Advances in Consumer Research, Volume 36

(Duluth, MN: Association for Consumer Research, 2009)

Preface

The 36th Annual Conference of the Association for Consumer Research was held at the Hyatt Regency Hotel in San Francisco, California, from October 23-26, 2008. These proceedings include summaries of the presentations made at the conference in symposia, competitive paper sessions, working paper sessions, roundtables, and the film festival.

ACR 2008 was the largest and most diverse ACR conference in the organization's history. The theme of the ACR2008 Conference was "Port of Call," which was intended to capture the vibrant and changing nature of our field. Researchers from thirty-three countries arrived in the commercial center of San Francisco, bringing their cargo of ideas and knowledge. Our goal was to highlight the international nature of our organization, our reliance on the conference as a marketplace of research, and the role of the conference in building intellectual and social connections. We believe the conference accomplished these objectives and highlighted new ideas, ideas that can shape the field.

ACR 2008 set records for attendance (1052 registered participants) and submissions (over 850 across all categories). We were able to accept 54% of the 104 symposium proposals submitted, 43% of the 487 competitive papers, 181 working papers, 10 films, and 7 roundtables. We wish to thank all of the authors who contributed by submitting research, reviewing papers and session proposals, serving on committees, and overseeing conference tracks. In particular, we are very grateful to Amna Kirmani and Jill Klein for chairing the working paper track, Jennifer Escalas and Lauren Block for chairing the roundtable track, Russell Belk and Marylouise Caldwell for chairing the film festival, Margaret Campbell and Robert Kozinets for chairing the doctoral symposium, and the twelve outstanding individuals who served as Associate Chairs for the competitive paper sessions: Rohini Ahluwalia, Michael Barone, Tanya Chartrand, Aimee Drolet, Ran Kivetz, Tina M. Lowrey, Rik Pieters, Linda L. Price, Aric Rindfleisch, Jaideep Sengupta, Baba Shiv, and Kathleen D. Vohs.

In addition to the usual conference sessions, one innovation this year was the organization of some paper sessions into "Embedded Conferences," which were subtracks of related work. These subtracks emerged organically from the high quality submissions we received, and were organized in sequence to highlight the connections across the sessions and allow interested conferees an opportunity to attend all of them. The Embedded Conferences covered the topics of Health and Eating, Magical Thinking, the Brand and the Self, and Quantitative Methods. The first two of these were followed by discussion sessions devoted to synthesizing the contributions across the paper sessions. We are indebted to David G. Mick and John Sherry for their valuable leadership in these sessions.

Several other people deserve our thanks for their help in running the conference, including ACR Executive Director Rajiv Vaidyanathan, ACR conference coordinator Patty Salo Downs, administrative director Jennifer Williams, Jimmy Wong for attending to a myriad details, webmaster Aleksey Cherfas for his extraordinary help with the web-based submission system, and Carol and Steve Barnett who were instrumental in preparing these proceedings. We also thank Punam Anand Keller, ACR President, for entrusting this conference to us. We will get her back someday. And we are very grateful to several previous conference chairs, particularly Angela Lee and Dilip Soman, for their support and their unfailingly helpful responses to our many random queries.

ACR DOCTORAL SYMPOSIUM

Friday, 24 October 2008
FILM FESTIVAL I-IV
8:00am–5:00pm

Can Buy Me Love
This Day is To Be Special: The Role of Exaggerated Contrast in an Indian Wedding
Behind Closed Doors: Gendered Home Spaces in an Arab Gulf State
Urban Archetypal Hedonistas
Bodily Experiences of Second Life Consumers
The Ties That Bind: Being Black, Buying, and Hope
Binomial Structure in Luxury: Analyzing Overseas Trip Experiences of Japanese Well-to-Dos
Everything You Always Wanted to Know About the Pre-Party
Behind Closed Doors: Opportunity Identification Through Observational Research
Consumption, Belonging, and Place

Friday, 24 October 2008
SESSION I
8:00am–9:15am

- 1.01 *From the Black Box to the Aquarium: How Brain Imaging Sheds 'Light' on the Underlying Mechanisms of How Marketing Actions Work*
- 1.02 *When the Going Gets Tough: How Metacognitive Difficulty Improves Evaluation*
- 1.03 *Status: Why Consumers Engage in Conspicuous Consumption and How They May Be Perceived*
- 1.04 *Those Troublesome Teens: Influences on Adolescent Consumption*
- 1.05 *Acculturation and Consumer Behavior: Building Cultural Bridges Through Consumption*
- 1.06 *Production and Reproduction of Consumer Culture in Virtual Communities*
- 1.07 *Justification and Choice*
- 1.08 *Materialism, Self-Esteem, and Well-Being*
- 1.09 *What's That I See? Visual Impact on On-line and Service Evaluation*
- 1.10 *Moving Beyond the Rabbit's Foot: Superstition and Magical Thinking in Consumer Behavior*
- 1.11 *Social Networks and Consumer Behavior*
- 1.12 *No Man Is an Island: Social Influences on Communications and Behavior*
- 1.13 *ROUNDTABLE: Understanding and Improving Consumer Personal Finances*

Friday, 24 October 2008

SESSION II

9:30am–10:45am

- 2.01 *The IAT in Marketing*
- 2.02 *New Perspectives in Global Branding*
- 2.03 *An Examination of the Complex Relationship Between the Self and Consumer Contexts*
- 2.04 *Bettering Business: When and How Consumers Value Pro-Social Marketing Efforts*
- 2.05 *Cross-Cultural and Intra-Cultural Effects on Consumer Responses*
- 2.06 *Freedom and Constraint: The Interplay of Consumer Agency, Social Relations, and the Market*
- 2.07 *Understanding Hedonic Misprediction: The Role of Lay Beliefs*
- 2.08 *Having It All: Rewards, Pleasures, and Self-Control*
- 2.09 *It Could Have Been So Different: The Influence of Alternative Generation on Beliefs and Preferences*
- 2.10 *“Roll Your Own” Religion: Consumer Culture and the Spiritual Vernacular*
- 2.11 *Comforting Social Presence, Depleting Social Influence*
- 2.12 *Sweetening the Deal: Consumer Responses to Promotions*
- 2.13 **ROUNDTABLE: Aesthetics and Consumption**

Friday, 24 October 2008

SESSION III

11:15am–12:30pm

- 3.01 *You Can Do It. We Can Help: Innovative Tools for Consumer Research*
- 3.02 *Revisiting Consumer Confidence: New Findings and Emerging Perspectives*
- 3.03 *Where You Are Can Change the Roads You Travel: Insights From Branding Research*
- 3.04 *Control Yourself: Consumer Responses to Impulse and Temptation*
- 3.05 *Cultural Contexts for Consumption: Practices, Experiences, and Biases*
- 3.06 *Does Authenticity Matter? The Importance and Interplay of Authenticity and Inauthenticity*
- 3.07 *Emotions, Social Comparison, and Deception in Interpersonal Interactions*
- 3.08 *The Mediating Influence of Consumption and Markets on Social Relationships*
- 3.09 *Mind the Mindset*
- 3.10 *Embedded Conference Discussion: Thinking about Magical Thinking*
- 3.11 *Novel Approaches to Understanding Context Effects in Choice and Judgment*
- 3.12 *Social Influences in Attitudes and Persuasion*
- 3.13 **ROUNDTABLE: Building the Transformative Consumer Research Community: Opportunities and Obstacles for Rising Scholars**

Friday, 24 October 2008

SESSION IV

2:00pm–3:15pm

- 4.01 *Beyond 2x2x2: Methodological Advances in Uncovering Consumer Decision Processes*
- 4.02 *Experiential and Informational Perspectives of Consumer Preference Consistency*
- 4.03 *Self-Expression and Brand Identity in Consumer Choice*
- 4.04 *Easy Come, Easy Go: Financial Decision-Making*
- 4.05 *Ritual Processes and Consumer Identity: Across Cultures and Time*
- 4.06 *Perspectives on Shopping Involvement*
- 4.07 *To Deal or Not to Deal: Exploring the Boundaries of Dynamic Inconsistency*
- 4.08 *The Real Thing: Demand for Myth and Counterfeit Brands*
- 4.09 *Challenges Facing Children and Family: Time, Technology, and Structure*
- 4.10 *Risky Business: Communication and Persuasion in the Context of Health Risks*
- 4.11 *Attentional and Inferential Effects of Point-of-Purchase Marketing*
- 4.12 *The Role of Attitude Structure and Attitude Certainty in Persuasion*

Friday, 24 October 2008

SESSION V

3:45pm–5:00pm

- 5.01 *Soft Concepts and Hard Measures: New Scales and Techniques for Understanding Brand Relationships and Affect*
- 5.02 *Marketing Issues in Politics*
- 5.03 *Brand Symbolism and Reference Groups: Perspectives on the Identity Value of Brands*
- 5.04 *Multifaceted Consumer Welfare: Broadening the Perspective*
- 5.05 *Consumer Culture: Theory, Politics, and Opportunities*
- 5.06 *Building an Understanding of What Makes Consumer Behavior Transformative*
- 5.07 *Consumer Perceptions of Value and Price*
- 5.08 *Food, Family, and Guns: Diverse Socialization Agents*
- 5.09 *Activating and Imagining the Self*
- 5.10 *How Can We Improve Consumers' Health?*
- 5.11 *Positive Emotions—Theory and Application*
- 5.12 *Are You Talking to Me? The Effects of Explicit and Inferred Advice in Consumer Judgment*

Friday, 24 October 2008

WORKING PAPER SESSION A

5:00pm–6:30pm

Saturday, 25 October 2008

FILM FESTIVAL V-VIII

8:00am–5:00pm

Can Buy Me Love

This Day is To Be Special: The Role of Exaggerated Contrast in an Indian Wedding

Bodily Experiences of Second Life Consumers

The Ties That Bind: Being Black, Buying, and Hope

Urban Archetypal Hedonistas

Behind Closed Doors: Gendered Home Spaces in an Arab Gulf State

Binomial Structure in Luxury: Analyzing Overseas Trip Experiences of Japanese Well-to-dos

Everything You Always Wanted to Know About the Pre-Party

Consumption, Belonging, and Place

Saturday, 25 October 2008

SESSION VI

8:00am–9:15am

- 6.01 *Sticker Shock: The Emotional Side of Pricing*
- 6.02 *Cognition and Sensory Perception: The Impact of Input from Sensory Modalities on Imagery, Memory, Information Processing, and Sensory Perception*
- 6.03 *Compensatory Consumption: How Threat Directs Consumers' Product Preferences*
- 6.04 *Objectification of the Body and the Self*
- 6.05 *Making Informed Product Decisions: Positioning, Customization, Co-Production, and Feature Design*
- 6.06 *Legitimation in the Marketplace*
- 6.07 *Where, When, and Why: Moderating and Mediating Effects in Judgment and Decision-Making*
- 6.08 *Patience, Attention to Time, and Consumer Cognition*
- 6.09 *Context and the Self in Memory and Emotion*
- 6.10 *Taking It to the Streets: Methodological Challenges of Doing Transformative Consumer Research on Health*
- 6.11 *Unraveling Motivation: Affective and Cognitive Processes Underlying Consumer Goals and Choices*
- 6.12 *Interacting with Technology: Search, Risk, and Experience*
- 6.13 *ROUNDTABLE: HLM: Hierarchical Linear Models*

Saturday, 25 October 2008

SESSION VII

9:30am–10:45am

- 7.01 *How Do You Really Feel about It? Emotional Processes and Product Evaluation*
- 7.02 *Context-Dependent Search*
- 7.03 *Symbolic Essence of a Brand: Meaning and Associations*
- 7.04 *Consumer Identity, Resistance, and Coping*
- 7.05 *Consumer Engagement in “Attention Economies”*
- 7.06 *Through the Looking Glass: New Ideas about the Consumption of Beauty*
- 7.07 *Taking the Load out of Choice Overload: Strategies for Reducing Cognitive Difficulty in Choice from Extensive Assortments*
- 7.08 *Time: It’s a Personal Thing*
- 7.09 *Bottom-Up Influences on Information Integration and Decision-Making: Information Type, Format, and Intercorrelation*
- 7.10 *The Effect of Conflicting Information and Natural Primes on Health Related Behaviors*
- 7.11 *Welcome to the Jungle: Understanding How Environmental Cues Influence Consumption in “The Wild”*
- 7.12 *Look How Good Looks: Ideals in Product and Ad Design*
- 7.13 **ROUNDTABLE: Conducting Consumer Research in Emerging Markets: Challenges, Issues and New Directions.**

Saturday, 25 October 2008

SESSION VIII

11:15am–12:30pm

- 8.01 *Hot Like Before: Emotional Memory in Communication*
- 8.02 *The Psychological Consequences of Choice*
- 8.03 *The Role and Construction of Brand Personality*
- 8.04 *Come On, Get Happy*
- 8.05 *And Then We Came to the End: Troubled Commercial Relationships*
- 8.06 *‘What Things Do’: Examining Things That “Matter” in Consumer Research*
- 8.07 *How You Say it Matters: Frameworks for Understanding Message Framing*
- 8.08 *The Impact of Time and Temporal Orientation on Consumer Behavior*
- 8.09 *Inside the Eye of the Mind: Effects of Mental Imagery on Beliefs and Preferences*
- 8.10 *To Indulge or Not to Indulge? Self-Regulation and Overconsumption*
- 8.11 *Encoding, Remembering, and Using Numeric Information: Implications for Pricing*
- 8.12 *When Does Your Advertising Matter: New Insights from Political, Advocacy, and Sponsorship Advertising*
- 8.13 **ROUNDTABLE: Intro To Social Network Methods**

Saturday, 25 October 2008

SESSION IX

2:00pm–3:15pm

- 9.01 *Aiming Higher and Lower: Setting and Shifting Standards of Evaluation*
- 9.02 *Chiaroscuro: The Darker (and the Lighter) Side of Information Processing*
- 9.03 *Different Selves Make the World Go ‘Round*
- 9.04 *Me, Myself, and I: The Role of Self Views in Prosocial Judgments*
- 9.05 *Beauty Is in the Eye (and Reaching for the Wallet) of the Beholder*
- 9.06 *The Consumption of Reading*
- 9.07 *I Want To Be Just Like Them, or Do I? Assimilation and Contrast Effects in Consumer Judgment*
- 9.08 *The Impact of Psychological Distance on Charitable Fundraising*
- 9.09 *Start Spreading the News: Personal and Impersonal Communication Effects for New and Known Options*
- 9.10 *Effects of Supersizing and Downsizing Packages on Consumption: Marketing and Policy Implications*
- 9.11 *What Makes Ideas Stick? How Characteristics and Contexts of Messages Influence Their Success*
- 9.12 *Bricks, Clicks, and Tricks: Influences on Consumer Shopping and Service Experiences*
- 9.13 **ROUNDTABLE: Consumer Neuroscience: Current State of Knowledge and Future Research Directions**

Saturday, 25 October 2008

SESSION X

3:45pm– 5:00pm

- 10.01 *Ego Depletion Strikes Again*
- 10.02 *Goals Shared with Others: How to Increase Motivation Toward Social Goals*
- 10.03 *The Good, The Bad, and The Ugly: Our Relationships with Brands*
- 10.04 *Going Green and Seeing Green: Social Routes to Conservation and Monetary Roadblocks to Consideration*
- 10.05 *New Perspectives on the Consumption Environment*
- 10.06 *When Consumer Behavior Meets Islam*
- 10.07 *It's the Context, Stupid: Situational Influences on Product Preferences*
- 10.08 *Close Contact: Consumer-Provider Interaction*
- 10.09 *Keeping Fit: The Role of Matching, Congruity, and Fit in Judgment*
- 10.10 *Embedded Conference Discussion: Health and Eating*
- 10.11 *Exclude or Include? Consideration Set Strategies and the Choice Process*
- 10.12 *Media Influences on Consumption*

