networking, and virtual economy—and test these as moderators along with median splits on the three consumer motivations for using virtual worlds.

This research will provide evidence of the relative accuracy of virtual worlds vs. traditional Web-based research for different marketing stimuli and consumer motivations. Response accuracy has important marketing applications ranging from advertising recall to accuracy in market research surveys. Our emphasis upon low-elaboration imagery processing has direct implications for advertising and consumer learning about product information in virtual worlds, and provides a methodological and theoretical foundation for extensions of this research to alternative modes of imagery instantiation and to higher-elaboration imagery and cognitive processing.

Conscious Consumption and its Components: An Exploratory Study

Caroline Roux, McGill University, Canada

Jacques Nantel, HEC Montréal, Canada

Background

Socially responsible, environmentally friendly, or ethical consumption, as well as other terms that are often used in a conceptually similar manner, are frequently found in the marketing literature (Antil and Benett, 1979). Yet, there does not seem to be much consistency in the various terminologies and definitions that have been offered (Antil and Benett, 1979) about these components of "conscious" consumption.

For example, Roberts (1995) states that research in marketing often equates socially responsible and environmentally conscious consumer behavior. Leigh, Murphy and Enis (1988), on the other hand, believe that ecologically concerned consumers are a subset of the

socially conscious category. Anderson, Henion, and Cox (1974), however, state that it would be unwise to interpret socially responsible and ecologically conscious consumers as constituting a single group. Furthermore, Webster (1975), as well as many other authors (e.g., Brooker, 1976; Antil and Bennett, 1979; Antil, 1984; Roberts, 1995; Roberts, 1996b), state that they were studying socially responsible consumers, but used dependent variables that concerned only the environment. Similarly, Carrigan and Attalla (2001) don't make a distinction between ethical and socially responsible consumers; while Copper-Martin and Holbrook (1993) state that the only significant stream of research on ethical consumer behavior has focused so far on environmental concerns. However, Shaw and Shiu (2003) mention that it is important to distinguish between "green" and "ethical" consumerism, because more wide-ranging ethical issues can add significantly to the complexity of consumer decisions, and ethical concerns are often ongoing and irresolvable.

Following Anderson, Henion and Cox's (1974) investigation more than 30 years ago, this study aims at better understanding the similarities and differences among the various types of "conscious" consumption. We focus on environmentally conscious, socially conscious and ethical consumption, because these domains received the most attention in the literature and also created the most confusion. Clearly, clarifying the main "conscious" consumption concepts is very important, because it will provide a foundation in understanding individual differences in consumption patterns that are becoming increasingly critical in the context of global warming.

Method

In order to study "conscious" consumption, a questionnaire was built from three major consumption scales. Socially responsible consumption was measured with the help of Roberts' (1995) SRCB scale (Socially Responsible Consumer Behavior), environmentally conscious consumption was assessed with Roberts' (1996a) ECCB scale (Environmentally Conscious Consumer Behavior), and ethical consumption was measured with Creyer and Ross' (1997) scale. These scales were selected because they appeared to be the most reliable ones available in the literature. They were pretested twice, mostly to test for their reliability and to reduce the number of items in each of them, in order to have a more parsimonious questionnaire. The final version of the questionnaire included 28 items taken from the three previous scales—eight from Roberts' (1995) scale, ten from Roberts' (1996a) scale and ten from Creyer and Ross' (1997) scale—which were randomized. It also included three items that measured participants' perceived level of identification with these three types of "conscious" consumption. The final version of the questionnaire was sent to the participants of a major Canadian Internet panel. All items were measured on a 5 point scale (with response categories ranging from totally disagree to totally agree).

Results

1338 questionnaires were returned (56.7% female, mean age=45), but many of them included missing data, which left us with 910 completed questionnaires for the environmentally conscious consumption scale, 949 for the socially responsible consumption scale, and 1200 for the ethical consumption scale. All scales provided satisfying results both at the exploratory (principal component analysis) as well as the confirmatory (structural equation modeling) level. The composition of two scales (Roberts, 1996a; Creyer and Ross, 1997) were however different from the original number of dimensions obtained by the authors. Indeed, three components were obtained for Roberts' (1996a) scale, instead of the two stated in his paper, and two for the Creyer and Ross (1997) scale, instead of the four stated in their article.

The factorial score of each scale was used to test for the correlation between each of them. All scales were highly correlated (SRCB-ECCB=0.588, SRCB-Ethical=0.544, and ECCB-Ethical=0.450; all $p < 0.001$), which suggests that there is an overlap among these different concepts of "conscious" consumption. In addition, the scales factor score and the respective participants' perception measures were strongly related (SRCB=0.504, ECCB=0.556, and Ethical=0.555; all $p < 0.001$).

Conclusion and Discussion

The results of this exploratory study suggest that the different concepts of "conscious" consumption overlap. We therefore investigated whether the different types of conscious consumption are nested or hierarchically ordered. Indeed, the percentages of participants' perceived level of identification to the different types of conscious consumption indicate that there are more participants who identify themselves as environmentally friendly (67.4%) than socially responsible (48.6%) or ethical (44.6%).² Further analyses partially supported this hierarchical relationship: People appear to become concerned about the environment first, possibly because it is concrete and easy to understand, and then become more conscious about their social responsibility (which involves broader issues like human and animal rights) and ethics (which takes into account the morality of our actions and is thus much more abstract). Although these results warrants further experimental investigations, it provides an avenue for reconciling the inconsistent use of these concepts in the literature. Equally important, a hierarchical view of "concern" or "consciousness" has important implications. Indeed, most field interventions aimed at raising consumers' "consciousness" seem to rely on more concrete actions first (e.g., making small behavioral changes), and then on more abstract actions (e.g., changing your mindset about consumption in general). Moreover, this conception of "conscious" consumption share defining characteristics with goal hierarchies and means-end chains, because the elements of their structure are organized hierarchically; with lower-level elements serving as means to achieve higher-level elements as ends (Pieters, Baumgartner, and Allen; 1995).

From Trash to Treasure: Freecycle.org as a Case of Generalized Reciprocity

Michelle R. Nelson, University of Illinois at Urbana-Champaign, USA

Mark A. Rademacher, University of Wisconsin-Madison, USA

FREE! Free software, songs, and stuff. The Internet provides a place to share technology, art and goods. Thus, Cyberspace may be fostering a new age of altruism that contrasts the egoism of commoditization (Belk 2007). Whereas sharing source code or Napster files offers a way to give without sacrificing ownership (Gielser 2006), giving tangible goods means letting go of the stuff-for good. Members of Freecycle.org do just that. Unlike traditional market systems or other second order (used) systems (e.g., craigslist), members give and receive goods absent monetary exchange. Thus, Freecycle serves as an apt forum to explore contemporary consumer gift systems and the phenomenon of reciprocity (Giesler 2006).

Reciprocity, a "set of rules and obligations that builds the complex pattern of give and take and helps establish moral standards of social solidarity" (Gouldner 1960, cf Gielser 2006), need not be tit-for-tat. Anthropological literature has revealed a continuum from *generalized reciprocity* (people give without expectation of anything in return) to *balanced reciprocity* (some expectation of repayment in a future exchange) to *negative reciprocity* (expectation of immediate repayment; Sahlins 1972).

We investigate Freecycle as an example of a traditional gift system with a focus on identifying how reciprocity is enacted and enforced. The multi-method approach included: (1) netnographic analysis of post content over a 1-month period; (2) an online survey (n=183) to elicit motivations for membership and to measure consumption attitudes and behaviors; and (3) depth interviews with nine members from a Freecycle group to gain a deeper understanding of Freecycle attitudes and behaviors. Analysis included both inductive and deductive as well as qualitative and quantitative approaches.

Findings

Gift Economy? Our analyses revealed distinct differences between Freecycle and traditional gift economies (e.g., Mauss 1925/1990). Traditional gift economies are defined by feelings of reciprocity (Malinowski 1953) that seem to represent a balanced or negative reciprocity. In this view, the "pure" gift does not exist (Mauss 1925/1990). Rather than being a "free and disinterested" social process, gift giving is inherently "constrained and self-interested." Gifts establish ties of reciprocity and interdependency among social actors and specific entities that provide benefits for both the gift giver and recipient (Hyde 1983; Malinowski 1953; Mauss 1925/1990). This traditional framework is altered, however, for Freecycle.org because of the predominance of a "generalized" reciprocity present within this community, as evidenced through the forum's structure, social rules, community and trust, articulated motivations and benefits of use.

Forum Structure. An average of 82 "offer and wanted" posts per day were observed in this community. Consequently, Freecyclers witness the flow of goods from one to another and see generalized reciprocity in action. These observations along with personal experience with Freecycle (the majority of our informants had experience in giving and receiving goods) may reinforce generalized reciprocity. Behavioral studies on humans (Berkowitz and Daniels 1964) and rats (Rutte and Taborsky 2007) suggest individuals may base cooperative behavior on prior experiences—irrespective of the identity of their partners. In other words, we can practice generalized reciprocity if we believe that others are doing so and we have experienced such acts of kindness in the past.

Rules and Social Norms. Although generalized reciprocity is typically witnessed in kinship groups or among villagers who know one another (Sahlins 1972), research in economics has found even with "constantly changing partners" (a.k.a strangers), elements of

generalized reciprocity were witnessed when self-enforcing social norms encouraged such behaviors (e.g., Bó 2007; Kandori 1992). The Freecycle group offered rules to ensure reciprocity and social norms helped enforce it. Guidelines were offered for the number of “Wanted requests” an individual could post; the frequency of repeat requests; and the requirement of placing an Offer before a Wanted post. Further, Moderators promote reciprocity by monitoring Offers-to-Wanted ratios and sending notes to those who practice negative reciprocity.

Community and Trust. Research on kinship groups has observed that there is maximum trust and minimum social distance among people who engage in generalized reciprocity (Sahlins 1972). Despite critiques of Internet communities as “faceless and fleshless” (DeGraff, Wann, Naylor and Robin 2001, 61) and arguments suggesting reciprocity may diminish among larger communities (Hyde 1983), Freecycle members repeatedly referred to the group as community and felt connected to other members. The connection, however, mirrors relationships of “limited liability” (Muñiz and O’Guinn 2001); nothing more is expected from members other than to donate and request items, and to pick up those items on time. Still, members discussed a consciousness of kind (“atypical consumers”) that manifested itself as a shared identity, which fostered trust (Muñiz and O’Guinn 2001).

Motivations & Benefits For Use. Although predicated on environmental activism, when asked why they use Freecycle, members repeatedly and passionately referred to receiving free stuff (egoism) and the “life” left in their goods and the possibility of sharing with others who needed them rather than environmental motives. This sort of generalized reciprocity is similar to that observed outside of kin groups—especially from those with wealth when they shared goods with those in need (Udehn 1996). Rather than leaving goods on the curb or donating to charity shops, Freecycle members wanted to know that someone would really benefit from their goods. Thus, the perceived need was an important part of this generalized reciprocity. Giving to those who demonstrated the most need in their ‘stories’ was a common practice. Thus, the deserving heuristic was applied, much like in dispositional strategies with family members (Price, Arnould, and Curasi 2000). Throughout the gift process, Freecycle members sacrifice monetary reward in favor of a feeling of helping others.

In sum, the existence of generalized reciprocity appears to operate in a contemporary online community. Different from traditional kin-based reciprocity, this forum allowed ‘strangers’ to freely give without expecting anything in return from the recipient. Rather, the group itself experiences reciprocity and perpetuates the gift exchange. Through this continuous exchange members appear to practice a new form of altruism while fulfilling the egoism of commoditization (Belk 2007). Freecycle is not a form of escape from the market (Kozinets 2002); the community remains firmly entrenched in the market (Arnould 2007).

Consumer Entrepreneurs: A Netnographic Study of Facebook’s Next Top Model

Marie-Agnès Parmentier, York University, Canada

“Have you always thought that you would do a better job than the girls on ANTM and CNTM and have always wanted to enter the competition? Well now you can!!! Get ready for this competition! Inspired by America’s and Canada’s Next Top Model, we are going to have our own Facebook Model Search.”

Silvia³, founder of the Facebook’s Next Top Model Competition

³Pseudonyms are used to preserve informants anonymity.

Consumer Culture Theory has an established tradition of examining consumers' creative appropriation of marketers' offerings (see Arnould and Thompson 2005). Concepts such as co-creation (Vargo and Lusch 2004), countervailing market responses (Thompson and Coskuner-Balli 2007), interagency (Kozinets et al. 2004), textual poaching (Jenkins 1992), and prosumption (Kozinets 2007) are part of that tradition.

Following the stream of research on audience participation in media culture (e.g., Jenkins 1992, 2006; Kozinets 2001; 2007) and the current interest in entrepreneurship in consumer tribes (Cova, Kozinets and Shankar 2007), this working paper focuses on fans who attempt to overcome the limited chances for participation in a particular institutional field. The project explores consumer entrepreneurship in the context of the grassroots Facebook competition for aspiring fashion models based on the reality TV hit "*America's Next Top Model*." One objective of the project is to refine our understanding of fans' producerly consumption activities and their relation to consumer entrepreneurship. A second objective is to examine the implications for marketers and other institutional members.

Background

On May 20th 2003, supermodel Tyra Banks launched the reality television series *America's Next Top Model* (ANTM). Now in its 10th cycle (season), ANTM has become a worldwide phenomenon broadcast in 90 countries (www.channelcanada.com/Article1140.html) with franchises in 40 including (www.tyrabanks.com) Australia, Britain, Canada, China, Germany, Israel, Norway, the Philippines, and Russia.

On ANTM, viewers are exposed to the transformation of everyday young women into potential top models as they compete for the chance at a modeling career. The show opens up a window—albeit a limited and potentially distorted one—on the modeling industry and allows viewers to learn about the norms and practices of the field via exclusive footage of high fashion photo shoots, runway shows, casting sessions, and advertising production.

Fashion modeling reality TV first appeared on North American screens only five years ago. Its emergence and popularity constitute a novel reality for the modeling field in that its production practices are increasingly being commodified (Sadrai-Orafai 2005). Fans' enthusiasm for the show paired with new affordable technologies and the possibilities of the Web 2.0. are resulting in producerly consumption activities ranging from fan fiction to wikimedia (cf. Kozinets 2007) to grassroots modeling competitions.

Method

Countless blogs (e.g., www.topmodelgossip.com), online discussion boards (e.g., www.fansofrealitytv/america-s-next-top-model-10/), and social networking groups (e.g., Addicted to America's Next Top Model) devoted to fans' interest in ANTM can be found on the Internet.

The focal site of investigation for this project is the Facebook's Next Top Model Competition (FNTM). This competition was launched in March 2007 by a fan of ANTM, an 18 year old high school student who created an outlet where aspiring models can compete for modeling exposure. In less than 5 days, the group grew from 100 members to 900. One year later, the FNTM competition, now in its third cycle, counts more than 3,000 members, making it the largest and most popular group of its kind on Facebook.

This paper is part of a larger netnographic (Kozinets 2002) project on the fandom of fashion modeling reality TV. I became interested in this grassroots competition while I was researching the different fan groups devoted to ANTM. My initial interest for this specific group was triggered by its professionalism. For instance, just like on television, contestants vie for "real" modeling prizes including photo shoots with professional photographers.

I made my entrée in June 2007. I contacted the founder and posted a comment to disclose my identity as a researcher. I since have been monitoring the activities of the group on a weekly basis. The data collected so far is comprised of a formal online interview and informal ongoing email exchanges with the founder, discussion threads, pictures, and posts. I plan on conducting additional interviews with members such as judges and contestants in order to reach theoretical saturation.

From the start, I have been engaged in an iterative process that is the hallmark of grounded theory (Strauss and Corbin 1998). My interpretation of the data is constructed through continuously moving between the literature and the individual postings, chunks of postings, entire discussion threads, interview data and the emergent understanding of the data set.

Preliminary Findings

Producerly consumption and consumer entrepreneurship

Not all fans actively engage in creative appropriation of the object of their fandom. Those who do, however, help co-create new meanings and products for other fans to appreciate. They add layers to the consumption experience of the original market offerings. In the FNTM group, fans who are aspiring models and those who are aspiring judges compete for a spot in the competition. The remaining members of the group can vote for their favourite contestants—an important difference from the television show—and share their critical evaluations of the different modeling performances.

On the one hand, consumer entrepreneurship surfaces on the part of the aspiring models who promote their potential and manage their trajectory in the competition. On the other hand, judges and lay-members alike participate in the management of an outlet for aspiring models to gain exposure, build photographic experience and win significant help to start a modeling career.

Implications for marketers and producers

These consumer entrepreneurs are reworking the traditional institutional arrangements of the field by expanding its modes of entry. They are also challenging—to some extent—the established legitimizing process typically experienced by fashion models.

Closer examination of the ripple effects of producerly consumption that results in consumer entrepreneurship should further our understanding of the co-creation paradigm.

Culture, Self-Control, and Consumer Financial Behavior

Dante Pirouz, University of California, Irvine, USA

Some people are better at saving money for the future, paying their bills on time, sticking to their diets, and living up to their promises. One common trait for these people is the ability to regulate behavior. Maintaining self-control, defined as the ability to monitor one's behaviors and choose actions that minimize negative outcomes (Baumeister 2002), is important to living a healthier and happier life. Individuals who exhibit self-control are more likely to have higher grades in school, more wealth accumulation, higher self-esteem, lower reports of psychopathology, less binge eating, lower levels of alcohol abuse, lower levels of addictions of all kinds, better relationships and more secure interpersonal attachments (Tangney, Baumeister, and Boone 2004).

Is there a cultural aspect to self-control? Previous work has found that culture can have a profound impact on how people process information and make decisions (Aaker and Sengupta 2000; Nisbett 2003; Nisbett et al. 2001; Nisbett, Peng, and Ji 2000). There is also evidence that the ability of self-control may have developed in humans as a result of the benefits gained from belonging to a close-knit cultural community (Vohs and Baumeister 2004). Experiments have shown that when people are excluded from social groups, they tend to demonstrate a decreased ability to regulate their behavior.

A key dimension of cultural orientation is collectivism-individualism. Collective cultures tend to emphasize group cohesion and harmony while individualistic cultures emphasize individualism and uniqueness. On the level of the individual, this construct is operationalized as an independent versus interdependent construal (Mandel 2003; Markus and Kitayama 1991; Singelis 1994). People who tend to hold more independent views are more likely to see themselves as distinct from others and view autonomy, self-sufficiency and the individual as important. Those who hold an interdependent self view will see themselves as interconnected with others and view connectedness, social context and the group as important. The independent view is usually ascribed to Westerners for example Americans and the interdependent view is usually associated with Easterners for example Chinese. One study found that subjects who were primed with an interdependent self-construal were more likely to take on financial risk but less likely to take on social risk versus those primed with a independent self-construal (Mandel 2003). However, this research emphasized the mediating effect of social network without looking at the role of self-control.

It has been argued that cultures vary in terms of the value they place on self-control (Fox and Calkins 2003; Logue 1995). Cultures where group cohesion and interdependence are important would be more likely to value self-control from their group members. If self-control is indeed a skill that can be taught and improved with practice, whether the development of this skill is coveted within a cultural group will have important implications for control-related behaviors in its members.

On the other hand, ethnic groups in the U.S. vary greatly in their propensity for financial risk. For example, recent work found that investment portfolios of Hispanic Americans tended to favor near-term savings, liquid and low risk investments versus non-Hispanic Americans even when controlling for income (Plath and Stevenson 2005). This leads to lower investment value and slower wealth accumulation rates for Hispanic American households. African American consumers also differ significantly from other Americans in their financial decision making in terms of financial product preference, product research and investment asset portfolio composition (Plath and Stevenson 2000). Investment portfolios for African Americans tend to concentrate in more conservative investments such as real property and life insurance assets in contrast with most Caucasian Americans who tend to hold higher corporate debt and equity securities. Overall, a test of the effect of race and ethnicity on financial risk tolerance found that Caucasian Americans had the highest

financial risk tolerance, followed by African Americans and Hispanic Americans (Yao, Gutter, and Hanna 2005). While in these studies Asian Americans were not included in the samples, these findings seem to indicate nonetheless that culture has an impact on consumers' financial risk decisions and product choices. This is contrary to the intuitive expectation that individuals with more self-control would tend to refrain from taking risks (Tangney et al. 2004; Weber, Blais, and Betz 2002). It may be that increased self-control allows individuals to feel confident taking on more financial risk. The seeming contradiction between self-control and risk-taking financial behavior among different ethnic groups offers an opportunity to investigate how culture impacts choices involving risk and whether these behaviors can explain the divergent financial choices that ethnic groups exhibit. These issues are the topic of this study.

While no study has yet been conducted on cultural variations in self-control, Kacen and Lee (2002) conducted a study on the opposite trait, impulsiveness, and found that collectivists have the same likelihood of the trait impulsiveness but show less overall impulse buying behavior. While the trait impulsiveness seems to be equally distributed regardless of culture, culture was an important determinant in the expression of that trait exhibited in impulse buying behavior. It may be that certain cultures and ethnic groups value self-control more than others and therefore tend to teach and reinforce this skill. That would mean that individuals in these cultures have more stamina when exercising their self-control "muscle."

Data were collected from 534 participants on their attitudes and behaviors when making financial choices. In addition, demographic (ethnicity, age, gender, etc.), investing and income information was collected. The survey was administered via an online questionnaire. These data were analyzed using partial least squares (PLS) to examine the latent and structural relationship between the variables. PLS was chosen as the method of analysis since it allows for complex measurement and theoretical models to be estimated simultaneously (Falk and Miller 1992; West and Graham 2004). Preliminary results of the analysis found that the participants who belong to collectivist ethnicities, such as Asian Americans, tended to have higher levels of self-control when making financial decisions. These participants also had lower levels of impulsive behavior versus ethnic groups with higher levels of individualism. This resulted in higher levels of savings behavior versus spending behavior and higher propensity for financial risk.

The Collecting Continuum: Incorporating Amateur Scientists and Scholarly Collecting Behaviors

Greta L. Polites, Bucknell University, USA

Natural history collections have seen a resurgence in popularity in recent years. Wealthy collectors from around the world successfully compete with museums to obtain rare specimens such as complete dinosaur skeletons. Tiny yet rare seashells can sell for thousands of dollars. Even ordinary collectors with limited funds can purchase fossils and archaeological treasures online. However, such collectors increasingly find themselves at odds with environmentalist sentiments and societal norms, manifested in calls for legislation to close collecting sites to non-scientists and preserve finds solely for the benefit of the general public. Thus developing a better understanding of the collecting behaviors of these individuals is important not only from a consumer behavior perspective (due to the large amounts of money exchanged), but also to society as a whole, so that responsible collecting behaviors can be encouraged while still allowing individuals to fulfill their innate need to “collect things.”

Collecting has been defined as “the process of actively, selectively, and passionately acquiring and possessing things removed from ordinary use and perceived as part of a set of non-identical objects or experiences” (Belk, 1995, p.479). Collecting is differentiated from hoarding, accumulating, investment acquisitions, and ordinary consumption. It is viewed as a form of “materialistic luxury consumption,” as the collected objects have been removed from their ordinary use or instrumental purpose (Belk, 1995). A “true” collection is believed to assume such importance to the collector that it will not be dispensed with unless absolutely necessary (Pearce, 1992).

Prior research has classified collectors based on either their *motivations for collecting* (see McIntosh and Schmeichel, 2004), *level of interest* (Wright and Ray, 1969), *types of objects collected* (Bryant, 1989), or overall *mode of collecting* (Danet and Katriel, 1989). While specific types of collections (e.g., stamp, book, teapot) have been investigated, researchers have tended to make generalized statements about all collectors, while pointing out that many exceptions occur. Most notably, prior literature has discussed in passing, but never clearly delineated, “scholarly” or “scientific” collecting. We argue that the motives, behaviors, and characteristics of “amateur scientist” collectors (i.e., advanced collectors in fields possessing professional counterparts, such as the natural sciences), like those of their counterparts, can differ substantially from those of the collecting population at large.

In particular, altruistic motives for collecting have been largely ignored or discounted. This results from the view that collecting to preserve items for future generations is simply a personal justification for extreme collecting behaviors, rather than a legitimate motivation (Belk, 1995). In other cases, such collecting has been associated with a personal need for purpose and destiny, and thus with a goal of achieving immortality (McIntosh and Schmeichel, 2004). However, fossil and artifact collectors have historically donated specimens to museums, provided curators with important scientific information on their finds, and assisted research efforts in numerous other ways, often without demanding any special recognition in return. Thus, is a denial of altruistic or selfless motives for collecting always appropriate where scientific collecting is concerned? Do amateur scientists truly donate only because the “pursuit is more important than the possession” (Belk et al., 1988)? Conversely, do institutional scholars always have altruistic motives for the collecting undertaken in their own jobs?

Using natural history collecting as a backdrop, and drawing from the author’s own years of experience as an amateur paleontologist, we present a series of hypothesized differences between “typical” consumer collecting (as described in Belk, 1995) and “scientific” or “scholarly” collecting. We further propose a new taxonomy of collectors, grounded in theories of serious leisure (Stebbins, 1979) and the amateur/professional continuum (Leadbeater and Miller, 2004), and incorporating features of past classification schemes, that includes all types of collectors while more accurately representing “scientific” or “scholarly” collecting.

On one end of the continuum are dabblers, novices, and casual collectors. Three different branches may occur from here (representing commercial, “popular,” and scientific collecting). In the realm of “popular” (e.g., stamp, coin) collecting, serious hobbyists may become “scholarly” hobbyists, but no true professional counterpart exists. In the realm of scientific collecting, devoted amateurs may become proams, the latter of which have professional/scholarly counterparts.

This taxonomy focuses on differentiating collectors at each major stage on the continuum based on *form, scope, expertise, motivation, and roles*. Overall, the continuum represents a transition not just from *undisciplined* to *disciplined* collecting behaviors, but also from *individualism* to *collectivism*. As we move further along each branch of the continuum, collectors exhibit an increasingly research-oriented approach to collecting, a narrower collecting focus, more specialized knowledge, and “altruistic” behavior.

Two phases of data collection support the proposed taxonomy. The first phase involved textual analysis of archived content from a listserv that promotes modern seashell collecting. Coding and analysis of discussions on the purpose and value of shell collecting indicate tension between casual collectors (interested primarily in the beauty of shells, enjoyment of collecting activities, or building of social bonds), and more advanced collectors (who, while sharing some of these interests, work closely with professional scientists and are very concerned with limiting the harm, via destruction of habitats and entire species populations, caused by widespread shell collecting). The latter group intentionally restricts their collecting activities to prevent environmental damage.

The second phase consists of a series of in-depth (1-2 hour), semi-structured interviews with fossil collectors ranging from novices and amateur scientists to institutional scholars. Findings indicate that many collectors (including professionals) feel conflicted by the internal compulsion to increase/complete their collections while still acting “responsibly.” Of particular interest are experiences and events that lead some collectors to move from one end of the continuum to the other over time. By determining what motivates a collector to work more closely with professionals, become more scholarly in their approach, and even relinquish valued specimens in their collection, we can inform research institutions on how to improve relations with amateur collectors and motivate them to collect in more “socially responsible” ways. Thus this study contributes not only to the collecting literature, but also informs the literature on individual motivation, particularly in regards to the practice of socially responsible behavior.

Beyond Vanity: An Investigation into Romanian Women's Beauty Identities

Larisa Puslenghea, University of Illinois at Urbana-Champaign, USA

Michelle R. Nelson, University of Illinois at Urbana-Champaign, USA

Women's perceptions of beauty are important not only because they determine beauty practices that, in turn, translate into consumption patterns, but also because they shape women's lives. In Eastern Europe, the transition from socialism to capitalism, beyond its political, economic and social components, has also implied a change of lifestyles (Coulter, Price and Feick 2003). These new lifestyles offer the possibility to reinscribe the obsolete socialist notion of gender equality into a new capitalist notion that allows for female empowerment. This study departs from the approach of authors such as Coulter et al. who argue that the 1990s have been a period of radical shift in the way women relate to beauty. Quite on the contrary, this undertaking shows that Romanian women have used the proliferation of market options to evolve along the same conceptual lines as before the fall of communism, instead of going through a phase of serious disruption.

Conceptualization

The paper reviews the main positions represented in the 'nature' versus 'culture' debate (Bordo, 1993; Brush, 1998; Fraser, 2001; Hurd and Griffin, 2007). On the one side, nature is defined as the raw material awaiting to be amended and thus inferior to culture, whereas the opposing approach presents nature as the perfect blueprint and, therefore, superior to culture. However, 'nature' is usually presented

as a discrete category, defying historical change, situated outside of culture and, thus, not subject to power relations. Paralleling this conceptualization is the discussion of the different approaches to a mind/body dualism focusing on the postmodern notion of 'natural' body as text, inseparable from its inscription. Such discussions are placed within the context of the broader debate on empowerment and cultural politics where the body is a "locus of social control" (Bordo, 1993, p. 33), acknowledging feminist works and Foucault's contribution. Particular attention is given to Foucault's notion of modern power and the way individual self-surveillance can be imposed with just one gaze, which plays in the normalization of the beauty industry. Finally, the recent theoretical contestation of the opposition between men and women is addressed in the light of postmodernism, insisting on women's agency even in processes that may be categorized as oppressive in previous conceptualizations.

Method

Fourteen semi-structured in-depth interviews were conducted with Romanian women ages 20 to 54 in 2007. Each interview was audio recorded and then transcribed and translated into English. The transcripts were then perused in an iterative process for emerging themes in a process of open coding and axial coding.

Major findings: Meanings of Beauty and Beauty Practices

These Romanian women relate repeatedly and in a decidedly nonlinear fashion to a multitude of beauty forms that could be subsumed under both 'cultural' and 'natural' models. In the constellation of perceptions with a cultural currency in Eastern Europe there appear to be competing hierarchies and complex dynamics among beauty types. For example, Cristina thinks that natural beauty is valued more than artificial appearance "with very flashy makeup", and Madalina feels this has to do with the implied deceitfulness since make up, through "tricks", makes even unattractive people look pretty. Beauty, for the women interviewed, is an intricate concept that simultaneously feeds into and emerges from almost all facets of life. Notably, beauty is a very mutable feature constantly being constituted, interpreted and contested through everyday interaction. For instance, Ana explains she appraises herself as beautiful or ugly based on how good she is at her job on a specific day or how well her romantic relationship is evolving at a given time.

For most respondents cosmetic use and the aura of artificiality that it brings about is acceptable only insofar as it covers up imperfections, that is only as long as it presents itself as an attempt of *mimesis* that reinforces the superiority and high social desirability of the 'natural' blueprint. Women are wary of the negative associations of cosmetic practices within their culture and therefore are much more willing to identify with practices termed "taking care of oneself" or "avoiding sloppiness" that somehow seem to feebly relate to traditional female roles such as nurturer or aesthetic arbitrator of the family.

Nevertheless, in this specific case, 'natural' beauty is not synonymous with the lack of any kind of cosmetic interaction (thus, not identified with nature as an ideal, untouched state), but it is a beauty that imitates the 'natural' look using makeup. In this case, 'naturalness' comes in degrees and hues and it is clearly culturally defined. Moreover, 'natural' beauty needs to be achieved and it requires significant efforts to maintain this 'natural' status. Here, the force of the belief in the superiority of nature is necessarily—yet paradoxically—complemented by an appeal to culture: with the supreme valuing of nature as a standard comes the realization of the fact that bodies are imperfect and need to be amended. Ironically, it is not the faith in the superiority of culture over nature, but the utopia of the natural body that makes these women resort to makeup in an attempt to emulate that ideal state.

The respondents in this study, regardless of age, seemed to agree that beauty is a specifically female characteristic and, thus, also a typically female responsibility. However, in the true spirit of postmodernism, it became apparent that there is no one linear discourse on beauty; instead there are a multitude of separate and often contradicting discourses (even stemming from the same woman!) that are being combined and recombined to construct meaning during the course of the conversation. Respondents did not rigorously adhere to one ideology, instead they switched between ideas belonging to such diverse intellectual sources as neo-Platonism, feminism, postmodernism and so on. Moreover, in their use of these ideas they recombined them in original ways to create new and interesting meaning. For example, although the ascendancy of the natural ideal was predominant among interviewees, they saw makeup, and thus culture, as the way to attain—even if just fleetingly and illusorily—an impression of that ideal. So, for them, nature and culture are both oppositional and complementary terms.

When Strangers Converse in Marketplace Environments: Effect of Service Provider-Related Versus Service Provider-Unrelated Conversations

Kaleel Rahman, American University in Dubai, UAE
Ulku Yuksel, University of Sydney, Australia

Customer-to-customer (C-to-C) interaction in service-oriented marketplace environments is an important aspect of consumer behavior (Harris and Baron, 2004). Hotels, airlines, hospitals, theatres, sporting events and trains are some examples of services where these interactions commonly occur. Understanding the C-to-C interactions is important for several reasons. Increased competition resulting in more choices to consumers has led to a situation where consumers seek compatibility of other customers in high contact services settings (Pratner and Martin, 1991) Increasing isolation of consumers due to divorce, lack of real social contacts and other similar reasons, consumers turn to marketplace environments to supplement interpersonal relationships (Martin and Pratner, 1989). In addition, service providers themselves expect their customer to share certain facilities like a queue, lounge and buffet.

Researchers have paid some attention to understand C-to-C interactions. For example, using market-oriented ethnography, Harris and Baron (2004) identified a stabilizing effect of conversations between strangers through *consumer anxiety reduction*, the *enactment of a partial employee role*, and the *supply of social interaction*. As McGrath and Otnes (1995) found in their taxonomy, roles performed by consumers in conversations with strangers include *help seeker*, *proactive helper*, and *reactive helper*. Using critical incidence techniques, Grove and Fisk (1997) categorized the percentage of different types of C-to-C interactions such as *verbal* (conversations), *waiting in line*, and *physical incidents* (other people's actions) and further categorized them into whether they are satisfying or dissatisfying incidents. Even though C-to-C interactions take different forms such as frowning at queue jumpers and smiling (Grove and Fisk, 1997), we limit our study to C-to-C conversations only.

Our research is an attempt at contributing to present literature by two dimensions. First, through a critical incidence technique, we divide C-to-C conversations into two types: *service provider-related* conversations and *service provider-unrelated* conversations. Second, we examine both positive and negative affective reaction to C-to-C conversations and their relationships with positive and negative word-of-mouth. We expect that affective reactions to service provider related conversations would be correlated to word-of-mouth behavior because the contents of these conversations are uniquely about the service provider. However, as we expect, affective reactions to service provider unrelated conversations would NOT be correlated to word-of-mouth behavior because the contents of these conversations involve customers' own interests but nothing about the service provider.

Data for this study was collected using the critical incidence technique (Gremler, 2004). Students enrolled in a senior undergraduate marketing course at a major university in an Eastern State in Australia participated in the study as part of their assignment requirement. In the beginning of their course, participants were informed about an assignment involving the importance of C-to-C conversations in services. They were asked to think about an incident in any services context where they had a conversation with another customer (but not with the service provider) whom they had never met before. The following week, in the beginning of the session, they were given a two-page response sheet. The original content of these two pages have diverse objectives and cover more issues than those relevant for the present paper. Below we describe only the relevant contents. On the first page respondents described the details of the incident.

The second part (page) of the task involved responding to the survey questions. For affective reaction, following from Holbrook and Batra (1987) we asked students "*What was your affective/emotional reaction to that interaction (your conversation with the other customer)? (Your reaction to the experience, not to how you would describe the experience)*".

Having collected the response sheets, the open ended responses from the first pages were analyzed. Then, both authors sitting in tandem divided service provider related and unrelated responses. The first pile included those incidents involving a conversation that directly refers to the service provider. Following is an example of the first pile:

"My seat on a longflight to London was next to that of an extremely friendly Irish woman. She spent the whole trip comparing the service, quality of food, prices and various other aspects of the service company (airline). We discussed the lack of leg room and space for our handbags in our economy seating, the poor and very minimal attendance of the hostesses and our anger (particularly hers) at the lack of an explanation for circling the airport many times before proceeding to land and the lack of warning as we entered an area of bad turbulence".

The second pile included those incidents involving a conversation that does not directly refer to the service provider but refers to other types of conversations like weather, personal background, and life in general. Following is an example of the second pile:

"I recently went to the USA for a holiday and on the return leg my plane was delayed in Hawaii for what turned out to be one night. Whilst we were waiting in the terminal one of the other passengers chatted and lent me his mobile phone so that I could call my parents and advise of the delay as he has free calls anywhere in the world on weekends as part of his phone deal. This was definitely a memorable event for me as I appreciated the fact he is a very nice person to be chatting and also helpful"

This procedure resulted in 64 responses for service provider related interactions, 37 responses for service provider unrelated interactions and 23 responses being excluded from the study which could not be categorized into one of the two piles.

In terms of measures, first, we measured both positive (joy) and negative (anger) affective response to C-to-C conversations using scales developed by Richins (1997) in consumer research. For "joy" two items, *happy* and *pleased* were used on a five point scale with endpoints of *did not feel at all* and *felt strongly*. The two items were strongly correlated (r .89) and internally consistent (alpha .94) hence we used these two items to form a single item measure of joy. For "anger", two items, *angry* and *irritated*, were used on a five point scale with endpoints of *did not feel at all* and *felt strongly*. The two items were strongly correlated (r .90) and internally consistent (alpha .95) hence we used these two items to form a single item measure of Anger.

Second, we measured both positive and negative word-of-mouth behavior using items developed by Brown et. al. (2005). For both positive word-of-mouth (PWOM) and negative word-of-mouth (NWOM) we used two items each on a seven point scale with endpoints of *strongly disagree* and *strongly agree*. The two PWOM items were strongly correlated ($r .93$) and internally consistent ($\alpha .96$) thus we used these two items to form a single item measure of PWOM (e.g., I spoke positively of the company to others). The two NWOM items were strongly correlated ($r .82$) and internally consistent ($\alpha .89$) (e.g., I said negative things about the company to other people). Hence, we used these two items to form a single item measure of NWOM.

Noting the mean evaluations regarding service provided related versus unrelated conversations, results show that consumers react more joyfully ($m 3.2$) when they engage in service provider-unrelated conversations than when they converse about the service provider ($m 2.6$) but the level of anger between the two groups are almost the same ($m 2.5$ vs. 2.4). We attribute these findings to the nature of conversations themselves. For example, consumers who find opportunities to talk about something of their own interests are likely to be happier than when they talk about anything else. But negative aspects of these conversations do not have to be different depending whether a conversation is about their own interests or not.

PWOM ($m 3.8$ vs. 3.4) are higher among those who conversed something unrelated to the service provider. However, NWOM is higher among those who talked about the service provider ($m 3.5$ vs. 2.5). These results are surprising and may have strong implications for consumer behavior in services marketing. We turned to correlation analysis for an alternative perspective.

Correlationwise, in terms of service *provider related* conversations, Joy and PWOM ($.655^{**}$) have significant positive relationships and Anger and NWOM ($.627^{**}$) have significant positive relationships (supports proposition). As these results indicate, when consumers talk about the company and become happy, they go and tell good things about the company. Similarly, when they talk about the company and become angry, they go and tell bad things about the company.

Interestingly, in terms of service *provider unrelated* conversations, relationship between Joy and PWOM ($.246$) are not significant (supports proposition). Hence, when consumers talk about something of their own interests and become happy, they do not go and tell good things about the company. However, relationship between Anger and NWOM ($.332^*$) is significant (rejects proposition). As this indicates, most interestingly, even when the conversations with strangers had nothing to do with the service provider, consumers tend to go and tell other people bad things about the service provider.

In sum, an effort previously not undertaken, we examine customer to customer conversations in services in terms of service provider related versus unrelated conversations. Then we examine positive and negative affective reactions to these conversations and their relationships with positive and negative word of mouth behavior. Contrary to our expectation, when the conversations with strangers had nothing to do with the service provider, consumers tend to go and tell other people bad things about the service provider. Implications of these findings, limitations and future research avenues are to be discussed in the completed paper.

The Moderating Role of Social Networks in Loss Aversion: Testing How Consumption in Network Subcultures Can Strengthen Consumer-Brand Relationships

Renée Ann Richardson, Harvard Business School, USA

The literature on consumers' relationships with their brands emphasizes that, when people form relationships with brands that mirror their social relationships, the norms of social relationships are used as guiding principles in their interactions with brands. Recent experimental research has shown that the types of relationship norms present during an exchange can moderate the degree of loss aversion that consumers experience. Building on this research, I use an experimental approach to investigate the impact of social networks on loss aversion, and how purchase behavior embedded in a network setting (for example, group shopping or an at-home party), impacts the degree of loss aversion felt by a consumer. Results show that respondents in the socially embedded exchange condition have a higher degree of loss aversion, as demonstrated by the gap between their selling prices (willingness to accept) and buying prices (willingness to pay). With this research, I hope to build a stronger bridge between social network literature and decision making theory.

Automatic and Effortful Processes in Socially Desirable Responding: A Cross-Cultural View

Hila Riemer, Ben-Gurion University, Israel

Abstract

In this paper we develop a theory to account for differences in Socially Desirable Responding (SDR) across cultures. Specifically, we deal with differences in the mechanism through which individuals from different cultures engage in the form of SDR/Impression Management (IM) in attitude questions. Based on a distinct definition of attitude in Eastern cultures and on the notion that collectivists are practiced at correcting for situational factors, we argue that collectivists engage in IM through an automatic process. Individualists' IM, on the other hand, is more effortful. Implications and directions for future investigation are discussed.

Introduction

This paper deals with the process through which people from different cultures engage in socially desirable responding (SDR) for impression management (IM). Despite the existing knowledge about cultural differences in people's tendency for SDR (e.g., van Hemet, van de Vijver, Poortinga, and Georgas 2002), researchers are not clear about the underlying mechanism for SDR (Johnson and van de Vijver 2002). We argue that for those with an individualistic cultural background or context SDR takes place through a deliberate or effortful process, whereas for those with a collectivistic cultural background or context it is more spontaneous or automatic. Next we present the theoretical background and develop our propositions. Then we discuss implications and directions for future investigation.

Theoretical Background and Conceptual Development

Research suggests that collectivists are more likely to engage in SDR compared to individualists (e.g., Triandis et al. 2001; van Hemert et al 2002). The reasoning for this is that collectivists conform in order to maintain good relationships. In contrast, individualists value uniqueness and social independence, and thus are less likely to conform (Triandis 1995). Further, according to Lalwani, Shavitt, and Johnson (2006), individualists see their responses as means for self-enhancement, but collectivists see them as means for IM.

Focusing on responses to attitude questions in survey settings, we address cultural differences in the underlying mechanisms of SDR/IM. Research on attitude measurement suggests that there may be cultural differences in the attitude construct. According to cultural researchers, collectivists are more comfortable with contradictory propositions than Individualists (Aaker and Sengupta 2000, Wong, Rindfleisch, and Burroughs 2003). Further, research conducted in western societies proposes that attitude consists of different dimensions (cognitive, affective, and behavioral), and that these dimensions will often be, at least to some extent, consistent with one other. Inconsistencies will lead to weaker or less stable attitudes (Festinger 1957; Breckler 1984; Cacioppo, Petty, and Geen 1989; Chaiken and Yates 1985). However, given that collectivists are comfortable with contradictory propositions, it would be reasonable to expect that in the East there is less pressure to bring components of attitude toward internal consistency. Moreover, definitions of attitude imply an *enduring* disposition. However, if collectivists are comfortable with contradictions between the different components at a given time, then they might also feel comfortable with contradictions between the same component at different times.

If collectivists are indeed more prone to expressing different attitudes in different situations, then the case of SDR can be viewed as a special case for this tendency. We argue that collectivists are more likely to engage in SDR in response to attitude questions because they make situational corrections. Individualists are less likely to make those situational corrections and thus are less likely to engage in SDR. This notion of situational correction in response to attitude questions is equivalent to the situational correction in attribution, that it is more prevalent in collectivists (relative to individualists, who make more dispositional attributions in social judgment) (Morris and Peng 1994).

How do these situational corrections take place? The possibility that variations in expressed attitudes of collectivists are due to different characteristics of attitude (more complex, situational dependent, and less enduring relative to attitudes of individualists), implies that differences in expressed social attitudes will occur spontaneously without need for deliberate editing and processing. This idea is also in line with recent research by Knowles et al. (2001) that claims that collectivists' correction for situational factors in making attributions takes place automatically. These researchers maintain that because this correction has been practiced frequently in collectivists it has become "automatized", and thus does not require substantial cognitive resources.

Whereas with regard to collectivists it is possible to claim *automatic* situational correction, the case with individualists is different. Based on the Western view, an attitude refers to an enduring disposition. Thus, all else being equal, people's actual attitude (unless changed) should stay similar across situations. What can change, though, is the *expressed* attitude. Adjustments in the expressed attitude may take place when one wishes to engage in IM using SDR. To be able to make this adjustment, however, one should invest cognitive resources in order to edit one's response. This implies an effortful process (Gilbert, Pelham, and Krull 1998). Thus, we propose:

P1: When collectivists engage in SDR/IM in responding to attitude questions, they do it automatically without investing substantial cognitive resources.

P2: When individualists engage in SDR for IM in attitude questions, they do it through a more effortful process.

Discussion

This perspective has theoretical and practical implications. Theoretically it contributes to an understanding of the processes through which people respond to surveys, and particularly to sensitive survey questions. Further, this research contributes to the understanding of cultural differences in the construct of attitudes. The idea that there are differences in the construct of attitude across culture is new. Insight into this notion may open a new stream of research into the differences between cultures, not only in terms of cognitive processes but also in terms of understanding concepts such as attitudes and emotions.

Practically, this research contributes to understanding the conditions in which SDR is more likely to occur. Insights into the role of culture in SDR may improve our ability to assess the validity of cross-cultural comparisons based on survey data.

Future research is needed to provide empirical support for the propositions presented here and to assess cultural differences in response to other types of questions (e.g., knowledge and behavior rather than attitude).

Flow and Attitude Toward the Website on the Evaluation of Products Present by Means of Virtual Reality: A Conceptual Model

Eva Tomaseti, Polytechnic University of Cartagena, Spain
 Salvador Ruiz, University of Murcia, Spain
 Nina Reynolds, Bradford University, UK

Abstract

The website represents the future of a company's business communications on the Internet, since it allows supplying large amount of information as well as creating virtual experiences with the product. In this context, virtual reality constitutes a technology which provides users with realistic and interactive virtual environments. In this paper, based on five groups of models, we analyze the effect of virtual reality presentations, by means of interactivity and richness, on flow and attitude toward the website, and the subsequent effect of those variables on online product evaluation.

Introduction

The key characteristic for the assessment of virtual reality in terms of consumer's experience is the concept of telepresence defined as the sensation of being in an environment created by a communication medium (Steuer, 1992). On the basis of sensory stimuli transmitted by Virtual Reality, individuals feel the perceptual illusion of being present and highly involved in the environment created by the medium, whereas they are physically in another place (Kim and Biocca, 1997). Telepresence is determined by two factors: interactivity and richness (Suh and Lee, 2005; Coyle and Thorson, 2001; Klein, 2003; Steuer, 1992).

Likewise, literature has highlighted flow (Hoffman and Novak, 1998) and attitude toward the website (Fortin and Dholakia, 2005; Fiore and Jin, 2003; Taylor and Todd, 1995) as important antecedents of Internet behavior. On the basis of this approach, we propose a model of the effect of interactivity and richness on product evaluation, including flow and the attitude toward the website as mediating variables.

Proposed Model

The model tested draws from five areas. First, the effect of interactivity and richness on attitudes draws from the work of Fortin and Dholakia (2005). In this study, the authors analyze the effect of interactivity on attitude toward the brand, attitude toward the ad, and purchase intention. Second, attitude toward the Web has been considered by Technology Acceptance Model (TAM) (Karahanna et al., 2006; O’Cass and Fecench, 2003) as antecedent of technology acceptance. Third, an extension of TAM, the Web Acceptance Model (WAM) (Castañeda et al., 2007) substitutes attitude toward the Web by attitude toward the website as predictor of future re-visit intention. Fourth, latter research in the adoption of innovations theory has used the evaluation of products to predict adoption (Nabih et al., 1997; Parthasarathy et al., 1995; Rogers, 1995; Klonglan and Coward, 1970). Fifth, Hoffman and Novak’s (1996) model takes into account the effect of telepresence on flow, and the effect of this outputs on behavioral variables.

In virtual reality literature, Sheridan (1992) uses the term interactivity to refer to the control of sensations and the ability to modify the environment, while Zeltner (1992) refers to the relationship between autonomy and interaction. Based on those dimensions, interactivity is then defined as the degree to which two or more communication parties can act on each other, the communication medium, and the messages, as well as the degree to which such influences are synchronized (Liu and Shrum, 2002). Richness is defined as the form in which the environment presents the information to the senses (Steuer, 1992).

Although different studies have analysed how the use of virtual reality affects attitudes towards the website (Fiore et al., 2005; Martin et al., 2005; Schlosser, 2003), there is no agreement on the interaction effect of attitude towards the website, interactivity and richness on intentions (Fortin and Dholakia, 2005; Park et al., 2005; Hopkins et al., 2004). However, based on Coyle and Thorson’s study, which tested that higher levels of interactivity and richness increase attitudes toward web sites, due to the fact that the virtual experience with the product is perceived as more similar to a direct experience, we proposed:

H1: Interactivity is positively related to attitude toward the website

H2: Richness is positively related to attitude toward the website

The flow state is defined as the holistic sensation that people feel when they act with total involvement (Csikszentmihalyi, 1977). Hoffman and Novak (1996) suggest that the success of online marketers depends on their ability to create opportunities for consumers to experience flow. They found a positive effect of interactivity and richness on telepresence and, consequently, of this variable on flow. The interactivity offered by virtual reality through a website favors communication, personalises the way the information and the product are presented, and increases enjoyment (Fiore and Jin, 2003). Similarly, the realistic experience provided by richness facilitates the occurrence of flow.

H3: Interactivity is positively related to flow

H4: Richness is positively related to flow

Marketing literature has also verified the positive relationship between attitude toward the ad and attitude toward the brand (Ko et al., 2005; Hopkins et al., 2004; MacKenzie et al., 1986). As such, we expect that attitude toward the website will influence attitude toward the product, yielding higher product evaluations. Therefore, an increase in attitude toward the website, as a result of increased interaction with the product and the possibility of obtaining detailed information (Ward and Lee, 1999), will positively impact product evaluation. As well, higher levels of flow imply a positive consumer experience (Finneran and Zhang, 2005) which will be manifested in a higher product evaluation.

H5: Attitude toward the website is positively related to product evaluation

H6: Flow is positively related to product evaluation

Finally, a higher level of flow is capable of conferring value to the online experience, which will positively influence attitudes toward the website (Finneran and Zhang, 2005; Mathwick and Rigdon, 2004).

H7: Flow is positively related to attitude toward the website

Method

The study was carried out with a sample of 177 university students. The experimental design was based on a website. The data collection process was completed online. We used a sport watch as the product as it belongs to a category frequently marketed on the Internet, and has been frequently used in virtual reality studies (Jiang and Benbasat, 2007; Daugherty et al., 2005; Jiang and Benbasat, 2005).

After visiting various websites, with a focus on well known brands of watches, we chose one representative commercial presentation which fulfilled the objectives of the study. The level of interactivity was manipulated through allowing subjects to obtain images of the product from different perspectives, as well as displaying information related to the product by using the mouse (Klein, 2003; Coyle and Thorson, 2001). In order to manipulate the variable richness, we followed the methodology used by Li et al. (2001) and Klein (2003). The product is presented in two sizes.

The initial page of the website presented the sport watch under one of four conditions (interactive/non interactive; high/low level of richness). Subsequently, participants evaluated the product (Mukherjee and Hoyer, 2001), the level of interactivity (Coyle and Thorson, 2001), their attitude toward the website (Martin, et al., 2005) and their flow state (Hoffman and Novak, 1996) during the visit to the website.

Results

We used confirmatory factor analysis (CFA) to test the discriminant validity of the measures. Results show that the model fit the data well. Then, we checked whether the correlations among the latent constructs were significantly less than one which provided evidence of discriminant validity. The internal consistency of the scales were tested using both the composite reliability (ρ_c), and the average variance extracted (AVE). All values were significantly greater than 0.60, and 0.50, respectively, and demonstrate internal consistency.

In order to verify the hypotheses, we used structural equation modelling with the Robust Maximum Likelihood Method and the asymptotic variance-covariance matrix. The fit statistics for the full model ($\chi^2(96)=238.49$; p -value=0.0; CFI=0.98; SRMR=0.050; RMSEA=0.072; NNFI=0.98) were within the acceptable ranges (the chi-square is significant, $p<0.05$; SRMR and RMSEA ≤ 0.08 ; and NNFI and CFI ≥ 0.90), which indicated a good model fit.

Results showed that interactivity and richness have a strong direct effect on attitude toward the website ($\beta=.74$; $p<0.01$; $\beta=.70$; $p<0.01$), and flow ($\beta=.98$; $p<0.01$; $\beta=.58$; $p<0.01$), therefore confirming H1, H2, H3, and H4. Moreover, we found a positive impact of attitude toward the website ($\beta=.37$; $p<0.01$), and flow ($\beta=.13$; $p<0.01$) on product evaluation, supporting H5 and H6. Finally, we observed a direct effect of flow on attitude toward the website, as proposed in H7 ($\beta=-.18$; $p<0.05$).

One important criterion of a model's success is its performance compared with that of rival models (Bagozzi and Yi, 1988). Based on Luna et al's (2003) model, we developed a rival model which hypothesized the opposite relationship between attitude toward the website and flow.

We compared our proposed model with the rival model using the following criteria: overall fit, percentage of the models' statistically significant parameters, and explained variance of the endogenous constructs. The overall fit for the rival model was equal to that of proposed model. However, in the rival model, the effect of attitude toward the website on flow was not significant at 95%. Finally, the explained variances for all endogenous constructs were the same in the proposed and rival model. These findings provided more confidence to the proposed model.

The Evaluation of New Utilitarian and Symbolic Products: The Effect of Attribute Type and Product Knowledge

Eva Tomaseti, Polytechnic University of Cartagena, Spain
Salvador Ruiz, University of Murcia, Spain

Abstract

Companies introduce new products whose success depends on consumer’s product evaluation. In this paper, we analyze the effect of the addition of three types of new attributes to a product (beneficial and image attributes and characteristics), with utilitarian or symbolic meaning, on its evaluation, and how this effect is moderated by product knowledge. Results show that the impact of attribute type and product knowledge depends on product meaning.

Introduction

The introduction of new attributes is one of the most common methods for developing new products. The impact of a new feature or attribute on product evaluation depends on the characteristics of the feature itself, the type of product to which the feature is added, the characteristics of the buying task, and other factors such as the marketing strategy or the competitive and social environment (Nowlis and Simonson, 1996). Besides the important stream of research which has already analyzed the impact of new attributes on new product evaluation (Mukherjee and Hoyer, 2001; Brown and Carpenter, 2000), little is known about the interaction effect of the different attributes added and the other factors. Focusing on the first two factors proposed by Nowlis and Simonson (1996), we propose that the impact of a new feature on new product evaluation must be analyzed considering not only the type of attribute and the type of product (in our case utilitarian or symbolic) as intrinsic elements to the product development, but also by individual factors, such as product knowledge.

The effect of the addition of new characteristics, beneficial attributes and image attributes on the evaluation of utilitarian and symbolic products

Although marketing literature has analyzed different attributes of products, Lefkoff-Hagius and Mason (1993) concluded that product attributes presented in marketing research (Hauser and Clausing, 1988; Hirschman, 1980) can be classified into three types: characteristics, beneficial attributes, and image attributes. These authors defined characteristics as those attributes related to physical properties, beneficial attributes as those related to the task or outcome referent, and image attributes as those which possess symbolic meaning (Meenaghan, 1995), and are related with visual (Eckman and Wagner, 1994) and promotional aspects. More recent classifications, as those presented by Veryzer (1998) and Michaut et al. (2002) are somehow equivalent to that of Lefkoff-Hagius and Mason.

Literature disagrees concerning the importance of the three kinds of attributes on product evaluation. Some authors, as Meenaghan (1995), Eckman and Wagner (1994), and Michaut et al. (2002), concluded that consumers tend to show a higher preference for image attributes than for functional aspects of the product. However, Hirschman (1987) and Moreau et al. (2001) concede more significance to technological and performance aspects. This discrepancy can be explained by product meaning. One of the most accepted classifications

distinguishes two kinds of products, functional or utilitarian and symbolics. It arises as a result of the existence of two individual necessities, functional ones, related to specific problems, and symbolic ones, that are the expression of self-image and social identification (Park et al., 1986). Then, functional products are those that possess some tangible characteristics that offer benefits to consumers (Fournier, 1991; Park et al., 1991; Bhat and Reddy, 1998; Kempf, 1999; Addis and Holbrook, 2002; Del Río et al., 2001), or have the ability to accomplish specific acts, based on properties such as their physical characteristics and features (Fournier 1991). Symbolic products are used to signify social position and/or self identity, not for functional benefits (Hirschman, 1981; Levy, 1959).

Literature related to the effect of different attributes on product evaluation observed a greater impact of brand name, compared to product benefits, on products with symbolic meaning (Del Río et al, 2001), while functional products tend to be evaluated on tangible features and cost, then secondarily on their intangible/image attributes (Sirgy and Johar, 1985). Furthermore, in their study centered in brand extensions, Park et al. (1991) found more favourable consumers' reaction when the new attribute is consistent with the brand concept. As such, consumers display a more positive reaction to functional than prestige extensions for functional brands, and to prestige than functional extensions for prestige brands. Therefore, applying this consistency to the combination of attribute types and product meanings as described above, we propose:

H1: Compared with the case where the new attribute is absent, the presence of a new characteristic or benefit in functional products increases the product evaluation more than the presence of a new image attribute.

H2: Compared with the case where the new attribute is absent, the presence of a new image attribute in symbolic products increases product evaluation more than the presence of a new characteristic or benefit.

Product knowledge and its effects on new product evaluation

Within the context of the adoption of innovations, marketing literature has highlighted the significant influence of knowledge on consumer's decisions (Saaksjarvi, 2003; Gatignon and Robertson, 1991; Alba and Hutchinson, 1987). Pre-existing knowledge of a product or service category determines the evaluation of new products connected with it (Saaksjarvi, 2003; De Bont and Schoormans, 1995). Product knowledge depends on the quantity of specific knowledge acquired by experience or training (Wood and Lynch, 2002). This influences the ability to understand and interpret information about products (Balabanis and Reynolds, 2001; MacInnis and Jaworski, 1989).

Based on Saaksjarvi's analogical learning theory, expert subjects value products upon new functions and intrinsic characteristics of the product (such as characteristics and benefits), while non experts based their evaluation on physical aspects (such as image attributes). Therefore, even when individuals value new products based on analogies (where there are no shared physical attributes), experts center their evaluation, mostly, on functional attributes, perceiving more utility (Irani, 2000), while non experts do it based on superficial or visible aspects of the product (Roehm and Sternthal, 2001; Roehm et al., 1999).

However, the degree of preference for functional attributes will be determined by product meaning. For utilitarian products, the understanding of new characteristics and new benefits will determine consumer decisions, but not for symbolic products, where those attributes lose importance in favour of image attributes. As such, for expert subjects, the difference of new utilitarian product evaluation obtained by the introduction of new characteristics and beneficial attributes will be higher than for non-experts. On the other hand, for symbolic products there will be no difference between experts and non-experts on product evaluation when new attributes are added, due to the fact that the image attribute (more valued for non-experts subjects) will be equally understandable for both experts and non-experts.

H3: The improvement on product evaluation based on the presence of a new characteristic or benefit in utilitarian products is higher for experts than for non-experts

H4: The improvement on product evaluation based on the presence of a new attribute (characteristic, benefit or image attribute) in symbolic products does not differ for experts and non-experts

Method

In order to choose a utilitarian and a symbolic product, a questionnaire was administered to forty students to evaluate different products (Allen and Ng, 2002; Allen and Ng, 1999). The product with the most utilitarian meaning was a personal computer and the one with the most symbolic meaning was a pair of casual sport shoes. To distinguish between characteristics, benefits and image attributes, a pretest was conducted with sixty students to classify a list of attributes related to PCs and casual sport shoes. In order to choose the new attributes, a new pretest was conducted to select the ones with the highest evaluation in the three categories and for both products.

To test the above hypotheses, three hundred and fourteen students participated in the 2 x 2 x 3 experiment: high vs. low product knowledge; utilitarian and symbolic product; and the three attribute types, characteristics and benefits vs. image.

All participants received a questionnaire booklet. The first page presented the product (a PC or a pair of casual sport shoes), which provided eight attributes without brand name. The selection of attributes included was based on the analysis of real ads and interviews with some experts. Then, they were asked to evaluate the product on a six-item, seven-point scale anchored by "bad/good", "like/dislike", "not useful/useful", "desirable/undesirable", "high quality/low quality", "favourable/unfavourable" (Mukherjee and Hoyer, 2001). After completing this initial evaluation, they were asked to provide some information related to product meaning and product knowledge (Smith and Park, 1992). The last page showed a new product. Fifty-three students evaluated a new PC with a new characteristic (Intel Pentium V), fifty-one with a new beneficial attribute (SODIMM SDRAM DDR NP CL2.5 PC2100 of 512MB for Thinkpad) and forty-two a new design in PCs, presented with the slogan "Dimension 4600C, the PC for those who enjoy the future, nowadays" (Lefkoff-Hagius and Mason, 1993). Concerning the symbolic product, a total of forty-three students completed the questionnaire with the new pair of casual sport shoes with a new characteristic (Ultralite midsole), forty-four with the new beneficial attribute (CLIMAWARM) and forty-six with a new design in shoes presented with the slogan "Columbia 23, for those who want something different". All brand names were fictitious. Although real products did not have the combination of characteristics set in the questionnaire, all of the attributes were real and exist in the market. Therefore, the level of novelty of each new attribute was analyzed, and they obtained very similar values.

Results

We used ANOVA to test the hypotheses. Results show that the improvement on evaluation of utilitarian products based on the additional introduction of a new characteristic or a new beneficial attribute was higher than when a new image attribute was added ($M_c=0.64$ vs. $M_b=0.54$, $p=0.82$; M_c vs. $M_i=0.12$, $p<0.05$; M_b vs. M_i , $p<0.05$), providing support for hypothesis H1. For the symbolic product, the presence of the new image attribute was similarly valued to the added new characteristic or new beneficial attribute ($M_c=0.36$ vs. $M_b=0.26$, $p=0.79$; M_c vs. $M_i=0.38$, $p=0.99$; M_b vs. M_i , $p=0.74$). Therefore, hypothesis H2 was not supported.

In order to test hypotheses H3 and H4, the sample was divided into two levels of product knowledge. High product knowledge level was attributed to those individuals who scored higher than the median. The rest were classified as non-experts.

For the utilitarian product, evaluation improvements based on the addition of the new beneficial attribute was higher for experts than for non-experts ($M_{\text{expert}}=0.73$ vs. $M_{\text{non expert}}=0.26$; $p<0.05$), but there were no significant differences on evaluation improvements when the new characteristic ($M_{\text{expert}}=0.58$ vs. $M_{\text{non expert}}=0.73$; $p=0.29$) or the new image attribute were incorporated ($M_{\text{expert}}=0.23$ vs. $M_{\text{non expert}}=0.03$; $p=0.56$), which partially supported H3. For the symbolic product, evaluation improvements of expert and non-experts were similar when adding a new characteristic ($M_{\text{expert}}=0.30$ vs. $M_{\text{non expert}}=0.43$; $p=0.61$), a new beneficial attribute ($M_{\text{expert}}=0.18$ vs. $M_{\text{non expert}}=0.35$; $p=0.34$) and a new image attribute ($M_{\text{expert}}=0.27$ vs. $M_{\text{non expert}}=0.45$; $p=0.47$), which provided support for H4.

The Influence of Evaluability in Nutrition Tables on Consumers' Food Preferences

Vivianne Visschers, ETH Zurich, Switzerland

Michael Siegrist, ETH Zurich, Switzerland

Consumers seem to scarcely use nutrition tables printed on food products (Cowburn & Stockley, 2005). If they pay attention to these tables, they often seem to have difficulties in understanding the nutritional value of the products. Based on the evaluability principle, we suggest that people's nutritional value understanding may be facilitated when they can compare products.

The evaluability principle posits that when people evaluate a product on an attribute that does not have clear boundaries or references (e.g. the amount of fat in a product), the presence of similar information about another product can affect this evaluation (Hsee, 1996). The information about the other product then functions as a reference class. Thus, a nutrition table that includes nutrition information about other, perhaps similar products should influence consumers' perception of this product. Furthermore, consumers do not consider multiple attributes at the same time when choosing between food products but prefer to base their choice on one attribute of these products (Scheibehenne, Miesler, & Todd, 2007). This implies that consumers may benefit from summary information in nutrition tables when evaluating the nutritional value of a product.

Based on the evaluability heuristic and previous studies, we hypothesize that nutrition tables with information about a reference product, that is, in addition, summarized, are easier to understand and are more likely to affect consumers' evaluation of the products. So that the latter is more in agreement with the products' nutritional value.

We tested this in a between-subjects experiment. Six different nutrition tables were developed, which varied on summary information and on evaluability. The summary information was the nutrition density index (NDI) of the food product, which is based on the product's balance between the amount of nutrients and the amount of energy (cf. Drewnowski, 2005). This resulted in a value between 1 (low NDI) and 5 (high NDI). Evaluability was varied by presenting, along side the NDI score of the product at hand, either the average NDI score of the product category or the NDI score of a very healthy product, namely an orange. In sum, we tested six different nutrition tables, a standard nutrition table (*control*) and five tables that contained the standard table plus one of the following: the product's NDI score (*NDI score*), the percentage daily value of each nutrient (*%DV*), a positive, negative or neutral smiley for each nutrient (*smiley's*), a bar on which the product's NDI score and the average NDI of the product category were presented (*NDI plus product category*), or a bar on which the product's NDI score and the NDI score of an orange (*NDI plus orange*) were shown. These six tables were developed for two products: yogurt, which is a relatively healthy product, and chocolate, which is a relatively unhealthy product. Each respondent viewed one of these tables for one of the two products and was then asked to complete a questionnaire. This contained items about their liking of and intention to buy the product, its perceived healthiness, knowledge about the different nutrients, the evaluation of the nutrition table, which information in the nutrition table had drawn their attention, the importance of food for their health, and some demographics.

Overall, respondents perceived the yogurt as healthier than the chocolate. In addition, they rated the chocolate as more attractive and had greater intention to buy it than the yogurt. Respondents' knowledge of the two products seemed sufficient; they correctly indicated that the yogurt contained more sodium than the chocolate and that the chocolate contained more energy, fat, saturated fat, carbohydrates, sugar, and fibers than the yogurt.

The type of nutrition table influenced respondents' liking and intention to buy the chocolate. Respondents who had viewed the control table liked the chocolate more and had greater intention to buy it than the respondents who had seen the NDI score, %DV, smiley's, or NDI plus product category. This effect was not found for the yogurt. The chocolate's liking-buying score was higher in the control table condition than in the other nutrition table conditions, and higher compared to the yogurt's liking-buying rating. This may indicate that the tables that included reference information, summary information, or both changed people's perception of chocolate so that it became more in line with its nutritional value, which was actually relatively low.

A second study, in which we examined three nutrition tables for a healthy yogurt and an unhealthy yogurt, showed that the reference information changed people's healthiness perception of the unhealthy yogurt. The results of our two studies may imply two things. First, nutrition tables that provide reference information only seem to change people's perception of food products with low nutritional value, so that people like them less or consider them to be less healthy. Second, reference information only influences people's primary

association with a product, and only when this association is not in line with the product's actual nutritional value. Consumers primarily associate chocolate with hedonic value and more with healthiness, reference information therefore changed these two perceptions of the two products.

In sum, this study suggests that the evaluability of nutrition table information can influence consumers' perception of a food product so that it corresponds to a greater degree with the product's nutritional value. An interesting suggestion for further research may be to study what kind of reference class induces this effect, thereby focusing on different food products.

The IAT is Not Enough: The Added Value of Projective Techniques in Consumer Research

Hendrik Slabbinck, Ghent University, Belgium
 Patrick Van Kenhove, Ghent University, Belgium

Introduction

Consumers do not only think and act rational. Also implicit or subconscious processes can influence their (consumer) behavior (e.g. Maison, Greenwald, and Bruin 2004). Consequently, in order to fully understand the consumer, both explicit and implicit attitudes have to be measured. Moreover, explicit attitudes can best be measured with direct measures and implicit attitudes with indirect measures (Greenwald and Banaji 1995).

One indirect measure that gets a fast growing support is the Implicit Association Test (IAT: Greenwald, McGhee, and Schwartz 1998). Apart from some exceptions (e.g. Blanton et al. 2006), the extensively tested psychometric properties of the IAT have mostly been approved (for an overview: see Nosek, Greenwald, and Banaji 2007). Whereas the IAT is frequently applied in research about stereotyping and prejudices, the interest by consumer researchers is also growing (e.g. Friese, Wanke, and Plessner 2006; Maison et al. 2004).

Another class of indirect measures are projective techniques. These research techniques appeared for the first time in consumer research in the 50's (Haire 1950). However, due to a lack of consensus on their psychometric qualities and subjective interpretation, these techniques disappeared virtually from attitude research. Yet, the interest in projective techniques seems to grow again (e.g. Boddy 2005; Vargas, von Hippel, and Petty 2004).

To conclude, two distinct indirect research techniques coexist, but, up to now, comparisons between both are very scarce (Sheldon et al. 2007). Hence, a clear need exists to compare the IAT with projective techniques. One important question that needs to be answered in this context is: "Are both techniques interchangeable, or do they measure distinct aspects of implicit attitudes?"

The relationship between the IAT and projective techniques

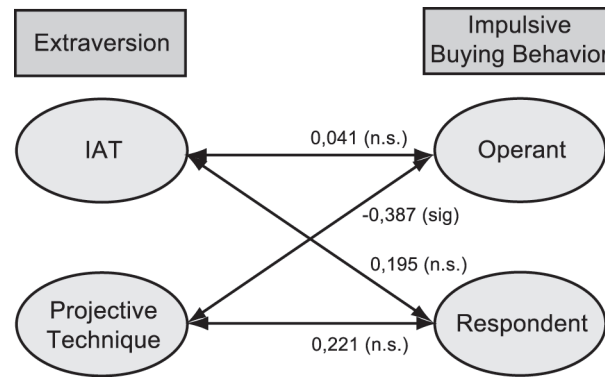

In the few studies in which the IAT was combined with a projective technique, the correlation between both is mostly non-significant or rather low. In the literature, we found correlations ranging from 0,11 (Vargas et al. 2004) to 0,28 (Meagher and Aidman 2002). Brunstein and Schmitt (2004) attribute this lack of correlation to method variance inherent to projective techniques, but Vargas et al. (2004) argue that low correlations can also indicate that projective techniques and the IAT assess different aspects of implicit attitudes. Next to Vargas et al. (2004) also Sheldon et al. (2007) showed that projective measures predict independently from the IAT a unique part of behavior. What is not clear yet is whether the IAT and projective techniques predict the same kind of behavior. According to McClelland et al. (1989), projective techniques outperform direct measures in the prediction of long term behavior and especially when behavior is triggered by activity incentives (e.g. long term job performance, ...), rather than social incentives. McClelland (1980) classifies this type of behavior as operant behavior. The IAT from its side, seems to outperform direct measures, especially if behavior is triggered by social incentives (e.g. prejudices, stereotyping, ...) (for an overview: Nosek et al. 2007). This kind of behavior can be classified as respondent behavior (McClelland 1980). Based on these findings, we hypothesized that projective techniques predict operant behavior whereas the IAT predicts respondent behavior.

Methodology

In order to operationalize this hypothesis, an exploratory study with 60 business students, was set up in which the personality dimension 'extraversion' was assessed by an IAT and a projective photoelicitation technique (selection of the most and least liked paintings out of a list 20 pre-tested paintings, followed by a semantic differential (based on the BFI: John, Donahue, and Kentle 1991)) measuring the extraversion of the paintings. The correlation between the liking of the painting and its extraversion rating can then be interpreted as a projective measure of the respondent's extraversion (procedure: see Liggett 1959).

Operant and respondent behavior were measured by nine five point likert items about impulsive buying behavior (IBB). IBB was chosen because a clear link exists between extraversion and IBB (Verplanken and Herabadi 2001). Respondent items comprised a stimulus element while operant items did not. An exemplar respondent item is "After having seen a TV commercial about sweets, I regularly indulge

FIGURE 1
Correlations between extraversion and impulsive buying behavior (n=60)

myself with some candy that I have in stock". An exemplar operant item is "When I come home from shopping, I am regularly surprised from all the unnecessary things that I bought". The items were factor analyzed and after deletion of three items, two factors could be maintained. The first factor clearly measured operant behavior and the second respondent behavior. The scores of each factor were summed which yielded into two reliable constructs (Operant: $\alpha=0,67$; Respondent: $\alpha=0,75$).

Results

As depicted in Figure 1, the results indicate that the projective measure indeed outperforms the IAT in predicting operant behavior. The projective, but not the IAT measure of extraversion correlated significantly with operant IBB ($r_{\text{IAT-operant}}=0,041$; $p>0,05$; $r_{\text{projective-operant}}=-,387$; $p<0,01$).

Concerning respondent behavior, we could not find any difference between both implicit measures of extraversion. The IAT nor the projective measure correlated with respondent IBB ($r_{\text{IAT-respondent}}=0,192$; $p>0,05$; $r_{\text{projective-respondent}}=.221$; $p>0,05$).

Discussion and follow up

In this first study, we found evidence that projective techniques and the IAT indeed predict different classes of behavior. However, it is not yet clear *why* they do so. A possible explanation could be that projective techniques are better in assessing personality traits than the IAT whereas (McClelland et al. 1989) the IAT will probably outperform projective techniques in the assessment of attitudes. (e.g. Nosek et al. 2007). This may also be a reason why in the current study, the IAT did not correlate with respondent IBB. Hence, to clarify the relation between implicit personality and attitudes, we will extend the current study in such a way that both, personality and attitudes are assessed separately by a projective technique and an IAT. We hypothesize firstly that personality assessed by a projective technique will outperform the IAT in predicting operant behavior. Next, we hypothesize that implicit attitudes measured by the IAT will outperform projective techniques in the assessment of respondent behavior.

The Meaning of 'Product Placement': An Interpretive Exploration of Consumers' Experiences of Television Programme Product Placement in the United Kingdom and Thailand

Rungpaka Amy Tiwsakul, University of Surrey, UK
Chris Hackley, Royal Holloway, University of London, UK

Television programme product placement is increasing in significance from both a managerial and a consumer cultural perspective. Product placement refers in this research to the inclusion of or reference to branded products or services in scripts or plots in any form of non-advertising mediated entertainment for promotional purposes. In Thai there is no precise translation for product placement. It is known as 'implicit advertising' or 'kod-sa-na-faeng'. Television studios are seeking new revenue streams to offset the decline in conventional paid-for advertising revenues, while branding and advertising agencies are moving towards more 'experiential' marketing tools to access consumers 'under the radar'. Questions arise about the implications of this practice for international managerial practice and consumer experience, with attendant issues concerning ethics, public policy and regulation in a climate of increasing globalisation of brands. To date, with a small number of exceptions, research in the area has focussed largely on single-country studies measuring the attitudes of non-segmented audiences towards placements in movies.

Product placement has played an important role as a relatively new emerging tool of integrated marketing communications (IMC) for several decades. Brand marketing organisations have typically been content with seeing brand exposure in mediated entertainment as an add-on, but many are now putting resources into the technique. One of its perceived advantages over traditional advertising is the access it affords to consumers' daily experiences. Through placements in television soap operas, situation comedies, quiz shows, and other genres, brands can be featured as meaningful artefacts in narrative contexts which have a powerful resonance for consumers. This popular culture phenomenon blurs the boundaries between entertainment and promotion. The meanings of the media and promotions, as a result, are intertwined through the postmodern practice of intertextuality by which consumers engage in endless cross-referencing (Jansson, 2002; Gould and Gupta, 2006). In other words, consumers bring an intertextual network of meanings through which they interpret and react to the placements to the product placements and media that brands are embedded in.

Although some literature (e.g. Fazio and Zanna, 1978; Smith and Swinyard, 1988) suggests that "attitudes formed through lived experience are stronger, more accessible, held more confidently, and more predictive of behaviour than those derived from mediated experience through advertising" (Wattanasuwan, 2003, p.72), in postmodernity mediated experiences of, for example advertising, product placement and television programmes, may be as powerful as lived experiences in forming attitudes relevant to 'the symbolic project of the self' (ibid). Branded goods are consumed not only for their utility but also for their symbolic value (Elliott and Wattanasuwan, 1998). Media representations of brands in advertising and entertainment can be powerful in suggesting particular meanings in association with marketed products and brands. Effectively, products become commodity signs (Baudrillard, 1981).

Product placement in movies has been studied by academic researchers, usually from a neo-positivist perspective which measures the brand recall, attitudes of consumers, and purchase intention to the practice. There are some robust findings but more studies are needed which take into account several other dimensions. Firstly, television is potentially a more powerful channel than movies for reaching into consumers' lives because the consumer engagement with favourite soap operas or dramas or other genres of the television show is more intimate and more regular than visits to the movies. Secondly, this quality of engagement cannot easily be accessed through quantitative data gathering methods. Thirdly, the strategies and rationalisations behind product placement practices need to be understood to complete the overall picture, since consumer interpretations are only one half of the process. In particular, the managerial strategies are important not only in making assessments about the contribution of product placement to the marketing management of brands but also in making judgements about the attendant ethical and public policy implications. Furthermore, product placement seems to carry features consistent with the 'interpretive' or 'postmodern' turn in consumer and marketing research, especially with regard to the symbolic role brands may play as resources for the production of self and social identity. In this regard it is important to consider product placement from an interpretive consumer cultural perspective, a perspective not yet evident in the literature. Finally, much is made today of the globalisation of brands and the emergence of consumer communities separated by ethnicity, nationality and religion yet linked through brand allegiance. It is therefore useful to examine the cross-cultural context. Consumers under forty constitute a useful group in this research as they are typically fully engaged with media and brand culture and are known to use brands in their self-identification processes.

This study, then, uses qualitative data gathering methods to explore television programme product placement from the subjective perspective of young consumers in the UK and Thailand. This perspective is supplemented by a detailed account of managerial practices of product placement offered by leading agencies in the field. In-depth interviews with agency practitioners, and discussion groups and elicited auto-ethnographic passages with consumers were the main data-gathering methods. All data were fully translated and transcribed. Data were then subject to an interpretive thematic analysis which, drawing on elements of discourse analysis, focussed on the 'interpretive repertoires' which seemed to constitute the major themes drawn upon in articulating experiences of product placement.

The UK and Thailand were chosen because the UK is an advanced economy with a relatively immature television product placement industry while Thailand is a developing economy in which television product placement is a well-established practice. The intention of the study is not to compare the respective cultures as such, since culture is not a fixed entity which allows direct comparison, although it is important to consider product placement within its local media infrastructure and consumer culture. Rather, the intention is to juxtapose two contrasting contexts in order to add contrast and shade to the respective findings.

The findings offer a thematic interpretation of some 40,000 words of transcribed data with consumers and practitioners focusing on three main areas: 1) the managerial practices and strategies surrounding the use of television product placement as an aspect of marketing communications management 2) the ways in which consumers engage with, understand and interpret brand placements in television shows and 3) the ways in which these interpretations feed into ideas of self identity and consumer culture. The study concludes that product placement on television is a sophisticated managerial practice which constitutes a powerful discourse of brand consumption. Consumers are highly attuned to this discourse and draw on it reflexively in their expressions of self-concept.

Exploring Consumer Risk Across Multiple Domains

Gulnur Tumbat, San Francisco State University, USA

Extended Abstract

Consumer live in a world filled with risk which has become a big debate in the last decades in various areas such as destruction of nature and environment, pollution of air, water, and food, health problems, national security issues and politics, crime, and technology (Beck 1992, Giddens 1992, Furedi 2002). Within psychology and its manifestation in consumer research (e.g., brand preference, product choice), decision making and information processing under risk and uncertainty has been of considerable interest to both judgment and decision making literatures. So far consumer researchers have created a useful yet incomplete picture of consumer risk since consumers are largely viewed as responding individually to risks according to various "heuristics" or frames of perception that structure their judgment According to Paul Slovic (2000), one of the foremost theoreticians of the psychology of risk, "the perception and acceptance of risk have their roots in social and cultural factors" (p. 221). Similarly, Lopes (1997) argues that attempts to explain all of risky choice behavior in the narrow terms of purely perceptual, purely cognitive, or purely motivational mechanisms will necessarily miss much of what impels people toward or away from particular risks. Douglas and Wildawsky (1982), for instance, explain that risk is a constructed idea and that humans act less as individuals and more as social beings that have internalized social structures. Socio-cultural aspects of consumers risk perceptions and risk-taking behavior offer significant contributions to consumer risk studies along with economic and cognitive approaches to study risk. Yet, despite their widely acknowledged significance, particularly in the context of consumption, social and cultural contexts have been largely ignored in our field [see few notable exceptions. Thompson (2005)'s study on birth practices reveals how people's risk perceptions are culturally constructed. Celsi, Rose, Leigh (1993) investigated cultural motivations and dramatic worldview that effect people's risk taking behavior in the case of high-risk leisure activities].

These prior studies, focus on single and isolated risk discourses around issues such as product or brand choice, health, finances, and leisure, among some others. Various streams of literature, however, suggest that modern day consumers are faced with a vast array of multiple and competing demands that they try to deal with simultaneously. Building on Beck and Giddens, Furedi (2002) for instance argues that we now live in a culture of fear and discourses around risks of life produce what he calls a cautious individual. Consumers are embedded in social systems and in their day-to-day lives they encounter multiple foci on risk. Examples of various domains may include financial (e.g., investments, future considerations, debts to pay), environmental (e.g., pollution, global warming, depletion of natural resources), social/cultural (e.g., changing society, changing needs, relationships), terrorism (e.g., terrorist attacks, bombings, hijackings), crime/safety (e.g., security systems, gated communities), health (e.g., organic food, holistic approaches), and natural (e.g.,

natural disasters such as earthquakes and hurricanes) risks. However, with the existing research on risk, we are unable to address possible variance in assessing risks in cross-context. How do people perceive risks in different risk domains? How do they manage (tensions and) their perceptions across these domains? How consumers live/ cope with various (and sometimes countervailing) risk discourses (e.g., economic, political, technological, environmental, social) and what kind of role consumption plays in those experiences? How various risk discourses are activated and negotiated in everyday life? How are consumers' practices related to one discourse is mediated through other risk discourses? Do they balance their practices related with competing risk discourses? Or do they trade off one against another? Do the risk perceptions and resultant practices shift toward one risk domain to another? Consumer researchers need to answer these important questions and thus reveal embedded and complex quality of multiple risk discourses and their reflections on consumption practices.

To address this theoretical gap, a poststructuralist perspective would offer insights into how consumers experience multiple risk discourses and what role their consumption practices play. The methods used for data collection include multiple steps. First, a questionnaire was distributed to 50 graduate students as part of a graduate course. After giving some information to them about the project, questions asked were about the types of risk discourses they can identify, how they think they are related to consumption, and how they deal with them in their daily life, and how they think they effect their consumption in general. The purpose of this step was to gather a sense of potential areas to probe in the second step of the data collection process that is in-depth interviews. Preliminary analysis suggests several themes around these practices as prioritization (focusing one over the other depending on context), distraction (choosing to be distracted by other issues about their lives), ignorance, accommodation (trying to be careful), and some shift (in consumption practices).

This study hopes to add to the existing body of research around risk in consumer behavior field by studying risks as discourses in order to provide a deeper understanding about social, historical, cultural constructions of risk. Furthermore, it attempts to shift the focus from individual and isolated risk domains as they are tackled in previous research to a more broader perspective of multiple risk domains as experienced and lived by consumers on a daily basis. Sharing these ideas and preliminary findings at ACR would definitely provide much needed feedback and comments, and would also open up potential collaboration among other consumer risk researchers.

Exploring the (Re)construction of The Body in Virtual Worlds: Consumption of Body as Experience

Handan Vicdan, The University of Texas-Pan American, USA
Ebru Ulusoy, The University of Texas-Pan American, USA

The main focus of interest on the body concept in consumer research evolved around the corporeal body. Body has been investigated as a project that modern consumers work on (Featherstone, Hepworth and Turner 1991; Schouten 1991), and as a means of self-presentation and socialization (Thompson and Hirschman 1995). Thus, modern consumers treated their bodies as not an 'end' but a 'means' of conveying a desirable image to others. Furthermore, with the emergence of new technologies, the presence of the body has been questioned. Some argued that these technologies have enabled people to break out of the finitude of their embodiment (Balsamo 2000; Turkle 1995). Others advocated the essential role of embodiment in any human experience (Argyle and Shields 1996; Froy 2003; Hansen 2006).

The growing semiotic potential of virtual worlds through multiplicity of symbols (Venkatesh 1999) allows for visual representation of one's physical self through avatars, which are "graphic icons representing users through various forms" (Chung 2005, p. 538). In this study, we explore the meanings attached to the avatars, and how and what consumers experience through these virtual bodies, in a 3-D virtual world called Second Life (SL).

We conducted netnographic research, which helped us understand the symbolic aspects of body, and develop alternative perspectives to the presence of the body in virtual worlds. Our preliminary data consist of our experiences as SL residents, and online/offline interviews with eight informants, all of which were in-depth and semistructured.

Findings derived from the meanings attributed to avatars reveal that preoccupation with the body is an essential part of virtual lives. The (re)construction of symbolic corporeal selves reflects the transforming urge of a modern consumer from perceiving his/her body as less of a tool for communication with and impression to others to an experience itself, an end that s/he playfully engages in for its own sake. The body itself becomes the experience in SL, rather than solely being a communication or impression management medium as it is perceived in first life (FL). Whereas FL is limited in the bodily creations; SL provides consumers the freedom to (re)construct their desired bodily creations and experiences.

Yet, the construction of body and the experiences lived through it in this symbolic realm are affected by consumers' FL selves and vice versa. In SL, consumers engage in experiences they can(not) immerse into in FL (e.g., flying, skydiving), and experiences they symbolically (e.g., death, suicide) and literally immerse into (e.g., having the sense of blood rush while the avatar is falling down). They gain the ability to engage in bodily experiences that they couldn't engage with their FL bodies because of physical or psychological constraints. Nevertheless, consumers build higher levels of empathy with their avatars, which strengthens the feeling aspect of experiences. Thus, SL experiences are not purely separated from those of FL and vice versa. FL selves are reflected on SL selves and vice versa during avatar (re)creation. In continuous (re)construction of bodily experiences, the paradoxes of *segregation* (e.g. SL gives the opportunity to do things one can't do in FL, and help mask FL appearances through avatars making socializing easier than FL) and *inseparableness* (incorporation of SL in FL or vice versa), and *possible* and *proper* are further intensified. SL consumers reflect their FL selves on SL selves and vice versa (e.g., keeping social distance in SL just like in FL; making avatars look like their FL selves and reflecting their SL selves on their FL selves, gaining skills through SL and reflecting that self-esteem gained in SL on FL experiences).

In SL, self-presentation is enhanced by immersion into SL experiences involving symbolic (re)construction and experience of several bodily selves. *Symbodiment*, a process in which consumers (re)construct and playfully engage in the symbolic creation and experiencing of their avatars, replaces the concept of disembodiment. Consumers reconcile their urge for physicality with the non-physicality of cyberspace in symbolic forms. They are devoid of bodily constraints, and are embedded in the scheme of symbolic forms (Venkatesh 1999). A person can become a mermaid and all of a sudden, grows a tail and experiences the transition into a leopard. A half-human cyborg changes his deep voice into a soft female voice while reading poems in SL. The body is experienced for the sake of itself rather than solely being used as a medium of self-presentation. "The boundaries delineated by cultural constructions of the body are both subverted and given free rein in virtual environments. With the body freed from the physical, it completely enters the realm of the symbol" (Reid-Steere 1996, p. 36). Hence, the continuous (re)construction of body through avatars becomes a symbolic experience, in which the body is present, not with its constraints but with its symbolic significance.

Reproducing and Subverting the Global Hierarchy: Revisiting Advertising in a Postcolonial Setting

Rohit Varman, Indian Institute of Management-Calcutta., India

Both consumers and marketers draw upon extant sociocultural discourses to give meaning to the products they consume or sell (Belk 1988; Costa 1998; Thompson and Haytko 1997; Zukin and Maguire 2005). Advertising is an important tool employed by marketers to draw upon the culturally constituted world to establish symbolic equivalence with dominant sociocultural discourses (McCracken 1988; Sahlins 1976). Several studies in the past have drawn upon the post-colonial framework (Bhabha 1994; Breckenridge and Van der Veer 1993; Chakrabarty 1992; Guha 1998) and have highlighted the role of orientalism in advertising (Cayla and Koops-Elson 2006; Mazarella 2003; Rajagopal 2001). My research adds to this body of knowledge by offering an understanding of the manner by which advertising draws upon extant sociocultural discourses of 'self' and 'other' to give meaning to products.

In order to understand the socio-cultural codes embedded in Indian advertising, I conducted content analysis of print and television advertising. This helped me to understand the representations and discursive practices of some of the advertising firms. My data base comprised of around 500 advertisements, which were collected over a period of one year. In order to understand the process of creation of advertisements and deployment of extant sociocultural codes, I conducted indepth interviews with executives working in the Creative area in advertising firms. I conducted these interviews with 13 Creative Executives working in the domains of copywriting and art direction from three large advertising firms in India. My sampling was purposeful and involved interviews with junior and senior creative personnel from Indian and Multinational advertising firms. This also helped me to achieve triangulation that is necessary for the trustworthiness of data.

In uncovering the creative process through which 'auto-orientalism' (Mazarella 2003; Said 1978) is employed, I argue that extant theorization based on the post-colonial framework has overemphasized the 'orientalist' discourse and has failed to comprehend two other significant features embedded in Indian advertising texts. First, building on Foucault's (1978) conceptualization of representation and power, I show that a subversive discourse of 'occidentalism' is an important part of comprehending the relationship between advertising and otherness in India. In this discourse of 'occidentalism', the west is interpreted as profane, impure, and perfidious. My dialectical interpretation of self-orientalism and occidentalism helps in overcoming the passivity imparted to a post-colonial society. The reinforcement and subversion of the local-global/East-West hierarchy in Indian advertising contribute to a richer understanding of cultural processes in a post-colonial setting that have been elided in extant interpretation. Second, my research shows that Indian advertising cannot be sufficiently situated within the post-colonial framework. Here, I argue that the privilege imparted to the colonial encounter in the post-colonial framework ignores the cultural elements that have emerged from other possible historical processes (Ahmad 1992). In particular, I highlight the role of social class in Indian advertising that has emerged from the society's experience of capitalism. I show that the class hierarchy is reinforced through representations that emerge from advertisers who belong to the social and economic elite of the society. I draw upon Bourdieu's (1984) conceptualization of *habitus* to analyze the role of creative personnel in the production of these class-based representations. Finally, I apply a critical perspective to advertising and understand its functioning as part of the culture industry (Horkheimer and Adorno 1944/1998; Jhally 1987). I critique this ideological role and see it as a ramification of, and further catalyst to, hegemony, globalization, and the maintenance and exploitation of cultural difference and hierarchy.

The Consumer Who Knew Too Much: Online Movie Piracy By Young Adults

Iris Vermeir, University College Ghent & Ghent University, Belgium

Online movie piracy or the unauthorized, unpaid downloading of movies from the internet, is beginning to grow as internet connections become faster. Moreover, the anonymity of internet lowers the perception of illegality of unethical behavior, clearing the road for online unethical behavior (Freestone and Mitchell 2004). Research has demonstrated that consumers do not perceive the movie industry as a victim of movie piracy (especially because of the high prices charged at the box office) and hence, do not perceive the unethicalness of movie piracy (Freestone and Mitchell 2004). Consequently, all over the world, anti-movie piracy campaigns are developed to communicate that movie piracy is wrong. It is assumed that communicating the unethicalness of this illegal activity will decrease actual piracy behavior. However, ethical research shows that consumers engage in illegal behaviors, even though they perceive them as unethical (Sinha and Mandel 2008; Easley 2005). A lot of social psychological and consumer research has already shown that the link between attitudes or beliefs and behavior most often is not that straightforward and depends on several attitudinal, contextual, and personal variables that moderate this relation (for a meta-analysis see Glasman and Albarracin 2006; Kraus 1995).

The purpose of this study is to look at some of the variables that could explain why consumers engage in movie piracy behavior even though they find it unethical. More specifically, action related knowledge, price perception and perceived effort for the legal alternative were investigated.

Because stronger attitudes, lead to more consistent behaviors (e.g. Fabrigar et al. 2006), we can expect that higher perceptions of unethicalness will lead to less movie piracy. Obviously, limited knowledge of how to pirate a movie, will also lead to less movie piracy, even though movie piracy is perceived as an ethical alternative. Action related knowledge is a necessary condition for behavior (Frey et al. 2006). Fabrigar et al. (2006) already found that subjects who possess less relevant knowledge display less attitude-consistent behavior. The question remains however, if consumers who possess action related knowledge will engage in movie piracy despite unethical perceptions of movie piracy. Action related knowledge could explain why so many consumers engage in movie piracy, even though they know it is unethical.

Furthermore, we argue that consumers, who perceive the legal alternative as too expensive, will engage in movie piracy even though they consider this an unethical activity. High price perception decreases intentions to engage in an activity (Chiang and Dholakia 2003). Consequently, consumers could feel they are allowed to engage in an unethical activity because they have a good excuse: the legal alternative is too expensive. Consumers can diminish perceived guilt for inappropriate behavior by using neutralization techniques like condemning the condemners (e.g. the corporation deserves the mistreatment because he previously engaged in some form of misbehavior—i.e. charging too much) (Strutton et al. 1994).

Finally, high perceived effort for the legal alternative will lead to less consistent behavior. In other words, subjects who perceive movie piracy as unethical could engage in movie piracy if they perceive effort necessary for the legal alternative is too high. If a subject is not willing to spend time and energy for the legal alternative (e.g. going to the movie theatre), positive attitudes will not lead to behavior (Dik and Aarts, 2007).

In order to test our hypotheses, a total of 490 young adults between 18 and 22 years old completed an online questionnaire. Participants were asked six attitudinal questions on their attitude towards movie piracy on a 7-point Likert scale ($\alpha=.85$). Furthermore, ethical perceptions of movie piracy were measured using 4 items (ethical, appropriate, permitted, proper) ($\alpha=.89$). Next, young adults indicate their action related knowledge (cfr. Roehm and Sternthal 2001), price perceptions and willingness to engage in effort for legal alternatives (cfr. Voss et al. 1998) on 7-point Likert scales. Finally, young adults were asked to indicate how much movie piracy they engage in (cfr. Cronin et al. 2000).

Significant main effects were found for ethical perception ($F(1,458)=33,26, p<.01$), knowledge ($F(1,458)=510,301, p<.01$), price perception ($F(1,458)=2,87, p<.1$) and willingness to engage in effort for a legal alternative ($F(1,458)=10,58, p<.01$). Young adults especially engaged in movie piracy when they perceive this activity as ethical, knew how to perform this behavior, and when price perception and perceived effort for legal alternatives was high. Significant interaction effects were found between ethical perception and knowledge ($F(1,458)=8,33, p<.01$) and ethical perception and price perception ($F(1,458)=5,76, p<.05$). Ethical perception determined behavior when behavioral knowledge was low: young adults, who did not really know how to pirate movies, engaged more in movie piracy when they perceived it as an ethical (versus unethical) activity. However, for knowledgeable young adults, ethical perception did not matter: they engaged in illegal movie piracy, regardless of their ethical perceptions. Furthermore, price perceptions of legal alternatives did not influence behavior differently for young adults who find movie piracy unethical. These 'ethical' young adults did not pirate movies a lot even if they perceived the legal alternatives as too expensive. On the contrary, 'unethical' consumers who find movie piracy ethical will engage more in movie piracy if they perceive legal alternatives as too expensive. We did not find an interaction effect between perceived effort and ethical perception. Young adults will engage more in movie piracy when they perceive the effort for the legal alternative as too high, regardless of their ethical perceptions. Possibly, perceived effort is rated relatively low in general ($M=3,88, SD=1,09$) to make young adults use this as an 'neutralization' to engage in unethical behavior.

Our results show that knowledge, price perception and willingness to perform effort influence movie piracy. Interestingly, it seems like young adults will engage in an illegal activity like movie piracy, despite their perceptions of unethicalness of movie piracy, if they know how to do it but not if they perceive legal alternatives as too expensive.

Team Purchase: Consumer Empowerment through Collective Actions

Jeff Wang, City University of Hong Kong, China

Xin Zhao, University of Hawaii, USA

Literature on consumer culture theory has illuminated the re-enchantment of consumption (Arnould and Thompson 2005; Firat and Venkatesh 1995). In contrast, the acquisition phase of purchasing is largely viewed as an individual decision-making process or an act framed by family traditions (Epp and Price 2008; Wallendorf and Arnould 1991). In this paper, we examine the phenomenon of team purchase as a collective act that is initiated and organized by groups of consumers in urban China (Arredy 2006). Through this ethnographic inquiry, we show how Chinese consumers have challenged the conventional market system and manipulated it to their own ends without necessarily aiming to escape the market as their counterparts in Western societies (see Kozinets 2002).

Team purchase is a consumer-organized collective activity gaining momentum just recently in urban China (Arredy 2006). It starts on the Internet, usually in chat rooms and discussion forums, where like-minded consumers devise plans to buy branded consumer products in large quantity at lower price. They then show up en masse at stores to demand discounts and more benefits. They usually defeat the merchants with their collective haggling. In addition to obtaining better pricing, they gain a sense of power and pride.

Team buyers unite to confront merchants. They defy the conventional retailer-buyer structure and demand concessions. By functioning as a team, they acquire negotiating power. The larger the team, the greater the discount they demand, knowing that sellers can make up their profits on larger volume. Instead of engaging in one-on-one negotiations, buyers collectively pressure the seller. The seller becomes an inferior in this face-to-face negotiation and often bends to consumers' demands. In other cases, consumers depend on the organizers—usually the Internet initiators—to reach deals with merchants. They save time and effort and rely on the savvy and pugnacity of other buyers to make deals for them. The team leaders are responsible for contacting the seller, negotiating the deals, and organizing other buyers to participate in the transaction. They may even take reasonability post-purchase if fellow buyers encounter problems with the products. In return, team leaders may receive a greater discount or a gift from the seller.

Team purchase is increasingly popular in China where multiple websites service consumers nationwide and numerous discussion forums facilitate discussions among interested people locally. With domestic market becoming increasingly complex, Chinese consumers have become more knowledgeable and self-protective than ever before. They have realized that individual effort is less effective than collective actions in the marketplace. Chinese consumers now apply the popular political ideology "solidarity is strength" and form groups to confront merchants. Collective acts are especially beneficial because consumer rights have yet to be effectively protected. When laws and regulations lack adequate enforcement, consumers use collective power to demand benefits and protection. The Internet serves as an important tool to organize people with similar concerns and interests. Consumers create alliances and act in unison against more dominant powers in the marketplace.

As an explorative study, we conducted depth-interviews with team buyers and merchants in four Chinese metropolises of Beijing, Shanghai, Guangzhou, and Shenzhen from June to August 2007. Our interviews started with grand tour questions that were followed by probing questions for meanings and experiences of team purchase (McCracken 1988). The interviews lasted from thirty minutes to one hour. They were conducted in Chinese and then transcribed and analyzed. We plan to participate in team purchases and collect more ethnographic data this summer. Through an iterative process (Arnould and Wallendorf 1994; Spiggle 1994), initial analysis has generated rich insights about the phenomenon. We have found that there exist distinctive differences between team purchase and other kinds of purchases such as Internet purchase, direct sale or wholesale. Participants employ a wide variety of strategies to ease transactions and reduce risks. Trust between buyers and merchants as well as between buyers and organizers emerges as an important issue. Organizer plays multiple roles as a negotiator, expert (or Prosumer, see Cova, Kozinets, and Shankar 2007), buyer, and a distributor. Interestingly, some buyers maintain their ties with team members by engaging in more team purchases and organizing activities afterward. For them, group purchases initiate consumption communities not necessarily based on brand (McAlexander, Schouten, and Koenig 2002; Muniz and O'Guinn 2001).

Although it has been recognized that consumers produce, acquire, and consume in form of communities (Belk and Costa 1998; Muniz and O'Guinn 2001; Schouten and McAlexander 1995) and that they protest against commercialization by engaging in consumer activism (Kozinets 2002; Kozinets and Handelman 2004), it is unclear how consumers collectively make purchase decisions and how they formulate a transient group to challenge the established orders in the marketplace. By studying team purchase, we explore the dynamics between consumers and merchants and examine how consumers collectively co-opt market offerings (Thompson and Coskuner-Balli 2007). We show the benefits, risks, rules and rituals of team purchase as compared to individual purchase. This research will also shed light on the discussions of strategies for consumer empowerment.

The Impact of Source and Item Characteristics on Consumer Responses to Flattery in Retail Sales Transactions

Sutapa Aditya, York University, Canada

Kelley Main, University of Manitoba, Canada

Darren Dahl, University of British Columbia, Canada

Consumer behavior research over the last 25 years has significantly informed us about persuasive communications in the context of interpersonal interactions in the marketplace (Friestad & Wright 1994; Campbell & Kirmani 2000; Main, Dahl & Darke 2007). Flattery is a common method of interpersonal influence applied by agents in the marketplace. Although research on flattery in marketing has primarily focused on its negative influence (Main et al. 2007), studies conducted in other disciplines such as psychology and organizational behavior provide evidence of a positive influence of flattery (e.g., Cialdini, 2000; Watt, 1993; Wayne & Ferris 1990). The purpose of the present research was to search for similar positive evidence of flattery in the marketplace context and identify the boundary conditions of such an outcome.

We focus on two potential conditions under which flattery may have a positive influence on consumers. The first factor is the target item of flattery. To date, the literature has primarily looked at flattery on a store item that consumers try on (e.g. Campbell & Kirmani 2000). We are interested in learning if there is any difference in trustworthiness when the salesperson flatters the consumer on an item he/she wears to the store. Literature on mere ownership suggests that an object is evaluated more positively by individuals when it is owned by them vs. not (Beggan 1992) since possessions are considered as one's extended self (Belk 1988). Evaluation of one's own possessions is therefore linked to one's self perception and feeling of self enhancement (Beggan 1992). However, the literature has yet to explore the impact of a salesperson's flattery on a possession. It may be possible that when a consumer is flattered on an item she/he owns, it enhances his/her self-perceptions and creates a positive feeling towards the interaction experience as well as the flatterer.

The second factor proposed in the current study is the attractiveness of the source. Prior work demonstrated that messages from an attractive source are considered significantly more persuasive as compared to messages from an unattractive source (e.g. Baker & Churchill 1977) and can increase product evaluations of a contaminated product (Argo, Dahl & Morales 2008). In addition, attractiveness creates a halo effect, in which attractive people are considered to have many other socially desirable personality characteristics. Therefore, the source becomes more persuasive in the perceiver's eyes. We predict that flattery will lead to higher satisfaction with the interaction experience when the salesperson is attractive vs. unattractive. Moreover, this will be strengthened when a highly attractive salesperson compliments on an item owned by the consumer, as opposed to an item from the store.

A total of 50 participants (19 male and 31 female) from a large eastern university took part in a field study and received payment for their participation. A 2 (product: own vs. store) X 2 (attractiveness: high vs. average) between subjects experimental design was conducted. The product was a manipulated variable and attractiveness was a measured variable. The primary dependent measures included

participant's satisfaction with the shopping experience, trust in the salesperson, and intentions to revisit the store. The cover story informed participants about a mystery shopping study on different stores on campus. The experimenter pretended to randomly choose a store from all stores on campus. In actuality, all respondents were sent to the same store and asked to try on a store item that appealed to them before returning to the experimenter to complete a questionnaire. The salesclerk in the store was a confederate who implemented the flattery manipulation either on the store or the own item.

Regression analysis revealed that the salesclerk's attractiveness had a significant main effect on participant's satisfaction with the shopping experience ($b=0.215$, $t=3.559$, $p<0.05$) and trustworthiness of the salesperson ($b=0.19$, $t=3.052$, $p<0.01$) which was qualified by a significant interaction of attractiveness and item on satisfaction ($b=0.28$, $t=2.346$, $p<0.05$) and salesperson trustworthiness ($b=0.369$, $t=3.134$, $p<0.01$). Simple slope analysis of the significant interaction effects revealed that when the clerk was less than average in attractiveness (1 standard deviation below the mean level of attractiveness), flattery on an item owned by the participant, as opposed to a store item, significantly reduced their satisfaction ($b=-1.124$, $t=-2.44$, $p<0.05$). However, when the salesclerk was above average in attractiveness, flattery did not lead to a significant difference in satisfaction level when the target of flattery was owned by the subject vs. a store item ($b=0.401$, $t=0.91$, $p>0.05$). For trustworthiness, a less than average in attractiveness salesclerk was perceived as less trustworthy when flattery occurred on participants' own item ($b=-1.004$, $t=-2.209$, $p<0.05$). Participants reported significantly higher trustworthiness in the clerk who was above average in attractiveness when consumers were flattered on their own item as opposed to a store item ($b=1.005$, $t=2.313$, $p<0.05$). Findings also suggested a significant interaction effect of clerk attractiveness and item on participants' intention to revisit the store ($b=0.742$, $t=4.19$, $p<0.001$) that demonstrated the same pattern as the above findings ($b=-2.331$, $t=-3.49$, $p<0.01$; $b=1.712$, $t=2.616$, $p<0.05$).

In summary, this research supports our prediction that attractiveness of the source and the target item of flattery are two possible conditions that may result in a positive outcome of flattery. As predicted, flattery led to higher satisfaction, trustworthiness and intentions to revisit the store when the persuasive agent was highly attractive (vs. less attractive) and the target item is owned by the consumer (vs. a store item). Therefore, the present study contributes to the extant literature on persuasion knowledge by providing some of the first evidence of positive outcome of flattery in the marketplace context.

Exploring the Relationship between Brand Personality and Geographic Personality: Consumer Perceptions of Sport Teams and Cities

K. Damon Aiken, Eastern Washington University, USA
Richard M. Campbell, Sonoma State University, USA

While a good deal of previous research has investigated the strategic implications of branding and related consumer-processing intricacies, researchers have yet to test the effects of geographic associations within brand names. That is, researchers have not yet empirically examined the notion of a marketer leveraging the image of a geographic region in relation to a specific brand name—thereby creating and shaping unique brand associations in the minds of consumers.

The differential affects of geographic associations to brand names has been labeled "geographic equity" (Aiken, Koch, and Madrigal, 2000). The concept of geographic equity is thought to depend upon (1) geographic personality and related image associations of a region, as well as (2) geographic awareness and memory. In essence, geographic personality is much like human personality as cities, regions, countries—geographic locales in general—project observable and measurable personality traits. Geographic awareness and memory are important factors in eliciting cogent images in the minds of consumers. Kotler, Haider, and Rein (1993) utilize a notion of collective memory when they define place image as "the sum of beliefs, ideas, and impressions that people have of a place" (p. 141). Not only is this image a mental picture held in common by a group, but it is also used as a familiar way of communicating about a city.

Our central research question focuses on the relationship between brand personality (Aaker, 1997) and geographic personality. Do professional sports teams (*as brands*, held within the set of brands in a league) have brand personalities that take on some of the associative traits of the geographic locales in which they play? For example, are the NY Giants perceived as exciting partly because they are located in “the city that never sleeps?” Are the Steelers viewed as tough and hard-working because they play in the blue-collar, working-class town of Pittsburgh? Similarly, across leagues, are the Los Angeles Lakers thought of as glamorous and sophisticated because they are so relatable to the glitz of Hollywood? The answers to these questions would seem to have direct implications for corporate communication decisions for both sports marketing and tourism marketing.

The scope of our research question necessitated four versions of a four-part survey. Our desire was to test the brand personality characteristics of the ten most recent Super bowl teams (and cities). Data were collected from a total of 382 university students in five different locations (Indianapolis, Chicago, Seattle, Oakland, and Charlotte). This design allowed for the testing of “self-other congruence” (Funder and Colvin, 1997) with respect to those with direct city experience and those without such experience. Subjects in the test locations should take an insider’s view with regards to their cities/teams. They were asked about their home cities/teams as well as two others (inclusive of those just mentioned as well as New York, Boston, Pittsburgh, Tampa Bay, and Philadelphia).

In general, fans do ascribe personality traits to both teams and cities. Moreover, measurements of the two constructs tend to correlate. Correlation coefficients ranged from .189 (the Ruggedness of Charlotte and the Ruggedness of the *Panthers*) to .623 (the competence of Pittsburgh and the competence of the *Steelers*). Interestingly, cities whose teams had recently participated in the playoffs were seen as more exciting (as were their teams). With regards to self-other congruence, perceptions between the insiders (with city experience) and the outsiders (without city experience) were quite different. In almost every case and across all five dimensions, city insiders consistently displayed lower ratings of the trait characteristics.

So, fans as consumers of sport likely tend to use geographic personality as a guide in formulating associative team/brand images. However, we should note that each of the five dimensions has a positive connotation. That is, people would probably like to think of their teams and their cities as sincere, exciting, competent, sophisticated, and rugged. Perhaps then, it should come as some surprise that city insiders relayed a downgraded view of their city’s/team’s personalities compared to outsiders. Alternatively, perhaps the insider’s viewpoint is simply more realistic, while the outsider’s viewpoint has been romanticized by various media. Regardless, we found no evidence of self-other congruence from this perspective.

In the future, given that personality evaluations seem to fluctuate according to win-loss records, it would be interesting to find out if fans go through a form of brand personality updating (Johar, Sengupta, and Aaker, 2005) from season to season. Perhaps, brand personality characteristics are not as resistant to change as widely believed, especially within the seasonal context of professional sports.

Finally, this research points to a number of other questions. In terms of the direction of the relationship for example, since the Chicago Bears are viewed as a tough, rugged, and mostly unsophisticated team, does this contribute to our views of the city of Chicago? Or, to the contrary, do we see Chicago as the birthplace of violent gangland behavior, the home of chilling lakeshore winds, and a place where only truly tough and rugged people could live; and consequently these opinions of the city shape our brand-image associations for the Bears? Moreover, how can we resolve brand image differences *within* the same city and *across* sports? Continuing with our Chicago example: Do the White Sox have a similar brand image as the Cubs? Or, looking across sports, do the Bears have a similar brand image as the Cubs? Thus, it appears that there are a great number of analytical intricacies yet to be explored.

Appraisal Theory of Emotions and Advertising Rhetoric: A Model of Consumer Reactions

Pia A. Albinsson, New Mexico State University, USA

Theories in consumer psychology on emotions used in advertising research have predominantly concentrated on two dimensions: valence and arousal. Measures of valence and arousal are used, respectively, to evaluate the degree of positive and negative feelings towards an ad and a person’s physiological level of excitement following exposure. The valence-arousal theory has been criticized for not measuring emotions that have distinct characteristics, but belong to the same valence (Lerner and Keltner 2000). For example, the difference between fear and anger or hope and happiness are hard to differentiate with the valence measures. In addition, these measures fail to specify whether emotions of the same valence differ in influencing consumer decision making and persuasion. Appraisal theory of emotion provides more emotional dimensions compared to the valence-arousal dichotomy and offers more detailed understanding of the antecedents and consequences of each emotion (Reisenzein and Hofmann 1993). Current research on emotion has found that emotions of the same valence differ in their antecedent appraisals (Smith and Ellsworth 1985; Roseman 2001). Appraisals also center on the individual consumers’ assessment of his current situation with respect to well-being (Ruth, Brunel and Otnes 2002). In recent years, appraisal theories of emotions have been used by marketers to examine consumers’ response to different health preventive advertising

campaigns (Block and Keller 1998; Eppright, Tanner and Hunt 1994; Eppright et al. 2002; Tanner, Day and Crask 1989; Tanner, Hunt and Eppright 1991).

Another research stream that has shown to increase processing outcomes, such as persuasion, is advertising rhetoric. This relatively new area of research includes verbal and visual rhetorical works. Ads utilizing rhetorical works have been shown repeatedly to enhance ad processing and brand attitude goals (e.g., McQuarrie and Mick 2003; Mothersbaugh, Huhmann and Franke 2002; Tom and Eves 1999; Toncar and Munch 2001). Research on advertising rhetoric has, to date, been concerned with only cognitive aspects; the interface with emotional appeals or appraisal theory has not yet been explored. By studying both advertising rhetoric and the appraisals of emotional appeals, interaction effects can be explored to find the most efficient combination to induce systematic emotional influences on persuasion.

The purpose of this paper is to use existing knowledge of appraisal theory of emotion and combine this with recent research findings on advertising rhetoric to develop a more encompassing model of appraisal theory, namely the Emotional Appraisal and Reactions Model (EARM), which builds on appraisal theory (e.g., Lazarus 1968; Rogers 1975) and extends the ordered protection motivation model (Tanner et al. 1991) and the appraisal tendency framework (ATF) (Lerner, Han and Keltner 2007).

The EARM includes seven parts: (1) Information sources, (2) Relevance Appraisal and Ad Stimuli Appraisal, (3) Felt Emotion(s), (4) Secondary Appraisal, (5), Revised Felt Emotion(s), (6), Reaction(s), and (7) Personal and Social Norms and Values. The information sources in the EARM differ from previous coping models in that it includes positive and negative emotional appeals in addition to the more commonly examined fear appeal. It also includes advertising rhetoric (e.g., rhetorical works) in addition to ad characteristics, brand information and environmental benefits or threats. Since appraisal theory of emotion stresses that the individual consumer appraises each event based on his current situation, in regards to his well-being, several moderators are accounted for in the model. As in former appraisal models consumers go through an initial appraisal phase. The EARM divides this initial appraisal into two parts where the consumers appraise the information sources for overall relevancy and congruency of their desired state of well-being in addition to responses to the ad stimuli itself. The consumers, then in turn, appraise their own ability to handle the specific information based on their specific coping mechanisms. The last part of the model, reactions, includes both behavioral intentions and actual behavior in response to the ad stimuli.

The EARM is tested through an experiment which manipulates the presence and type of emotional appeal (i.e. hope, fear, and neutral) and verbal rhetorical works (i.e. trope, scheme, and nonfigurative) in a public service announcement (PSA) promoting a website endorsing a healthy lifestyle. Besides the emotional appeals and the verbal rhetorical works manipulated in the headlines and sub headlines all other elements of the target communication is held constant across conditions. In addition, several mediating and moderating variables were tested. Study 1 measured several dependent variables (depth of processing, memory and persuasion (behavioral intentions) while Study 2 measured only persuasion (actual behavior of visiting the advertised website) through a follow-up survey administered seven days later to the same participants as in Study 1. Results generally support the hypotheses that the dependent variables of depth of processing, memory and persuasion are increased when combining emotional appeals with advertising rhetoric in print advertising.

This research has useful implications for researchers, practitioners and consumers since it extends previous research streams in consumer research. The EARM contributes to researchers' understanding of how emotional appeals indirectly influence consumer reactions to ad stimuli, as well as assist practitioners in designing more effective ads and spending their limited ad budgets more efficiently. Future research needs to explore different combinations of advertising rhetoric and emotions to find the combination that is most effective in inducing desired preventive health behavior.

The Effect of Document Language Quality on Consumer Perceptions

Arancha Pedraz-Delhaes, Leger Marketing, Canada

Muhammad Aljukhadar, HEC Montreal, Canada

Sylvain Senecal, HEC Montreal, Canada

Abstract

The authors propose a model that describes how the quality of language in documents accompanying the product shapes consumer perceptions. Language quality impacts perceptions by determining document evaluation. Document evaluation fully mediated the relations between language quality and both product and organization evaluations, implying that documents accompanying the product are a vital extrinsic cue used by consumers to evaluate the product and the organization. For their part, product and organization evaluations formed consumer behavioral intentions. Findings also show comprehensibility to be affected by language quality, and support the notion that documents accompanying product are secondary products as document evaluation directly influenced intentions.

Empirical work on language quality is scant. As the majority of documents accompanying the product (hereafter, "documents" or "instruction guides") are initially written in English (TCEurope, 2005), and as studies of document quality have been mainly conducted by researchers in English-speaking milieus (where the quality of language in documents does not suffer from translation issues), little attention has been given to the role played by language quality. Simultaneously, literature delineates the importance of extrinsic cues in shaping consumer perceptions. In this work, we hypothesized that language quality will determine both document perceived quality and document evaluation or affection. We also hypothesized that documents accompanying the product are important extrinsic cues used by consumer to infer product quality. Similarly, based upon attribution theory, we postulated that document evaluation will shape consumer perceptions of the product's manufacturer and that product and organization evaluations will determine behavioral intentions.

The independent variable in our model and experiment was the language quality of the document, which is defined as the text's conformity to established linguistic conventions of the targeted audience. As the research was conducted in a French-speaking North American city, focus groups and the experiment were performed in French. Two focus groups indicated the soundness of the hypothetical relationships, showing consumers to exhibit low levels of tolerance to inferior language quality in documents and to express various negative responses ranging from deception to intentions of boycotting the manufacturer. In a following laboratory experiment that involved 116 participants drawn from a consumer panel, the independent variable was operationalized by three levels. Version A of the instruction guide had no errors, whereas version B had few spelling and grammatical errors, and version C had additional syntactical and vocabulary errors. The versions were prepared based on real examples from existing guides. The task consisted in assembling a product (chest box) with one randomly assigned version. The manufacturer's identity was concealed from participants. Upon task performance, participants filled out a questionnaire which measured the dependent and potential influencing variables.

Document quality was measured using the document quality scale (Guillemette, 1990). We only included the items pertaining to six of the seven suggested dimensions (systematic arrangement, understandability, credibility, task relevance, demonstrativeness, and fitness). Where oblique rotation suggested the previous dimensions, factor analysis implied two dimensions. The first dimension ($\alpha=0.96$) pertained to the majority of document quality dimensions and hence was used to reflect document quality in general. The second dimension ($\alpha=0.87$) dealt mainly with document understandability and was thus used to examine whether language quality affected perceived comprehensibility.

Document evaluation ($\alpha=0.92$) was measured using the five items of two scales reflecting the satisfaction toward a specific object (Eroglu and Machleit 1990, α reported=0.87; Spreng, MacKenzie, and Olshavsky 1996, α reported=0.94). Because product evaluation was considered by some researchers as cognitive (Smart, Madrigal, and Seawright, 1996) and by others as affective (Doll and Gholamzera, 1987; Eagly and Chaiken, 1993; Torkezadeh and Doll, 1993), we included both elements. Product evaluation was therefore measured using Peracchio and Meyers-Levy's scale (1994, α reported between 0.85 and 0.92) with the exception of one item removed and the addition of three of the four items proposed by Leclerc, Schmitt, and Dubé (1994, α reported>0.92). As expected, these items were found to result in one dimension ($\alpha=0.94$).

Organization evaluation was measured using the only scale found to reflect the general attitude toward company (Goldsmith, Lafferty, and Newell, 2000, α reported=0.94, α obtained=0.97). Intentions were measured using the three items of intention to buy as in Patterson, Johnson, and Spreng (1997, α reported=0.97), the three items of positive recommendation intention of Price and Arnould (1999, α reported=0.95), and the three items of negative recommendation intention adapted from Blodgett, Hill, and Tax (1997, α reported=0.97). The previous items were adapted to each measure the product and organization intentions. One item was used to verify the manipulation.

ANOVA analysis revealed that language quality significantly affected document quality dimensions. The impact of language quality on document perceived comprehensibility was clear and significant for all language quality levels, leading us to conclude that even a few

spelling and grammatical errors reduce comprehensibility. The presence of a marginal main effect of objective written language proficiency ($p=0.075$) implies that comprehensibility was affected more for individuals with better written language skills. The presence of a moderating role of gender ($p=0.057$) indicates that women enjoyed higher comprehensibility than men, although only for version A.

The impact of language quality on general document quality was apparent. Nevertheless, the presence of few grammatical and spelling errors (version B) marginally affect document general quality ($p=0.110$), while when there were more errors concerning the vocabulary and syntactical elements (version C), the difference was pronounced and significant.

Language quality shapes perceptions of the product and organization by influencing document evaluation. The impact of language quality on document evaluation was important and significant for all levels, implying that document evaluation was determined by document language quality, regardless of personal or demographics factors. No main or moderating effects were found for educational level, objective written language proficiency, and importance accorded to language quality on the previous relationship. However, we found a main effect for age ($p=0.030$), implying that older consumers had higher document evaluation for all language quality levels and showed more tolerance to inferior language use. Interestingly, no significant correlation was found between educational level and objective written language skills.

Document evaluation fully mediated the relationships between language quality and both product and organization evaluations, implying that language quality impacts both product and organization evaluations through document evaluation. Product and product category knowledge were not found to influence the relationship between document evaluation and product evaluation, indicating the saliency of language quality on product perceptions. For their part, product evaluation shaped the intentions toward the product, and organization evaluation shaped the intentions toward the organization. Findings support the notion that documents accompanying the product are secondary products (Smart, Madrigal, and Seawright, 1996) as product evaluation partially mediated the relation between document evaluation and product intentions.

I Really Want to Like It: Motivated Liking

Aner Tal, Duke University, USA
Dan Ariely, Duke University, USA

Motivations to like products can alter consumers' evaluations of and choices of products. Studies 1 and 2 demonstrate enhanced liking for music thought to indicate refinement and sophistication in people who like it. Study 3 demonstrates that these effects occur counter to people's expectations, ruling out belief-confirmation and social-desirability as explanations. Study 4 replicates the findings using choices that bear immediate consequences (listening to full songs) and a different motivation: believing oneself to have high emotional-intelligence. Further studies will explore additional motivations and product domains and investigate the process through which consumers learn to like products they are motivated to like.

Why do we like certain products rather than others? The traditional view in consumer choice theory has preferences develop based on processing of intrinsic product attributes (Simonson, in press; Bettman et al., 1998). However, liking can be based on reasons extrinsic

to product attributes. You might, for instance, like something simply because of its “warm glow of familiarity” (Titchner, 1912), as demonstrated through extensive research on mere-exposure (Bornstein, 1989; Zajonc, 1968; 2000). You might like a product due to situational influences and cues (Berger & Fitzsimmons, in-press; Ferraro et al., in-press). Current physiological state, such as hunger or cold, might also influence liking (Cabanac, 1979). Prominently, expectations can also shape liking (Deliza & MacFie, 1996; Hirt, 1990; Lee et al., 2006; Ragnathan et al., 2006).

Motivational bases for evaluation are also prevalent. A broad literature regarding cognitive dissonance indicates that people can come to like items retroactively due to different motivations to justify their decisions and align them with attitudes (Cardozo, 1965; Cohen & Goldberg, 1970; Cummings & Venkatesan, 1976). Famously, Brehm (1955) showed that following choice people bias evaluations to favor their chosen alternative. Further, lack of a possibility to change one’s choice may enhance liking (Gilbert and Ebert, 2002).

Some research outside the dissonance literature has also offered evidence for motivated liking. Berger & Heath (2007) showed effects of social group desirability on liking. Similarly, social motivations’ influence on liking have been demonstrated by Escales and Bettman (2003; 2005), who showed the influence of identification groups on felt connection to brands. In psychology, merely expecting to interact with someone affected liking towards that person (Miller & Marks, 1982).

Dissonance primarily explores post-choice alterations of evaluation. The effects of motivations existing prior to choice and consumption have garnered less attention (though see Riis & McClure, in preparation). In this work, we explore whether motivation to like novel stimuli affected actual post-consumption liking and choice. Further, we seek to establish whether motivations can be artificially implanted by an external source, a possibility with potentially extensive marketing implications.

Study 1: Everybody Likes Opera

The first study aimed to examine whether thinking that liking for music shows one to be a more refined, sophisticated listener enhances liking for such music over alternatives associated with less sophistication.

Methods. Participants ($N=57$) listened to and evaluated two songs. The study was a 2 (song) X 2 (order) X 2 (motivation) within subjects design. The stimuli were international songs chosen following pretests that identified them as having moderate complexity and low familiarity.

After listening to each song, participants read reviews of the songs. Manipulations for motivation to like were embedded within the reviews, such that the songs were touted as either simple or complex, and indicating a person to be of either refinement and sophistication or of simple tastes. The wording was designed to avoid direct implications for enjoyability.

Dependent variables were self-reported enjoyment and desire for more information anchored by 1 (not at all) and 9 (very much) scales, and quality of song rated on a 9 point scale anchored by 1 (very low) and 9 (very high). Cronbach alpha for the three measures was .779, so the measures were averaged as a single DV.

Results. We ran ANOVA analysis controlling for song and order of manipulation, including song X condition interaction (non-significant). Participants reported enhanced impressions of the songs for which liking was ostensibly indicative of higher sophistication: $F(1, 106)=3.89, p=0.05$. LSmeans were 5.9 for low sophistication, and 6.6 for high sophistication.

Discussion. When liking for a song was described as indicating higher sophistication (due to its complexity), participants evaluated the song more highly than when it was described as indicating lower sophistication (due to its simplicity). The effects could potentially be explained by social desirability, as participants might indicate how participants *want to seem* rather than how they truly feel about the songs. Thus, in the next study we added a choice phase where participants could choose between CD collections of the two musical styles for a drawing. Given that such choices could have actual implications for the participants, the choice measure could reasonably be expected to be more indicative of participants’ true liking for the songs.

Study 2: Effects on Choice

Method. The general methodology was similar to that of study 1. After completion of the first part of the study, participants ($N=59$) were asked to choose a compilation of one of the two musical styles for a drawing.

Results and discussion. As before, participants evaluated songs more highly when liking for them was presented as indicating greater sophistication: $F(1, 113)=4.82, p=0.03$, LSmeans 5.8 (low) vs. 6.4 (high). This enhanced evaluation seemed to reflect participants’ genuine feelings about the songs, as it was reflected in CD choices that could have real consequences. Participants were more likely to choose the high-sophistication CD (70%) than the lower sophistication CD (30%): $F(1, 113)=20.84, p<.0001$. Again, note that both choice and evaluation occurred prior to choice, and so could not be explained by post-choice dissonance reduction.

Study 3: Belief Confirmation?

Arguably, being told that a more complicated song indicates greater sophistication would lead people to believe complex songs should and would be liked more, and subsequently lead to expectation fulfillment. The design of the studies reported above reduces the credibility of such an explanation. For one, information regarding the songs’ complexity was presented either before or after each song was played (between-participants). If the process was simply one of expectation-fulfillment, information should have had greater effect if presented before songs. If anything, results indicate the opposite (information presented after each song yielded a greater effects).

We know, however, that beliefs can alter judgment retroactively, after consumption experiences (Braun, 1999). If this type of retroactive belief-confirmation occurred here, beliefs in a song’s complexity indicating sophistication would lead people to expect they would like complex songs more than simple songs. If people do not think they would like such songs better, the process whereby the previous effects were obtained cannot, by definition, be one of simple belief-confirmation

To test this notion, we presented participants in the third study ($N=32$) with an account of the relation between liking for complex songs and sophistication similar to studies 1-2. However, instead of listening to the songs, participants just rated how much they expected to enjoy simple (condition 1) or complex (condition 2) songs. Participants assigned to the complex-song rating condition expected to enjoy songs less (3.73) than participants assigned to the low-complexity condition (4.58): $t(1, 50)=2.14, p=.04$. Thus, it appears that the process

whereby consumers come to like that which they are motivated to like is not simply one of belief confirmation. Consumers' expectations for liking are in fact the reverse of their actual reported liking given a chance to listen to songs.

Study 4: The Bach Effect

Method. The current study employed a different motivation in order to generalize our results. Specifically, we told participants that liking for some music styles is diagnostic of emotional-intelligence. Under the guise of familiarizing them with the idea, participants heard three 30-second song samples in each of three styles. After listening to each sample, participants were told about its associated level of emotional-intelligence (high, low, or non-indicative). As an incentive-aligned dependent variable, participants ($N=59$) were asked to choose three songs to listen to. They could choose the full songs from which they'd heard clips, songs of the same styles, or unrelated control songs.

Results. Participants ($N=45$) chose more songs from styles presented as diagnostic of high emotional-intelligence (1.4) than from those presented as non-diagnostic (.77) or diagnostic of low emotional-intelligence (.84). The overall effect controlling for country and interaction (non-significant) was highly significant: $F(2, 126)=8.29$, $p=.0004$ contrast between low and medium to high.

Limitations and Further Studies

The studies reported here provided some evidence for the influence of different motivations on product evaluation and choice. Further studies will explore additional motivations and explore the process through which consumers learn to like what they want to like. Suggested mechanisms include differential encoding during consumption, post-choice editing of memories, and motivationally-biased construction of evaluation. Notably, motivations to like could be so powerful that they override the robust expectation fulfillment processes known in current research.

The Impact of Accent Stereotypes on Service Outcomes and Its Boundary Conditions

Ze Wang, University of Kansas, USA
 Aaron Arndt, Old Dominion University, USA
 Surendra Singh, University of Kansas, USA
 Monica Biernat, University of Kansas, USA

“When we listened back to calls people had complained about often they were fine. Some people wanted the member of staff to fail because they were in India. I don’t know why that should be, but when customers start voting with their feet, you have to respond.”

—Adrian Web (Call Center Manager, BBC news, 2/14/2007)

The accent of service providers may positively or negatively bias customer perception of service quality—especially in service contexts where visual cues are absent (e.g., call centers). In this research, we explore the effects of accent stereotypes in a variety of call center situations. With two laboratory experiments, we demonstrate that even with identical service outcomes, customers’ perception and interpretation of their service experience changed as a function of customer service employee accent (i.e., British, Indian and American). However, biases caused by accent stereotyping decrease when relevant objective information is available (i.e., the industrial norm).

Sociolinguistics literature (Lippi-Green 1994, Giles and Powesland 1975) suggests that accent is an important indicator of one’s ethnicity, regional affiliation and social class. Even though accents may be subtle, individuals are still able to perceive and distinguish among different accents (Cargile 2000; Giles, Williams, Mackie and Rosselli 1995). People attribute positive traits to certain types of accents based on the prestige of the class or group that possess it (e.g., sophistication and politeness associated with British accent) (Ladegaard 1998). In contrast, people also discriminate against the speakers with foreign accents (e.g., African-American, Indian, and Mexican-American) which may “link to skin that isn’t white, or signal a third-party homeland” (Lippi-Green, 1997, p.239). People’s general tendency to evaluate individuals’ performance more harshly than others upon accent has been a persistent finding in extant literature (Baugh 2000; Purkiss et al. 2000).

We extend these theories by examining accent stereotyping effect in the service context and testing its influence on customer satisfaction and customer evaluation of employee performance. Additionally, based on previous literature on stereotypical influence on causal attributions (Hewstone 1990; Jackson, Sullivan and Hodge 1993), individuals tend to attribute stereotype-consistent behavior to internal stable causes and stereotype-inconsistent behavior to external unstable causes. We hypothesize that American customers are more likely to attribute favorable service to individual employee factors and attribute unfavorable service to external firm factors when an employee has an American or British accent. However, the attributions are reversed for employees with an Indian accent.

The impacts of accent stereotype on service outcomes depend on the informational context during the service. Research on stereotyping effect (Kunda and Thagard 1996) suggest that stereotyping is most likely to occur if customers do not have background information or other objective cues to make their judgment. Thus we hypothesize that the influence of employees’ accent on customers’ perception and evaluation of the service encounter should disappear, or at least decrease, if customers are informed of industrial norms.

We conducted two empirical studies to test our hypotheses. The first study was designed to test the hypotheses that the accent stereotypes will bias customers’ perception and evaluation of their service experience. Participants were asked to listen to taped phone calls between a customer and a bank employee from the perspective of the customer. Consistent with our hypotheses, we found that accent stereotypes influence both customer evaluation of employee performance and customer satisfaction. Even though service scenarios and conversation scripts were identical, customers rated the performance of employees with Indian accents much lower than the performance of employees with American and British accents. The influence of accent stereotyping on customer satisfaction was moderated by the service outcome. When the service outcome was favorable, the British accent was rated more positively than the American accent but, contrary to our hypothesis, the Indian accent was not rated more negatively than the American accent. However, when the service outcome was unfavorable, customer satisfaction in the Indian-accent condition was significantly lower than it was in American or British accent condition.

The second study examined the moderating effects of information availability. We tested whether accent stereotypical effects would decrease with the presence of other judgmental cues. In the high information condition, customers were informed of the industrial norms about the specific type of service; whereas in the low information condition, customers were not provided with any background information. As predicted, accent stereotypical effects on customer satisfaction were no longer significant after customers had more information to make judgment. However, the negative bias against the Indian accent was so strong that even when customers were informed of industrial norms, they still rated Indian-employee’s performance as the lowest. Another noteworthy finding from this experiment was the difference in customer causal attribution across conditions. We measured customers’ attributions by coding open-ended question responses. When employees from favorable outgroup (British) or ingroup (American) performed well, customers attributed this favorable outcome to their internal factors. When they provided poor service, customers attributed this unfavorable outcome to the external factors. The reverse is true when the employee was from an unfavorable outgroup (Indian).

In summary, we show across two studies that accent stereotypes bias customer evaluation and interpretation of service outcomes. Whereas they display a positive bias toward the British accent, customers show a strong negative bias against the Indian accent. They also make stereotype-consistent attributions about service outcomes. These stereotypical effects on service outcomes are partially reduced when customers are informed of other relevant information.

How Does the Defensive Consumer Choose?

Laurence Ashworth, Queen's University, Canada

Andrew Wilson, York University, Canada

Peter Darke, York University, Canada

Abstract

The present study extends research on the defensive model of suspicion (Darke and Ritchie 2007) to the context of consumer choice. Prior research shows defensive suspicion induces negative product attitudes, but the implications for consumer choice have not yet been examined. We predict that defensive suspicion should lead to decisions that help minimize the chance of being tricked or misled. An experiment shows consumers who are experimentally induced into a suspicious mindset are more likely to defer their product choices when they have the opportunity, and more likely to choose an inexpensive versus premium alternative for forced choices.

Conceptualization

Historically, consumer choice research has focused on shifts in preferences related to the emphasis of various aspects of the choice task (e.g. Dhar and Sherman 1996; Dhar and Simonson 1992; Simonson and Tversky 1992). More recently, choice research has begun to focus on the goals of the consumer (Bettman, Luce, and Payne 2008). In this vein, the current research examines choice in the context of defensive goals evoked when consumers are actively suspicious about marketer tactics.

The current research adopted Darke and Ritchie's (2007) dual process model to predict the effects of suspicion on consumer choice. Their model distinguishes between specific and generalized suspicion, type of information processing (heuristic vs. systematic), and processing goals (accuracy vs. defense). Traditionally, trust has been regarded as a simple heuristic cue. Indications that a particular source is trustworthy lead to greater agreement without much thought about the argument's merits (e.g. Petty, Cacioppo, and Schumann 1983). Further, some forms of suspicion (e.g., ulterior motives) are known to increase systematic processing, leading to more careful thought and greater differentiation between strong and weak arguments (Priester and Petty 1995). This pattern is consistent with what Darke and Ritchie (2007) call accuracy-based suspicion, where initial distrust evokes the goal of forming a valid opinion, leading to greater objective processing, and attitudes reflective of the true merits of the arguments (see also Campbell and Kirmani 2000). However, they suggest that suspicion can also be more defensive in nature. Such defensive suspicion biases judgment in a way that helps protect the self-esteem or material interests of the consumer from perceived threats.

Darke and Ritchie (2007) support their defensive bias hypothesis in a series of experiments. A debriefing was used to inform subjects they had been deceived by an initial ad, followed by evaluations of a second advertisement for a different product presented under the guise of a separate study. The results indicated that advertising deception evoked defensive processing goals in the sense that consumers felt fooled or tricked. In order to avoid being misled again, consumers adopted more negative attitudes towards subsequently advertised products, even those advertised by unrelated second-parties. Process analyses showed that the initial deception led to generalized distrust towards advertisers—dubbed defensive stereotyping. Additional evidence argued against the alternative possibility that these effects were due to negative affect evoked by the deception manipulation. Importantly, there were a number of sources of evidence that these effects were produced through biased processing. For instance, advertising deception led to negative attitudes whether strong or weak arguments were included in the second ad, which is consistent with a defensive bias because accuracy-based processing should have produced greater differentiation between strong and weak arguments rather than uniformly negative responses. In addition, defensive stereotyping was observed only when consumers were the direct victims of the advertising deception (high ego-involvement), and not when they merely learned of it second-hand (low ego-involvement). Finally, consumers relied on their generalized suspicions to make attitude judgments even when highly diagnostic information was available that the second-party advertiser was trustworthy (Darke, Ashworth, and Ritchie 2008).

The above evidence suggests that advertiser deception evokes defensive goals that have the effect of negatively biasing subsequent product attitudes. However, it is not clear what implications such generalized suspicions have for consumer choices within a set. The study described here examines these implications. In general, we propose that consumer suspicion is likely to lead to more conservative choices. This can take the form of delaying choice when that option is available, in the same way that negative emotions (Luce 1998) or difficult decisions (Dhar 1997, Dhar and Nowlis 1999) can lead to delayed choice. When forced to choose, suspicious consumers are likely to avoid high priced options that purport to be of higher quality in favor of lower price (and quality) options because more modest product claims are less likely to evoke defensive concerns (Darke and Ritchie 2007).

Method

A sample of 229 adults (137 females), aged between 18 and 91 (mean 34.1) were randomly assigned to a 2 (suspicion: yes or no) x 2 (firms: same or different) between subjects design. Suspicion was manipulated by a procedure similar to Darke and Ritchie (2007) as described above. The effectiveness of this manipulation was confirmed through a check. Results showed that participants in the suspicion condition felt more fooled by the initial ad, relative to controls ($M_s=5.32$ versus 3.54 , $t(207)=13.66$, $p<.001$; seven-point scales).

Following the suspicion manipulation, participants began what was ostensibly a separate study conducted by another researcher. Participants were presented with three choice tasks across different categories (binoculars, microwave ovens, and mp3 players). In each case, one option was presented as higher quality and price than its alternative. Subjects could choose either of the two options, or to delay their choice altogether. The second factor was manipulated by presenting the alternatives as being offered by a single retailer, or by two competing retailers. Note that these retailers were always fictitious and *were unrelated to the initial advertiser who had deceived participants*.

Major Findings

Participants in the suspicion condition were more likely to delay than were control participants ($F(1,224)=4.39, p=.037$). Delaying participants were asked to imagine circumstances in which a choice was necessary, and to choose between the two alternatives. In this case, suspicious participants were more likely to choose the inexpensive option compared to controls. Additional evidence showed that these effects occurred through generalized suspicion rather than any negative affect associated with the initial deception. Overall, this study provides initial support for the notion that suspicious consumers may defer choice when possible, and seek refuge in less expensive alternatives when a choice must be made.

Further experiments in this project will attempt to replicate these findings, while extending them by investigating boundary conditions. Stronger (weaker) effects are predicted under conditions of relatively subjective (objective) quality claims. When quality claims are attributed to an objective third party source (e.g. Consumer's Union), the effects of suspicion are hypothesized to be extinguished.

How I Feel is More Important Than How You Feel: The Role of Process and Outcome Emotions on Object Evaluation

Sinem Atakan, University of Michigan, USA

Katherine A. Burson, University of Michigan, USA

Richard P. Bagozzi, University of Michigan, USA

All of the products we buy are produced either by other people or, in part, by us. Once we decide that we need a new product such as a coffee table, a sweater or a mug, we have the option to buy it or we can make it ourselves. The Home Depot, Build a Bear and other stores encourage consumers to become more involved in the production process. This research explores the effects of process-related and outcome-related emotions on object-self relationship and valuation of products. Specifically, three studies explore when and how making a product oneself will increase or decrease the final valuation of the object compared to a product constructed by someone else.

Common wisdom suggests that consumers will derive utility from participating in the construction of a product and perhaps be more satisfied with it than if they had simply purchased the product. However, imagine that the process of crafting a mug is quite unpleasant for the consumer (the clay feels clumpy and gross, etc.). This process is likely to color the consumer's final evaluation of the mug differently than if the process was pleasant (he loves the texture and smell of clay). Furthermore, the consumer is likely to have feelings about the final product that are unrelated to the process. For example, he may feel proud or ashamed of the outcome regardless of whether the process was pleasant or unpleasant. In either case, the object may be contaminated by the emotions and gain a symbolic meaning. As a result of the process and/or outcome emotions, consumers may identify with and become more attached to the object.

I propose that process and outcome emotions 1) contaminate the object by giving it a symbolic meaning, 2) symbolic meaning of the object affect identification with and attachment to the object, 3) alter valuation of the object. Previous research (Norton & Ariely, 2007) suggests that self involvement enhances the value of objects but does not explain the process or make any distinction between process and outcome emotions. Importantly, I predict that although both process and outcome emotions will affect evaluation, only process emotions will affect valuations of self made objects more than other made objects, despite the fact that the emotions themselves may not differ for self and the other person. When the outcome emotion is negative (positive), it does not matter whether it is self or another person who made the object. The consumer will be unhappy (happy) either way. However, when self is involved in the process, reactions to the object are likely to be stronger.

In the first two studies, all participants read a story describing the process of making a mug. The final outcome was held constant by showing the same mug picture in all conditions. Process emotions were manipulated by telling half of the participants that the process was pleasant and telling the other half that it was unpleasant. Producer in the story was either the participant himself or another participant in the experiment. As predicted, an ANOVA on object evaluation yielded a process emotion by producer interaction. Participants in the pleasant process condition evaluated the object more highly than the others. The effect of process on object evaluation was stronger if the participant imagined that he had made the object. This was not because participants could not imagine how another person would feel in the process. In fact, in both studies, they predicted no difference between their own process emotions and those of another person. Furthermore, study 2 reveals how the self-object relationship takes shape. Symbolic meaning of the object mediates the effect of the building process on identification as well as attachment. Process emotions contaminate the object and give it a symbolic meaning. People become attached to or identify with the object because of the object's symbolic meaning.

In a third study, I find evidence that outcome emotions affect evaluation of an object beyond the role of process emotions outlined above. Pride enhances evaluation of objects and shame diminishes the evaluation of the same object. Also, whether from the process or the outcome, positive emotions enhance symbolic meaning of objects and result in identification with as well as attachment to the object. Symbolic meaning of the object also mediates the effect of outcome emotions on attachment and identification. Unlike the first two studies, there was no interaction between producer and emotion on evaluation of the object, symbolic meaning of the object, or attachment. When emotions are related to the outcome (rather than the process), there is no distinction between self and other. Process emotions seem to be a stronger factor in shaping the self-object relationship than the outcome emotions.

My findings show that emotions that are evoked in the process as well as outcome emotions may enhance or diminish the value of objects by giving symbolic meanings to objects and therefore by shaping consumers' identification with and attachment to the objects. If the outcome emotions are negative (positive), consumers are unhappy (happy) about the product regardless of who produced the object. On the other hand, process creates stronger response in object evaluation if self is involved. This research contributes to how self is extended to objects (Belk, 1988) and how consumers come to bond with the objects. The findings can help marketers to create additional value for consumers by understanding how the process and outcome emotions result in over or undervaluation of the objects.