Saturday, 25 October 2008

WORKING PAPER SESSION B

5:00pm–6:30pm

Table of Contents

PRESIDENTIAL ADDRESS

<i>Building Theory and Breaking Boundaries: Welcome to the Real World</i>	1
Punam Anand Keller, Dartmouth College, USA	

Symposium Summaries

SYMPOSIUM SUMMARY

<i>From the Black Box to the Aquarium: How Brain Imaging Sheds ‘Light’ on the Underlying Mechanisms of How Marketing Actions Work</i>	4
Hilke Plassmann, California Institute of Technology, USA and INSEAD, France	

The Good, the Bad and the Forgotten-An fMRI-study on Ad Liking and Ad Memory

Peter Kenning, Zeppelin University, Germany
Michael Deppe, University of Muenster, Germany
Wolfram Schwindt, University of Muenster, Germany
Harald Kugel, University of Muenster, Germany
Hilke Plassmann, California Institute of Technology, USA and INSEAD, France

Neural Correlates of Deception Detection: A BOLD Imaging Study

Adam Craig, University of South Carolina, USA
Yuliya Komarova, University of South Carolina, USA
Stacy Wood, University of South Carolina, USA
Jennifer Vendemia, University of South Carolina, USA

A Salesforce-Specific Theory of Mind Scale: Tests of Its Validity by Multitrait-Multimethod Matrix, Confirmatory Factor Analysis, Structural Equation Models, and Functional MRI

Roeland C. Dietvorst, Erasmus University, The Netherlands
Willem J. M. I. Verbeke, Erasmus University, The Netherlands
Richard P. Bagozzi, University of Michigan, USA
Carolyn Yoon, University of Michigan, USA
Marion Smits, Erasmus University, The Netherlands
Aad van der Lugt, Erasmus University, The Netherlands

SYMPOSIUM SUMMARY

<i>When the Going gets Tough: How Metacognitive Difficulty Improves Evaluation</i>	8
Aparna A. Labroo, University of Chicago, USA Sara Kim, University of Chicago, USA	

The ‘Instrumentality’ Heuristic: When Metacognitive Difficulty Signals Means Instrumentality

Sara Kim, University of Chicago, USA
Aparna A. Labroo, University of Chicago, USA

When Products Feel Special: Low Fluency leads to Enhanced Desirability

Anastasiya Pocheptsova, University of Maryland, USA
Aparna A. Labroo, University of Chicago, USA
Ravi Dhar, Yale University, USA

Contrast and Assimilation Effects of Processing Fluency

Hao Shen, Chinese University of Hong Kong, China
Yuwei Jiang, Hong Kong University of Science and Technology, China
Rashmi Adaval, Hong Kong University of Science and Technology, China

Safe and Easy or Risky and Burdensome? Fluency Effects on Risk Perception and Effort Prediction

Hyunjin Song, University of Michigan, USA
Norbert Schwarz, University of Michigan, USA

SYMPOSIUM SUMMARY

Status: Why Consumers Engage in Conspicuous Consumption and How they may be Perceived 12

Joseph C. Nunes, University of Southern California, USA

The Intrinsic Benefits of Status: The Effects of Evoking Rank

Aarti S. Ivanic, University of Southern California, USA
Joseph C. Nunes, University of Southern California, USA

Effects of the Density of Status Distribution on Conspicuous and Inconspicuous Consumption by Low-Status Consumers

Nailya Ordabayeva, INSEAD, France
Pierre Chandon, INSEAD, France

Stigmatizing Materialism: On Stereotypes and Impressions of Materialistic Versus Experiential Consumers

Leaf Van Boven, University of Colorado at Boulder, USA
Margaret C. Campbell, University of Colorado at Boulder, USA
Thomas Gilovich, Cornell University, USA

SYMPOSIUM SUMMARY

Acculturation and Consumer Behavior: Building Cultural Bridges Through Consumption 16

Lisa Peñaloza, University of Utah, USA

Acculturation, Religion and Consumption in Normative Political Ideology

Andrew Lindridge, Open University Business School, Germany

A Comprehensive Model for Hispanics' Acculturation: Antecedents and Impacts on Store and Brand Loyalty

Aviv Shoham, University of Haifa, Israel
Sigal Segev, Florida International University, USA
Ayalla Ruvio, University of Haifa, Israel

How Do Historical Relationships Between The Host And Home Countries Shape The Immigrants' Consumer Acculturation Processes?

Nil Ozcaglar-Toulouse, Universite de Lille, France
Tuba Ustuner, City University London, UK

Unique or Different: The Role of Consumers' Need for Uniqueness in the Acculturation Process

Ayalla Ruvio, University of Haifa, Israel
Walsh Gianfranco, University of Koblenz-Landau, Germany
Sigal Segev, Florida International University, USA

SYMPOSIUM SUMMARY

Production and Reproduction of Consumer Culture in Virtual Communities 20

Aron Darmody, York University, Canada

Ryszard Kedzior, Swedish School of Economics and Business Administration, Finland

I Get by with a Little Help from My Friends: Consumer Creativity in Virtual Communities

Aron Darmody, York University, Canada
Eric P. H. Li, York University, Canada

Mapping Out Digital Materiality—Insights for Consumer Research

Richard Kedzior, HANKEN, Finland

Virtually Me: Youth Consumers and Their Online Identities

Natalie Wood, Saint Joseph's University, USA
Lan Nguyen Chaplin, University of Arizona, USA
Michael Solomon, Saint Joseph's University, USA

Pursuit of the Sacred in the Era of Infantilization: A Multi-sited Ethnography of Online Gaming in China

Jeff Wang, City University of Hong Kong, China

Xin Zhao, University of Hawaii at Manoa, USA

Gary Bamossy, Georgetown University, USA

SYMPOSIUM SUMMARY

Justification and Choice 27

Aner Sela, Stanford University, USA

Jonah Berger, University of Pennsylvania, USA

Guilt as Motivation: The Role of Guilt in Choice Justification

Uzma Khan, Stanford University, USA

Ravi Dhar, Yale University, USA

Ayelet Fishbach, University of Chicago, USA

Variety, Vice, and Virtue: How Assortment Size Influences Option Choice

Aner Sela, Stanford University, USA

Jonah Berger, University of Pennsylvania, USA

Wendy Liu, University of California, Los Angeles, USA

Choice Satisfaction Can Be the Luck of the Draw

Katherine A. Burson, University of Michigan, USA

Simona Botti, London Business School, UK

Functional Alibi

Anat Keinan, Harvard Business School, USA

Ran Kivetz, Columbia University, USA

Oded Netzer, Columbia University, USA

SYMPOSIUM SUMMARY

Moving Beyond the Rabbit's Foot: Superstition and Magical Thinking in Consumer Behavior 31

Eric Hamerman, Columbia University, USA

The Impact of Thinking Style on Sympathetic Magical Thinking

Thomas Kramer, Baruch College, USA

Lauren Block, Baruch College, USA

Can Switching Brands Help Your Favorite Team Win the Big Game?

Eric Hamerman, Columbia University, USA

Gita Johar, Columbia University, USA

Causes and Consequences for the Belief in Tempting Fate

Jane Risen, University of Chicago, USA

Thomas Gilovich, Cornell University, USA

Why Calling Attention to Success Seems to Invite Failure

Justin Kruger, New York University, USA

Jane Risen, University of Chicago, USA

Thomas Gilovich, Cornell University, USA

Ken Savitsky, Williams College, USA

SYMPOSIUM SUMMARY

Social Networks and Consumer Behavior 36

Andrew Stephen, Columbia University, USA

Jonah Berger, University of Pennsylvania, USA

Opinion Leadership and Social Contagion in New Product Diffusion

Raghuram Iyengar, University of Pennsylvania, USA

Thomas Valente, University of Southern California, USA

Christophe Van den Bulte, University of Pennsylvania, USA

Social Hubs: Do They Exist and What is their Role?
Jacob Goldenberg, Hebrew University, Israel
Donald Lehmann, Columbia University, USA
Sangman Han, Sungkyunkwan University, Korea

Creating Contagious: Cascades in Spatially Dispersed Social Networks
Andrew Stephen, Columbia University, USA
Jonah Berger, University of Pennsylvania, USA

SYMPOSIUM SUMMARY

The IAT in Marketing 38

Claude Messner, University of Basel, Switzerland
Joachim Vosgerau, Carnegie Mellon University, USA

Order Effects in the IAT
Claude Messner, University of Basel, Switzerland
Joachim Vosgerau, Carnegie Mellon University, USA

Looking Past the Claims: A Psychometric Analysis of the Implicit Association Test
Hart Blanton, Texas A&M University, USA

Assessing the Assumptions Behind the IAT
Peter Stuetgen, Carnegie Mellon University, USA
Peter Boatwright, Carnegie Mellon University, USA

SYMPOSIUM SUMMARY

New Perspectives in Global Branding 41

Carlos Torelli, University of Minnesota, USA

A Measure of Brand Values: Cross-Cultural Implications for Brand Preferences
Carlos Torelli, University of Minnesota, USA
Aysegul Ozsomer, Koc University, Turkey
Sergio Carvalho, University of Manitoba, Canada
Hean Tat Keh, Peking University, China
Natalia Maehle, Norwegian School of Economics and Business Administration, Norway

A Cross-Cultural Study of the Antecedents of Brand Credibility
Tülin Erdem, New York University, USA
Joffre Swait, University of Florida and Advanis Inc., USA
Ana Valenzuela, Baruch College, USA

Consumers' Local-Global Identity: Measurement
Yinlong Zhang, University of Texas at San Antonio, USA
Adwait Khare, Quinnipiac University, USA

SYMPOSIUM SUMMARY

An Examination of the Complex Relationship Between the Self and Consumer Contexts 45

Lan Nguyen Chaplin, University of Arizona, USA

Celebrity Endorsement and Self-Brand Connections
Jennifer Edson Escalas, Vanderbilt University, USA
James R. Bettman, Duke University, USA

When Poor Brand Extensions Result in Favorable Brand Evaluations
Shirley Y. Y. Cheng, University of Illinois at Urbana-Champaign, USA
Tiffany Barnett White, University of Illinois at Urbana-Champaign, USA
Lan Nguyen Chaplin, University of Arizona, USA

The Shaping of Social Identity: Assimilation/Contrast Responses to Ad Exposure

Mark Forehand, University of Washington, USA
Andrew Perkins, Rice University, USA
Americus Reed II, University of Pennsylvania, USA

SYMPOSIUM SUMMARY

Bettering Business: When and How Consumers Value Pro-Social Marketing Efforts 49
Nicole Verrochi, University of Pennsylvania, USA

The Self And Social Signaling Explanations For Consumption of CSR-Associated Products

Aronte Bennett, New York University, USA
Amitav Chakravarti, New York University, USA

Getting Gold by Going Green: The Importance of Fitting the Message to the Mindset

Kelly Goldsmith, Yale University, USA
Ravi Dhar, Yale University, USA

Moral Identity and Attributions of Corporate Social Responsibility

Nicole Verrochi, University of Pennsylvania, USA
Americus Reed II, University of Pennsylvania, USA
Jennifer Tong, Singapore Management University, Singapore

SYMPOSIUM SUMMARY

Freedom and Constraint: The Interplay of Consumer Agency, Social Relations, and the Market 53
Michelle Barnhart, University of Utah, USA
Lisa Penaloza, Ecole des Hautes Etudes Commerciales du Nord, France

Agency, Identity and Materiality: The Storied Life of a Family and their Table

Amber M. Epp, University of Wisconsin-Madison, USA
Linda L. Price, University of Arizona, USA
Eric J. Arnould, University of Wyoming, USA

Negotiating Agency in the Elderly Consumption Ensemble

Michelle Barnhart, University of Utah, USA
Lisa Penaloza, Ecole des Hautes Etudes Commerciales du Nord, France

Moving Across the Gift Economy and the Market

J.S. Maroux, University of Montreal, Canada

SYMPOSIUM SUMMARY

Understanding Hedonic Misprediction: The Role of Lay Beliefs 56
Jane Ebert, University of Minnesota, USA

Anticipating Adaptation to Products

Jing Wang, Singapore Management University, Singapore
Nathan Novemsky, Yale University, USA
Ravi Dhar, Yale University, USA

Too Much of a Good Thing: Insensitivity to Rate of Consumption Leads to Unintended Satiation

Jeff Galak, New York University, USA
Justin Kruger, New York University, USA
George Loewenstein, Carnegie Mellon University, USA

Affective Forecasting and Psychological Distance: The Surprising Impact of Distant Events

Jane Ebert, University of Minnesota, USA
Tom Meyvis, New York University, USA

Inconsistency Between Predicted and Actual Sensitivity of Evaluation or Liking to Attribute Values

Jiao Zhang, University of Miami, USA
Christopher Hsee, University of Chicago, USA

SYMPOSIUM SUMMARY

“Roll Your Own” Religion: Consumer Culture and the Spiritual Vernacular 60

Linda Scott, University of Oxford, UK
Pauline Maclaran, Keele University, UK

Bidding Brigid: Objects of Petition and the Euhemerized Goddess
Darach Turley, Dublin City University, Ireland

“Living a Magical Life”: Sacred Consumption and Spiritual Experience in the Italian Neo-Pagan Community
Diego Rinallo, Bocconi University, Italy

Spiritual Tourism: Mystical Merchandise and Sacred Shopping in Glastonbury
Pauline Maclaran, Keele University, UK
Linda Scott, University of Oxford, UK

SYMPOSIUM SUMMARY

Comforting Social Presence, Depleting Social Influence 64

Anne-Laure Sellier, New York University, USA

Still Preoccupied with 1985: The Effect of Imagined Interaction on Preference for Nostalgic Products
Kathleen E. Loveland, Arizona State University, USA
Dirk Smeesters, Erasmus University, The Netherlands
Naomi Mandel, Arizona State University, USA

The Impact of Social Cues on Message Persuasiveness: The Role of Time Horizon Perspective
Anne-Laure Sellier, New York University, USA
Vicki Morwitz, New York University, USA

Why Do People Fall Prey to Social Influence Techniques? A Limited-Resource Account of Compliance
Kathleen D. Vohs, University of Minnesota, USA
Bob Fennis, University of Twente, The Netherlands
Loes Janssen, University of Twente, The Netherlands

SYMPOSIUM SUMMARY

Revisiting Consumer Confidence: New Findings and Emerging Perspectives 68

Zakary Tormala, Stanford University, USA

An Amplification Perspective on Attitude Certainty
Zakary Tormala, Stanford University, USA
Joshua Clarkson, Indiana University, USA

The Failure to Transmit Certainty: Causes, Consequences, and Remedies
Derek Rucker, Northwestern University, USA
David Dubois, Northwestern University, USA

Intuitive Confidence and the Effect of Option Valence on Preference Projection
Leif D. Nelson, University of California, San Diego, USA
Joseph Simmons, Yale University, USA
Jeff Galak, New York University, USA

SYMPOSIUM SUMMARY

Does Authenticity Matter? The Importance and Interplay of Authenticity and Inauthenticity 72

Tandy D. Chalmers, University of Arizona, USA
Linda L. Price, University of Arizona, USA