The Unexpected Impact of User Manual at the Pre-purchase Stage on Product Evaluation and Purchase Intention: An Exploratory Study

Benoit Aubert, Grenoble Ecole de Management / Customer Equity Institute, France
 Olivier Trendel, Grenoble Ecole de Management / Customer Equity Institute, France
 Daniel Ray, Grenoble Ecole de Management / Customer Equity Institute, France

Abstract

In order to better understand capability and usability of products, an increasing number of consumers read user manuals at the pre-purchase stage. The objective of this exploratory research is (i) to understand the impact of reading user manual at the pre-purchase stage on product evaluation and purchase intention and (ii) to investigate mediating and moderating effects. In an experiment, we found that user manual exposure may positively influence product evaluation and purchase intention, as long as the perceived pedagogical quality of the manual is high. User manual evoked usage vividness and perceived customer education are mediating this effect.

Research background

The rising number of products' features can overwhelm consumers with concerns on capability and usability of products (Thompson and al. 2005). Such complexity may lead consumers to face difficulties when evaluating an offer at the pre-purchase stage (Bell and Eisingerich 2007). Thus, consumers search more and more for product usage information at the pre-purchase stage such as product usage instructions (Higgins and Shanklin 1992). They can for instance easily download user manuals through companies' websites in order to get proper usage information.

It is thus reasonable to question the "return on investment" of letting consumers read user manuals at a pre-purchase stage. So far, literature on user manuals remains scarce and legitimately focuses on post-purchase issues (Celuch, Lust and Showers 1992; Wiese and al. 2004). The goal of this study is not to understand why some customers read user manual at the pre-purchase stage, but rather to explore the impact of such a behavior on product evaluation and purchase intention and also to propose a possible underlying mechanism. From a managerial point of view, this research provides companies with indications about the value of positioning user manuals as pre-purchase communication tools.

To analyze the effects of user manuals on product evaluation and buying intention, the role of perceived customer education and user manual evoked usage vividness has been investigated. Perceived customer education reflects the degree to which customers perceive having been educated on a product by a company and is an antecedent of skills improvement, usage and consumer satisfaction (Aubert 2007). User manual evoked usage vividness refers to the quality of product usage related mental imagery (Babin and Burns 1998; MacInnis and Price 1987).

From the existing literature we hypothesized that reading user manual before purchase improves perceived customer education and consequently product evaluation and buying intention (Honebein 1997). We also hypothesized that user manual evoked usage vividness

mediates the link between user manual exposure and perceived customer education: the more a customer is able to clearly represent himself using the product mentally when reading a user manual, the more he should perceive having been well educated by the company (MacInnis and Price 1987).

Evidence of the impact of user manual at the pre-purchase stage

138 students from a major European business school participated in an experiment on the evaluation of a new digital multi-featured camera soon to be available on the local market. User manual (present, absent) was the only between subject factor that was manipulated. 68 students were provided with 4 original sources of information: one document on how to choose a digital camera, one copy of the web page for the camera, one document presenting the technical specification of the camera and a consumer report for this camera. The 70 other students were provided with the same 4 sources of information plus the original user manual for this camera. Students were asked to spend as much time as needed (up to 30 minutes) to study the different documents. They were informed that in a second part they would have to give their opinion on the camera.

We controlled that the average time spent reading the documents was greater in the user manual present condition than in the user manual absent condition ($M=24.1$ min. and 20.1 min., $p<.01$). We also controlled that product feature knowledge was the same for the 2 experimental groups (all p NS). As hypothesized, we found that students in the user manual present condition perceived being better educated to use the product by the company than students in the user manual absent condition ($M=5.38$ and 3.93 , $p<.01$). We also found that product evaluation and purchase intention were greater in the user manual present condition ($p<.01$ and $p<.1$ respectively). In order to test the mediating role of perceived customer education we performed several regression analyses (Baron and Kenny 1986; Shrout and Bolger 2002) and found, as expected, that perceived customer education fully mediates the relationship between user manual exposure and product evaluation or purchase intention. In particular, the effect on user manual exposure on product evaluation or purchase intention disappears (p NS) when perceived customer education is entered in the model.

Understanding the underlying mechanism

In a second part we studied the specific impact, on perceived customer education, of 3 variables that qualify user manual exposure: exposure duration, level of attention and importance given to this source of information when evaluating the product. We found a significant relationship (marginally significant in the case of exposure duration) between these 3 variables and user manual evoked usage vividness (all $p<.01$ for attention and importance and $p<.1$ for exposure duration) and a significant relationship between user manual evoked usage vividness and perceived customer education ($p<.05$). Moreover, we found that user manual evoked usage vividness fully mediates the relationship between the 3 variables qualifying user manual exposure and perceived customer education.

Finally, as suggested by Hennig-Thurau and al. (2005), we tested the moderating effect of 2 variables: user manual perceived pedagogical quality (a key variable controllable by companies) and customer expertise with the product category, on the relationship between the 3 exposure variables and usage vividness. Following Jaccard, Wan and Turrisi (1990) procedure, we found that perceived pedagogical quality conditions the impact of the 3 exposure variables on user manual evoked usage vividness (all p for the interaction variables $<.05$) such as a poor level of pedagogical quality precludes the existence of the relationships. Interestingly, we found no moderating effect of customer expertise with digital cameras (all p for the interaction variables NS). Thus, companies do not have to take it into account.

Conclusion and further research

This research unveils that encouraging potential customers to read user manuals at the pre-purchase stage may positively influence product evaluation and purchase intention, as long as the perceived pedagogical quality of the manual is high. User manual evoked usage vividness and perceived customer education are key mediators between user manual exposure and behavioral antecedents. In further studies, we investigate the impact of other dimensions of user manual evoked imagery.

Do Confident Consumers Search More? Examining The Relationship Between Multidimensional Self-confidence and External Information Search

Caezilia Loibl, The Ohio State University, USA
Soo Hyun Cho, The Ohio State University, USA
Florian Diekmann, The Ohio State University, USA
Marv Batte, The Ohio State University, USA

Conceptualization

The present study examines the implications of Bearden, Hardesty, and Rose's (2001) consumer self-confidence scale for external information search. While the consumer behavior literature has long suggested that consumer information search is influenced by their self-confidence, a rigorous analysis of the information search strategies of consumers with different levels of self-confidence is lacking. The present study aims to fill this void by employing the Bearden, Hardesty, and Rose scale to assess consumer self-confidence for the specific case of university extension provided consumer information. In particular, we examine the differences in information acquisition of high-confident and low-confident consumers and investigate which demographic variables influence consumer self-confidence measures in the context of information search.

Method

A total of 3,000 questionnaires were mailed to a random sample of Ohio residents in May and June 2007. An overall response rate of 32 percent was achieved, and a total of 787 responses were used for the analyses reported here. For this survey, we slightly revised the wording of the original consumer self-confidence scale to reflect the information search context and we excluded the market interface measure, which we deemed unrelated for the information search context. Our specific focus was on consumer information provided by a university extension program, including the following consumer interests: nutrition and health, youth and families, money matters, natural resources and environment, yard and garden, business and community, and farming and food production. The factor analysis described in Bearden, Hardesty, and Rose (Study 3), was repeated to confirm the validity of the revised scale.

K-means cluster analysis was used to identify consumer information strategies by analyzing the number of information sources respondents use to gather consumer information from a list of 29 information sources and the frequency of source use. The four-cluster solution proved the best solution: Cluster 1 (17% of the sample), representing consumers practicing a multi-source, high-information strategy; Cluster 2 (39%), representing consumers practicing an Internet-based moderate-information strategy; Cluster 3 (18%), representing consumers practicing a moderate-information strategy based on traditional, offline information sources; and Cluster 4 (26%), representing consumers practicing a low-information strategy.

Major findings

Relationship of self-confidence level and information search. The sample was split into high- and low-CSC consumers. Respondents whose scores on each of the five items assessing consumer self-confidence were above the midpoint (> 4) were classified as high-CSC consumers (N=105, 13.3%). A univariate general linear model was fit to the data using information cluster membership as the dependent variable. The CSC-level measure, demographic variables, and variables resulting from the interaction of the two were used as independent variables. We found that high-CSC consumers are significantly more likely to practice a high-information search strategy, even after controlling for the demographic variables and the interaction effects.

Predictors of consumer self-confidence level. Only a few studies have examined predictors of consumer self-confidence. Demographic influences had been found for age and gender. The literature is scarce despite Bearden, Hardesty, and Rose's call for examining demographic influences to identify variables that could serve as surrogates for consumer self-confidence measures. The present study extended previous analyses by examining the influence of nine demographic variables on consumer self-confidence measures. To test this proposition, several ordinary least squares regression models were fit to the data using the five consumer self-confidence measures as the dependent variables and demographic measures as independent variables. Our findings show that overall consumer self-confidence is primarily related to financial resources.

To conclude, Bearden, Hardesty, and Rose proposed a model of consumer self-confidence that distinguishes between six measures of self-confidence as related to consumer and marketplace phenomena. To date, this distinction has not been examined in the context of external information search. We have shown that consumer self-confidence measures act as significant predictors of information search activity, that high-CSC consumers are engaged in more search activity, and that consumer self-confidence scores are dependent on a limited number of demographic influences. These findings provide strong support for the view that consumer self-confidence improves the prediction of the search behavior of consumers.

A Research of the Effect of Gift Promotion and Its Spillover Effect

Chung-Hui Tseng, National Chengchi University, Taiwan

Yung-Chien Lou, National Chengchi University, Taiwan

Lien-Ti Bei, National Chengchi University, Taiwan

Gift promotion is taken as a common technique in most industry for a long time. However, the exact effect of gift promotion is nearly neglected by most managers as well as scholars, because it is believed that the higher the gift price is, the more successful gift promotion works. But, must it be true? In this study, the author questioned that the effect of gift promotion does not necessarily show a positive relationship with the gift price. In other words, if the gift price is much higher, even equal to the main product, consumer may think this is unreasonable, and then more possibly give a negative evaluation to the promotion deal. Thus, the purpose of this study was to deeply examine the effect of gift promotion.

In this study, gift promotion was defined as “buy A, get a free gift B”; that is, A and B were different products. Furthermore, promotion depth was taken as a main independent variable and defined as a percentage of gift price by main product price (eg. If an ad says: “Buy a Pair of Nike Running Shoes NT\$2000, Get a Free Gift—a Casio Watch (Market Value NT\$200)”, the promotion depth is 10%; that is NT\$200/NT\$2000). By experiment design, promotion depth was manipulated as ten groups (10%, 20%,..., 100%), and brand images of main product and gift were chosen to be two moderators in this study.

Before main studies, a preliminary study was conducted in order to make sure the existence of turning-point of gift-promotion depth. Therefore, an one-factor experimental design (ten groups of gift-promotion depth) was conducted. The finding was that the turning-point of gift-promotion depth did exist. Following, an 10x2x2 between subject design was further held, and totally 975 valid questionnaires was gathered from two collages in Taipei city.

Three themes were arranged to further investigate effects of gift promotion. Inferences and discussions were based on literature of reference price and anchor-adjustment theory. In the first research theme, it is proposed that there is a turning point in promotion depth—50% of promotion depth, and the turning point was fluctuant in accordance with brand image. If the brand image was high, the turning point was 50%; however, if the brand image was low, the turning point was downward to 40% under low brand image of main product and downward to 20% under low brand image of gift. Based on these findings, promotion depth was divided into two categories—reasonable (depth before turning point) and exaggerated (depth after turning point) promotion depth—in order to do further investigations.

The second research theme focused on the effect of reasonable or exaggerated promotion depth and its interaction with brand image of main product and gift. Findings were (a) In the range of reasonable promotion depth, the deeper the promotion depth was, the higher the perceived value of product bundle was (eg. positive relationship). However, in the range of exaggerated promotion depth, negative relationship was exhibited. (b) The deeper the promotion depth was, the higher the price perception of gift was. In the range of reasonable promotion depth, as the depth increased, value-adding level of gift decreased. In the range of exaggerated promotion depth, as the depth increased, value-discounting level of gift increased. (c) The brand image of main product and gift did show significant moderating effect.

The third research theme was going to investigate whether the discounting perception toward gift would spill to other products with the same brand of the gift, or spill to the same product with other brand. In this study, we defined the phenomenon as a “spillover effect” of gift promotion. Findings were: (a) No matter in the range of reasonable or exaggerated promotion depth, gift promotion did cause discounting of perceived value toward other products with the same brand of the gift and to the same product with other brand. That is, spillover effect did exist. (b) As the promotion depth increased, the spillover effect would first go downward then upward. In other words, the relationship between promotion depth and spillover effect showed a type of U-shape. Findings of this study will enrich literature of promotion as well as offer practical suggestions to managers implementing strategies of gift promotions.

What Really Matters When Differentiating: A Neuroscientific Approach

Martin Reimann, Stanford University, USA
Carolin Neuhaus, University of Bonn, Germany
Margit Enke, Technical University of Freiberg, Germany
Thomas Bender, Technical University of Freiberg, Germany
Bernd Weber, University of Bonn, Germany

Marketing managers' daily business is dedicated to fighting commoditization. That is, the process of trying to differentiate their firm's products in a marketplace where competitors offer essentially products with identical core attributes, e.g., in terms of quality. Prior research and managerial practice, however, lack insight about which aspects of differentiation resonate in acceptance and purchase among consumers. Moreover, consumers' affective and cognitive processes when deciding between a standard offering and a differentiated one are not yet well understood. Should the product packing be re-designed? Should marketing managers offer products at lower prices than the competition? Or, does a strong brand drive product success in a commoditized marketplace?

Methodology. To answer these questions, we digitally rendered pictures of 20 everyday products from sunscreen to table water along the line of three distinct variables: packaging design, brand, and price. For example, the well-known Evian spring water was shown in its original form (i.e., Evian brand, designed bottle, higher price) as well as in a rendered form with a different brand or a different bottle or at a lower price.

In a brain scanning session using functional magnetic resonance imaging (fMRI), 17 participants (gender: 9 male, 8 female; mean age: 24.9; occupation: students) bought or rejected original and rendered offerings. We chose fMRI because it has become one of the most prominent noninvasive methodologies for imaging brain activity in humans. Moreover, fMRI has made it possible to enhance our knowledge about how individuals process different stimuli. As such, fMRI allows for a direct measurement and localization of brain activations and offers several advantages over more traditional measurement approaches: (1) the ability to provide confirmatory evidence about the existence of an intrapersonal phenomenon; (2) the generation of a more fundamental conceptualization and understanding of underlying processes; and (3) the refinement of existing conceptualizations of various phenomena.

Results. Among other findings, our fMRI data suggest that design differentiated products activate areas related to reward anticipation to a significantly larger extent than non-differentiated and branded products. This suggests that marketing managers can trigger reward anticipation among consumers when offering products under a differentiated design.

In summary, we identified several relevant brain areas involved with three distinct differentiation strategies—packaging design differentiation, brand differentiation, and price differentiation. Utilizing fMRI, we were able to (1) provide confirmatory evidence about the existence of an intrapersonal phenomenon (i.e., reward anticipation relating to design differentiated products) and (2) generate a more fundamental conceptualization and understanding of these underlying processes.

Brand Dilution Effects on Franchises

Noelle Nelson, University of Minnesota, USA
Barbara Loken, University of Minnesota, USA
Christine Bennett, University of Minnesota, USA

Prior literature on brand dilution has shown that when brands extend into new product domains, information about the extension that is inconsistent with the parent brand can affect the parent brand. However, most research on brand dilution has been performed in the context of product brand extensions. Product brand extensions are those in which the manufacturer is under the control of the parent brand and therefore, sanctioned by the parent brand manufacturer. Another context that may be potentially important for understanding brand dilution is the impact of a new retail opening with a franchised brand name.

Franchises are a good way for companies to expand quickly at relatively little cost. The franchisor charges a fee to the franchisee for the use of its brand, advertising, and other brand elements, while leaving varying amounts of control to the franchisee. A good example of a franchise is McDonald's. McDonald's franchisees benefit from McDonald's Corp. national advertising and brand strength, but are able to tailor some aspects of the store to the region or target market.

However, any McDonald's patron who has noticed the absence of his/her favorite item in a specific McDonald's can tell you that franchisees do not always deviate from the parent company in a positive way. This research examines cases in which parent brands have little control over some franchisee failures, but may, nonetheless, experience dilution effects. We examine the impact of consistent and inconsistent franchise openings through the use of brand partnerships. While research has examined the impact of co-branding (e.g. Siminon and Ruth 1998) in side-by-side retail contexts (Levin and Levin 2000) and in pairings of brands in retail displays (Buchanan, Simmons and Bickart 1999), researchers have not examined co-brands in franchise contexts in which the franchisee has some control over the use of co-brands.

In our research, we used a known company that was unlikely to yield ceiling or floor effects on loyalty: Bally's Fitness Centers. Bally's is a nation-wide chain of fitness centers that is operated on a franchise basis. Abundant past research has found that consistent extensions are better liked than inconsistent extensions. In the present study, we described Bally's as opening a new fitness center, and as part of the information received by participants, the new Bally's fitness center also housed a small restaurant.

Our consistent experimental condition was to combine Bally's with a small Panera (café/bistro). The inconsistent condition was Bally's with a small McDonald's restaurant. Because fast food sold through McDonald's is widely perceived to be unhealthy, it was expected to be perceived as quite inconsistent with the image of a fitness center. We also included a control condition, in which participants were not given information on a restaurant in the new Bally's.

Also, to rule out the argument that people simply do not know that Bally's is a franchise, and therefore apply negative information as if the parent company had control over the extension, we gave half of the participants information about Bally's as a franchise, and half no information. In particular, those who received franchise information were told that franchises are companies in which the franchisees can make decisions and changes to their specific store without interference from the parent company. The resulting experiment employed a three (extension type: inconsistent, consistent, control) by two (information about franchises vs. no information).

During the experiment, undergraduates completed a pencil and paper questionnaire about Bally's Fitness Centers. First, a description of the company Bally's was given, with franchise information either present or absent. Following the information about the parent company, information on the new Bally's (ostensibly opening in downtown Chicago) was given. Participants were told that the new Bally's would have a small Panera, McDonald's or were not given information about the new Bally's (control condition to obtain baseline views of Bally's).

Following the descriptions, participants were asked to rate both Bally's the parent company and the new downtown Chicago Bally's. Participants gave their impressions of whether Bally's (parent or extension) was roomy, high-end, and health-focused, as well as giving their overall evaluations.

Our results showed that though franchising should allow consumers to isolate negative feedback to the specific franchisee (i.e., the new Bally's store), information about the extension still leaks onto the parent company. Reminder information about Bally's as a franchise did not seem to help participants isolate the feedback to the specific store. Specifically, participants in the McDonald's condition rated both the parent Bally's and the new Bally's as being more crowded, less health-focused, less high-end, and overall more negative than the control condition.

However, it should be noted that the parent brand can also benefit from decisions made by the franchisee. That is, in the Panera condition, participants rated both the parent and new Bally's as being at least as good as the control condition (if not better) on the measures mentioned earlier.

Therefore, in the current research we replicate previous research that finds consistent extensions to be more favorably valued than inconsistent extensions. We extend these findings by showing that the parent brand (overall franchise in this case) can even benefit or be harmed by feedback from the extension when the extension is not under the parent's control.

In future research, we plan to examine whether high consumer familiarity with a brand will prevent negative spillover from extensions which are not controlled by the parent brand. Generally, we seek to find situations in which parent brands can be immune to these negative effects.

Remembering Taste Experiences: Constructed Preferences from Suggestion

Amanda Wudarzewski, Brock University, Canada

Antonia Mantonakis, Brock University, Canada

Seema Clifasefi, University of Washington, USA

Daniel Bernstein, Kwantlen University College, Canada

Elizabeth F. Loftus, University of California, Irvine, USA

Abstract

It is well known in the literature on decision-making that utility can be derived from the anticipation of, the experience of, or the recollection of an event (Elster and Lowenstein 1992). We propose a fourth source of utility, utility derived from a false memory. We show that people can be influenced by false suggestion (for a consumption experience that did not occur), which can lead to a false memory, and result in a change in preference, which can be in either direction (i.e., preferences can increase or decrease). We propose a fluency hypothesis to account for our findings.

Memories are malleable, and current information can influence retrospective memory (Loftus and Palmer 1974). Utility can be derived from the anticipation of, the experience of, or the recollection of an event (Elster and Lowenstein 1992). We propose a fourth source: utility derived from false memory.

Post consumption feedback does not affect preferences (Lee, Frederick and Ariely 2006). Participants were assigned to one of three groups: where the ingredient was not disclosed; where participants received the "true" information *before* tasting the beer, or where they received the information *after* tasting the beer. Preferences towards the beer did not change in the *after* condition. However, "false" post-

consumption feedback does affect preferences (Braun 1999). Participants tasted orange juice diluted with vinegar. After, an advertisement was presented claiming the juice was “great tasting”. Participants used more positive words when describing their experiences with the juice, and the brand was more likely to be chosen.

Our investigation used these two somewhat contradictory findings as a motivator to our study. Our objective was to determine whether utility (either an increase or a decrease in preferences) can be derived from false memories. “Familiarity” is a possible mechanism that could play a role. Suggestion, which involves imagining having liked or disliked something, increases one’s familiarity with an autobiographical experience. When a judgment is made on a subsequent occasion, this enhanced familiarity, or “fluency” could be misattributed to an autobiographical memory instead of to the suggestion (Bernstein et al. 2005b). The fluency hypothesis may account for why Lee et al. (2006) failed to observe a change in preference. Assuming that the post-consumption suggestion induced cognitions that were non-elaborative, participants may have not had the opportunity to experience “familiarity” that the beer tasted like vinegar.

We aim to first obtain increases and decreases in preferences within the same experiment, using the same critical item.. We chose an item that is relatively neutral for our sample of participants—white wine.

Hypotheses

H1: Participants who receive feedback that they loved (got sick from) wine will increase their confidence that such an experience occurred to them because of the cognitive elaboration that the experimental groups performed.

H2a: After feedback and elaboration, participants in the experimental groups will demonstrate an increase (decrease) in preference towards wine.

H2b: After feedback and elaboration, participants in the experimental groups will be more (less) likely to choose wine in a hypothetical situation.

H2c: After feedback and elaboration, participants in the experimental groups will show a higher (lower) willingness to pay (WTP) for wine.

Method

Participants

Ninety-three students from a large northeastern North American university participated.

Experimental Design

We used a 2 [valence (Love x Sick groups)] x 2 [suggestion (Suggestion x No Suggestion)] between-subjects design.

Procedure and Materials

We randomly assigned participants to the Love/Suggestion group, the Love/No Suggestion group, the Sick/Suggestion group, or the Sick/No Suggestion group. In an initial session, participants completed the Food History Inventory, which contained 24 events, including “loved (got sick from) drinking white wine” depending on what group they were assigned to. Participants also completed the Party Behavior Questionnaire, which asked participants to rate their likelihood of consuming food/drink items. Finally, participants completed the Food Preferences Questionnaire, where they rated food and drink items in terms of how much they enjoy eating/drinking each. Interspersed within these questionnaires were filler questionnaires to disguise the true nature of the experiment.

One week after session one, participants returned for a second session and half were given a false suggestion about their responses from session one. Participants were told their previous responses were entered into a computer, which generated a profile of their experiences with certain foods. The profiles were presented as if they had been individually tailored, although they contained the false suggestion. A portion of the profile was identical for all groups, but the critical event, “you loved (got sick from) drinking white wine,” was embedded in the profile for the Suggestion groups. The No Suggestion (control) groups received filler items

Participants then completed an elaboration phase where they responded to questions about their profile. Participants were instructed to imagine the setting in which the experience might have taken place, where they may have been at the time and who they may have been with. The experimental groups answered these questions about the critical event.

Next, participants completed the Food History Inventory, Party Behavior Questionnaire, Food Preferences Questionnaire (to assess the change from session one), and the Food Costs Questionnaire where participants indicated their WTP for different food items (including “a bottle of white wine”). Finally, participants completed a Memory or Belief Questionnaire where they answered questions about their memory for the events mentioned in the profile, or to imagine what *might* have happened. Participants elaborated by providing as many details as possible.

Results and Discussion

Food History Inventory

The Love/Suggestion group ($M=.92, SD=1.60$) showed an increase in confidence that the event (loved drinking white wine) occurred, $t(12)=2.07, p=.03$. The Sick/Suggestion group ($M=2.00, SD=2.57$) also showed an increase in confidence that the event (got sick from drinking white wine) occurred, $t(13)=2.91, p=.06$.

Food Preferences Questionnaire

The Love/Suggestion group ($M=1.00, SD=1.15$) showed increased preference for wine, $t(12)=3.12, p=.004$. The Sick/Suggestion group ($M=-.64, SD=.93$) showed a decrease in preference for wine, $t(13)=2.59, p=.011$.

Party Behaviour Questionnaire

The Love/Suggestion group ($M=62, SD=1.12$) was more likely to indicate intent to consume wine, $t(12)=1.98, p=.035$. The Sick/Suggestion group ($M=-.29, SD=.82$) was more likely to avoid wine, $t(13)=1.29, p=.10$.

Food Costs Questionnaire

The Love/Suggestion group ($M=\$13.92, SD=4.29$) had a higher WTP for wine ($M=\$10.53, SD=2.69$), $t(28)=2.65, p=.006$. The Sick/Suggestion condition ($M=\$13.71, SD=5.00$) indicated a lower WTP for wine, ($M=\$10.82, SD=4.51$), $t(23)=1.50, p=.073$.

In summary, participants who received the suggestion had higher confidence that the critical event happened to them. We also found changes in preference based on the false suggestion. This is the first study to examine utility derived from false memory in terms of both increases and decreases in preference in the same experiment. We demonstrated that utility derived from false memory of an experience can form the basis of the subsequent recollection of (Food History Inventory), and the subsequent anticipation of (Party Behaviour Questionnaire), experience.

Is It *Just* the Thought That Counts? Experimental Investigation into the Gift Giving Effort Effect

Risto Moisio, California State University, Long Beach, USA
 Mariam Beruchashvili, California State University, Northridge, USA

Abstract

Even if consumer researchers have long contended that the effort put forth into a gift is vital, specific effects of gift-giving effort on one of its most important consequences—acts of reciprocity have not been examined. The purpose of this research is to investigate the phenomenon of perceived gift giving effort from the recipient's perspective. In this research, we empirically demonstrate what we describe as the gift giving effort effect, the idea that perceived gift giving effort sparks acts of reciprocation by the gift recipient in an array of everyday life situations.

If it is just the thought that counts, why have alongside the rows and rows of ready-made Hallmark greeting cards for any occasion a shelf with blank cards? Why offer consumers avenues to expand even more effort into gifts by providing countless gift selection workshops, online guides and tutorials, and even gift consulting services? If it is just the giving of a gift that counts, why do we see so many traces of consumers investing their emotional, psychic, and temporal efforts into the gift giving process? Why is the unifying theme of the effort in gift giving paradoxically important at the same time as the market parades more emphasis on gifts themselves? At least at the outset, it appears that a gift that reflects considerable amount of effort, not just the recognition of another person, is crucial to gift giving. The purpose of this research is to investigate the phenomenon of gift giving effort from the recipient's perspective. In this research, we empirically seek to examine what we describe as the gift giving effort effect. With this term we intend to capture the idea that perceived gift giving effort sparks one of the most fundamental processes in gift giving, acts of reciprocation by the gift recipient in an array of everyday life situations.

Our research builds on the extant literature in consumer behavior that has repeatedly recognized the pivotal role of gift giving effort in processes of gift giving (Sherry 1983). We build on the idea that the effort put forth into a gift is vital (e.g., Belk and Coon 1993; Sherry, McGrath, and Levy 1993). Gift giving effort is evidenced through multidimensional expansion of human energy, whether monetary or psychic in the form of gift giver's emotional investment that is highly valued by the recipient of the gift (Robben and Verhallen 1994). The effort expended in a gift in terms of money, time, and emotional effort is important, according to some researchers, because it signals to the recipient that the giver has made a selfless sacrifice, a characteristic of a perfect gift (Belk 1996; Belk and Coon 1993). Such sacrifice expressed through thought and effort invested in the gift by a marital partner makes a gift favorite to the gift recipient (Wolfenbarger 1990). Consumers also tend to perceive gifts that manifest effort as more successful (Wooten 2000). Others recognize how the adding of a hand-written message converts a generic birthday card into a personal gift to the recipient (Dodson and Belk 1996). In romantic relationships, a gift that reflects the expenditure of personal time and effort is perceived by the recipient as a symbol of love and of transference of the giver's self to the recipient (Belk and Coon 1993). Thus, while we learn from these studies that consumers associate emotional value with gifts imbued with effort, it remains unknown whether perceived gift giving effort impacts one of the most well-known consequences of gifts, reciprocation (e.g., Bodur and Ghromann 2005; Dorsch and Kelly 1994; Rynning 1989). The purpose of our research is to address this gap. We posit that the prevailing theory of gift giving grounded in reciprocity norm does not fully account for the gift giving effort effect.

In a series of experiments, we demonstrate that perceived gift giving effort affects the recipient in ways that cannot be explained by the prevailing theory of norm reciprocity. We examine a novel theoretical mechanism grounded in anthropological research by the seminal

theorist of gift, Mauss (1954) who proposed that gifts represent vessels that contain and transmit the gift giver's spirit or *hau*. Across several studies, we investigate the gift giving effort effect. In studies 1a-1c, we demonstrate that perceived gift giving effort increases acts of reciprocity towards the gift giver in various everyday situations. We also seek to rule out alternative explanations of the gift giving effort effect. Specifically, our results show that neither gratitude, nor indebtedness, nor positive mood bias account for the gift giving effort effect. In study 2, we also examine gift giving effort effect in public (possibility of being evaluated by an audience) and private (no audience) situations. Consistent with social norm account, we find that gift giving effort increases reciprocation for high self-monitors in public but not in private situations. In private situations, social norm does not seem to account for our findings. In studies 3 and 4, we extend the underlying theoretical mechanism and the boundaries of the gift giving effort effect. We examine the role of reciprocation wariness and how it affects the gift giving effort effect. In study 3, we find that reciprocation wary participants are more likely to reciprocate in private as well as public situations. In study 4, we replicate and reverse the gift giving effort effect showing that gift giving effort may also backfire. Collectively, our findings speak to the importance of gift giving effort and particularly to the role of contagion in driving the gift giving effort effect. Our findings also show the boundaries of gift giving effort unaddressed in prior research on gifts more broadly.

Consumer Alienation by Brands: Examining the Roles of Powerlessness and Relationship Type

Preeti Krishnan, University of Manitoba, Canada
 Namita Bhatnagar, University of Manitoba, Canada
 Rajesh Manchanda, University of Manitoba, Canada

The development of relationship theory in consumer research, with brands being considered as quasi-human relationship partners (Fournier 1998), has provided the foundation for examinations of consumer-brand relationships (e.g., Aaker, Fournier, and Brasel 2004; Aggarwal 2004, 2005; Muniz and O'Guinn 2001). The social relationship metaphor has been adopted in this domain and norms of *human* social ties have been found to govern consumption choices and behaviors (Fournier 1998; Aggarwal 2004). The negative fallouts of human ties many times include *felt alienation*—i.e., a sense of exclusion that is experienced by one of the relationship partners when the other induces a relationship stressor (i.e., a circumstance that is unfavorable or perceived as such; Panksepp 2005; Seeman 1959, 1975). Though studied extensively within sociological contexts (e.g., for women abandoned by their husbands; Arokach 2006), felt alienation remains unexamined within the domain of consumer-brand relationships. In this paper, we develop a process model of consumer alienation induced as a consequence of negative brand decisions, and propose that existing consumers can feel alienated by a brand, when their consumer-brand tie is subjected to a managerially-imposed relational stressor (e.g., closing of a convenient retail location, pulling of a product line from the shelf, or abandonment of a sub-brand; Fournier 1998; Muniz and Schau 2005).

We investigate how *powerlessness* (i.e., the perceived inability to amend an unfavorable situation or outcome, encompassing a sense of helplessness), considered by many scholars as an aspect of and antecedent to alienation (e.g., Ashforth 1989; Blauner 1964; Seeman 1959), influences consumer emotions, attitudes, and behavioral intentions under stressful situations, and specifically propose that a greater sense of alienation or exclusion will be experienced amongst those consumers that perceive themselves to be *powerless* (*vis-à-vis powerful*) in influencing brand decisions. This relationship is expected to be moderated by the relationship type that exists between brand and consumer, the treatment meted out by the brand during consumer efforts at decision reversal, outcomes of this effort, and perceived sincerity of any apologies proffered. Consumer-brand *relationship types* can vary on perceptual dimensions where they are seen as

predominantly economic/transactional in nature (termed “exchange”, as seen amongst business people) or based on social bonds (termed “communal”, as seen amongst friends; Aggarwal 2004, 2005; Clark and Mills 1993). A change in perceived relationship type is expected once a stressor is introduced within a relationship—especially, one that transforms from communal to exchange amongst those consumers that feel powerless in influencing brand decisions.

Propositions of this research are tested within a series of laboratory experiments that use business undergraduate student samples. The service context of on-campus banking was used (found to be highly involving for the student sample, and used in prior research; Aggarwal 2004). Respondents were asked to imagine that they patronize the on-campus location of a hypothetical bank that then announces the intention to move far away off-campus (thus introducing a relational stressor). The first study examines the impact of variations in perceived powerlessness to change the bank’s decision to relocate (control, powerless, versus powerful) and pre-existing relationship type (communal versus exchange) on attitudes toward the bank/employees/decision, felt alienation, emotions, behavioural intentions, and relationship transformation. The second study builds on the first by examining the additional impact of positive versus negative treatment by the bank while dealing with consumer efforts to reverse its relocation decision. Finally, study three examines the impact of perceived sincerity of apologies made by the bank upon reversal of its original stressful decision.

Results indicate that the mere presence of the stressor causes consumers to feel powerless to change the bank’s decision and thus alienated by the brand. As the level of perceived power declines, consumers’ sense of powerlessness, felt alienation, and intensity of negative emotions increase, making attitudes toward the bank/employees/decision and behavioral intentions unfavorable, and causing consumers to transform their relationship with the brand to be less social/friendly (communal) and more businesslike (exchange). Negative (positive) treatment of consumers by the bank is found to exacerbate (alleviate) the magnitude of perceived powerlessness, felt alienation, negative emotions, unfavorable attitudes and behavioral intentions. Attitude toward the decision (vis-à-vis bank/employees) is found to be most sensitive to perceptions of power, such that as perceived power declines, this attitude is least favourable—suggesting that consumers evaluate the stressor as a one-time negative event with the company and do not transfer negative emotions and cognitions generated from this event onto their more general attitudes towards the bank/employees. Felt alienation mediates the relationship between perceived powerlessness and consumer attitudes, which in turn mediate the impact of felt alienation on behavioural intentions.

This research has implications for both marketing theory and practice. From a theoretical standpoint, alienation and powerlessness find relevance and application within the domain of consumer-brand relationships, thereby, paving the way for interdisciplinary research. Our findings also support the stance of sociologists that consider powerlessness to be antecedent to alienation. Further, this research demonstrates that unlike human bonds, the perceived relationship dichotomy (communal and exchange) is not distinctive within consumer-brand ties, as the element of transaction/exchange is unavoidable here. From a managerial perspective, companies need to ensure that they avoid fostering feelings of powerlessness and perceptions of negative treatment amongst consumers while implementing unpopular brand decisions. Results found here also suggest that brands need not be overly anxious about overall equity dilution and consumer boycotts when a one-time negative decision has to be made.

Limitations and avenues for future research are also identified. Longitudinal data collection from real-life bank customers is planned to substantiate findings from student samples and to refine the process model. Future research is planned to evaluate the relevance of other aspects of alienation (delineated in sociology as—normlessness, meaninglessness, social isolation, and self-estrangement; Seeman 1959) to consumer-brand ties. Additional studies will also examine the impact of other relational stressors (e.g., breach of trust by company, presence of attractive alternatives) and contexts where relationship dichotomies are more distinct (e.g., high-risk investment banking, psychiatric counselling).

Pulling-up or Pushing Down? Exploring Pro-leader and Anti-trailer Processing in Multi-option Consumer Choices

Simon J. Blanchard, Pennsylvania State University, USA

Margaret G. Meloy, Pennsylvania State University, USA

Kurt A. Carlson, Duke University, USA

Prior research has demonstrated that consumers distort new information to favor the option that is leading during a binary choice process (Carlson and Pearo 2004; Russo, Meloy and Medvec 1998). However, an unanswered question is whether and how consumers distort information in choices involving more than two options? Specifically, do decision makers evaluate new information to favor the leading option, to disfavor the trailing option(s), or do they do both? And what effect, if any, does the number of options in the consideration set have on how new information is evaluated? The current work seeks to address these questions.

Payne (1976) found that in multi-option settings, individuals quickly eliminate certain options from their consideration sets using limited information (see also Ordóñez, Benson, and Beach 1999). As such, the earliest focus in a choice process might be on eliminating options, perhaps by denigrating the trailing option(s). After the set is sufficiently reduced, processing to favor the leader may be the norm. As such, a primary objective of this work is to separate two types of processing: pro-leader and anti-trailer, and to determine if either or both dominate multi-option choice.

In *pro-leader* processing, respondents evaluate attribute information as overly favorable toward the option that is currently leading. Alternatively, *anti-trailer* processing involves the evaluation evaluate of new information as overly unfavorable toward the option that is trailing. The trailer is the option that was least preferred after seeing the previous piece of information. We test for both types of processing, as well as their onset, in an experimental study.

To examine the roles of pro-leader and anti-trailer processing in preferential choice, we traced not only how individuals processed new information, but we also tracked the relative strength of preference for each of the options throughout the choice process. Two decision contexts were used, restaurants and scholarship applicants. Restaurants represent a context in which individual preferences are more likely to drive the decision and the attributes used were more narrative. The scholarship scenario required that participants be more objective in their evaluations.

Participants and Design

The sample consisted of 244 students who received extra course credit for their research participation. Each was randomly assigned to one of twelve conditions. The manipulated factors were the number of available options (2, 4, or 6), the scenario (restaurants or scholarship applicants), and the order in which the attributes were presented (counter balanced forward or backward). Neither the scenario nor the information order had any impact on the results so they will not be discussed further.

Measures

Participants reviewed attribute information sequentially, where one page contained information for all of the options for that attribute. After reviewing the attribute information, participants gave two separate sets of responses. The first asked for an evaluation of each option using only the information on that page. Responses were captured on 9-point attractiveness scales (one for each option), where 1="very unattractive" and 9="very attractive". The second set of responses captured current cumulative preferences based on all the information seen to that point. This was accomplished with a race track image, on which participants placed the names of the options on the track for the portion of the choice process (i.e., race) that had been completed so far. Since the choice process was divided into six attributes, the race track was divided into six equal length segments. After each attribute was reviewed, participants put the name of the leading option at the front of the segment and the names of the other options somewhere further behind on the race track. The relative positions of the options were used to assess which option(s) were leading, trailing, or in between after each attribute.

By computing mean evaluations for each option on attribute t , conditional on whether the option was leading, trailing, or neither on attribute $t-1$, we can assess whether individuals engage in pro-leader, anti-trailer, or both types of processing. That is, pro-leader (anti-trailer) processing occurs when evaluations of the leading (trailing) option are significantly higher (lower) than when this same option is not leading (trailing).

Results

The evidence reveals that participants engaged in both pro-leader processing ($M=0.51$, $t(243)=7.87$, $p<.05$) and in anti-trailer processing ($M=0.42$, $t(243)=6.68$, $p<.01$). Moreover, analysis of variance revealed that both pro-leader processing and anti-trailer processing increased as the number of options present in the choice set increased (pro-leader: $F(2,232)=3.18$, $p<.05$; anti-trailer: $F(2, 232)=4.56$, $p<.05$). In other words, the greater the number of options being considered, the greater the tendency to support the leader and denigrate the trailer.

We used paired samples t-tests to assess the point at which (i.e., the serial position in the choice process where) each type of biased processing became significant. In the two-option case, the onset of pro-leader and anti-trailer processing were identical. In this case, biased processing occurred at the fourth attribute ($t(58)=2.64$, $p<.05$). In the four option case, pro-leader processing occurred earlier, on the third attribute (i.e., there was evidence of pro-leader processing on attribute three, four, five, and six, all $p<.05$), whereas anti-trailer processing did not appear until the fourth attribute (i.e., it existed for attributes four through six, all $p<.01$). In the six option case, pro-leader processing occurred even after just one attribute (all $p<.01$), while anti-trailer processing started with the third attribute (all $p<.05$).

Discussion

Participants engaged in both pro-leader and anti-trailer processing of new information, and the tendency to do so increased as the number of options increased. We did not find evidence to support the idea that consumers would use anti-trailer processing to eliminate

options before using pro-leader processing to build support for an option to be selected. Rather, we found that both types of processing occur early in the choice process, and that the greater the number of options, the earlier they occur.

The Effect of Social Trust on Consumers' Memory of Ads

Aiyin Wang, McGill University, Canada
Ulf Böckenholt, McGill University, Canada

Conceptualization

Social trust—opinions about whether one's fellow man can be trusted—have become important because of its observable consequences on economic exchanges (Warren 1999). A high level of social trust is commonly believed to encourage economic growth, because it reduces "transaction costs" resulting from social interactions. In contrast, a low level of social trust is argued to lead to economic barriers because of the lack of mutual confidence (Arrows 1972). In the marketing domain, marketing communication might be less effective to consumers with low levels of social trust because they tend to be more "defensive, watchful and vigilant" (Lewicki, McAllister and Bies 1998; p. 446). Consequently, they are more likely to scrutinize received information, and hence are less vulnerable to persuasive messages. However, as many advertisements receive little attention making them ineffective, close scrutiny by consumers can be valuable to the marketers. For instance, when the primary goal of the ad is to have consumers memorize some improved features of a new line of product, consumers with low level of social trust may look at the ad more carefully and therefore memorize better the features mentioned on the ad.

The extant literature suggests that people process information differently under different levels of trust (Schul and Mayo 2004; Priester and Petty 1995). Specifically, this research suggests that a low trust mind-set⁴ motivates individuals to engage in more elaboration of the received messages than those with high trust mind-sets; even when the trust mind-set is unrelated to these messages. When information is processed at a deeper level by elaboration, recall and recognition of this information can also be enhanced as suggested by the "depth of processing model" (Craik and Jacoby 1976). Accordingly, consumers with mind-sets that are low in trust might be better at memorizing information in ads.

In this research, we are primarily concerned with high and low trust mind-sets induced by positive and negative generalized social trust (i.e. opinions about whether one's fellow man can be trusted) rather than ad-related trust. We expect that the activation of different levels of trust mind-sets will affect consumers' information processing style. That is, consumers with low trust mind-sets process ad information deeper than consumers with high trust mind-sets by securitizing the ads and possibly generating counter-arguments. We suggest that, this process will in turn improve the recall of ad information because of deeper information processing. Furthermore, we expect the effect of levels of trust mind-set on memory to be qualified by the type of messages provided in the ads (Darke and Ritchie 2007). Specifically, we expect that the effect of level of trust will be less pronounced when the type of message is about subjective claims as opposed to objective attributes.

Method

To test these hypotheses, we conducted a 2 (level of trust: high trust vs. low trust) x 2 (type of messages: objective attributes vs. subjective claims) mixed factorial design. One hundred and six university students were randomly assigned to either a high trust mind-set condition, or a low trust mind-set condition. All participants were asked to read a flyer which contained the manipulation of the high or low trust mind-set, and three experimental ads for three products. In the high trust mind-set condition, participants read a wallet dropping story from Reader's Digest (Mutz, 2005) with a trust-inducing content⁵ prior to the presentation of the printed ads. In the low trust mind-set condition, participants read the same wallet dropping story but with a distrust-inducing content.⁶ Involvement of the products was measured before the mind-set manipulation, and products with the highest and lowest involvement were selected for analyses. Each ad contains two types of information, objective attributes and subjective claims (e.g. "Ultra-Fiber fiber supplement is a source of natural fiber" vs. "Taking Ultra-Fiber fiber supplements, you will live healthier, better than ever!"). Need for cognition (Priester and Petty 1995) and general trust toward advertising (Darke and Ritchie 2007; Obermiller, Spangenberg and Maclachlan 2005) were measured as possible covariates for all the participants before presentation of the flyer. Subsequently, participants were asked to perform a recognition task regarding product attributes and claims made in the ads. Finally, purchase intentions were measured for all participants.

⁴Although there is debate on viewing trust and distrust as bipolar or two separate constructs, in the present research we assume that low trust refers to distrust and high trust refers to trust.

⁵In this condition, the story only reports about the people who try to return the wallet after finding it.

⁶In this condition, the story only reports about the people who kept the wallet after finding it.

Results

In order to dissociate memory accuracy from criterion shifts in the recognition of true and false statements, we conducted a signal detection theory (Green & Swets, 1966) analysis. Accuracy of memory (how well a person discriminates between correct and false statements) was estimated by the distance measure d . Results from a 2(level of trust) x 2(gender) x 2(product) x 2(types of message) ANOVA showed a significant two-way interaction of level of trust and message type ($F(1, 102) = 4.647, p\text{-value} = 0.033$). Specifically, when the message type is about objective attributes, participants with low trust mind-sets are higher in memory accuracy ($d = 1.12$) than participants with high trust mind-sets ($d = 0.83; F(1, 104) = 5.854, p = 0.017$); whereas when the message type is about objective claims, there is no difference between the two groups. There is also a main effect of message type ($F(1, 105) = 7.037, p = 0.009$), where objective attributes ($d = 0.97$) are better memorized than subjective claims ($d = 0.79$) for both groups in which participants have either high or low trust mind-sets. In summary, when the messages are objective attributes, participants with low trust mind-sets perform better in the recognition task than participants with high trust mind-sets. This result is consistent with the hypothesis that activation of a low trust mind-set triggers more careful processing of ad information and builds a stronger memory for participants with low- than high-trust mind-sets. However, when the messages are subjective claims, the level of trust did not have an effect on memory accuracy any longer, which supported the prediction that message type moderates the effect of level of trust. In addition, all participants memorized better the objective attributes than subjective claims. This result suggests that objective attributes may receive more attention than subjective claims, and that these attributes are scrutinized more by participants with low trust mind-sets than those with high trust mindsets. Subjective claims, on the other hand, may activate the negative stereotypes towards advertising in general (Darke and Ritchie 2007), and hence receive little attention from participants. Further analyses on possible covariates suggest that neither need for cognition nor general trust is correlated with the dependent variable d . The effect of level of trust on purchase intention is not significant for both products. This may be due to the lack of a main effect of level of trust on memory accuracy. A significant difference in purchase intentions may be obtained in a future design in which stimuli ads contain only objective attributes as messages.

Contribution

Although much attention has been paid to the effect of low trust on information processing, little is known about its effect on memory. In addition, possible boundary conditions that qualify this effect have not been sufficiently discussed. The results of our research contribute to the theory of trust and distrust by suggesting that, when the ad information is about objective attributes, consumers with low trust mind-sets memorize ad information better; whereas when the ad information is about subjective claims, this effect weakens considerably. Second, research in consumer behavior has focused mostly on manipulating stimuli (ads)-relevant trust, and did not consider effect of social trust. The manipulation of different levels of social trust provides another dimension of trust that can influence consumers' information processing. Finally, our research offers also insights for practitioners by suggesting that low level of trust can enhance memory of certain type of ads information, whereby increase the effectiveness of marketing communication. From consumers' perspective, our research adds to their knowledge of persuasion by indicating that distrust does not always reduce the influences that ads impose on them.

The Impact of Perceptual Combination Effects on Asymmetry in Co-Branded Products

Lisanne Bouten, Delft University of Technology, The Netherlands
 Effrosyni Petala, Delft University of Technology, The Netherlands
 Amrita Kumar, Delft University of Technology, The Netherlands
 Erik Jan Hultink, Delft University of Technology, The Netherlands

Abstract

Previous research has shown that perceptual (visual) and conceptual (textual) information can influence perceptions of (a)symmetry between two concepts that are part of a composite concept. We believe the same logic applies to co-branded products. One brand may be dominant over the other brand. An experiment with young women shows that perceptual cues influence perceptions of asymmetry (rather than conceptual cues). In addition, the perception of asymmetry mediates the effect of perceptual cues on product evaluation.

When two brands with different product portfolios develop a joint product, consumers perceive such a co-branded product as a composite concept. A composite concept is a combination of two categories referred to as a head and a modifier category (Wisniewski 1996, 1997). Park, Jun and Shocker (1996) studied the influence of combining conceptual cues on the consumers' perception of a co-branded product and found that respondents associated it more with the brand mentioned first (i.e., the header) than the brand mentioned last (i.e., the modifier). Thus, consumers perceive an asymmetry between the brands.

Besides the conceptual cues studied by Park et al. (1996), perceptual cues may also influence perceptions of asymmetry. Gregan-Paxton, Hoeffler, and Zhao (2005) examined how a single perceptual cue (i.e., a cell-phone or a PDA picture) and a single conceptual cue (i.e., a cell-phone or a PDA label) influenced the consumers' classification of a composite concept (e.g., combination of a PDA and a cell-phone). Their results showed that participants based their categorization on the perceptual cue rather than the conceptual cue.

Although these last results are relevant for the categorization literature, the before mentioned results do not necessarily apply to co-branded products. Gregan-Paxton et al. (2005) have not used any brands in their study, although a brand can form a relevant cue in itself (Boush and Loken 1991). In addition, the perceptual information of Gregan-Paxton et al. (2005) was similar to an existing product without any modification (e.g., it looked like a regular cell-phone). Co-branded products generally do not look exactly similar to an existing product of one brand, but are a modification of that product. This modification is achieved through the addition of design and/or brand elements of the other brand, creating a perceptual header-modifier relationship.

Here we compare the influence of combining perceptual cues to that of combining conceptual cues on perceptions of asymmetry between brands and on consumer evaluations of the co-branded product. For this purpose, we created an advertisement for a new co-branded moisturizing acne-control face-wash. This product combines the attributes of moisturizers (Nivea) and acne-control products (Clearasil) into a single product.

Method

The experiment used a two (combination of perceptual information more similar to Clearasil or Nivea) by two (combination of conceptual information more similar to Clearasil or Nivea) between subjects design. Based on this design we created four different advertisements. The relevant perceptual and conceptual cues were determined through a series of pre-tests. The combination of conceptual cues was similar to that used by Park et al. (1996) (e.g., "Clearasil acne-control face-wash with Nivea moisturizer"). A product designer created the perceptual cues: a thin white tube with blue graphics (more similar to Nivea), and a robust light- and dark blue tube with red graphics (more similar to Clearasil). The logo of the brand more similar to the perceptual information was visually superimposed over the logo of the other brand, imitating the conceptual header-modifier effect.

Our sample consisted of 107 women between the age of 14 and 25 years ($M=17.9$), derived from the target population. Our dependent, perceptions of asymmetry between brands, was measured by three pre-tested items: "which brand does the product belong to more", "to which brand is the product more related", and, derived from Park et al. (1996), "which brand is more associated with the product" (7-point scale ranging from 'mostly Nivea' to 'mostly Clearasil', $\alpha>0.8$). A two item 7-point scale measured product evaluation (Park et al. 1996). Finally, we controlled for familiarity, preference for one of the brands, relevance of 'moisturizing' and 'acne-control' for the target group, brand relevance during the purchase decision, and attitude toward the package.

Results

Perceptual information influences the perception of asymmetry between the brands ($F=78.63, p<.001$). The brand that is most similar to the perceptual information dominates. However, conceptual information has no influence on the perception of asymmetry ($F<1, NS$). Perceptual information also influences product evaluation ($F=6.61, p<.02$), with the perceptual information similar to Nivea more positively evaluated. Mediation analysis (Baron and Kenny 1986) shows that perception of asymmetry fully mediates the effect of perceptual information on product evaluation. Adding the control variables as covariates does not change these results.

Discussion

Gregan-Paxton et al. (2005) found that perceptual information influences categorization rather than conceptual information. However, they did not examine whether consumers perceive a possible asymmetry between the parts of a composite concept. We did, and we found that only perceptual information influences the perception of asymmetry in a co-branded product. Our findings also add to current co-branding literature, as this literature stream has only focused on the influence of conceptual information on evaluation (Park et al. 1996). We found that the consumers' perception of asymmetry mediates the effect of perceptual information on product evaluation. Thus, a co-branded product is differently evaluated when a particular brand is dominant through the product's visual appearance.

Previous categorization studies that investigated the simultaneous use of conceptual and perceptual information examined synthetic non-product stimuli (e.g., drawings with fictitious category labels) (Medin, Wattenmaker, and Hampson 1987; Yamauchi and Markman

2000). As a consequence of using synthetic stimuli, participants had to learn category membership during the experiment. Participants did this by combining both information sources offered. Thus, the independent influence of perceptual and conceptual information was difficult to assess. In contrast, we used familiar and discriminative conceptual and perceptual information, making the distinction between the influence of these cues on perceptions of asymmetry possible.

According to Gregan-Paxton et al. (2005) conceptual information becomes more important when perceptual information is less familiar. As we used both implicit and explicit perceptual and conceptual information it may be interesting to study the use of only implicit perceptual information (e.g., showing design elements of the brands without logos). It may be that when perceptual information is less explicit, consumers will rely more on conceptual information. Firms may thus be better able to influence the perception of asymmetry by adapting certain elements within the perceptual information, and thereby influencing product evaluation.

Transfer of Value from Decision Interruption

Mathew S. Isaac, Northwestern University, USA

C. Miguel Brendl, Northwestern University, USA

Imagine a shopper whose cell phone rings while she is in the middle of choosing between two pairs of shoes at a department store. In consumption contexts like this one, purchase decisions are often temporarily delayed by unexpected and irrelevant interruptions. From a psychological standpoint, there is considerable evidence that decision interruption, and goal interruption more broadly, alters affect, attitudes, and choice. For example, Liu (2008) demonstrated that interruptions can impact the relative valuation of items in a choice set by shifting one's focus from feasibility to desirability of the potential options, thereby impacting choice itself. Our research contributes to the literature on goal interruption by providing the first empirical demonstration that the interruption and subsequent resumption of a decision task also affect the *value* placed on the chosen object.

Two opposing forces are activated when a decision, task, or goal is interrupted. On the one hand, an interruption generates negative feelings, such as annoyance and anxiety, and inhibits task performance since an impediment has been placed in front of an active goal (Bailey and Konstan 2006; Schiffman and Greist-Bousquet 1992; Schuh 1978). On the other hand, an interruption seems to be followed by a positive motivational force that increases recall (Zeigarnik 1927), resumption of the interrupted activity (Ovsiankina 1928), and valuation of the interrupted task (Cartwright 1942). It remains an open question as to when each of these forces is likely to dominate. Nelson, Meyvis, and Galak (working paper) recently found that participants watching an enjoyable television program evaluated the program more favorably when it was interrupted by commercials as compared to participants who viewed the program without interruption. The authors proposed a novel positive consequence of interruption, namely that it prevents hedonic adaptation to a pleasurable event.

Regardless of whether the net value of an interruption is positive or negative, we contend that individuals interrupted during a decision task routinely misattribute the value derived from task interruption to the decision object. There is considerable evidence that decision makers transfer the value created from using a specific decision-making process or strategy onto the outcome that they select. In explaining how value from a process can transfer to an object that is evaluated *after* goal pursuit has concluded, Higgins et al. (2003) proposed the concept of value confusion, claiming that "because people confuse the value experience [of the process or decision strategy] with the value experience of evaluating a subsequent object, they transfer the former to the latter." We argue here that, as a function of task involvement, interruption creates either net positive or net negative value for the decision task. This valuation subsequently spills over onto the chosen decision object.

Research by Wang and Calder (2006) on transportation (a highly analogous construct to involvement) supports our prediction that highly involved individuals will be more sensitive to the negative forces of decision interruption, whereas less involved individuals will be more sensitive to the positive forces of interruption. The authors found that participants who were highly transported by a narrative evaluated advertisements that did not intrude on their transportation experience (i.e. by appearing at the end of a magazine article) more positively than less transported participants. The pattern was reversed if the advertisements intruded on the transportation experience (i.e.

by appearing in the middle of the article). Evidently, participants who were highly transported by the narrative perceived an interruption to the transportation experience as a negative event that became associated with the advertisement. Of note is that Wang and Calder's research focused on evaluations of the interrupting event (the advertisement) rather than the task (the narrative) or a decision object, which may somewhat limit the applicability of their findings to the present research. Nevertheless, we reasonably hypothesize that involvement may moderate whether the positive forces or the negative forces associated with interruption will prevail.

In experiment 1, we attempted to show whether decision interruption would affect choice valuation, using task involvement as a potential moderator. Participants made a choice from a set of baby video monitors (if in the low involvement conditions) or a set of video iPods (if in the high involvement conditions). For half the subjects, this decision task was unexpectedly interrupted for 20 seconds. Stimuli were created such that one option in each choice set was objectively the most attractive and therefore chosen by nearly all participants across conditions. Four dependent variables related to the chosen object were captured after all participants had made a selection: Willingness to Pay (WTP), Satisfaction, Attitude, and Likelihood to Trade. On all four measures, highly involved participants who had been interrupted valued the chosen object (i.e., the selected iPod) less than participants who had not been interrupted. Conversely, participants in the low involvement conditions valued the chosen object (i.e., the selected baby monitor) more if they had been interrupted. A manipulation check confirmed that the experiment's involvement manipulation (the use of video iPods vs. baby monitors) was effective. We acknowledge that the involvement manipulation used in experiment 1 is subject to a host of alternate explanations since iPods and baby monitors differ along many dimensions, including familiarity and level of hedonism/utilitarianism. Nevertheless, our findings provide strong evidence that the effects of decision interruption transfer onto the chosen object, given the differences in valuation exhibited by interrupted and non-interrupted participants. The results also illustrate that interruption can cause spillover of *either* positive or negative affect onto the decision object, thereby raising the question as to when each type of affect will transfer, that is, which factors moderate the value transfer effect.

In subsequent experiments, we attempt to provide more rigorous support for task involvement as such a moderator by varying involvement at the level of the individual and keeping product information constant across participants. Assuming involvement moderates the value transfer effect, we intend to explore *why* increased involvement would cause individuals to be more influenced by the negative forces of decision interruption. Finally, we seek to implicate value confusion as the mechanism underlying the altered valuation of decision objects following an interruption.

The Appeal of Hidden Products

Aaron Brough, Northwestern University, USA

Can hiding a product from view increase its appeal? Normally, marketers aim to increase product visibility. However, this research suggests that products related to recently-fulfilled goals are evaluated more favorably when hidden than when visible, whereas the reverse is true for products relating to active goals. For example, a consumer who is not hungry may prefer food items in opaque packaging rather than transparent packaging, whereas a hungry consumer may exhibit the opposite preference.

Prior research has shown that objects relevant to active goals are evaluated more favorably than those relevant to recently fulfilled, inactive goals (Ferguson and Bargh 2004). The present research identifies an object's perceptual status as a moderator of this effect and suggests that occluding products relevant to fulfilled goals can boost their attractiveness, but occluding products relevant to active goals can decrease their attractiveness.

I propose a two-part explanation for this effect. First, given a limited capacity to attend to objects within the perceptual field, individuals may prefer not to clutter their surroundings with objects that could distract them from the pursuit of active goals. Thus, the adaptive practice of avoiding products related to already-fulfilled goals facilitates focusing on products relevant to active goals. Second,

concealing a product from sight constitutes a form of avoidance. Therefore, obstructing one's view of an object related to a fulfilled goal reduces clutter in the visual field and helps satisfy the motivation to avoid potentially distracting objects. As this motive is satisfied, value is generated that can transfer to product evaluations. Across several studies, I attempt to demonstrate that compatibility between an individual's goal status and a product's perceptual status enhances product attractiveness.

A preliminary study examined how 58 participants differed in their evaluations of the U.S. Postal Service after reading a passage adapted from Horton and Rapp (2003) about a fictional character whose implied goal to walk to the mailbox was either fulfilled or unfulfilled. During the passage, the mailbox either remained visible or was hidden from the main character's view. When the character's goal was fulfilled, participants reported more favorable attitudes toward the U.S. Postal Service when the mailbox was hidden than when it was visible. However, this difference was not found among participants who read the version of the story in which the character's goal was unfulfilled. Because this study was not designed with the above hypothesis in mind, two additional studies were designed to more directly test the notion that products related to fulfilled goals are evaluated more favorably when hidden than when visible.

The first study compares evaluations of hidden products (opaque packaging) to visible products (transparent packaging) when participants have either an unfulfilled or a fulfilled goal to quench their thirst. Of 200 online participants, half were instructed to imagine that they were "extremely thirsty" and the other half were instructed to imagine that they were "not at all thirsty." All participants were then asked to choose between two plastic cups of water—one opaque and the other clear. Whereas the opaque cup was preferred by only 18% of participants in the thirsty condition, it was preferred by 27% of the participants in the not-thirsty condition. Thus, among participants whose goal to quench thirst was inactive, the water was more attractive when it was hidden from their sight by opaque packaging.

Because participants' choices may have been influenced by actual thirst levels, a second study was conducted in the laboratory in which thirst was manipulated. Furthermore, a behavioral measure rather than a self-reported measure was used as the primary dependent variable in the second study. Adopting a procedure similar to that used in Brendl et al. (2005), all participants consumed several salty pretzels upon arriving at the lab. Participants were then assigned to one of three conditions—very-thirsty, moderately-thirsty, or not-thirsty. Participants in the not-thirsty condition drank a full bottle of flavored water; those in the moderately-thirsty condition drank half of a bottle, and those in the very-thirsty condition did not drink anything. Participants who did not finish eating the pretzels or drinking the water were excluded from the analysis. Analysis of self-reported thirst confirmed that the thirst manipulation was successful.

Following the thirst manipulation and a filler task, participants learned about a new energy drink and were told that they would be permitted to sample it. On the desk of each participant were two cups—one opaque and one clear. Participants were instructed to bring one of the cups to the front of the room where they could pour as much or as little of the energy drink as they liked into their cup and drink it. The dependent measure of interest was the amount of beverage they consumed. As predicted, participants in the not-thirsty condition drank more when the beverage was poured into an opaque cup than when it was poured into a clear cup ($M=53.8\text{mL}$ vs. 37.7mL). However, the reverse was true for moderately-thirsty participants; they consumed more of the beverage when it was easily visible in a clear cup than when it was partially occluded in an opaque cup ($M=74.8\text{mL}$ vs. 50.0mL). Not surprisingly, the amount consumed by participants in the very-thirsty condition was higher than the other two conditions and did not differ by the cup into which it was poured ($M=98.5\text{mL}$ (opaque) vs. 94.0mL (clear)).

Judging by consumption, the results of the second study suggest that participants whose thirst-quenching goal had already been fulfilled found the beverage more attractive in an opaque than in a transparent container, but that the opposite occurred for participants with an active goal to quench their thirst. A ceiling effect seems to exist in that once thirst levels reach a certain threshold, the container makes no difference in the attractiveness of the beverage.

Together, the evidence from these studies suggests that hiding a product from view can increase its appeal to consumers when that product is related to a recently fulfilled goal. By helping consumers avoid objects that might distract them from active goals, the act of visually concealing a product can actually enhance its attractiveness.

The Interaction Effect of Mood and Price Level on Purchase Intention

Fengyan Cai, The Chinese University of Hong Kong, China

Felix Tang, The Chinese University of Hong Kong, China

Jian-Min Jia, The Chinese University of Hong Kong, China

Abstract

The present study examines the interaction of price level and mood on purchase intention. It integrates the mood congruency argument and mood regulation argument of affect influence by specifying how consumers' affective state influences their interpretation of price as a mood lifting, mood threatening, or neutral cue, which in turn guide their behavior. The experiment demonstrates that consumers in positive mood have higher intention to purchase a regular-priced product than consumers in negative mood, consistent with

the mood congruency explanation. However, the reverse is true when the price of the product is high, as predicted by the mood regulation explanation.

Extant literature on impulsive and compulsive consumption demonstrated that people in positive or negative mood are more likely to buy than people in neutral mood (e.g., Faber and Christenson 1996). On the basis of the theory about mood congruency and mood regulation, the present study explores the interaction effect of price level and mood on consumers' purchase intention.

In terms of the impact of mood on behavior and judgment, there are two kinds of arguments. The mood congruency argument predicts that people in positive mood are more likely to believe the environment is benign and in turn more likely to do something (e.g., consumption), whereas negative mood is expected to lead to a less favorable evaluation of the environment, which inhibits actions (e.g., don't buy anything) (Bower 1981; Andrade 2005). The mood regulation argument states that people try to regulate their feelings to maximize their hedonic state (Isen 1987). It predicts people in positive mood will try to maintain and protect their positive mood, whereas people in negative mood are motivated to improve their mood. These motivations are contextual, stored in memory, and cannot be activated without situational cues (Vallerand 2004).

Price is an important marketplace cue for consumers (Gijbrecchts 1993). On one hand, it represents the amount of money consumers must give up to get the product (Volckner and Hofmann 2007). On the other hand, many consumers use price as a quality cue (Erickson and Johansson 1985). Thus, high price can be seen positively (good quality) and negatively (high cost). In the present study, we argue that whether consumers perceive high price as a good quality cue or as a high cost cue may depend on their incidental affective state. Specifically, since people in negative mood usually believe that shopping especially buying hedonic product will make them feel better (Faber 1992; Rook 1987), high price may be regarded as good quality and treated as a mood lifting cue; conversely, people usually avoid spending too much money on products they want to buy instead of products they should buy as such consumption may make them feel guilty later (Okada, 2005), in this respect, high price may be perceived as high cost and treated as a mood threatening cue. Interpreting the high price level as a signal of good quality product acts as a mood lifting cue; likewise, interpreting the high price level as high cost acts as a mood threatening cue. According to mood regulation argument mentioned above, people in positive mood have the motivation to protect their positive mood and people in negative mood try to improve their negative affective state, thus people in positive mood may be more sensitive to mood threatening cue (high cost), while people in negative mood are more likely to pay attention to the mood lifting cue (good quality). Therefore, we propose *H1a: For a high price product, people in negative mood are more likely to buy than those in positive mood.*

As utilitarian product with a regular price does not lift or threaten consumers' mood, both mood lifting cue and mood threatening cue are absent when a product's price is regular. Andrade(2005) demonstrated that people in positive mood are more likely to try a product than those in negative mood when mood lifting cue or mood threatening cue is absent. Based on mood congruent argument and Andrade's (2005) findings, we derived our *H1b: For a product with regular price, people in positive mood are more likely to buy than those in negative mood.*

Previously, we argue that people in positive mood perceive high price as a mood threatening cue while people in negative mood perceive high price as a mood lifting cue, so people in negative mood should perceive the quality of high-priced product better than those in negative mood do, which in turn influence consumers' purchase intention. Thus, we expect a mediation effect of perceived quality. That is, *H2: The interaction effect of mood and price on purchase intention is mediated by perceived quality.*

One hundred students participated a 2 (price level: high vs. regular) x 2 (mood: positive vs. negative) between-subject experiment for extra course credit. Mood manipulation method and experiment procedure were adopted from Zhang and Fishbach (2005). The stimulus was a ball pen, pretested and priced at RMB10 (approximately US\$1.20) in the high price level condition and RMB3 (approximately US\$0.40) in the regular price level condition. Perceived quality and purchase intention were the dependent variables. The manipulation of mood was successful ($F(1,98)=20.834, p<0.01; M_{\text{positive}}=5.76, M_{\text{negative}}=3.37$) and all scales were reliable, with Cronbach level above 0.70. The results of a two-way ANOVA showed that the interaction effect of mood and price level on purchase intention was significant ($F(1,96)=24.3, p<0.01$), the direction accorded with our expectation, and the simple main effects were also significant (Regular price condition: $M_{\text{positive}}=4.07, M_{\text{negative}}=3.11$; High price condition: $M_{\text{positive}}=2.91, M_{\text{negative}}=4.23$). Therefore, our H1a and H1b were supported. The results of hierarchical linear regression showed that the significant impact of the interaction term (Price*Mood) on purchase intention ($b=0.897, t=3.00, p<0.05$) became non-significant when perceived quality was added ($b=0.740, t=1.74, p>0.05$), supporting our H2.

This study contributes to the literature in two ways. Firstly, it extends existing literature about the impact of mood on behavior by demonstrating that it is consumers' perception of external cue instead of the cue per se that lead to different impact of mood on consumers' decision. Secondly, the evidence suggests that people in negative mood are more likely to buy expensive utilitarian product and people in positive mood tend to buy relatively cheap utilitarian product.

Hear Is the Thing: The Influence of Sound-to-Writing Correspondence on Brand Name Processing

David Luna, City University of New York, USA
Marina Carnevale, City University of New York, USA
Dawn Lerman, Fordham University, USA

Abstract

Consumer research suggests that the sound of a brand name may influence consumer preferences. We explore how consumer auditorily process novel, non-word brand names and whether spelling the brand name correctly (e.g., when typing the name on a web browser) affects brand evaluations. Building on psycholinguistic research, we present the results of two empirical studies that investigate the underlying mechanisms of sound and sound-to-writing processing. Both phonetic and semantic associations to the auditorily presented brand name can lead to greater spelling accuracy.

A brand name may be a word or a non-word (i.e., a string of sounds that doesn't exist as a meaningful word, like Google). Consumer research has investigated some aspects of how brand sounds influence brand evaluations (e.g., phonetic symbolism; Lowrey and Shrum 2007; Yorkston and Menon 2004). However, little is known about how consumers process and later use sounds more generally. Moreover, the stimuli typically used to explore the effects of sound on evaluations have been visual, rather than auditory.

We present the results of two studies that explore how brand names are auditorily processed and how transcribing the auditory stimuli affects brand evaluations. Accurate spelling of a brand name presented auditorily (e.g., radio ads) is relevant because of the potential influence of correct spelling on the ability to find the brand (e.g., either online or at stores).

English is said to be a "deep" language, in which phonemes (i.e., sound representations) predominantly lack of a one-to-one relationship with graphemes (i.e., a letter or group of letters that represent a phoneme). The sound-to-writing correspondence of a word determines its level of consistency (Ziegler, Stone, and Jacobs 1997). For example, the phoneme /_@f/ corresponds to different graphemes, such as aff and alf. Therefore, the words staff and half have *inconsistent* sound-to-spelling mappings. Conversely, some phonemes (e.g., /_@g/) are represented by only one grapheme, so they have *consistent* mappings (ag), used in different words (e.g., tag, rag). This is an important distinction because it affects the process by which sound is transcribed.

There are two main routes to spelling (Coltheart 1981; Morton 1979). Through the direct route, that typically applies to frequently encountered words (Houghton and Zorzi 2003), individuals access the spelling of a word by retrieving semantic/phonological representations of the word stored in memory. When a non-word or an unfamiliar word is met, however, an indirect route occurs—that is, each of the phonemes is individually transcribed into its corresponding grapheme. Therefore, for novel non-word brand names, the consistency of a sound may facilitate their transcription by decreasing its ambiguity.

Non-word spelling might lead, however, to the use of both routes. For example, in cases of lexical priming (a word that sounds like the non-word is presented before the non-word), individuals can relate the non-word to one for which they already have a phonological representation, so the direct route could be used in addition to the indirect route (Cuetos 1993; Seymour and Dargie 1990).

In this research, we suggest that brand evaluations may be affected by the process of spelling the brand name. Successfully solving the spelling task may positively affect brand evaluations so the elaboration consumers engage into stimulates interest. This, however, should only happen for ambiguous (i.e., inconsistent) non-words.

Study 1

Method. Eighty-nine undergraduate business students participated in the study. We designed a 2 (consistency: consistent or inconsistent) x 2 (spelling prime: prime or no prime) between-subjects experiment. Each participant was exposed to eight audio clips, and, after each of them, had up to three trials to spell the brand name correctly. The sum of the number of trials left unused by each participant was utilized to assess one of the dependent variables: accuracy of spelling. Following the spelling task, the other dependent variable, brand evaluation, was measured through a seven-item scale.