American Self-Enhancement Culture and the Cyborg Consumer: Consumer Identity Construction Beyond the Dominance of Authenticity
Markus Giesler, York University, Canada
Marius K. Luedicke, University of Innsbruck, Austria

Perceptions of Authenticity in Advertisements: Negotiating the Inauthentic

Tandy D. Chalmers, University of Arizona, USA

Linda L. Price, University of Arizona, USA

The Cultural Privileging of Personal Authenticity: A Critical Postmodern Perspective

Jay M. Handelman, Queen's University, Canada

Robert V. Kozinets, York University, Canada

SYMPOSIUM SUMMARY

Emotions, Social Comparison, and Deception in Interpersonal Interactions 76
Eduardo Andrade, University of California, Berkeley, USA

Gaming Emotions

Eduardo Andrade, University of California, Berkeley, USA

Teck-Hua Ho, University of California, Berkeley, USA

A Theory of Peer-induced Fairness in Games

Teck-Hua Ho, University of California, Berkeley, USA

Xuanming Su, University of California, Berkeley, USA

Pinocchio's Pupil: Using Eyetracking and Pupil Dilation To Understand Truth-telling and Deception in Sender-Receiver Games

Joseph Tao-yi Wang, National Taiwan University, Taiwan

Michael Spezio, California Institute of Technology & Scripps College, USA

Colin Camerer, California Institute of Technology, USA

SYMPOSIUM SUMMARY

Novel Approaches to Understanding Context Effects in Choice and Judgment 79
Anastasiya Pocheptsova, University of Maryland, USA

Tactile Experience with Warm Objects Alters Judgments and Decisions

Lawrence E. Williams, University of Colorado at Boulder, USA

John A. Bargh, Yale University, USA

Perceptual Boundaries: Helping You See Better but Making You Think Less

Yan Zhang, University of Chicago, USA

Aparna A. Labroo, University of Chicago, USA

Not in My Backyard: The Influence of Arbitrary Boundaries on Consumer Choice

Jeff Galak, New York University, USA

Justin Kruger, New York University, USA

Paul Rozin, University of Pennsylvania, USA

The Effect of Context on Memory-based Judgments

Anastasiya Pocheptsova, University of Maryland, USA

Nathan Novemsky, Yale University, USA

SYMPOSIUM SUMMARY

Beyond 2x2x2: Methodological Advances in Uncovering Consumer Decision Processes 82
Siegfried Dewitte, Catholic University Leuven, Belgium

The Why and When of Context Effects

Martijn Willemsen, Eindhoven University of Technology, The Netherlands

Eric J. Johnson, Columbia University, USA

Understanding Dynamic Processes in Consumer Behavior

Suresh Ramanathan, University of Chicago, USA

Good Practice in Experimental Moderation Designs

Siegfried Dewitte, Catholic University Leuven, Belgium

Measuring Consumer Risk-Return Tradeoffs

Roundtable Summaries

ROUNDTABLE

Understanding and Improving Consumer Personal Finances 809

Chairs:

Lisa E. Bolton, The Pennsylvania State University, USA
Paul Bloom, Duke University, USA
Joel Cohen, University of Florida, USA

Participants:

David Glen Mick, University of Virginia, USA
Ron Paul Hill, Villanova University, USA
Kathleen D. Vohs, University of Minnesota, USA
Amar Cheema, Washington University, USA
John G. Lynch, Duke University, USA
Vanessa Perry, The George Washington University, USA
Gal Zauberman, University of Pennsylvania, USA
James Burroughs, University of Virginia, USA
Cynthia Cryder, Carnegie Mellon University, USA
Scott Rick, University of Pennsylvania, USA
Eldar Shafir, Princeton University, USA
Stephen Spiller, Duke University, USA

ROUNDTABLE

Aesthetics and Consumption 810

Chairs:

Henrik Hagtvedt, University of Georgia, USA
Vanessa Patrick, University of Georgia, USA

Participants:

Wesley Hutchinson, University of Pennsylvania, USA
Joan Meyers-Levy, University of Minnesota, USA
JoAndrea Hoegg, University of British Columbia, Canada
Darren Dahl, University of British Columbia, Canada
Rajagopal Raghunathan, The University of Texas at Austin, USA
Rui Juliet Zhu, University of British Columbia, Canada
Rolf Reber, University of Bergen, Norway
C. Page Moreau, University of Colorado at Boulder, USA
Frederic Brunel, Boston University, USA
Annamma Jamy Joy, University of British Columbia, Canada
Jonathan Schroeder, University of Exeter, UK
Ravi Chitturi, Lehigh University, USA
Joseph Alba, University of Florida, USA
Michael Luchs, College of William & Mary, USA
Xiaoyan Deng, University of Pennsylvania, USA
Rishtee Kumar Batra, Boston University, USA

ROUNDTABLE

Building the Transformative Consumer Research Community: Opportunities and Obstacles for Rising Scholars 812

Chair:

Julie L. Ozanne, Virginia Polytechnic Institute and State University, USA

Participants:

Dipankar Chakravarti, University of Colorado at Boulder, USA
Ron Paul Hill, Villanova University, USA
David Glen Mick, University of Virginia, USA
Benet DeBerry-Spence, University of Illinois at Chicago, USA
David Crockett, University of South Carolina, USA
Krittinee Nuttavuthisit, Chulalongkorn University, Thailand
Amitava Chattopadhyay, INSEAD, Singapore
Simone Pettigrew, University of Western Australia, Australia
Peter Wright, University of Oregon, USA
Rohit Varman, Indian Institute of Management, India
Laurel Anderson, Arizona State University, USA
Stacey Menzel Baker, University of Wyoming, USA
Lisa Bolton, Pennsylvania State University, USA
Tonya Williams Bradford, University of Notre Dame, USA
June Cotte, University of Western Ontario, Canada
Susan Dobscha, Bentley College, USA
Cornelia Pechmann, University of California, Irvine, USA
Linda L. Price, University of Arizona, USA
Jose Antonio Rosa, University of Wyoming, USA
Namika Sagara, University of Oregon, USA
Sridhar Samu, Indian School of Business, India
Andrea Scott, Pepperdine University, USA
Sonya Grier, American University, USA
Humaira Mahi, San Francisco State University, USA
Dilip Soman, University of Toronto, Canada
Ashlee Humphreys, Northwestern University, USA
John Kozup, Villanova University, USA

ROUNDTABLE

HLM: Hierarchical Linear Models 813

Chair:

Dawn Iacobucci, Vanderbilt University, USA

Participants:

Gerri Henderson, Northwestern University, USA
Adam Duhachek, Indiana University, USA
Jim Oakley, University of North Carolina, USA
Steve Hoeffler, Vanderbilt University, USA
Steve Posavac, Vanderbilt University, USA
Simona Botti, London Business School, UK
Katherine A. Burson, University of Michigan, USA
Pankaj Aggarwal, University of Toronto, Canada

ROUNDTABLE

Conducting Consumer Research in Emerging Markets: Challenges, Issues and New Directions 814

Chair:

Humaira Mahi, San Francisco State University, USA

Participants:

Laurel Anderson, Arizona State University, USA
Eric Arnould, University of Wyoming, USA
Russ Belk, York University, Canada
Dipankar Chakravarti, University of Colorado, Boulder, USA
Amitava Chattopadhyay, INSEAD, Singapore
Catherine Demangeot, Strathclyde University, UK
Rika Houston, California State University–Los Angeles, USA
Eric Li, York University, Canada
Tamara Masters, University of Utah, USA
Mary Ann McGrath, Loyola University, Chicago, USA
Alokparna Monga, University of South Carolina, USA
Anirban Mukhopadhyay, University of Michigan, USA
Aysegul Ozsomer, Koc University, Istanbul, Turkey
Raj Raghunathan, University of Texas at Austin, USA
Akshay Rao, University of Minnesota, USA
Bill Rhyne, University of California, Davis, USA
Umberto Rosin, Ca Foscari University of Venice, Italy
Baba Shiv, Stanford University, USA
Yiping Song, Fudan University, Shanghai, China
Mourad Touzani, ISG, University of Tunis, Tunisia
Linda Tuncay, Loyola University, Chicago, USA
Hester Van Herh, VU University, The Netherlands
Alladi Venkatesh, University of California, Irvine, USA

ROUNDTABLE

Intro To Social Network Methods 816

Chair:

Dawn Iacobucci, Vanderbilt University, USA

Participants:

Gerri Henderson, Northwestern University, USA
Adam Duhachek, Indiana University, USA
Jim Oakley, University of North Carolina, USA
Steve Hoeffler, Vanderbilt University, USA
Steve Posavac, Vanderbilt University, USA
Simona Botti, London Business School, UK
Katherine A. Burson, University of Michigan, USA
Pankaj Aggarwal, University of Toronto, Canada

ROUNDTABLE

Consumer Neuroscience: Current State of Knowledge and Future Research Directions 817

Chairs:

James R. Bettman, Duke University, USA
Drazen Prelec, Massachusetts Institute of Technology, USA
Carolyn Yoon, University of Michigan, USA

Participants:

William Hedgcock, University of Iowa, USA
Mary Frances Luce, Duke University, USA
Hilke Plassmann, California Institute of Technology, USA and INSEAD, France
Baba Shiv, Stanford University, USA
Ale Smidts, Erasmus University, The Netherlands
Stacy Wood, University of South Carolina, USA
Akshay Rao, University of Minnesota, USA
Brian Knutson, Stanford University, USA
Adam Craig, University of South Carolina, USA
Vinod Venkatraman, Duke University, USA
Martin Reimann, Stanford University, USA
Scott Rick, University of Pennsylvania, USA

PRESIDENTIAL ADDRESS

Building Theory and Breaking Boundaries: Welcome to the Real World

Punam Anand Keller, Dartmouth College, USA

I decided on the topic for this speech on a flight home from a meeting with a group of university administrator, financial planners, and faculty. The goal of our meeting was to identify initiatives to help new university hires save more for retirement. I was so upset at everyone's impressions of consumer research that it was fitting that I wrote the outline of this speech on the only paper I could find on the plane—motion sickness bags!

I have faced similar resistance from business school colleagues, and dare I say, even marketing colleagues who are not here today. They cannot get over why we care about how consumers process simple information. They don't understand why we wash away individual differences in our random designs. They are bewildered by why we don't study the decision context since it determines the constraints that prevent consumers from achieving their goals.

It is clear to me that our crash course on the philosophy of science, starting with the premise that theories are universally generalizable, is falling on deaf ears. We can either accept that our work is going to live and die on the sheets of journal paper, or, we can enhance the impact of our work by taking it further so that others can apply it.

Today, I would like to share concrete examples of how we can use the real world to build theory—not by learning a new skill set—but simply by leveraging the wealth of knowledge in this room. My hope is that you will leave with a richer appreciation for consumer research, with fewer boundaries between different types of consumer research, and an irresistible urge to share your research in the real world!

The first part of my talk is on building theory. It contains three approaches for making both a theoretical and practical contribution. The second part of my talk describes three scholarly benefits when we break boundaries. So I begin

The first approach for building theory in the real world is based on the topics we study. At least six previous ACR presidents have urged us to undertake research that is relevant to consumers. Relevance has been defined in a number of ways, as examining consumers in natural contexts by Valerie Folkes and Terry Shimp, as macro consumer behavior by Russ Belk and Marsha Richins, and as individual and collective well-being by Alan Andreasen and David Mick. Of the thousand plus paper and film submissions for this conference, up to 25% were on transformative consumer research topics that included consumer self-control, resistance and coping, family relations and civic values, health and financial planning, the environment, and materialism and subsistence. We have growing evidence that scholars from other disciplines, applied researchers, practitioners, and even consumers themselves, are all hungry for insights on these topics. The second approach is based on the premise that theories are strengthened when they are tested in real world conditions that challenge them. The third approach suggests real world testing enables us to identify moderators and mediators for building theory. You are going to see these red boxes on all my slides for building theory.

In preparing this speech I interviewed a small, diverse group of ACR members who I refer to as the Fab Five. Some have been doing consumer research for decades, others for just a few years. These five researchers draw on a varied set of basic disciplines—such as psychology, sociology, anthropology, and economics. They use a variety of methods and live and work in different parts of the world. But all had one thing in common—they were looking for

contexts that would demonstrate the value of theory while remaining open to building theory after giving it a run in the real world. They are Brian Wansink from Cornell, Jill Klein from Insead, Deborah Small from the University of Pennsylvania, Dilip Soman from the University of Toronto, and Maura Scott from the University of Kentucky. They all illustrate how real world engagement can serve both the consumer and help develop theory. I will weave their stories with my own. Let me begin first by offering some views based on my own research.

I met my co-author Annamaria Lusardi, an economist, three years ago—when she asked me to speak at a conference on retirement saving. I told her I not only did not DO research on retirement saving, but I did not know how to save! She assured me I could present my health research since health and retirement planning decisions are similar on so many dimensions. She was right and our work together began. We started by identifying barriers to savings in lab studies, focus groups, in-depth interviews and work-place observations. Some employees could be helped by opening a dialogue about how to overcome saving barriers.

However, this does not help a large percentage of employees who said they wanted to open a retirement account, but did not know where to start. Upon further prodding, we found that not knowing where to start meant not knowing how much time the decision would take, what information was needed to make the decision, and how much money was involved. It was clear to us they needed a simple how-to plan instead of a big benefits packet! We created a simple plan that contained the information they wanted.

We also made the plan concrete by breaking it up into specific tasks with time estimates because inter-temporal discounting theory indicates this method would reduce procrastination. We gave this simple, cost-effective, theory-based planning tool to Dartmouth's Human Resources department who used it with all new university employees. Compared to a control condition, this plan resulted in a 5 fold increase in enrollments—from 8% to over 42% of new Dartmouth employees. Hundreds of new employees opened a supplementary retirement account within two months. The Dartmouth study encouraged TIAA-CREF to put our research method and planning tool on their website to encourage other education institutions to use our methods.

You're probably thinking—is that all it took. That's exactly how I want you to think! Consumer research is powerful! And we gave back to the theory. There was nothing in the inter-temporal discounting literature on the role of planning to reduce procrastination? We tested this hypothesis by running experiments with undergraduates in a variety of health and wealth contexts to demonstrate that plans reduce feasibility concerns which in turn reduce procrastination. We used consumer insights and we replaced consumer insights! That is my example of how we built theory in the real world. Now on to my examples from colleagues I mentioned to you earlier.

Brian Wansink was living in Iowa in the early '80s when he was inspired by the farmland around him—to do something that would get Americans to eat a healthier diet—a very hot topic today. But when he started testing the waters two decades ago, talking with other researchers about his ideas, they were less than receptive. One person even said to him, "Why don't you do something theoretical, something important? Nobody's interested in food." That was news to Brian; he thought everybody was interested in food. Besides he knew he could build a wide array of theories in this rich context. He

was right. Fast forward to today. Brian's counterintuitive findings contribute to our theoretical understanding of perceptual biases. Brian's findings on the conditions that lead to overconsumption have influenced numerous health policies. My least favorite of Brian's findings is the use of taller glasses to prevent the over pouring of alcohol.

If a topic does not grab you, there are two other ways you can use the real world for building theory. First, theories are strengthened when they are tested in conditions that challenge them. A few years ago, I was reading about a debate in the depressive realism literature. Proponents of this phenomenon believe depressed people are more realistic because they are more likely to update their risk estimates when they are given credible information, whereas people who are not depressed stick with their priors. Objectors argue that the phenomenon is not universal or "real" because it is always tested in contexts where there was an optimistic bias—thereby if one was pessimistic one was also more accurate. To support the view that depressed people would be more open to lowering their risk estimates I started looking for contexts in which people typically inflated their risks and where there was an objective measure of accurate risk.