Each audio clip provided the following information: product/service featured in the ad, last words in the website ad, and brand (website) name. We manipulated consistency of the brand names using the norms provided by Ziegler et al. (1997). The priming condition consisted of having the last word in the website ad prime (e.g., ..remove the tag) or not prime (e.g., ..remove the paint) the intended spelling for the monosyllabic, non-word brand name that immediately followed (e.g., Pag.com).

Results. Results showed a significant interaction of priming and consistency on spelling accuracy ($F(1, 88)=13.60, p<.001$). For consistent brands, respondents were able to use the direct route to spelling regardless of priming condition. However, for inconsistent brands (which initially inhibit the direct route to spelling), priming had a positive effect on spelling accuracy ($F(1, 85)=20.05, p<.001$).

Interestingly, spelling accuracy influenced brand evaluations in the inconsistent condition ($F(1, 49)=3.94, p<0.05$), but not in the consistent condition ($F(1, 38)=.45, p=0.505$). Therefore, only when the direct route to spelling was inhibited (inconsistent non-words), evaluations were enhanced by guessing the correct spelling.

Study 2

Study 2 examines how, when the direct route to spelling is inhibited, increased semantic elaboration can lead to greater spelling accuracy and higher evaluations. We expect that, for inconsistent brands, semantic elaboration will only enhance brand evaluations when the direct route is facilitated by priming.

Method. Seventy-five undergraduate students participated in the study. We designed a 2 (Semantic elaboration: elaboration or no elaboration) \times 2 (spelling prime: prime or no prime) between-subjects experiment. Semantic elaboration was operationalized by changing the word used in the priming sentence to be congruent (e.g., fuel) or incongruent (e.g., staff) with the product category (e.g., cars). We used study 1's inconsistent brand names. The procedure and measures were the same as in study 1.

Results. Results showed that both elaboration and spelling prime had significant main effects on spelling accuracy ($F(1, 74)=4.54, p<0.05$ and $F(1, 74)=18.45, p<.01$, respectively). Those effects were qualified by a significant interaction of priming and elaboration on brand evaluations ($F(1, 74)=5.75, p<0.05$). As expected, when primed, participants in the elaboration condition had higher brand evaluations than those in the no-elaboration condition ($F(1, 74)=4.10, p<.05$). In the no-prime condition, however, there was no effect of elaboration on brand evaluations ($F(1, 74)=1.816, p=.18$). Finally, spelling accuracy proved to be a significant predictor of brand evaluations ($F(1, 74)=5.99, p<0.05$).

Conclusion

By exploring the underlying mechanisms of sound-to-writing processing, we develop a greater understanding of how consumers process brand names auditorily and how can these processes be facilitated and affect brand evaluations.

The Influence of Service Employee Characteristics on Customer Choice and Post-Choice Satisfaction

Nancy J. Sirianni, Arizona State University. USA
 Iana Castro-Nelson, Arizona State University. USA
 Andrea C. Morales, Arizona State University. USA
 Gavan J. Fitzsimons, Duke University. USA

Abstract

Interaction with a frontline employee is common in most retail and service encounters in which customers are looking to make product and service choices. During these customer-employee interactions, customers are exposed to service employees' personal characteristics, such as their displayed creativity, which can influence consumer behavior. The proposed research seeks to develop an understanding of how service employee characteristics influence customer choice and post-choice satisfaction.

Frontline employees are the store associates, sales floor personnel, and other service workers who personally interact with customers in retail and service encounters (Ellinger, Almadag, and Ellinger 2007). Past research notes the importance of these employees in their interactions with customers, as these workers can have a powerful impact on customers' perceptions of the brand and the firm, and on customers' overall satisfaction with the service encounter and the firm (Czepiel, Solomon, and Surprenant 1985; Zeithaml, Berry, and Parasuraman 1996; Zeithaml, Bitner, and Gremler 2006).

Each and every action by frontline employees can contribute to the total experience of customers (Pine and Gilmore 1999), including employee-demonstrated attitudes and behaviors, which can influence customers' perceptions of the service rendered (Bowen and Schneider 1985). In sum, the literature has demonstrated that customer-facing employees' actions play a pivotal role in shaping customers' experiences during the service encounter, but outside of studies of employee attractiveness (Reingen and Kernan 1993), little is known about how service employees' appearances can influence customer preferences and behavior during these interactions.

For example, does a person choosing to redecorate his or her house prefer a creative- or conservative-looking interior designer? Does having a creative-looking interior designer lead the person to make more creative choices and, if so, how high is the person's post-choice satisfaction? Our research seeks to address these questions.

Past work in psychology and marketing has provided compelling evidence that individuals can be primed to behave in certain ways. Priming studies are concerned with the temporary activation of an individual's representations and how these internal readinesses interact with environmental information to produce perceptions, evaluations, motivations and social behavior (Bargh 1997). Our proposed research seeks to extend priming theory by investigating how service employees' appearances can influence customers and their choices during service encounters and understanding how these choices are evaluated by customers.

Pre-tests-Method and Results

Three pre-tests were conducted to determine how respondents would evaluate customer-facing employees on five dimensions, some of which were derived from the services literature, including competence, internal personality factors, external personality factors, creativity and conservativeness. In pre-test I, respondents were asked to evaluate photographs of employees on the five dimensions mentioned above. In pre-test II, respondents were asked to evaluate job titles (for example, interior designer) on the same five dimensions. Based on the results of pre-tests I and II, photographs and job titles were chosen to be tested together. In pre-test III, participants were asked to evaluate the employee in the photograph based on the job title given. The conditions included photographs and job titles that were matched (creative photo and creative job title) and photographs and job titles that were mismatched (creative photo and conservative job title). Participants were also asked to indicate the likelihood that they would hire the employee in the photograph to perform the job title specified.

The results from the pre-tests indicate that customers evaluate service employees differently based on whether they look creative or conservative. Participants were more likely to hire the service employees in the conditions where the photograph and job title matched (creative photograph and creative job title or conservative photograph and conservative job title) than in the conditions where the photograph and job title did not match.

Study 1-Method and Preliminary Results

The goal of the pre-tests was to develop an understanding of how customers would evaluate service employees on five key dimensions (competence, internal personality factors, external personality factors, creativity, and conservativeness) and whether the employees' appearance (creative or conservative) would influence the customers' likelihood to hire that employee. Study I was designed to address the question: Do employee characteristics (for example displayed creativity) affect customer choice and, if so, how satisfied are customers with those choices?

Data were collected from a convenience sample of 271 students enrolled in an introductory Marketing course at a large southwestern university. Participants were randomly assigned to one of two conditions: creative or conservative. The study employed the use of a confederate who was either creatively dressed or conservatively dressed, based on the condition. The confederate provided participants with the cover story that she worked for a major office supply company that was seeking customer feedback on one of its products. Participants were told that they would be given a pen as a gift for their participation and that they could select the color of the pen. Participants were presented with both creative and conservative pen color choices and were asked to make an actual choice.

After completing a number of filler tasks, participants answered questions regarding their overall evaluations and quality of the pen, satisfaction and regret with their pen choice, evaluations of the service employee (confederate), their own need for uniqueness, and their own chronic creativity motivation.

To check that the confederate portrayed the desired characteristic, participants completed an evaluation of the confederate on the five dimensions discussed above. Participants in the creative condition rated the confederate as more creative and less conservative than participants in the conservative condition, who rated the confederate as less creative and more conservative. The differences in scores were statistically significant at the $p < .05$ level.

The initial analysis focused on the key dependent variable of pen choice. While there were no significant differences in pen choice between the creative and the conservative conditions, a large number of the participants (32 percent) chose a creative-colored pen in the creative conditions. Further analysis will be conducted for post-choice satisfaction and regret.

Discussion

Our initial findings shed light on the importance of service employee appearances, offering a fresh perspective that customers have preferences regarding the personal characteristics of the frontline employees with whom they interact and that these characteristics can potentially influence customer choice during customer-employee service encounters. Our future work in this area will extend this investigation to include post-choice satisfaction and regret to further understand how these choices are evaluated after they are made. The

results of our study may have strong managerial implications, given that customers may not be as satisfied with their choices when these choices were influenced by the employees' characteristics, and their reduced satisfaction with the choice could influence their overall satisfaction with the experience and the firm.

The Consequences of Retailer vs. Media Communication About the Use of Intrusive Marketing Practices on Customer Attitudes, Satisfaction, Trust and Loyalty

Marco Lalos, University of Lausanne, Switzerland

Ghislaine Cestre, University of Lausanne, Switzerland

This study is encompassed in a broader research that investigates the boundaries of privacy and intrusiveness and differentiates their specific influence on consumer attitudes and customer-firm relationship constructs. Privacy has been extensively studied (Culnan, 1993; Dahl, Manchanda, & Argo, 2001; Hoffman & Novak, 1999; Phelps, Nowak, & Ferrell, 2000; White, 2004). Despite confusions between the two concepts by a number of authors, privacy can be defined as the perceived control over one's personal information and control over unsolicited presence of others (Goodwin, 1991), and intrusiveness as the interruption of a process (Li et al., 2002). Intrusiveness is considered to have deep implications on customer-firm relationships and in advertising (Aaker & Bruzzone, 1985; Edwards, Li, & Lee, 2002; Ha, 1996; Wang and Calder, 2006).

This study focuses on the impact that communication about the use of a data collection method, perceived to be intrusive, may have on consumers' attitudes, satisfaction, trust and loyalty. In this study, intrusiveness is contextualized in a retail environment, following the work of Larson, Bradlow and Fader (2005) and Klabjan (2005). The retail context provides flexibility to manipulate compensation, communication, and intrusiveness. Intrusiveness is operationalized in the form of a data collection method based on RFID⁷ technology, earlier findings having revealed that RFID elicits high levels of perceived intrusiveness. Due to RFID's reported salient effect on consumers, it can be expected that individuals informed about the presence of such intrusive data collection method in the retailing environment, will report less favorable attitudes and satisfaction concerning their shopping experience, than if unaware of RFID's presence.

H1: Individuals' attitudes and satisfaction toward the retailer are less positive when information about the existence and purpose of an intrusive consumer data collection method is provided by the retailer, than when no information is provided

Building on the social exchange theory (Emerson 1981; White, 2004), it can be argued that intrusiveness effect can be outweighed (moderated) by an expected benefit, such as a compensation given to consumers. Individuals were shown to value compensations differently (Davis, Bagozzi and Warshaw, 1989), thus, different compensation types can be expected to arouse differently attitudes and satisfaction. Three types of compensations, economic, functional and hedonic, are defined in the literature (Gefen, Karahanna, and Straub, 2003; Moon and Kim, 2001). Younger individuals were shown to be more sensitive to economic rewards than more mature individuals, who may seek to experience diversity and service quality (Venkatesh et al. 2003). Economic compensation was thus retained in this study, based on a student sample, as it is expected to outweigh perceived intrusiveness, positively affecting attitudes and satisfaction.

H2: Individuals' attitudes and satisfaction toward the retailer are unaffected by information provided by the retailer about the existence and purpose of an intrusive consumer data collection method, when economic compensation is provided

⁷Radio Frequency Identification

Misleading communication can be perceived by consumers as deceiving (Darke & Ritchie, 2007). Hiding the purpose or existence of data collection practices will likely be perceived by consumers, upon awareness, as misleading, and may elicit feelings of irritation or betrayal, thus generating lower levels of trust and loyalty. Conversely, if the retailer openly communicates, consumer's levels of trust and loyalty may remain unchanged:

H3: Individuals' level of trust and loyalty remain unaffected when the retailer communicates openly about its data collection practices; it is negatively affected when the communication is made by a third party (media)

A scenario-based experiment was carried out among a group of 79 students, to test the hypotheses. Portrayed goods and store type were chosen to be familiar to respondents. To assess the effects of communication / no communication (H1), and of compensation (H2) on attitudes and satisfaction, respondents were placed in one of two scenarios: either the retailer informed them about the use of RFID (placed on shopping carts and product packagings), or there was no information provided. Three types of compensations (economic, functional or hedonic) were proposed by the retailer as means to arouse their attitude and satisfaction positively. To test retailer-induced vs. media-based communication on consumers' trust and loyalty (H3), respondents were placed in one of two scenarios: either the retailer informed them about the use of RFID, or they were later informed by the press about it. Loyalty and trust in the retailer were measured at different times with one hour interval. Validated Likert scales were used to measure every construct, reporting satisfactory Alphas. Manipulation checks were successful and intrusiveness was controlled: no RFID ($M=4.07$, $SD=1.47$) vs. RFID ($M=5.12$, $SD=1.21$, $F(1,40)=6.29$, $p=0.016$). ANOVAs and paired-sample t-tests were run to test the hypotheses.

H1 is supported. The averages of the three attitudes (under economic, functional and hedonic compensation) were calculated, lower attitudes toward the retailer under the retailer-communication scenario ($M=4.30$, $SD=1.42$) than under the no-communication scenario ($M=5.25$, $SD=1.17$, $F(1,40)=5.48$, $p=0.024$) were confirmed. Similarly, lower levels of satisfaction were confirmed under the retailer-communication scenario ($M=4.06$, $SD=1.23$), than under the no-communication scenario ($M=5.02$, $SD=1.13$, $F(1,40)=6.99$, $p=0.012$).

H2 is supported. No significant attitude change was reported between the no-communication scenario ($M=5.30$, $SD=1.49$) and the retailer-communication scenario ($M=4.66$, $SD=1.73$, $F(1,40)=1.632$, $p=n.s.$). Also, no significant change in satisfaction occurred, despite the communication: no-communication ($M=5.15$, $SD=1.36$); retailer-communication ($M=4.50$, $SD=1.60$, $F(1,40)=1.955$, $p=n.s.$)

H3 is supported. Regarding trust: under the retailer-communication scenario, prior trust ($M=3.77$, $SD=1.32$) is not significantly higher than trust after stimulus ($M=3.66$, $SD=1.18$, $t(20)=0.51$, $p=n.s.$). Under the media-communication scenario, prior trust ($M=4.03$, $SD=1.032$) is significantly higher than trust after stimulus ($M=3.27$, $SD=1.25$, $t(36)=4.40$, $p<0.001$). Regarding loyalty: under the retailer-communication scenario, prior loyalty ($M=4.43$, $SD=1.34$) is not significantly higher than loyalty after ($M=3.92$, $SD=1.48$, $t(20)=1.54$, $p=n.s.$). Under the media-communication scenario, prior loyalty ($M=4.84$, $SD=1.33$) is significantly higher than loyalty after ($M=3.58$, $SD=1.70$, $t(36)=4.98$, $p<0.001$).

This research reveals the dilemma of choosing between disclosing truthfully the use of intrusive data collection methods knowing the impact on attitudes and satisfaction, and deciding not to communicate and bear the risk of a significant decrease in the levels of trust and loyalty should customers learn about the use of intrusive methods from a third party. These results encourage pursuing the research by manipulating new moderating variables over a heterogeneous population.

Is Seeing Believing? Consumer Responses to Opacity of Product Packaging

Sucharita Chandran, Boston University, USA

Rishtee Kumar Batra, Boston University, USA

Benjamin Lawrence, Boston University, USA

Product and packaging design has shown to influence consumer reactions and purchase behaviors (Bloch 1995; Holbrook and Anand 1992; Raghurir and Greenleaf 2006; Veryzer 1993, 1999). Research in visual aesthetics has focused on product shapes and dimensions (Krider, Raghurir, and Krishna 2001; Yang and Raghurir 2005) while one specific characteristic of packaging, its opacity or lack of transparency has received little attention (Dantas et al. 2004). This research addresses this important aspect of packaging design, transparency, which has been neglected in visual marketing research. Three studies investigate if and when transparency in packaging affects consumers' product attitudes and examines trust as a mediating factor.

Study One

Study one was an exploratory study aimed at understanding how packaging of familiar and unfamiliar brands affects consumers' perceived quality, trust, and willingness to pay. This study employed a 2(Brand: Familiar/Unfamiliar) X 2(Packaging: Clear/Opaque) between-subjects design in which 128 participants were asked to evaluate either an opaque package of mouthwash or a comparable clear package manufactured by either Lander's (unfamiliar brand) or Listerine (familiar brand). Subjects were asked how much they would be willing to pay for the mouthwash and then to rate the perceived quality of the product. Next, participants were asked to describe what input they used when making their judgments of quality regarding the mouthwash. Finally, participants answered a series of four questions aimed at gauging their familiarity with the brand and attitude toward the brand. Neither novelty nor attractiveness of the packaging were found to be significant covariates in explaining any of the key dependent measures and were thus not used for further analysis.

With respect to perceived quality, a two-way ANOVA revealed a significant interaction effect between brand and packaging ($F(1,127)=3.85, p=.052$) such that for Lander's mouthwash, participants felt that the mouthwash was of better quality when packaged in a clear bottle than opaque bottle (mean 3.70 versus 3.47) but the opposite was true for Listerine (mean 5.38 versus 5.96). For willingness to pay, a two-way ANOVA also revealed a significant interaction effect between brand and packaging ($F(1,127)=5.41, p<.05$) such that for the unfamiliar brand of mouthwash (Lander's) participants were willing to pay significantly more for a clear bottle (mean=\$3.23) versus an opaque bottle (mean=\$2.73). Interestingly, however, when the brand of mouthwash was familiar (Listerine), there was no significant difference in participants' willingness to pay for clear versus opaque bottles (mean=\$3.72 versus \$4.12). An analysis of participants' open-ended responses indicated that for unfamiliar brands, consumers were skeptical of the contents of bottle of mouthwash where as for a more familiar brand; there was not a sense of distrust due to packaging. Study two further examines the role of trust in the process of forming product attitudes based on packaging attributes.

Study Two

Study two examined the role of product type upon response to packaging design. In this 2(Product: Cough syrup/Toilet Cleaner) X 2(Packaging: Clear/Opaque), between-subjects study, 133 participants rated one of four possible product-packaging combinations along five performance-related dimensions. As in the past study, in order to rule out product attractiveness as an alternative explanation for the findings, two measures were utilized to gauge product attractiveness, but were not found to be significant.

With respect to perceived performance, a two-way ANOVA revealed a significant interaction effect between product and packaging ($F(1,132)=21.11, p=.000$), with all means being significantly different from one another. Participants evaluating the toilet bowl cleaner felt that a transparent package was of poorer quality than an opaque package (mean 1.74 versus 3.87) while for cough syrup, the opposite was true, they felt that a transparently packaged cough syrup was of better quality than an opaquely packaged cough syrup (mean 3.33 versus 2.77). A mediation analysis revealed that trust was a significant mediator in the inference of product quality from product packaging such that for combinations that were inconsistent with expectations (e.g. clear toilet bowl cleaner), participants' trust for the product was significantly lower than conditions in which packaging was consistent with expectations (e.g. opaque toilet bowl cleaner). Given that trust is a mediating mechanism that helps explain the results found in both study one and study two, the next study sought to reverse the effects of study two by enhancing trust in the inconsistent product packaging conditions.

Study Three

Study three was identical to study two in most dimensions. For this study, only the toilet cleaner product category was used, with the goal being to enhance trust in the transparently packaged toilet bowl cleaner and thus enhance ratings of product quality and performance. 89 subjects participated in a between-subjects study in which packaging (clear/opaque) was manipulated as well as the presence or absence of trust-enhancing information (eco-friendly claims made/no claims made). To increase the level of trust in the

inconsistent toilet bowl cleaner package a claim was made that the packaging reflects an attempt to be environmentally friendly. The dependent measures taken in this study were identical to those in study two, however, additional measures of participants' eco-friendliness were taken to rule out environmental consciousness as a possible confound.

The results of study three support the claim that trust is a mediating mechanism in evaluating product packaging elements. We found a significant interaction between the presence of trust-enhancing eco-friendliness claims and packaging ($F(1,88)=15.47, p=.014$) such that when eco-friendliness claims were not made regarding the product packaging, participants preferred the opaque toilet bowl cleaner significantly to the transparent toilet bowl cleaner in terms of product quality (mean 3.48 versus 1.69) but when eco-friendliness claims were made, participants did not evaluate the product qualities as being different from one another (mean_{opaque} 3.54 versus mean_{clear} 3.45). Again, trust was found to be a significant mediator in this process. Though there seems to be clear preferences for product packaging across product categories, these preferences can be shifted when information is provided that will enhance the level of trust in non-traditional packaging.

In light of our significant findings related to packaging transparency and its influence on trust, willingness to pay, and perceived quality, product designers would be well served in contemplating which type of packaging in what contexts is appropriate. Going forward we would like to further investigate the process in which transparency influences attitudes toward products. For instance, when considering organic products the transparency of packaging may be a significant factor in relating authenticity and perceptions of purity. While with other product categories transparency may negatively influence quality perceptions, for example when the package contains noxious chemicals such as bleach or when consumers prefer to avoid visual evidence of efficacy.

The Perception of Family Brand Entitativity and Varieties of Family Brands

Joseph W. Chang, Vancouver Island University, Canada

Yung-Chien Lou, National Chengchi University, Taiwan

Conceptualization

Entitativity is defined as the degree to which a social aggregate is perceived as the degree of "being entitative" and "having the nature of an entity" (Campbell 1958, p. 17). Perceived entitativity has become the default concept of group perceptions for emerging research exploring the antecedents of perceived entitativity, as well as the organization, formation, function (or use), maintenance and revision of stereotypes (e.g. Fiske 1998). The antecedents of group perceptions, including interaction, importance, outcomes, goals, similarity, duration, size, and permeability (Lickel, Hamilton, Wierzchowska, Lewis, Sherman and Uhles 2000), are suggestive cues for the perceptions of group coherence and entity, which lead to different routes of mental processes. Coherent groups are perceived as high entitative groups, whereas incoherent groups are perceived as low entitative groups. The perceived entitativity then affects the following psychological mechanisms of the formation of mental representation (stereotyping), trait attribution (or endowment) to group members, and subsequent group judgments (Crawford, Sherman, and Hamilton 2002). On-line (or integrated) processing is activated if the groups are perceived as high entitative groups, whereas memory-based (or retrospective) processing is elaborated if the groups are perceived as low entitative groups (McConnell, Sherman, and Hamilton 1997). As the cognitive processes underlying evaluations are common (Johar, Maheswaran, and Peracchio 2006; Loken 2006), it is expected that at least some influences on the perception of social groups apply also to the perception of family brands. The classification about social groups may be similar to the classification about family brands. Perceived entitativity may activate different cognitive processes and result in different evaluations about family brands. However, this concept has not yet been implemented to family brand evaluations. Therefore, this research examines the applicability of the eight entitativity measures in group perceptions on family brand evaluations.

Method

The eight measures of perceived entitativity are utilized to measure 40 prestigious family brands (e.g., Coca-Cola, Microsoft, IBM, etc.) selected from the Top 100 Global Brands of BusinessWeek (2006). Around 70 students (200 valid cases expected) participated in

this study and received a reward of course credits for the participation. Participants are undergraduate business students at a university in North America. In order to ensure the quality of responses, voluntary participants were invited to a laboratory where the data were collected with one-on-one basis. To avoid systematic responding biases, participants were randomly assigned to one of the nine experimental groups with different orders of family brand names (three different orders) and measures (three different orders). In addition to a questionnaire of twelve pages, a 40-page booklet (one brand on a page) with color pictures of brand extension portfolios and brand logos of 40 popular family brands in consumer goods industries was provided for the evaluations. All the participants rated the 40 family brands on the extent to which each qualified as a family brand (entitativity measure). Participants rated each family brand on a 9-point scale ranging from 1 (not a family brand at all) to 9 (very much a family brand) for the entitativity measure and then rated the same 40 family brands on the eight properties. In each case, after being given a definition of the property, participants rated the family brands on the 9-point scale. It took about 40 minutes to go through the rating process.

Results

Descriptive analyses were performed for the mean ratings of each family brand, which yielded a range of mean ratings from 4.41 to 7.56. This evidence indicates that participants did see substantial variation among the family brands. *Correlational analyses* were conducted to identify how the properties of these family brands were related to each other and to entitativity. The results indicated that seven properties, except permeability (as expected), were positively correlated with entitativity. Moreover, size was inter-correlated with five properties (duration, importance, interaction, and similarity); goals and importance were inter-correlated with four properties (duration, outcomes, importance, and similarity; duration, interaction, size, and goals); duration, outcomes, and similarity were inter-correlated with three properties; and permeability was inter-correlated with only two properties. Furthermore, *regression analyses* were performed to examine the relationship of these properties to entitativity. The results indicate that goals ($\alpha=.38$) and duration ($\alpha=.36$) were the most influential predictors of entitativity, followed by interaction ($\alpha=.22$), outcomes ($\alpha=.19$), importance ($\alpha=.15$), size ($\alpha=.15$), permeability ($\alpha=.14$), and similarity ($\alpha=.06$). These eight properties were highly correlated with the entitativity measure ($R=.88$) and account for the large majority ($R^2=.77$) of the variance in entitativity ratings. In conclusion, these results indicated that several of these variables were strongly correlated with entitativity and accounted for a substantial portion of the variation in entitativity, which parallels the finding for social groups (Lickel et al. 2000). However, the pattern of inter-correlation acrossing properties for family brand evaluations is slightly different from the pattern for social groups which showed five properties (interaction, importance, goals, outcomes, and similarity) were highly inter-correlated. Finally, *k-means cluster analyses* were conducted specifying between three and six clusters to examine whether there were different types of family brands defined by unique patterns of property ratings, as well as whether these different types of family brands differed in entitativity. A 40 x 9 matrix in which each cell contained the average rating of a single family brand on a single property was created by averaging the 70 participants' ratings of each of the family brands for each of the nine properties. Clusters were then generated on the basis of the eight properties (entitativity exclusive). The five-cluster solution was found to be the most stable solution for the interpretation. Cluster 1 family brands (e.g., American Express) are small and have high levels of goals and similarity. Cluster 2 family brands (e.g., GE and Panasonic) are low in similarity, interaction, and outcomes, but of moderate duration and size. Cluster 3 family brands (e.g., Disney) are high in duration and size, but low in outcomes and similarity. Cluster 4 family brands (e.g., AVON) are relatively low in outcomes, size, importance, and interaction. Cluster 5 family brands (e.g., Toyota) are high in duration, goals, and similarity. Cluster 3 family brands are the highest in entitativity followed by Clusters 1, 2, 5, and 4. In conclusion, the results indicated that, as with social groups, properties of perceived entitativity are effective antecedents that may cluster family brands into groups, which subsequently elaborate different cognitive processes for family brand evaluations.

The Effects of Nine-ending Prices and the Need for Cognition in Price Cognition

Shih-Chieh Chuang, Chung Cheng University, Taiwan

Chaang-Yung Kung, Chao-yang University of Technology, Taiwan

Yin-Hui Cheng, National Penghu University, Taiwan

Shu-Li Yu, Chaoyang University of Technology, Taiwan

The use of nine-ending prices is popular among retailers. According to a previous report, 30% to 65% of all prices end in the digit nine, and evidence from an econometric analysis of UPC retail scanner data and surveys of retail price practices showed that consumers perceive nine-ending prices to be significantly lower than prices that are just one cent higher (Stiving and Winer, 1997; Schindler and Kirby, 1997; Thomas and Morwitz, 2005). This issue has attracted the interest of researchers since as early as 1936 (Ginzberg, 1936). More recently, Anderson and Simester (2003) suggested that the last digit of a price has a significant impact on receiving revenues, even though nine-ending prices change the price of products by just one cent.

Although monetary promotions such as nine-ending prices cause consumers to purchase more, some research has suggested that the effect of such prices depends on the amount of attention that consumers pay to the decision to purchase (Schindler and Warren, 1988; Zaichkowsky, 1988). The amount of attention is likely to be affected by a variety of factors, including consumer involvement, motivation, and the opportunity to process price information. Another important variable that has largely been ignored in the literature is the need for cognition (NFC), which may be a crucial element that affects consumer perceptions of nine-ending prices. This research investigates the NFC as a facet of consumer personality that reflects a tendency to engage in and even enjoy evaluating prices, as it motivates comparative thought. It is proposed that consumers with a high and low NFC will exhibit different consumer behavior. The research divides consumers into two price cognition groups: high and low price cognition. Two subsequent experiments using these groups revealed that consumers with a low NFC tend to perceive nine-ending prices to be significantly cheaper than zero-ending prices.

Literature Review

Need For Cognition (NFC)

The need for cognition (NFC) is the tendency for people to engage in and enjoy thinking. Petty and Cacioppo (1986) demonstrated that the NFC is not related to the traditional conception of intelligence. Individuals with a high NFC are more likely to have a stronger intrinsic motivation to engage in cognition and to attempt to reduce any errors that they might have made. Being motivated by interest, enjoyment, or the challenge of work is termed intrinsic motivation. Individuals with a low NFC, in contrast, do not enjoy thinking.

Petty and Cacioppo (1986) indicated that the NFC is cognition to the extent that individuals engage in it on account of their intrinsic motivation. Based on this theory, numerous research associated with the NFC has verified that individuals with a high NFC possess stronger intrinsic motivation, and engage in cognition to reduce errors made when purchasing, whereas individuals with a low NFC do not enjoy the evaluation process. Park and Hastak (1994) found individuals with a low NFC to be reluctant when faced with cognitive endeavor and to prefer to avoid arduous discussions or deliberation; therefore, they tend to be easily influenced by others.

Given the foregoing ideas, we expect that the differences in consumer preferences for engaging in and enjoying relatively effortful cognitive processing of information, such as the NFC, are likely to influence the responses of consumers to nine-ending pricing tactics. In the sections that follow, we review the relevant literature and develop our hypotheses. We describe two experiments that we conducted to examine our predictions using the rightmost numerical digit (Study 1) and the leftmost numerical digit (Study 2) in a price.

Rightmost digit effect (nine-ending effects)

Previous studies have shown that consumers perceive a nine-ending price to be significantly lower than a price just one cent higher (\$3.60 vs. \$3.59). This pricing technique is termed "psychological pricing," apparently because of the belief that nine-ending prices act on the consumer via "special psychological effects" (Schindler and Kibarian, 1993; Bray and Harris, 2006).

Schindler and Kirby (1997) proposed two effects to explain this psychological effect. The first is the perceived-gain effect, which refers to the perception of consumers that nine-ending prices indicate that the retailer is giving a small amount back to the consumer. For example, a consumer might interpret a price such as \$29 as involving a \$1 discount from \$30. The second reason is termed the underestimated price effect, which refers to the perception of consumers that a nine-ending price such as \$29 is encoded as \$20. Both the perceived-gain effect and the underestimated price effect make the product seem much cheaper to consumers than if it carried a zero-ending price, and trigger an enhanced buyer response (Gendall, Holdershaw, and Garland, 1997).

Brenner and Brenner (1982) explained that the perceived-gain and underestimated price effects are the result of a limited capacity on the part of consumers to make a cognitive effort to focus on directly accessible information. They held that consumers who are exposed to price information store only the more valuable parts of the message they receive, in this case the first digits of a number. For example, when the price is \$299, the digit 2 is more significant information than the first 9, which in turn is more significant than the next 9. Consumers therefore recall that the price is \$200, then that it is \$290, but rarely that it is \$299. This limit on cognitive capacity explains why consumers always perceive a nine-ending price to be a cheaper price than a zero-ending price. A study based on cognitive capacity by Schindler and Warren (1998) found that the effects of nine-ending prices depended on the amount of attention consumers paid to the decision to purchase. Consumers who were under greater time pressure paid less attention to each price and were therefore more likely to ignore the rightmost digits.

In accordance with the literature, we expect the NFC to moderate the perception of price for nine-ending prices. We expect individuals with a high NFC to pay more attention to information central to the purchase decision and to engage in more thought about the decision than individuals with a low NFC. Consumers with a high NFC are only influenced by actual price discounts, whereas consumers with a low NFC are affected by discount signals regardless of actual price discounts (Inman et al., 1990). Consumers with a high NFC are therefore less influenced by marketing or psychological tactics. When consumers with a high NFC are faced with a nine-

ending price, they realize that it is only one cent lower than the zero-ending price, and no large discrepancy is created in their perception of price. Conversely, consumers with a low NFC are more likely to be affected by psychological tactics when faced with a nine-ending price, as they have a low motive to process price information and prefer to use heuristics by reading prices from left to right. This renders them liable to underestimate prices (Coulter, 2001).

Our hypothesis is therefore as follows:

H: Consumers with a low NFC will be more likely to perceive nine-ending prices to be lower than zero-ending prices than will consumers with a high NFC.

The data from the two experiments also provide cumulative evidence for the role played by the NFC in the nine-ending price effect. Consistent with our prediction, a high NFC reduces the magnitude of the nine-ending price effect. We demonstrate that consumers with a low NFC will be more likely to perceive nine-ending prices to be smaller than zero-ending prices than will individuals with a high NFC. We also found that the influence of the NFC on the price-ending effect is exerted not only on the rightmost digit (Study 1), but also on the leftmost digit (Study 2). This research contributes to the literature by offering empirical evidence that the NFC effect influences the nine-ending effect. A related question is whether it is important to use nine-ending prices. In response, we show that a nine-ending price is sometimes, but not always, perceived to be lower than a price that is one cent higher, and reveal that the perception is more likely to occur when consumers have a low NFC, as they are more likely to perceive no difference between nine-ending and zero-ending prices. There seems to be a domain invariant cognitive phenomenon underlying the popularity of nine-ending prices.

The Moderating Effect of Product Familiarity on the Endowment Effect

Ya-Chung Sun, Vanung University, Taiwan

Chien-Huang Lin, National Central University, Taiwan

Shih-Chieh Chuang, National Chung Cheng University, Taiwan

Yin-Hui Cheng, National Penghu University, Taiwan

In monetary-based trade, goods held by sellers are sold in exchange for monetary funds held by a buyer. Although the task of a seller is to sell its merchandise and the task of a buyer is to get the goods s/he needs, when doing so, the main goal of both seller and buyer is to maximize their gains (Goldman, Kraus, & Shehory 2004). But, how do consumers decide on the highest price they are willing to pay for a desired product? And, how do they decide on the lowest price they are willing to accept for a product they wish to sell?

The assessment of objective values refers to the fact that "people are required to estimate the least price they are willing to accept (WTA) when selling something and the ceiling price they are willing to pay (WTP) when buying something".

Most economists argue that the gap between WTA and WTP should converge for most commodities. However, experimental research has shown that the values of WTA and WTP might remarkably differ, even for the same object. This discrepancy in selling and buying price for the same object is rooted in the status of ownership and is termed “the endowment effect” (Kahneman et al. 1990).

Familiarity is defined as the number of product-related experiences that have been accumulated by the consumer (Abla and Hutchinson 1987). For example, familiarity with a product may lead to the use of prior product-related knowledge to direct the acquisition of information (e.g., information search; Brucks 1985) and the evaluation of information (e.g., to make compensatory trade-offs; Bettman and Park 1980).

Familiarity gives experienced consumers several advantages. It decreases the information search for existing alternatives (Bettman and Park 1980), provides a superior ability to encode new information (Jeffries et al. 1981), and allows the consumer to pay attention to relevant information and ignore irrelevant information (Johnson 1993).

Hence, this study explores whether consumer’s product familiarity influences the endowment effect on the selling price and buying price. It is reasonable that the perceptions of value of both seller and buyer are influenced by product familiarity and therefore indirectly moderate the endowment effect.

Experiment 1

The purpose of this study is to test our hypotheses that ownership and the level of product familiarity interact and influence subjective valuation. The product familiarity of the participant was experimentally measured and its effect on endowment effect was observed.

The experiment was conducted by a factor-two level (ownership: owner vs. non-owner) between-subjects design. A total of 206 undergraduate students at the University of Vannung participated in this experiment as part of their course requirement marketing management class, and were randomly and equally assigned to one of two different experimental conditions.

These statistics strongly support our assumption that the endowment effect is larger when people have a lower level of product familiarity than people with higher level of product familiarity.

Experiment 2

Experiment 1 supports hypothesis one. However, the way we measured familiarity may not exclude the influence from other variables, such as prior knowledge or experience. To further demonstrate the endowment effect on product familiarity, experiment 2 manipulated the main variable to examine our hypotheses.

The objective of Experiment 2 aims to manipulate product familiarity rather than to measure product familiarity to test the robustness of the endowment effect.

The experiment was conducted by a 2 (ownership: owner versus non-owner) x 2 (product familiarity: high versus low) between-subjects design. A total of 204 undergraduate students at the University of Vannung participated in this experiment, and were randomly and equally assigned to one of four different experimental conditions.

As we expected, the analysis revealed a significant interaction between the endowment effect and product familiarity. The endowment effects are smaller when people have a higher level of product familiarity than for those who have a lower level of product familiarity.

Conclusion

All other things being equal, sellers tend to pursue a higher selling price for an owned object than they would be willing to pay as buyers (e.g. Kahneman, Knetsch, and Thaler 1990). However, as proven by the results of three experiments in this study, the level of product familiarity can affect the magnitude of the endowment effect. The endowment effects are smaller when people have a high level of product familiarity and the endowment effect is small when people have a low level of product familiarity. Hence, the level of product familiarity can be classified as a moderator in the endowment effect.

Postconsumption Motivation—What Happens after a Need is Satisfied?

Robert Kreuzbauer, University of Illinois at Urbana-Champaign, USA

Chi-yue Chiu, University of Illinois at Urbana-Champaign, USA

This paper reports results from a new research direction called *Postconsumption Motivation* which tries to study motivational effects after basic social needs have been satisfied through consumption. Consumers purchase products or brands in order to satisfy certain needs, however, what are the motivational forces that drive consumers to act in a certain way after the brand is consumed? Is it even possible to predict any kind of behavior after consumption? Based on the theory of optimal distinctiveness we demonstrate that consumers who consume a brand that allows them to satisfy their need for distinctiveness, have an increased desire for being connected to other people. This example is counterintuitive since (as existing theories in consumer behavior would predict) one would expect that when a consumer gets the feeling of being unique or distinctive by using a certain brand (e.g. wearing sunglasses from Gucci one feels distinctive from lower class people) this person should also continue to feel or act as a distinctive individual. However, as our studies showed, the opposite happens. Our theoretical concept is based on Brewer's theory of optimal distinctiveness (ODT, 1991) which asserts that individuals desire to attain an optimal balance of belongingness and distinctiveness *within* and *between* social groups and situations. These two motives are in constant opposition with each other; when there is too much of one motive, the other must increase in order to counterbalance it and vice versa. We tested this concept in 2x2x2 full-factorial between-subject experimental setting. In a first step consumers had to watch a 3 minutes slide presentation (that contained pictures from unique individuals combined with sentences and words that were associated with distinctiveness) that activated their need for distinctiveness. Then the experimental group (distinctiveness group) received a brief advertising message about a tea-bag brand which is associated with uniqueness (i.e. it helps the consumer to feel distinctive). In the control condition the participants received a message about the same tea-bag brand, but with a neutral content. Both groups had to rate the attractiveness of the advertising message (and returned the ratings to the experimenter) and then received one real tea-bag as a gift. That is, participants in both groups had an increased need for distinctiveness (through the slide presentation), then people in the experimental group learned that this brand is associated with distinctiveness and would therefore serve as a means to satisfy this particular need which finally happened after they received the tea-bag. After having rated how much this tea-bag would enable them to feel distinctive, participants were asked whether they would now prefer to work in a group or alone for the next task. We assumed that after their need for distinctiveness was satisfied through the tea-bag they would rather prefer to work in a group than alone since now—according to ODT—their need for belongingness would be activated. However, for the control group, this effect should be significantly weaker, since these participants never associated distinctiveness with the brand and would therefore not have successfully satisfied their need through the received tea-bag. The results confirmed our hypotheses. Participants in the experimental condition felt that the tea-bag would let them feel significantly more distinctive than participants in the control condition and also had a significantly higher preference towards working in a group (i.e. higher need for belongingness) than the control group. The experimental group also showed higher overall preference towards the tea-brand. In a second experiment we followed the same procedure than in study 1, however this time participants received a false tea-bag brand, that is, when the experimenter distributed the tea-bags he told the participants that his research assistant accidentally bought the wrong tea-bags, so he could only give them a different brand than the one in the advertising. The idea behind this procedure was that, in this experiment, both groups (1. group with distinctiveness message and 2. group with neutral message) were unable to satisfy their need for distinctiveness, as they haven't received the brand that was associated with distinctiveness. We therefore expected that both groups (compared to the experimental group from study 1) would also have a decreased feeling of distinctiveness for the tea-bag brand (since this was not associated with distinctiveness inside the ad) and consequently a decreased preference towards working in the group, since their need for belongingness wasn't activated accordingly due to the fact that distinctiveness wasn't sufficiently satisfied in the first task. Again our results were consistent with the hypotheses. In addition to that both studies also contained a memory recognition task where in the final part of the study participants were asked to recall adjectives which they read in the first rating of the advertising message. These results also confirmed the hypotheses. Participants who received the distinctiveness message and the correct tea-bag brand could remember significantly more adjectives than participants from the other three groups.

We believe that these results show important findings of a very new direction in consumer research where consumers motivational reactions are studied after a certain need has been satisfied. We assume that research in postconsumption motivation can help to better understand consumption as a continuing process that does not stop after a need has been satisfied. Our results are based on two strong experimental tests and also provide an explanation for the underlying theoretical framework of this process. In a further step we conduct studies that test the effect when consumers' need for belongingness is activated at the beginning and we will present these results together with those discussed above at the conference.

The Role of Common Features in Decision Conflict Resolution

Anish Nagpal, The University of Melbourne, Australia
Adwait Khare, Quinnipiac University, USA
Tilottama Chowdhury, Quinnipiac University, USA
Ameet Pandit, The University of Melbourne, Australia

Abstract

During decision conflict resolution, features that are shared among alternatives are thought to cancel out and not play any role in choice because they are non-diagnostic; only the unique features help the consumer make a decision. In this research, we specifically examine how features that are shared among alternatives affect decision difficulty. Our results indicate that common attributes do matter; they do not simply cancel out. Further, how common attributes matter seems to depend on the type of decision conflict. Under approach-approach conflict, common attributes enhance the perceived advantage; thereby increasing the ease in decision-making. However, under avoidance-avoidance conflict, common attributes seem to enhance the perceived disadvantage, thereby increasing decision difficulty.

Introduction

Consider a consumer who faces a choice between two cars, car A and car B. Both the cars share a few bad features such as bad warranty, low horse-power, etc. However, each car has unique good features; car A has better fuel efficiency whereas car B is very safe. Such a decision creates an approach-approach conflict because the consumer is drawn towards both the alternatives. Alternatively, consumers face avoidance-avoidance conflict when they have to choose between two products that are equally unattractive. In the above example, consider both cars share a few good features such as good warranty, high horse-power, etc. However, each car has unique bad features; car A is not fuel efficient and car B is ranked low on safety. The literature argues that during such a conflict resolution process, the features that are shared among the alternatives cancel out and do not play a role in choice because they are non-diagnostic (Houston and Sherman 1995; Tversky 1972). The decision rests upon comparing only the unique features. Decisions that involve a comparison of only the good unique features (approach-approach conflict) are easier and take less time than those involving a comparison of only the bad features (avoidance-avoidance conflict).

In this research we question the assumption that common features cancel out and have no role to play in conflict resolution.

Decision Conflict and Decision Difficulty

Research shows that an approach-approach conflict takes less time and is easier to resolve than an avoidance-avoidance conflict. This has been verified in a number of experiments (Barker 1942; Chatterjee and Heath, 1995; Dhar and Nowlis 1999; Houston, Sherman, and Baker 1991; Hovland and Sears 1938; Sears and Hovland 1941; also see Anderson, 2003 for a review). The question of whether common features cancel out and play no role in the decision is an interesting one. Products often share a number of features with their competitor's products and it is logical to assume that the common features should cancel out and not affect the outcome. In fact, prospect theory (Kahneman and Tversky 1979) and the information restructuring framework (Coupey 1994) argue that the common features are cancelled out by consumers before they evaluate the relative attractiveness of the products. However, recent research has shown that common features can affect choice (Chernev, 1997, 2001). For example, using the confirmatory reasoning framework (Klayman 1995; Lord, Lepper, and Ross 1979; Russo, Medvec, and Meloy 1996; Russo, Meloy, and Medvec 1998), Chernev (2001) showed that when consumers have already established preferences and the common features shared between the products are attractive, consumers make choices that confirm their prior preferences. However, when the attributes are equally important or consumers have no prior preferences, common features seem to have no impact on preferences. Even if that is the case, we believe that common features may impact other decision process characteristics such as decision difficulty.

Hypothesis Development

Consider the case of a consumer who is deciding between two cameras that have better features than a previously viewed camera, which is out of stock. This situation creates an approach-approach conflict (Chatterjee and Heath, 1995). Although consumers might face decision conflict, it is much easier to make a choice in such a situation because both the products are equally attractive (Chatterjee and Heath, 1995; Dhar and Nowlis 1999; Houston, Sherman, and Baker 1991). Once the consumer realizes that both the cameras are attractive and develops a liking towards one of the products, the other features of the camera, albeit shared with the other camera, should strengthen the already established preference for the camera and make the decision easier (Chernev 2001; Russo, Medvec, and Meloy 1996; Russo, Meloy, and Medvec 1998). Hence, as the number of common features increase, the decision to choose one of the two attractive cameras becomes more and more easy.

H1: In an approach-approach conflict, decision-making becomes easier as the number of common features shared between the products increases.

Now consider the case of a consumer who is deciding between two cameras that have worse features than a previously viewed camera, which is unfortunately out of stock. This situation creates an avoidance-avoidance conflict (Chatterjee and Heath, 1995), making the decision very difficult. It is reasonable to suggest that the consumer will process the other features of the cameras to help make the decision. However, if the other features are shared, it would add further to the frustration and disappointment of not being able to break the tie. Thus, we propose that when consumers face two unattractive products, the common features will make the decision even more difficult.

H2: In an avoidance-avoidance conflict, decision-making increases in difficulty as the number of common features shared between the products increases.

We now describe study 1 that tests the hypotheses stated above.

Study 1: Effect of Common Features on Decision Difficulty

Eighty-two undergraduate college students participated in study 1 in exchange for a chance to win a \$50 gift certificate from the university bookshop. Participants were exposed to either approach-approach or avoidance-avoidance conflict using product descriptions that were adapted from Chatterjee and Heath (1996). Common features were manipulated at four levels, zero common features, one common feature, two common features, and three common features. The principal dependent variable was decision difficulty which was measured by asking the participants the following three questions, "How simple was the task to evaluate the cameras (reverse-coded)," "how difficult was the task to evaluate the cameras," and "how easy was the task to evaluate the cameras (reverse-coded)." All three questions were anchored at "Strongly Agree" and "Strongly Disagree." The mean of the three questions was calculated to give a single measure of decision difficulty (Cronbach-alpha=0.94).

Results

Conflict type significantly affected decision difficulty ($\alpha=-1.14, p<.05$). This indicates that approach-approach conflict is more difficult to resolve than avoidance-avoidance conflict, which is a surprising result. The number of common attributes also significantly affected decision difficulty ($\alpha=-0.52, p<.05$). More importantly, the interaction was also statistically significant ($\alpha=0.99, p<.05$). We found that under approach-approach conflict, the number of common attributes significantly affected decision difficulty ($\alpha=-0.47, p<.05$). The negative significant coefficient suggests that as the number of common attributes increases, decision difficulty decreases. Thus, H1 received support. Under avoidance-avoidance conflict, the number of common attributes also significantly affected decision difficulty ($\alpha=0.22, p<.05$). The positive significant coefficient suggests that as the number of common attributes increases, decision difficulty increases. Thus, H2 received support. Results of both hypotheses' tests are unchanged when the importance ratings of all attributes, unique and common, are included in the model.

Discussion

Our results indicate that common attributes do matter; they do not simply cancel out leaving decision-making unaffected. Further, how common attributes matter seems to depend on the type of conflict in decision-making. When decision options are superior to an unavailable option (approach-approach conflict), common attributes enhance the perceived advantage even more and thereby increase the ease in decision-making. On the other hand, when decision options are inferior to an unavailable option (avoidance-avoidance conflict), common attributes seem to enhance the perceived disadvantage even more and thereby increase the discomfort in decision-making. Our findings indicate that assuming common attributes to be irrelevant can lead to incorrect conclusions about decision-making. Our results are promising and we intend to conduct further research to understand the role of attribute valence (both common and unique attributes can be positive vs. negative in valence) and consequences for the final decision (are some options more vs. less likely to get chosen).

The Inertia of Motion

Sunaina Chugani, The University of Texas at Austin, USA
 Rajagopal Raghunathan, The University of Texas at Austin, USA
 Ying Zhang, The University of Texas at Austin, USA

A mindset has been described as a highly accessible set of cognitive procedures that are activated upon use (Gollwitzer, Heckhausen, & Stellar, 1990; Gollwitzer & Bayer, 1999). Extant literature has confirmed that if a cognitive procedure gets activated in a certain situation, it is more likely to be activated for use in subsequent behavior to which it is applicable (Smith, Branscombe, & Bormann, 1988; Smith 1990, 1994; Gollwitzer & Bayer, 1999). Thus, we posit that Newton's first law—an object at rest (motion) stays at rest (motion) unless acted on by an outside force—has parallels in the human realm. Specifically, individuals in a state of psychological motion (e.g. who perceive that they have begun a task) will exhibit a greater propensity to maintain the motion state (e.g. by engaging in a subsequent task) than those in a state of rest. This "Inertia of Motion Hypothesis" predicts that an individual in a state of motion will (1) exhibit a greater propensity to engage in a subsequent task and, due to the greater readiness for motion, (2) exhibit a faster rate of progress through a given task. Two studies test these predictions.

In Study 1, participants were seated at separate computers and were asked to answer some simple demographic questions. Upon completion, half were told that they had completed the first section of the study (motion state condition), and the other half were told that the demographic questions were merely preliminary and that they had not yet started the study (rest state condition). Both groups were then informed that they would be required to wait for about five minutes until all participants were ready to proceed. In addition, participants were told that, if they wished, they could engage in an optional task while waiting by clicking on an icon at the bottom of the screen. The optional task consisted of word puzzles in which participants had to create as many words as possible from a string of letters presented to them. The amount of time it took for participants to click on the optional task icon served as a measure for their propensity to engage in a subsequent task. The rate at which participants generated the words in the task was taken as their rate of progress through the task. Results showed that those in the motion condition clicked on the icon for the optional task sooner (after $M=61.48$ seconds) than participants in the rest condition (after $M=104.60$ seconds), $t(117)=3.38, p<.01$. Further, those in the motion condition generated each word at a faster rate ($M=12.08$ seconds per word) than those in the rest condition ($M=17.28$ seconds per word), $t(113)=3.18, p<.01$. Thus, those in the motion condition exhibited a greater propensity to maintain their motion by choosing to engage in an optional task sooner than those in the rest condition, and, because of their greater readiness for further motion, proceeded through the optional task at a faster rate than those in the rest condition.

Study 2 was designed to provide triangulating evidence for the inertia of motion hypothesis by exploring the effect of taking away the experience of psychological motion. After the same state manipulation used in Study 1 (state: rest vs. motion), half of the participants simply proceeded to the next part of the study (no interrupt condition). The other half were interrupted by learning that they had to wait for "about two minutes" to make sure all participants were ready to proceed to the next part of the study (interrupt condition). For those in the motion condition, the period of disengagement imposed by the interruption was expected to take away their experience of psychological motion and thus mitigate their propensity to maintain that motion. For those in the rest condition, the interruption should simply extend their period of rest and was not expected to alter their state. Next, all participants then encountered an impression formation task; they were presented with one piece of information at a time about a target person and were instructed to stop requesting more information when they felt confident enough to form an impression of the target (adapted from Martin, Ward, & Achee, 1993). The average time spent on each piece of information was recorded as a measure of speed of progress through the task. Analysis of this data revealed an interaction between the state and interrupt variables, $F(3, 39)=3.73, p=.06$. As expected, without an interruption, individuals in motion spent significantly less time on average examining each piece of information ($M=3.05$ seconds per piece) than those at rest ($M=4.34$ seconds per piece), $F(1, 19)=3.55, p<.05$. This was a replication of the rate of progress findings from Study 1. In the interrupt condition, there was no significant difference between those in the motion condition ($M=3.91$ seconds per piece) and those in the rest condition ($M=3.36$ seconds per piece), $F(1, 20)=0.43, p>.50$. So, taking away the experience of psychological motion mitigated the propensity of those in the motion condition to maintain their motion, causing them to behave no differently from those in the rest condition. A simple contrast illustrates the overall effect more clearly: the motion, no interrupt condition (the only condition in which participants experienced unmitigated motion) proceeded through the pieces of information at a faster rate ($M=3.05$ seconds) than those in the other three conditions combined ($M=3.90$ seconds per piece), $F(1, 41)=3.92, p=.05$. So, these results triangulate the results from Study 1 by showing that taking away psychological motion results in a mitigation of the propensity to maintain motion.

These studies provide evidence that once an individual perceives himself to be “moving”, the experience of psychological motion activates a motion state, resulting in a propensity to maintain motion. This exhibits itself behaviorally through (1) an increase in the propensity to engage in a subsequent task, and (2) a faster rate of progress through a given task. The relationship between psychological motion and the propensity to maintain that motion was reinforced by showing that when psychological motion is absent, so too is the propensity to maintain motion.

Self-Image Congruence Models Conceptualized as a Product Affirmation Process

Michael K. Coolson, Shippensburg University, USA

Madoka Kumashiro, Goldsmiths University of London, UK

Marketing scholars understand and account for the process of self-image congruence models—we incorporate products/brands into our self-concepts (e.g., Onkvisit and Shaw, 1987, Prentice, 1987) and often desire those products that match and express to others our self-concept, personality traits, and core values (Dolich, 1969). However, does this desire extend to products that represent both the “good and bad” of who we are? Additionally, can such products affect one’s emotions and actually help to change one’s self-concept? While self-image congruence models suggest that we tend to seek brands that match our personality, the distinction between the expression of one’s actual self (both the “good and bad” aspects of one’s self-concept), one’s enhanced self (self-concept aspects that others tend to favor) and one’s ideal self (the aspects to which an individual aspires but not necessarily to which others aspire) in consumer behavior remains less clear. Solomon (2007) has suggested that the vast amount of consumer research has been mixed regarding the influence of the different types of self-concept traits on product evaluation, and Solomon seems less certain that self-image congruency models can explain preference for simple/functional products, such as a toaster or a day-planner. In an attempt to clarify the mixed evidence regarding self-image congruence models, we sought to apply a robust theory of close relationships, namely the Michelangelo Phenomenon (Drigotas, Rusbult, Wieselquist, and Whitton, 1999, Rusbult et al., 2005), to explain the evaluation of products that match our actual, enhanced, and ideal selves and the effects of these products on one’s emotions and personality.

Drigotas and his colleagues developed a model of partner affirmation in close relationships (Drigotas, Rusbult, Wieselquist, and Whitton, 1999). These authors proposed that the process of behavioral confirmation (Darley and Fazio, 1980, Snyder, Tanke, and Berscheid, 1977) is likely to be quite powerful in that close partners exert strong/frequent impact on one another across diverse behavioral domains. Accordingly over time, each person is likely to exert considerable impact on the other’s “self”—the other’s traits, values, and behavioral tendencies. To the extent that the confirmation process aligns with each person’s ideal self, each is likely to enjoy movement toward his or her ideal self, and the relationship will flourish. Affirmation describes the extent to which the partner’s perception and behavior aligns with the individual’s ideal self. Such affirmation is termed the “Michelangelo Phenomenon.” Affirmation has been shown to yield enhanced personal and couple well-being (Campbell, Sedikides, and Bosson 1994; Drigotas et al. 1999).

The process of affirmation seems more intuitive in the context of a romantic relationship than in consumer behavior—indeed, one must be willing to accept that a consumer and a brand can have an interdependent relationship in which each exerts powerful effects on the other. Susan Fournier (1998) put out such a call to researchers to use close relationship theories in psychology to understand the relationship between consumer and brand, conceptualizing the brand as an animated partner to the consumer. At present, we make the argument that products can affirm the consumer’s ideal self. Additionally, we offer the presumption that “product affirmation” exerts significantly more powerful effects on a consumer’s emotions, personality, and product evaluations than products which verify or enhance one’s self-concept (alternatively labeled as “product verification” and “product enhancement” respectively). Furthermore, if our assumption of product affirmation is reasonable, then any type of product which brings one closer to his/her ideal self, whether it is used for hedonic or utilitarian purposes, should yield significant affirmation effects.

We conducted three studies to empirically test the proposition of product affirmation. The first study (study 1) was a simple non-experimental (survey design) study to initially establish the association of product affirmation with changes in a consumer’s emotions, personality, and product evaluations. Study 1 used a sample of alumni students of a moderately sized state-funded university in the northeastern United States, and results provided significant support for product affirmation effects. Using college student samples, the second and third studies used experimental manipulations to pit product affirmation effects on a consumer’s emotions, personality, and product evaluations against product verification effects (study 2) and product enhancement effects (study 3). Study 2 asked participants

to generate traits in their actual and ideal selves, whereas study 3 asked participants to generate traits in their enhanced and ideal selves. Both studies then prompted participants to think about and list a product for each of the two traits that would seem to show the participant as a person possessing each respective trait. Finally, after coming up with a product for each trait, participants were asked to rate their agreement on a series of Likert-type scales measuring the hedonic and utilitarian value of each respective product and the extent to which they would feel confident, lovable, attractive, excited, anxious, relaxed, disappointed, happy, and annoyed as a result of owning/using the product. Participants were also asked to rate their agreement on Likert-type scales measuring the extent that they liked each product associated with its respective trait.

Analyses employing mixed analysis of covariates (ANCOVA) designs (with product affirmation as the between-subjects factor and product verification (study 2)/product enhancement (study 3) as the within-subjects factors and using the product's hedonic and utilitarian scores as covariates) yielded strong and consistent support for product affirmation effects on a consumer's emotions, personality, and product evaluations and decidedly weaker and inconsistent product verification and product enhancement effects. That is, products aligned with the consumer's ideal self were evaluated more favorably and brought about more positive changes in the consumer's emotions and personality compared to products aligned with the consumer's non-ideal self. Alternatively, analyses did not exhibit parallel support for products aligned with the consumer's actual self (product verification) or products aligned with the consumer's enhanced self (product enhancement). Finally, these product affirmation effects operated above and beyond the product's hedonic or utilitarian value to the consumer. Such results seem to have profound implications for the revision of self-image congruence models in accounting for the apparently superior effect of product affirmation.

Taking Cues from Others: The Effect of Distinct Self-Views on the Persuasiveness of Extrinsic Brand Popularity Information

Yun Lee, University of Iowa, USA

Abstract

This research examines how the situational accessibility of distinct self-views influences the persuasiveness of extrinsic popularity information used in advertising. Two studies provide initial support for the hypothesis that the accessibility of different types of self-views affects how people interpret extrinsic brand popularity information used in advertising. Study 1 showed that the more individuals were accessible with interdependent self-views, they were more likely to favorably evaluate a brand presented with extrinsic popularity information in advertising. Study 2 showed that individuals with interdependent self-views were more likely to favorably evaluate a brand presented with extrinsic popularity information than individuals with independent self-views.

Conceptual Framework

Prior work has suggested that consumers use the relative brand popularity as a positive indicator of the brand's quality (Dean 1999; Huang and Chen 2006; Szymanski, Bharadwaj, and Varadarajan 1993). However, while brand popularity information has been frequently incorporated into advertising as a common practice for companies (Dean 1999), the effect of distinct self-views on the persuasiveness of extrinsic brand popularity information is yet to be clearly understood. Therefore, this research examines how the situational accessibility of distinct self-views influences the persuasiveness of extrinsic popularity information used in advertising. In this research, I propose that, due to different types of goals associated with distinct self-views, consumers with interdependent self-views are more likely to favorably evaluate a brand presented with extrinsic popularity information than consumers with independent self-views.

The distinction between the interdependent and independent self-views has been made through the different types of conflicted structure of goals (Singelis 1994; Triandis 1989). Individuals with interdependent self-views tend to be more sensitive to situations and social contexts and contingent upon the feelings, thoughts, and behavior of others (Kanagawa, Cross, and Markus 2001). The goals of individuals with dominant interdependent self-views are flexibility and variability to be connected with and belonged to others. Thus, those with interdependent self-views show greater relationship-relevant self-view tendencies enacting appropriate behaviors based on others' views, fostering harmony and fitting in with others. Since interconnectedness with and belongingness to others are the central focus of individuals with interdependent self-views (Kitayama et al. 1997), these individuals are more likely to hold a flexible and variant self-view to conform to situational and contextual norms (Kim and Markus 1999) and act in accordance with behaviors and decisions of others over their internal, personal attributes or characteristics (Markus and Kitayama 1991; Signelis 1994; Stapel and Koomen 2001).

In contrast, the goals of individuals with dominant independent self-views are uniqueness, individuality, autonomy, assertiveness, and independence distinctly separate from others (Aaker and Lee 2001). Thus, individuals with independent self-views tend to be more autonomous and invariant across situations and social contexts, and more focus on their own feelings and thoughts. Therefore, those with independent self-views show greater relationship-irrelevant self-view tendencies to accentuate self-related features and minimize the influence of others, resulting in emphasizing uniqueness, separateness, and distinctness of individuals (Baaren et al. 2003). Since expressions of one's unique, personal attributes are the main focus of individuals with independent self-views, these individuals are more likely to hold a bounded, stable and invariant self-view to pursue individualized internal characteristics and attributes that are clearly distinguished from others.

The preceding discussions suggest that the impact of extrinsic brand popularity information should vary based on relative accessibility of interdependent versus independent self-views, due to goal (in)compatibility between different types of self-views and extrinsic brand popularity information. Specifically, I predict that consumers with interdependent self-views should interpret extrinsic brand popularity information as values by which they can harmoniously fit in with others and maintain interconnections with and belongingness to others (Aaker and Lee 2001). In contrast, consumers with independent self-views should interpret a brand with extrinsic popularity information less favorably than consumers with interdependent self-views, because their goals characterized with being unique, distinct, separate, and different from others (Aaker and Lee 2001; Singelis 1994; Triandis 1989) are not compatible with values extrinsic brand popularity information represent. Therefore, I hypothesize that the more consumers are accessible with interdependent self-views, the more they will favorably evaluate a brand presented with extrinsic brand popularity information (study 1). I also hypothesize that individuals with interdependent self-views will be more likely to favorably evaluate a brand presented with extrinsic brand popularity information in advertising than individuals with independent self-views (study 2).

Study 1

To test H1, the extent of interdependent self-views was measured by instructing participants to write down short stories about similarities they have with family members or friends (Trafimow, Triandis, and Goto 1991). Then they were asked to indicate the degree to which they focused on others than selves (Lee, Aaker, and Gardner 2000) on a seven-point scale (1=not at all, 7=very much). Participants were then asked to review the 2008 Tiburon GS print ad presented with extrinsic popularity information (i.e., the bestselling car! 89% of consumers who reviewed 2008 Tiburon GS selected this car) and indicate their favorability toward the brand on a seven-point scale (1=very unfavorable, 7=very favorable). As predicted, the results showed that the more participants were assessable with interdependent self-views, they were more likely to favorably evaluate a brand presented with extrinsic brand popularity information in advertising ($F(1, 96)=6.618, p=.012$).

Study 2

In study 2, interdependent versus independent self-views were manipulated. Participants were asked to think about how they are similar to (interdependent) or different from (independent) family members or friends and write down short stories about their thoughts (Trafimow, Triandis, and Goto 1991). The procedure to measure brand favorability was similar to study 1. The results showed marginally significant effect of different types of self-views on the persuasiveness of extrinsic brand popularity information. Participants with interdependent self-views were more likely to favorably evaluate a brand presented with extrinsic popularity information than participants with independent self-views ($M_{inter}=5.12$ vs. $M_{indep}=4.75, t(98)=1.804, p=.074$).

Results and Discussion

These results are consistent with the previous findings showing that people tend to more focus on features, benefits, and values which are compatible with their goals of self-views (Aaker and Lee 2001; Gardner, Pickett, and Brewer 2000). Two studies reported here provide initial evidence that different types of self-views affect how consumers interpret extrinsic popularity information used in advertising. Distinct self-views encourage consumers to have different perspectives on goal pursuit (Aaker and Lee 2001; Lee, Aaker, and Gardner 2000) and then seek values and benefits which is consistent with their goals of self-views, which in turn affects their attitudes toward the brands shown in advertising.

Moderating Role of Member Identification on the Relationship Between Network Centrality and Opinion Leadership / Satisfaction

Seung Hwan (Mark) Lee, University of Western Ontario, Canada

June Cotte, University of Western Ontario, Canada

Opinion leaders are defined as individuals who influence the purchasing behavior of other consumers in a specific product domain (Flynn, Goldsmith, and Eastman 1996). Opinion leaders play a critical role in diffusing information across social systems (Chaney 2001). Burt (1999) posited that opinion leaders need to be socially connected inside a network, not isolated, to effectively spread information. However, we believe that the degree to which individuals become opinion leaders is not only tied to the extent which they are socially connected, but also the level in which they identify with their network.

Member identification is the degree to which one feels belongingness to an organization of which the person is a member (Bhattacharya, Rao, and Glynn 1995). When a person identifies with a club, he/she tends to define him/herself in terms of the club (Mael and Ashforth 1992). We believe that a person with high member identification (HMI) is likely to accrue greater benefits from being in a central position than a person with low member identification (LMI). As HMIs are passionate about their social club, they are likely to be recognized as the face of the club, thus having higher likelihood that they become strong influencers.

Furthermore, we test whether network centrality predicts satisfaction with the club, and whether member identification also acts as a moderator to this relationship.

H1: Network centrality is positively related to opinion leadership.

H2: Network centrality is positively related to club satisfaction.

H3: The relationship between network centrality and opinion leadership is higher for HMI than LMI.

H4: The relationship between network centrality and club satisfaction is higher for HMI than LMI.

Methodology

Participants & Procedure. In total, we collected data from 64 of 125 (response rate, 51.2%) students who were members of a university ethnic social club. To be a member of the club, one was required to purchase a membership at any point in the academic year. Network data were collected using the roster method (Wasserman and Faust 1997). In this method, we provided the students with an alphabetical listing of the names of all of the club members and asked to them to indicate their degree of friendship regarding each member.

Measures. We used the friendship matrix (64x64) into the network program UCINET (Borgatti, Everett, and Freeman 1999) to obtain differences in closeness centrality scores. Closeness centrality measures how many nodes on average it takes for an individual to reach everyone else in the network. Individual with high closeness centrality has the shortest path to all other nodes (Freeman 1979).

We obtained differences in centrality scores for the QAP regression analysis (non-parametric technique) to overcome the issues of non-independence of data points. Using ordinary least squares (OLS) is inappropriate as network data do not suffice the assumptions of independence of observation (e.g. Gibbons and Olk 2003). We interpret the outcomes of QAP analysis as having a higher (lower) closeness centrality score compared to others in the network.

For other measures, we used established scales from previous literatures. We assessed opinion leadership using a 6-item scale developed by Flynn et al. (1996). We assessed satisfaction using a 6-item scale developed by Baldwin, Bedell, and Johnson (1997). We measured member identification using a 6-item scale developed by Mael and Ashforth (1992). Lastly, we used gender as control in all of our analysis as studies have shown differences in gender effects in networks (e.g. Burt 1992)

Data Analysis. To test our hypothesized moderation of member identification, we used a median split ($m=4.33$) to divide the data into two groups. Data from high member identification (HMI, $n=33$) and from low member identification (LMI, $n=31$) were analyzed separately using QAP network regression analysis to test the relationship between closeness centrality and opinion leadership / club satisfaction. The use of two-group comparison using QAP is not uncommon (Borgatti and Cross 2003), and is used to identify possible moderators.

Results

All of our four hypotheses were supported by our data. Closeness centrality was positively related to opinion leadership ($\alpha=7.725$, $p<0.01$, $r^2=15.8\%$). Closeness centrality was also positively related to club satisfaction ($\alpha=6.83$, $p<0.01$, $r^2=11.8\%$). As for our test for moderation, we found full support for hypotheses 3 and 4. For the HMI group, closeness centrality was positive and significant in predicting opinion leadership ($\alpha=4.741$, $p<0.05$, $r^2=14.0\%$) and club satisfaction ($\alpha=6.639$, $p<0.01$, $r^2=18.1\%$). However, for the LMI group, the regression coefficient was not significant ($p>.05$, ns). The control variable gender was not significant.

Discussion

This study has few limitations. First, we acknowledge that the extent of the individuals' network reach beyond the social club which can influence the level of opinion leadership and satisfaction with the club. However, we feel that using the club network was appropriate as our dependent variables are likely to depend heavily on the network itself. Second, scholars have noted that response rate of under 50% would deem the network data to be unreliable and 70% to be desirable (Burt and Minor 1983; Scott 2000). Because we were only able to obtain 51.2% of the entire network, the network measure of closeness centrality is inevitably affected by the non-response. Thus, future research should devote to examining network with higher response rates.

The research can be extended in several ways. First, a longitudinal study would be appropriate to examine the development of friendship networks over time with respect to the variables mentioned in this study. In addition, this research can be enhanced by examining other structural dimensions (e.g. betweenness centrality, structural holes), and how it plays a role in predicting outcomes.

Albeit preliminary, this research provides contribution to the opinion leadership and the satisfaction literature. We find that in social clubs, member identification with the club plays an important role in identifying effective opinion leaders. Therefore, marketers should target those in central positions who identify strongly with their social club. Additionally, this research also shows that individual's who identify with their club garner higher satisfaction as a result of being in a central position.

An Investigation of College Students' Influence on Parents' Innovation Adoption

Jianping Liang, University of Western Ontario, Canada

June Cotte, University of Western Ontario, Canada

It has been twenty years since Gatignon and Robertson (1985) developed a model of the diffusion process. However, little research has been done in the context of a family's adoption of innovation, especially Gatignon and Robertson's unique focus on interpersonal communication transfer, one of the most important issues in diffusion research. Herein, we extended the intra-family influences on innovation literature with a study of college students' influences on their parents' innovation adoption.

Building on Cotte and Wood (2004), we suggested that influence within a family may be one important indicator of adoption probability. Prior family influence research has focused on intergenerational (parent to child) or intragenerational (sibling to sibling) influences in consumer socialization (Cotte and Wood 2004; Moore, Wilkie, and Lutz 2002). Intergenerational influence (IGI) research literature assumed that the direction of the influence on consumer behavior is from the older parent to the younger child (Moschis 1988). Comparatively little work has yet been explicitly done on upward intergenerational "influence", i.e., the "influence" of children on parents, and none explicitly has considered the role of adult offspring as innovation "influences" on their parents. In Brooks' (1957) seminal study, the difference between "influences" and "requests", especially within the family, was discussed. For example, if a mother is asked by her child to buy a brand of coffee, it is considered the child's "request". If a mother is told by her child that a brand of coffee is good, and she takes her child's words into consideration and is free to make the purchase, it is considered the child's "influence". Although the child's "request" was the focus in most of the previous research (see John 1999), the child's "influence" is the focus of this paper. "Influence" is defined as the power to affect somebody's actions, character or beliefs, especially by providing examples for them to follow and winning their admiration (p.611), while "request" is defined as an act of asking for a thing in this way (p.996, Crowther 1995).

Most of the previous research involving children in a family has investigated the "request" of adolescents under the age of 18 in the family (see John 1999). As children become adults, they are often considered being more mature, knowledgeable, and trustworthy by parents. Potentially they may become opinion leaders and "influence" parents, rather than merely "request" purchase. An opinion leader is considered to have the distinguishing characteristic of being sought by others for information and advice regarding the field in which s/he is a leader (Brooks 1957; Gatignon and Robertson 1985; Childers 1986; Rogers 2003). At the college stage, most young adult children live with people other than family members. However, many college students are not totally independent and still need various kinds of support from parents. The frequent communication and interaction possibly lead to a potential channel for the innovation diffusion process to occur.