I chose the breast cancer context for these reasons. Women overestimate their risk of breast cancer by a factor of five! The national average is about 25% as compared to what it should be—around 5%. How do I know what it should be? There is a medical algorithm that can calculate each person's risk of breast cancer based on the individual's history. Although we showed baseline risk estimates were not different for non-depressives and depressives, depressives lowered their risk estimates when they received their individual breast cancer medical risk estimate, whereas non-depressives did not update. This real context allowed me to make a theoretical contribution to the theory of depressive realism by showing depressed people were more realistic even when they had to be more optimistic to be realistic.

Not all contexts are perfect for building this theory. Earlier this year someone asked me whether the risk of terrorism attacks would be a perfect context to study the robustness of the depressive realism phenomenon. I asked the same two questions—Do we have evidence that people are inflating the risk of a terrorist attack, and is there an objective risk estimate of a terrorist attack? Along the same lines, you might ask yourself, "What are my parameters for a good context?"

Dilip Soman can tell you what he is looking for in a context to build his theories. Dilip is interested in heuristics and biases in decisions involving time, effort, and money. He is always looking for real contexts where there is an element of uncertainty—conditions that are ripe for making budgeting "mistakes"—conditions where his interventions should have the biggest impact. Picture this—Dilip gave Non Government Organization or NGO staff members from agriculture, dairy, construction, labor, artisans, and women's cooperatives a crash course in mental accounting. Dilip selected farmers for his study because their wages were seasonal and construction workers because their wages were the most unpredictable. See, he found an opportunity to build theory—are budgeting mistakes the same for unpredictability and seasonality? Dilip encouraged both farmers and construction workers to save by giving them their wages in multiple sealed envelopes instead of a single envelop. And once the microfinance institution knew the farmers were able to manage their money better, they gave them more loans to run small agriculture businesses. Dilip continues to build theory on heuristics and biases in multiple foundations.

Deborah Small selected charitable giving as the context for testing and building her theories. Can you guess some of her theories? You can play this game with your colleagues where you

reveal the context and ask others to guess the theory or vice-versa. Deborah is interested in emotional biases in judgments. She was seeking a context that connected peoples' emotions and actual behavior. Interestingly, she observed her counterintuitive idea in the field before she developed a theoretical test for it.

Contrary to the literature, the most effective charity advertisements showed pictures of happy not sad victims. The charity context also sparked her interest in sympathy biases in decision-making because it allowed her to examine why and how much people give to charity. Published in JCR and JMR, both studies have made theoretical contribution and had an impact in the arena of charitable giving. And Debra has since collaborated with different charitable organizations in various field experiments.

These examples demonstrate that synergy between lab and field studies allow us to build theory AND make a practical contribution. An observation in one context motivates testing a question in another. And it really doesn't matter where you start. I like the way Baruch Fischhoff labels research as basic-applied and applied-basic to emphasize the seamlessness between the two ways to build theory.

The third theory building approach is based on finding new moderators and mediators in the real world. If you are vigilant you will observe when people around you are not behaving theoretically—according to your theory that is.

Jill Klein went to Thailand in 2005, just after that devastating tsunami, to participate in recovery efforts. She and others were handing out gifts—new possessions—to people who had lost everything. Jill discovered that contrary to the body of work that associated materialism with a host of negative outcomes, she observed the benefits of material goods, especially for teens. She and her co-author wrote an article along with a white paper for meeting the needs of teens in other similar natural disasters. She offered an examination of theoretical boundaries *and* a proposed workable solution for a real-world problem.

Maura Scott also built theory by identifying a previously unknown moderator. Maura Scott's prediction that 100 calorie packs would not result in lower calorie consumption was confirmed among a segment of the population, the restrained eater. Similar to the movie character Bridget Jones, this type of eater writes down her weight and the things she has eaten in a daily journal. Like Bridget who finds herself with two guys, the restrained eater ends up overeating. Maura's work has won awards and she published her dissertation work in JCR.

I have shared three different ways that my colleagues and I have built theories in the real world—by identifying theories that shed insights on a topic you and others care about, by selecting real contexts to test the robustness of theory, and by identifying moderators and mediators from natural settings. I see this approach as a win-win situation. We build our theories and make them more accessible to others. We may even generate the discussion and public policy changes that directly improve consumer welfare.

You, as a scholar, have even more to gain. Building theories in the real world will inspire you to reexamine your research and teaching boundaries. You will learn to appreciate new methods, get a richer, cross-disciplinary view of your theory, and you can leverage your research in the classroom. Let me give you concrete examples of each of these benefits.

First, you get to learn—really learn—again. You learn to examine your theory with new methodologies. I have found that nothing teaches you the value of different types of consumer research than when you are trying to solve a real problem. The methodological distinctions that are so important to us here in this room seem trivial to outsiders. Originally trained as an experimental information processor, Brian Wansink has worked with market-

ing modelers to model eating behavior such as diminishing sensitivity to meal size change. I too used to be an information processor who now devours the behavioral decision theory literature to understand how people make choices.

Like Dilip Soman, I have greater appreciation of sociology and interpretive research because it can capture the context in which consumers live and make decisions. I even took a class on ethnography in the sociology department to improve my ability to fold the context into theory.

This training was handy when a grant from The National Endowment for Financial Education enabled Anna and I to shoot videos of different employees, talking about why and how they save. In other words how they met their goals by overcoming their barriers. If you watch these videos on the Dartmouth website, you will conclude, and I concur, that I need to learn a lot from our members who participate in ACR's film festival.

Next, I learnt to develop quantitative predictive models for the Health Marketing Division of the Center for Disease Control. I was devastated when I found out CDC was uncomfortable extending consumer research lab findings without additional field tests. And if CDC cannot use our health consumer research, who can! I asked Don "Meta" Lehmann to teach me how to develop a predictive model based on a meta-analysis of all the lab research on health communications. This health communication model is based on a sample size of over 22,000 subjects, has twenty-two message factors, across several health contexts, and six individual differences. If you are interested in using the data, let me know and I will send it to you. CDC gave me the nod when I showed that the lab-based model could predict the effectiveness of their national exercise ad campaign.

Second, you will view issues from the frames of a variety of disciplines to create a more complete picture of problems and their causes, and the theories that can be used to solve them. Dilip's website states he never misses an opportunity to talk to anyone smart or famous. He regularly gets together with scholars from economics, finance, health sciences, public policy, and sociology among others. I too participate in several cross-disciplinary groups.

One group on cost effective consumerism is made up of academics from law, economics, bioethics, medicine, psychology, neuroscience, and fields I did not even know existed like neuroeconomics. I meet with another group of scholars from public health, economics, psychology, psychiatry, medicine, and public policy—all of whom share an interest in improving personal health. I also meet with marketing managers and academics at the Marketing Science Institute meetings to discuss how to increase employee participation in corporate well-being programs. And there are so many more opportunities to break boundaries at special conferences like the Transformative Consumer Research Conference in Villanova, and one on Leveraging Consumer Psychology for Effective Health Communication in Michigan.

Third, the beauty of building theory in the real world is that it is easy to leverage your research in the classroom. Who wouldn't like to break the boundaries between research and teaching? Deborah parlays her research into her Consumer Behavior class by analyzing her students' emotions in photographs. Jill Klein uses her research on consumer boycotts and crisis management in her Social Marketing elective and International Executive Programs. Brian Wansink holds his class in a food lab. Dilip's class on Foundation for Integrative Thinking has projects to challenge students to tackle critical consumer issues such as encouraging young people to save.

Like these consumer researchers, I see my career as a three-legged stool; there is a teaching leg, a research leg, and a community/public policy leg. The three are inextricably linked, which

creates synergy. The more synergy I have, the more I can leverage what I do and the easier it is to take and give back to the real world.

In closing, please join me in thanking Jill, Maura, Dilip, Brian and Deborah, for sharing their stories with us. I want to acknowledge Lauren Block and Annamaria Lusardi for inspiring me to do health and wealth-related consumer research. I want to thank Brian Sternthal and Alice Tybout for teaching me how to design theoretical and applied research. A toast to Sidney Levy—You connect theory and practice with unparalleled joy and creativity. To my parents for giving me confidence that far out striped my abilities. To a true partner, my husband Kevin. And to my children, Carolyn and Allison, who insist I keep it real by asking me what I really do.

I hope you are inspired to care for your theories by giving them new meaning in a real context. For me, passion bestows meaning—so I thank you for giving me this opportunity to share my passion for consumer research.

SYMPOSIUM SUMMARY

From the Black Box to the Aquarium: How Brain Imaging Sheds ‘Light’ on the Underlying Mechanisms of How Marketing Actions Work

Hilke Plassmann, California Institute of Technology, USA and INSEAD, France

EXTENDED ABSTRACTS

“The Good, the Bad and the Forgotten-An fMRI-study on Ad Liking and Ad Memory”

Peter Kenning, Zeppelin University, Germany

Michael Deppe, University of Muenster, Germany

Wolfram Schwandt, University of Muenster, Germany

Harald Kugel, University of Muenster, Germany

Hilke Plassmann, California Institute of Technology, USA and INSEAD, France

Memory is a central construct in both, advertising research as well as in neuroscience. We know from research in advertising that affect-laden ads are likely to be better recalled and better recall is likely to correlate with ad effectiveness (Ray and Batra 1983; Ambler and Burne 1999). Researchers suggest that ad memory might be “the temporal link between ad input and buying occasions” (Ambler and Burne 1999, p. 27). Interestingly, based on conditioning theories most ads use positive affect-laden stimuli and only more recently marketers started also to use negative affect-laden stimuli such as for health marketing purposes (e.g. for lung cancer prevention). In neuroscience, research has shown that distinct brain areas encode positive affect-laden stimuli (e.g. parts of the Medial Prefrontal Cortex and the Striatum) and negative affect laden-stimuli (e.g. Insular, Amygdala). There is also evidence that affective (e.g. pleasant or aversive) events are better remembered than neutral events (Hamann et al. 1999). Research in neuroscience suggests that these emotional memory effects are mainly driven by attention.

In the current study we investigated whether ads that vary in ad liking elicit changes in brain activity that corresponds to areas shown to be involved in the processing of stimuli with different affective valence. In addition, we explored the existence of emotional memory effects and how these effects differ with affective valence of the ads.

We first conducted a pre-study to quasi-normalize 45 print ads by asking 160 subjects to judge their liking of the ads. Based on the results we classified 10 ads as liked, 10 as disliked and 10 as neutral. These 30 ads were then used as stimulus material in an fMRI study. We scanned brain activity of 22 healthy and right-handed subjects (12 males, aged between 24-34 years) while they judged their liking of the 30 print ads. Every 10 seconds a new ad was projected into the visual field of the subjects. The volunteers were asked to decide whether they like or dislike this ad by pressing one of the two corresponding buttons on a magnetic resonance compatible response box. The responses were recorded with the use of specific software. Immediately after scanning, we asked the subjects to fill out a questionnaire to sample their recall of the different ads.

We found that liked and disliked ads are processed in distinct neural networks. Liked ads induced increased activity changes in higher order visual areas, the fusiform face area (FFA), the ventromedial prefrontal cortex (VMPFC), the posterior cingulum (PCC) and the ventral striatum (VS), in particular the nucleus accumbens (NCC). Activity increases in higher order visual cortices may reflect increased visual attention during viewing the attractive visual material (Shimojo et al. 2003). The FFA has been characterized as an area specialized in face recognition and perception (Grill-

Spector et al. 2004). This finding is interesting because indeed most of the liked ads contained faces whereas the disliked and neutral ads did not to that extend. The VMPFC is a region that plays a fundamental role in decision-making, especially in the context of preference and value representation (Bechara et al. 1999; Bechara 2004). Finally, our data suggests that exposure to attractive ads leads to increased cerebral blood flow in areas of the human reward system, in particular the VS/NCC (Knutson et al. 2000, O’Doherty et al. 2004). In contrast, disliked ads are accompanied with activity changes in the insular region. Activation in the insular is consistently seen in studies of pain and distress, hunger and thirst, autonomic arousal and unfairness (Sanfey et al. 2003). A recent study showed that excessive prices activated the insular prior to the purchase decision (Knutson et al. 2007). In addition, we found that disliked ads induce activity changes in areas associated with the motor cortex. The motor cortex consists of regions in the cerebral cortex involved in planning, control, and execution of voluntary motor functions. This finding might be due to the fact that our subjects responded quicker to aversive stimuli in order to make them disappear from screen.

In the next step of the data analysis, we generated recall scores and tested their correlation with different degrees of ad liking. As expected we found significant differences in ad recall between the three different ad-liking groups. We found that highly liked ads lead to the highest ad recall, followed by the disliked and, finally, the neutral ones.

Our findings offer important insights for advertising research and practice. One interesting finding is that there is a high correlation between ad liking and the use of faces in the ads. This preliminary finding calls for future research to better understand the role of faces, facial expressions and also eye gazes for ad liking, ad recall and ad memory. Then, our findings show that both, ad liking and ad disliking lead to increased ad recall as compared to neutral ads. In a next step it would be interesting to investigate how ad liking influences attitude towards the brand and brand preference. Do conditioning theories hold here that ads that trigger activation changes in areas encoding negative affect will have a negative impact on the attitude towards and preference for the advertised brand? An alternative scenario would be that positive spillover effects could be found based on contrasts effects. Taken together, this research contributes not only to a better understanding of how advertising affects consumers’ perception, affective encoding and memory, but also extend knowledge referring to the role of the emotion processing for memory effects that serve as basis for every day (economic) decision-making.

“Neural Correlates of Deception Detection: A BOLD Imaging Study”

Adam Craig, University of South Carolina, USA

Yuliya Komarova, University of South Carolina, USA

Stacy Wood, University of South Carolina, USA

Jennifer Vendemia, University of South Carolina, USA

Although many definitions of deceptive or misleading advertising have been offered, most researchers agree that for an advertisement to be deceptive it must assert or imply something that is “objectively false” (e.g., Shimp and Preston 1981). However,

differences in interpretation and operationalization of advertising deceptiveness have resulted in substantial theoretical dispute and consequently, research effort (e.g., Russo et al. 1981). Unsurprisingly, much research in the past has been dedicated to features and attributes of advertisements that have a potential to mislead consumers (e.g., Armstrong et al. 1979; Barone et al. 2004; Burke et al. 1988; Shimp 1978). Burke and his colleagues (1988) for instance, investigated various message forms identified in past research as having the potential to deceive consumers by implying unrealistically high levels of brand attribute performance; their results showed that certain message forms in particular increased false brand attribute beliefs, affect, and purchase intentions. More recently, Darke and Ritchie (2007) have investigated short and long-term consequences of deceptive advertising on consumer perception and subsequent behavior and found that consumers engage in defensive stereotyping and direct negative affect towards subsequent, unrelated advertisements. Consequently, there are conflicting findings pertaining to the effect of deceptive advertising on affect and subsequently, on purchase intentions which may be explained by the mechanisms that guide deception detection. However, little evidence exists for what processes underlie consumer detection of deception in advertising even though such an insight has a potential of helping resolve a number of related theoretical arguments. Hence, the objective of the present work is twofold: first, we attempt to identify the neural correlates of deception detection using fMRI methodology, and second, we investigate the differences in consumer processing of varying levels of deceptive advertisements.

Although functional MRI methodology is relatively novel in consumer research (e.g., Yoon et al. 2006; Plassman et al. 2007), it has been used in the field of psychology to study deception effort (Kozel et al. 2004; Vendemia et al. 2006) and revealed complex processes in the anterior cingulate involving attention, working memory, and executive control. In the context of deceptive advertising, fMRI may be particularly informative as the traditional cognitive expectancy disconfirmation approach has often failed to reveal consistency in what individuals perceive as misleading information (Grunert and Dedler 1987). For instance, Shimp (1978) notes that inferences made from incomplete comparisons in advertisement messages differ among people: while some consumers assess a certain advertising message as deceptive, there are others who detect no deception when exposed to the same message. Hence, idiosyncrasies in cognitive structures involved in advertisement perception have made it largely impossible to investigate the processes underlying consumer detection of advertising deception via traditional behavioral methodology. Interpersonal deception detection research shows similar inconsistency in that primed knowledge for deception likelihood does not increase observers' accuracy at detection (Toris and Depaulo 1984).

In order to explore the neural functions underlying deception detection, college students (N=25) viewed 15 advertisements for new products that varied in their level of perceived deception potential (as determined by pretesting). Each advertisement was assigned to one of three categories (based on pretesting with college students (N=180) from the same population as the subsequent imaging study): low deception potential, mildly deceptive, and highly deceptive. The advertisements consisted of a product picture and descriptive paragraphs similar to a catalog format and were viewed for 50 seconds each.

Broadly described, we observe an inverted-u effect of neural activity where greater processing resources are expended for products that seem moderately deceptive compared to products that have either low or high potential for deception. Based on results from Darke and Ritchie (2007), we predict and find that neural

activity associated with comparative processes and hypothesis-testing will be greater in conditions of moderate deception than in low deception conditions as suspicion will not be active in low deception conditions. In comparing processing between moderate and high deception conditions, neural activity associated with highly deceptive advertisements shows truncated processing resulting from the discounting of invalid messages (Schul et al. 1996; Schul et al. 2004). Additionally, prior research suggests that affective processing should also be greater in conditions of higher deception (Darke and Ritchie 2007).

Neural processing evidence from this fMRI study suggests that individuals have quick attentional responses to potentially deceptive claims in accord with behavioral theories of marketplace "defensive" vigilance and biological theories of threat surveillance. Further, the pattern of neural activation suggests an early two-stage process in which heightened attention is first preferentially directed toward highly deceptive material but that this attention shifts as processing of highly deceptive material is truncated and increased attention and belief reasoning is directed toward believable and moderately deceptive material. We interpret these data as indicating a potential risk of moderately deceptive material in that such claims generate prolonged attention as well as expanded comparative processing similar to that garnered by believable claims. While our data do not speak to resulting biases, if a potentially deceptive claim is simultaneously being evaluated for credibility and relative benefit, this would provide a situation in which individual's credibility judgments may be colored by evaluations of relative benefit.

This research contributes to the existing literatures on deception by describing the brain's early processing response to potentially deceptive information and by examining this process within the domain of marketplace deception. We find neural evidence that supports recent consumer theories of "defensive surveillance" (Darke & Ritchie 2007) and is in accord with broader conceptualizations of persuasion knowledge in the marketplace (Friestad & Wright 1994). Like recent fMRI research on belief reasoning, we find that activation in BA 7 (Goel & Dolan 2003) and BA 40 (Sommer et al. 2007) is associated with the larger deception detection process. Our findings distinguish between claims that vary in perceived deceptiveness. Importantly we identify "stage 1" visual attention differences that suggest preferential initial processing of highly deceptive claims as well as subsequent "stage 2" processing differences that suggest preferential processing of moderately deceptive and believable claims.

"A Salesforce-Specific Theory of Mind Scale: Tests of Its Validity by Multitrait-Multimethod Matrix, Confirmatory Factor Analysis, Structural Equation Models, and Functional MRI"

Roeland C. Dietvorst, Erasmus University, The Netherlands

Willem J. M. I. Verbeke, Erasmus University, The Netherlands

Richard P. Bagozzi, University of Michigan, USA

Carolyn Yoon, University of Michigan, USA

Marion Smits, Erasmus University, The Netherlands

Aad van der Lugt, Erasmus University, The Netherlands

In order to be successful, it is imperative that salespeople immerse themselves into the nuances of the customer's organization and pay special attention to subtle cues communicated by customers. By doing so, salespeople can put themselves into the shoes of the members of the buying center and mentally simulate what customers indicate or say they want, and why they want to buy. Following recent developments in neuroscience, we term such processes, interpersonal mentalizing and define it as the activity of inferring another person's beliefs, desires, risk preferences, intentions, and other mental states or events (Frith and Frith 2003). The

ability to engage in interpersonal mentalizing and read the mind of the customer has some affinity to the adaptive selling concept (e.g., Spiro and Weitz 1990); and the functioning of the drivers of adaptation in selling interactions, in turn, rests on assumptions about, and processes going on, in the mind of salespeople. Yet research to date has utilized methods based only on verbal self-reports.

Our goal is to study brain processes of salespeople who score high versus low on interpersonal mentalizing processes. The neuroscience literature suggests that interpersonal mentalizing is a hardwired brain process that occurs spontaneously and largely unconsciously in social encounters and is centralized in a distinct network of brain regions: the most consistently activated regions with mentalizing tasks are the medial prefrontal cortex (MPFC), left and right temporo-parietal junctions (TPJ), and left and right temporal poles (TP). Based on a growing body of evidence, we hypothesize that those who are high (versus low) in interpersonal mentalizing skills display greater coordinated activation of all modules implicated in this network.

We investigated the role of mentalizing in personal selling in four studies. In the first study, a paper and pencil measure that operationalized interpersonal mentalizing concepts in a selling context was designed and administered to 132 salespeople. We refer to the measure as the salesperson theory of mind (SToM) scale in order to stress the context-specific aspects of our measure and differentiate it from a generalized theory of mind (ToM) scale which we use to test criterion-related validity. The results showed that salespeople exhibit different degrees of interpersonal mentalizing which can be represented in four distinct, but related, dimensions, and further the measures of SToM achieve convergent, discriminant, and criterion-related validity. Moreover, high versus low scorers on the SToM-scale are relatively more adaptive in selling situations, are better able to take the perspective of customers, and show less fear of being evaluated negatively in selling situations. Study 2 replicated findings of Study 1 and also showed that the four dimensions of SToM relate significantly with performance. The performance measures were then validated on a new sample of high and low performers.

Study 3 examined the construct validity of measures of SToM by use of the MTMM matrix and CFA and also tested nomological validity. The measures showed high trait variance, low error variance, and very low method variance. Performance was found to be driven largely by SToM: rapport building influenced performance indirectly through social anxiety and the other three dimensions of SToM influenced performance directly.

Study 4 used functional magnetic resonance imaging (fMRI) to discover whether different functioning of brain regions provide evidence for individual differences in the ability to mentalize interpersonally, and in addition provide evidence that the four dimensions of SToM discriminate between high and low mentalizers. We tested the hypothesis that high (vs. low) interpersonal mentalizers display relatively greater activations of specific regions of the brain (i.e., the MPFC, TPJ, TP) that have been consistently reported in the literature to be associated with mentalizing tasks.

Twenty participants (10 high and 10 low scorers on the SToM-scale) were recruited for the fMRI study. The fMRI protocol consisted of three experimental conditions: Interpersonal mentalizing (IM), Process, or Unlinked sentences. Participants listened to five stories of each type presented in a counterbalanced manner while lying supine in a full-body 3.0 T GE scanner; and functional images were acquired. In the IM condition, participants listened to stories and were instructed to imagine the intentionality of the people interacting with each other in the story. In the process condition, they thought about how people operate according to well-established

scripts. The IM and process conditions were designed to be different at a subtle level; whereas the IM condition explicitly required interpersonal mentalizing, the process condition did not. Finally, in the unlinked sentences condition, participants listened to a series of sentences that did not form a coherent story. Each story was followed by a question that the participant was instructed to answer silently to oneself. The process and unlinked sentences conditions served as control conditions.

Our results were largely consistent with our hypothesis: the high (vs. low) scorers on the SToM scale showed more activity during the mentalizing task in the MPFC and TPJ regions of the brain, but this effect was much weaker in the TP regions, and was nonexistent when we compared the interpersonal mentalizing task with the unlinked sentences task. A closer inspection of the data shows that the TP regions were in fact activated highly in both the high and low mentalizing groups of salesperson participants. To the extent that such activation in the TP regions relates to the formation and use of mental scripts (e.g., Frith and Frith 2003, p. 465), we speculate that both high and low scoring salespersons equally use script-based thinking. It thus appears that only for salespersons high in interpersonal mentalizing is the entire network consisting of the MPFC, TPJ, and TP fully activated, whereas for persons low in interpersonal mentalizing, only part of the network, the TP, is activated. Hence we find evidence suggesting that salespeople differ in their utilization of the mentalizing network, and that these differences have considerable behavioral correlates. We explore possible explanations for the differences in brain activity between high and low mentalizers. Finally, implications of our findings for the selection and training of salespersons are considered.

SYMPOSIUM SUMMARY

When the Going gets Tough: How Metacognitive Difficulty Improves Evaluation

Aparna A. Labroo, University of Chicago, USA

Sara Kim, University of Chicago, USA

SESSION OVERVIEW

Ample research establishes that feelings serve as information about preferences. An important source of feelings is the subjective characteristics of a stimulus itself (Schwarz 2004). Research argues that subjective feelings of ease of processing the stimulus are beneficial and increase liking towards the stimulus (Berlyne, 1966; Bornstien, 1989; Zajonc, 1968). This is because people implicitly associate ease with familiarity and personal relevance. Consequently, subjectively easy (vs. difficult) to process stimuli are also evaluated as more familiar and self-relevant and are preferred. However, is it possible that under certain situations, feelings of metacognitive difficulty might increase evaluation? For example, looking to become a better person, might you decide to donate more to a charity simply because processing difficulty made it seem more instrumental, because usually you invest effort in what is instrumental and you unknowingly reversed this correlation in your mind? Or celebrating a special occasion, might feelings of difficulty in coming up with the name of the chosen restaurant make it seem more exclusive? After struggling through a students' hard to read assignment that employs small font might you find the next one so much more lucid but actually only its font is larger? And to what extent do these effects emerge because of feelings of familiarity or because of the misattribution of affect? For example, if after struggling to pronounce the name of a food additive you come to think it is more dangerous, is that because it feels unfamiliar or because it feels negative? These are some questions we investigate in this session.

In contrast to existing research arguing for a positive effect of ease of processing on evaluation, in this session we discuss three situations—when the target is a means to fulfill an accessible goal (paper 1), when the target is a special occasion product (paper 2), and when the target follows a difficult to process prime (paper 3)—under which subjective difficulty of processing increases liking of the target object. Finally (paper 4), we discuss how metacognitive difficulty might increase perception of effort needed to accomplish a task at hand, thus tying the session to the initial proposition (paper 1) that effort perception can sometimes be a good thing.

Paper 1 by Kim and Labroo argues that when a target product is a means to attain an accessible goal, people employ an “effort heuristic” to judge its instrumentality as a means. This is because people investing effort to pursue goals use those means that are most instrumental in accomplishing their goals. When assessing the value of the target in fulfilling an accessible goal they also reverse this correlation inferring that effort signals instrumentality. Thus, subjective difficulty increases desirability of an object that is a means to fulfill an accessible goal.

Paper 2 by Pocheptsova and Dhar adds to our understanding of the impact of metacognitive difficulty on evaluation of products in a second way. It suggests that when scarcity or infrequency is a good thing as in the case of special occasion products, a “scarcity heuristic” kicks in and subjective feelings of difficulty make products appear more rewarding by increasing perceptions of scarcity.

Paper 3 by Shen, Jiang, and Adaval next establishes a positive impact of metacognitive difficulty on subsequent evaluations. The authors suggest that subjective feelings of difficulty that arise from perceptual processing create an illusion of increased ease towards

judgments that follow. Thus judgments about a target are not only affected by processing fluency of the target but also affected by processing fluency of the material preceding the target information.

Finally, Song and Schwarz discuss the situations where difficulty signals danger and where it signals required effort to pursue ones' goals. They demonstrate that when people make judgments about risk-related targets, low processing fluency signals a lack of safety increasing expected risk associated with the target. Additionally, in a situation where people make judgments about effort-related activities, low fluency signals a need to invest higher effort. They discuss the mechanism underlying these phenomena in terms of affect and familiarity.

All four papers are closely related, well grounded in theory, advancing and consolidating research on metacognition and consumer preference formation. Each paper comprises of several experiments, and presents novel findings in an area of growing interest to consumer researchers.

EXTENDED ABSTRACTS

“The ‘Instrumentality’ Heuristic: When Metacognitive Difficulty Signals Means Instrumentality”

Sara Kim, University of Chicago

Aparna A. Labroo, University of Chicago

Do people crave for things just because they seem subjectively difficult to get? Take a look at “Mysterious Flirting 101” on the Web, which authoritatively proclaims that “everyone’s heard that you should play hard to get in order to attract the person you like.” Evidence from an experiment also confirms that female rats that play hard to get are more likely to keep their male mates interested (Erskine, 2005). Even children appear to want things that simply feel difficult to get. Try holding a toy out to a young child just beyond his or her grasp, and watch the child bounce all around you. Then, hand the toy over and watch how quickly the child loses all interest in it. In the current research, we consider the following question: does a feeling of subjective difficulty (vs. ease) sometimes increase the allure of the object under consideration, and why?

Contrary to the commonplace observations just discussed, ample evidence suggests that feelings of subjective ease rather than difficulty increase preferences of objects (Berlyne, 1966; Bornstien, 1989; Schwarz, 2004; Zajonc, 1968). For example, abstract images, line drawings, and pictures are evaluated more favorably when their perceptual characteristics are subjectively easy to process (vs. blurry) or when they have been presented on a previous occasion. Because personally relevant and familiar objects come to mind easily, people implicitly associate ease with familiarity and personal relevance (Schwarz, 2004). Consequently, subjectively easy (vs. difficult) to process objects are also evaluated as more familiar, self-relevant, and desirable.

In the current research, however, we propose that when people have a highly accessible goal before evaluating a target object, subjective difficulty (vs. ease) of processing will improve its evaluation. This is because people with an accessible goal who evaluate the target object need to assess its instrumentality in fulfilling their goal. We propose that at this time an “effort heuristic” might help ascertain how instrumental the target being consid-

ered is toward fulfilling their accessible goal. In particular, we propose that because effort during goal pursuit is usually expended in whichever means is most instrumental, people implicitly associate effort with instrumentality of a means. They might reverse this correlation in their minds to also perceive effort as a signal of instrumentality of the target means in fulfilling the accessible goal. Thus, subjective difficulty (vs. ease) might improve evaluation of a target object that is a means towards fulfilling an accessible goal because, based on the belief that people generally put in effort in whichever means is most instrumental, effort signals value. When no clear goals are accessible or when the target object is not a means to fulfill an accessible goal, ease (vs. difficulty) of processing will improve evaluation, replicating the results found in previous research. We test this across three experiments.