Methodology. To the best of our knowledge, this is the first study to explore the influence of college students on their parents' innovation adoption. In order to investigate further on the mechanism of innovation diffusion from college students to parents, we conducted in-depth interviews with thirteen college students at a large North American university. Based on the in-depth interviews, we conducted a survey with 119 college students, as well as 51 of their parents. Data from both college students and their parents were cross-validated and used in the data analyses. Logistic regression was used to examine factors related to whether college students have told parents on innovation and whether parents have adopted the innovation told by their children in the last six month.

Major Findings. We found that college students' opinion leadership does not directly influence parents' innovation adoption. Rather, college students' opinion leadership influences parents' product category knowledge, which subsequently influences parents' innovation adoption.

We also found that the relationship between parents' product category knowledge and their innovation adoption is moderated by the innovativeness of the innovation such that the higher the parents' knowledge, the more likely their adoption, regardless of the innovativeness of the innovation, whereas when parents have lower knowledge, they are much more likely to adopt low innovative innovation than high innovative innovation.

According to the innovation diffusion literature, both homophily (i.e., the degree of similarity between pairs of individuals) and heterophily (i.e., the degree of dissimilarity) are important in determining the innovation diffusion (Rogers 2003). We only found the effects of homophily in social value, which indicated that the more similar the social value between college students and parents, the more likely that the college students tell parents about innovations and the more likely that their parents adopt the innovations.

Finally, Ekstrom, Tansuhaj and Foxman (1987) found that children's influence varies by family communication pattern and thus is stronger in families high in concept-orientation (i.e., children are encouraged to develop their own ideas and express their views more openly, see also McLeod and Chaffee 1972). We found that college students in more concept-oriented families are more likely to tell parents about innovations, but have no more influence on parents' innovation adoption than those in less concept-oriented families. On the other hand, emotional closeness between college students and parents does not influence whether college students tell parents about innovations, but influence parents' adoption, such that the higher the emotional closeness, the more likely the parents' adoption.

The Effects of Phonetic Symbolism on Comparative Price Perceptions

Keith S. Coulter, Clark University, USA

Psycholinguistics is a specialized area within the field of cognitive psychology that is focused upon the development, production, comprehension, and usage of language. In general, psycho-linguistic features may influence both the memorability and perception of words through their ability to convey meaningfulness (Eysenck 1979). One attribute that has been shown to have an impact on the meaningfulness of a word is phonetic (or "sound") symbolism, which refers to the ability of particular phonemes (i.e., the fundamental building blocks of sound in a language) to convey information.

At the broadest level, researchers typically categorize phonemes in terms of vowels versus consonants. Vowels are then sub-categorized on a front versus back distinction (which refers to the position of the highest point of the tongue during pronunciation), whereas consonants are typically categorized as either fricatives (i.e., s, f, v, and z) or stops (i.e., p, k, t, b, g, d, and hard c). These front/back and fricative/stop distinctions are important because they have been consistently related to a variety of spatial dimensions. For example back-vowel sounds (e.g., "u" as in "dusk") and stop consonants are typically associated with perceptions of *large* size, whereas front vowel sounds (e.g., "e" as in "bee") and fricatives are typically associated with perceptions of *small* size (Sapir 1929; Newman 1933; Klink 2000; Yorkston and Menon 2004). The effect may be the evolutionary result of using resonant cavity and "formant dispersion" (i.e., the difference between resonance frequencies) as a cue to body size (Fitch 1994; 1997; Fitch and Hauser 2002).

Research in numerical cognition suggests that price-name phonemes may impact price perceptions due to the manner in which prices are processed and encoded. According to Dehaene's (1992) triple code model, numbers can be mentally represented and manipulated in three different forms: visual, auditory, and analog. The visual (Arabic) code represents numbers on a spatial visual medium on the basis of their written form in Arabic numerals (e.g., 72); the auditory verbal code is generated through a phonological representation in which each number is represented by a sequence of phonemes (e.g., "seventy" and "two"); the analogue magnitude code represents numbers as judgments of relative "size" arrayed in parallel-format along a left-to-right-oriented mental number line (Dehaene, Bossini, and Giraux 1993). Research has demonstrated that the verbal, visual, and analog representations are neurologically connected: paths link the different representations both within and across (i.e., through the corpus callosum) left and right hemispheres of the brain (Noel 2001).

Consistent with prior research in this area, we expect that *both* phonological and analog magnitude representations will be evoked when consumers are exposed to comparative price advertisements, and that the phonological representations may affect relative analog encoding (Monroe and Lee 1999; Roediger and McDermott 1993; Coulter and Coulter 2005; Coulter and Norberg 2007; Vanhuele, Laurent, and Dreze 2006; Vanhuele and Dreze 2002). More specifically, sale-price phonological codes that have been demonstrated to be associated with perceptions of "smallness" (i.e., fricatives and front vowels) should increase the likelihood that sale prices are perceived as small in comparison to regular prices, and that regular prices are perceived as large in comparison to sale prices, thereby increasing the magnitude of the perceived discount. Conversely, phonological codes typically associated with perceptions of "largeness" (i.e., back vowels and stops) should decrease the likelihood that sale prices are perceived as small in comparison to regular prices, thereby decreasing the magnitude of the perceived discount. We tested these assumptions in the context of three experiments.

Experiment 1 involved a between subjects ($n=150$) design in which participants were exposed to comparative price advertisements. Regular prices in the target ads were identical, but the sale prices contained either fricative and front vowel (e.g., \$7.66) or back vowel and stop (e.g., \$7.22) price endings (cents digits). To ensure verbal encoding and consistent with previous studies in this area (cf. Vanhuele, Laurent, and Dreze 2006), participants were instructed to read silently to themselves any (sale) prices they encountered; they were further told to rehearse the prices internally to keep them in memory. To account for the effects of cross-condition differences in actual percentage discounts, we derived an adjusted perceived price discount measure (APD) by subtracting the actual from the perceived percentage discount, and then dividing by the actual percentage discount. ANOVA revealed that APD [$F(4,130)=37.51, p<.001$], value assessments, and purchase intentions were significantly greater in the front vowel/fricative conditions than in the back vowel/stop conditions, even though actual discount was lower in the former case(s).

A limitation of our first Experiment was that the automatic and non-conscious nature of the numeric processing precluded our ability to administer a direct and definitive manipulation check. Thus, one could argue that extraneous factors associated with the specific sale price numbers (e.g., size, appearance, or "representativeness") might have impacted our results. Therefore, in Experiment 2 we utilized a task paradigm that employed *phonological suppression* to impede auditory price encoding (Dehaene 1992).

We hypothesized that verbal rehearsal of three different attribute-related phonological phrases during stimulus viewing would cause participants to suppress the phonological codes associated with price processing, while still encoding the appropriate analog magnitude representations (Lee and Kang 2002). Suppression of auditory codes associated with front vowel/fricative and back vowel/stop consonant sale prices should then assuage the relative distortion of analog magnitude representations associated with price discount encoding observed in Experiment 1. ANOVA results confirmed that supposition.

One might still argue, however, that findings were driven by *non*-phonetic characteristics of the chosen number combinations, and that these effects were suppressed when participants recited attribute-related information. Therefore in Experiment 3, we again examined the effects of phonetic suppression on price discount perceptions associated with two different regular/sale price combinations. However, we examined the proposed effects across English versus Chinese-speaking subjects. We utilized sale prices that may be characterized as front vowel/fricatives in one language, but back vowel/stops in another. ANOVA results revealed significant price phoneme x suppression x language effects, thus lending strong support to our hypotheses.

Does the Devil Really Wear Prada? Social Relations Analysis of Brand and Human Personalities

Maxim Polonsky, University of Connecticut, USA

Robin A. Coulter, University of Connecticut, USA

Nearly a half-century ago, Levy (1959) advanced the idea that brands are reflective symbols of the self. In the ensuing years, marketers and consumer researchers have focused on leveraging and understanding the many facets of brand symbolism. Aaker's seminal work (1997) linking brand personality characteristics to human personality characteristics is noteworthy, and has served as the bases for others' investigation of these associations (Caprara, Barbaranelli, and Guido; Johar, Sengupta, and Aaker 2005). This human-brand personality research is directly related to other work that has considered how consumers use brands to communicate something about their own identity (Belk 1988; Escalas and Bettman 2005; Kleine, Kleine and Kernan 1993), as well as to reinforce personality and attitudes toward themselves (Escalas and Bettman 2003; Fennis and Pruyn 2007; McCracken 1988).

Indeed companies expend great efforts to create brand images that are meaningful to consumers (Gobé 2007), and research on self-congruity theory (Sirgy 1982; Swann, Stein-Seroussi, and Giesler 1992) argues that consumer brand purchasing behavior is determined by the interaction between perceptions of the product and the personality of the consumer; that is, consumers prefer brands with a symbolic function that is congruous with their self-identity. Thus, individuals often engage in selective exposure behaviors that maximize both, consistency and pleasure of self-expression. Fennis, Pruyn and Maastrand (2005, 376) found a transfer effect from brand personality to consumer personality and concluded that "brands are capable to 'make us who we are.' Not only are brands chosen by consumers because they highlight some aspect of who we are or want to be, they also shape or highlight these aspects." Aaker (1999) documented that self-schematic traits lead to stronger brand preferences; that is, people prefer brands with which they share personality characteristics.

Another important theoretical aspect of the human-brand personality association is symbolic interactionism (Solomon 1983). Specifically, Solomon (1983, 320) focused on three perspectives: 1) a consumer's self-concept is based on perceptions of the responses of others, 2) a consumer's self-concept functions to direct behavior, and 3) a consumer's perception of the responses of others to some degree reflects those responses. Relatedly, research has demonstrated that consumers evaluate and compare their self-concept with the image of a stereotypic and generalized brand user (Sirgy 1982). Further, some have argued that individuals may have a preference for one brand over the other because they perceive themselves as similar to and identify with people who are generally perceived to use that brand. Further, numerous studies have supported this in-group brand association effect (Erickson and Sirgy 1992; Heath and Scott 1998; Hong and Zinkhan 1995; Sirgy 1985).

Although there have been many contributions to the human-brand personality association within the past decade, research has not captured the duality of human-brand personality in a social context. The purpose of our research is to draw and build upon theoretical work on brand personality, self-congruity theory, symbolic interactionism, and interpersonal perception, as well as the social relations modeling work (Kenny 1994; Kenny and Albright 1987) to delve into the association of brand and human personality characteristics. We introduce the Social Relations Model (SRM) as a means to consider the social meaning and perception formation as dynamic processes, and where

the self is both, a perceiver and a target of perception. The SRM model “permits simultaneous estimation of dispositional, situational, and interactional determinants of behavioral phenomena” by employing round-robin experimental design, and recognizes individuals to be both, a target and a perceiver (Malloy and Kenny 1986, 222). Specifically, the social relations modeling approach enables us assess dyadic data to address the questions such as: If a person is seen to be extraverted, is she also associated with extraverted brands? If a person sees herself to be extraverted and prefers extraverted brands, do others also see her as extraverted and preferring those brands? If a person sees herself using some particular brand, does she see others using the same brand? To further assess the SRM and its contributions related to understanding the human-brand associations, we conducted two studies.

The purpose of study 1 was to identify brands in the automobile and clothing categories that had a “consensus” personality. Study 1 involved two data collections. First, 70 undergraduates at a large northeastern university participated in an online study in which they rated 24 automobiles and 24 clothes brands (34 semantic differential items) to with regard to the Big Five personality characteristics—Agreeableness, Extraversion, Conscientiousness, Emotional Stability, and Openness (Goldberg 1990) and two additional traits, Sophistication and Ruggedness, identified by Aaker (1997). We identified automobile and clothing brands with a high Cronbach’s alphas for the personality scale, high means, and low variances. In the second data collection, 40 MBA students were provided with a definition of the seven personality characteristics and asked via a free association task to name a brand that they associated with each personality characteristic. Based on these data collections, we identified to 22 brands, 11 each for automobiles (i.e., extroversion—Volkswagon; emotional stability—Volvo; ruggedness—Hummer) and clothing (i.e., extroversion—NIKE; emotional stability—Old Navy; ruggedness—Levis). Consistent with the SRM in study 2, we conducted a round-robin experiment, with 25 groups consisting of 3 or 4 members per group. The group participants (who were not previously acquainted with one another) were asked to interact with one another for ten minutes, so that each participant could have an initial understanding of the individual’s personality characteristics. After the introduction period, each participant rated each group member on 25 semantic differential personality items. Next, the participants reported the likelihood (7-point Likert-scale) of brand use for their group members for each of the 22 brands (from study 1), and then reported their own likelihood of use. Finally, group participants were whether they perceived other group members as thinking they would use the brand. Our work contributes by extending the theoretical and empirical work related to human-brand associations, and our findings provide useful insights about the social meanings of brands.

Brands: The Opiate of the Non-Religious Masses?

Ron Shachar, Tel Aviv University, Israel and Duke University, USA

Tülin Erdem, New York University, USA

Gavan J. Fitzsimons, Duke University, USA

Keisha M. Cutright, Duke University, USA

Brands have become a ubiquitous presence in today's world, affecting the everyday lives of consumers in many ways. Beyond providing general product benefits, brands maintain unique personalities (Aaker 1997) that consumers often capitalize on to express who they are to themselves and others in their lives (Aaker 1999). The personalities of brands also seem to enable their ascent to cult-like, or even religious, status in the lives of their consumers, supporting the notion that the sacred realm of religion and the secular world of consumption are often intertwined (e.g. Belk, Wallendorf and Sherry 1989). The popular press has even proclaimed brands as the "new religion" (Financial Times 2001).

While the potential relationship between religion and brands has generally been acknowledged, systematic research on the relationship between religiosity and the importance of brands in consumers' lives is noticeably lacking (but, see Rindfleisch, Burroughs & Wong's working paper for a recent exception). Thus, this research focuses on the relationship between religiosity and one indicator of the importance of brands in consumers' lives that we refer to as "brand reliance". We define brand reliance as the degree to which consumers prefer branded goods over goods without a well-known national brand (e.g., generics). Our objective is to establish that a relationship exists whereby individuals with different levels of religious commitment (religiosity) differ systematically in their brand reliance.

In our first study, we examine the relationship between religiosity and brand reliance at a macro level, using state level data. We find that higher religiosity, as measured by the number of congregations and self-reported church attendance, is associated with lower levels of brand reliance (as measured by two separate indexes reflecting the relative presence of brand focused vs. non-brand focused retailers). Further, we find that this result is strongest in high income states.

In our second study, we complete a micro-level analysis. We measure brand reliance by asking participants to make a series of choices among branded and generic products. We then relate the responses to individuals' reported church attendance. Consistent with the macro-level analysis results, we find that higher religiosity is associated with lower brand reliance, but only among high income individuals.

Given these two highly consistent studies, we aim to conduct additional research to allow us to better understand the factors underlying this relationship between religiosity and brand reliance. We speculate that religion and brands satisfy a common need, and it is this underlying need that links religiosity and brand reliance. For example, our findings may reflect differential strategies for maintaining a sense of belonging between religious and nonreligious individuals. For the religious, this need may be fulfilled through attendance at religious services. For the nonreligious, this need may be fulfilled by belonging to brand communities.

We also aim to better understand why we observe the link between brand reliance and religiosity largely for high income consumers. A number of plausible explanations are possible for this finding, but perhaps the most intuitive and parsimonious is that high income consumers have larger consideration sets. In other words, their income allows for the consideration of a much broader range of products than that of low income consumers. This leaves room for factors such as religiosity to influence their choices. Alternatively, low-income and high-income individuals may have qualitatively different consumption goals. Low-income individuals may use consumption as largely a means of survival. Conversely, high-income individuals may use consumption to serve higher-order goals (e.g. need for belonging, risk compensation) that can also be achieved through religion.

In addition to exploring the psychological explanations for the observed effects, future research might also explore the implications to firms. For example, retailers who are interested in promoting their store brands (versus the national brands) might consider using physical cues that remind shoppers of their religious beliefs in the store (e.g. dramatic cathedral ceilings at the entrance, religious-like music). Similarly, they might consider advertising their store brands through media that attract a greater percentage of religious consumers, or using spokespersons that are associated with strongly held religious beliefs. Conversely, retailers that focus on national brands or place lower strategic importance on their store brand lines should probably avoid such cues and outlets.

In terms of what implications our results may have for consumers, one could argue that our findings should not promote any changes in their behaviors if the status quo leads to the greatest consumer satisfaction. Thus, future research should determine whether or not the nonreligious are more satisfied after buying a brand, while the religious are more satisfied after buying a store brand.

In sum, this research has identified what we believe to be a very interesting empirical phenomenon, supported by two distinct methodological approaches. We believe this evidence will be of great interest to the consumer research community, and hope that it will spur research as to why there is a relationship between religiosity and brand reliance, as well as how an understanding of this relationship might best be applied.

In Death and in Love: Sacred Trade-offs in the Death Care and Wedding Industries

A. Peter McGraw, University of Colorado at Boulder, USA

Derick Davis, University of Colorado at Boulder, USA

Funerals and weddings represent two of the largest purchases consumers make. In the United States, the average funeral costs \$6,500 (and can reach \$10,000 with burial costs) and the average wedding costs more than \$27,000 (AARP 2000; FTC.gov; Rheault 2007).

Funeral and wedding purchases pose unique challenges; consumers typically have little purchasing experience and make decisions under time pressure, while subject to the scrutiny of friends, family, and acquaintances. Furthermore, the respective industries have been subject to criticism for unscrupulous sales and marketing practices (e.g., Mitford 1998; Boden 2003; Mead 2007).

We examine a particular challenge facing consumers purchasing funerals or weddings. Consumers purchasing products and services in these domains are reluctant to engage in price-based trade-offs, which we contend puts them at risk of overspending. A growing literature examines how consumers are unwilling to engage in trade-offs between the secular (e.g., money) and the sacred (e.g., love and commitment; Baron and Spranca 1997; Belk, Wallendorf, and Sherry 1989; Fiske and Tetlock 1997; McGraw, Tetlock, and Kristel 2003). Such taboo trade-offs produce a variety of negative outcomes, including moral distress, moral contamination, decision avoidance, and decision refusal (Tetlock, et al. 2000; McGraw and Tetlock 2005; see also Luce, Bettman, and Payne 1997). We examine how price-based trade-off avoidance leads to non-compensatory decision strategies and spendthrift decisions.

A funeral purchase implicitly requires a price be placed on a deceased loved one's memorial. A wedding purchase similarly requires a price be placed on a ceremony that represents a couple's love and commitment. We argue such purchases are seen as secular-sacred transactions and lead to price-based trade-off avoidance. Consumers do not want to undervalue sacredly held values by trading off price versus other attributes, such as product quality or quantity. Thus, consumers engage in non-compensatory choice strategies and chose premium options rather than balancing price against other attributes.

We present three studies that demonstrate consumers' greater willingness to pay for death care and wedding products compared to other routine purchase situations. We also show the effect is due, in part, to consumers' reluctance to engage in price-quality trade-offs.

Study 1 demonstrates that consumers are willing to pay more for products that are associated with funerals and weddings than no specific association, even when those products are judged to be of the same quality. Participants stated their willingness to pay (WTP) for four products (e.g., candles, thank you cards) that were randomly assigned for use in either a funeral, a wedding, or for "any reason" (control). Participants' WTP for products used as part of a funeral ($M=\$31.42$) or memorial service ($M=\35.21) were significantly higher than for the control ($M=\$18.23$). Despite higher WTP values for funeral- and wedding-related products, judged quality of these products did not differ from control.

Study 2 used a matching versus choice procedure (Slovic 1991; see also Luce, Payne, and Bettman 1999) to examine consumer's unwillingness to make price-based trade-offs in funeral purchase decisions. Participants were randomly assigned to either a control or memorial dinner condition and were presented with two product options for use at the dinner. Respondents were asked to state the missing price (taboo trade-off) or quantity (routine trade-off) that would make them indifferent between low and high quality options. They were then asked to choose between the two matched options.

When faced with a price vs. quality trade-off, participants in the funeral condition chose the high-quality/price option more often than control (68% vs. 51%) and chose more of the same product when faced with a price vs. quantity trade-off (75% vs. 38%). But consistent with our hypothesis that non-price-based trade-offs are not taboo, quantity-quality trade-off choices did not differ between conditions (68% vs. 65% for the funeral and control condition, respectively).

Study 3 examined the effect of different techniques to reduce spendthrift preferences for high-price high-quality goods with sacred associations. Participants were instructed to perform a price matching task between lower-quality/lower-priced thank you cards and a higher-quality option with no price listed (as in Study 2). The cards were to be sent to attendees of a wedding or funeral. Participants in the control condition were subsequently asked to make a choice between either option. The debiasing conditions were designed to encourage price-quality trade-offs by presenting either sacred or economic reasons to make price-based trade-offs. First, the difficult nature of price-based trade-offs in sacred domains was described, and the subsequent inclination of consumers to choose premium options was stated. Respondents in the economic debias condition were told that rational consumers recognize trade-offs are necessary in all situations including sacred events. Respondents in the sacred debias condition were told that no amount of money captures the importance of the situation, and therefore the meaning of the event should not be expressed through spending. In both conditions, participants were then encouraged, in light of this information, to treat the choice between the matched options as they would any run-of-the-mill purchasing decision.

Participants in the control condition chose the high-price, high-quality option 86% of the time, which is consistent with findings from Study 2. Those who read the economic debiasing statement chose the high-price, high-quality option 60% of the time, whereas participants

who read the sacred debasing statement chose the high-price, high-quality option only 41% of the time, a significantly different proportion than the control.

The project has implications for when and how policy makers and consumer advocates should intervene on behalf of consumers. Specifically, we address how interventions that simply encourage rational economic behavior of consumers without removing the taboo nature of the exchange may not be as effective as interventions that take into account the value-signaling role money in the evaluation of sacred purchases.

The Impact of Semantic vs. Lexical Relations on the Strength of Inter-brand Linkages

Jing Lei, University of Ontario Institute of Technology, Canada

Niraj Dawar, University of Western Ontario, Canada

Research Background and Hypotheses

Brands are not cognitively independent in the way that consumers store them in memory. Rather, due to a variety of reasons, including common product category or common features, similar trade dress and design, similar or related advertising, complementary usage, and even proximate shelf location, consumers may establish associative linkages between brands to help them navigate the "brandscape" in which they consume. The strength of these linkages are said to be an important predictor of the magnitude of spillover effects in which external information (e.g. advertising or negative news) about a brand can change evaluations of related brands that are not directly implicated (Lei et al. 2008; Roehm and Tybout 2006). Therefore, it becomes important to understand what determines the strength of associative linkages between brands.

Prior research has primarily examined brand-related linkages based on semantic similarities such as common product features and shared product category (e.g., KitKat-Smarties). However, brands may also be linked through more superficial lexical similarities such as phonetically or orthographically similar brand names (e.g., Nescafé-Nestea). We propose that brand linkages based on these two types of relations (i.e. semantic vs. lexical) have different levels of strength, depending on the manner in which brand information was learned. Specifically, we propose that semantic linkages will be stronger when consumers learn interrelations between brands in a high task involvement condition, whereas lexical linkages will be stronger when consumers rely on heuristics to associate brands in a low task involvement condition. These propositions are explained in detail below.

Associative network theory (Collins and Loftus 1975) suggests that consumers organize information in networks that represent both semantic (e.g., Maid-Servant) and lexical (phonemic and orthographic similarities) relationships (e.g., Maid-Made) (see also Hennessey et al. 2005). These associations are encoded or learned through exposure to, and elaboration of information in the environment (Gardial and Biehal 1985). A critical aspect of the learning process is the level of task involvement (Petty and Cacioppo 1981). Task involvement determines the cognitive capacity allocated to the encoding and, therefore, the extent of elaboration that the information receives (Schmitt et al. 1993). In particular, high task involvement is characterized by a thoughtful, intentional learning process that allows elaboration of

the stimulus information (Petty and Cacioppo 1986). In contrast, under low involvement, product/brand information may be learned incidentally with little cognitive effort or elaboration.

Therefore, when brand information is learned under high (vs. low) task involvement, consumers are more likely to rely on “deep” (vs. “surface”) cues to establish links between new and existing brand information. “Deep” cues include abstract, underlying functional properties of a brand such as product and category similarity, and common or complementary usage, whereas “surface” cues refer to more concrete, sensory properties of the brand such as the linguistic characteristics of brand names, and the color of the product and its package (Zhang and Sood 2002). The elaboration of “deep” cues is facilitated by systematic processing but requires more cognitive effort, whereas “surface” cues are often used as heuristics, with little effort involved. We propose that linkages based on semantic relations will be stronger when consumers learn interrelations between brands in a high involvement condition. However, lexical linkages will be stronger when consumers rely on heuristics to associate brands in a low involvement condition.

Experiment and Results

To test the impact of semantic vs. lexical relations between brands, we developed a fictitious brand Nestello (a chocolate candy bar). Nestello is lexically linked with brands such as Nescafé but semantically linked with brands such as KitKat (we also developed seven other filler brands). Each fictitious brand was presented on a card describing information such as the product category, the company, and the brand name, and each card was printed in a different font and size. Eighty subjects were randomly assigned to a 2 (high vs. low task involvement) X 2 (lexical vs. semantic relation) between-subjects ANOVA design. Following established practice (Schmitt et al. 1993), we manipulated the level of task involvement by instructing subjects to focus on either the information presented or the font and size of the text information on each card. Strength of association between brands was measured using a computer-assisted response time sequential priming method (e.g., Bargh and Chartrand 2000; Herr et al. 1996).

The results showed a significant interaction term ($F(1, 72)=25.38, p<0.001$) between task involvement and type of relations between brands. Specifically, the Nestello-to-KitKat association (semantic relation) was significantly stronger in the high involvement condition than in the low involvement condition (5.95 vs. 5.05, $p<0.05$), whereas the Nestello-to-Nescafé association (lexical relation) was significantly stronger in the low involvement condition than in the high involvement condition (4.53 vs. 3.40, $p<0.05$). Thus our hypotheses were supported.

Implications

The above finding suggests that consumers rely on different types of cues (semantic vs. lexical) to establish brand associations in different learning environment. In other words, the strength of a linkage is influenced by not only the type of relations between brands, but also the cognitive process through which the linkage is initially established. Our finding also suggests that surface-level lexical attributes are important conduits through which brands can be associated in memory. It implies that lexical similarities can help firms position a new brand closely to an established brand for positive halo effects, irrespective of whether the new brand is in the same or a different product category. However, it also suggests that the scope of contamination imposed by a negative message may be larger than what is normally expected. For example, a brand that seems to be “unrelated” due to the absence of semantic similarities, may nevertheless be affected by the negative information about a related brand through lexical linkages. To further test this, we are conducting follow up studies to examine the impact of semantic vs. lexical brand linkages on spillover effects between brands. Overall, this research shows that the lexical attributes of a brand, which have not received much attention in previous research, can have significant influence on the cognitive structure of inter-brand linkages.

Hot Stimuli and Arousal: Implications for Temporal Orientation, Trial and Price

Brittany Duff, University of Minnesota, USA

Ron Faber, University of Minnesota, USA

Recently studies have empirically demonstrated the effects of 'hot' stimuli on temporal orientation and consumption impatience. Hot stimuli are appetitive, rewarding or hedonic stimuli (Berridge 2004) that activate an affective 'go' system, in contrast to the cool, cognitive system (Metcalf and Mischel 1999). It has been shown that exposure to hot stimuli results in activation of the relevant neural systems which focuses the individual on smaller-sooner rewards, increases probability of making unplanned purchases and increases consumption impatience, even in domains unrelated to the stimuli (Li 2008; Van den Bergh, Dewitte and Warlop 2008).

Hot stimuli can be any sensory input including visual stimuli. Interestingly, visual-based studies select stimuli that vary primarily on arousal, yet arousal is not viewed as a causal mechanism. For example, the pictures Li (2008) chose from the International Affective Picture System (IAPS; Lang, Bradley and Cuthbert 2005) to represent hot versus cool stimuli had similar positive affective valence but differed on arousal (food vs. landscapes).

While, in these studies, appetitive activation has been found to focus attention on immediate rewards (and therefore devalue future rewards) differences in post-exposure arousal have not been found. This is surprising since the manipulations used, such as exposure to 'sexy images' of women, have previously been found to have effects through arousal (LaTour, Pitts and Snook-Luther 1990). Additionally, IAPS pictures are often used in research on motivated attention where arousal level is seen as representing the intensity of activation of the appetitive or aversive nature of the image (Lang, Bradley and Cuthbert 1998).

Past work has found that arousal at time of information processing can affect that processing (Sanbonmatsu and Kardes 1988). However, initial arousal was not assessed in the studies on appetitive stimuli. Initial arousal may impact the effect of the arousal level of the stimulus such that attentional focus to an immediately available reward is greatest when the stimulus matches the initial arousal level of the individual. Zajonc (1980) argued that hot system activation occurs at both the level of the stimulus and the individual, and, therefore, both should be measured. Therefore, examining initial activation or arousal states may be important for research on hot stimuli.

Method

To assess whether initial arousal may be affecting this process, an experiment similar to Li (2008) was conducted. Initially, 2 pictures with similar valence but differing in arousal were selected based on IAPS normative ratings. These images were of a deer drinking water (cool) and a team of skydivers jumping (hot). To further ensure the selected images met the desired criteria, a pre-test was conducted with 52 undergraduate students. As expected, the images were perceived as similar in valence [$M_{\text{deer}}=6.37$, $M_{\text{skydive}}=6.84$, $t(51)=1.65$, $p>.1$, n.s], but, were significantly different in arousal [$M_{\text{deer}}=5.73$, $M_{\text{skydive}}=7.48$, $t(51)=6.76$, $p<.001$].

These images were placed in constructed advertisements for either a hedonic or utilitarian product to see if product type would have an effect separate from the arousal level of the picture. A pre-test of products showed that a vacation/travel company and an insurance company differed significantly on perceptions of being hedonic [$M_{\text{travel}}=8.0$, $M_{\text{insurance}}=4.5$; $t(17)=5.72$, $p<.001$] as well as 'utilitarian' [$M_{\text{travel}}=3.94$, $M_{\text{insurance}}=7.78$; $t(17)=-7.47$, $p<.001$].

The primary study was conducted with 190 undergraduates. Subjects first filled out a questionnaire assessing their initial arousal on a 4-item scale along with other filler items. After completing the questionnaire, participants were exposed to one of the four ads (arousing picture/hedonic product; arousing picture/utilitarian product; non-arousing picture/hedonic product; non-arousing picture/utilitarian product). Participants then answered questions about the ad and then were asked to assess their happiness at winning a \$100 prize today, in one month, six months and one year. This was followed by filler items as well as questions assessing post-exposure arousal level.

Results

A repeated-measures ANOVA for happiness at receiving \$100 was run with time (today vs. one month, six months and one year in the future) as a within-subjects variable and picture arousal, product type and initial arousal as between-subjects variables. A median split was performed on initial arousal scores. The mean level of arousal for the low group was 2.93, while the high groups mean arousal was 5.45 [$t(189)=-19.73$, $p<.001$].

Ad-type (hedonic vs. utilitarian) with happiness at time of receiving \$100 ($F(1.62, 292)=2.26$, $p>.1$, n.s.), was not significant nor was ad-type and initial arousal, ($F(1.62, 292)=.91$, $p>.3$, n.s.). However, as predicted, there was a significant interaction with picture type (arousing vs. unarousing) and initial individual arousal level (high vs. low) affecting happiness at receiving money over time [$F(1.62, 292)=6.91$, $p<.05$]. This indicates that these pictures, similar to those chosen as 'hot' stimuli, do interact with initial arousal level in terms of the steepness of the discounting curve.

The means demonstrate opposite patterns for those with low and high initial arousal. For those low in initial arousal, discounting is steepest when exposed to the ad with the low arousal picture. For those high in initial arousal, the discounting curve is steepest when exposed to the ad with the high arousal picture. The results of discounting for the high arousal group (which showed more delay discounting when exposed to the high arousal picture) mirror those found in other studies (e.g. Li 2008). However, the fact that the low arousal group exhibited the opposite pattern is striking and points to the importance of assessing initial arousal and the role it may play in consumption impatience. Work in health communication has similarly pointed to the need to match arousal level of the message with the arousal level of the viewer for optimal effects (Stephenson and Southwell 2006).

As predicted, picture type (arousing/non-arousing) had a significant effect on arousal difference score: arousal at time 2 (post-exposure) minus arousal at time 1 (pre-picture exposure) [$t(189)=-1.884$, $p<.05$, one-tailed]. This arousal difference score, was higher for the arousing picture (skydivers) than the unarousing picture (deer) ($M_{\text{deerdifference}}=.42$, $M_{\text{skydivediff}}=.19$). In turn, this arousal difference score had significant effects on trial of the product [$M_{\text{lowdiff}}=4.59$ vs. $M_{\text{highdiff}}=5.17$; $F(1,173)=3.99$, $p<.05$] and price participants were willing to pay [$M_{\text{lowdiff}}=\$893.81$ vs. $M_{\text{highdiff}}=\$1626.03$; $F(1,173)=3.9$, $p<.05$].

Mental Ownership as Important Imagery Content

Silvia Feuchtl, University of Vienna, Austria

Bernadette Kamleitner, Queen Mary, University of London, UK

Abstract

Previous research has shown that mental imagery influences consumer experiences. Most research on mental imagery has focused on imagery vividness. What people actually imagine has hardly been assessed. We propose mental ownership as a powerful imagery content. An online experiment supports this proposition. Path models show that mental ownership partially mediates the effect of imagery vividness on attachment and attitudes, which in turn influence behaviour. In particular, mental ownership strongly predicts attachment, which significantly increases intentions towards getting the mere-mentally owned product.

Phrases such as "Yes, I can see myself driving that car" indicate that mental imagery is present in consumers' everyday language, and it seems that consumers use their imagination to decide on what to buy. Indeed, marketing scholars and practitioners are well aware of the importance of mental imagery for consumer behaviour (e.g., MacInnis & Price, 1987; Phillips, 1996; Schroeder, 2005).

Several studies have shown that the more vivid and strong mental imagery, the more attitudes towards an ad or a product improve (e.g., Babin & Burns, 1998; Gregory, Cialdini, & Carpenter, 1982). Interestingly, whereas we know quite well that vividness matters, we know much less about what people actually imagine. This paper aims at contributing to our understanding of the importance of imagery content by proposing mental ownership as a particularly powerful imagery content

There are at least three criteria that a powerful and marketing-relevant imagery content needs to meet. Ownership meets them all: First, consumers must be able to experience or feel what they imagine. People are able to develop a "sense" of ownership (e.g., Heyman, Orhun, & Ariely, 2004; Pierce, Kostova, & Dirks, 2003), and experiences of psychological ownership are clearly not restricted to factual possessions (e.g., De Dreu & van Knippenberg, 2005; F. W. Rudmin, 1994).

Second, a powerful imagery content needs to be something that frequently preoccupies consumers and is hence able to come to one's mind spontaneously or "naturally". Ownership considerations and consequences clearly impact everyday life and differentiating between "mine" and "not mine" is a routine practice in most cultures.

Third and in order to be relevant for marketing, a powerful imagery content must be able to influence how consumers feel and behave towards an object. As indicated by several theoretical streams rooted in economics (endowment effect; e.g., Thaler, 1980) and psychology (mere-ownership effect and attachment; e.g., Beggan, 1992) ownership has the capacity to significantly influence how consumers feel about and behave towards an owned object.

To deal with the specific case of a sense of ownership in situations where there is no actual ownership we coin the term 'mental ownership'. Mental ownership is defined as a sense of ownership for a factually not owned product. The phrase 'a sense of ownership' denotes that mental ownership is more than merely imagining a situation of possession. It requires a shift in the person-product relation (or reference point), thus, that not getting a mentally owned product feels like a loss instead of a non-gain.

Our research model proposes that vivid mental imagery about an object can lead to mental ownership which, in turn, leads to the typical consequences of actual ownership: an increase in attachment and attitudes. Subsequently, attachment and attitudes are supposed to influence behavioural intentions and behaviours aiming at making the mere mentally owned object actually available to the imaginer.

To test the research model, 613 participants were presented with the information that either a new coffeemaker or a new car was being introduced to the market. Participants were then shown depictions of the same product in three different colours in an online experiment. To manipulate the degree of mental ownership, participants either had to actively choose a model in a particular colour (experimental group, EG), or they were simply informed that the product was available in three different colours (control group, CG). The rationale behind this manipulation was that the act of choosing can create an ownership like association between the chooser and the chosen object

(Gawronski, Bodenhausen, & Becker, 2007). After being informed of the different colour options participants were presented an ad for the (chosen) product. Subsequently, participants were asked to fill in a questionnaire assessing reactions to the ad (imagery vividness, mental ownership, attachment, attitudes, and behavioral intentions) and demographic characteristics. Overall, a 2 (choice EG vs. no-choice CG) x 2 (car vs. coffeemaker) experimental design was achieved.

The manipulation of mental ownership was successful and it was not due to an effect of the manipulation on mental imagery. To test the proposed research model we ran several path models in AMOS. First, we assessed a model without mere-mental ownership. In this model we restrained all paths leading to and from mental ownership to 0. None of the fit-indices reached the required levels. Second and to test the proposed mediating function of mere-mental ownership, we assessed a model with mere-mental ownership as a mediator, which led to satisfying levels of model fit. Overall there is support for the partial mediation proposed in the research model. Mere-mental ownership decreases the influence of imagery vividness on attachment and attitudes and it significantly predicts product attachment and attitudes. These main results hold for both products even when the paths are constrained across groups.

In addition and in contrast to most previous research we show that neither mental imagery nor mental ownership directly influence behaviour. In particular, attachment seems to predict behavioural intentions. This finding fits into a growing stream of research which indicates that attachments rather than attitudes are important indicators of behaviour (e.g., Park, MacInnis, & Priester, 2006; Thomson, MacInnis, & Park, 2005). Interestingly, the importance of attachment also underlines the importance of mere-mental ownership. Our results show that mere-mental ownership has considerably more impact on attachment than on attitudes. Hence, mental ownership seems to be indeed a powerful imagery content. Considering that people's imagery content can probably be influenced, mental ownership, like factual ownership, might prove to be of tremendous theoretical and practical importance in several contexts and disciplines.

Dinner Out with Independent Self-Construal Consumers: Wow, This is Bad Wine

Eugenia C. Wu, Duke University, USA

Sarah G. Moore, Duke University, USA

Gavan J. Fitzsimons, Duke University, USA

Imagine that you are asked to select a restaurant for dinner with a group of friends. Which restaurant do you choose? We usually know what to choose for ourselves, but what happens when there are others involved? More specifically, how do you choose when you must consider not just your own preferences but the predilections of those around you?

As consumers we are often required to choose collectively, on behalf of ourselves and others. We decide on behalf of others when we select the restaurant for a dinner outing, pick the toppings for a shared pizza or choose the movie for a group jaunt to the theater. Despite the frequency of such decisions, existing research has focused primarily on choices made for and by individual consumers (Bettman, Luce and Payne 1998). Decisions in a group context have been addressed mainly in research on family decision-making (Corfman and Lehmann 1987) and in the negotiations literature in terms of collective decisions made for and by the group (Oetzel 1998). In this research, we attempt to understand some of the factors which influence consumption choices on behalf of others.

We focus on self-construal and expertise, both factors which have a substantial impact on consumer behavior (West, Brown and Hoch 1996; Aaker and Schmidt 2001). Self-construal theory proposes that individuals differ fundamentally in how they construe the self; independents see themselves as unique and autonomous while interdependents define themselves in the context of their social relationships, roles and duties (Markus and Kitayama 1991). Research on expertise suggests that consumers may also differ in their levels of knowledge concerning particular consumption decisions (Alba and Hutchinson 1987). In two studies, we examine the influence of these factors on a common decision made on behalf of others: choice of wine for the table at a restaurant.

The wine choice situation requires individuals to balance their own preferences with those of the group—but unlike past research that investigates how individuals' self-choices are influenced by others' choices (Ariely and Levav 2000), we put individual and group preferences in conflict by asking individuals to make a choice for the entire group and not just themselves. We expect that independents will choose better (more expensive) wines of the type of wine they prefer (e.g., red versus white), sacrificing the group's welfare to maximize their own utility. Interdependents should make more balanced choices and choose bottles that are equally expensive; they may even self-sacrifice by choosing more expensive bottles of the type they prefer less.

We conducted the studies online, using a national sample of participants who self-identified as wine drinkers. Participants read that they went out to dinner with a group of friends, and that they had been elected to choose the wine for the evening—one bottle of red and one bottle of white—and that they were not to exceed a total budget of \$110. Individuals then viewed a real wine list and selected one red and one white wine; we asked them to indicate the prices of the wines and to rate the quality of the two wines. We measured preferences for red and white wine by asking how often participants drank red versus white wine and measured self-construal (Singelis 1994). In Study 2, we also asked a number of wine-related questions to ascertain individuals' expertise.

As an initial illustration of our predicted effects, in Study 1, one strongly independent individual, a white-wine drinker, disregarded our instructions and selected two bottles of white wine, ignoring the group and satisfying his own preferences (he was excluded from our analysis). Our major dependent variables were the prices of the two bottles of wine individuals selected. We conducted a repeated measures analysis on the prices of red and white wine, using self-construal, wine preference, and expertise as independent variables. In both studies 1 and 2, we found similar results. First, we found an interaction between self-construal and wine preference. As predicted, independents' wine choices were influenced strongly by their preferences: the more they preferred red (white) wine, the more expensive a bottle of red (white) wine they chose. Interdependents chose more equally priced wines regardless of their preferences—in fact, they chose slightly more expensive bottles of the wine they did not prefer.

In Study 2, we measured expertise and found a three-way interaction between self-construal, wine preference, and expertise. While expertise did not influence the decisions of interdependents, independents' wine choices were influenced by their knowledge of wine.

Independent novices were the most self-interested, choosing red and white wines that were as expensive as possible, depending on their wine preferences. Independent experts also significantly increased the prices of red and white wines they chose according to their own preferences, but did so to a lesser degree than novices.

Importantly, these results are not driven by individuals' assumptions about others' preferences—independents who liked red wine did not choose more expensive red wines because they assumed everyone at the table would be drinking red wine, just like them. Most participants thought the break down of red versus white wine drinkers at the table would be about 50/50, and these predictions did not differ according to self-construal.

Our initial study suggests that independents sacrifice others' interests for their own and behave selfishly even when making decisions for a group. This initial study raises a number of interesting questions. What motivated independent experts in our study to make less biased choices for the group? What might encourage independent individuals to make better group choices? In a future study, we plan to manipulate group characteristics to answer some of these questions: for example, what if the group is comprised of wine experts vs. novices, or red vs. white wine drinkers? Manipulating these characteristics will uncover the dynamics that underlie individuals' choices on behalf of others.

In conclusion, when selecting someone to make a decision for other people, choose individuals with interdependent self-construals—or you might end up drinking house wine while they enjoy an award winning blend.

The Influence of Observed Body Movements on Consumer Behavior

Simon Ineichen, University of Basel, Switzerland

Arnd Florack, Zeppelin University, Germany

Oliver Genschow, University of Basel, Switzerland

An astonishing finding of research on embodied cognition is that motor behaviors and muscle contractions affect cognitive processes (Strack, Stepper, & Martin, 1988; Förster & Strack, 1996; Strack & Neumann, 2000; see for an overview Niedenthal, Barsalou, Winkielman, Krauth-Gruber, & Ric, 2005). In line with this research, recent studies found that body movements also have an impact on consumer judgments and behaviors (Förster, 2003; 2004). In these studies, participants rated products (Förster, 2003) or tasted a soft drink (Förster, 2004) and, at the same time, were asked to execute certain body movements. For instance, they were instructed to press their hand either up against the table from underneath, or down onto the table. Pressing one's hand up from underneath results in arm flexion, a movement that is related to grabbing something and pulling it towards oneself. It is argued that such movements are associated with approach-related behaviors and cognitive representations. In contrast, pressing one's hand down, results in arm extension, a defensive movement used to keep something at distance. It was found that arm flexion led to more positive judgments of a drink (Förster, 2003) and an increased drink intake (Förster, 2004).

In this study, we examined whether not only the execution, but already the observation of body movements affects consumer behavior. There is evidence that, observing other's actions, observing individuals seem to run an internal simulation of the observed behavior. This simulation occurs automatically (Gallese, 2001) and leads to neural activation in brain areas associated with the execution of the movements (Buccino et al., 2001). Also, there is indirect evidence for such a simulation to occur. Some mental disorders as well as orbito-frontal lesions lead to the symptom of echopraxia: the impulsive repetition of observed actions or heard sentences that occur with reflex-like immediacy (Lhermitte, Pillon, & Serdaru, 1986). We assumed that the observation of a body movement leads to a mental simulation of the movement and, thus, affect cognitive processes in the same way as the execution does.

However, we also assumed that individuals differ in the degree to which they are susceptible to the effects of observed body movements. Research on empathy has shown that people differ significantly in the degree to which they can feel the internal states of others

(Chlopan, McCain, Carbonell, & Hagen, 1985). Based on these findings, we assumed that for observers that are empathic with the observed person, observing the execution of motor actions should result in automatic cognitive responses similar to those elicited by actually carrying out those actions.

Method

Fifty-nine female undergraduate psychology students participated in the study for a small reward and partial course credit. Participants first completed a questionnaire for trait empathy (Leibetseder, Laireiter, Riepler, & Köller, 2001). Subsequently, they answered questions according to sports and recent consumption of food, drinks, and alcohol. Then, the experimenter provided participants with a glass of water and asked them to drink from it until they feel not thirsty any longer. Afterwards, the experimenter presented them a short video showing an athlete exercising with a bell bar. In the approach condition, the athlete was standing upright, pulling the weight from his waist to his chest, executing arm flexions against the weight. In the avoidance condition, he was lying on his back, pushing the weight up from his chest, doing arm extensions. Before the video started, participants obtained a glass with 300 ml of a drink which was said to be a new functional sports drink. The experimenter told participants that they should taste the drink and could drink as much as they wanted to do. After participants watched the video and tasted the drink, the experimenter thanked and debriefed the participants. The main dependent measure was the amount participants drank from the offered drink.

Results

We conducted a regression analysis with the amount participants drank as dependant variable and empathy as well as the dummy coded type of movement in the video as predictors. As expected, we found empathic observers to consume more of the drink while watching the approach related arm flexion movement than while observing the avoidance related arm extension movement. Observers low in empathy drank less when watching arm flexions than when watching arm extensions. The interaction term of empathy and type of movement had a significant effect on the amount participants drank from the offered drink. The main effects of empathy, and type of movement were not significant.

Discussion

Studies have shown that body movements and muscle contractions influence judgments and behaviors (e.g., Förster, 2003; 2004). Since the observation of other people's movements tends to elicit neural activations similar to those elicited by executed movements (Buccino et al., 2001), we assumed that also the observation of body movements affects consumer behavior. Our findings support this assumption for empathic observers. When observing arm flexion, a movement that is associated with grabbing and pulling something closer, high empathic observers drank more of an offered drink. When observing an arm flexion, a defensive movement that is involved in keeping distance and essentially incompatible with consumption, empathic observers drank less. Less empathic observers, in contrast, exhibited the inverse pattern.

Our findings extend recent research on embodied cognition showing that consumer behavior might be affected by processes related to motor areas in the brain. Previous research has shown the influence of own body movements. We showed that also the representation of body movements of others leads to similar effects. Further research should examine whether body movements, for instance in TV advertising spots, may have long time effects on the product evaluations or whether observing body movements has only immediate effects on evaluations and behavior.

Determinants of Customer Dependence and its Effects on Customer Trust in Interpersonal based Buyer-Seller Relationships

Kareem Abdul Waheed, Institute of Management Technology, Dubai, UAE
Sanjay S. Gaur, Auckland University of Technology, New Zealand

Abstract

Traditionally, customer dependence is viewed as a structural constraint in relationship outcomes. The effect of customer dependence on power, control and opportunistic behavior in buyer-seller relationship context is well researched. This paper views customer dependence as a positive relationship construct, identifies the determinants of customer dependence and explains the effects of customer dependence on customer satisfaction and customer trust. The paper is based on an empirical study carried out in farmer-chemical fertilizer retailer relationship—a commonly found interpersonal based buyer-seller relationship in India.

Conceptualization

Many customers in developing country like India build and maintain personal relationships directly with the small-scale retailers. Customer dependence, satisfaction, trust and loyalty on retailer play an important role for building and maintaining such relationships (Anderson and Narus, 1990; Morgan and Hunt, 1994; Andaleeb, 1995). There is considerable research in retailing that focuses on customer's satisfaction, trust and loyalty (e.g. Westbrook, 1981; Macintosh and Lockshin, 1997; Reynolds and Beaty, 1999). Customer dependence has been studied in marketing channels and industrial buying literature (e.g. Andaleeb, 1995; 1996; Lusch and Brown, 1996; Gassenheimer, *et al.*, 1996; Gassenheimer, *et al.*, 1998; Joshi and Arnold, 1998) and not well in retailing. Retailing involves interpersonal based buyer-seller relationships. To the best of our knowledge in the field, no study has researched customer dependence in the interpersonal based buyer-seller relationships. In this paper, we have proposed a model on determinants of customer dependence and its effects on customer trust in interpersonal based buyer-seller relationships context.

We identified product familiarity and market uncertainty as two determinants of customer dependence. First, if the customers' knowledge is limited in understanding their own requirements and how well the supplier's product could be used, they have to depend on their supplier to supply the products in accordance with their requirements. Second, if there is perceived uncertainty about availability of alternative supplies and suppliers, it would act as an exit barrier for the relationship with one supplier and would lead to a dependence based relationship.

Further, we examined the effects of customer dependence on trust. We proposed two types of positive effects on trust—one direct effect and the other indirect effect via satisfaction. A widely prevailing argument suggests a hypothesis—increased levels of perceived customer dependence on the supplier has a negative impact on customer trust, which was however not empirically supported (Monczka *et al.*, 2002; Handfield and Bechtel 2002). An interpersonal trust development perspective of Lewicki and Bunker (1996) is adopted in this paper to support the hypothesis—customer dependence on supplier leads to customer trust. Lewicki and Bunker (1996) posit three stages of trust development in interpersonal relationships in professional context: calculus-based trust, knowledge-based trust and identification-based trust. We equate customer dependence to calculus-based trust and hence it further leads to enhancement of trust. We contend, even when the buyers are in dependent position, the extent and quality of experience gained during the interactions could lead to positive effects on trust. Similarly, majority of the studies that focus on TCA (transactional cost analysis) approach suggest direct or indirect negative causal relationship between dependence and satisfaction (Gassenheimer, *et al.*, 1998; Andaleeb, 1996). By applying Lewicki and Bunker model, we contend, customer dependence also leads to satisfaction. Many studies empirically proved the positive relationship between satisfaction and trust (Batt and Rexha 1999; Kennedy *et al.* 2001).

Last, we proposed a negative moderating role of satisfaction on the relationship between customer dependence and trust to reemphasize that satisfaction acts as a major contributor in developing trust rather than dependence.

Method

A survey was carried out to empirically validate the model in farmer-chemical fertilizer retailer relationship, which is an example of a typical interpersonal based buyer-seller relationship in Indian context. Madurai, Pudukottai and Trichy districts of Tamil Nadu state were selected for the study. One taluk having higher fertilizer consumption from each of the above districts was selected. A taluk is the major revenue, administrative and planning unit in the district. The total sample size for this study was 300 farmers. The questionnaire was first translated to Tamil and then was translated back to English with the help of English and Tamil language translators independently (Brislin, 1980; McGorry, 2000). The earlier version of the English questionnaire was compared to the back-translated questionnaire and inconsistencies were removed after consultation with the translators (Brislin, 1980; McGorry, 2000). All the variables included in the study were measured using the scales available in the literature [product familiarity—Oliver and Bearden (1985); market uncertainty—Batt (2000); customer dependence—Batt (2000); customer satisfaction—Kennedy *et al.* (2001); customer trust—Holden (1990)].

All the measures were subjected to convergent validity and discriminant validity test using AMOS. Hypotheses testing were carried out specifically for determinants of customer dependence and its direct effect on trust by Confirmatory Factor Analysis using AMOS. The indirect effect of customer dependence on trust via satisfaction and the moderation effect of satisfaction hypotheses were tested by multiple regression analysis using SPSS.

Major Findings

There are well-documented researches suggesting the importance of customer dependence for long-term buyer-seller relationships. But limited researches in marketing domain have looked at the phenomenon of customer dependence in the market place. Our study conceptualized and empirically tested the determinants of customer dependence and its effects on customer trust. The customer perception

of market uncertainty was empirically proven as an important determinant for the customer dependence. Perceived product familiarity was also found to reduce customer dependence on the seller.

Our main contention of the study that analyzes the effect of customer dependence on customer trust was well supported. Basically, this result emphasized the applicability of interpersonal trust development perspective in interpersonal based buyer-seller relationships. We view the development of calculus-based trust as a process that leads to the customer dependence. The possible subsequent interactions between the buyer and seller add to the knowledge of each other and positive experiences, which could possibly lead to information symmetry between them. Information symmetric situation between the buyer and seller evolves when the customer has identification-based trust on the seller. Identification-based trust between the buyer and seller leads to joint goals, cooperative behavior, collective decision-making and collective efforts. Hence, this result negates the exaggerated negative consequences of customer dependence in buyer-seller relationships.

Our other contention of the study, the customer dependence has positive impact on customer satisfaction, did not get empirical support. We suggest this research question for further probe. Finally, our last hypothesis is related to the negative moderating effect of customer satisfaction on the positive relationship between customer dependence and customer trust was also supported. This result again emphasizes the importance of customer satisfaction in creating customer trust when compared to other variables.

The Effects of Intimacy on Consumer-Brand Relationships

Katharina Guese, University of Lausanne, Switzerland

Karine Gautschi Haelg, University of Lausanne, Switzerland

Interest in consumer-brand relationships (CBR) has emerged among scientists over the last decade (e.g., Fournier 1998). Nevertheless, no study investigated the effects of intimate CBR within an experiment. Subsequently, we examine the effects of intimacy and anthropomorphization on consumer brand perception. Moreover, this paper investigates whether a consumer feels more intimate with an anthropomorphized brand.

In the marketing literature, the assumption predominates that consumers attribute human characteristics to brands (e.g., Aaker 1997). For instance, given that brands are received as a gift or that they are utilized by a close friend or a family member, people are encouraged to humanize them (Rajagopal 2006). Anthropomorphization can be defined as viewing human characteristics in non human forms or events (Guthrie, 1993). Extending this line of thought, Fournier (1998) suggests that brands, like humans, serve as a legitimate relationship partner. One of the characteristics of human relationships (Miller and Lefcourt 1982) as well as of CBR (Fournier 1994; Fournier 1998) is intimacy. Intimacy can be described as “feelings of closeness, connectedness, and bondedness in loving relationships” (Sternberg 1986, p. 119). According to researchers in the field of interpersonal relationships, intimacy is an essential component of relationships among adults (Gaia 2002). In marketing research, Fournier (1994; 1998) assesses that intimacy is characterized by a detailed knowledge of the brand and a special brand meaning for the customer.

Following the perspective that life is given to a brand in the consumer’s mind (Aggarwal 2004; Ouwersloot and Tudorica 2001), we can assume that customers tend to build relationships with brands as with human beings. This in turn leads to the proposition that consumers tend to elaborate relationships with brands. The first overall prediction is that individuals who established an intimate relationship with a brand feel more trust towards this brand and a higher level of brand partner quality than if they do not sense this intimacy. Secondly, it is assumed that people tend to feel more trust towards the brand and a higher level of brand partner quality if it is perceived as having human characteristics.

To analyze these hypotheses, we conducted a scenario-based 2 (intimate/ non intimate) x 2 (anthropomorphized/ non anthropomorphized) ANCOVA with a final number of 63 participants. A fictitious fashion brand served as stimulus. The wording of the non intimate condition was mainly copied from an existing marketing text utilized by a famous brand. As defined by Hook et al. (2003), the brand description of the intimate condition included the components of intimacy: elements of love and affection, personal validation, self-disclosure and trust. The manipulation check was performed on the basis of a 9-item intimacy scale (Cronbach’s Alpha=.926) by Nysveen and his colleagues (2001), which was modified from Fournier (1994). While the non anthropomorphized scenario was written in an impersonal style, in the anthropomorphized scenario, the brand expressed itself as a person. A single item represented the brand’s anthropomorphization. As regards the dependent variables, the partner quality scale by Fournier (1994) was first utilized to measure to what extent the respondent perceives the brand as a good partner. Five items reflected this variable (Cronbach’s Alpha=.926). Secondly, participants completed the 10-item scale by Hess (1995) to indicate their trust level towards the brand (Cronbach’s Alpha=.761). Respondents fashion involvement served as covariate (Tigert et al. (1976); Cronbach’s Alpha=.769).

The main purpose of the experiment reported here was to examine the effects of intimacy and anthropomorphization on brand trust and brand partner quality. First, we successfully manipulated intimacy in the case where the brand was not anthropomorphized by the use of brand descriptions. Participants who received the intimate and non anthropomorphized text presented higher levels of intimacy than participants in the non intimate and non anthropomorphized condition $F(1,27)=8.89, p<.01$. In terms of our first hypothesis, we found that the use of intimate components in creating a CBR results in significantly higher levels of trust; $F(1,27)=5.05, p<.05$ and partner quality; $F(1,27)=6.36, p<.05$, compared to the use of traditional non intimate cues. Therefore, we propose that intimacy increases brand trust and brand partner quality. Analyses to test the second hypothesis, could not be completed because the manipulation did not present the expected results.

The first contribution of this work consists in its being the first study to successfully manipulate the perceived intimacy of a customer in the course of an experiment and, subsequently, to assess its effects on brand trust and brand partner quality. Therefore, the research question suggesting that marketers can establish an intimate relationship with a brand is affirmed. This result is even more significant, as intimacy is known to increase over time (Shimp and Madden 1988) and as it has never been manipulated in an experiment to analyze the CBR. Secondly, this work provides further insight into the performance aspects of brand management because the study proposes and empirically supports the idea that intimacy plays a pivotal role in a CBR. Additionally, this enlarged understanding of intimate relationships is crucial for marketers as it lays emphasis on the necessity to elaborate intimate feelings in CBRs because they represent a competitive advantage compared to competitor brands.

Notwithstanding these contributions, there are some limitations which suggest interesting opportunities for future research. First, the limited number of observations per experimental condition lowers the generalizability of the results. Furthermore, the external validity is limited due to the overrepresentation of women in the sample. Future research may replicate our study by using a larger counterbalanced sample. Secondly, given that a well-established multidimensional measurement of brand anthropomorphization does not exist in the literature, our unidimensional measurement limits the internal validity of the results. It is possible that the absence of a main effect on anthropomorphization stems from this lack of internal validity and that a replication of the study using a multidimensional scale could increase this validity. Therefore, future research should elaborate an appropriate scale and may replicate our study.

A Meta-Analytic Review of Fear Appeals: A Terror Management Perspective

David M. Hunt, University of Wyoming, USA

Stephanie Geiger-Oneto, University of Wyoming, USA

Omar Shehryar, Montana State University, USA

Fear appeals—persuasive messages designed to scare people into complying with a message by threatening negative consequences of non-compliance (Witte 1992)—are used in a broad range of social marketing contexts including drinking and driving, smoking cessation and prevention, domestic violence, food safety, and HIV/AIDS prevention. Scholarly interest in fear-based communications has been maintained for over fifty years. Three theories, drive theory (Janis & Feshbach, 1953), protection motivation theory (PMT; Rogers, 1983), and the parallel response theory (PRT; Tanner, Hunt, & Eppright, 1991) have guided much of the extant research on the efficacy of fear appeals. This body of research has demonstrated weak, but reliable effects of fear upon attitudes, intentions, and behaviors (Boster and Mongeau 1984; Mongeau 1998; Witte 2000). Relatively weak associations between fear and outcome variables has led to calls for research to identify plausible moderators between fear and persuasive outcomes (Witte 2000).

Across all three major theoretical approaches to fear appeal research, the dominant paradigm asserts that differences in the level of fear lead to differences in the persuasiveness of a message (Keller and Block 1996; Rogers 1985; Witte 1994). However, this approach overlooks the potential influence of the qualitative nature of the threatened consequence. Fear appeal messages vary not only in terms of the level of fear, but also in terms of the qualitative nature of the threatened consequence. For instance some consequences pose social threats, some pose threats of injury, and some pose threats of death. Terror Management Theory (TMT) (Greenberg, Pyszczynski, & Solomon 1986) suggests that messages threatening death produce responses to fear appeal messages that differ from responses to social threats or to threats of injury (Shehryar and Hunt 2005). Specifically, TMT suggests that fear appeals that make mortality salient may result in rejection of messages inconsistent with the cultural worldviews of message recipients. This suggests that extant theoretical approaches grounded in the level-of-fear paradigm under-predict the conditions under which fear-based messages will be rejected.

Terror Management Theory posits that even subtle reminders of mortality increase the need to defend and strengthen one's cultural worldview. Treatments considered equally noxious, such as threatening someone with serious injury, intense pain, or social embarrassment do not evoke mortality salience and do not lead to a defense of cultural worldviews (Greenberg, Pyszczynski, Solomon, Simon, & Breus, 1994). The distinction between responses to the fear of death versus responses to other noxious consequences has important implications for fear appeal research. Specifically, when individuals highly committed to a worldview are exposed to a death-threat-based message that conflicts with that worldview, they will reject the message's recommendation.

We hypothesize that when messages conflict with recipients' cultural worldviews, the qualitative nature of the threatened consequence will moderate the relationship between commitment to that worldview and persuasiveness of the message such that:

Hypothesis 1: When messages conflict with the cultural worldview of recipients, fear appeals that threaten death as a consequence will be negatively related to message acceptance and positively related to message rejection.

To test this hypothesis, we employ meta-analytic techniques to synthesize the findings of extant fear appeal research. Drawing on Terror Management Theory (Greenberg, et al., 1986), we distinguish between studies that used death as a threatened consequence from studies that did not. Studies included in the analysis are coded for the nature of threatened consequence and the degree to which the recommended message conflicts with the cultural worldview of the sample. To assess the moderating influence of nature of threat, effect sizes across a 2x2 experimental design (mortality salient vs. mortality non-salient threat) and (consistent cultural worldview vs. inconsistent cultural worldview) will be compared.

The purpose of this meta-analysis is not to settle any dispute among competing theoretical approaches. Instead, we offer a complimentary theoretical perspective to supplement extant understanding of fear appeal efficacy. Specifically, exploring the efficacy of fear appeals from the perspective of TMT contributes to fear appeal research in at least two ways. First, the categories of death and non-death-related consequences are discrete. Comparatively, there are no broadly accepted standards for what constitutes a high fear appeal, a moderate fear appeal, or a low fear appeal (Keller 1999). Fear communications differentiated by the qualitative nature of the threatened consequence avoids the debate over the constitution of fear levels. Second, this meta-analysis extends the theoretical domain of fear appeal research by offering TMT as an additional framework from which to examine the efficacy of fear-based communications. The TMT perspective allows future inquiry to examine the nature of fear as a factor moderating fear appeal outcomes thereby extending current research beyond the one-dimensional level of fear paradigm.

Why 'Fast Food' Triggers 'McDonald's' and 'Burgerking' Triggers 'Fast Food': Antecedents of Brand Typicality and the Relationship Between Category and Brand

Jia Liu, Monash University, Australia

Els Gijsbrechts, Tilburg University, The Netherlands

Dirk Smeesters, Erasmus University, The Netherlands

Very typical brands are assumed to be categorized faster upon a brand cue (brand-to-category direction) and to be recalled faster upon a category cue (category-to-brand direction) than less typical brands. We, however, propose that brand typicality effects are asymmetric in the brand-to-category and category-to-brand direction. We examine to what extent two different antecedents of brand typicality drive this asymmetry, namely family resemblance (FR) and frequency of instantiation (FOI). Three studies examine the relationship between FR and FOI, and their impact on the link between brand and category, in a context of real brands. The findings reveal that FR is more important in determining how fast a brand is categorized given a brand cue, whereas FOI is more influential in determining the speed of brand recall in the presence of a category name.

The Portion-Size Effect: How Increasing the Number of Portion-Size Options Can Increase the Volume of Food Consumption

Jing Lei, University of Ontario Institute of Technology, Canada
 Tripat Gill, University of Ontario Institute of Technology, Canada

Research Background and Hypotheses

Among the many contributing factors to obesity, the steadily increasing portion-sizes of food over the past 30 years (also known as “super-sizing”) are among the most criticized (e.g., Cutler et al. 2003; Wansink 2004). The increase in portion-sizes is said to have affected both the consumption norms (i.e., how much is appropriate to eat?) and the consumption monitoring accuracy (i.e., how much has been eaten?), and has ultimately led to increasing food intake (Chandon and Wansink 2007; Wansink and Ittersum 2007). While these two factors may explain why consumers overeat in a given portion size, it is not clear what causes them to choose a portion size (e.g., large) that is larger than their physiological need (e.g., medium) in the first place. In the current research, we propose that consumers’ choice for portion-sizes is influenced by the number of portion-size options available in the environment. Specifically, it is proposed that merely adding larger portion-size options (e.g., adding an “Extra Large” option to the set of “Small, Medium and Large”) can increase the volume of food consumed. In other words, over-consumption can occur not only by increasing the portion-size of existing options but also by adding new (and larger) portion-size options. We propose that this effect occurs as a result of 1) the change in consumption norms for the appropriate portion-size, and 2) the reduction in the consumption guilt associated with consuming larger portion-sizes. These two mechanisms are explained in detail below.

Wansink and colleagues (e.g., Kahn and Wansink 2004) suggest that people tend to rely on consumption norms to decide how much is appropriate to eat. These norms can be influenced by external cues that are present in the environment. The number of available portion-size options can be one such cue. For example, if the number of larger portion-size options (e.g., large, extra large drink; double, triple hamburger) increases, people may assume that there is a reason that these larger options are offered and use this information to guide their choices (Schwartz 1996). Specifically, the increasing presence of larger size options may signal that it is appropriate or socially acceptable to order a larger portion-size. As a result, the choice for larger portion-sizes may increase and accordingly the average consumption volume of food would increase.

Secondly, while the current super-sized environment may lead consumers to believe that “more is better” (Wansink 2004), the current environment of “calorie-consciousness” also leads consumers to regulate how much they consume (Cutler et al. 2003). The latter self-regulation may make consumers feel guilty to choose the “large” option from the set of “small/medium/large” (S/M/L) options. However, if another “extra-large” (XL) option is added to this set, consumers may feel less guilty to choose the “large” option from the set of S/M/L/XL options. The reduced feeling of guilt may consequently increase the choices for larger sizes as the number of portion-size options increases.

Experiments and Results

Two experimental studies were conducted to test the effect of increasing portion-size options on consumption volume. The studies used hypothetical scenarios where subjects were told to imagine that they were in a restaurant and decided to order either a beverage or a fast food meal from different sets of portion-size options. Experiment 1 (n=64) employed a 2 (3 vs. 4 portion-size options) * 1 (vanilla milkshake) between-subjects design, in which participants had to choose from either 3 options (small/medium/large) or 4 options (small/medium/large/extra large) of vanilla milkshake. We also asked the participants to estimate the amount of calories contained in each portion-size after they made the choice. We found that in the 4 (vs. 3) option condition, more people chose the “Large” option (33.3% vs. 13.4%, $z=1.69$, $p=0.05$) and fewer people chose the “Small” option (26.2% vs. 45.5%, $z=-1.56$, $p=0.06$). The proportion of people choosing “Medium” was not significantly changed (35.7% vs. 40.9%, $z=-0.41$, $p=0.34$). We also found that the average number of calories consumed was significantly increased when participants were given 4 (vs. 3) portion-size options (629 vs. 523 calories, $t=2.49$, $p=0.02$). Furthermore, we found that participants significantly underestimated the number of calories contained in each portion-size ($p<0.001$ for all conditions).

Experiment 2 was conducted to investigate if the above results can be replicated in a fast food meal scenario and whether providing calorie information would influence participants’ portion-size choices. Experiment 2 (n=187) employed a 2 (3 vs. 4 portion-size options) * 2 (calorie information provided vs. not provided) between-subjects design using a fast food meal scenario (chicken salad). We found that more people chose the “Large” option in the 4 (vs. 3) option condition when no calorie information was provided (45.7% vs. 20%, $z=2.69$, $p<0.001$), whereas this change was not significant when calorie information was provided (38.8% vs. 31.0%, $z=0.78$, $p=0.22$). We also found that fewer people chose the “Small” option in the 4 (vs. 3) option condition regardless of whether calorie information was provided or not (8.2% vs. 21.4%, $z=-1.80$, $p=0.04$; 6.5% vs. 18.0%, $z=-1.70$, $p=0.04$). Furthermore, the results show that the average number of calories consumed was significantly increased when participants were given 4 (vs. 3) portion-size options (393 vs. 333, $t=4.42$, $p<0.001$).

Implications

The above results confirm our prediction that the choice for larger portion-sizes increases as the number of portion-size options increases. This finding violates the principle of regularity based on the normative probability choice model (e.g., Tversky 1972); specifically that the probability of choosing a particular option (e.g., “large”) cannot be increased when the number of offered options increases. More importantly, our finding indicates that the mere increase in the number of portion-size options offered can lead to over-consumption. The two proposed underlying reasons that lead to this effect, namely the changes in consumption norms and consumption guilt, are to be tested in subsequent studies. Overall, this research aims to provide insights into the impact of a specific type of

environmental factor (i.e. number of portion-size options) on food consumption and suggest implications for managers / public-policy makers to address the issue of over-consumption.

A Taxonomy of Price Behaviour

Björn Ivens, University of Lausanne, Switzerland
Brigitte Müller, University of Lausanne, Switzerland
Katharina Guese, University of Lausanne, Switzerland

Abstract

Many of the classical retail chains attempt to counter discounters' aggressive expansion strategy by introducing low-priced private label product assortments. In this paper, we analyze the relationship between consumers' price behavior and their reactions toward the classical retailers' low price products. Based on survey data we first develop a taxonomy of customers' price behavior. This taxonomy is built from several dimensions of consumers' price behavior. We then analyze if the price behavior cluster consumers' belong to has an impact on their response to classical retailers' low-price products. The paper closes with a discussion of the results and directions for future research.

Over the past years, the international expansion of hard-discounters such as Aldi or Lidl has led to a shift in the European retail landscape. The relative market share of this type of retail format has constantly grown (Denstadli et al. 2005; Business Insights 2006). Traditional retail chains have long had difficulties finding an appropriate strategic reply. The most important move for many retailers has consisted in introducing an assortment of low-priced products which are sold at prices comparable to those of the hard-discounters products. For example, in Switzerland two major players dominate the retail market, i.e. Coop and Migros. Together they hold approximately 72% of the national retail market and traditionally both have been selling their products at average to upper price points (Von Ungern-Sternberg and Jametti 2007). When German hard-discounters Aldi and Lidl have entered the Swiss market, both Swiss retail chains have established discount price product ranges. The strategic function of these new product assortments in both cases is to retain price sensitive customers and prevent them from switching to the new competitors. An important question in this context is whether these products attract all types of customers or whether specific customer groups are more likely to buy them. The purpose of this paper is to provide elements to answer this question.

Consumer's price behaviour

In a broad stream of research, different constructs describing customers' price behavior have been conceptualized (e.g. Lichtenstein et al. 1990; Vanhuele and Drèze 2002) and their impact on purchasing decisions has been demonstrated (e.g. Ailawadi et al. 2001; Estelami and Lehmann 2001).

Lichtenstein et al. (1993) distinguish several constructs describing different aspects of customers' price behavior. Four constructs reflect the negative role of price: (1) Price consciousness; (2) Value consciousness; (3) Sale proneness; (4) Price mavenism. Two constructs reflect the positive role: (5) Price-quality scheme; (6) Prestige sensitivity.