In all three experiments, we manipulate difficulty of processing using either blurry or clear font, in line with a methodology used in previous experiments (Novemsky et al. 2007). Experiment 1 examines whether a highly accessible mood goal leads participants to prefer LeVour chocolate when information regarding the chocolate is subjectively difficult (vs. easy) to process. We find that participants primed with a mood goal evaluated LeVour chocolate more favorably and were willing-to-pay more for the collection when the ad was difficult (vs. easy) to process, but participants primed with a conflicting self-control goal preferred LeVour and were willing-to-pay more for the collection when it was easy (vs. difficult) to process, as did neutral-goal participants. In order to ensure that our results apply beyond hedonic products and to ensure that metacognitive effort is more than a justification for choosing hedonic products (Kivetz & Simonson, 2002), experiment 2 employed donation amount as the dependent variable. Charity materials, which pretested as unpleasant and negative, ensured that neither they nor the donation to the charity provided immediate pleasure. As we expected, participants primed with the goal to be a better person donated more money when they were given blurry (vs. clear) materials. In contrast, participants in the neutral-goal condition donated more money when the materials were clear (vs. blurry), replicating research on ease of processing. Finally, Experiment 3 used a chronic measure of goal to replicate this effect. It also established that instrumentality of the target object as a means to fulfilling the accessible goal mediates the effect, and the effect is attenuated when people are unable to misattribute effort to effectiveness of the target in fulfilling the accessible goal. The effects were not because of perceived scarcity of the target and people liking what is scarce. As a set these studies thus demonstrated that the effect of metacognitive ease or difficulty of processing a target object on evaluation of the target object will depend on whether metacognitive difficulty is information to the motivational system regarding effectiveness of the target object toward fulfilling an accessible goal.

“When Products Feel Special: Low Fluency leads to Enhanced Desirability”

Anastasiya Pocheptsova, *University of Maryland*
Aparna A. Labroo, *University of Chicago*
Ravi Dhar, *Yale University*

Existing research posits that feelings of high fluency which signal familiarity with an object improve its evaluation (e.g. Schwarz 2004, Winkielman et. al 2003). In a departure from those findings, we demonstrate that *low* fluency can sometimes enhance evaluation of a product. We argue that in the context of special occasion high-end goods, higher fluency which indicates abundance of the product makes the products feel less special, and this translates into lower value. Thus, low fluency of processing of special-occasion

products will make them feel more special and positively affect judgments.

Consistent with our proposition, we find, across four studies, that consumers prefer special-occasion products more when processing fluency is low. In Study 1 we show that consumers are willing to pay more for gourmet cheese that a specialty online retailer is introducing when its description is printed in a hard-to-read vs. easy-to-read font. However, the effect of font on evaluation reverses for regular cheese, which is consistent with the existing literature. Study 2 replicates these effects in the context of a special occasion versus everyday restaurant and using a different manipulation of fluency: ease of thought generation. Study 3 provides evidence of the underlying process. Study 3 manipulates the product context by using a word jumble task to prime special vs. everyday concepts and thus making different lay theories accessible, while keeping the product constant, to show the role of lay theories in the interpretation of fluency experience. We find that ease (vs. difficulty) of processing increases evaluation of the product when participants are previously primed with “everyday,” but difficulty (vs. ease) of processing increases liking of the product when participants are primed with “special.” Finally, Study 4 directly measures people’s lay beliefs to see if individual differences in beliefs account for the effect of fluency on preference. We find that consumers prefer chocolate truffles more when the information about them is presented in a difficult font. Interestingly, this effect of difficulty of processing holds only for people who have a belief that chocolate is for special occasions. We also show that when participants correctly attribute the difficulty of processing to the font, they correct (reduce) their evaluation.

Our findings contribute to the growing literature on fluency effects on product evaluations. We posit that the effect of fluency on judgments is context dependent and show that contrary to previous findings low processing fluency can lead to an increase in liking. Merely framing a product as special occasion or simply priming people with the construct of special occasion prior to the evaluation task can reverse the effects that have previously been observed in the ease of processing literature. Understanding the role of fluency in consumer decisions provides the marketers with the set of new tools to lure customers to buy their products. Current paper highlights the importance of consumption domains and consumers lay theories in the interpretation of fluency experiences and thus suggest more nuanced marketing tactics for creating attractive product offerings and improving sales.

“Contrast and Assimilation Effects of Processing Fluency”

Hao Shen, *Chinese University of Hong Kong*
Yuwei Jiang, *Hong Kong University of Science and Technology*
Rashmi Adaval, *Hong Kong University of Science and Technology*

Consumers often encounter information sequentially when browsing through magazines. For example, they might encounter articles that are perceptually easy or difficult-to-read because of the font used. These articles might be followed by ads for products. How does the subjective experience of reading an article that is easy or difficult-to-read influence readers’ reactions to a product ad that is encountered subsequently?

Some streams of research suggest that the product that is encountered subsequently will be evaluated more unfavorably if it is preceded by difficult-to-read information than if it is preceded by easy-to-read information (an assimilation effect). For example, work by Winkielman and Cacioppo (2001) suggests that positive affect is elicited if there is high processing fluency and negative affect if there is low processing fluency. If this is the case, then

several theories would predict that the affect elicited by the first task might transfer to the second task, leading to assimilation. Previous research by Fiske (1982) and Sujun (1985) also suggests assimilation effects. According to this work, feelings about the first stimulus could be transferred to the second stimulus if these two stimuli are perceived as belonging to the same category. However, other streams of research suggest that the second product will be evaluated more favorably if the processing of previously encountered material is difficult than if it is easy (a contrast effect). This could occur through three mechanisms. The first, a perceptual process, suggests that people adapt to the level of past stimuli and judge new stimuli in relation to an adaptation level (Helson 1964). Thus, difficult reading experiences could lead people to adapt to that low level of processing fluency and subsequently encountered ads could be contrasted with this adaptation level and might seem easier to process leading to more favorable evaluations. The second mechanism that predicts such effects (Adaval and Monroe 2002) suggests that participants might make a deliberative judgment of the ease or difficulty of processing information about the first product that is encountered (e.g., “This is so hard to read.”) and then use this as a standard for judging the processing difficulty of information about the second product (“This is much easier”). Finally, contrast effects could occur because people might form unfavorable evaluations of the object described by the difficult to read information that is encountered first and use these evaluations as a basis for judging the second product.

Experiment 1 demonstrates how perceptual fluency elicited in one situation can lead to contrast effects in a second situation and whether this effect occurs without participants’ awareness (as we predict) or is the result of deliberative cognitive activity. Participants were presented with a movie review (in either a difficult- or easy-to-read font) on a webpage and were told to either form an impression of the movie review or the webpage on which it was presented. Next, they were asked to evaluate a product described in an ad that used an easy-to-read font.

We assumed that participants would experience low fluency when they read the review presented in difficult font (Novemsky et al. 2007). If an easy-to-read ad is encountered later, the experienced change in fluency might be attributed to the product described in the ad and might lead participants to evaluate it more favorably than they would if the ad was preceded by an easy-to-read movie review (a contrast effect). If the above effect occurs without awareness, it should be evident only when participants focus on forming an impression of the movie review because other participants (asked to form an impression of the webpage) are more likely to evaluate aspects of its layout (such as the font, white space etc.). This process should increase sensitivity to the fonts used in the ad. The increased awareness and deliberative comparison of these fonts with those seen in the webpage earlier might reduce the effect. Results were consistent with these assumptions.

In experiment 2, participants were presented with the product ad after they had read a movie review in an easy- or difficult-to-read font. However, after they evaluated the product, they also evaluated the font of the ad and movie review. Then, they were presented with a second movie review (that was in a font similar to the first one) and a second product ad. We assumed that evaluation of the fonts in the preceding task would draw participants’ attention to fonts and should lead them to attribute processing ease or difficulty to the fonts used. Consequently, they should stop using these subjective feelings to evaluate the product in the second ad. Results were consistent with this assumption and showed that the proposed contrast effect was obtained for the product in the first ad, but disappeared for the second product ad.

Experiment 3 investigated the conditions in which assimilation effects might occur by manipulating both the fluency of the first stimuli and the relatedness between the first and second stimuli. Participants were asked to read a movie review that was presented in either difficult or easy-to-read fonts. After they had read the review, they were exposed to an ad for popcorn presented in easy-to-read font. However, in one condition the relationship between the movie and the popcorn ad was made explicit. In the other condition, this relationship was not obvious. After, reading the ad, participants were asked to evaluate the popcorn. The results of experiment 3 showed that assimilation effects occur when the two experiences are categorized together. Thus, when participants read that they could enjoy popcorn while watching the movie (high related condition), they categorized the popcorn and the movie as part of the same experience. Consequently, the difficulty of processing the movie review as a result of the fonts was transferred to the popcorn leading to an assimilation effect. In contrast, when the relatedness between the popcorn and the movie was not emphasized, the evaluation of the popcorn increased (a contrast effect) because of the processes demonstrated in previous experiments.

“Safe and Easy or Risky and Burdensome? Fluency Effects on Risk Perception and Effort Prediction”

Hyunjin Song, University of Michigan

Norbert Schwarz, University of Michigan

Six experiments extend the exploration of processing fluency to risk perception and effort prediction. Familiar stimuli are often perceived as less risky than unfamiliar ones (Slovic, 1987; Zajonc, 1980). This raises the possibility that variables that affect the perceived familiarity of a product will also affect perceptions of the risks associated with the product. One such variable is the fluency with which product information can be processed. In cognitive research, the fluency-familiarity link is reflected in erroneous recognition judgments (e.g., Whittlesea, Jacoby, & Girard, 1990) and strong feelings of knowing (e.g., Koriat & Levy-Sadot, 2001) for perceptually easy-to-process stimuli. Previous research also demonstrated, however, that processing fluency is hedonically marked and that high fluency elicits a positive affective response (e.g., Winkielman & Cacioppo, 2001). Affect associated with fluency also may be involved in intuitive judgments of risk. In light of this fluency-safety link, in the first three studies, we propose and test that difficult-to-process stimuli are perceived as more hazardous than easy-to-process stimuli, using ease of pronunciation as a manipulation of fluency.

Study 1 examined people’s hazard ratings of ostensible food additives that were described with easy-to-pronounce or difficult-to-pronounce names. We predicted and found that people perceived hard-to-pronounce substances as more harmful than easy-to-pronounce substances. Study 2 replicated this finding and examined the mediating roles of feeling of familiarity and affect. As a large body of research into the role of affect in evaluative judgment demonstrates, positive affect elicits more favorable evaluations than negative affect (see Schwarz & Clore, 2007, for a review), this raises the possibility that low risk perception for fluent objects in Study 1 and 2 may be based on high preference driven by positive affect. Study 3 addressed this possibility by examining the influence of processing fluency on judgments of risk in a risk-approach situation (the excitement and adventurousness of amusement park rides) as well as in a risk-avoidance situation (the sickening effects of amusement park rides). If the effect of fluency on judgments of risk is a mere preference based on affect, low processing fluency should result in negative evaluations of amusement park rides, which should be perceived as less exciting as well as more sicken-

ing. If risk judgment is distinct from preference associated with fluency, however, low fluency may increase risk judgments regardless of whether risks are negative (sickening effects of rides) or positive (adventurousness of rides). Study 3 supported the latter prediction: amusement park rides with difficult-to-pronounce names were rated as more exciting as well as more sickening than rides with easy-to-pronounce names. These results further indicate the distinctive effects of fluency on risk perception.

Based on the logic that people tend to misread their current feelings as about the target of judgment at hand (Schwarz, Song, & Xu, in press), the next three studies show that people mistake the fluency of reading instructions as bearing on the ease of completing the described task. In Study 4, participants read exercise instructions either in easy-to-read fonts or in difficult-to-read fonts and predicted longer completion time and low fluency of movements in an exercise when instructions were printed in difficult-to-read fonts than in easy-to-read fonts. In addition, participants were more willing to incorporate the exercise in their daily routine when they read the instructions in easy-to-read fonts than in difficult-to-read fonts. In Study 5, participants read a recipe for a Japanese roll in easy-to-read fonts or in difficult-to-read fonts. They predicted that preparing the roll would take more time, and reported less willingness to try the recipe, when the fonts were difficult rather than easy to read. Study 6 further showed that participants perceived the recipe as requiring more skill from the cook when it was presented in a difficult to read font.

SYMPOSIUM SUMMARY

Status: Why Consumers Engage in Conspicuous Consumption and How they may be Perceived

Joseph C. Nunes, University of Southern California, USA

EXTENDED ABSTRACTS

“The Intrinsic Benefits of Status: The Effects of Evoking Rank”

Aarti S. Ivanic, University of Southern California
Joseph C. Nunes, University of Southern California

Status, defined as one's ranking in the vertical stratification of social groups, is recognized as an important motivator of human behavior. The attainability and procurement of status has evolved over time from titles bestowed by birth to those earned or achieved. Today, a consumer can obtain status by demonstrating loyalty to a firm. More and more companies have begun stratifying customers in order to award their best customers with status. Elite customers are provided perks that enhance the experience and inducements that make future purchases more appealing. Special services, whether it is preferential seating, extended store hours and special sales, differentiate classes of customers into tiers of haves and have-nots. Whether it is admission to exclusive events or waiting in a special queue at the airport, each is a signal that the consumer is one of the haves. While many benefits signal one's status to others, firms also provide consumers with benefits that are consumed in private. For example, Continental airlines provides a dedicated phone line, priority on wait lists, expanded award availability and a no middle seat guarantee to Platinum members who fly at least 100,000 miles. These are benefits that are likely to go unnoticed by other fliers and often fail to appreciably alter the travel experience. The Platinum member's wait on the help line may occasionally take longer than normal or the flier may not clear the wait list despite having been bumped to the top. Yet, we propose elite members still derive emotional benefits from these perks making the airline's decision to provide these benefits a prudent one.

Research in marketing has focused on status goods for which the primary benefit is social. Veblen (1899) suggested that individuals acquired and consumed certain goods to signal their wealth and thus place in society to others. The marketing literature has shown that consumers acquire and use status goods to convey a particular image to those around them (Bagwell and Bernheim 1996). This conspicuous consumption of ones' status generates psychological responses such as feeling unique, distinctive and different from others (Tian, Bearden and Hunter 2001; Belk 1988; Tian and McKenzie 2001; Lynn and Harris 1997). However, not all benefits of status are social. Researchers have hypothesized that the attainment of status is no different from an “intrinsic emotional goal” that generates positive, affective reactions and emotions such as happiness and pride (Berger, Wagner and Zelditch 1985; Urda and Loch 2005). Yet, the intrinsic benefits of status have largely gone unexplored. In our work, we focus on the emotional gratification that accompanies the exercise of one's position or what is commonly referred to as “pulling rank” separate from the material and social benefits. We argue that utilizing one's status is emotionally gratifying as it makes one's elevated position or status identity salient.

We propose that *achieved* status (i.e., profession, status through a loyalty programs) can be represented by *role* identities and *endowed* (i.e., gender, race) status by *social* identities. We show that this distinction differentially impacts how individuals behave when these status identities are activated. Research has suggested

that by activating a particular identity, attitudes and behaviors consistent with that identity are brought to mind, which in turn cause individuals to behave in a manner consistent with these attitudes (Reed 2004; Forehand and Deshpande 2001). Identity salience has been shown to impact one's attitude towards others (Deshpande, Hoyer and Donthu 1986), performance on quantitative tests (Shih, Pittinsky and Ambady 1999) and brand loyalty as well as preferences for prestige products (Deshpande, Hoyer and Donthu 1986). Yet, individuals do not always conform to the attitudes of a particular status group. We will show that there are instances where individuals act in discordance with the group norms and activated group stereotypes. In our work we explore the crossroads of status and identity theory and show that *status* identity salience differentially impacts consumers' behavior, specifically how much they are willing to pay for a product.