The extent to which a consumer is price conscious or a price maven varies between individuals. These concepts describe the personality of each consumer. While scholars have analyzed the relationship between various aspects of consumers' price behavior and outcome variables, little is known about the extent to which typical patterns of price behavior exist. From a managerial vantage point, however, the existence of price behavior clusters or segments would be of high relevance. To the best of our knowledge, the constructs described above have not yet been used in order to segment customers.

Research methodology and results

A total number of 471 questionnaires were collected from consumers. The structure of respondents corresponds to the one in the relevant regional population with regard to gender and age. The scales included in the questionnaire are mostly drawn based upon the ones

developed by Lichtenstein et al. (1993): Value consciousness (4 items, $\alpha=.692$), Price consciousness (3 items, $\alpha=.869$), Sale proneness (3 items, $\alpha=.703$), Price mavenism (4 items, $\alpha=.780$), Price quality scheme (3 items, $\alpha=.746$) and Prestige sensitivity (3 items, $\alpha=.729$).

In our analysis, we proceeded in two steps. First, we used cluster analysis in order to uncover a potential segment structure in consumers' price behavior. Analysis of variance shows that the three identified clusters differ significantly along five of the six active cluster variables. Only for prestige sensitivity we observe no significant differences. Analysis of discriminance shows that the probability that objects in the data base are correctly allocated to the clusters is 92.5%:

Cluster 1 (value-oriented shoppers) is characterized by high value and low price consciousness. Sale proneness is also lower as for the other two clusters. Consumers see themselves as price mavens and score the highest on price-quality scheme.

Cluster 2 (price-oriented shoppers) is composed of consumers who show low value but high price consciousness as well as relatively high sale proneness. On price mavenism and prestige sensitivity they have average scores.

Cluster 3 (sale-driven shoppers) is composed of sale prone consumers who score low on both price and value consciousness, on price mavenism and on price quality scheme.

The second step aims at identifying the buyers of discount-price products. Using analysis of variance, we also analyzed whether significant differences exist in the three groups' response to low price product assortments at classical retailers. We included three independent variables in the analysis, i.e. consumer attitude towards discount-priced products, consumer attitude towards that specific retail brand and consumers frequency of buying the specific retail brand. For all three independent variables there are significant differences ($p<0.05$) between the three shopper clusters. Value-oriented and price-oriented shoppers buy more frequently low price products than those driven by sales. A similar pattern is observed concerning cluster 3. Sale-driven consumers have the least favorable attitude toward discount-priced assortments and the specific assortment brand and also buy less frequently the brand. On the contrary, we can observe that value and price-oriented consumers evaluate these types of products more favorably and buy them more frequently.

Implications and future research

By elaborating this taxonomy, we shed light on the link between key constructs in behavioral pricing and consumer response to discount concepts. For managerial practice, our results imply that the managers of retail brands should adapt the positioning of their discount-price brand(s). In particular, strategies need to be designed to communicate precisely with the price segment who responds positively to the discount-priced brands as compared to the segment of sale prone shoppers which is mainly focusing upon price promotions for national brands.

Future research is undertaken in order to focus not only focus upon respondents' reactions toward the classical retailers' discount-priced assortments but also compare consumers' attitudes towards the discount retailers (Aldi and Lidl) with attitudes toward discount-priced assortments. This would allow identifying potential motivational gaps in buying one or the other offering.

Effects of Personal Values on Brand Equity

Eda Gurel Atay, University of Oregon, USA

Brand equity, "marketing effects uniquely attributable to the brand" (Keller 1993, p. 1), has been studied by several researchers (Aaker and Keller 1990; Sivakumar and Raj 1997). Many of these studies found that high equity brands benefit from more loyal and satisfied customers, higher purchase intentions, and more frequent use of the product/service. Because brand equity has so many important implications, it is essential to understand how to build brand equity (Keller 1993; Kirca, Jayachandran, and Bearden 2005). One way to build brand equity is to position a brand accordingly. Positioning is a fundamental part of a company's marketing strategy since it describes

the distinctive place of each brand in the target consumers' minds and provides clear bases to compare different brands in a product category (Kotler, 2003; Prince, 1990). In a way, the result of successful positioning is the successful creation of brand equity. And, since consumers decide with their purchases which brands have more equity than others, it is important to consider them when establishing a brand's position. One of the most important characteristics of people, hence consumers, is their personal values. Accordingly, the aim of this paper is to examine effects of brand positioning based on personal values on brand equity.

Values are described as the most important construct by many researchers (Rokeach 1973; Kahle 1996) in social science. They are central to people's lives (Kahle and Timmer 1983), are enduring and difficult to change (Rokeach 1973), and guide behaviors and judgments across specific situations (Rokeach 1973; Kahle and Timmer 1983) including consumer behaviors. Indeed, research on consumer means-end chains (Gutman, 1982; Reynolds, 1985) consistently finds that the core reason consumers choose products is value fulfillment. These findings suggest that values can have a strong impact on brand equity. Specifically, in this paper, it is hypothesized that customers form more favorable attitudes toward a brand if its position in their minds is consistent with their values (Jayawardhena 2004). Favorably formed attitudes, in turn, contribute to paying more attention to the brand (Roskos-Ewoldsen and Fazio 1992). Finally, paying more attention to a brand contributes to higher brand equity (Dhar and Simonson 1992) in terms of purchase intentions, positive word-of-mouth intentions, and actual buying behaviors.

To test these hypotheses, an online study was conducted with 226 university students. After completing List of Values (cf. Kahle 1996), participants were directed to a web site where they could have an online shopping experience. This web site gave information on three brands from a single product category. Two of the brands were aimed to represent different value dimensions characterized by Homer and Kahle (1988): external values (i.e., sense of belonging, being well-respected, and warm relationships with others) or internal values (i.e., self-fulfillment, self-respect, and sense of accomplishment). The other brand did not highlight any specific value. To stress external values, the message included phrases like "new member of your family, taking care of others, loved ones, and being appreciated". To stress internal values, in contrast, phrases like "reward yourself, just for you, and what you want" were used. Each participant was presented with these three messages in a random order. After examining the brands by reading product descriptions, participants completed measures of attitude toward each brand (bad/good, negative/positive, unfavorable/favorable, something I dislike/something I like, not at all attractive/attractive, and undesirable/desirable). Then, participants were asked to buy one product from several product categories. There were eight brands in each product category and participants had 10 seconds to examine these eight brands and decide which one they would buy (of course, without paying money). Three of the brands were the same as in the first part of the study. The time a participant spent in examining each brand was recorded as a measure of attention. After participants chose one brand from each category to buy, they completed purchase intention and word-of-mouth intention questions for these three brands. Moreover, participants' choices were used to measure their actual buying behaviors.

Regression analyses indicated that as the score on the composite index of external values increased, attitudes toward the brand that stressed external values became more favorable ($\alpha=.142, t=2.145, p<.033$). However, the relationship between the composite index of internal values and attitudes toward the brand reflecting internal values was significant only at .087 level. In other words, attitudes were predicted significantly by external values but not by internal values. In contrast, attention paid to brands that reflected internal values was significantly influenced by attitudes toward those brands ($\alpha=.157, t=2.374, p<.018$) while attention paid to brands stressing external values was not affected by the attitudes toward those brands. Similarly, spending more time in examining the brands reflecting internal values resulted in significantly higher purchase intentions for those brands ($\alpha=.187, t=2.857, p<.005$) but not for other brands. Attention had also a significant positive impact on word-of-mouth intentions for brands stressing internal values ($\alpha=.191, t=2.866, p<.005$). However, the relationship between attention and purchase intention for brands reflecting external values was significant only at .066 level ($\beta=.123, t=1.847, p<.066$) and the results were not significant for word-of-mouth intentions. Finally, to look at the relationship between attention and buying behavior, attention was recoded as "less attention" and "more attention" by using median-split. The analyses revealed that while only four participants who paid less attention to the brands reflecting internal values chose those brands to buy, 25 participants who paid more attention to those brands chose them to buy ($\chi^2(1, N=226)=17.445, p<.001$). Likewise, only 15 participants who paid less attention to the brands reflecting external values chose those brands to buy while 31 participants who paid more attention to the brands reflecting external values chose them to buy ($\chi^2(1, N=226)=7.543, p<.006$).

The present research shows that even a single message based on personal values is capable of increasing brand equity through attitudes and attention. That is, positioning messages highlighting some personal values affect attitudes positively. Attitudes, on the other hand, affect brand equity through attention. However, most of the results were confirmed for brands associated with internal values. One reason for this might be the characteristics of the sample. University students were employed to run this study and it is highly possible that these participants endorsed internal values more than external values.

Overall, even though the conceptual model was partially supported by the data, it provides some insights into the importance of values in creating brand equity. Indeed, it is expected that brand equity studies will be more meaningful if personal values are taken into consideration.

Comparative Knowledge and Consumer Choice

Liat Hadar, University of California at Los Angeles, USA

Sanjay Sood, University of California at Los Angeles, USA

Abstract

We examined whether manipulating consumers' subjective knowledge would alter their preferences. In two studies we manipulated participants' feeling of relative knowledge or ignorance by presenting a reference group which was more or less knowledgeable or by presenting a loosely related question that varied in difficulty. Participants' choices were affected by their perceived relative knowledge. We found that participants who felt relatively knowledgeable were less susceptible to judgmental biases and reported that they were more likely to join retirement saving plan they knew little about.

Previous research on risky choice has shown that when people are primed to believe that they are comparatively ignorant they become more risk averse; when they are primed to believe that they are comparatively knowledgeable they become more risk seeking (Fox & Tversky, 1995; Fox & Weber, 2002).

The current paper examines whether non-risky consumer choice can be altered by manipulating consumers' feeling of knowledge. Such findings may have very valuable consequences to domains in which consumers make suboptimal decisions such as employees' tendency not to sign up for retirement saving plans. By designing plan information that would make consumers feel more or less knowledgeable about retirement saving, we might be able to help more consumers by encouraging them to save for retirement. We conducted two studies that provide preliminary evidence for the role of subjective knowledge in consumer choice.

In Study 1 we examined the effect on comparative knowledge on the conjunction fallacy, the mistaken belief that the conjoint events (A&B) are more likely than their constituents (A or B) when instances of the conjunctions are easier to recall (Tversky & Kahneman, 1983). 196 students were asked to imagine that they are offered four new medication packets, similar in number of pills and costs. These medications treated different symptoms: sore throat, weakness, fever, or fever particularly caused by sore throat. Participants were asked which medication they would be more likely to buy if they were to buy one of them. Participants in the "relative knowledge" condition were told that "The pharmaceutical company is presenting this choice to random people in downtown xx as well as to UCLA undergraduate students"; participants in the "relative ignorance" condition were told that "The pharmaceutical company is presenting this choice to Medical students and doctors at the university as well as to UCLA undergraduate students". This information was given to the participants after the four medications had been presented and before they made their choice. We hypothesized that participants would feel relatively knowledgeable compared to random people in downtown, but relatively ignorant relative to Medical students and doctors.

Following the conjunction fallacy, we expected that, overall, more participants would choose the medication that treats fever caused by sore throat than the medication that treats fever only. Moreover, we expected participants in the "relative knowledge" condition to be more confident in their knowledge about medications compared to participants in the "relative ignorance" condition, and thus be more careful in their choice of medication and less susceptible to the conjunction fallacy.

The results supported our hypotheses: the proportion of participants who chose the "fever by sore throat" treatment (i.e., the conjunction) was lower than the proportion of participants who chose the "fever" treatment (i.e., the constituent event) in the "relative knowledge" condition (33.96% versus 66.04%, $p=.001$ one-tailed). No differences were found in the "relative ignorance" condition (46% versus 54%, $p=.2142$ one-tailed). In other words, making people feel that they are more knowledgeable made them less susceptible to the disjunction fallacy.

Study 2 examined the role of subjective knowledge in saving choices. Participants were provided information about retirement saving plans and were told that they would subsequently be asked to estimate on a 7-point Likert scale the likelihood that they would join such retirement plan in the future, when they have steady jobs. Participants were further informed that before they estimate the chances of

joining the retirement plan, they would be asked a question that would allow the researchers to estimate their general knowledge about financial markets. Half of the participants were given a difficult question and half were given an easy question. We hypothesized that those who received the easy question would feel knowledgeable about financial markets and thus more comfortable announcing that they are likely to join a retirement plan they know only little about; in contrast, participants who received the difficult question would feel less knowledgeable about financial markets and thus less comfortable announcing that they are likely to join a plan they know only little about.

An analysis of the results revealed that participants who received the easy question indicated that they were more likely to join a retirement saving plan in the future than participants who received the difficult question, although both received the same amount of information about retirement saving (5.5 versus 5, on average, $p < .05$).

The results of the two studies provide preliminary support to the notion that subjective knowledge may impact judgment and consumer choice, and that consumer choice may be altered by manipulating subjective knowledge.

Choosing How Many Options to Choose From: Does it Depend on Affective Priming?

Sebastian Hafenbrädl, University of Lausanne, Switzerland

Ulrich Hoffrage, University of Lausanne, Switzerland

Chris M. White, University of Lausanne, Switzerland

When making purchase decisions, how many options do people wish to have available? Does this number depend on people's affect towards the product? To address this, we combined two research areas, the "tyranny of too much choice" and "affective decision making".

Tyranny of too much choice

Larger choice sets offer advantages: As compared to smaller choice sets, they are likely to contain better options (assuming options are randomly sampled from the population), leading to better decision outcomes. On the other hand, larger choice sets also have disadvantages: More options require more computation, both for screening and comparing the options, leading to a more effortful and time consuming decision process. This trade-off between outcome-satisfaction and process-satisfaction is therefore integral to understanding how people determine the number of options they wish to have available, which we refer to as their desired-set-size (DSS).

Reutskaja and Hogarth (2009) measured satisfaction with a choice made from a set of gift boxes whose size ranged from 5 to 30 options. They observed an inverse U-shaped relationship between satisfaction and the size of the choice set. This suggests that initially the benefits of having a larger choice set are greater than the costs, causing satisfaction to increase. However, as the size of the choice set continues to increase, the additional costs exceed the additional benefits, causing satisfaction to decrease.

Despite recent interest in the tyranny of too much choice, the size of the choice set has nearly always been determined by the experimenter (e.g., Iyengar & Lepper, 2000; White et al., submitted). In real life, however, people can usually determine the size of their choice set themselves by visiting as many stores as they wish and stop considering more options at any time. Much could be learned by asking participants to determine the size of the choice set themselves, but as far as we are aware, this has only been done in studies reported by Salgado (2005) and Chernev (2006).

Affective decision making

The above cost-benefit analysis ignores affect and emotions even though they play a role in choice situations. It is not only options themselves that evoke affect, rather, what happens prior to a judgment or decision can also cause options to be evaluated in an affective manner. Hsee and Rottenstreich (2004) found that people's Willingness-to-pay (WTP) for items depended on whether a person is computationally primed (achieved with a questionnaire containing items that required them to perform computations) or affectively primed (achieved with a questionnaire containing items that required them to examine and report their feelings).

Predictions

Similar to Hsee and Rottenstreich (2004), we predicted that people who were computationally-primed would exhibit a constant sensitivity to an increase in the number of items. In contrast, we predicted that people who were affectively-primed would appear to be insensitive to the number of items.

Procedure. First, the 160 participants were told that they could choose 5 (or 10, manipulated between subjects) postcards of their university's campus. Second, they completed either the affective or computational-priming questionnaire (adapted from Hsee and Rottenstreich 2004). Third, they determined their WTP and their DSS from which they could choose their 5 (or 10) cards. The minimum set size was either 5 postcards (or 10, according to the condition); the maximum was 100 postcards. Fourth, these three steps were repeated with Christmas present tags (order counterbalanced) and with different priming questions. Participants were given the opportunity to take home their chosen items.

Results and Discussion

The calculation-primed participants were willing to pay significantly more for 10 cards than for 5. In contrast, the affectively-primed participants were largely insensitive to the number of items they would choose. This predicted pattern was only significant for some of the dependent variables and was affected by whether outliers were removed from the data. In the full dataset, the interaction was significant when considering all dependent variables together (with a MANOVA), but when each dependent variable was analyzed separately (with separate ANOVAs) it was only statistically significant for the DSS that was stated a second time at the end of the experiment, although there was also a tendency towards this interaction for the DSS that was stated initially. In the trimmed dataset, the interaction was significant when considering all dependent variables together, but when each dependent variable was analyzed separately, it was only statistically significant for the DSS that was stated a second time and marginally significant for WTP.

After the experiment, several participants said that they did not perceive watching the pictures as an investment of time, that is, a cost they had to pay in order to select some good ones, but that they had intrinsically enjoyed seeing them. This could explain the added noise in the measures elicited before people actually watched the pictures.

There was no correlation between the two measures of costs, hypothetical financial costs (WTP) and expected temporal and cognitive costs that will subsequently be realized (DSS). This was surprising because these variables showed similar patterns of mean data. This suggests that, contrary to the well-known expression “time is money”, people do not naturally treat the two concepts as being equal. Investigating the mental relationship between these two concepts could therefore be a fruitful area for further research.

We also measured participants’ satisfaction with the choosing process and the chosen items. Reutskaja and Hogarth (2009) found satisfaction to be an inverse U-shaped function of the manipulated choice set size. In contrast, we found that there was no linear or nonlinear relationship between DSS and the two reported satisfaction measures. The fact that participants determined the size of the choice set themselves provides two plausible explanations for the lack of a relationship. First, people may have been able to determine the set size that would yield the maximum overall satisfaction for them. Second, people may have become committed to their stated DSS and therefore did not want to report regretting having too many or too few options, as that would imply that they had previously made an imperfect judgment.

Multiple Motives, Multiple Selves: What Motivates Consumption

Tracy R. Harmon, Syracuse University, USA
 Anand Kumar, University of South Florida, USA
 David Ortinau, University of South Florida, USA

One of the least contested claims in marketing is that individuals are motivated to enhance their self-esteem and establish consistency in their self-concept when engaging in symbolic consumption (Levy 1959; Grub and Grathwohl 1967; Levy 1986). However, less attention has been directed towards additional identity motives guiding self-brand interactions. Recently, in the social psychology literature, motives beyond self-esteem and self-consistency were found to aid in identity construction namely: efficacy, meaning, distinctiveness, and belonging (Vignoles, Regalia, Manzi, Gollidge, and Scabini 2006). These alternative motives can provide a richer understanding of how and why individuals are motivated to engage in self-brand interactions.

When brand associations are used to construct one’s identity or to communicate one’s self to others, a self-brand connection is formed (Escalas and Bettman 2000; 2005). Self brand connections measure the degree to which individuals have incorporated brands into their self-concept (Escalas and Bettman 2003; 2005). Presumably, self-brand connections will be enhanced as brands are chosen to achieve specific identity goals. This is due to identity commitment, which is associated with expectations of behavior relevant to identity goals (Foote 1951). Identity commitment serves as a boundary criterion in determining how motivations from social influence will be handled. To illustrate, a person committed to the identity of “soccer mom” will interpret marketing stimuli differently than one committed to a “corporate executive” identity.

An individual is likely to support and be more committed to preserving a particular identity when it is more central (Settles 2004). As stated earlier, centrality is influenced by multiple identity motives, which are related to a specific identity within the individual. Therefore a highly central identity should lead to stronger self-brand connections as various motives are satisfied. The key determinant of this proposed relationship is brand associations congruent with the self-image. Therefore the following hypothesis is offered:

A brand that is very popular and used by many different types of people (e.g., a BMW) may have different meanings to consumers based on the different identities that are presented through brand usage. It is expected brand symbolism will moderate the formation of

self-brand connections due to the brands ability to communicate something about the individual. It is hypothesized that in cases when centrality is low, brand symbolism will be the primary source of self-brand connections. Thus it is expected that brand symbolism will moderate the effects of identity centrality on self-brand connections.

Methodology

Using a methodology developed by Vignoles et al. (2002), participants freely generated a list of identities then rated them for its centrality on automobile purchases (dependent variable) and for its association with motivations of self-esteem, distinctiveness, continuity, self-efficacy, belonging, meaning, recognition, consistency, and security (independent variables). The main analysis was designed to evaluate the unique contributions of each motive rating to predictions to identity centrality.

Results

Overall, the results indicate individuals do in fact assign varying levels of importance to their identities in a consumption environment. The findings suggest centrality is a viable construct for understanding how individuals manage multiple identities in consumption decisions. Participants rated as more central, those identities that provided a sense of self-esteem and that gained them recognition with regard to their automobile. Together, these motives seem to suggest individuals are motivated more so by internal self aspects (self-esteem) compared to other's acknowledgement of them (recognition). This finding is quite interesting because it these motives are not consistent with Grub and Grathwohl's Model of Consuming Behavior (1967) and Sirgy's (1982) Product-Image Congruity Theory. Ideally, the more participants rated an identity as satisfying feelings of self-esteem or self-consistency, the more they should have considered it as central to their decisions. However, when considered with the other eight motives, the effects of these two motives were attenuated and failed to be strong predictors of identity centrality. Brand symbolism as a moderator between identity centrality and self-brand connection was evidenced from the findings. Brands that were perceived as more symbolic resulted in higher self-brand connections when the identity was central to the automobile category. When combined with the psychological importance, an identity that is congruent with brand associations, but is also congruent with the typical user and/or brand personality, stronger connections to the brand are likely. This interactive effect between brand symbolism and identity centrality is worth exploring further.

When the Ingroup Fails to Indicate Brand Meaning: Exploring the Role of Identity Centrality in Self-brand Connections

Tracy R. Harmon, Syracuse University, USA
 Anand Kumar, University of South Florida, USA
 David Ortinau, University of South Florida, USA

Self-brand connections are defined as the degree to which a consumer has incorporated the brand into their self-concept (Escalas and Bettman 2003, 2005). Escalas and Bettman (2005) found that brand associations consistent with an ingroup led to stronger self-brand connections compared to brand associations inconsistent with an ingroup. This is because brands become more meaningful the more closely they are linked to an individual's identity. But what happens to this relationship if another identity other than the ingroup identity is associated with the brand? Or how are self-brand connections influenced if the reference group is associated with multiple brands? This study seeks to address the former question by examining the nature of multiple identities in the formation of self-brand connections.

Markus and Kunda (1986) put forth the term "malleable" (or working) self-concept to refer to an individual's various self-conceptions (e.g. ideal self, perceived self, social self) which function to provide an interpretative and evaluative context for the overall view of the self (Markus and Wurf 1987). To date the consideration of multiple selves has been omitted from research linking reference group influence to self-brand connections (Escalas and Bettman 2005; Chaplin and Roedder-John 2005). This omission leads to questions surrounding the differential attitudes and cognitions within the perceived reference group. This is supported by literature in social psychology which suggests individuals assign a level of significance to their identities which directly impacts group driven attitudes, behaviors, and cognitions (Vignoles, Regalia, Manzi, Gollidge, and Scabini 2006; Settles 2004; Stryker and Serpe 1994). It is argued that because individuals possess multiple identities, an individual's self-brand connection should be reflective of the identity that is most central to the brand. In simpler terms, if the brand is associated with a particular ingroup, then the ingroup identity should carry the most psychological importance in interactions with the brand.

Identity centrality, defined as the psychological importance one places on a given identity (Settles 2004) can aid in explaining how individuals negotiate multiple identities exacerbating one and buffering others. Identity centrality requires conscious awareness and is usually measured by asking individuals to rank different identities according to their importance (Rane and McBride 2000). Self-brand connections are likely to be enhanced when an ingroup identity is central to the brand compared to when it is not. This research shows that the differential self-brand connections within the ingroup are due to the lack of value expressive influence by other reference group members when centrality is taken into consideration.

Methodology

The procedure was a replication of that used by Escalas and Bettman (2005). Changes dealt with the order of measures and the incorporation of the identity centrality measure.

Results

The consideration of identity centrality in this study was based on the expectation that ingroup members will form differential self-brand connections for the brand image match condition. Extending these findings, identity centrality positively moderated self-brand connections for the ingroup. This result is significant in that it reveals the significance of centrality in examining self-brand interactions. It is not enough to say that an identity is salient to a particular brand. As evidenced in the results, identity centrality leads to stronger self-brand connections in the brand image does match condition. This difference among ingroup members indicates there is varying levels of importance within the group. From a marketer's stand point this could mean the difference in message effectiveness. Salience may be sufficient enough to encourage an individual to attend to a particular message. But is it enough to create an emotional bond? Is it enough to get the consumer to buy the product? It is argued that centrality is true a catalyst for self-brand connections.

The moderating influences of identity centrality on outgroup brand associations was insignificant. It difficult to hypothesize the directional influence of identity centrality in outgroup effects due to various meanings associated with outgroups. Identity importance can be hypothesized to influence the outgroup but it will vary depending on the desired degree of divergence from the outgroup. For instance, an individual may declare an outgroup but may desire to eventually become one its members (e.g. fraternities and sororities). Or perhaps an individual may have some level of similarity with the outgroup. These scenarios make it difficult to predict how identity centrality will influence self-brand connections.

Brand associations not matching the image of the outgroup were lower for individuals with an independent self-construal compared to interdependent self-construal. This finding was consistent with Escalas and Bettman's (2005) results. They reasoned that outgroup brand associations will have the greatest effect on participants with independent self construals due to their strong differentiation needs. This was evidenced in this study as well.

Identity centrality moderated the influence of self-construal such that the degree of self-brand connections for independent versus interdependent self-construal was reversed. Interdependents formed lower self-brand connections than independents. Interdependents were thought to shift their focus from outgroup differentiation to ingroup differentiation, leading to lower self-brand connections. By doing this they are attempting to show ingroup favoritism and seeking distinctiveness from the outgroup. Lower self-brand connections for individuals with interdependent self-construals is more in line with the self-construal research which views interdependents are more collectivist in nature (Singelis 1994). The contrast in findings due to identity centrality may be worth investigating the continued use of the self-construal to examine individual differences in self-brand connections.

Overall, the pattern of results supports the general idea proposed in this essay: individuals use brands to create or communicate their self-concept partly in an effort to meet certain identity goals (e.g. self-verification, self-enhancement) and do it more so when a particular identity is central.

Brand Origin or Product Origin? The Effects of Country of Origin Fit on Brand Evaluation

Sangwon Lee, University of Central Florida, USA

Zachary Johnson, University of Central Florida, USA

Xin He, University of Central Florida, USA

In previous research streams on the topic, the term country of origin has been defined as either brand origin or product origin (country of manufacture); brand origin referring to the home country of the brand, and product origin referring to where the product was actually made. Regardless of the definition used for country of origin in a particular paper, the research outcome has consistently shown that consumers make inferences about product quality based on either definition of country of origin. Alternatively, this research argues that country of origin evaluations are comprised of three components: 1) brand origin 2) product origin, and 3) fit between brand origin and product origin.

The term "country of origin fit" refers to whether or not the brand origin is the same as the product origin; if the brand origin and product origin are the same country, this congruence leads to a fit. No fit refers to the situation when the brand origin is one country and the product origin is another country. To this concept of country of origin fit, previous research has been silent.

The current research offers a theory-based empirical examination of country of origin fit. The purpose of the present study is to examine whether processing fluency enhanced by fit will affect brand evaluation. The product origin is often different from brand origin due to several management reasons, but the exact influence on brand evaluation was not clear. This research suggests that the effects of fit between brand origin and product origin can be explained by processing fluency.

The findings of this research extend the country of origin research streams. First, this research extends the previous research by expanding the country of origin evaluation to three components: 1) brand origin 2) product origin, and 3) fit. Second, several studies examined country of origin effects on product quality evaluations from the management perspective (Paterson and Jolibert 1995; Maheswaran 1994). However, little theory-based research has examined consumer perceptions that influence country of origin evaluations (Gurhan-Canli and Maheswaran 2000). This research extends the extant research by introducing information fluency theory from the consumer's perspective. Third, the findings of this research extend processing fluency research. Theoretically, previous researches have examined processing fluency within the single category of product or word. This research extends the literature by adding another stimulus for processing fluency such as fit between two different levels of brand and product. Fourth, this research extends the previous country of origin research by introducing fit which will strengthen the country of origin effects on brand evaluation.

To examine how fit influences brand evaluation, two streams of research will be discussed. First, stereotype literature is examined to show the relationship between fit and information processing fluency. Second, processing fluency literature is reviewed to show the relationship between information processing fluency and brand evaluation (Lee and Aaker 2004). Stereotype literature suggests that if the information is more consistent with stereotypes, people can more easily process information because consistent information is expected and is therefore conceptually more fluent (Bodenhausen and Lichtenstein 1987; Lee and Aaker 2004; Macrae et al. 1994; Sherman et al. 1998). In our context, if the brand origin is the same as the product origin, people can more readily process information because product information is consistent with consumer stereotypes (brand information) and will be more fluent. Processing fluency literature has shown that processing fluency can lead to enhanced affective judgments (Lee and Aaker 2004). According to this view, when people are presented with a brand that is easy to process, the positive experience of fluent processing leads to more positive evaluation of the brand. Similarly, in the context of this research, the processing fluency enhanced by the country of origin fit may lead to more positive attitude toward the brand.

Hypothesis 1 suggests that the fit of the country of the brand origin and the product origin will lead to more positive attitude toward the brand than no fit. To test this hypothesis, 170 undergraduate business students from a major southeastern university participated in

the between subject experiment that is designed to test whether the country of origin fit will affect brand evaluations. To control the quality inferences from the brand name and country, mock brand and country names were created for the stimuli (e.g. GLOBAL brand and Country J, K). The stimuli also specified that both countries are known for producing the same quality product. Study 1 supports the notion that the fit of the country of brand origin and product origin has an impact on attitude toward the brand. There was a statistically significant difference at the $p < .05$ level in attitude toward the brand scores for two different fit conditions ($F(1, 168) = 4.50, p < .05$). Thus, the fit leads to more positive attitude toward the brand than no fit.

Based on the result of study 1, study 2 will be designed to further explore the moderating effect of the quality of brand origin on the relationship between fit and attitude toward the brand. Previous research shows that country of origin is likely to affect interpretation of information about specific product attributes especially when country of origin is conveyed before the attribute descriptions (Hong and Wyer 1990). In the context of this research, we propose that processing fluency enhanced by the country of origin fit will strengthen the country of origin effects on brand evaluation. Thus, depending on initial quality of brand origin, the attitude toward the brand will be either more positive or more negative.

For the second study, 2 brand origin (high quality, low quality) x 2 country of origin (fit, no fit) between subjects experiment will be designed to create one of four possible experimental conditions: (1) High-quality brand origin with the same product origin, (2) High-quality brand origin with the different product origin that produces equally high-quality products, (3) Low-quality brand origin with the same product origin and (4) Low-quality brand origin with the different product origin that produces equally low-quality products.

Why Humor Breaks Resistance to Influence: Implicit Effects of Distraction and Positive Affect

Madelijm Strick, Radboud University Nijmegen, The Netherlands
Rick B. van Baaren, Radboud University Nijmegen, USA
Rob W. Holland, Radboud University Nijmegen, USA
Ad van Knippenberg, Radboud University Nijmegen, USA

Humor in advertising has been identified as a peripheral cue that can enhance the effectiveness of advertisements without conveying any information about the quality or function of the brand. Furthermore, it has often been suggested that humor has the unique quality to overcome resistance to persuasion (e.g. Sternthal and Craig 1973; Nabi, Moyer-Guse, and Byrne 2007). How does humor do this?

To approach this topic it is very useful to have a clear definition of humor. Researchers have decomposed the experience of humor into two phases: (1) a cognitive phase needed for incongruity-resolution, which poses cognitive demands, and (2) an affective phase, in which positive emotions are experienced (Deckers and Devine 1981; Suls 1972; Watson, Matthews, and Allman 2007). Given the relation between cognitive distraction and yielding to persuasive messages (e.g. Festinger and Maccoby 1964; Keating and Brock 1976) and the general beneficial effects of positive affect on advertising effectiveness (e.g., Stuart, Shimp, and Engle 1987), both the cognitive and the affective phase may be responsible for breaking resistance. We present three experiments that disentangle these two components of humor and examine their influence on product memory, attitudes, behavior and resistance to influence.

Nowadays, implicit associative processes play an important role in shaping our views of products and brands. Therefore, in the present research we used an evaluative conditioning paradigm to unobtrusively associate products with humor (see De Houwer, Thomas, and Baeyens 2001 for a review). To rule out confounding mood effects, humor was manipulated within subjects.

In Experiment 1, novel energy drink brands were unobtrusively associated with either humorous or control (i.e. non-humorous) cartoons. In line with the conceptualization of humor as a distracter, humor impaired the recognition of associated products. Yet, an evaluative priming task (Fazio 2001) showed that the automatic evaluations of these products were enhanced due to association with unrelated humor. These memory and implicit liking effects were not correlated. Finally, these enhanced evaluations mediated the relation between association with humor and overt product choice. These findings indicate that humor dissociates product memory from implicit product liking and choice.

In Experiment 2, novel energy drink brands were consistently paired with humorous (i.e. cognitively demanding and positive) sentences, whereas other products were paired with sentences that were either (1) equally demanding but neutral (2) equally positive but undemanding (3) undemanding and neutral. Afterwards, product recognition and explicit product liking were assessed. Furthermore, behavioral consequences were assessed by giving participants the opportunity to spend discount coupons on the beverages. The results showed that cognitively demanding sentences reduced product recognition, whereas the positivity of the sentences had no effect on product recognition. These findings suggest that the cognitive demands of humor, not the positive affect it evokes, underlie the distraction effect. Furthermore, positive sentences enhanced attitudes and behavioral preferences towards products, irrespective of cognitive demands. Overall, these findings indicate that the dissociating effect of humor on product memory and liking are unique to humor. Other positive cues also enhanced product liking, but they did not distract attention.

In Experiment 3, attitudes toward novel peppermint brands were conditioned using the same experimental conditions and stimulus material as Experiment 2. For half of the participants, the conditioning phase was preceded by a written instruction that provoked resistance to influence. In this resistance condition, it was explained to participants that the experiment was conducted in collaboration with an untrustworthy advertising agency that would use the research results to spam them with E-mail and SMS text messages. Participants in the control condition read a neutral control instruction instead. Next, all participants were exposed to the same conditioning procedure. Afterwards, brand recognition and implicit brand liking (using the evaluative priming task) were employed. The memory and liking effects of Experiment 1 and 2 were replicated. In addition, the results of the implicit attitude measure indicated that humorous information enhanced implicit brand attitudes in both the resistance and control condition. Other (i.e. less-distracting) positive cues, however, only enhanced implicit brand attitudes in the control condition. Furthermore, we found a significant positive correlation between distraction (i.e. brand recognition impairment) and implicit product liking in the resistance condition. These results indicate that humor overcomes resistance due to its quality to distract attention from products, not by evoking positive affect.

These three experiments show a robust pattern of results that extend our knowledge of implicit effects of humor in advertising in several ways. First, as far as we know, we are the first to show conditioning effects of humor on implicit attitudes, which in turn predict overt product choice. Interestingly, association of a product with unrelated humor enhances its attractiveness in a way that is dissociated from the accessibility of the product in memory. This finding suggests that humor can affect responses to brands even if consumers do not explicitly infer and/or memorize them. Furthermore, unlike previous research, we directly compared humor with other positive, non-humorous, emotions and show that the distraction effect is unique to humor. These findings fit very well with theories of humor processing that focus on incongruity-resolution (Deckers and Devine 1981; Suls 1972; Watson, et al. 2007).

Finally, we have found clear evidence that humor overcomes resistance to influence by distracting attention. Participants that were motivated to offer resistance were able to discount the influence of positive cues when these cues were undistracting. They were unable, however, to resist the positive influence of humor. The positive correlation between distraction and implicit brand attitudes indicates that the distraction of humor is responsible for this effect. The conceptualization of humor as both a distracter and a motivator of liking and approach behavior has interesting implications for various research domains in consumer psychology that involve self-regulation.

Existential Anxiety and Essentialism Explain Negative Reactions Toward Brand Extensions

Pelin Kesebir, University of Illinois at Urbana-Champaign, USA

Ying-yi Hong, University of Illinois at Urbana-Champaign, USA

Terror Management Theory posits that the knowledge of one's mortality, combined with a biologically rooted desire for self-preservation, is apt to create paralyzing existential terror. As revealed by a variety of studies, individuals seem to hold on to their cultural worldviews in an attempt to manage this terror (Greenberg et al. 1990). Cultures, as shared symbolic conceptions of reality, not only give meaning and order to existence, but also provide a venue for expanding and perpetuating oneself in a larger beyond. Individuals thus seek solace in the knowledge that whereas they might be mere mortals, the cultural worldviews they subscribe to are imperishable and everlasting.

Brands, to the extent they represent cultural values, may carry a similar death-anxiety mollifying function. Highly revered brands that represent the culture's core values and are perceived to be "timeless" are also commonly referred as iconic brands. If such brands function as a buffer against death anxiety, it stands to reason that brand extensions may be perceived as contamination of these icons and thus lead to increased death anxiety and engender negative responses.

One individual difference variable that might influence the degree of negative reactions toward brand extensions is essentialism. Essentialism is the tendency to believe that there are stable and unchangeable underlying essences to entities. Previous research on essentialism has examined essentialism toward social categories, such as race, sexual orientation and ethnic groups, and found that essentialist beliefs are associated with stereotyping and prejudice (Haslam et al. 2006). For example, people who believe that there are important, inherent, and stable differences between heterosexuals and homosexuals are more likely to endorse stereotypes about homosexuals.

People who generally endorse essentialistic beliefs may also exhibit essentialism toward brands—a tendency to believe that there are stable and unchangeable underlying essences to brands. Such people might be bothered by brand extensions, since brand extensions by definition damage the "essence" of the original brand and "contaminate" it. We hypothesized that a high degree of essentialism might engender negative reactions toward brand extensions, particularly when the brand in questions is representative of cultural values and the individual has chronically high or experimentally increased death anxiety.

Study 1 aimed to show that when reminded of their mortality, highly essentialistic participants would disapprove more of a brand extension scenario involving a highly iconic brand. Participants first completed a 21-item measure of Essentialism, and then were randomly assigned into a mortality salience or control condition. In the mortality salience condition participants were asked to answer two open-ended questions about their mortality, whereas in the control condition they answered two similar questions about dental pain. After this manipulation, all participants read a scenario about Coca Cola Peppermint—"a beverage that is quite similar to regular Coke, however has a distinct peppermint aftertaste." Following this, participants responded to three questions about Coca Cola Peppermint on a seven-point Likert scale. These questions were: (a) "How good do you think Coca Cola Peppermint is going to taste," (b) "How much do you approve of Coca Cola's efforts to come up with new tastes," and (c) "How much do you agree or disagree with the following statement: Products such as Coca Cola Peppermint dilute the image of Coca Cola, and weaken the brand."

Participants' responses to these questions were separately submitted to univariate general linear model analyses, which revealed, as expected, a significant Mortality prime x Essentialism interaction, for all three different questions: Participants in the mortality salience condition were more likely to think that Coca Cola Peppermint would taste bad, to the extent that they were high in essentialism. Similarly, participants reminded of their mortality disapproved more of Coca Cola's efforts to come up with new tastes, and believed that products such as Coca Cola Peppermint diluted the image of Coca Cola and hurt the brand—again to the extent that they were essentialistic. Importantly, in our analyses we controlled for the need for cognitive closure (Kruglanski and Webster 1996), which allows us to conclude that the observed effect of essentialism is unique and different from a general potential effect of closed-mindedness.

Study 2 replicated and extended Study 1 by demonstrating that high death accessibility combined with high essentialism leads to more negative reactions toward brand essentialism, and the magnitude of this effect is influenced by how much the brands in question represent cultural values. Participants first completed an implicit measure of death-thought accessibility. The measure was designed as a word-completion task and included word fragments that can be completed in either death-related or unrelated ways (e.g., G R A _ E can be completed as “grave” or “grape”). After this measure of death accessibility, participants rated on a seven-point scale how much they believed certain brands/cultural icons (e.g., Crest, Tom Hanks) represented American values. This was followed by brand extension scenarios involving the brands participants were just asked about. These scenarios were: (a) Crest coming up with a lip moisturizer, (b) Lipton introducing “Lipton Soup,” (c) Tom Hanks recording a rock album, and (d) Some producers filming a sequel to the movie Casablanca. After each scenario, participants answered the same questions about their reaction toward these extensions as in Study 1.

Our results revealed a significant Death Accessibility x Essentialism interaction as a predictor of negative reactions toward brand extensions, across four different scenarios. Furthermore, we found a Death Accessibility x Essentialism x Value representativeness interaction, which confirmed our hypothesis that a combination of high death anxiety and essentialism leads to particularly antagonistic responses toward brand extensions when the brands are highly representative of cultural values.

These two studies, taken together, suggest that a brand extension can be interpreted as threatening and perceived negatively, if the brand is highly representative of the culture’s values, and if the consumer is high in essentialism and death-thought accessibility. It seems that individuals embrace iconic brands as instances of their cultural worldview, and the desire to hold on to them, in their “pure form”, is more pronounced for people who are experiencing a combination of high essentialism and death anxiety.

The Role of Affect, Music and Self-awareness in Consumer Information Processing

Iris W. Hung, National University of Singapore, Singapore

Robert S. Wyer, Jr., Hong Kong University of Science and Technology, China

Although consumers’ evaluations of a product are obviously based in part on the favorableness of their attributes, at least two other factors can come into play. First, consumers may base their evaluations of a product on their positive or negative affective reactions to it. Second, they might imagine using the product in a particular situation and base their judgments on the desirability of doing so. Both effects depend on people’s use of their subjective reactions as a basis for judgment. A contingency in the effects, therefore, may be the extent to which individuals are likely to consult these reactions for use as a basis for judgment rather than relying on more objective criteria. The present research examined this possibility.

Theoretical Background

Affect as information. People’s tendency to use the affect they are experiencing and attribute to an object as a basis for judging this object is well established (Schwarz & Clore 1996). In the product domain, however, there are two qualifications. First, people are only likely to base their judgments of a product on their feelings if the product is normally based on hedonic criteria rather than utilitarian considerations (Pham 1998; Yeung & Wyer 2004, 2005). Second, the affect consumers are experiencing may influence their judgments only if these feelings are salient to them at the time and, therefore are a prominent source of information.

Contextual influences on product judgments. Consumers who are called upon to evaluate a product may often imagine themselves using the product in a particular situation and base their judgments on the feeling they anticipate to result from doing so. To this extent, their evaluation may depend in part on the particular situation they happen to consider, and this, in turn, may be influenced by features of the situational context in which the evaluation is made. For example, people who are asked to evaluate products while listening to music may imagine themselves using the products in a situation similar to that in which this music is often encountered, and may base their judgments on their feelings about doing so.

Effects of self-awareness. Note that people’s use of the affective reactions as an informational basis for judgments, and the thoughts and feelings that result from imagining the use of the product in a given situational context, both require consultation of their subjective emotional or cognitive responses. To this extent, it may depend on their general sensitivity to these responses. This sensitivity may be influenced by their self-awareness, or the attention they pay to themselves as an object (Duval & Wicklund 1973). According to Scheier and Carver (1977), increasing people’s consciousness of their internal feelings should increase their use of their feelings as a basis for judgment. In the present context, this could have two effects. First, if products spontaneously elicit positive or negative affect, self-awareness may increase the tendency to use this affect as a basis for evaluating these products. Second, self-awareness may increase the tendency to imagine oneself using the product in a particular situation and to base evaluations of the product on the desirability of doing so. Thus, if listening to music activates thoughts and feelings about a situation in which this type of music is normally played, self-awareness might increase evaluations of products that are typically used in this situation. Evaluations of products that are *not* typically

used in that particular situation, however, should not be influenced by people's self-awareness. Two experiments investigated these possibilities.

Method

In experiment 1, participants were asked to evaluate a series of products under conditions in which their self-awareness was experimentally manipulated by placing participants in front of a mirror (for evidence of the effectiveness of this procedure, see Duval and Wicklund 1972). Participants were randomly assigned to six conditions of a 2 (high vs. low self-awareness) x 3 (music type: social vs. relaxing vs. none) design. The products they judged varied systematically in terms of the criteria used to evaluate them (hedonic vs. utilitarian) and the context in which they were used (social vs. non-social).

In the music conditions, participants were told that the purpose of the study was to investigate how students do two things at the same time. They were listening to either the social or non-social relaxing music while reading a simple passage. After listening to the music for 3 minutes, they were asked to perform an ostensibly unrelated product evaluation task while the music was playing. On this pretense, they evaluated 14 products that pretested to vary in terms of the criteria normally used to judge them (hedonic vs. utilitarian) and the situational context in which they were typically used (social vs. nonsocial). After making these evaluations, participants reported their reactions to the music. In the no-music conditions, participants evaluated the products without the music playing.

Experimental design and procedures in experiment 2 were identical to those in experiment 1 except that participants evaluated a list of products that were typically used either in a social, or in a non-social relaxing environment.

Results

The results of both experiments confirmed our predictions. Participants reported being more likely to report imagining themselves using the products when they participated in front of a mirror (high self-awareness conditions). Furthermore, participants in both studies evaluated hedonic products more favorably in the presence of a mirror than in its absence, whereas their judgments of utilitarian products were unaffected. When social music was played, self-awareness increased evaluations of product that were normally used in a social environment, and when relaxing music was played, it increased evaluations of products that were normally used in a relaxing environment.

In combination, the results provided insight into the conditions in which consumers are likely to use their affective reactions as a basis for product evaluations, the impact of situational context on these evaluations, and the different ways that self-awareness can exert an influence on consumer judgments.

The Effect of Option Number in Directional Comparison

Yu-chen Hung, National University of Singapore, Singapore

Catherine Yeung, National University of Singapore, Singapore

Research shows that when consumers compare between two options based on their specific attributes, they pay more attention to one of the options (the "focal" option) than the other one (Dhar and Simonson 1992). They map attributes of the focal option onto the attributes of the non-focal option, and weight the unique attributes of the focal option more heavily than those of the non-focal option. Hence, they prefer the focal option more (less) when the unique attributes are favorable (unfavorable) (Houston, Sherman and Baker 1989). This is referred as the "direction-of-comparison" effect. The direction of comparison effect has only been demonstrated in experiments in which two alternatives were considered, and has not been generalized to a more realistic, multiple-option comparison settings (Sanbonmatsu, Kardes and Gibson 1991, Mantel and Kardes 1999, Houston and Sherman 1995, Houston, Sherman and Baker 1991). The purpose of our study is to investigate the direction of comparison effect in multiple-option comparison.

Past research has shown that the direction-of-comparison effect requires one to store the specific attributes of the available options in memory, such that they can later serve as a basis for an attribute-based comparison (Mantel and Kardes 1999). When specific attributes are not available in memory, no feature matching occurs between the focal option and the non-focal option, so the focal option is not preferred more (or less). When the number of alternatives increases, it becomes harder to store attribute information in memory. Feature matching among options is also less likely. If so, the direction-of-comparison effect should disappear as the option number increases. We, however, showed that this was not the case in 3 lab experiments and 1 field study. In experiment 1, we required participants to compare 2, 3, and 4 alternatives, respectively, and showed that the direction-of-comparison effect not only sustained, but became more and more apparent as the number of option increased from 2 to 4. We demonstrated the focal option was more likely to be chosen when the

comparisons were among attractive attributes, while the focal option was more likely to be rejected when the comparisons were among unattractive attributes. Besides, participants' willingness to pay increased (decreased) when comparison was among attractive (unattractive) attributes, as option number went from 2 to 4. We showed that the direction-of-comparison effect was augmented, rather than attenuated, in multiple-option comparison. The augmentation reflected in choice and willingness to pay.

The augmented direction-of-comparison effect in multiple-option settings has two implications. First, the focal option benefits from comparison among attractive alternatives. Second, the focal option disadvantages when comparison is among unattractive alternatives. We refer to the former as beneficial effect, and the later as disadvantage effect. If the augmentation show in study 1 is robust, we expect that the beneficial effect helps focal option, even when the focal option is objectively the weakest options among all alternatives. On the other hand, the disadvantage effect harms the focal option, even when it is the strongest among all options. For example, consider a house with designer furniture versus a house with good location. Although designer furniture is attractive, it is not as important as good location. A house with designer furniture is referred as weak option in this example. When the house with designer furniture becomes the focal option, it is not necessarily appealing because people compare it with the other house in good location. But as the number of option increases, the direction-of-comparison effect predicts that the house with designer furniture, which is the weak focal option, enjoys the beneficial effect and would be well chosen. We conducted experiment 2 to test the prediction that the beneficiary effect promotes a focal option, to the extent that it can help a weak alternative. We selected a number of house attributes from pretests and composed the focal option with the weaker attributes. In experiment 2, our participants were required to compare either 2, 3 or 4 houses and indicated which house they would like to visit most. In supportive of this prediction, we demonstrated that the focal option was mostly chosen among all alternatives, despite that it was the weak option.

The second implication from the augmented direction-of-comparison effect is the disadvantage effect. The disadvantage effect transpires when people compare across unattractive attribute. We reason that the disadvantage effect hurts the focal option, even when it is the relatively stronger alternative. We tested the disadvantage effect in study 3. Similarly, we had pretests and composed the focal option with minor negative attributes (e.g. poor pool maintenance in a condominium), whereas the other options had major negative attributes (e.g. the rooms are too small). The participants compared either 2, 3 or 4 options and indicated which condominium they would like to visit. Consistent with our prediction, the focal option lost its choice share significantly as the number of option increased, despite that it was the strongest among all alternatives.

We offer an explanation for the augmented direction-of-comparison effect. The direction-of-comparison effect happens because of the differential attention received by the focal option to the non-focal option. As the number of option increases, people still pay more attention to the focal option, and the non-focal options share the rest of attention. Therefore, the differential attention paid to the focal option relative to the each non-focal option increases. As a result, the direction-of-comparison effect enlarges when people have more options to choose from. The differential attention contributes to the beneficiary effect shown in experiment 2 and the disadvantage effect shown in experiment 3. To test this explanation and replicate findings from previous experiments, we conducted a field study. In this study, the participants compared attractive hampers by sequentially reading the hampers in a booklet. The results showed that people took the last hamper as the focal option, and the choice share of the weak hamper increased significantly when it was presented last. On the other hand, the participants who flipped the booklet back and forth paid no differential attention. Hence, there was no beneficiary effect for the weak hamper when it was presented at last.

Perceived Quality, Packaging and Self-Image Congruence: An Application in the Cosmetics Market

Ahmad Jamal, Cardiff University, UK

Mohammed Sajid Khan, American University of Sharjah, UAE

Matoula Stamatia Tsismetzi, Cardiff University, UK

The study aims to explore the impact of perceived quality, perceptions of packaging and self-image congruence on customer satisfaction, loyalty and word of mouth intentions. The study specifically focuses on make-up cosmetics, and in particular cosmetics choices made by women, for which no previous research exists. The market analyst, Key Note (2007), highlights a number of important

trends in the market including the dominance of global brands enjoying strong brand awareness and loyalty levels with a need to strike a balance between persuading consumers to try new products and retaining brand loyalty to existing favourites. Also, the main users tend to be the younger people (mainly females) showing a heightened sense of pride in the way they look. Also, most customers recognize the potential of cosmetic products in making a positive contribution towards their self images. Moreover, usage of premium cosmetics, particularly those bearing the name of international fashion houses, leads to the development of feel good factor supported by high prices and exclusivity offered by the brands (Key Note, 2007). Despite the significance of perceived quality, packaging and self-concept, no previous research has investigated their effects on important performance measures such as satisfaction, loyalty and word of mouth within this crucial market. The paper aims to fill these gaps in the literature.

Following Zeithaml (1988), we consider perceived quality (PQ) to be a consumer's judgment about a product/brand' overall excellence or superiority (Zeithaml, 1988). PQ is an important subjective attribute (e.g., Grapentine, 1995) and an information cue (Lee and Lou, 1996; Monroe and Dodds, 1988). As perceptions of quality go up, consumers can better recognise the differentiation and superiority of the brand through their long term personal experiences with the brand (Lusar; 2001; Yoo et al., 2000). Such perceptions help develop strong, favourable and unique brand associations in consumer minds (Keller, 2001). Prior research has reported PQ to be an important antecedent of satisfaction (e.g., Cronin and Taylor, 1992). Moreover, Oliver (1999) argues that consumer perceptions of product quality and/or product superiority can generate a strong sense of brand-directed preference leading to the development of loyalty. Hence, we expect direct links from PQ to satisfaction, loyalty and word of mouth intentions.

The cosmetic industry is highly competitive and product innovation is the key to success as the product life cycle tends to be short (Kumar et al., 2006; Underwood, 1999, 2003). The emphasis is on creating differentiation at the point of sale through packaging (Doyle 2004). Bottles are designed that are softer to the touch, have sleeker and sexier shapes, are easier to hold and less likely to break. Moreover, products have to offer added value with dual functionality and special visual effects to stand out and get attention from the consumer (Doyle, 2004). To achieve this effect, the industry relies on consumers' perceptions of beauty and the recent developments in new technology have allowed firms to create a wide scheme of colours and packs (Kumar et al., 2006; Silayoi and Speece, 2007, Underwood et al., 2001). We argue that positive evaluations of packaging can help in meeting customer expectations and hence influence satisfaction judgements, loyalty levels and word of mouth intentions.

A review of literature suggests that consumers can express themselves by choosing brands whose personalities are perceived to be congruent with their own personalities (Aaker, 1999; Sirgy 1997). Moreover, during the consumption process, a product-user image interacts with the consumers' self concept generating a subjective experience referred to as self-image congruence (Sirgy, et al. 1997). A number of studies have established the effects of self-image congruence on attitudes, brand preference, purchase intentions, customer satisfaction and word of mouth intentions (Ericksen, 1996; Sirgy et al., 1997, 1991; reference to authors' prior published work). While the effects of self-image congruence have been tested for different product categories (e.g., automobiles, mobile phones, athletic shoes, jewellery), these have never been tested within the cosmetics market. We expect self image congruence to be related to satisfaction, loyalty and word of mouth intentions. Moreover, as per prior research, we also expect direct links from satisfaction to loyalty (e.g., Oliva et al. 1992; Selnes 1993 and from loyalty to word of mouth (Dick and Basu 1994).

Data was obtained from female cosmetic users in a leading metropolitan city in the UK using self-administered questionnaire, which contained measures adopted from previous research. After the pilot testing, 300 questionnaires were distributed among users of cosmetics make-up brands who expressed their willingness to participate using a mall intercept procedure. The procedure resulted in 193 usable questionnaires. This was followed by exploratory factor analysis, Pearson correlation tests and quantification of scale reliabilities via alpha scores. Three multiple regressions were computed. The first one revealed high and significant beta weights for PQ ($\beta=0.383$, $p<0.000$, $t \text{ value}=6.374$), packaging ($\beta=0.296$, $p<0.000$, $t \text{ value}=4.6702$) and low but significant beta for self-congruence ($\beta=0.166$, $p<0.042$, $t \text{ value}=2.046$) with the independent variables accounting for about 47% of the variance in satisfaction scores (adjusted R square=0.465, F statistic=56.714). Second equation revealed high and significant beta weights for satisfaction ($\beta=0.554$, $p<0.000$, $t \text{ value}=6.176$), packaging ($\beta=0.235$, $p<0.008$, $t \text{ value}=4.6702$) and low but significant beta for self-congruence ($\beta=0.149$, $p<0.014$, $t \text{ value}=2.478$) with the independent variables accounting for about 48% of the variance in loyalty scores (adjusted R square=0.481, F statistic 45.408). However, the PQ to loyalty link was neither high nor significant. Results for final equation revealed high and significant beta weights for satisfaction ($\beta=0.432$, $p<0.000$, $t \text{ value}=6.506$) and PQ ($\beta=0.291$, $p<0.000$, $t \text{ value}=4.530$) and low and significant beta weights for loyalty ($\beta=0.165$, $p<0.001$, $t \text{ value}=3.363$) and packaging ($\beta=0.187$, $p<0.002$, $t \text{ value}=3.082$) with the independent variables accounting for about 88% of the variance in word of mouth scores (adjusted R square=0.684, F statistic=84.062). Hence, all except quality to loyalty and self-image to word of mouth links were supported. Given that no prior research has investigated the effects perceived quality, packaging perceptions, self-image congruence on satisfaction, loyalty and word of mouth intentions, we believe our study will go some way in helping brand managers developing a better understanding of consumer behavior within the rapidly growing and multibillion pounds cosmetic and personal care industry (Chandler 1995; Wurdinger 1996).

Payment Frequency Discount vs. Payment Amount Discount: The Framing Effect on Preference Reversal

Ji Hoon Jhang, University of Colorado, USA
Jungkeun Kim, University of Minnesota, USA

Theoretical Background

Across many product categories, widespread are multiple payments plans with which consumers pay certain amounts of money by schedule. By allowing consumers to choose the plan that serves them best, companies are attracting more consumers. Despite the topic's importance and pervasiveness, empirical studies on the effects of different payment plan framings are scarce.

In addition, multiple payment plans are often accompanied with price discounts. These price discounts are one of the most common promotional tools used by marketers to attract consumers (Monroe 2003). In this situation, we can think of several ways to frame a price discount. For example, imagine that the suggested price of a product is \$160. Consumers are required to pay 4 payments of \$40. The store can provide the \$40 price discount and can quote \$120 as the final selling price with multiple payments. Specifically, price discount can be either: 1) a payment *frequency discount*-which reduces the payment frequency from 4 to 3, holding the amount of each payment constant; or 2) a payment *amount discount*-which reduces each payment amount from \$40 to \$30 without changing the payment frequency. In addition, we can generate several framing methods to express the price discount as below⁸ (Figure 1).

Mainly drawing on prospect theory (Kahneman and Tversky 1979; Tversky & Kahneman 1991) and mental accounting (Thaler 1985), we investigate consumers' preferences between the payment frequency discount and the amount discount across different framing conditions. Therefore, the purpose of this research is to explore: 1) how framings influence consumers' preferences between the payment frequency discount and the amount discount, yielding a preference reversal; and 2) under what conditions the effect of framings is attenuated.

Preference Reversal between Gain Framing and Loss Framing

Researchers have shown that people have different preferences for multiple gains and losses (Linville and Fischer 1991; Thaler 1985). Put differently, people prefer segregated gains and integrated losses. On the basis of this theory, we can predict preference reversal. Specifically, in our loss framing condition, based on $\{U_{FD} [(-\$40) + (-\$40) + (-\$40)] > U_{AD} [(-\$30) + (-\$30) + (-\$30) + (-\$30)]\}$, we can expect that people prefer the payment frequency discount to the payment amount discount. On the other hand, in our gain framing condition, based on $\{U_{FD} (\$40) < U_{AD} (\$10 + \$10 + \$10 + \$10)\}$, we can expect the opposite pattern:

H1a: People will prefer the payment frequency discount to the payment amount discount in loss framing condition.

H1b: People will prefer the payment amount discount to the payment amount frequency in gain framing condition.

H1c: There will be a preference reversal across loss framing and gain framing conditions.

Study 1

Drawing on the notion that people prefer segregated gains and integrated losses, we investigated consumers' preferences for two discount plans (the payment frequency discount vs. the payment amount discount) with different framings (loss framing vs. gain framing). Sixty-two participants (average age=21.7, 59.7% female) were offered two discount plans, along with one of two framings, as shown in Table 1. The participants were then asked to rate their likelihood of choosing one plan over the other with a 10-point scale (i.e., (-5)-frequency discount preferred; (5)-amount discount preferred).⁹ Responses were recoded such that "1" represents a preference for the payment frequency discount and "10" represents a preference for the payment amount discount. Therefore, a value of "5.5" indicates no preference between the two discount plans.

The ANOVA revealed a main effect of the framings ($F_{1,60}=9.45, p=.003$), indicating the preference reversal between two framing conditions. Specifically, the participants preferred the frequency discount to the amount discount in the loss framing condition (mean=4.21, $t^{10}=2.22, p=.035$), but showed an opposite preference in the gain framing condition (mean=6.70, $t =2.14, p=.045$). Furthermore, we analyzed the inferred choice. Sixty-one percent of the participants in the loss framing condition chose the frequency discount plan, whereas, in the gain framing condition, only 32.3% chose the frequency discount plan (Chi-Square=5.25, $p=.022$). In sum, the results support Hypothesis 1.

This result shows that consumers prefer paying less frequently to paying lower amounts of money each time when they regard the payment plans as losses, while they show the opposite pattern if they consider the payment plans as gains.

Preference Reversal between Double Loss Framing I and II Conditions

In the double loss framing I condition, we expect that people will show no preference between the two discount plans because the "frequency discount" and the "amount discount" are both losses for consumers. In contrast, in the double loss framing II condition, we expect that people will prefer the frequency discount to the amount discount because people are expected to be more sensitive to changes in the frequency than in the amount.¹¹

H2a: People will show no preference between the two discount plans in the double loss framing I condition.

H2b: People will prefer the payment frequency discount to the payment amount discount in the double loss framing II condition.

H2c: There will be a preference reversal across the double loss framing I and II conditions.

Study 2

The purpose of Study 2 is to examine the preference reversal in the double loss framing I and II conditions. Except for the double loss framing conditions, the other experimental procedures were identical to those of Study 1. Sixty-two participants (average age=21.8, 41.9% female) were randomly assigned one of two experimental conditions.

The ANOVA revealed a main effect of framings ($F_{1,60}=5.03, p=.029$), indicating a preference reversal between the two framing conditions. Specifically, the participants preferred the frequency discount to the amount discount in the double loss framing II condition (mean=4.13, $t =2.56, p=.016$), but showed no difference in the double loss framing I condition (mean=5.50, $t <1$). Therefore, the result supports Hypothesis 2.

⁸We named the first category above "loss framing" because it merely shows the payment amounts, which are definitely perceived as losses to consumers whereas we named the second category "gain framing" because it focuses on price discounts, which are definitely gains to consumers. We also named the remaining two categories "double loss framing" because they contain the payment frequency and payment amount, which are double losses to consumers.

⁹We measured choice and relative preference with one scale.

¹⁰All t statistics hereafter refer to comparing the mean with the neutral point (i.e., "5.5").

¹¹We assume that people calculate the payment frequency and payment amount along with the same scale. In addition, we also assume diminishing sensitivity (Tversky and Kahneman 1991).

FIGURE 1

<u>Framing</u>	<u>Payment Frequency Discount</u>	<u>Payment Amount Discount</u>
Loss framing:	\$40, \$40, \$40	\$30, \$30, \$30, \$30
Gain framing:	 \$40, \$40, \$40, \$40 \$40, \$40, \$40	 \$40, \$40, \$40, \$40 \$30, \$30, \$30, \$30
Double loss framing I:	3 payments of \$40 each	4 payments of \$30 each
Double loss framing II:	 4 payments of \$40 each 3 payments of \$40 each	 4 payments of \$40 each 4 payments of \$30 each

Disappearing Preference Reversal under the Provision of Reasons

Previous studies have demonstrated that people show different preferences when asked to provide reasons or not (Shafir, Simonson, & Tversky 1993; Simonson 1989). In our discount condition, we expect that people prefer the payment frequency discount when they are asked to provide reasons for their preferences because the reason(s) regarding the payment frequency discount is (are) easier to generate than the reason(s) regarding the payment amount discount.¹²

H3: People will prefer the payment frequency discount to the payment amount discount when they are asked to provide reasons for their preferences.

Study 3

Study 3 explored the boundary condition in which the effects of previous studies are attenuated. The experimental design was a 4 (Framings: loss vs. gain vs. double loss I vs. double loss II) between-subject design. All experimental materials were the same as those in Studies 1 and 2. The only difference was that all participants were asked to provide reasons for their preferences. We expected that the frequency discount would be preferred in all four framing conditions, insofar as it is much easier for the participants to provide reasons for fewer payments. One-hundred-sixty-five participants (average age=20.7, 58.2% female) were randomly assigned one of four experimental conditions.

As anticipated, there were no differences across the experimental conditions ($F_{3,161}=2.53, p >.05$). Specifically, the frequency discount was preferred to the amount discount in most framing conditions (means=3.59, 3.77, & 4.40, all p 's <.05) except in the double loss framing II condition (mean=5.14, $t <1$). The reasons provided by the participants also confirmed Hypothesis 3; most participants mentioned fewer payments as reasons.

General Discussion

This study examined the preference reversal between the payment frequency discount and the payment amount discount across four different framings. Three experiments demonstrated that consumers' relative preference for the frequency vs. the amount discount is systematically changed by different framings. In addition, this research showed that this preference reversal disappeared when people were asked to provide reasons for their preference. This research demonstrates the tenets of mental accounting (i.e. the segregation of gains and the integration of losses) and finds interesting results regarding the relative importance of the frequency vs. the amount discount in consumers' preferences. In sum, this study can contribute to an understanding of the role of the framing effect on price discounts.

Attribute Order Effects on Consumer Judgment: The Role of Ideal Point Availability and Attribute Importance

Ying Jiang, University of Ontario Institute of Technology, Canada
Jing Lei, University of Ontario Institute of Technology, Canada

The primacy effect in a decision context refers to the fact that information appearing early in the sequence has a stronger effect on judgment than does subsequent information (e.g., Kardes and Herr 1990). One explanation to this effect is that individuals bias their interpretation of the subsequent information to cohere with the disposition evoked by the initial information (also known as the “information-distortion” effect). For example, Bond et al. (2007) found that consumers tend to form an initial disposition (e.g., like or dislike) toward a product based on a positive or negative attribute, and this disposition subsequently biases their evaluations of other attributes. This finding suggests that presenting positive (negative) attribute information early in the sequence increases (decrease) consumers’ favorability toward the product.

An underlying assumption of the above finding is that consumers’ initial disposition toward a product is installed by valenced attribute information. However, in many occasions product information is presented neutrally or is perceived to be neutral. Hence, an interesting question is whether neutral information can also evoke an evaluative disposition that subsequently influences the interpretation of other attributes. Further, the two attributes used to install the initial disposition in Bond et al.’s (2007) study are both important attributes (e.g., functionality and price of a PAD). Thus, it is yet to know whether the disposition evoked by a trivial attribute can bias the evaluation of subsequent important attributes. In this research we propose that the impact of a target neutral attribute on the evaluation of other attributes depends on whether consumers have readily available preferences (or ideal points) for attributes and the relative importance of the target attribute. These propositions are explained in detail below.

When approaching a decision problem, some consumers have well articulated preferences for product attributes whereas others do not (Chernev 2003). For example, consumer A wants an MP3 player with a memory of at least 8GB, a battery that can last for at least 24 hours of audio play, and a price within the range of 200 dollars; whereas consumer B does not have specific requirements although acknowledging the importance of these attributes. Previous research suggests that the availability of ideal points influences consumers’ decision process (Chernev 2003). In particular, consumers with readily available preferences evaluate product alternatives in search of attributes that match and confirm these preferences. Therefore, when a target attribute, although presented neutrally, matches (does not match) a consumer’s ideal point for the attribute, it may lead to a positive (negative) predisposition that can influence the evaluation of subsequent attributes. However, this predisposition is only likely to have a strong effect on other attributes when the target attribute is perceived to be more important than or at least equally important as the subsequent attributes. In contrast, when consumers do not have specific requirements for attributes, the neutral target attribute is less likely to cause a strong evaluative disposition that can bias the interpretation of subsequent attributes. Therefore, we propose that:

H1: When a target neutral attribute is perceived to be more important than or at least equally important as other attributes presented later in the sequence, the neutral attribute will have a stronger distortion effect on other attributes for consumers with (vs. without) ideal points for attributes.

When the target neutral attribute is less important than the attributes presented later, consumers are likely to form a weak disposition toward the product regardless of the availability of ideal points. For consumers with readily available ideal points, a weak disposition may not bias their evaluation of other attributes because they will use the ideal points as a benchmark to judge these attributes and form strong evaluative opinions. However, for consumers without readily available ideal points, a weak preliminary disposition may still influence their evaluations of other attributes presented later as they do not have specific criteria to judge these attributes. Therefore, we propose that:

H2: When a target neutral attribute is perceived to be less important than other attributes presented later in the sequence, the neutral attribute will have a stronger distortion effect on other attributes for consumers without (vs. with) ideal points for attributes.

To test the above hypotheses, we conducted an experimental study using undergraduate students from a North American university. The study employed a 2(ideal point availability: available vs. not available) × 2(target attribute importance: important vs. less important) between-subject design. Participants were first given a decision scenario in which they needed to purchase an MP3 player as a gift for their friend. In the scenario, the ideal point availability and the relative importance of the target attribute were manipulated. Based on the established procedure of Bond et al. (2007), we used the *stepwise evolution of preference* (SEP) method to measure if the target attribute presented early in the sequence would 1) bias the evaluation of the subsequent attributes; 2) influence consumers’ purchase decision of the product; and 3) influence consumers’ confidence about their decisions. Furthermore, follow up studies have been designed to replicate the expected findings from the current experiment by using different products and decision scenarios.

Our research expects to contribute to the literature of information distortion in product judgment in several ways. First, previous research shows that consumers’ preliminary disposition toward a product can be evoked by valenced attribute information (Bond et al. 2007) or product comparison (Carlson, Meloy, and Russo 2006). However, we suggest such predispositions can also be installed by neutral attribute information. This extends the existing theory by generalizing the information-distortion effect to different judgment tasks. Second, prior research has primarily examined the information-distortion effect as a main effect. Little is known about the moderating factors that could lead to a more nuanced set of effects. This research aims to take our understanding about the information-distortion effect beyond the simple main effects by demonstrating key interactions and contingences in the contexts of product judgment.

Does Feedback Always Facilitate Learning?: Degree of Preference Development and Degree of Feedback Complexity

Jaewoo Joo, University of Toronto, Canada

A long tradition of research based on the MCPL paradigm suggests that when feedback is provided, people learn functional relationships between cues and outcomes (Brehmer and Brehmer 1988; Hammond 1955). It has been found that feedback not only facilitates learning of the relationship between attributes and product quality (Meyer 1987) and between attributes and others' preferences (West 1996) but also stabilizes preferences by providing a framework to correctly identify the relationship between attributes and self preferences (West, Brown and Hoch 1996).

As classic papers emphasized feedback as a learning facilitator, it has been extensively discussed what influences the impact of feedback on task outcomes (Hutchinson and Alba 1991). The moderators that have been found include learner variables such as goal or motivation, situation variables such as memory load or time pressure, cue characteristics such as salience or valence, and finally feedback type such as cognitive feedback. Further, at least two previous research projects revealed that outcome feedback, when an error on a particular task is large, can lead to negative task performance because people keep changing their original strategies and learning does not occur (Arkes et al. 1986; Hogarth et al. 1991).

As it is found that outcome feedback does not always facilitate learning, some researchers pay attention to a different type of feedback: cognitive feedback (Balzer, Doherty, and O'Connor 1989; Doherty and Balzer 1988; Todd and Hammond 1965). Compared with outcome feedback that provides information only about a true model, cognitive feedback provides information about relations: relations among cues, subject's judgment, and criterion variable in environment. This approach is mapped on to Lens model suggested by Hammond et al. 1975).

The present research aims to demonstrate that even cognitive feedback does not always lead to an improved task outcome. More broadly speaking, our objective is to investigate when cognitive feedback hinders or does not hinder people from improving outcomes. In the present research, we consider learning as stabilizing self preferences (West, Brown and Hoch 1996) and consider feedback as cognitive feedback: providing information about a functional relationship between attributes and pre-feedback preferences.

Here, we aim to demonstrate that the extent to which preferences are stabilized differs depending on one variable about learners and one variable about feedback quality: how much a pre-feedback preference is developed and how complicated a feedback is. The former variable, *the degree of preference development*, refers to how much pre-feedback preferences can be explained by available cues (attributes). For instance, some people are aware of several wine-related attributes that determine their preferences. In this case, their wine preferences are highly developed. Whereas, others evaluate wines without knowing much about what makes them prefer or choose, suggesting that their wine preferences are poorly developed. The proportion of pre-feedback preferences predicted by attributes will determine preference consistency. The latter variable, *the degree of feedback complexity*, refers to the amount of relationship-relevant information contained by feedback. For instance, suppose that a type of grape, a winery, and a production year can fully determine pre-feedback preferences. Simple feedback provides information about only one key factor and how it affects preferences (e.g., "you like wine produced later"), whereas complex feedback provides information about how all three attributes affects preferences (e.g., "you like the wine produced later, the wine created at a certain region of France, and the wine made by Shiraz..."). In other words, the number of attribute about which feedback provides information determines feedback complexity.

We have two testable hypotheses: feedback stabilizes the preferences of (1) those who developed a low degree of pre-feedback preferences more greatly than the preferences of those who developed a high degree of pre-feedback preferences and (2) when the degree of complexity is lower than higher. The former hypothesis (1) is suggested by an idea that people who do not develop their own preferences (i.e., novices) have more rooms to learn their own preferences than those who already develop preferences (i.e., experts). The latter hypothesis (2) is consistent with the effect of information overload on decision making, suggesting that overwhelming information confuses people and prevent from learning (Lurie 2004). Interestingly, the second hypothesis that the fewer attributes will benefit preference stabilization suggests a discrepancy with a finding in West, Brown and Hoch (1996).

We conducted a 2 (degree of preference development: low vs. high) x 2 (degree of feedback complexity: low vs. high) between-subjects design study by using 30 carefully designed chair pictures which consist of 5 binary attributes. Participants rated their preferences about 15 chairs, received one feedback, and then rated preferences about another 15 chairs. People whose R² about the first 15 preferences were lower than 0.6 are categorized as a lowly developed pre-feedback preference group and others belong to a highly developed pre-feedback preference group. Half the participants received simple feedback which provides directional relationship about only one strongest attribute, whereas the other half received complex feedback which tells directional relationships about all five attributes.

FIGURE 1
RESEARCH FRAMEWORK

FIGURE 2
R-SQUARE OF PREFERENCES BEFORE AND AFTER FEEDBACK IS PROVIDED

Results suggest hypothesis 1 but not hypothesis 2. The R^2 about the preferences increases when pre-feedback preferences are lowly developed, whereas it decreases when pre-feedback preferences are highly developed (0.21 vs. -0.4, $F=17.71$, $p<.01$), supporting the former hypothesis. As for the latter hypothesis, although the effect is not significant, data provide a directional support by demonstrating that simple feedback more strongly stabilizes preferences than complex feedback (0.12 vs. 0.05, $F=1.38$, $p>.2$). We hope to increase the number of observations to increase statistical significance. It is worth noting that neither those who lowly develop pre-feedback preferences (+0.09) nor those who highly develop pre-feedback preferences (-0.02) fail to increase their R^2 after feedback was provided.

Probably, the most interesting findings come from those who highly develop pre-feedback preferences and receive complex feedback. Their preferences become significantly destabilized after feedback is provided (-0.08, $t=-1.67$, $p=.10$), implying that feedback does not simply benefit but harms those who already developed their own preferences.

Accept or Reject?: How Task Valence Interacts With Product Information Processing To Alter Purchase Decisions

Uma Karmarkar, Stanford University, USA

Brian Knutson, Stanford University, USA

Baba Shiv, Stanford University, USA

Though behavioral research on decision-making has described in rich detail the ways that framing can affect the nature of a decision, we still do not fully understand the emotional and cognitive processes by which this takes place. Previous studies have investigated decisions framed as either choosing a desirable option, or rejecting an insufficiently appealing one, and have found results suggesting that the type of decision increases the salience of positive (choose) or negative (reject) information (e.g. Shafir 1993, Ganzach and Schul, 1995.) However, in these experiments the decisions are between two or more items and always lead to one option emerging as a winner. Thus the decision task changes the nature of the comparison or tradeoff between options as opposed to the evaluation of each one.

Recent work has illuminated the importance of positive and negative affect when evaluating individual products in a shopping context. Knutson et al. (2007) used functional magnetic resonance imaging (fMRI) to show that presentation of a product activated brain areas that respond to reward anticipation such as the nucleus accumbens. Price information appeared to activate the insula, a separate brain region. Thus this work supported the notion of distinct gain and loss neural centers whose balance contributed to the final decision whether or not to purchase the product. Focal analyses in these areas revealed that activation in these regions enabled prediction of the decision based on the comparative strengths of the localized signals. These results appear to reflect a “translation” of the overall complex cognitive and affective response to a balance of distinct affective evaluations.

Using a combination of fMRI and behavioral experiments, we look to build on this work by examining whether task information that emphasizes processing related to gain and loss can also change the desirability of an individual item in a shopping type context. In our design, participants made an accept or reject decision about purchasing a single item after being presented dichotomous information related to that item’s perceived reward value versus the potential negative impact of its price. This design was based off the task used in the Knutson et al. (2007) work, and the list of products were selected to be highly desirable to the participant pool of young adults. Each person made forty do (do not) accept decisions and forty do (do not) reject decisions; thus eighty separate products were presented in total. The order of accept versus reject choice tasks and the decision type for any individual product were counterbalanced across participants. Participants received an endowment at the beginning of the experiment and their decisions had real monetary consequences. One accept trial and one reject trial were chosen randomly at the end of the experiment and if a participant had chosen to buy the product on those trials, they were required to pay back part of the endowment to receive it.

In our first experiments, for each trial, participants viewed a discounted price, and were then shown the associated product. Findings indicated that people chose to buy approximately the same total number of items in both the accept and reject conditions. Moreover, decision reaction times in trials where the participant chose to buy the item were longer than those in no-buy trials, possibly indicating more conflict or difficulty in the decision to make a purchase. However, there was no difference between reaction times in the accept and reject tasks for buy choices or in reaction times for no-buy choices. Average preference and willingness-to-pay ratings, reported on seven-point scales, were also not significantly different between accept and reject framed decisions.

For a second set of participants, the salience or impact of the price was minimized by presenting a photo of the product first, and then listing its price afterwards. Results showed that under these conditions, significantly *more* products were purchased under reject than accept decisions. Again, there was a main effect of slower reaction times on any trials (accept- or reject-type) in which an item was bought. However, across both buy and no-buy choices, reaction times for reject decisions were significantly slower than accept ones, indicating that it was more difficult to reject purchase of an item when the salience of price was decreased. Interestingly, average preference for the purchased items was higher in the accept condition than in the reject condition though willingness to pay ratings were the same across decision types.

These behavioral findings imply that minimizing price, an easily processed feature that can be used as a decision heuristic, makes the nature of evaluation in a reject decision more complex. Additional experiments involving fMRI will complement this work and examine activation of specific brain areas such as the anterior cingulate cortex, shown to be involved in conflict during decision making. We predict greater anterior cingulate activation in tasks where the information most congruent with the choice type is minimized in the decision process. This methodology can also allow us to investigate the question of whether accept and reject decisions preferentially activate positive or negative emotional neural circuitry respectively.

Moderate Copy Complexity Enhances the Persuasiveness of Direct Marketing

Tina M. Lowrey, University of Texas at San Antonio, USA

Youngseon Kim, University of Texas at San Antonio, USA

Copywriters increase readability by eliminating complicated words and reducing sentence length, hoping that more individuals will read the piece, resulting in increased response rates. Whether this yields the desired results has not been fully addressed. In exploratory research, we obtained samples from two direct mail houses that had conducted split-copy tests on simple vs. complex versions of their direct marketing. In all cases, simplification involved shortening the copy, so the effects of complexity were confounded with length. Research on complexity in advertising has been done on magazine copy—much briefer than the average direct marketing piece. Moderate complexity seems to enhance memory and persuasiveness, but no research has been conducted on longer texts such as direct marketing. We present two laboratory experiments that isolated complexity from length as the independent variables that could impact order intentions, and a third experiment which tested whether the medium carrying the message also influences persuasiveness.

Experiment 1

In Experiment 1, we expected that:

- H1: Moderate complexity offers will be associated with greater intention to order than simple offers.
- H2: Those higher in involvement will be associated with greater intention to order than those low in involvement.
- H3: Order intentions will be greatest for those high in involvement exposed to moderately complex versions.

Method

Participants and Procedure. Eighty-five college students participated in for course credit, ran in groups of 12 seated at cubicles in a laboratory. Participants were asked to read at their own pace the material on the desk in front of them, which was the direct marketing offer. When finished reading, participants were instructed to raise their hands to receive the next phase. The researcher collected the offer and provided the participants with the measurement booklet, which they were instructed to complete at their own pace. Upon completion, the participants were free to leave the laboratory.

Stimuli. The direct marketing pieces for a collectible were written after extensive pre-testing. The four versions created were: short/simple; short/moderate; long/simple; long/moderate. Simple versions had high school level Fog indices of 10.75 (long) and 11.45 (short), whereas the moderate versions had college level Fog indices of 14.60 (long) and 13.70 (short). The short versions had 600-650 words, and the long versions had 850-900 words.

Dependent Variables. Intention to order was measured on a nine-point scale with a higher number indicating a greater intention to order, and a thought-listing task was included.

Results and Discussion

H1, H2 and H3 were supported. Those who received the moderate versions had higher intentions to order (Mean=2.98) than those who received the simple versions (Mean=2.05; $F(1, 83)=3.99, p<.05$). Those who reported high levels of involvement had greater order intentions (2.96 vs. 2.04; $F(1, 83)=3.78; p<.05$) than those at low levels of involvement.

High involvement participants who received the moderate offer had higher order intentions than all other participants ($F(1, 81)=9.24; p<.005$), and had a marginally higher mean number of positive thoughts (1.91 vs. 1.43; $F(1, 51)=3.53; p=.07$)

In Experiment 1, the expected results were obtained but the order intentions were quite low on a nine-point scale. Experiment 2 was designed to provide an offer that might be of more overall interest to all participants. The same hypotheses were tested.

Experiment 2

Method

Participants and Procedure. One hundred three college students participated for course credit, with an identical procedure to that of Experiment 1.

Stimuli. The offer was re-written for a different collectible selected after additional pre-testing.

Dependent Variables. An intention to order scale and a thought-listing task were included.

Results and Discussion

Complexity exerted a main effect on order intentions (5.00 vs. 3.77; $F(1, 101)=6.23; p<.05$). Involvement exerted a main effect, with high involvement participants having higher order intentions (5.57 vs. 3.36; $F(1, 101)=23.48; p<.001$). Involvement did not moderate the impact of complexity on order intentions, as in Experiment 1, but t-tests showed partial support for the relation.

Experiment 3

Experiment 3 involved a 3 (simple vs. moderate vs. complex copy) X 2 (short vs. long) X 2 (print vs. broadcast) manipulation of direct marketing for the same item used in Experiment 2. The addition of a radio commercial was intended to test the hypothesis that the persuasiveness of copy in radio commercials will decrease as the complexity of copy gets beyond moderate complexity. However, the persuasiveness of copy in the print offer is not expected to decrease as the copy gets more complex.

Method

Participants and Procedure. Two hundred forty-one college students participated for credit in 16 sessions run in the same laboratory. However, a computer-mediated experiment was utilized. Each of the participants was randomly assigned to a cubicle with a computer monitor, which showed a randomly pre-selected condition. The participants in the print conditions read the direct marketing offer on the screen at their own pace and then responded to the questionnaire. The participants in the radio conditions listened to the commercial on headsets and then responded to the questionnaire.

Stimuli. Six print versions of direct marketing offers and six radio commercials were prepared, with an addition of an even more complex version (over 15 for both short and long versions).

Dependent Variables. Intention to order was measured on a five-point scale and a thought listing task was included.

Results and Discussion

There was no main effect for complexity but there was one for involvement, such that those who reported high levels of involvement had greater order intentions (2.91 vs. 2.16; $F(1, 239)=21.69$; $p=.000$) than those at low levels of involvement. The interaction between length and medium on intentions was also significant ($F(1, 182)=4.338$; $p=.039$).

The effect of length on counterarguments, with long versions having more counterarguments than short versions, was significant ($F(1, 227)=3.92$; $p=.049$). The effect of medium on support arguments, with print versions having more support arguments than radio versions was marginally significant ($p=.091$).

The Influence of Progress Presentation Format on Repurchase Intention in Loyalty Programs

Jessica Y. Y. Kwong, The Chinese University of Hong Kong, China

Susanna Y. N. Wong, The Chinese University of Hong Kong, China

Studies on loyalty programs have identified important antecedents that facilitate consumers' decision to join a loyalty program (Kivetz 2003), choice of a particular kind of program (Kivetz and Simonson 2002), and program evaluation (Yi and Jeon 2003). However, getting consumers to join a loyalty program is only half the battle. A loyalty program is effective in building customer loyalty only if the program encourages its members to persist and do repurchases.

Progress, defined as the percentage of goal completion, plays a critical role in people's motivation to persist toward a goal. As described by goal gradient principles (Hull 1932), people become more motivated as their progress towards a goal increases. Similarly, consumers have higher intention to repurchase as they get nearer to the end of a loyalty program. A few studies have thus far shown that repurchase intention increases when actual progress increases (Garland and Conlon 1998; Kivetz et al. 2006) and when progress is artificially advanced (Nunes and Dreze 2006). The present research adds to this line of works by showing that the same actual progress could result in different repurchase intentions when the progress information is presented using different formats.

Specifically, we argue that progress information presented by figure displays (e.g., a status triangle) can be more effective in enhancing customers' repurchase intention as compared to the same information expressed in numbers (e.g., 874 points out of 1,900 points). This is because figure displays can induce a greater perceived progress as compared to numerical display when designed appropriately. When expressed in figure displays, progress is indicated by the percentage of shaded area. Because area estimation is often biased by the salient dimension of a figure (Krider, Raghubir, and Krishna 2001), estimation of progress should be biased accordingly.

To illustrate the bias in progress estimation, consider a case where progress is presented using a status triangle. A progress of 46% would be represented by shading 46% of the triangle (shading starts from the top of the triangle). Because people estimate the area of a triangle mainly on the basis of its height, the ratio between the area of the shaded triangle and that of the full triangle (which indicates the progress) will be driven by the ratio of the heights of the two. This will always lead to an overestimation of the percentage of the shaded area and hence the perceived progress. This should in turn enhance program members' intention to persist and repurchase.

We further argue that the above prediction on the greater influence from figure displays will uphold even when the two display formats are used simultaneously. A simultaneous presentation not only provides a more direct test for the unique influence of one format over the other but it also allows us to explore the underlying mechanism for their relative dominance. We propose that figure displays dominate over numerical displays because estimation of progress via the former path is easier.

It is cognitively less demanding to estimate progress in figure displays because consumers substitute the area calculations with a direction comparison of the relative size of the salient dimension only. This turns a numerical computation process into a relatively simple perceptual task. Thus, we may expect that the relative dominance of figure displays should be particularly pronounced when the numerical computation of progress is non-trivial. In other words, figure dominance should be attenuated when the numerical computation of progress is facilitated.

Two scenario experiments with undergraduates as participants were designed to assess our notions. Experiment 1 assessed how perceived progress and repurchase intentions in a loyalty program differed with the use of figure displays versus numerical displays. Participants reported significantly higher perceived progress and intention to repurchase ($ps<.05$) when the progress information was supplemented by a figure display (i.e., a status triangle in which 46% of the area was shaded) than when the same progress information was presented in numbers alone (i.e., you accumulated 874 points out of 1,900 points). This supports the idea that repurchase intention could be enhanced by presenting the same progress in figure displays as compared to numerical displays.

Experiment 2 further tested if the relative influence of figure versus numerical displays is attenuated when the computation of numerical information is easy. A 2 (presentation format: figure displays vs. no figure displays) x 2 (ease of computation: easy vs. difficult) factorial design was employed. In the easy condition, the participants accumulated 460 loyalty points out of 1,000 points, whereas in the difficult condition, the participants accumulated 874 out of 1,900 points. Thus across all the conditions, the participants had completed 46% of the loyalty program but they differed in the ease in calculating the progress (percentage). The interaction between presentation format and ease of computation was significant on both perceived progress and intention to repurchase ($p<.05$). The presence of figure displays significantly increased the perceived progress and intention to repurchase only when the numerical computation is difficult ($ps<.05$), but not when the computation is easy (NS). The results were consistent with our notion that the influences of the two display

formats stem from the ease in processing the two modes of information. The advantages of using figure displays to encourage repurchase are compromised when the computation of the actual progress is inherently easy.

In sum, we demonstrated that the formats in which progress information is presented play a substantial role in encouraging loyalty program members to persist and repurchase. The findings also suggest that the effects of presentation formats depend on the ease in processing the two different modes of information.

Consumer Entry Decision in Promotional Games Based on Chance: Do the Perceived Odds of Winning Matter?

Sandra Laporte, HEC Paris, France

Promotional games represent significant investments for marketers: \$1.83 billion were spent in 2006 in this kind of sales promotion (Promo Magazine, 2007). Their goals may be to make a product or service known, to collect information for direct marketing purposes or to build brand image. To achieve this, firms often wish to maximize the number of participants. This is particularly true for promotional games relying on a chance mechanism to designate winners (lotteries, sweepstakes, instant win games, etc.), which potentially address a greater number of entrants than skill-based contests. However, so far, consumer research has offered few guidelines on the impact of design characteristics on participation likelihood for promotional games based on chance (Ward and Hill, 1991).

One of these characteristics which directly impacts the cost of the promotion for the firm is the number of prizes, i.e. the number of winners. This piece of information is considered to contribute significantly to the game attractiveness and is made as salient as possible in the associated advertisement (Feinman, Blashek and McCabe, 1987). But are consumers actually sensitive to the number of prizes when making their entry decision? This number is an incomplete indication of the probability to win (i.e. the numerator), since typically no indication is given on the number of participants (i.e. the denominator). Thus, the consumer is placed in a decision under uncertainty, in which the ambiguity on the probability to win stems from the limited availability of probability cues. Following research on scope neglect and magnitude insensitivity (e.g. Frederick and Fischhoff, 1998, Kahneman, Ritov and Schkade, 2000, Hsee and Rottenstreich, 2004), our hypothesis is that in most cases, people estimation of their probability to win, and then their participation likelihood, is not an increasing function of the number of prizes. We contend it is due to the lack of *evaluability* of this variable, i.e. the "impossibility to evaluate the desirability of one level when it is presented in isolation" (Hsee, 1996; Hsee et al., 2005): a consumer may not be able to judge if a game offering 10 prizes is associated with a *good* or *bad* probability to win.

Three scenario-based pilot studies investigate the impact on consumer entry likelihood of different kinds of probability cues embedded in advertisements for promotional games based on chance. By probability cue, we refer to the elements in the game design contributing to the probability to win but insufficient to estimate it precisely, like the number of prizes (study 1a: 1 vs. 10 week-end trips to win), the geographical scope of the game (study 1b: 100 winners in Paris vs. 100 in France) or the frequency of drawings (Study 1c: A winner every day vs. every week vs. every month). We only find an impact of the magnitude of the probability cue on participation likelihood in the temporal frequency format: In study 1c, respondents (N=165) declare on a 9-point scale to play more often when the winning instants are happening every day than every month ($m_{\text{day}}=3.790$, $m_{\text{month}}=1.374$, $p<0.05$). Thus, the evaluability of the probability cue seems greater when it takes the form of the temporal frequency of drawing compared to the number of prizes or the geographical scope of the game.

In Study 2, we test if the insensitivity to the geographical scope of the game is due to the incapacity to estimate the number of participants it represents. People have to give their likelihood to choose between a Gaumont or an UGC movie theater to watch a movie on a Saturday night: the UGC is 10-minute further but is randomly drawing 100 spectators among its multiplexes¹³ who each win 10 free tickets. In a full factorial design, we manipulated the geographical scope of the sweepstake (low scope: all spectators in Paris vs. high scope: all spectators in France) and the amount of information (no information vs. the average number of UGC screens and spectators on a

¹³In most countries, the entry in a promotional game must not require any monetary consideration in order not to be regarded by the legal interdiction against commercial lotteries (Feinman, 1987).

Saturday night in Paris/France). The probability cue has no impact on respondents estimated probability to win ($N=107$, $m_{\text{Paris}}=.389$, $m_{\text{France}}=.586$, $p=.357^{14}$), while the amount of information has a main negative effect ($m_{\text{noinfo}}=1.020$, $m_{\text{nspectators}}=-0.045$, $p<.001$). More interestingly, the interaction between the information amount and the geographical scope is not significant ($p=.531$), meaning that people do not become more sensitive to the scope when they know its value with precision. It does not reduce the difficulty to figure out if the geographical scope covered by the game is a positive or a negative signal for their probability to win.

Study 3 tests how visualizing the number of prizes makes consumers more sensitive to this probability cue by helping them realizing if, taken into isolation, a given number is large or small. Two between-subject factors are manipulated orthogonally in the ad for a sweepstake: the number of prizes (2 vs. 12 iPods), which is given in digits and the number of pictures showing the prizes (1 picture vs. as many pictures as iPods to win, i.e. 2 or 12 pictures). When only one picture shows the prize category, people estimated probability is not sensitive to the number of prizes, thus replicating study 1a ($N=108$, $m_{2\text{iPods}}=0.104$, $m_{12\text{iPods}}=0.109$, $p=0.984$), while when there are as many pictures as prizes at stake, respondents estimations become magnitude sensitive ($m_{2\text{iPods}}=-0.76$, $m_{12\text{iPods}}=0.532$, $p=0.02$).

We are currently looking for other means to increase the sensitivity of estimated probability to win to the number of prizes, while gaining more insights about the underlying mechanism. Moreover, this research tackles consumer decision making under an original kind of uncertainty, which is an intermediate case between the absence of any probability cue (i.e. choice under ignorance, e.g. Hogarth and Kunreuther, 1995) and vaguely (or imprecisely) defined probabilities through numerical ranges, verbal expressions or graphical representations (e.g. Kuhn, 1997, Hönekopp, 2003). Here, uncertainty is contextualized in the case where people are only provided with one of the elements necessary to come up with probability estimation, either the numerator part (number of prizes, drawing frequency) or the denominator part (geographical scope).

The Interpersonal Hot Hand Fallacy: Endorsement of Promotional Games by Previous Winners

Sandra Laporte, HEC Paris, France

Extensive research has already emphasized the specific role of similarity with others on beliefs, judgments (e.g. Feick and Higie 1992; Suls et al. 2000) and behaviors (Burger et al. 2004; Shang et al. 2008) in contexts characterized by incomplete information. This research deals with a new effect of interpersonal similarity: we contend that similarity can affect judgment under uncertainty in the context of promotional games based on chance or state lotteries. This kind of entry decision is characterized by uncertainty since the advertisements designed to recruit the participants do not communicate the probability to win. Thus to answer the question “How likely am I to win this drawing?”, we show that people rely on their similarity with the previous winners and believe they have more chances to win the random drawing when they are similar to the previous winner than when they are dissimilar.

A common advertising practice used by brands or national lotteries is consistent with this assumption: it consists in featuring winners of previous drawings, with pictures and few personal details (e.g. first name, age, place of living, occupation), in order to foster the participation in the next drawing (Roger 2005). We confirmed this hypothesis in lab: we manipulated the similarity between subjects and

¹⁴Analyses were realized on estimated probability to win after the transformation recommended by Tukey (1977, p397). We add 0.5 to the probabilities and then take the Napierian logarithm of the sum.

featured previous winners through age. In the similar condition, the advertisement for the sweepstake showed the picture of a couple of previous winners with about the same age as the respondents, while in the dissimilar condition featured previous winners were older. Age similarity had a significant effect on how much time respondents were willing to spend to enter the sweepstake¹⁵ measured by a 7-point scale ($N=113$, $m_{\text{sameage}}=3.115$ vs. $m_{\text{older}}=2.03$, $t=1.799$, $p<0.05$ (one-tailed)).

We contend that similarity with previous winners enhances the entry likelihood through the estimated probability to win. In line with the Attribute Substitution Model (Kahneman and Frederick 2002), consumers may substitute their similarity with previous winners (heuristic attribute) for probability to win the next drawing (target attribute). The three conditions to apply this model are indeed satisfied: First, the probability to win the lottery is not directly available. Secondly, similarity judgment is a natural assessment in social judgment and represents a good candidate as a heuristic attribute: social perception theories have shown that people tend to automatically rely on salient attributes such as gender, age, ethnicity or national origin to categorize people as similar or dissimilar (Brewer and Harasty Feinstein 1999; Fiske et al. 1999; Mussweiler 2003). Thirdly, consumers are likely to rely on heuristics to estimate their probability to win a promotional game based on chance because time and not money is required to participate (Monga and Saini, 2008) and the entry decision is likely to be low-involving. Hence, our main hypothesis is that people may estimate their probability to win as higher when previous winners are similar to them. This pattern of results extends the well-established Hot Hand Fallacy (Gilovich, Vallone and Tversky 1985) from the intrapersonal to the interpersonal domain: People treat similar or dissimilar previous winners as the two possible outcomes of a binary random process. The hot hand is interpersonal because the two consecutive winners are not the same person but are similar. In line with research showing that gamblers tend to believe that luck is an individual attribute responsible for winning (Wagenaar and Keren, 1988; Rogers and Webley, 2001), luck benefits here to a category of persons.

Studies 1a&b tested the Interpersonal Hot Hand Fallacy when interpersonal similarity was manipulated through gender (1a) and educational background (1b). Respondents estimated their probability to win the impending drawing to be greater when the last two winners had the same gender as them ($N=50$, $m_{\text{samegender}}=0.872$ ¹⁶ vs. $m_{\text{differentgender}}=0.286$, $t=1.817$, p (one-tailed) <0.05) or when they were pursuing the same kind of academic studies as them ($m_{\text{samestudies}}=1.077$ vs. $m_{\text{differentstudies}}=0.252$; $t=2.643$; $p<0.05$).

Study 2 replicated the influence of similarity with previous winners on the estimated odds of winning by manipulating similarity through age: the photograph and the associated legend presented either a 70-year old couple (dissimilar condition) or a 29 year-old couple (i.e. the average age of respondents, similar condition). Respondents thought they had higher chances to win the next drawing when they were similar to the previous winners ($m_{\text{sameage}}=0.354$ ¹⁶) than dissimilar ($m_{\text{older}}=-0.140$, $t=2.109$, $p<0.05$), and this difference could not be attributed to the Availability Heuristic. The estimated probability of winning mediated the impact of similarity on participation likelihood (Baron and Kenny 1986, MacKinnon 2007).

Study 3 investigated the impact of the number of similar/dissimilar previous winners featured, as the number of observed previous outcomes has been shown to be a moderator of the Hot Hand Fallacy (Ayton and Fisher, 2002; Johnson, Tellis and Macinnis, 2005). When one single previous winner was featured, the Interpersonal Hot Hand occurred as in previous studies: people estimated they had a higher chance to win the next drawing when the previous winner had the same gender as them than when the previous winner had a different gender ($N=43$; $m_{\text{same gender}}=0.124$ vs. $m_{\text{different gender}}=-0.870$; $t=2.095$; $p<0.5$). When three previous winners were featured, gender similarity had no effect ($N=51$; $m_{\text{same gender}}=-0.907$ vs. $m_{\text{different gender}}=-0.970$; $t=0.135$; $p>0.5$). Moreover, the alternative explanation related to the activation persuasion knowledge was ruled out.

The main contribution of this research is to show a new kind of hot hand fallacy caused by a similarity judgment. It also extends the existing literature dealing with the influence of similarity and identity congruency. While unrealistic optimism can bias the evaluation of anonymous, random-picked in-group member on social traits (Klar and Giladi 1997), here we show that the observation of what happened to an anonymous in-group member can also influence the likelihood judgement of an event occurring to oneself.

The Effects of Expertise on the Processing of Alignable Versus Nonalignable Features

Myungwoo Nam, INSEAD, Singapore
Jing (Alice) Wang, University of Iowa, USA
Angela Y. Lee, Northwestern University, USA

What makes a product different than other competing products? To come up with a brand positioning, marketers need to identify a point of difference that makes its product different from other competing brands. For example, Sharp argues that its LCD panels have superior response times compared to other brands, making its TVs better equipped to show fast-action programs such as sporting events. On the other hand, Sony's Playstation 3 emphasizes that it is the only new generation console that is capable of playing Blu-ray discs and differentiate itself from Microsoft's XBOX 360 which cannot play high definition video format without an add-on HD DVD drive. All of these positioning strategies strive to win over consumers by communicating product information that differentiates their brand from the competitors. They differ, however, in the type of differentiating feature they promote. The first positioning strategy focuses on attribute values that are different along the same dimension. We refer to this strategy as emphasizing alignable differences. On the other hand, the latter strategy emphasizes the feature that is unique to a particular brand. We refer to this type of strategy as differentiating on nonalignable differences.

An important question to marketers is which of these two strategies is more effective in differentiating its brand compared to other competing options. Prevailing findings in the literature suggest that alignable differences influence consumer decisions more than non-alignable differences because alignable differences are easier to compare than nonalignable differences (Gentner and Markman 1993; Zhang and Markman 1998).

The current study investigates a condition under which nonalignable differences are used as a basis of product evaluation that differentiates alternative options. Specifically, consumer expertise is identified as a moderating variable that influences processing of alignable versus nonalignable options.

The relative importance of alignable differences in product comparison and choice can be explained by the diagnosticities of types of attributes as well as ease of processing of alignable features relative to nonalignable features (Feldman and Lynch 1988; Zhang and Markman 1998). Specifically, alignable differences can be directly compared across different options and allow unambiguous comparisons (Slovic and MacPhillamy 1974). The ease of comparison between two alignable features makes them diagnostic in product evaluation. For example, even a novice consumer who has little knowledge about digital cameras can use number of pixels as an indicator of picture quality in choosing camera. On the other hand, consumers will have difficulties in comparing two brands on nonalignable differences. One of the reasons is that it is difficult for consumers to determine how good nonalignable attributes are without making direct comparisons with other brands. When judging the expected utility of a nonalignable attribute value, consumers need to have sufficient knowledge to interpret the expected benefit of attribute level, and make a comparison between it and the relevant standard from memory. Given the difficulty of interpreting expected benefit of the nonalignable attribute, novice consumers would resort to cognitively less demanding task of comparing alignable attributes.

The current study focuses on the effects of expertise on processing of alignable versus nonalignable features. Experts' familiarity with the product category reduces cognitive effort and frees up cognitive resources (Alba and Hutchinson 1987). In addition, experts are better able to infer associated benefits from attributes than novices (Maheswaran and Sternthal 1990).

This analysis suggests that despite the majority of studies that found dominance of alignable differences over nonalignable differences in product judgment, consumer expertise may moderate this effect. When consumers have substantial knowledge about the product category, it is likely that they would focus more on nonalignable features rather than alignable features. Specifically, we

hypothesize that more knowledgeable consumers are better able to infer the benefits of nonalignable features, and that this ability would make them to pay more attention to nonalignable features and use them as a basis for their judgments.

Three studies were conducted to test this hypothesis. Study 1 investigated relative attention that participants place on alignable versus nonalignable differences. It was expected that experts would pay more attention to nonalignable differences than novices because their abilities to process and compare nonalignable differences is greater than those of novices. The study had a one factor (expertise: high vs. low) between-subject design. MP3 player category was chosen as a focal product category. The results showed that there was a main effect of expertise. The analysis revealed that the percentage of experts who chose alignable difference (8.7%) was much smaller than experts who chose nonalignable differences (91.3%) as the most distinguishing feature. On the other hand, 37.5% of novices chose alignable difference and 62.5% of them chose nonalignable difference as the most distinguishing feature ($\chi^2(45)=5.44, p<.02$).

Study 2 investigated how experts and novices search for alignable versus nonalignable product information. The study had a 2 (alignable vs. nonalignable) x 2 (experts vs. novices) mixed design. One hundred twenty seven undergraduate participants were asked to evaluate two brands of tennis racquet after reviewing product information on the computer. The results showed a main effect of alignability, such that participants reviewed more alignable features than nonalignable features ($M=5.01$ vs. 3.88 ; $F(1, 125)=62.66, p<.001$). Subsequent planned contrasts showed that novices reviewed more alignable features than experts ($M=5.16$ vs. 4.86 ; $t(125)=2.05, p<.05$), whereas experts reviewed more nonalignable features than novices ($M=4.03$ vs. 3.73 ; $t(125)=1.96, p<.05$). The results of study 2 showed that experts focused more on nonalignable features than alignable features. On the other hand, novices paid more attention to alignable features than nonalignable features.

Study 3 used brand evaluations as a dependent measure to test the effects of expertise on processing of alignable versus nonalignable features. A 2 (experts vs. novices) x 2 (superior alignable vs. superior nonalignable) design was used. Similar to study 1, MP3 player category was used. The results indicated that the interaction between these factors was significant. Follow up contrasts revealed that experts evaluated the target brand more favorably in superior nonalignable condition ($M=5.81$) than those in superior alignable condition ($M=4.98, F(1, 96)=10.80, p<.001$). The result is consistent with our expectation that experts focus on nonalignable attributes and are able to infer benefits from these attributes. On the other hand, novices evaluated the target brand less favorably in superior nonalignable condition ($M=5.35$) than those in superior alignable condition ($M=3.81, F(1, 96)=5.75, p<.05$), replicating previous studies that showed consumers' initial focus on alignable features (Zhang and Markman 1998).

Best-Laid Plans...: Understanding the Processes Underlying the Planning Fallacy

Jaehoon Lee, University of Texas at San Antonio, USA

L. J. Shrum, University of Texas at San Antonio, USA

Jongwon Park, Korea University, Republic of Korea

Abstract

The planning fallacy refers to the systematic tendency to hold a confident belief that one's own task will proceed as planned. Research has provided evidence of the tendency to underestimate the completion time for future tasks. The purpose of this research is to extend the previous research to a consumer behavior context and examine possible underlying processes. Our findings suggest that people underestimate their shopping completion times but overestimate their shopping duration times. Our findings also indicate that people with a high interpersonal locus of control tend to underestimate the shopping times more so than those with a low interpersonal locus of control.

Conceptual Background

Most people have probably had the experience of planning to complete a paper within a few days but taking a week to complete it because they underestimated the time to complete the paper. This is referred to as the *planning fallacy*, which is the systematic tendency for people to underestimate how long a task will take to complete, even though they are often aware that certain types of tasks invariably take longer to complete. A number of studies (Buehler and Griffin 2003; Buehler, Griffin, and Ross 1994; Byram 1997; Newby-Clark et al. 2000) have demonstrated that this tendency is surprisingly robust and has been shown to persist regardless of whether people are asked to consider various possibilities (e.g., future, pessimistic, or optimistic scenarios, need for accuracy, task decomposition). However, despite this robustness, surprisingly little is known about the underlying processes (but see Kruger and Evans 2004). The purpose of the

current research is to address that issue. As a first step, we begin by investigating possible individual differences variables that may moderate the effect.

One individual difference variable we expected to moderate the planning fallacy effect is locus of control. Locus of control refers to the degree to which people believe that outcomes of their actions are under their own control (internal locus of control) or outside their own control (external locus of control) (Paulhus 1983). Paulhus specified three primary spheres of control: *personal efficacy* that is associated with personal achievement, *interpersonal control* that is associated with other people and groups, and *sociopolitical control* that is associated with social and political events. Within each of these dimensions, people with an internal locus of control believe they have control over their actions and outcomes, whereas people with an external locus of control believe they have little control. If one explanation for the planning fallacy effect is that people tend to underestimate the external forces that can upset their plans for task completion and overestimate their ability to control those external forces, then we would expect internals (relative to externals) to exhibit more of a planning fallacy effect and thus underestimate the time it would take to complete a given task.

A second individual difference variable we investigated was regulatory focus (Higgins 1987). Regulatory focus is a theory of self-regulation that proposes two types of foci: a promotion focus (primarily concerned with maximizing gains) and a prevention focus (primarily concerned with minimizing losses). Promotion-focused people are oriented towards fulfilling their hopes and aspirations, whereas prevention-focused strive to avoid negative outcomes and failures. If one explanation for the planning fallacy effect is that people look at shorter completion times as more “successful” than longer completion times, then promotion-focused people should show a larger planning fallacy effect than prevention focused people.

In sum, we expect a planning fallacy main effect, but we expect this effect to be qualified by two separate interactions with locus of control and regulatory focus.

Method

About three weeks before Valentine’s Day, students ($n=133$) who had a significant other, were planning on buying a Valentine’s Day gift, and had not completed the gift purchase yet were randomly assigned to one of three experimental conditions: a best-case scenario (assume that “things will go as well as they possibly can”), worst-case scenario (assume that “things will go as poorly as they possibly can”), and a no-scenario condition. In the best- and worst-case conditions, participants were instructed to make predictions based on the scenarios (i.e., told that if the scenario they described is what actually happens to them, when will they complete their Valentine’s Day shopping (completion time) and how long will it actually take them to do the shopping (duration)). Next, participants were asked to make final predictions on their actual completion time and shopping duration (ignoring their scenarios). Participants in the no-scenario condition made final predictions only. Next, participants completed the locus of control (Paulhus 1983) and regulatory focus measures (Higgins et al. 2001). A few days after Valentine’s Day, participants were contacted and asked when they had completed their shopping (actual completion times) and how long it took them (actual duration times).

Results

We tested for an overall planning fallacy effect by examining the differences between the predicted and actual completion time and shopping duration as a function of scenario condition. People underestimated their shopping completion times regardless of their scenario condition ($ps<.001$). The planning fallacy effect is indicated in the no-scenario condition in which participants’ predicted completion times averaged 12.4 days but their actual completion times averaged 15.6 days, or about a 25% underestimation. In spite of this general underestimation of completion time, however, participants *overestimated* how long it would take them to actually conduct the shopping (duration), again regardless of condition ($ps<.02$). In addition, the degree of the overestimates of shopping duration was greater in the best-case scenario than in the worst-case scenario ($p<.05$).

We next investigated the effects of the individual difference variables on the planning fallacy effect. The magnitude of the planning fallacy did not differ as a function of any of the individual difference variables. However, in terms of estimating the duration of shopping time, those with low interpersonal control overestimated their shopping duration time ($M=67.9$ min.) to a greater degree than those with high interpersonal control ($M=38.6$ min.). However, due to high variability, this difference was not significant ($p=0.14$). In addition, interpersonal control moderated the planning fallacy effect in the best-case condition, with those high in interpersonal control underestimating to a greater degree than those low in interpersonal control ($M=2.67$ days vs. $-.21$ days, with a negative number indicating overestimation, $p<.10$). We also found that people with high sociopolitical control overestimated shopping duration to a greater degree ($M=81.05$ min.) than those with low sociopolitical control ($M=42.06$ min., $p<.05$) and that people with high prevention focus overestimated shopping duration to a greater degree ($M=62.1$ min.) than those with a low prevention focus ($M=32.65$ min., $p<.10$).

In conclusion, in this experiment we replicated previous research on the planning fallacy effect, and did so within a consumer behavior context. We also provided preliminary evidence of some possible underlying mechanisms. Future research will be aimed at better understanding the individual differences results and developing methods for manipulating the underlying processes.

Preserve Self or Impress Others: Mortality Proximity and Guilt Advertising

Sooyeon Nikki Lee-Wingate, Fairfield University, USA

Since the initial discussions by Ghingold (1981), the construct of consumer guilt has received some attention in the consumer behavior literature (e.g., Lascu 1991), mostly related to hedonic or luxury consumption (Kivetz and Simonson 2002). To further enrich understanding of the guilt construct, the current research investigates conditions under which advertising utilizing guilt appeals can be more effective.

Guilt appeals stress how you should (or should not) do something in order to avoid violating moral standards, as such transgressions will produce unwanted guilt. I classify guilt appeals into two categories, based on the focal users of the market offering and the direction of intended guilt manipulation. Interestingly, these two types attempt to manipulate the amount of guilt people anticipate in two opposite directions. The first category, *guilt-lessening appeals*, focuses on indulgences for purchasers themselves (e.g., spa treatment, expensive jewelry, etc.) to lessen guilt most consumers feel about self-indulgent consumption. These argue: "It's about time you *should* do something for yourself. You are worth it." The second category, *guilt-magnifying appeals*, intends other people than the purchaser as the focal users (e.g., children's education, birthday gifts, insurance, wills, etc.) and attempt to magnify the level of guilt most consumers feel about having to uphold socially desirable behaviors involving their loved ones. These ask "Are you doing what you *should* be doing for your loved ones?" In this research, the compliance to these two types of guilt appeals is the primary dependent variable.

The extant literature suggests a list of mediators of the process within which advertising appeals influence guilt perceptions and purchase intentions of consumers: self-esteem (Ghingold 1981; Lascu 1991), locus of control (Rotter 1966; Ghingold 1981; Lascu 1991), susceptibility to guilt (Kivetz and Simonson 2002), motivation to comply (Carlsmith and Gross 1969), and self-competence (Deci 1975; Lascu 1991), to name a few. However, few moderators have been studied. Specifically, under which conditions can guilt appeals be more effective, regardless of individual-level mediators? Moreover, do these moderators operate in unique processes?

The key moderator in this research is drawn from mortality salience, a well-studied construct in the Terror Management Theory (TMT; see Greenberg, Solomon, and Pyszczynski 1997). I draw on the two different motivations underlying TMT: self-preservation and impression management. Mortality salience has been shown to increase likelihood of behaviors that *a*) preserve own material interests, under self-preservation motivation, and *b*) are socially desirable, under impression motivation (Maheswaran and Agrawal 2004). Consistent with the self-preservation motivation of defending own material interests and increasing self-worth, mortality facilitates purchase of high-status objects (Mandel and Heine 1999), for which guilt-lessening appeals are usually employed. Similarly, materialism helped buffer consumers from mortality (Arndt, Solomon, Kasser, and Sheldon 2004). In these contexts, mortality salience appears to foster the motivation where a boost of self-worth becomes compulsory—which may simultaneously favor compliance to guilt-lessening appeals. At the same time, mortality salience has also been linked to impression motivation that promotes socially desirable behaviors (Jonas, Schimel, Greenberg and Pyszczynski 2002). Socially desirable behaviors usually involve other people, who often are the foci of guilt-magnifying appeals. In this line of reasoning, I hypothesize that preservation motivation will increase compliance to guilt-lessening appeals that promote self-indulgent consumption, whereas impression management will increase compliance to guilt-magnifying appeals that recommend socially desirable consumption.

It is important to distinguish these two distinct mechanisms of motivation (Maheswaran and Agrawal 2004). I hypothesize a new variable of mortality proximity to do exactly that. It is interesting that TMT literature does not differentiate the focal death person in terms of proximity to the perceivers (proximal vs. distal). If a consumer feels a specific type of death is proximal to him or herself, then it will not only generate stronger effects of death-thought accessibility, but also create and strengthen specific motivation regarding self-preservation (versus social impression management) for subsequent behaviors. For example, if a college-aged student views news about how some college students commit suicides, then the resulting death-thought accessibility will be more focused on self-preservation motivation (perhaps resulting in the purchase of a luxury item for oneself) than viewing a story about rising occurrences of deaths caused by breast cancer in middle-aged women, which may perhaps be more focused on impression management motivation regarding their mothers (perhaps resulting in buying a luxury gift for mother's day).

Thus the hypotheses to be tested in this research are as follows:

H1: Proximal mortality will increase compliance to guilt-lessening appeals via inducing motivation of self-preservation.

H2: Distal mortality will increase compliance to guilt-magnifying appeals via inducing motivation to enhance socially desirable impressions.

The results of this research will theoretically aid the understanding of how consumer guilt construct operates in the advertising context, considering mortality proximity as a moderator. In addition, results will contribute to the progress of literature on mortality by suggesting a moderator that determines which process is evoked under mortality salience. Practical recommendations of this research inform advertisers using guilt appeals to choose a context that primes the appropriate sort of mortality proximity. For example, TV shows

such as ER, House, Law and Order, or CSI mentioning particular sicknesses, murders, or accidental deaths that may proximally affect a particular segment more so than others can be considered to maximize favorable receptivity of guilt appeals.

Mood Awareness and Brand Extension

Kang-Ning Xia, Yuan Ze University, Taiwan
 Yu-Tse Lin, Fu Jen Catholic University, Taiwan

This study primarily explored the effects of mood on brand extension. Previous research indicated that mood did influence consumers' acceptance of brand extension (Kahn, 1995; Menon and Kahn, 1995). For example, consumers with positive mood may adopt more diverse brand extensions than consumers with negative mood (Barone, Miniard, and Romeo, 2000). In other words, the happy ones can accept the larger difference between extension brand and parent brand than the sad ones. In spite of rich evidence that show the influence of mood on brand extension, there was little research discussing the mechanism behind the influence process.

Furthermore, previous research about the relationship of mood and brand extension neglected the issue of the mode of brand extension. When firms execute brand extensions, there are at least two types of extension policy (Park, Mileberg, and Lawson, 1991); the first is to focus on the similarity of brand concepts or brand image, for example, Rolex watches extended to its bracelets series. The other is to emphasize on the similarity of product characteristics, such as Timex watches extended to its timekeepers. Therefore, the objective of this study is to discuss if mood has the same influence on these two types of brand extension and the mechanism behind the influence process.

Actually, mood influences consumers' attitudes in a quite complicated way, and the purpose of this study is to probe that in various mood awareness (conscious and unconscious) and mood level (good mood and bad mood), the consumers' acceptance and preference to brand extension may be different. There are two mood awareness condition should be discussed: motivational mood and backdrop mood (Luomala and Laaksonen, 2000). As to the motivational mood, people experience mood in a conscious way and can aware of the source of mood; this kind of mood may involve cognition process. As to the backdrop mood, people are just in good or bad mood without being aware of it.

Mood awareness is the critical factor that influences whether mood influence attitude directly or via cognition components (Xia, 2007). When consumers are under backdrop mood and doesn't aware the source of mood, the mood can reflect to the attitude directly. It means good mood lead to more acceptance of brand extension, while bad mood lead less preference to the brand extension.

On the contrary, when the consumers are under motivational mood and can aware the sources of moods, the mood effect is indirect and involved cognition elements. It means in motivational mood, good mood leads to the heuristic thinking approach, and consumers will care more about the heuristic cues (Monroe, 2003; Suri and Monroe, 2003), for example, the brand image. On the contrary, bad mood leads to the systematic thinking style (Bless, Bohner, Schwarz, and Strack, 1990; Bless, Mackie, and Schwarz, 1992; Mackie and Worth, 1989; Sinclair, Mark, and Clore, 1994; Worth and Mackie, 1987), and the consumers will pay more attention to the attributes that related to the product itself (Xia, 2007).

When applying the above discussion to brand extension, it is suggested that in backdrop mood (unconscious situation), mood influences brand extension attitude directly; It leads to the hypothesis 1:

H1: When consumers in happy mood and can't aware of it (backdrop mood), their preference and recall to brand extension will be higher than the bad mood one.

On the other hand, in motivational mood (conscious) situation, mood will influence consumers' attitude via biasing information process. Good mood leads to pay attention to heuristic cues, for example, the brand image. Therefore, when facing brand extension, consumers prefer the brand concept similarity extension to the product characteristic similarity extension. It leads to the hypothesis 2:

H2: When consumer in a happy mood and can aware of it (motivational mood), their preference and recall to brand concept similarity extension will be higher than to product characteristic similarity extension.

On the contrary, bad mood leads to the systematic thinking style, and the consumers will pay more attention to the attributes that related to the product itself. Hence, bad mood consumers incline to accept the product characteristic similarity extension more. It leads to hypothesis 3:

H3: When consumer in a sad mood and can aware of it (motivational mood), their preference and recall to brand concept similarity extension will be lower than to product characteristic similarity extension.

A 2 (mood level: good vs. bad)*2 (mood awareness: motivational vs. backdrop)*2 (brand extension type: product similarity vs. brand concept similarity) experiment was designed to examine the hypotheses, and there were 160 respondents randomly assigned in one of the above conditions.

The result of this study can be discussed in two parts. First, in the backdrop mood (unconscious) situation, it is hypothesized mood influences attitude directly. The results supported H1, and show that good mood leads to higher acceptance to brand extension, while bad mood leads to lower preference to brand extension. In the backdrop mood, there is no difference between the acceptances of two modes of brand extension.

In motivational mood, it is hypothesized good mood leads to focus on brand image. The results also supported H2 and indicated that consumers prefer the brand concept similarity extension to the product characteristic similarity extension. Moreover, H3 was also supported by the results that indicated bad mood consumers prefer product characteristic similarity extension more, and relative to product characteristic similarity extension, they don't like brand concept similarity extension.

Action-Driven Evolution of General and Enduring Preference Hierarchies

Ab Litt, Stanford University, USA

Abstract

How can 'mere' actions and choices, independent of their expected or actual outcomes, shape preferences and choice rationales themselves? A difficulty-varying- α model is constructed to investigate the effects on preferences of making cross-domain product choices in attribute trade-off conflicts. Employing principles of persistence and generality, the model inspires a set of hypotheses regarding the evolution of stable and generalized attribute importance hierarchies, as well as preference amplification and switching behaviors.

Supporting simulation results are described, which form the basis for behavioral experiments in development to test model predictions. Implications for taste acquisition, “lifestyle marketing”, and personality are also currently under study.

Conceptualization

The emphasis in much of behavioral decision research is on the processes by which preferences lead to actions, such as choices and judgments. The present work examines the less studied reverse of this relationship: how actions and choices, independent of expected or actual outcomes, affect preferences and choice rationales themselves. A difficulty-varying- α model is constructed to investigate the effects on preferences of making cross-domain product choices in attribute trade-off conflicts (ATCs). The model and accompanying simulations inspire a set of hypotheses concerning the generality of the action-to-preference effects in terms of cross-context evaluation attributes. For instance, if I choose comfy clogs over durable boots, might I become more likely to choose a power-drill with a soft-grip handle than one with a lifetime warranty? Through this generality, the model provides a precise explanatory framework for within-domain findings of Hoeffler and Ariely (1999), and also allows for extended behavioral predictions that both cut across domains and explore more complicated phenomena in action-driven preference evolution. It embodies two basic principles by which actions shape preferences:

- 1) Persistence: The effects of an individual’s actions can influence how the individual continues to act, e.g., in subsequent choices, and so on. That is, preference attribute weights don’t simply *shift* following an action, but are able to systematically *evolve* over time and a series of actions.
- 2) Generality: Re-valuations occur via attribute re-weighting, and so actions can have effects beyond any specific options at hand, on any process or decision which taps those same attributes.

Simulations of multiple ATC decisions are useful for testing and exploring these principles, because they allow for the exact control (or randomization) of initial weights, choice difficulty, ATC presentation order, and interactions thereof. The simulations also inspire behavioral paradigms currently being designed to test various model predictions.

Model and Primary Hypothesis

Choice options are represented as fixed vectors of attribute values, which identify the specific attributes defined as choice-relevant for that option, and the nature of the information available on that attribute (divergence from zero). For instance, products $A=[.9, .2, _, _]$ and $B=[.1, .8, _, -.7]$ might both be defined on durability and price, but eco-friendliness might only be of relevance to product B. A weight vector, w , captures the importance and valence of all the attributes to an overall valuation, V , of an option. This is naturally defined as the dot product of these vectors:

$$V(\text{option } X; w) = \langle X, w \rangle$$

In an ATC between two options, X and Y, the choice policy is defined to be the selection of the option with higher overall valuation, $V(X; w)$ or $V(Y; w)$. After a choice has been made, attribute weight updating occurs in response to the motivation to resolve dissonance aroused by having to make the ATC choice. Components of w are increased for attributes on which the chosen option, X, is strong and decreased for those on which the X is weak, and vice versa for the rejected option, Y. Given the manner in which w , X, and Y are defined as vectors, this translates into the update rule

$$w \leftarrow w + \alpha \cdot X - \alpha \cdot Y \text{ (for choosing X, rejecting Y)}$$

The degree to which w is updated in this way on any single choice is determined by the value of α . Here, a variable-alpha approach can be utilized to produce psychologically realistic results. The notion of a variable α (i.e., systematic epoch-to-epoch differences in how much weight is given to new information) is a powerful general principle in machine learning, and seems relevant to other domains of psychology as well. For instance, in learning behaviors, it seems plausible that people use high alphas in early-stage learning (since they have little expertise, and a high alpha allows quick learning of basic and general facets), and then move to reduced alpha values when they have proceeded to later, fine-tuning stages (since low alphas allow behaviors that have already been learned to stay robust against deviations encountered in the exploration of limiting and extreme cases).

Here, it seems natural that α be correlated with the *difficulty* of the decision, since more difficult decisions arouse more dissonance, and greater efforts for dissonance reduction. A clear formulation of ATC difficulty is the degree to which options have close value equivalence, and also exhibit a high degree of trade-off between different attributes. The first aspect is akin to the absolute valuation *difference* between two options. The second corresponds directly to the *orthogonality* of the two option vectors, which is simply the closeness of their dot product to zero. Thus, ATC difficulty for a choice between A and B is defined as follows:

$$\text{difficulty} \propto 1/(\langle A, B \rangle \cdot |V(A) - V(B)|)$$

This difficulty determination is fed into a sigmoid clamp to define $0 < \alpha < 1$ for a given ATC, giving α approaching 1 with increasing decision difficulty:

$$\alpha = 1/(1 + e^{\langle A, B \rangle \cdot |V(A) - V(B)|})$$

A key consequence of this variable- α policy and the persistence and generality principles is that, as repeated choices are made in ATCs between different options, the spreading out of attributes caused by a higher α in the early stages will make later choices *easier*, since attribute preferences have been “pulled apart” from each other by choices in earlier ATCs with high between-attribute trade-offs.

This will reduce σ_a for these later choices, and hence the relative change to the weight vector. Thus, even with randomized or zeroed initial weights, and randomized ATC presentation of randomly defined options, a *stabilizing dominance structure* for the attribute weights should eventually arise.

H1: Repeated ATC choices will evolve a stabilized attribute importance weight hierarchy.

Additional behaviors predicted by this model reflect the outcomes of such choice-driven evolution of attribute hierarchies. First, if the evolution process spreads out weights in a manner consistent with how those attributes favored an earlier choice, it can make an individual more satisfied with that earlier choice:

H2: Repeated ATC choices can result in preference amplifications on re-evaluation.

Conversely, if the evolution process spreads out weights in a manner *inconsistent* with how those attributes favored an earlier choice, it can make an individual less satisfied with the earlier choice, and indeed reverse preference directionality:

H3: Repeated ATC choices can result in preference switches/(de-)acquisitions on re-evaluation.

Findings and Future Directions

Support for H1-H3 is provided by a series of six simulation experiments, each using 25 products randomly defined either within-domain (i.e., on all of the same attributes) or sharing definitions for only a sub-set of general attributes. For H1, simulations using five-attribute products beginning with random initial weights evolved dispersed and stable dominance hierarchies within 10 binary ATC iterations ($H_a: \sigma_{init} < \sigma_{final}; F(4, 4) = 56.7453, p < 0.001$). Similar dominance evolution for *only* shared attributes evolved when ATC choices were simulated for products across different domains. For H2 and H3, valuation computations using initial versus evolved weights showed that, even if the weight evolution process occurred over different product domains, initial preferences could be amplified in some cases ($\approx 44\%$ of pairs, $\max(\text{lincrease}) = 187\%$) and switched in others ($\approx 15\%$ of pairs, $\max(\text{reversal}) = 213\%$), depending on the degree to which the sequence of ATC decisions conforms to either the preconditions of H2 or H3.

The low iteration requirements for these simulations suggest practical behavioral tests. Currently under design are repeated cross-domain ATC tasks measuring effects on confidence, WTP, difficulty judgments, distortion, switching propensity, and direct measurement of attribute weights using conjoint analysis techniques. Broader implications of H2-H3 for taste acquisition, “lifestyle marketing”, and personality stability are also under study.

Consumers Commit the Planning Fallacy for Time but not for Money

Stephen A. Spiller, Duke University, USA

John G. Lynch, Jr., Duke University, USA

The planning fallacy is defined as: “The tendency to hold a confident belief that one’s own project will proceed as planned, even while knowing that the vast majority of similar projects have run late” (p. 366, Buehler, Griffin, & Ross, 1994). Because individuals plan for money as well as time, discussions of the planning fallacy often conflate underestimating time costs with underestimating money costs. Kahneman and Tversky (1979), Buehler and colleagues (1994), and others use both cost overruns and schedule overruns as motivating examples of the fallacy, but most subsequent research examines the fallacy only as it pertains to time (though see Ulkumen, Thomas, & Morwitz, 2008, for work on duration-based budgets rather than project-based budgets). We consider the extent to which consumers underestimate time and money expenditures and find that the planning fallacy for money is absent or considerably reduced relative to the planning fallacy for time.

The planning fallacy is usually attributed to using singular data about the plan under consideration to the neglect of distributional data regarding other similar plans (Kahneman & Tversky, 1979; see Buehler, Griffin, & Ross, 2002, for a review), but there is nothing inherently different about using singular vs. distributional data for time or money. Recent research has considered the extent to which time is perceived more flexibly than money (e.g., Okada & Hoch, 2004; Zauberman & Lynch, 2005). To the extent that predictions of money expenditures are either less biased (due to less flexible perceptions) or more binding (due to greater ability or willingness to constrain costs) than predictions for time expenditures, the planning fallacy will be more pronounced for time than for money. Kruger and Evans’s (2005) study 1 provides preliminary suggestive evidence by showing that participants who listed everyone on their holiday shopping list (compared to those who did not) estimated that their holiday shopping would require 40% more days, 96% more hours, but only 9% more money. We test the cross-resource difference in the planning fallacy directly using self-reported susceptibility to the planning fallacy and measures of actual and predicted expenditures.

Studies 1a and 1b

In studies 1a and 1b, we measure consumers’ beliefs about their own time and money expenditure predictions. In study 1a, 1113 online panelists reported the severity and frequency with which they committed the planning fallacy for time spent on “major projects” or money

spent on “major purchases”. Participants reported a greater planning fallacy for time than for money as assessed by both severity ($t(1111)=5.13$, $p<.0001$; $M_{\text{Time}}=8.417$, $M_{\text{Money}}=7.723$ on 13-point scales) and frequency ($t(1111)=7.50$, $p<.0001$, $M_{\text{Time}}=2.939$, $M_{\text{Money}}=2.284$ on 6-point scales). In study 1b, 1551 online panelists reported the severity and frequency with which they committed the planning fallacy for time or money on “major shopping trips”. We replicated the effect for frequency ($t(1549)=3.476$, $p=.0005$; $M_{\text{Time}}=2.442$, $M_{\text{Money}}=2.199$ on 6-point scales) but not severity ($t(1549)<1$, $p=.3771$; $M_{\text{Time}}=4.224$, $M_{\text{Money}}=4.171$ on 7-point scales).

Study 2

If consumers commit the planning fallacy for time but not for money, forming more time plans will be associated with having less time than expected, whereas forming more money plans will not be associated with having less money than expected. One hundred five participants reported their propensity to form time or money plans for the short- and long-runs and how much they agreed with the statement “I often find I have less [time / money] at the end of the [day / month] than I expect”; resource was varied between subjects, time span was varied within subjects. Individuals with high propensities to form time plans report having less time than expected ($r_{\text{short-run}}=.398$, $p=.003$; $r_{\text{long-run}}=.399$, $p=.003$), but individuals with high propensities to form money plans do not report having less money than expected ($r_{\text{short-run}}=-.046$, $p>.5$; $r_{\text{long-run}}=-.217$, $p>.1$). These cross-resource differences are significant ($p's<.02$).

Study 3

In study 3, we measure actual cross-resource differences in the planning fallacy using predicted and actual time and money expenditures. Ninety-three undergraduate participants completed up to ten online surveys. In survey 1, they described four plans they recently formed (short- and long-run plans for time and money), and how much time or money they expected to spend on each. Every other day for 16 days, participants reported in surveys 2-9 whether they completed each of their short-run plans and, if so, how much time or money they spent on it. Seven to eight weeks later, participants reported in survey 10 the same measures for their long-run plans. Plans that did not have an identified goal or endpoint (e.g., “I plan to stay caught up in my studies daily” has no completion date) were excluded from our analyses. We used $\log(\text{actual expenditures} / \text{expected expenditures})$ as our dependent variable to allow cross-resource comparisons in the same metric. For uncompleted time plans, we took participants’ last report of *not* completing their plan as a conservative proxy for their actual completion time.

Thirty-six participants had useable plans of all four types. A 2 (time, money) \times 2 (short-run, long-run) repeated measures ANOVA indicated a main effect of resource ($F(1,35)=18.57$, $p<.0001$); neither the effect of horizon nor the interaction approached significance ($p's>.4$). Participants underestimated their time expenditures ($M_{\text{Log(Actual/Expected)}}=.522$, indicating 41% underestimation) and overestimated their money expenditures ($M_{\text{Log(Actual/Expected)}}=-.173$, indicating 18% overestimation). A similar analysis using only participants who completed all four plans ($N=21$) showed similar results (Time: $M_{\text{Log(Actual/Expected)}}=.175$, indicating 16% underestimation; Money: $M_{\text{Log(Actual/Expected)}}=-.189$, indicating 21% overestimation; $F(1,20)=3.32$, $p=.0832$).

Discussion

In three studies, we demonstrated that consumers commit the planning fallacy for time but not for money, that they acknowledge this difference, and that individuals who form more time plans have less time than expected whereas individuals who form more money plans do not have less money than expected. We have not yet explored boundary conditions or tested the process behind these differences. One explanation we are currently examining is that because it may be easier to constrain money expenditures than time expenditures, money expenditure predictions are just as optimistic as time expenditure predictions but are self-correcting because actual money expenditures are constrained to meet the optimistic predictions whereas actual time expenditures are not.

Principles of Geometric Accounting. Is Bigger Always Better When It's Free?

Igor Makienko, University of Nevada, Reno, USA

While planning sales promotion campaigns retailers often face a dilemma what to offer as a free gift. Monetary value or cost of a gift is probably the main factor in such a situation. However, gifts of the same monetary value may be very different in their sizes and this factor may affect consumers' deal perceptions.

According to Taylor et al. (1979) visual stimuli that are more salient but not necessary more important may have disproportionate effect on consumer's judgments.

To our knowledge nobody investigated the effect of the actual size of a free gift on deal perceptions and purchase intentions. Literature review reveals few studies that are only reminiscent of our topic. For example, Wansink (1996) reports that larger packages encourage consumption. Package shapes that attract more attention are perceived to contain greater volume of a product (Folkes and Matta, 2004).

In our research we investigate how the price of a promoted product (high vs. low) and the size of a free gift (smaller than vs. bigger than the promoted product) affect consumers' deal evaluations and purchase intentions.

Conceptual Background

We suggest that when the value of a free gift is ambiguous consumers may infer it based on its size and the price of a promoted product.

Krider et al. (2001) propose that initial comparison between two figures is based on a single, most salient at a time of evaluation dimension. Though in sales promotion context consumers do not choose between the two items it is still a joint outcome context (Nunes and Park, 2003) and size dimension may be very salient especially if a gift is bigger than a promoted product.

To estimate the value of a gift, consumers may use some heuristic relating the monetary value of a gift to its size. Based on one of the main assumptions of normative economics—that more is preferred to less we suggest that size-value relation is likely to be positive. However, another factor—price of a promoted product may reverse this relationship.

Low and Lichtenstein (1993) investigated double promotions—when consumers are offered a price discount (Was... Now...) and a free gift—and found that when stated reference price was high, respondents evaluated deals with expensive gifts more favorably than those with cheap gifts. The reverse was true when the stated reference price was low. The authors conclude that higher reference prices 'absorbed' both the discount and high monetary value of a free gift while low reference prices resulted in a 'too-good-to-be-true' situation and negative consumers' attributions that adversely affected deal perceptions. When consumers feel that retailer is giving too much they may question the quality of a product or a gift or both (Friestad and Wright, 1994). Retailer's credibility is likely to be low as well.

In a similar vein Raghubir (2004) suggests that consumers make inferences about the value of a free gift based on the price of a promoted product and expected discount rate in the industry. The author shows that well-established brands may be adversely affected when they are offered as free gifts with low-priced products.

Extending this logic to our context we expect an interaction between the size of a gift and the price of a promoted product. When the price of a promoted product is high, offering bigger size gifts is likely to improve deal perceptions. On the other hand, with low-priced products bigger size gifts will hurt deal perceptions and retailer's credibility.

Methodology

In our study we chose a backpack as a promoted product and a plush toy dog as a free gift and employed a 2 (\$60/high vs. \$30/low promoted product price) x 2 (gift size smaller than vs. gift size bigger than that of a promoted product) between-subjects full-factorial design.

Results and Major Findings

Manipulation checks showed that price levels and sizes were perceived as intended. Respondents were not significantly different in their perceptions of believability of presented sales promotion and quality of a backpack.

Dependent variables were measured with well-established scales and all scales were reliable (α s ranged from 0.809 to 0.945).

To analyze the data we used one-way ANOVA where condition served as an independent variable. Results for attitude toward the deal ($F(3,114)=5.692$, $p=0.001$), perceived value ($F(3,114)=5.395$, $p=0.002$), purchase intentions ($F(3,114)=3.072$, $p=0.031$) and retailer's credibility ($F(3,114)=3.87$, $p=0.011$) were significant.

Post-hoc tests showed that when a \$60 backpack was offered with a smaller dog, respondents had significantly lower deal perceptions and perception of retailer's credibility than in any other condition. This result may be related to a noticeable discrepancy between a \$60 price that respondents were exposed to and their estimates of a fair price for a backpack (\$31.42) in high price condition. While a bigger size gift was able to justify high deal price, a smaller size gift could not do this job. Enhanced deal perception was due to respondents' higher quality evaluations of a bigger size gift ($p=0.005$).

In a low price condition counter to our hypothesis bigger size gifts did not hurt respondents' deal perceptions and retailer's credibility. Probably \$30 price was not low enough to make respondents generate negative attributions about the quality of the dog and influence their deal perceptions. Indeed, perceived quality of the dog in low price conditions did not vary significantly with the change in its size.

Overall our study supports the notion that the size of a free gift may affect deal perceptions. Bigger size gifts with ambiguous monetary values are likely to enhance perception of a deal when they are offered with high-priced products. On the other hand, when price of a promoted product is low bigger size gifts may not help in enhancing deal perceptions.

Accuracy and Affiliative Motivations in Socially Influenced Decision Making

Ted Matherly, University of Maryland, USA

People are often asked to make decisions based solely on socially acquired information—that is, their observations of the choices of others. Social influence has generally concluded that the general desire to make accurate decisions (Chaiken, Giner-Sorolla and Chen 1996) will lead individuals to conform to the choice of a large number of people, because consensus creates a perception of accuracy (Martin and Hewstone 2001). Recent research by Berger and Heath (2007) demonstrated that this generalized conformity may be moderated by the degree to which a product category is able to serve as a signal of group identity. Given the biasing effects of multiple motivations suggested by social judgment theory (Kruglanski and Sleeth-Keppler 2007), we believe the presence of an affiliative goal, where individuals make choices to express their connections to other people, provides a compelling explanation for observed differences in behavior based on the size of the group of people who have made a particular choice.

We propose that, in a socially influenced choice scenario where an individual can observe groups of differing sizes choosing among options, which are otherwise the same, the individual's varying motivations will influence their choices in a specific way. When no other motivations are active, choices will be consistent with classic theories of social influence (Sherif 1936), such that option selected by the largest group of people will be instrumental to their fundamental accuracy goal. However, when individuals possess an affiliative motivation, it will interact with their accuracy motivation to lead them to seek a means of achieving both goals simultaneously (Kruglanski, et al. 2002). Because options preferred by smaller groups are presumed to be stronger signals of identity (Berger and Heath 2007), the presence of an affiliative motivation will bias their perceptions of what their most accurate choice is, such that they will perceive the option preferred by the smallest group as the most likely means of achieving both goals (Kruglanski and Ajzen 1983).

In a preliminary study, we manipulated participant's affiliative motivation through an article describing a recent victory by their university's football team and answering a series of elaboration questions designed to elicit recollections of the game and the participants' affective reactions to the outcome. In a subsequent, presumably unrelated study, they were asked to make the "best" choice between three brands of a product: one preferred by a majority of a national sample and a small minority of their university's students, another preferred by a small minority of a national sample and a majority of their university's students, and a third choice preferred by larger minorities of both the national and university samples. The modal choice of those participants whose affiliative motivations were not activated by the elaboration task (based on a median split) was that chosen by the majority of the national sample, thereby satisfying an accuracy motivation. On the other hand, those whose affiliative motivations were more likely to select the option preferred by the minority of the national sample and the majority of their fellow university students. These results suggest that the presence of an affiliative motivation may alter perceptions of the "best" choice in a socially influence decision making scenario.

Our program of studies will begin with a more exacting test of the proposed relationships. Participants will first be asked to list several small campus groups that they feel they are a part of. Next, we will activate a general affiliative motivation (as opposed to the university-specific affiliative motivation of the preliminary study) through a lexical decision task combined with subliminal priming of words either associated with the concept of affiliation or of neutral words. Participants will then be presented with a series of supposed product usage data sets; wherein a majority of one of the campus groups they have listed earlier will use the product. In one condition, a minority of the students' full campus will be users, while, in the other, a majority of the campus will be users. Participants will rate their purchase likelihoods and satisfaction with their choices. Thus, our study will use a 2 (prime: affiliative, neutral) between- x 2 (campus user group size: small, large) within- subjects design. We anticipate an interaction of these two factors, such that those in the affiliative prime condition would be more likely to purchase when the campus user group is small vs. large, while we expect the opposite pattern in the neutral prime condition, where accuracy concerns would encourage purchase when a larger number of people have also purchased.

While our findings would provide evidence to suggest a motivational account for varying social influence outcomes, they are somewhat limited due to the artificial nature of the study itself. As a more realistic test of our hypotheses, our second study is designed to replicate a real-world choice situation. Fifteen participants will first complete the same lexical decision priming task from our first study. Next, a networked computerized choice system will present a choice among several brands of products, along with information about how many of the other participants in the lab have chosen each brand. Immediately after, three confederates will register the same choice, creating a small group within the session. Participants will then make their choices at their own pace. We anticipate that those participants with in the affiliative prime condition will be more likely to make their choices earlier, compared to those in the neutral prime condition. They will be more likely to choose with the confederates early on, but as more people choose and the adopting group becomes larger, this

likelihood will decrease. On the other hand, those in the neutral prime condition will be more likely to choose with the largest group who has made the same choice.

Our results will provide a convincing demonstration of the role of motivation in guiding the interpretation of social influence information. These findings present useful extensions into other areas of marketing research, including the diffusion of innovations, hot products, as well as the role of individual and decision-level situational factors in influencing decision making.

Narrative Transportation for Product Evaluation: Can Consumers Make the Difference?

Ellis A. van den Hende, Delft University of Technology, The Netherlands
Brent McFerran, University of British Columbia, Canada

Abstract

Narrative transportation (i.e., immersion into a story) has shown positive results in both psychology and marketing studies. In our product evaluation research with narrative scenarios, increased transportation experienced by the consumer (i.e., the reader) helps to surrogately experience the product and helps to list more benefits. Our results indicate that for some products transportation will increase evaluation, but for others it does not. Transportation, as opposed to what previous literature suggests, provides diverse consumer evaluations.

Visual imagery has shown to facilitate consumers' evaluation of a product (e.g., Hoeffler 2003). One way to facilitate imagination is by using narratives. When reading a narrative, people get lost in the story and experience what the main character experiences. This process is called narrative transportation (Green and Brock 2000). The narrative experience allows readers to have a vivid image of what they read, they feel what the character is feeling, and thus forget the world around them. Solely positive effects of transportation have been reported so far; we aim to extend these findings by showing that transportation can also result in diverse and negative evaluations.

Various studies show that transportation changes the beliefs of the reader. For example, Green and Brock (2000) found that after reading a murder story, increased narrative transportation resulted in a change of beliefs of real world statements (e.g., penalties for murder). Transportation also resulted in more positive evaluations of advertisements (e.g., Escalas 2007). Extending previous research, we will provide deeper understanding of the effects of narrative transportation for product evaluation research with consumers.