In Study 1, we show that when one's *achieved* status identity is made salient, individuals engage in behaviors that match the expectations associated with that status-role. In Study 2, we demonstrate that status role-congruent behavior results in the intrinsic benefit of prestige, distinct from the social benefit of identity signaling or any material or more tangible benefit. We demonstrate that while possessing status results in an elevated sense of prestige, individuals heighten these feelings by exercising their status (choosing to wait in a special status-only queue).

We extend our result to a consumer domain in Study 3 showing how making a relatively high *achieved* status identity salient leads individuals to pay more for a product than when a low status identity is activated. In doing so, high status individuals fulfill their status-role by acting in line with the behavioral expectations (i.e., pay more than low status individuals) associated with that role. In Study 4a, we document a racial stereotype which suggests that traditionally characterized high status individuals (i.e., White Americans) will pay more for a product than low status individuals (i.e., African Americans). In study 4b, we show how making an individual's *endowed* status identity (race) *implicitly* salient results in behavior congruent with the stereotype (i.e., African Americans pay *less* than both White Americans and the baseline-control group), while making a low-status racial identity *explicitly* salient causes individuals to act in discordance with the stereotypes (i.e. African Americans voluntarily pay *more* than both White Americans and the baseline-control group).

As firms increasingly endow their most loyal customers with status, it is important to better understand how consumers respond to status rewards which are conferred by a firm. Our results underscore the importance of understanding how consumers derive intrinsic benefits, in addition to social and material benefits, from status reward consumption. Further, we provide a better understanding of how status identity salience can result in differential responses to status cues utilized by marketers.

"Effects of the Density of Status Distribution on Conspicuous and Inconspicuous Consumption by Low-Status Consumers"

Nailya Ordabayeva, INSEAD
Pierre Chandon, INSEAD

It is a well-known and well-deplored fact that less well-off people spend more on status-enhancing positional products and save less money as a proportion of their income than richer people (Bagwell and Bernheim 1996; Christen and Morgan 2005; Duesenberry 1949). Economists have argued that one solution to this problem is to increase the density of the distribution of status by redistributing wealth through income or consumption taxation (Frank 1985, 1999). Although increasing status density can reduce envy and overall positional spending, this argument overlooks that it can increase the gains in status (i.e., improvement in social rank) resulting from conspicuous consumption for people at the lower tiers of the distribution. Therefore, increasing status density may have the unintended effect of actually encouraging low-status people to choose conspicuous consumption over savings.

In this research, we examine how the distribution of status across people affects choice between spending and saving, conspicuous and inconspicuous consumption by low-status people. We hypothesize that (1) increasing status density (i.e., increasing the proportion of people with an average level of status) encourages

positional spending among low-status people even though it reduces their envy, (2) this occurs because of the higher gains in status resulting from conspicuous consumption in a dense (vs. wide) distribution, and (3) this occurs only when positional utility is primed and only in a competitive social environment. We test these hypotheses in five experiments.

In Study 1, we examined the effect of status density on envy and choice between spending and saving by low-status people. We manipulated between subjects the distribution of people's endowments with a positional product—the number of rose bushes in the front garden. In the scenario, 10% of people had no rose bushes. Forty percent of people had two rose bushes in a dense distribution and only twenty percent did so in a wide distribution. Buying three bushes enabled the 10% of people with no bushes to get ahead of 40% of people in the dense distribution and only 20% in the wide distribution. We found that low-status people were less envious but spent more in the dense (vs. wide) distribution. Furthermore, we found that social comparison orientation influenced envy but not positional spending. This suggests that conspicuous consumption is driven by status gains and not by envy or social comparison orientation.

In Study 2, we tested whether our theory accurately predicts the conspicuous consumption of high-status as well as low-status individuals in the context of decisions made for themselves rather than for hypothetical others. The participants were told that they would play an ultimatum game and try to split 10 chocolates with one other participant. Prior to the game, they were randomly assigned one star (low status) or three stars (high status), and they saw a dense or a wide distribution of stars obtained by previous participants. The participants were told that the number of stars would be public during the game and could affect their final outcome in the game. Consequently, before the actual game, the participants were given a chance to buy two additional stars at their own expense. We measured the willingness to buy stars and found that, consistently with our theory, low-status individuals were more willing to buy additional stars in a dense (vs. wide) distribution, but the opposite occurred for high-status individuals.

In Study 3, we distinguished between conspicuous and inconspicuous consumption and checked whether high status density indeed enhances perceived gains in status. The participants read two scenarios (house garden and ski trip) and judged how willingly low-status people in a dense or a wide distribution would spend money on positional products (rose bushes in the front garden and branded scarves for a ski trip) or non-positional products (pine trees in the back garden and unbranded scarves for a ski trip) and to which degree each type of spending would improve their status. We found that high status density encouraged conspicuous consumption but discouraged inconspicuous consumption. We also found that perceived status gains were higher in the dense (vs. wide) distribution for both positional and non-positional products. This indicates that high status density leads low-status people to choose consumption over saving only for positional products.

In Study 4, we further tested the moderating role of positional utility, but not as an inherently given product characteristic, but as a primed mindset. We also examined whether status is inferred from rank in the distribution of income, as assumed in previous literature, as it is in the distribution possessions. First, the participants engaged in a sentence scrambling task, which primed positional or non-positional utility. Then they studied a newsletter about their rival colleagues, which featured a dense or a wide distribution of their salaries. Finally, the participants needed to choose between an expensive trendy restaurant (positional option) and an inexpensive traditional bistro (non-positional option) for dinner with these

colleagues. We measured the preference for the positional option, and found that a dense distribution of income increased the preference for the positional option only when positional utility was primed.

In Study 5, we further explored boundary conditions by examining the effect of reference group competitiveness. The participants read the same newsletter with a dense or a wide distribution of income as in Study 4, except that in the competitive group condition, the scenario featured rival co-workers, and in the cooperative group condition, it featured old friends. The participants faced the same decision between a trendy restaurant and a traditional bistro. The results showed that high income density strengthened people's preference for the positional option in the "rivals" condition but not in the "friends" condition.

In summary, we show that high status density increases conspicuous consumption among people in the lowest tier of the distribution across various distributions of status, in hypothetical and real decisions, and in the distributions of product endowments and income. Our results provide insights about the drivers of conspicuous consumption and the potential effectiveness of wealth redistribution policies and thus have important implications for future research and public policy.

"Stigmatizing Materialism: On Stereotypes and Impressions of Materialistic Versus Experiential Consumers"

Leaf Van Boven, University of Colorado at Boulder
Margaret C. Campbell, University of Colorado at Boulder
Thomas Gilovich, Cornell University

Observers of consumer behavior routinely fret about modern society's materialistic pursuit of happiness and well-being. Americans are reputed to value "having" over "being," which gives rise to alienation (Fromm 1976). Childhood consumer culture (Schor 2004) is charged with stoking materialistic desires that can only be satisfied by overspending (Schor 1999) and overworking (Schor 1993)—symptoms of a "suicidal" "affluenza" (De Graaf 2001; Lasn 2000). These materialistic desires are thought to contribute to declining social engagement (Lane 2001; Putnam 2000) by "crowding out" social relations (Kasser 2002; Lane 2001).

Not just social critic hyperbole, behavioral science indicates that materialistic consumers, those who believe that material possessions can make them happy, rate their social relations less favorably (Kasser and Ryan 2001), are more likely to be from divorced families (Rindfleisch, Burroughs, and Denton 1997), and are more likely to be diagnosed with psychological disorders

reflecting poor social functioning, including separation anxiety, paranoia, and narcissism (Cohen and Cohen 1996). Most explanations of the negative correlation between materialism and social relations focus on materialistic consumers' personalities and proclivities (Burroughs and Rindfleisch 2002; McHoskey 1999; Richins and Dawson 1992).

In this paper we shift the focus from materialistic consumers themselves to the stereotypes, or mental representations, that other people have of materialistic consumers. Using consumers who purchase experiences to gain happiness and life satisfaction as a comparison, we suggest that people stigmatize materialistic behavior by applying relatively unfavorable stereotypes of materialistic versus experiential consumers. That materialistic behavior is stigmatized—regarded as "worthy of disgrace or disapproval" (dictionary.com)—leads people to form relatively unfavorable impressions of consumers who are associated with materialistic behavior.

We tested the nature of people's stereotypes of materialistic and experiential consumers in one pair of studies. Participants were asked to generate the traits associated with materialistic and experiential consumers (study 1). A separate group of participants rated the traits associated with materialistic consumers less favorably than the traits associated with experiential consumers, despite not knowing the traits' initial association. In another study, participants rated specific material purchases made by materialistic consumers as more extrinsically motivated and less intrinsically motivated than specific experiential purchases made by experiential consumers (study 2).

These stereotypes of materialistic and experiential consumers influenced people's impressions of others' consumer behavior in another study in which people from various demographic groups formed an impression of another consumer (study 3). Participants learned only that the consumer purchased a prototypically material purchase (a new shirt) or a prototypically experiential purchase (a ski pass), without explicit mention of the distinction between materialistic and experiential purchases. Participants evaluated the consumer of a prototypical material purchase less favorably than the consumer of a prototypical experiential purchase. The stereotypes of materialistic and experiential consumers were sufficiently potent to influence people's impressions of each other during face-to-face conversations about materialistic versus experiential purchases, despite the fact that the experimenter constrained the conversation topic (study 4).

In study 5, we experimentally manipulate the extrinsic versus intrinsic motives underlying consumers' acquisition of prototypical material and experiential purchases. We showed that participants formed less favorable impressions of consumers who made extrinsically motivated purchases (e.g., skiing to gain "bragging rights") than of consumers who made intrinsically motivated purchases (e.g., buying a new watch because of its enduring value), independent of whether those purchases were prototypically materialistic or experiential.

The present research indicates that because there is a stigma attached to materialistic consumers, materialistic consumer behavior may not foster successful social relationships as well as experiential consumer behavior. The results of these studies undoubtedly reflect culturally constructed and shared values, like the cultural construction of materialism more generally (Belk 1985; Burroughs and Rindfleisch 2002). Stereotypes about materialistic and experiential consumers carry cultural meaning in much the same way as do specific products (Richins 1994) and brands (Aaker, Benet-Martinez, and Garolera 2001). Our studies thus imply that consumers in a particular cultural context—predominantly members of

middle socioeconomic class—attach a stigmatization to materialistic consumers that leads them to form relatively unfavorable impressions of consumers associated with materialistic purchases.

The results of these studies provide consistent evidence that materialistic consumers are stigmatized compared with experiential consumers and that people form relatively unfavorable impressions of consumers who are associated with materialistic purchases. These results have important and complementary implications both for consumer welfare and for marketing practitioners. For consumers, these results suggest that, to the degree they desire to be favorably evaluated, they might avoid being associated with materialistic consumer behavior. Or, expressed more positively, these results reiterate a useful strategy for investing their resources in pursuit of happiness—to purchase experiences rather than possessions (Van Boven and Gilovich 2003). Similarly, when making materialistic purchases, consumers should highlight their intrinsic motivations for the purchases. For marketers, these results highlight the potential benefits of emphasizing experiential products, material products' intrinsically appealing attributes, and of avoiding associations with materialistic stereotypes.

SYMPOSIUM SUMMARY

Acculturation and Consumer Behavior: Building Cultural Bridges Through Consumption

Lisa Peñaloza, University of Utah, USA

SESSION OVERVIEW

This Special Session focuses on one of the most characteristic phenomena of the 21st century—immigration and *acculturation*. By presenting findings from four countries, it aims to advance acculturation theory and provide consumer behavior researchers with a forum to share ideas, perspectives, and theories relating acculturation to consumption. Since the acculturation-consumption link remains under-researched, scholars are likely to be interested in a cutting-edge forum on it. The session will also offer a networking opportunity for scholars pursuing acculturation research. By bringing together researchers who study the wide range of behavior of different ethnic minorities around the globe, the session can *contribute* to the consumer behavior field by advancing the theory on acculturation. The *likely audience* will include researchers interested in studying acculturation and cross-cultural consumer behavior.

The four papers span a wide range of consumers' acculturation aspects. The *first paper* on Indian UK immigrants argues that religion's role in acculturation is often oversimplified; it demonstrates that religion, through acculturation, should be seen as a normative political ideology. The *second paper* on US Hispanic immigrants investigates the relationships between acculturation and consumer attitudes and behaviors. Its findings suggest that individual and environmental factors affect immigrants' chosen acculturation strategy and that acculturation levels determine consumers' loyalties to brands/stores. The *third paper* extends acculturation theory by integrating a historical perspective into it. It argues that the host and the original countries' historical relationships affect immigrants' consumers' acculturation. It compares consumer identity construction of French Algerian and Turkish immigrants. The *fourth paper* on Israeli Russian immigrants argues that being immigrants involves a sense of distinctiveness from the host country's population, which may be accompanied by negative feelings of being outsiders rather than positive feelings of being unique. Consumers' need for uniqueness among immigrants was found to be associated with acculturation motivation and ethnic identification.

EXTENDED ABSTRACTS

“Acculturation, Religion and Consumption in Normative Political Ideology”

Andrew Lindridge, Open University Business School, Germany

Calls for studies into religion's influence on consumption (e.g., Douglas and Craig 1992) have not produced a significant response. We address these calls by considering how religions and related acculturation tensions affect consumption. We advance existing theories within a group of second-generation Indians living in Great Britain who have experienced, to varying degrees, segregation on the basis of their ethnicity and, more importantly, religious identity. Specifically, differing religions as acculturation agents result in consumption choices that reflect differing acculturation and political/ideological outcomes. This is illustrated by exploring these themes through the ultimate expression of Western culture; individuality expressed through materialistic consumption, a choice supported by previous research into aspects of these

themes (Crockett and Wallendorf, 2004; White and Dahl, 2007). Consumption can be identified with specific cultural-religious meanings (McCracken 1986). Religion's meaning and effect on consumption must be considered in the context of social (formal laws, informal social norms) and personal choices (individuals' religious adherence and their need to express a religious identity; Cosgel and Minkler 2004a/b). Hence, how an individual uses consumption to express their strength of and identification with religion will ultimately express their identification with their ethnic group, their acculturation level and political/ideological outcomes.

We followed Venkatesh's (1995) qualitative ethno-consumerism framework and interpretivist studies (e.g., Holt and Thompson 2004). The sample consisted of 16 British-born Indian women from a British university. All were self-identified as second generation Indian, aged 18-25, and consisted of six Hindus, six Sikhs and four Muslims. Participants were interviewed using semi-structured questions over 13 months, each on two separate occasions.

All participants' behaviours were typical of a dialogical acculturation model by switching behaviours to adapt across contexts and had similar acculturation levels on language, food and media consumption, and clothing. All had experienced difficulties over their ethnic and religious identities and acknowledged sharing similar amount of time in engaging with their religious identity and related behaviours. All noted the complexity of their religious identity within their own acculturation identity. Of particular interest was how Hindus and Sikhs religious identity reflected Cosgel and Minkler's (2004) social choice, in contrast to Muslims' personal choice.