We propose that transportation increases differences in product evaluations and predictions of product success. Transported readers should not evaluate all products equally. These readers recognize differences in attractiveness of products. When using product scenarios (i.e., narratives in which a main character is using a product) to evaluate the potential success of products in a new market, increased transportation on the part of the reader facilitates surrogately experiencing the new product. The more the reader gets transported, the more experience is gained and the more benefits are perceived. Perceiving the benefits allows for consideration of these benefits. People who were less transported have not experienced the benefits and will give a lower evaluation. We expect that differences in evaluations and success predictions will be present between people who were transported to a greater extent versus people who were transported to a lesser extent, but this will depend on the valence of the focal product. Transportation facilitates picking up the differences in valence of products. Thus, consumers who are more transported into a scenario about a product that is new to the market will not evaluate all products equally. Thus, we predict an interaction, rather than a main effect, where transportation heightens evaluations for products with high potential market success more than those with a lower likelihood, rather than boosting evaluations for all products.

Products were selected with various levels of success in other markets than the market of the participant population. Pretesting with experts from industry confirmed two food products distinct in level of predicted success on the target market. A scenario was written in which a main character was either eating a special microwaveable ice cream (pretested as a less attractive product for the target market) or drinking a special fruit juice (pretested as a more attractive product for the target market). Both storylines were identical, except for the focal product. Numbers of product features and benefits were balanced. Transportation was manipulated directly (increased vs decreased) through instructions (see Green and Brock 2000), and the two scenarios were used (ice cream vs fruit juice) in a between subjects design (n=107). Levels of transportation (adapted from the Green and Brock 2000 scale), success prediction and product evaluation were measured.

The manipulation check on transportation was successful ($F=9.301, p<.01$). Results showed a main effect for transportation on the number of benefits listed by the participants ($F=4.805, p<.05$). Results also showed a significant interaction between the focal product and transportation on product evaluation ($F=3.809, p=.05$) as well on success prediction ($F=9.186, p<.01$). Comparing contrasts indicated that the product success predictions and product evaluations differed significantly between increased and decreased transported participants in the fruit juice condition (fruit juice: increased transportation>decreased transportation; product evaluation $t=2.296, p<.05$, success prediction $t=3.558, p<.01$), but not in the ice cream condition (product evaluation, $t=-.525, NS$, success prediction, $t=-.822, NS$). Thus, higher levels of transportation on the side of the reader into a scenario did not result in more positive evaluations and success predictions for both products. For the fruit juice, higher levels of transportation resulted more positive product evaluation and success prediction. However, for the ice cream the product evaluations and success predictions were equal for higher and lower levels of transportation on the side of the reader.

This study used a positive and negative product (as pretested). Apparently, either our scenario or our transportation manipulation was not strong enough to reverse the effect of transportation for the ice cream that was pretested as a product with more negative valence. In a next study we will manipulate the valence of the ice cream in the scenario directly (positive vs negative). We will combine this variable with transportation instructions (increased vs decreased) in a between subjects design. We expect to find that transportation increases the perceived negative impression of the ice cream that was showing up in the first study.

Discussion

With our studies we provide insight in the process of transportation for product evaluations. Our results indicate that for some products transportation will increase evaluation, but for others it does not. Transportation, as opposed to what previous literature suggests, provides diverse evaluations of competing products. In a follow up study we would like to show the mechanism of benefit processing. It could be that with the help of narrative transportation consumers can behave like experts and predict market success successfully through the use of narratives or scenarios.

Blue or Red? Exploring the Effect of Color on Cognitive Task Performances

Ravi P. Mehta, University of British Columbia, Canada
Rui (Juliet) Zhu, University of British Columbia, Canada¹⁷

Color is a basic aspect of human perception and has intrigued many researchers to study its impact on cognition and behavior. For example, color has been shown to affect test performance (Soldat et al. 1997) and well being of hospital patients (Verhoeven et al. 2006). Research in marketing has shown that cool colors (e.g., blue) are often associated with more favourable product evaluations, higher purchase intentions, and a stronger inclination to shop (Babin et al. 2003).

While the above findings are intriguing, they often lack rigorous theoretical understanding of why those effects occur. In addition, inconsistent results have been reported in the color literature. For example, conflicting results have been found as to whether warm versus cool colors enhance cognitive task performance. While some researchers have found that cool color (e.g., blue) led to better performance than warm color (e.g., red; Elliot et al. 2007; Soldat et al. 1997), others have observed the opposite (e.g., Hatta et al. 2002; Kwallak and Lewis 1990).

This paper intends to reconcile the above discrepancy and advance theoretical understanding of how and why color affects human cognition. We suggest that different colors can activate alternative types of regulatory focus, and consequently affect performances on different types of cognitive tasks. People also develop shared associations with colors (Elliot et al. 2007). While red is often associated with dangers and mistakes (Elliot et al. 2007), blue is frequently associated with openness and freedom (e.g., sky and ocean; Kaya and Epps 2004). Such color-induced associations have the potential to activate alternative types of regulatory focus. Regulatory focus theory suggests that people can achieve their goals in two different ways, either with a promotion or a prevention regulatory focus (Higgins 1987). Individuals who adopt a promotion focus perceive their goals as hopes and aspiration, and *eagerly* approach matches to their goals. In contrast, those who adopt a prevention focus perceive their goals as duties and obligations, and *vigilantly* avoid mismatches to their goals. We propose that red, due to its associations to danger and failures, is likely to activate a prevention focus because it cautions people to guard against such negative outcomes. Blue, however, is expected to activate a promotion focus, due to its associations to openness and freedom and thus its focus on achieving positive outcomes. Further, empirical studies involving regulatory focus theory have revealed that while a promotion focus increases performance speed and creativity, a prevention focus enhances performance accuracy (Friedman and Forster 2001; Forster et al. 2003). Following this line of research, we hypothesize that red, if activating a prevention focus, should enhance performance on detail-oriented cognitive tasks, whereas blue, if activating a promotion focus, should lead to better performance on creative tasks. A series of experiments provide systematic support to our theorizing.

¹⁷The authors would like to thank Joan Meyers-Levy for her very helpful comments on an earlier version of the paper. Financial support from the Social Sciences and Humanities Research Council of Canada is gratefully acknowledged.

All studies were run on computers and color was manipulated via background screen color. The first study employed two tasks to test the basic hypothesis that red/blue can induce primarily a prevention/promotion focus. First task involved indicating a preference for a prevention or a promotion focused brand from the same product category (Zhou and Pham 2004). The second task asked participants to solve a set of anagrams containing prevention, promotion or control target words. Results supported our hypothesis that red (blue) activates primarily a prevention (promotion) focus. Individuals in the red (blue) condition showed higher preference for brands featuring prevention (promotion) benefits and took significantly less time to solve prevention (promotion) focused anagram words. An auxiliary study demonstrated that our color manipulation did not affect mood.

Study 2 examined whether red (blue), due to activated prevention (promotion) focus, can enhance performance on detail-oriented (creative) cognitive tasks. A detailed-oriented task (a memory task) and a creative task (generating creative uses of a brick) were employed. As anticipated, better performance (i.e., accuracy) was observed in the red versus blue or control condition for the memory task, while those in the blue condition produced more creative responses in the creative task.

Study 3 replicated study 2 results using a different set of tasks, namely a proofreading task (detail-oriented) and a Remote Associates Test (creative task; Mednick 1962). More importantly, it offered insights on the underlying mechanism. We found that red can activate a prevention focus and thus enhance performance on a task requiring attention to detail, whereas blue can activate a promotion focus and therefore enhance performance on the creative task.

In the final study, we tested an important marketing implication from our theorizing. If red leads to prevention focus, it should enhance persuasion when paired with an ad that features images that are unambiguously related to the target product (e.g., specific product details). This is so because such clearly unambiguous, product-related images ensure these prevention-focused individuals that everything is in order and the ad involves no ambiguity. In contrast, blue, due to its activation of promotion focus, should enhance persuasion when paired with an ad that features images that are remotely related to each other and to the product. As such a setup provides opportunities for these promotion-focused individuals to engage in creative processing. An ad featuring either unambiguously or remotely related images was adopted from Zhu and Meyers-Levy (2007). As expected, those in the red condition were more persuaded when the ad featured unambiguously related images than remotely related ones, whereas the opposite was true for those in the blue condition.

In sum, findings from this paper contribute to our knowledge in two ways. First, it reconciles a conflicting set of results observed in the color literature (i.e., whether red or blue enhances cognitive performance?). We demonstrate that while red leads to a prevention focus and thus better performance on detail-oriented tasks, blue leads to a promotion focus and thus better performance on creative tasks. Second, findings from this research offer important marketing insights. While prior research has demonstrated that blue generally leads to more favorable consumer responses, our theory and data suggest conditions where red can enhance persuasion.

Unconscious Information Processing Reduces Information Overload and Increase Product Satisfaction

Claude Messner, University of Basel, Switzerland
Michaela Waenke, University of Basel, Switzerland

Abstract

Consumers are less satisfied with a product chosen from an extended assortment than one from a limited assortment (Iyengar & Lepper, 2000). Presumably, information overload is responsible for decreased satisfaction. Decreasing information overload during the decision process should therefore increase satisfaction. One possibility to increase processing capacity is unconscious information processing (Dijksterhuis et al. 2006). We demonstrate that a spontaneous selection from an extended assortment leads to an information overload as well as extensive conscious information processing. However, unconscious information processing is one way to enjoy the advantages of an extended assortment without an information overload.

When given the choice between a limited and an extended assortment, consumers tend to prefer the extended assortment. Indeed large assortment sizes have some advantages: consumers experience more fun (Iyengar & Lepper, 2000) and the probability that the consumer's needs will be satisfied increases with the assortment size (McAlister & Pessemier, 1982; Kahn, 1995). Nevertheless, surprisingly, consumers are less satisfied with a product chosen from an extended assortment than one from a limited assortment (Iyengar & Lepper, 2000). Presumably, information overload is responsible for decreased satisfaction. Decreasing information overload during the decision process in a large assortment should therefore increase satisfaction relative to a small assortment size.

One possibility to increase processing capacity is unconscious information processing (Dijksterhuis, Bos, Nordgren & van Baaren, 2006). Unconscious information processing is an unconscious rumination, which starts automatically as soon as a consumer is consciously thinking about something other than the target product. Compared with conscious information processing, the capacity of the unconscious is less limited (Dijksterhuis & Nordgren, 2006). Previous research has shown that after complex decisions, consumers are more satisfied with their decision when they processed information unconsciously than consciously (Dijksterhuis, 2004; Dijksterhuis & von Olden 2006; Dijksterhuis et al., 2006). Based on these assumptions we expect that unconscious information processing could be one solution for consumers to benefit from an extended choice by reducing the negative effects of information overload. We predict that the negative effect on satisfaction when choosing from a large assortment compared to a small assortment diminishes when consumers base their choice on unconscious information processing.

Method

We conducted a study in which the participants chose a praline in a 3 (selection mode) x 2 (assortment size) between-subject design. A third of the participants saw the assortment once and were asked to write down their thoughts on the pralines before they chose one praline (conscious condition), a third chose one praline spontaneously (spontaneous condition) and a third saw the assortment once and solved anagrams for five minutes before they selected a praline (unconscious condition). Half of the participants selected one praline from a limited assortment (6) and the other half from an extended assortment (24). After the selection, the participants evaluated the taste and hedonic experience of the praline as well as the pleasure and satisfaction with their choice on a seven-point scale. Because of the high intercorrelation, we report the mean of the four variables (Cronbach α =.78).

Results

The results are in line with our predictions. As expected, the interaction between selection mode and assortment size is significant, $F(2, 174)=7.41, p=.0008$. Participants in the conscious condition evaluated the praline from an extended assortment less positively ($M=5.26, SD=1.12$) than from a limited choice ($M=5.81, SD=0.74$), $t(58)=2.24, p=.03$, replicating previous findings. Similarly, the participants in the spontaneous condition evaluated the taste of the praline from an extended choice less positively ($M=5.33, SD=0.81$) than from a limited choice ($M=5.84, SD=0.99$), $t(58)=2.17, p=.03$. However, the participants in the unconscious condition evaluated the taste of the praline from an extended choice more positively ($M=6.04, SD=0.54$) than from a limited choice ($M=5.50, SD=0.96$), $t(58)=2.71, p=.009$.

Conclusion

The aim of this study was to investigate conditions in which the consumer could profit from an extended choice. Elaborating choices from an extended assortment quickly reaches the limits of conscious information processing. However, unconscious information processing is one way to enjoy the advantages of an extended assortment without an information overload. Retailers may be well advised to provide distraction from choosing when increasing the range of options.

Matching Product Newness to Consumer Exploratory Buying Behavior: Strategies for Effective New Product Launch

Anne Michaut, HEC Paris, France

The topic of new product acceptance has figured prominently in the marketing literature. Understanding and predicting accurately new product acceptance has become a key success factor on today's markets. As a consequence, innovation features as a key challenge in business research today. A plethora of studies have focused on consumer response to innovation (Hauser, Griffin and Tellis 2006). Yet, only few studies investigated the relationship between new products' and consumers' characteristics. Moreover, the cross-cultural dimension has become increasingly vital to companies in terms of new product diffusion (e.g. Tellis et al. 2003; Golder and Tellis 2004). This paper proposes to match elements of product newness to the existing two-dimensional conceptualization of exploratory buying behavior (see Baumgartner and Steenkamp 1996). It also intends to integrate cultural variations by testing the hypotheses in a cross-national context, using 5 countries in Europe (UK, Germany, France, Italy and Spain).

In terms of consumers' personality characteristics, researchers quickly recognized the applicability of exploratory behaviors to important areas of consumer behavior. Activities such as innovative behavior in product purchase, variety seeking, brand switching, recreational shopping, and information search are manifestations of exploratory tendencies in the consumer buying process (Baumgartner and Steenkamp 1996). Yet, Baumgartner and Steenkamp (1996) proposed that a two-factor conceptualization of exploratory consumer buying behavior might be more useful than the initial seven facets. Following this observation, they developed the Exploratory Buying Behavior Tendency (EBBT) scale, with two forms of exploratory buying behavior: Exploratory Acquisition of Products (EAP) and Exploratory Information Seeking (EIS) based on the distinction between *sensory* and *cognitive* stimulation seeking.

In terms of new product characteristics, past studies have shown that perceived product newness can have a major impact on the product's diffusion and adoption (Gatignon & Robertson 1991; Rogers 1976). Yet, more recently, Calantone and colleagues (2006) concluded that product innovativeness *per se* has no direct effect on new product profitability and meta-analyses results (Szymanski, Kroff and Troy 2007; Montoya-Weiss and Calantone 1994; Henard and Szymanski 2001) revealed that newness and performance are positively related but that the average bivariate effect remains small to moderate in size. In terms of marketing research, it appears relevant to study the effect of variables associated to product newness rather than the effect of newness in itself. Following this observation, recent research has focused on more specific product characteristics associated to product newness: e.g. complexity (Mukherjee and Hoyer 2001), uncertainty related to really new products (Hoeffler 2003), and familiarity with the product category (Dahl and Hoeffler 2004). We propose to follow Berlyne's theory of collative variables, stating that newness is accompanied by other properties, closely related, but sufficiently distinct from newness itself to produce their own influence on the direction of stimulus selection or the strength of any stimulus selection process (Berlyne, 1960, 1966). We argue product newness can create *sensory* or *cognitive* stimulation depending on its accompanying variables. Namely, we propose that variables such as change or surprise produce *sensory* stimulation (further labeled sensory newness). In contrast, variables such as complexity or puzzlingness produce *cognitive* stimulation (further labeled cognitive newness).

What are the likely effects of the product newness on liking? And more importantly, what are the likely interactions between product newness, consumer exploratory behavior and cultural characteristics? Drawing a parallel between the consumer exploratory buying behavior (EAP and EIS) and the product profile (sensory and cognitive newness); we expect congruency between the product profile and the consumer profile to yield higher product liking than incongruency between the two. More specifically, we expect (1) consumers with high (low) EAP to show higher (lower) liking for sensory new products as sensory newness should satisfy *sensory* stimulation seeking. Similarly, we expect (2) consumers with high (low) EIS to show higher (lower) liking for cognitive new products as cognitive newness should satisfy *cognitive* stimulation seeking. At the cultural level, individualism and uncertainty avoidance have been related to consumer innovativeness. We expect (3) consumers in countries with high (low) individualism to show higher (lower) liking for sensory new products as they are 'different' from existing ones; and (4) consumers in countries with high (low) uncertainty avoidance to show lower (higher) liking for cognitive new products as they comprise more uncertainty.

The results from a large study conducted in 5 European countries (i.e. UK, Germany, France, Italy and Spain) with 150 to 180 respondents per country evaluating 36 new products each (in the detergent category) partially supported our predictions. The analysis was conducted using a three-level hierarchical linear model with product characteristics (Level 1), personality characteristics (Level 2) and cultural characteristics (Level 3). Multigroup confirmatory factor analysis (Steenkamp and Baumgartner 1998; Byrne 1998) was previously performed to address the issue of measurement invariance across countries.

Specifically, in terms of main effects, we find a positive effect of consumer exploratory behavior on new product liking (EAP and EIS), a positive effect of sensory newness and negative effect of cognitive newness on new product liking. Moreover, we find that the negative effect of product cognitive newness on liking increases as EIS increases and that the positive effect of sensory newness decreases as EAP increases. This suggests that *incongruity* between the personality and product profile yields higher product liking. In terms of cultural characteristics, we find that the negative effect of product cognitive newness on liking is reinforced as uncertainty avoidance increases and that the positive effect of sensory newness on liking is emphasized as individualism increases. Hence we find that congruity between the culture and product profile yields higher product liking. In conclusion, our results show that personality and cultural characteristics are not a negligible source of variation in new product evaluation and new product liking in particular. Product characteristics should not be dissociated from personality and cultural characteristics when evaluating new product liking.

As always, our research has several limitations that present opportunities for future work. The present study is based on a reduced number of product and personality characteristics. Further research should examine the influence of more extent product and personality characteristics.

Understand the Role of Hybrid-level Country of Origin in Consumers' Product Evaluations.

Yupin Patara, Rutgers University, USA

Kent B. Monroe, University of Illinois at Urbana-Champaign and University of Richmond, USA

The Country of Origin Labeling Act 2002 will become effective in 2009. There has been concern by consumers as to the relative quality of products led to questions as to the meaning of a "Made in ..." label especially from more than one origin. Using Cue Consistency Theory as a theoretical foundation, how multiple extrinsic cues such as brand, price and certification cobrand interact with a hybrid-level of the country of origin to influence consumers' perceptions of quality is studied. The findings explain the role of a hybrid-level of the country of origin in consumers' product evaluations.

This research investigates a series of studies to examine the influence of the pattern of cues, namely cues consistency such as *brand, price, certification cobrand and a hybrid-level of the country of origin* upon the manner in which these cues are used in product evaluations. The situation to be studied is when several extrinsic cues are provided how consumers form their perceptions of product quality, value and willingness to buy.

The research questions are:—(1) How do consumers evaluate "Made in ..." label as a hybrid-level of country of origin? (2) How do consumers utilize a hybrid-level of country of origin information along with *brand, price and certification cobrand* when evaluating products' quality?

Conceptualization

When consumers are uncertain about the quality of products, they may use extrinsic cues to judge the quality claims made by the sellers (Monroe 2003). A product's *brand name* is a cue for customers representing images that they have formed about the brand and may be used as an indicator of quality (Rao and Monroe 1989). Brucks, Zeithaml and Naylor (2000) find that when price is paired with a consistent brand cue, the quality evaluation is enhanced. Chao (1989) finds the same enhancement when pairing price with positive country of origin brand.

According to cue consistency theory (Slovic 1966; Maheswaran and Chaiken 1991; Miyazaki, Grewal, and Goodstein 2000) when a set of cues is consistent each cue will reinforce a subsequent judgment. If a brand name is capable of signaling quality, then the presence of country of origin as an additional signal to endorse and signal the primary brand's product quality may enhance quality perceptions.

It is because they provide enhancing impact and are likely to be used jointly in overall evaluations. Similarly, *country of origin* cues can also influence consumers' quality perceptions and their confidence in the quality of the product. People form an initial concept of a product on the basis of its country of origin and this concept once formed can influence how information about the product's specific attributes is interpreted (Hong and Wyer 1990).

Inconsistent cues may signal contradictory information. Moreover, evaluations with inconsistent cues may depend upon some consistent subset of the inconsistent cues. Consumers may focus on the negative cue and anchor their perceptions of quality based more on the negative cues (Ahluwalia 2002; Campbell and Goodstein 2001).

Hypotheses

- H1: There will be an interaction effect of price and a *hybrid-level of the country of origin* on consumers' perceptions of product quality, such that the effect of either cue will be stronger when paired with a consistent (i.e., *High price/ Strong hybrid-level of the country of origin*) versus inconsistent cue.
- H2: There will be an interaction effect of brand and country of ingredient origin on consumers' perceptions of product quality, such that the effect of either cue will be stronger when paired with a consistent (i.e., *Familiar Brand/ Strong hybrid-level of the country of origin*) versus inconsistent cue.

For a High Price Level of a Product

- H3a: When the brand is highly familiar cobranded with a reputable certification agency, an increase in proportion of *hybrid-level of the country of origin* from a strong country of origin will result in an increase in the perception of quality.
- H3b: When the brand is highly familiar cobranded with a reputable certification agency, an increase in proportion of *hybrid-level of the country of origin* from a strong country of origin will result in an increase in the perception of quality.
- H3c: When the brand is highly familiar cobranded with a reputable certification agency, an increase in proportion of *hybrid-level of the country of origin* from a strong country of origin will result in an increase in the perception of quality.

Findings

Study 1. The hypothesized effect from H1 reveals a significant price x ingredient origin information interaction on perceived quality ($F(170)=6.95, p<.001$). We found no mean differences for the inconsistent conditions relative to price and ingredient origin pairing ($F < 1, NSP$). The effect of either cue will be stronger when paired with a consistent (i.e., *High price/ Strong hybrid-level of the country of origin*) versus inconsistent cue.

Study 2. The hypothesized effect from H2 reveals a significant brand x ingredient origin information interaction on perceived quality ($F(162)=5.51, p<.01$, see figure 5). We found no mean differences for the inconsistent conditions relative to brand and ingredient origin pairing ($F < 1, NSP$). The effect of either cue will be stronger when paired with a consistent (i.e., *Familiar brand/ Strong hybrid-level of the country of origin*) versus inconsistent cue.

Study 3. The hypothesized effect from H3 reveals that when the brand is highly familiar cobranded with a reputable certification agency, an increase in proportion of *hybrid-level of the country of origin* from a strong country of origin will result in an increase in the perception of quality ($t(150)=3.83, p<0.001$), increase in the perception of value ($t(150)=4.73, p<0.001$), and willingness to buy ($t(150)=1.88, p<0.05$).

Discussion

Study 1 and 2 provide strong support for the cues consistency hypotheses. The target cue is a stronger predictor of perceived quality when paired with a consistent. Study 3 provide support for the proportion of the *hybrid-level of the country of origin* hypotheses that when the brand is highly familiar cobranded with a reputable certification agency, an increase in proportion of *hybrid-level of the country of origin* from a strong country of origin will result in an increase in the perception of quality, value and willingness to buy.

Does Time Fly When You're Counting Down? The Effect of Counting Direction on Subjective Time Judgment

Edith Shalev, New York University, USA
Vicki G. Morwitz, New York University, USA

Web users watching video clips of commercials, news items, or music online can tell how much time has elapsed from the beginning of the video and the total duration of the video clip by looking at a digital counter usually located at the bottom of the pop-up media player. Are these video segments more entertaining when the timer counts the elapsed time downward or upward? Suppose your gym instructor asks you to do 25 sit-ups. Does time seem to pass by more quickly and are you more willing to do additional sets of sit-ups if you count down from 25 to 1 or up from 1 to 25?

This research examines the impact of counting events upward vs. downward on the perceived duration of the interval containing the events as well as on consequences associated with the duration of the interval. We propose that the end of a counting down sequence (7, 6, 5, 4, 3, 2, 1) evokes more favorable feelings than the end of a counting up sequence (for example 19, 20, 21, 22, 23, 24, 25) because it draws the counter's attention to the prospect of goal attainment at an earlier stage (assuming that adults do not consider the mere act of counting itself to be enjoyable or engaging, we suspect they hold an implicit goal of completion towards most tasks that involve counting). Past research suggests that an earlier perception of proximity to the goal results in greater positive emotions than a later one (Carver and Scheier 1990, Kivetz et al 2006, Nunes and Dreze 2006). Additionally, it has been shown that individuals tend to misattribute the favorability associated with the end of an experience to the overall favorability of that experience (Fredrickson and Kahneman, 1993). As a result, we hypothesize that individuals will interpret a counting down experience as more favorable and shorter than a counting up experience. Since individuals high in need for cognition (NFC) have been shown to devote more attention to their own thinking and meta-cognitive experiences (Petty et al, 2007), we expect the effect of counting up vs. down will be larger for individuals high in NFC.

In study 1 we asked participants to imagine doing twenty five sit-ups. Half were asked to count their sit-ups from 1 to 25 (upward) and half were asked to count from 25 to 1 (downward). Counting downward resulted in estimation of shorter exercise duration and in perception of faster completion pace compared to counting upward. Conversely, downward counters held more favorable attitudes towards the counting task and were more willing to continue counting sit-ups than upward counters.

In study 2 we asked participants to count twenty five geometrical shapes. We manipulated two factors between participants: counting direction—upward or downward and counting range—half counted between 1 and 25 and half counted between 26 and 50. We hypothesized that counting downward will be perceived as shorter and as more enjoyable than counting upward only for the 1-25 range where the final countdown sequence is indicative of the distance to one's completion goal (5, 4, 3, 2, 1), but not for the 26-50 range (where the countdown ends with 29, 28, 27, 26, 25). The results were consistent with our hypotheses. Downward counters estimated the duration of the counting task to be shorter than upward counters in the 1 to 25 ranges but not in the 26 to 50 ranges. This study also rules out task complexity as an alternative account for the downward counting effect. Regardless of the range counted, participants indicated that downward counting is more difficult than upward counting (yet the downward counting effect was not obtained in the 26 to 50 range).

In Study 3 participants were asked to estimate the duration of a waiting interval in which they counted either from 1 to 60 or from 60 to 1. They were asked to imagine waiting on the phone for a service representative. We manipulated the counting direction between participants and measured NFC. Consistent with our hypotheses, the counting direction effect was found only for individuals high in NFC.

In Study 4 we manipulated two factors between conditions: counting direction—upward vs. downward—and primed goal—completion vs. accomplishment. We also measured NC. Following the priming manipulation, we used the same procedure as in the sit-up study. The results replicated the NFC moderation obtained in study 3: only participants who were high in NFC demonstrated the downward counting effect on time perception. Furthermore, only for those high in NFC was the counting direction effect moderated by the primed goal. Specifically, participants who were primed with a completion goal perceived time to be shorter following downward counting. On the other hand, those who were primed with an accomplishment goal perceived time to be shorter following upward counting.

In sum we find across studies that counting down experiences are perceived as shorter and as more favorable than counting up experiences. Our results support the hypothesis that this effect depends on the implicit goal one holds towards the counting task. These findings have important managerial implications because they suggest that consumers may find the same experience more enjoyable and effective when the events or time units associated with it are counted downward. To mention just a few examples where this effect can be applied: managers of call centers, directors of fitness DVDs and designers of online video segments can improve the appeal and effectiveness of their products with hardly any effort.

The Influence of Consumer Mood State on Mental Imagery Processing of Advertisement and Brand Evaluation

Jun R. Myers, California State Polytechnic University, USA
Sela Sar, Iowa State University, USA

Advertising appeals that encourage imagined consumption imagery are well known to be effective marketing communication tools to enhance brand attitudes and behavioral intentions. However, our understanding of the effectiveness of using mental imagery of consumption is still far from clear. This research focuses on exploring the influence of consumers' mood state on the generation of consumption mental imagery and product and brand evaluations.

Mental imagery processing is defined as a process by which sensory information is represented in working memory during encoding, processing and retrieving of information (McInnis and Price, 1987). According to this definition, imagery processing is a processing mode, not a knowledge structure (e.g., specific schemas or scripts). The instantiation of a schema or script generates imagery. In consumer research, the *availability-valence hypothesis* directly addresses the persuasion effects of message evoked imagery on judgment and evaluation (Kisielius and Sternthal, 1986). It suggests that sensory imagery information is more available than semantic information at the time of judgment, and more likely to activate existing information structures. Therefore, effects of imagery processing on learning, evaluation and judgment are stronger than the processing of non-vivid, pallid or abstract information (Anderson and Bower, 1980; Kisielius and Sternthal, 1984, 1986; Tversky and Kahneman, 1974). Furthermore, the availability-valence hypothesis postulates that whether vivid information enhances, undermines or has no effect on persuasion depends on the relative valence (or "favorability") of the information in relation to the message advocacy. When the valence of thoughts in working memory is positive toward message advocacy, it will enhance persuasion. (Kisielius and Sternthal, 1986).

Recently in psychology, the influence of mood state on information processing has drawn a lot of attention. It has been shown that mood state can significantly influence how people process incoming and self-generated information (e.g., Forgas, 1995; Schwarz, 1990). However, little research has investigated the influence of mood state on consumers' use of mental imagery in processing marketing communication messages. Two theoretical frameworks suggest great potential to predict how different consumer mood states can affect the way consumers use mental imagery in processing brand information and forming brand evaluations.

The "cognitive capacity view" (Mackie & Worth, 1989) contends that positive affective state renders people less able to process incoming information because happy affect activates many positive thoughts in memory, and these thoughts occupy people's attentional capacity. In contrast, negative affect is less likely to generate thoughts to the extent that could take up much cognitive capacity. This view is consistent with the findings in current consumer behavior literature involving the use of positive consumption imagery in advertisement to induce greater extent of mental imagery processing, and reduce cognitive scrutiny and counter-arguments of message claims (Escalas, 2004). From this view, positive mood provides more resources for consumers to engage in imagery generation, and thus facilitates the generation of mental images regarding positive consumption experience, and reduces consumers' critical scrutiny and analytical examination of the message argument.

The "hedonic contingency view" suggests that people in a negative mood state are motivated to process information. They think that such processing can have hedonic value to their mood state (Wegener and Petty, 1994). This view renders support for the use of positive consumption imagery: when consumers are in a negative mood state (versus positive mood state), they are more likely to be motivated to engage themselves in the hedonically pleasant experience of imagining the future consumption. The motivation to change negative mood should be higher than the motivation to keep the positive mood state. Based on the hedonic contingency view, it would be expected that the ease of imagery generation in response to imagery appeals in the ad message will depend on the hedonic consistency of the mood state in regard to the valence of the imagery. When consumers are in negative mood, there is a heightened hedonic value to engage in positive consumption imagery processing. When consumers are in positive mood, such hedonic value to engage in positive consumption imagery processing should be diminished.

The two theoretical frameworks suggest different predictions in regard to the generation of consumption mental imagery and brand evaluations. The "cognitive capacity view" suggests that positive mood state (versus negative mood state) will provide more resources for the generation of mental imagery of consumption by reducing the resource allocated on message scrutiny. The "hedonic contingency view" predicts that negative mood state provides heightened motivation to the use of mental imagery of future consumption. This research aims to test these two seemingly competing views.

An experiment involving 254 subjects was conducted to test the influence of mood state on consumers' use of mental imagery to process advertising information. The experiment was a 3 (mood state: negative vs. neutral vs. positive) x 2 (imagery appeal: present vs. absent) between subject factorial design. Results support that mood state influences the extent of mental imagery processing and brand evaluations. Specifically, the more positive consumer's mood state is, the more extensive mental imagery is used in the processing of advertisement, and the more positively consumers evaluate the advertised brand. Results also suggest that the extent of imagery processing mediates the influence of mood state on brand evaluation. In short, results indicate that processing resources seem to play an important role in determining the impact of consumers' mood state on mental imagery processing and brand evaluation.

Seeing Ourselves in Others: Consumer Compliance with Recommendations Made by Ambiguous Agents

David A. Norton, University of South Carolina, USA
Rebecca W. Naylor, University of South Carolina, USA

Abstract

This research investigates how compliance with a recommendation made by another consumer is affected by the amount of information provided about the reviewer and the perceived similarity of the reviewer. In Study 1 we demonstrate that, given no information about a reviewer (i.e., the reviewer's characteristics are ambiguous), consumers project their own characteristics onto the reviewer, resulting in compliance likelihoods that are similar to compliance with a recommendation made by a reviewer presented as similar (vs. dissimilar) to the target consumer. In Study 2 we demonstrate that the false consensus effect is responsible for these results.

Consumers seeking recommendations on products and services have typically obtained this information from two primary sources, professional agents who are paid to make such recommendations (e.g., movie critics, interior decorators) (Solomon 1986; West 1996) or friends and family members who provide this information through word-of-mouth communication (Brown and Reingen 1987). However, Internet technology now offers consumers a new source for product information: consumer-to-consumer recommendations in which no personal information is provided about the reviewer (e.g., online user reviews that are posted with no identifying information about the reviewer other than a user name).

The primary research question we seek to address is: how do consumers respond to recommendations made by an ambiguous reviewer (whom we define as a reviewer about whom no personal information is available)? Previous research on agent recommendations suggests that giving consumers more information about a product recommender will increase compliance with the recommendation if that recommender is demographically similar to the consumer (Feick and Higie 1992). Gershoff and Johar (2006) demonstrate, for example, that consumers overestimate an agent's knowledge based on over-reliance on similarity cues in a close relationship. Hence, past research suggests that reviewer ambiguity would *decrease* compliance with reviewer recommendations since consumers will be unsure whether the reviewer is similar (which would increase compliance) or dissimilar (which would decrease compliance) to themselves. However, Norton, Frost, and Ariely (2007) argue that ambiguity can be beneficial in some contexts (e.g., potential dating partners are liked more when people have less information about them because more information increases the likelihood of discovering dissimilarity between oneself and a potential partner).

We propose that, when provided with no identifying information about a reviewer, consumers project their own characteristics onto that reviewer in a manner consistent with the false consensus effect (in which consumers tend to overestimate the prevalence of their own attitudes in the general population; Ross, Greene, and House 1977), such that consumers respond as positively to recommendations made by ambiguous reviewers as they do to recommendations by reviewers that they know are similar to themselves. Essentially, we propose that when information about reviewers' tastes is left ambiguous, participants assume these reviewers share their own tastes and attitudes.

To test our hypotheses, in Study 1 each participant read a restaurant review ostensibly written by another consumer and then indicated their intentions to visit the restaurant they read about. The review was designed to be slightly positive in order to make the restaurant attractive but to avoid ceiling effects. The text of the review was held constant across all conditions, and amount and type of reviewer information was manipulated such that participants saw either (1) no information about the reviewer (ambiguous reviewer condition), (2) information about a reviewer who was similar to the average student at their university (similar reviewer condition), or (3) information about a reviewer who was different from the average student at their university (dissimilar reviewer condition). In the similar and dissimilar reviewer conditions, the participants saw nine units of demographic information (e.g., age, gender, university attended, etc.) that were either similar or dissimilar to themselves (gender) or to the average student at their university (age, university attended). After reading the review, participants rated, on a scale of one ("not at all likely") to nine ("extremely likely"), how likely they would be to try the restaurant. Participants also rated how similar they thought the reviewer was to themselves in terms of similarity in restaurant taste.

In order to analyze the results of Study 1, we used orthogonal contrast codes comparing (1) the similar reviewer condition to the ambiguous reviewer condition and (2) the ambiguous and similar reviewer conditions to the dissimilar reviewer condition. We found, as predicted, that participants in the similar reviewer ($M=5.99$) condition showed no difference in likelihood of trying the recommended restaurant compared to participants in the ambiguous reviewer condition ($M=6.00$), $F(1, 216)=0.00$, $p>.95$. However, compliance with the recommendation was significantly lower for the dissimilar reviewer condition ($M=5.37$) compared to the similar and ambiguous reviewer conditions, $F(1, 216)=11.01$, $p<.01$. In order to demonstrate that the differences we find in restaurant trial are indeed caused by differing perceptions of similarity, we compared participants' ratings of similarity in the similar versus ambiguous reviewer conditions. As expected, participants perceived the reviewer in the ambiguous condition to be equally similar to themselves ($M=5.42$) compared to the reviewer in the similar reviewer condition ($M=5.59$), supporting our false consensus explanation. Further, the difference in perceived similarity between the dissimilar reviewer condition ($M=4.46$) and the other two conditions mediated the relationship between the dissimilar versus similar and ambiguous reviewer conditions and likelihood of trying the restaurant, $z=3.93$, $p<.01$.

The goal of Study 2 was to provide additional evidence that these results are driven by the false consensus effect. We hypothesize that alerting participants to the potential bias of the effect (i.e., warning participants about the tendency to see oneself in ambiguous others) decreases compliance with an ambiguous reviewer's recommendation. Hence, Study 2 used the same restaurant review context and three-level (ambiguous reviewer vs. similar reviewer vs. dissimilar reviewer) variable and added a two-level warning variable (such that participants were either warned about the false consensus effect or not warned).

The results of Study 2 support our predictions; we found a significant interaction between the warning variable and the similar reviewer versus ambiguous reviewer contrast, $F(1, 286)=2.90$, $p<.01$. With no warning about the false consensus effect, the results of Study 1 were replicated such that there was no difference in compliance with the recommendation between the similar and ambiguous reviewer information condition ($M=6.17$ for both conditions). However, when participants received a warning about the potential impact of the false consensus effect, they were significantly less likely to try the restaurant in the ambiguous reviewer condition ($M=5.18$) than in the similar reviewer ($M=6.35$) condition, thus providing additional evidence that the false consensus effect drives our results.

Corporate Syntheses: Consumers' Role in Mergers and Acquisitions

Eleni-Zoi Papavasileiou, Boston University, USA

Mergers and Acquisitions (M&As) have been a major trend over the past three decades; companies internationalize and strengthen their presence by acquiring profitable targets. In 2005, the total value of M&As worldwide was \$2.7 trillion, an increase of 38% compared to that of the previous year (Ettenson 2006). Thus, very few topics have gained as much attention in media and business research as M&As (Bouwman, Fuller, and Nain 2003). However, even though the total value and number of M&As continue to increase, a recent Mc Kinsey report (1997) notes that only one in five deals manages to create shareholder value.

Conceptualization

Research in various disciplines such as finance and strategy has investigated M&As. Existing research examines post-acquisition financial performance and points to a poor conclusion: "acquisitions do not create superior post acquisition performance for acquiring firms" (King et al. 2004).

One of the failures of the finance-based view of M&As is that managers pay little attention to the way they should present the M&A to consumers. Ettenson and Knowles (2007) notice that prior to an M&A deal, managers try to identify only the "hard" assets- property, equipment, patent, and drilling rights, but very rarely discuss the "relational" assets- corporate reputation, consumers' goodwill, and brands. Basu (2002) wonders "who's thinking about customers and critically-the brands? At the moment no one". However, the success of an M&A also depends on how external stakeholders and more specifically consumers perceive the M&A. They could either like it and support it, or dislike it and abandon their support towards the company after the M&A. Therefore, researchers and practitioners call for moving from "deal breaker-factors that prevent a deal from closing" to "deal maker-factors that enhance the chances of success after the merger" (Ettenson and Knowles 2007).

This paper suggests two main antecedents for consumers' attitudes and behavioral intentions after the M&A: 1) consumers' perceptions of the degree to which the two corporate images match, 2) naming of the company.

Corporate Image Matching

Broniarczyk and Alba (1994) extend the brand extension literature suggesting that in their brand extension evaluation, consumers consider the *psychological similarity* between the two brands (perceived similarity between the associations of the two brands). Broniarczyk and Alba (1994) and Park et al. (1991) suggest that the effect of consumers' perceived "fit" between the two brands dominates the effects of brand affect and category similarity. Similarly, this paper suggests that in their M&A evaluation, consumers consider the degree to which the two corporate images match.

Corporate Name

Cohen and Murphy (1984) investigate the attribute formation when two concepts come together to form a composite concept. The two authors report a minimum rule for the attribute formation of a composite concept: "*if something is not a 'good' A, it cannot be a 'good' AB*". In the M&A case two companies come together to form a new company. Following Cohen's and Murphy's (1984) minimum rule, when the matching between the two corporate images is low, the use of a combined name (i.e. after the FedEx UPS merge, both companies will operate under the FedEx UPS name) may be confusing and harm consumers' attitudes.

Cohen and Murphy (1984) and Hampton (1987) report a maximum rule; when a constituent of a composite concept is salient on a particular attribute, then this attribute will also be salient in the composite concept. Applied in the M&A context, when the two corporate images match, both companies' images will be stronger in the event that both companies start to operate under a combined name.

Tversky and Kahneman (1981) suggest that consumers are "less willing to accept a surcharge than to forego a discount." In other words, the two authors suggested that losses (negative events) loom larger than gains (positive events). In the M&As context, the low matching pair of companies could be perceived as a negative event (loss) and the high matching pair of companies as a positive event (gain). This paper suggests that consumers are more likely to support the separate naming strategy in the low matching case- loss case (each company continues to operate under its own name) than the combined naming strategy in the high matching case- gain case (both companies start to operate under a combined name).

Methodology

We used a 2 (high/ low matching) x 4 (4 naming strategies) within-subjects experimental design, with 107 college students participating. The experiment was conducted in two phases. First, we asked participants to provide the associations that came to their minds upon the presentation of one pair of companies. We used two pairs of companies: Starbuck's-Dunkin Donuts and FedEx-UPS. Each participant was randomly assigned to one pair. Participants were also asked to rate the degree of matching between the two corporate images. Afterwards, participants were informed that the two companies merged and were asked to express their attitudes and behavioral intentions toward each one of the four naming strategies: Strategy 1: both companies start to operate under a combined name (i.e. FedEx UPS), Strategy 2: both companies start to operate under the name of the first company (i.e. FedEx), Strategy 3: both companies start to operate under the name of the second company (i.e. UPS), Strategy 4: each company continues to operate under its own name (i.e. FedEx, UPS). At the end, potential covariate measures were collected.

Results

The data were analyzed in a regression framework. The dependent variables were the differences between consumers' attitudes and behavioral intentions vis-à-vis the four alternative naming strategies (for example: consumers' attitudes vis-à-vis Strategy 1- consumers' attitudes vis-à-vis Strategy 2, consumers' behavioral intention vis-à-vis Strategy 1- consumers' behavioral intention vis-à-vis Strategy 2). The independent variable was the degree to which the two corporate images match (High/Low).¹⁷ The results provided broad support for our conceptualization.

Consistent with our predictions, consumers preferred naming strategy 1 (combined naming) in the high matching case and naming strategy 4 (separate naming) in the low matching case ($\beta_{\text{str.1-str.4}}=-.477$, $p_{\text{str.1-str.4}}=.000$). Consumers also preferred naming strategy 1 (combined naming) in the high matching case and naming strategies 2 and 3 (names of the 1st and 2nd company) in the low matching case ($\beta_{\text{str.1-str.2}}=-.348$, $p_{\text{str.1-str.2}}=.000$, $\beta_{\text{str.1-str.3}}=-.228$, $p_{\text{str.1-str.3}}=.025$). Finally, consumers preferred naming strategies 2,3 in the high matching case and naming strategy 4 in the low matching case ($\beta_{\text{str.2-str.4}}=-.246$, $p_{\text{str.2-str.4}}=.014$, $\beta_{\text{str.3-str.4}}=-.295$, $p_{\text{str.3-str.4}}=.004$). Matching had an expected analogous effect on consumers' purchase intentions. Consumers are more likely to purchase when naming strategy 1 is used in the high matching case and naming strategy 4 is used in the low matching case ($\beta_{\text{str.1-str.4}}=-.319$, $p_{\text{str.1-str.4}}=.003$, $\beta_{\text{str.1-str.2}}=-.145$, $p_{\text{str.1-str.2}}=.112$, $\beta_{\text{str.2-str.4}}=-.234$, $p_{\text{str.2-str.4}}=.021$, $\beta_{\text{str.3-str.4}}=-.280$, $p_{\text{str.3-str.4}}=.002$).

As expected, consumers were more likely to support the separate naming strategy in the low matching case than the combined naming strategy in the high matching case. More specifically, in the low matching case, 69% of consumers chose naming strategy 4 (separate naming) as the most appropriate, whereas 27% of consumers chose naming strategy 1 (combined naming) as the most appropriate in the high matching case (if y is our dependent variable and x our independent variable, $y=-1.877x+0.509$, for $x=0$ -high matching-, $y_0=0.509$ and for $x=1$ -low matching-, $y_1=-1.368$, $|y_1|$ is significantly higher than $|y_0|$).

Implications

Both researchers (Basu 2006; Ettenson and Knowles 2007) and practitioners (Knowles and Ettenson 2007) begin to acknowledge that marketing could play a beneficial role when companies negotiate an M&A. More specifically, this paper proposes two key factors that influence consumers' reactions to M&As: degree to which the two corporate images match and naming strategy. Apart from the financial analysis that managers should do when considering an M&A, they may also need to think of more marketing-oriented assets such as consumers, corporate images and rebranding. This paper suggests that the matching between the two corporate images as well

¹⁸All regression coefficients are standardized. Coding for the matching between the two corporate images is 0 (1)=high (low) matching.

as the naming strategy (combined vs. separate) affect consumers' perceptions of M&As. Choosing the less favorable naming strategy may harm both consumers' attitudes and purchase intentions. Thus, managers should first understand how consumers think of the two corporate images, and choose the naming strategy accordingly.

The Role of Regret under Task Difficulty: A Boomerang Effect

Kirsten Passyn, Salisbury University, USA

Mita Suján, Tulane University, USA

Previous research has documented the advantages of high self-accountability emotions, such as guilt and regret, over low self-accountability emotions, such as fear, in motivating self-protection behaviors, such as wearing sunscreen or eating high fiber foods (Passyn and Suján, 2005). In accord with functional theories of emotion (Frijda 1986, Lazarus 1981), this research supports the idea that high self-accountability emotions motivate and drive self-protection behaviors. However, these findings are limited to simple domains where perceptions of self-efficacy are high.

Thus, previous research has only shown the ability of emotions to impact behaviors that participants feel capable of engaging in. This raises the questions as to the impact of high-self accountability emotions in more complex and demanding domains, for example, resisting peer pressure. When you heighten task difficulty, creating more uncertainty of one's ability to perform the task, Protection Motivation Theory (PMT) would predict a decline in self protection behavior (Rogers 1983). Thus, when a person feels incapable of performing the task they are less likely to do so.

The purpose of this research is to examine the impact of high self-accountability emotions under conditions of high task difficulty. We tested our hypotheses in the context of condom usage. Outwardly, most people perceive condoms usage as an efficacious behavior, they are readily available and easy to use. However, actual rates of condom usage are low because in the heat of the moment the task of actually stopping, finding, and using a condom is difficult (Bradford and Beck 1991). In a pretest we assessed participants' perceptions of condom usage difficulty and self-efficacy. Participants were either exposed to an in the moment message describing the difficulty of actually stopping and asking to use a condom or not exposed to any message. As predicted the results indicated when simply asked about condom usage participants report low task difficulty ($M=2.8$) and strong levels of self-efficacy, ($M=3.78$). However, when they were exposed to the manipulation perceptions of task difficulty increased significantly ($M=4.2$) and self-efficacy dropped significantly ($M=2.73$)*. In conclusion, our pretest demonstrates that while college students believe that condom usage is easy, reminding them of the urgency of the moment significantly increases perceptions of the real difficulty of using condoms.

Our study was a 2(task difficulty: present vs. absent) X 2(emotion: fear vs. regret) design. Task difficulty was manipulated using the manipulation described above. Emotions were manipulated using either a fear/low self-accountability message or a regret/high self-accountability message that discussed the threat of Chlamydia. Both messages concluded with a tagline to use condoms. Manipulation checks confirmed that participants in the fear (regret) conditions felt significantly more fear (regret) than participants in the other conditions. Additionally, the self-efficacy manipulation did not impact the intensity of the felt emotions, so there was no difference among the fear(regret) conditions. Furthermore, the task difficulty measure indicated significantly higher perceptions of task difficulty when participants were exposed to the "in the moment" message. Thus the manipulations were effective.

In support of previous emotion research the regret conditions combined resulted in significantly stronger behavioral intentions than the fear conditions combined ($M=7.5$ vs. 4.8, respectively). Among the fear conditions, as predicted by PMT, task difficulty significantly decreased perceptions of self-efficacy ($M=3.7$ vs. 2.7) and intentions to use condoms ($M=5.5$ vs. 4.1). However, and in conflict with PMT, among the regret conditions there is a boomerang effect; increasing task difficulty significantly increases perceptions of self-efficacy ($M=3.7$ vs. 4.3) and boosts behavioral intentions ($M=6.9$ vs. 8.1). Thus in the process of motivating difficult behaviors regret actually erases self-efficacy doubts.

The pattern of results cannot be attributed to emotional intensity. Thus the boomerang effect did not result from increased emotional intensity but instead increased motivation through personal responsibility. That is regret, when the task is difficulty forces individuals to be more determined enhancing perceptions of personal responsibility ($M=7.4$ vs. 8.4) and therefore self-efficacy and behavioral intentions.

In conclusion, as predicted by PMT for traditional fear appeals increasing task difficulty result in minimal self protection behavior. As predicted by emotion research regret results in strong self-protection behaviors. Importantly however, perceptions of self-responsibility override even perceptions of task difficulty, resulting in a boomerang effect and enhanced self-efficacy and behavioral intentions. This research illustrates the power of regret to promote self-protective behaviors even when the behaviors are difficult.

Self-Relevant Brand Alliances: When Do Consumers (Not) Fit?

Nicole Verrochi, University of Pennsylvania, USA

Americus Reed II, University of Pennsylvania, USA

Abstract

Successful brand alliances possess high fit between brands forming the alliance. However, many brand alliances contain elements relevant to consumers' identities. Two studies demonstrate that regardless of fit between the parent brands, if one brand is low in fit with the consumer's identity, the brand alliance is perceived poorly. Thus, current conceptualizations of brand alliances need to be broadened to include consumers and their identities. By considering the target market's conception of each brand, and how each is self relevant to the target, it is possible to build a more comprehensive and accurate representation of successful brand alliances.

During the mega-merger boom of the late 1980s and early 1990s, joint branding flourished in the marketplace. Consumers are now accustomed to seeing ingredient branding (NutraSweet in Diet Coke), co-branding (Frito-Lay chips with KC Masterpiece barbeque sauce), and other forms of branding alliances. Despite this abundance, empirical research on how consumers perceive these co-brands is still in its infancy, and what determines a successful brand alliance remains unclear.

The purpose of the current research is to demonstrate the need for a wider view when considering the role of fit in brand alliances. Specifically, we suggest that there are three connections that need to be high in fit for a brand alliance to have the highest probability of success (positive attitudes, purchase intention, choice). These three connections are the link between the two brands, which is commonly examined in brand alliance research, and the two links between each parent brand and the consumer. By including the consumer in our conceptualization of fit, researchers on brand alliances will better understand the mechanisms driving attitude transfer and, ultimately, choice.

Research on effective brand alliances has grown out of the brand extension literature. In this way, many similar factors reappear—specifically the question of fit: do these two brands fit? Because the most prevalent comparison in brand alliances is one brand with another, fit is often conceptualized as complementary product attributes, functions or uses (Park, Jun and Shocker 1996; Samu, Krishnan and Smith 1999). Complementarity can be defined as the requirement of one product for the use or operation of the second product (Samu et al. 1999). And, as with brand extensions, the degree of complementarity is related to the ability of activation to spread from one product to the other. The point of difference is that with brand alliances researchers examine the transfer of attitude from two branded products to a new concept.

In the attitude literature, there is an associated stream of literature regarding consumers' social identity-based attitudes (e.g., Reed 2004). Brands that are strongly connected to a consumer's identity allow people to express themselves, and have been shown to be more resistant to counterpersuasion tactics than less identity-relevant brands (Bolton and Reed 2004). These papers suggest that incorporating the fit (conceptualized as identity relevance) between each of the two parent brands and the consumer will enhance our understanding of successful brand alliances.

This paper incorporates the theoretical approaches of both the brand extension and social identity-based attitude literatures to test whether higher fit between a consumer and the two parent brands may enhance attitudes toward the brand alliance. A set of two experiments test the hypothesis that low fit between consumer and either parent brand will result in lower attitudes toward the brand alliance. Fit is manipulated through priming participants with either high-fit or low-fit identities, or by manipulating the brands involved in the brand alliance effort. All other aspects of the stimuli are the same between conditions. Participants were exposed to an advertisement, and then subsequently asked for evaluations of the alliance.

Study 1A primed three different identities that consumers can possess: athlete, student and fashionista. After increasing the salience of one identity, participants were asked to evaluate a current brand alliance, Nike+ iPod, indicating their perceptions of inter-brand fit and attitude toward the alliance. Systematic differences were found across the three identities, such that those participants viewing the advertisement through the lens of their stylish identity expressed more positive attitudes and perceived greater fit than the participants with athlete or student identity primed (attitude: $F(2, 63)=4.972, p < .01$; fit: $F(2, 63)=6.136, p < .01$). While this data demonstrates that a salient identity can influence consumers' attitudes, it remained unclear whether this was due to the stylish identity or to the hypothesized match between perceptions of the shoe (its relative fashion versus functionality) and the relative identity.

Study 1B sought to demonstrate that it is the match between the values of the salient identity (functionality for runners versus fashion for stylish identities) and perceptions of the product that drive the change in perceived fit and attitude. To this end, a more specific identity (runner) was primed in order to focus on the functionality of the shoe, and different sneaker brands were used to manipulate the perceived deliverables of the product. Specifically, we hypothesized that runners would perceive higher fit and possess a more positive attitude toward brand alliances containing shoe brands perceived as highly functional (Mizuno, New Balance) versus highly stylish brands (Nike, Adidas). The converse would be true for the participants with fashionista identity activated. The interaction of shoe brand and identity

was, as hypothesized, significant for both attitude ($F(1, 130)=4.797, p<.05$) and perceptions of brand alliance fit ($F(1, 130)=8.943, p<.005$). These results implicate the need for a match between the consumer identity and the product perceptions in order for a brand alliance to be evaluated positively.

To our knowledge, there has been no effort to include consumer self-conceptions in models of brand alliance success. This set of studies represents a first attempt to consider how different consumer identities can impact both perceptions of brand alliance fit and attitude toward the alliance. Drawing from the social identity-based attitude literature, we extend the concept of complementarity, or brand alliance fit, to include the consumer. Moving from a dyadic to triadic level of analysis allows consumer researchers to have a deeper understanding of the products that consumers are likely to see as “acceptable” in brand alliances. The experiments presented here provide reliable evidence for the importance of including this consumer-focused fit into evaluations of brand alliance structure, suggesting that successful efforts require not only high inter-brand fit, but also a strong brand-consumer connection. Taken together, these studies provide support for the value in taking the consumer into account when defining brand alliance fit, as different identities will emphasize diverse brand values—not all of which are complementary.

Looking for Great Discounts—How Store Coupons Shape Attention, Product Memory, and Store Impressions

Charles Y. Z. Zhang, University of Michigan, USA
Norbert Schwarz, University of Michigan, USA

Coupons are a widely used tool of sales promotion and numerous studies examined their impact on consumer behavior (see Raghubir, Inman and Grande, 2004, for a review). While most of the available research focused on product or brand coupons, retailers may use generic coupons to attract customers to their stores. Such coupons take a variety of forms, typically as conditional dollar-off coupon (\$X off any purchase above \$Y), unconditional dollar-off coupon (\$X off any purchase), or percentage-off coupon (Z% off any purchase). On theoretical grounds, it is likely that store coupons influence what customers attend to once they are in the store. The present research addresses this possibility. We predict, and find, that such coupons induce consumers to focus on products in a price range close to the minimum purchase requirements of the coupon, as indicated by biases in consumers’ memory for the goods offered.

Rationale

Several lines of research suggest that consumers who receive a dollar-off coupon may attempt to make a purchase in the price range of the coupon’s minimum purchase requirement. First, the perceived value of a given discount increases with the percentage saving it provides. For example, Tversky and Kahneman (1981) observed that consumers are more willing to drive 20 minutes for \$5 off a \$15 product than for \$5 off a \$125 product. Similarly, Krishna et al. (2002) found in a meta-analysis of 20 coupon studies that consumers’ think they saved more money when a given face value results in a high rather than low percentage discount. Second, specifically for unconditional coupon holders, purchasing a product at or just above the coupon’s face value amounts to receiving the product for “free”, which is particularly attractive (Ariely, 2008). Hence, consumers with and without a dollar-off coupon may pay differential attention to items at different price levels. This differential attention, in turn, may affect their later recall of the items offered as well as their impression of the store. This prediction is consistent with psychological research that shows that attention and memory are a function of goals and motivation (e.g., Anderson and Pichert, 1978; Klinger, 1977).

Studies

Method. We built an online office supply store using a real online shopping platform. The store had about 20 items, priced \$5-\$30, with product descriptions, pictures, and price information copied from the website of a major office supplies store. The lower priced items (below \$10) were stationary and paper products, whereas the higher priced items (above \$20) were computer accessories.

Study 1. Fifty-four business undergraduates browsed the store and did vs. did not receive a coupon that offered “\$5 off any purchase.” Participants were encouraged to make a hypothetical purchase decision during browsing, but were not required to do so. Next, participants completed an unrelated experiment as a filler task. Subsequently they estimated the average price of all items offered in the store, and evaluated how much variety the store offers in the lower and higher priced product categories (paper products vs. computer accessories).

As predicted, participants who received a \$5-off coupon purchased items that had a lower price than participants who received no coupon, estimated that the average price of all items offered in the store is lower, and provided more favorable ratings of the variety that the store offers in the paper products category

Study 2. Following the same procedures, participants received either a “\$5-off-any-purchase” or a “\$5-off-a-\$20-purchase” coupon. Going beyond Study 1, participants’ click-stream data were captured as a measure of what they attended to and a memory task with free recall of all items offered was added.

Compared to the \$5-off-\$20 group, the \$5-off group clicked on more low-price and fewer high-price items, confirming that the type of coupon influences product search. Moreover, they also recalled more low-price items and fewer high-price items.

Conclusions

Our findings highlight an unintended side-effect of dollar-value coupons. Consumers perceive the identical coupon as more valuable when it provides a high (e.g., \$5 off \$10) rather than low (e.g., \$5 off \$50) percentage discount (Krishna et al., 2000). To maximize the benefit of a given coupon they attempt to find products that are priced close to the purchase requirement of the coupon, thus maximizing the percentage discount. As a result, consumers who receive a low requirement coupon pay more attention to low-priced products than consumers who do not, biasing their memories and impressions of the store. While the specific effects will depend on the specific coupon type, our findings provide first evidence that coupons channel consumers’ attention with downstream effects on store impressions. Unfortunately, these impressions may be more important in the long run than any short-term sales increase.

The Effect of Temporal Framing on Product Choice

Andrea Heintz Tangari, University of Arkansas, USA

Ronn J. Smith, University of Arkansas, USA

This research focuses on the temporal framing of a cost savings message for an energy efficient product, a compact fluorescent light (CFL) bulb. In two experiments, we examine the effects of three different temporal frames of cost savings (one month, one year, and lifetime). We investigate how the framing impacts product choice, purchase intentions, attitudes, and perceptions of savings. Additionally, we look to see if consumers’ temporal orientation (a predisposition toward future outcomes versus present outcomes) will moderate the effect of the temporal framing of savings.

Conceptual Background

Research on the level of construal in decision making has led to formulation of Construal Level Theory (CLT), which demonstrates how people’s perceptions of proximal events are construed in lower-level, concrete terms; whereas distal events are construed in higher-level, abstract terms (e.g. Liberman and Trope 1998). CLT can affect choice and preference such that a product that is favored in the near future, due to framing of specific concrete attributes, might not be favored in the distant future based on those same attributes. CLT also posits that the value associated with distant future situations is increased over delay while the value associated with near future situations is discounted over delay.

A person’s temporal orientation also has the possibility to play a role in how a person construes different events. Some have suggested that temporal orientation—a predisposition to focus one’s attention on the past, present, or future—influences subsequent behavior and attitudes (e.g. Lasane and Jones 1999; Strathman, et al. 1994).

Study 1

The first study examines how the temporal framing of savings of a CFL bulb influences purchase intentions, attitudes, and perceptions of savings. We predict that consumers will have higher evaluations regarding the CFL bulb in the temporally proximal savings frames compared to the more abstract and temporally distal lifetime savings frame.

A total of 78 undergraduate research participants completed the survey. The sample was 68% male with a mean age of 21. Subjects received a sheet that showed a picture of a 60-watt equivalent CFL bulb in its packaging. The label on the CFL package differed across the three temporal framing conditions and indicated the average amount of savings in one month, one year, and lifetime one could expect from changing one bulb and all bulbs in their home to this CFL bulb.

Results: To analyze our prediction we ran the three temporal framing of savings conditions on the dependent variables purchase intentions, CFL attitude, and perception of savings. The temporal framing of savings did significantly influence perceptions of savings ($F=10.83, p<.001$) and purchase intentions ($F=3.16, p<.05$). Perceptions of savings and purchase intentions were significantly higher in the proximal one month and one year frames than the temporally distant lifetime frame ($p<.05$). The temporal framing of savings did not

significantly influence attitude toward the CFL bulb ($F=2.43, p=.09$) although the means were in the expected directions such that attitude decreased as the temporal distance of the savings frame increased.

Study 2

In study 2 we tested if a consumer's temporal orientation moderated the effect of the temporal framing of savings. We predict that given the distal lifetime frame, future-oriented consumers will not discount savings, will have higher attitudes and will choose CFL bulbs over incandescent bulbs compared to present-oriented consumers. A total of 69 undergraduate research participants completed the survey. The sample was 47% male with a mean age of 21. Temporal framing of savings was manipulated, while temporal orientation was a measured variable. The temporal framing of savings was similar to the first study and had three temporal framing conditions. To measure temporal orientation the Temporal Orientation Scale (Lasane and Jones 1999) was used to determine if subjects were present or future-oriented.

Results: To analyze our predictions we ran 3 (temporal framing of savings: one month vs. one year vs. lifetime) x 2 (temporal orientation: present vs. future) MANOVA on the dependent variables of CFL attitude, and perceived CFL savings. Given the dichotomous light bulb choice variable, we ran logistic regression to test the interaction.

The logistic regression results indicate that the interaction between the temporal framing of savings and temporal orientation was significant for product choice ($\chi^2=14.70, p<.01$). In the lifetime condition, future-oriented subjects are much more likely to buy CFL bulbs (100%) compared to present-oriented subjects (33%; $\chi^2=9.59, p<.005$).

The interaction was significant for perception of savings ($F=3.66, p<.05$). Future-oriented subjects ($M=5.91$) had higher perceptions of savings given the lifetime condition compared to present-oriented subjects ($M=4.50, p<.05$). For attitude, the interaction was not significant ($p>.10$).

Discussion

In two experiments we assessed the effects of temporal framing on purchase intentions, product choice, attitude, and perception of savings. In the first study we found that in general, participants had lower purchase intentions and somewhat lower attitudes given the most distal lifetime frame compared to the proximal frames. It also appears that consumers discount the savings from a CFL bulb as temporal distance increases. In the second study we found that given the lifetime frame, present-oriented consumers were *less* likely to choose the CFL bulb over the incandescent and also viewed the savings from a CFL bulb as much lower compared to future-oriented consumers. These results seem to indicate that present-oriented consumers discount savings at a greater rate than future-oriented consumers.

This research is especially important given the recent focus on energy efficiency. Thus, this research also provides managerial implications. It appears that more consumers can be reached using proximal compared to distal frames of savings. Finding the most effective way to communicate the savings and efficiency of a product that will help consumers choose the better product is not only important to the manufacturers and marketers, but will be better for society in general.

Impact of CSR Communication Strategies on Attitude Change after a Crisis

Virginie Solelhac, Pompeu Fabra University, Spain

Recent studies have shown that consumers demand more information about companies' corporate social responsibility (CSR). However, communicating only positively about CSR, guaranteeing the absence of any unethical process along the whole supply chain, may result in greater deterioration in consumers' attitude in the event of an ethical crisis. Building from the literature on schema discrepancy and attribution theory, we analyze the effect of several communication strategies on attitudes and attitude change after a crisis. Evidence is found that using a two-sided communication message is the strategy that minimizes the impact of a crisis on attitudes towards the company.

A Painful Choice: Embodied Influences on Choice Perception

Aner Tal, Duke University, USA

Elements of consumers' overall situation might infuse judgments of choice difficulty and product dimensions. Contrary to prior research, such choice-extrinsic influences on judgment may not be susceptible to discounting through attribution. Further, choice-extrinsic effects on judgment might be somewhat specific in that physical difficulty affects judgments relating to a feeling of discomfort, but not ones tangential to it, such as choice satisfaction. I demonstrate that the physical discomfort caused by a hand-press leads to judgments of greater choice difficulty as well as lower ratings of manufacturer ethics, but not to lower choice satisfaction (studies 1-2). If explicitly

asked to exclude the hand-press difficulty from judgment, consumers can discount the physical pain from judgments of difficulty, but not from judgments of the ethicality of manufacturing conditions (study 2), demonstrating that attribution-discounting is limited.

Making choices is effortful and depleting (Johnson & Payne, 1985; Iyengar & Lepper, 2000). Choosing one option often involves giving up others, which consumers are reluctant to do (Anderson, 2003; Gilbert and Ebert, 2002; Shin & Ariely, 2004).

But what determines how painful choices are, both in terms of the effort involved and in terms of post-choice feelings such as regret? Aspects of the choice set itself are obvious candidates. The more options there are, for instance, the harder the choice (Iyengar et al., 2006; Schwartz, 2004). Similarly, the greater the quantity of information, the harder it is to analyze (Johnson & Payne, 1985; Bockenholt et al., 1991). The extent of differences among options (Iglesias-Parro et al., 2002) and emotionality of the product domain (Luce, 1998) also make choice harder.

Elements external to the choice itself that are not directly relevant to the choice itself can also affect the pain of choosing. Mood, for instance, might alter the manner in which people approach choice and experience its painfulness (Tice et al., 2001). Affect in general might transfer from an unrelated source in the environment to an object of judgment. Extensive research in psychology has documented instances where affect generated by elements unrelated to an object infuses judgment (Forgas, 1995; Mayer et al., 1992). People tend to attribute their feelings to objects, and thus, when focused on an object of evaluation, believe affect emanates from the object (Higgins, 1998). More generally, people see their feelings as indicative of the adaptiveness of their environment, so that judgments might become negatively infused given negative feelings due to ambiguity as to the source of the low adaptiveness indicated by negative feelings (Fridja, 1999; Barret and Salovey, 2002).

Generally, it's believed that affect should only influence unrelated judgments if the source of affect is unknown. When people are aware of the true source of their feelings, they realize that the feelings are unrelated to the object of judgment, and can discount them (Schwartz & Clore, 1983). Thus, people will only use affect in judgment if they believe it to be relevant (Clore, 1992; Yeung & Wyer, 2004) and cannot attribute it to judgment-external elements (Reber et al., 2004; Schwarz & Clore, 2003). If affect is attributed to external sources, people will discount it and avoid its influence on judgment (Higgins et al., 2003; Darke et al., 2006).

However, one might question the pervasiveness of people's ability to discount irrelevant sources of affect given correct attribution. After all, if people are bad at identifying the source of sensations as irrelevant to begin with, why should they be able to correctly parse out extraneous feelings out once those are pointed out (Winkielman, 1997)? Further, people may be able to discount extraneous effects in some instances, but not in others. In other words, some feelings might more easily infuse some judgments (e.g., physical difficulty and mental difficulty). Similarly, people might have an easier time discounting certain affective sources (e.g., physical difficulty) from specific, analogous evaluations (e.g., mental difficulty), while being unable to discount these affective sources from less obviously related evaluations (e.g., ethics).

Study 1 focuses on decision effort. I posit that physical difficulty might be a generalized feeling that is not discounted even if its source is apparent and obviously extraneous to the decision. The negative emotion aroused by choice effort can in turn influence evaluation of the option chosen (Gabriano & Edell, 1997). However, if the infusion of irrelevant feelings is specific to judgments that are alignable with the feeling, satisfaction might not be influenced by physical difficulty.

Study 1: Hard Pressed

Methods. Participants ($N=109$) were asked to hold a hand-press while choosing among four digital cameras. Each option was represented by a name and a picture, along with a description along 11 product attributes. We manipulated difficulty by altering the pressure level on the hand-press, and by requiring participants in the difficult condition to press the device to its limit. In contrast, participants in the easy condition used the device on its easiest setting and were asked to press it on a level that's comfortable for them. All participants held the hand-presses pressed until making their choice.

At the end of the choice participants were asked to report how effortful the choice was and how pleased they were with their choice. They were then asked to report to what extent they followed instructions, as well as felt pressure and pain (manipulation checks that indicated increased pain and pressure on the higher difficulty level).

Results and discussion. Participants who reported not using the hand-press as instructed ($n=10$) were dropped from analysis. Participants in the "difficult" condition reported greater choice effort (5.43) than participants in the "easy" condition (4.57): $F(1, 96)=4.49$, $p=.04$. There was no effect on how pleased participants were with their choice ($p>.4$).

It appears, then, that difficulty of pressing the hand-press seeped into judgment of choice effort, but not into product evaluation. The differential effects on perceived effort and evaluation might indicate a difference in the manner of arriving at those judgments. It might be that difficulty affects difficulty judgments, but not option evaluation and satisfaction. Thus, it might be that the *influence of choice-extrinsic elements on judgment is restricted to judgments on dimensions similar to that of the choice-extrinsic element*.

Study 2: Good and Hard

Judgment of ethics should also be influenced by physical discomfort, since moral judgments are related to feelings of emotional discomfort (Haidt, 2003). However, the link of ethics to discomfort is less clear than the link of (physical) discomfort to (mental) discomfort. Accordingly, I predicted that: A) There would be a significant effect of hand-press difficulty on judgment of ethical manufacturing conditions. B) Given explicit instructions to discount hand-press difficulty from evaluation, participants would no longer display the effect on choice difficulty, but would continue to display the effect on ethics judgment.

Methods. Participants ($N=23$) faced the exact same scenario as in study 1. However, all participants were instructed to note that the questions are about the choice rather than about the hand-press task. In addition, a measure of judged ethicality of manufacturing conditions was added.

Results and discussion. Given instructions to discount the hand-press task from their judgment, participants in the hard hand-press condition did not rate choice difficulty as being higher than those in the easy hand-press condition ($p>.5$). However, despite instructions to discount the hand-press task from judgment, participants in the hard condition still judged manufacturing conditions as being less ethical

(4.7) than participants in the easy condition (6): $F(1, 22)=4.82, p=.04$. A further study will attempt to reverse the order of judgment to determine whether the lack of discounting in ethics judgment was due to the nature of the judgment or simply due to the fact that physical difficulty had already been discounted from the choice difficulty judgment. Even if the latter is true, the findings would be interesting in the context of attribution and discounting of irrelevant inputs, since they would indicate that once people have discounted an irrelevant input from one judgment, they would not discount it from further judgments even if it does affect those latter judgments.

General Discussion

Irrelevant inputs to judgment might be more limited in their “contaminative” effects than generally believed. Accordingly, it appears that physical difficulty due to an unrelated task external to the choice process affects judgments of choice difficulty and manufacturer ethics, but not judgments of choice satisfaction. Irrelevant feelings might affect judgment only on dimensions that are alignable with the specific feeling. Directly relatable (mental difficulty) as well as less directly relatable (ethics) judgments can be affected. However, when the relation of the irrelevant input is less obvious than the relation of physical to mental difficulty, people might not be able to discount the irrelevant input even given explicit instructions to do so. Thus, people’s capacity to discount an irrelevant input from judgment might be more limited than generally believed.