Hindu participants viewed their religious identity only as an aspect of their life, engaged on a selective basis when needed. Religious-consumption was limited to specific festivals or family gathering. Life in Britain represented an easy transition without acculturation tension. In contrast, religion for Sikhs produced a stronger sense of religious identity, albeit one that didn't adhere closely to Sikh religious teachings. Religious orientated consumption was minimized; instead their families used conspicuous consumption to reinforce a public image of acculturation success; a public display that centred on their interactions around their local Gurdwara (a Sikh religious building). Muslims expressed a distinct distancing from Western-cultural consumption narratives. Materialistic behaviours were dismissed as un-Islamic. Their narrative reflected an acculturation paradox. Whilst they rejected aspects of their parents' Indian culture towards materialistic consumption, they attempted to forge an Islamic identity that rejected Western-cultural values of consumption whilst accepting the more liberal aspects of British society. The latter was behaviourally strongest of all participants on the basis of religious identity. Their behaviours reflected aspects of White and Dahl's consumer identity and dissociative influence (2007) and Crockett and Wallendorf's (2004) on political ideology in consumer behaviour. Why these differences emerged partly lied in participants' choices to access their religion's teachings and how they negotiated and understood their acculturation experiences. In sum, religion's affect on acculturation and consumption is more complex than previously thought. Normative and political ideologies need to be considered with acculturation and religion's consumption impacts.

"A Comprehensive Model for Hispanics' Acculturation: Antecedents and Impacts on Store and Brand Loyalty"

Aviv Shoham, University of Haifa, Israel
Sigal Segev, Florida International University, USA
Ayalla Ruvio, University of Haifa, Israel

Global immigration and cultural diversification highlight the importance of acculturation. Immigrants bring cultural characteristics from their native countries, while adapting to new cultures changes attitudes and consumption behavior (Berry, 1980). Consumer behavior acculturation studies are scarce, lack integration, and tend to be theoretical rather than empirical (Ogden, Ogden & Schau, 2004). We integrate concepts from acculturation and consumer behavior literature and our empirical study identifies individual and environmental factors affecting acculturation, uses a bi-dimensional acculturation concept, and explores the impact of the chosen acculturative strategy on US Hispanics' consumption. *Acculturation* refers to social/psychological changes resulting from contacts between individuals from different cultures during which immigrants acquire attitudes, behaviors, and cultural identity of host and integrate them with their original cultures' (Herskovits, 1936). Acculturation theories address immigrants' adaptation to host cultures. A bi-dimensional model of acculturation includes original culture maintenance (OCM) and host culture adherence (HCA) (Berry, 1980), which provide a better fit to the acculturation reality, allowing individuals to maintain or neglect their original culture while participating in the host culture (Cabassa, 2003).

We include ethnic identity, adaptability to change (individual level) and intercultural peer contact (environmental level) as antecedents. *Ethnic Identity* refers to individuals' affiliation with a cultural group. While ethnic identity and acculturation are related and affect immigrants' adaptation, research on their relationship is inconsistent. Some view ethnic identity as influenced by acculturative changes in the new culture over time (Ward, 2001). Others argue that ethnic identity affects acculturation (e.g., Peñaloza, 1994). While acculturation is a process of change, ethnic identity may or may not be static (Ogden, et al., 2004). Hence, we view ethnic

identity as an antecedent of integration into the host culture. *Adaptability to change* refers to individuals' ability to cope with and adapt to changes. It affects cultural adjustment and change-accepting immigrants should adapt more to the new culture (Valdes, 2002). *Intercultural Peer Contact* refers to the extent of immigrants' contact with peers from the host culture, who can inhibit or accelerate acculturation (Searle & Ward, 1990)

Notably, Hispanics may (Segal & Sosa, 1983) or may not (Saegert et al., 1985) be more brand-loyal than others. We broaden loyalty to include brands and stores, add an orientation dimension (Hispanic/General Market), and argue that assimilators will prefer General Market (GM) brands/stores and acculturating individuals will prefer ethnic ones.

Methodology, Findings, and Conclusions

A sample of 208 Hispanic-origin individuals in the Miami area provided data. English and Spanish questionnaires were used with scales for intercultural peer contact, ethnic identification, adaptability to change, acculturation, and brand and store loyalty.

Individuals with conational peers and strong ties with them used OCM acculturation strategy. As conational peers satisfy immigrants' need for a social framework in the host country, they discourage immigrants from seeking friendships with host-culture individuals. Ethnic identity was associated with OCM but not HCA acculturation strategy. Individuals' sense of pride, belongingness, and satisfaction with their original culture reduced their adoption of the host culture. Tolerance to change facilitated the utilization of HCA acculturation strategy and decreased the use of OCM strategy. The data mostly supported the proposed relationships between the two acculturation strategies and consumer behaviors. Hispanics, who adhered to the host country exhibited loyalty to Anglo stores and brands and disloyalty to Hispanic stores (but not Hispanic brand). Two possible explanations for this finding: practically, GM stores in the study's region sell a variety of Hispanic ethnic products that might satisfy the basic needs of assimilated individuals; at the image level, assimilators might deliberately refrain from being seen in ethnic stores, which might signal their differentiation and segregation and categorize them as outsiders to the dominant society. Hispanics high on OCM should be loyal to Hispanic stores and brands, and will not associate OCM with loyalty to Anglo stores and brands.

"How Do Historical Relationships Between The Host and Home Countries Shape The Immigrants' Consumer Acculturation Processes?"

Nil Ozcaglar-Toulouse, *Universite de Lille, France*
Tuba Ustuner, *City University London, UK*

Following the deaths of two second-generation immigrants of *banlieue*, weeks of rioting in the Paris region forced the French media to pay more attention to the country's minorities. We believe that these minorities, marginalized as such, experience 'dominated consumer acculturation' (Üstüner and Holt, 2007). Much like the rural-to-urban migrants that Üstüner and Holt studied, these minorities live in a society that undermines the building blocks of their identities: their ethnicities. In Üstüner and Holt's study the form of domination was based on social class. The rural-to-urban migrants constituted the lowest class in the city and therefore were bearing a heavy class-based social stigma. Additionally, the consumer acculturation processes they experienced were more problematic than previously argued in the literature.

Several studies have investigated the socio-historic patterning of consumption (see Arnould and Thompson 2005). In particular, there is an evolving consumer research literature which focuses on consumer acculturation and identity construction of immigrants. Peñaloza's (1994) studied the consumption experiences of Mexicans in the US and provided a dynamic approach to acculturation models. Oswald (1999) saw acculturation as a form of cultural swapping and argued that immigrants borrow cultural elements of the home and host country. Askegaard, Arnould, and Kjeldgaard (2005) argued that the transnational consumer culture is also an acculturative agent. While this literature contributed to our understanding of consumer acculturation it did not consider the historical, social, and cultural context within which acculturation takes place. Üstüner and Holt's study (2007) is an exception, which argued that migrants are not the sole acculturation agents: social and historical factors also matter. Coining the term 'dominated consumer acculturation' Üstüner and Holt demonstrated how class-based domination shaped rural-to-urban migrants' acculturation to their new social setting.

We extend Üstüner and Holt's critical approach to acculturation and argue that social-class is only one form of domination. Most immigration today takes place from less developed, mostly colonized countries, to more developed, mostly colonizing countries. The forms of domination these immigrants face in their host countries are not limited to social-class. There are historical tensions between the host and home countries, stigmas associated with each other's cultures. Accordingly, we are interested in uncovering the ways in which such a cultural history shapes immigrants' collective memories and consumer identities. We ask two questions: How is the colonial social memory represented in immigrants' personal identities and expressed through consumption? What are the impacts of tensions on immigrants' acculturation process?

This research considers both the generational and ethnic differences among immigrants to answer these questions. It com-

pares consumer identity construction processes of second-generation Algerian immigrants (with a colonial past) to that of Turkish immigrants (without a colonial past, but with recent tensions with France). While Algerians' social memory carries mixed feelings and memories about France and the colonial period, Turks' does not. While Turkish immigrants do not have a similar cultural history and institutional memory, tensions have emerged between France and Turkey over Turkey's historical relationships with Armenians and Kurds and over its demand to become an EU member. The study then compares acculturation processes of second-generation immigrants. If communitarian allegiances are based on regional, village, or ethnic ties and historical narratives for first-generation immigrants, for second-generation ones, however, they often take the form of emotional/nostalgic attachments to a particular origin or to a 'second-hand memory'. This attachment is more mythic than real, and often a corresponding reinforcement of the division between 'them' and 'us'. This is particularly the case in a context of exclusion and stigmatization, like in the *banlieue*. While this study is a work-in-progress, we will present the first comparative analysis at the conference.

This research is supported by the French "Agence Nationale de la Recherche" (ANR).

"Unique or Different: The Role of Consumers' Need for Uniqueness in the Acculturation Process"

Ayalla Ruvio, *University of Haifa, Israel*
Walsh Gianfranco, *University of Koblenz-Landau, Germany*
Sigal Segev, *Florida International University, USA*

Uniqueness holds a positive connotation in Western societies. It involves a feeling that sets individuals apart from the crowd, but in a manner that is appreciated by others. Tian et al. (2001, p. 52) defined consumers' need for uniqueness (CNFU) as "the trait of pursuing differences relative to others through the acquisition, utilization, and disposition of consumer goods for the purpose of developing and enhancing one's self-image and social image". CNFU is a means for satisfying NFU by using possessions creatively, making unpopular consumption choices, and avoiding buying and consuming commonly used products. According to Tian et al. (2001), all individuals use these consumption behaviors to some extent to establish a unique social image. Immigrant

consumers often feel different from the population in the host country on the acquisition and use of consumer goods. Such distinctiveness is often accompanied by a feeling of being outsiders rather than by being unique. Thus, consumption is culturally-bound, which requires immigrants to adapt their behavior to the host country's consumer culture (Ownbey & Horridge 1997; Peñaloza 1994). Hence, the issue of reference groups becomes more complex for immigrants. The original ethnic community has its own language, customs, and consumption behavior whilst the new host community exerts pressure on immigrants who want to build a new life and develop a sense of belonging to adopt its consumption style (e.g., Deshpande, Hoyer & Donthu 1986; Xu et al. 2004). Under these conditions, expressing uniqueness is a challenge.

Immigrants can overcome this challenge by acculturating as a means of creating a unique self-image. By adopting the consumption behaviors of the host population, immigrants can set themselves apart from their original ethnic group, but in a manner that is approved by the majority host population. In this case, a strong motivation to acculturate will be positively associated with CNFU that is benchmarked against the original ethnic group. Alternatively, immigrants can take the opposite approach for establishing a unique identity. They can express their ethnic identity in order to distinguish themselves from the majority host population. In this case, individuals will acquire, use, and display possessions that highlight their ethnic group. Choosing to express uniqueness in this manner will be appreciated by the original ethnic group but may result in social and even legal sanctions from the majority host population. We argue that immigrants' CNFU is associated with their motivation to acculturate and with consumer behavior. Consumers' susceptibility to interpersonal influence (CSII) and ethnic identity serve as predictors of CNFU, which serves as an antecedent to acculturation strategies. Innovative shopping and the desire to purchase unique products were used as consequences of acculturation strategies. All constructs were tested in relation to the host community (the general Israeli population) and to the original culture (the former Soviet Union-FSU).

Method, Findings, and Conclusions

Information was gathered using a closed-end questionnaire from a convenience sample of 177 adult immigrants from FSU. Structural equation modeling was used to test the model.

Individuals with a strong FSU identity display their uniqueness in the FSU community. No relationships were found between identification with the Israeli community and CNFU. On the other hand, susceptibility to influence from the Israeli community was associated positively with uniqueness manifestations in the FSU community and the general Israeli population. No relationships were found between susceptibility to influence from the FSU community and CNFU. The expression of CNFU in the FSU community was associated positively with the original culture maintenance strategy of acculturation and host culture adherence. CNFU's projection in the Israeli community was negatively related to the original culture maintenance strategy of acculturation and had no relationship with host culture adherence. High host-culture-adherence individuals had a strong desire for unique Russian products and a high level of shopping innovativeness for Israeli and Russian products. Immigrants who chose to preserve their original culture demonstrated a strong desire for unique products and innovative shopping for Russian products only. In sum, immigrants do fuse the formation of their unique identity with their chosen acculturation strategy, which ultimately affects their consumer behavior.

SYMPOSIUM SUMMARY

Production and Reproduction of Consumer Culture in Virtual Communities

Aron Darmody, York University, Canada

Ryszard Kedzior, Swedish School of Economics and Business Administration, Finland

SESSION OVERVIEW

The emergence of consumer culture is rooted in the fact that consumption became a central facet of modern life. In order to understand consumer behavior in contemporary society it is necessary to explore the myriad consumer practices through which consumer culture is (re)produced. Such practices can be studied on the individual, societal or institutional levels, and consumer culture can also be viewed as both a material consequence and a symbolic representation of consumer actions. Many of the most recent and significant developments within consumer culture have been Internet-related phenomena such as online brand communities, social networking sites and consumer-inhabited virtual worlds. In this session we explore issues pertaining to the (re)production of a consumer culture by looking at consumer-constructed virtual identities, new interactive contexts of brand-consumer relationships and alternative regimes of materiality present in digital environments. Following is a presentation of the main themes covered in this symposium:

Online Identity Performance and Maintenance

As evidenced by previous research (e.g. Turkle 1995; Markham 1998) virtual environments represent a potent stage for identity construction and identity play. Much like in the offline world, consumers use marketplace resources such as brands and ideologies to represent their *Selves* online. Schau and Gilly (2003) for instance, demonstrate how consumers use brands and hyperlinks to create multiple non-linear cyber self-representations. However, recent developments in social networking sites (SNSs) and virtual worlds have presented consumers with myriad of other opportunities to pursue their virtual identity projects. Consumers online act as cultural bricoleurs mixing and matching different forms of digital cultural resources in order to create narratives of their identity. Consumer-generated as well as market-produced content constitutes the core of popular web platforms such as YouTube or Second Life. These examples attest to the significance of understanding consumer behavior in virtual environments, hence this track explores different practices that consumers employ to orient themselves in a new virtual reality.

Mapping Out Digital Materiality

Non-physical aspects of consumption play increasingly important roles in many facets of the economy, including production (i.e. as evident in the Post-Fordist shift from structured manufacturing to flexible, information-driven service industries), but also in the constitution of brand value (Arvidsson 2006), and of commodity value (which has become ever more dependent on non-material components such as aesthetics). The valorization of product and service experiences as means to achieving competitive advantage serves as a good illustration of this process (e.g. Pine and Gilmore 1999). In addition, the notions of the society of spectacle (Debord 1994[1967]) and hyperreality (Baudrillard 1983[1970]) demonstrate how the non-material composition of consumption is reflected in the fact that consumers frequently encounter products only in the form of mediated representations such as marketing communications (advertising), or other pop-culture outlets (TV shows, magazines). Moreover, in the information economy, even

the traditionally tangible processes of production are increasingly governed by non-material functions involving knowledge, science, expertise, systems, planning and cybernetic skills. Contemporary consumption can be characterized by growing dematerialization of objects and commodities (Slater 1997). Taking as a starting point digital materiality of the virtual world (i.e. *Second Life*) we problematize new *materialities* which are beginning to dominate our contemporary culture.

Understanding the Impact of Consumer-Generated Content for Cultivating the Brand-Consumer Relationship in the Marketplace

Consumer-generated content on the Internet provides abundant and valuable resources for marketers and brands to better understand current consumer practices and to more accurately predict emergent ones. The new technology not only provides an expanding array of platforms on which consumers can share their opinions and concerns, but it also facilitates closer and more engaging ongoing relationships between consumers and brands (Cova and Pace 2006; Muniz and O'Guinn 2001). Within this relationship the consumer is more empowered and granted a more influential and active voice in the process of brand-meaning construction and (re)positioning (Muniz and Schau 2005). Moreover, in virtual communities such as *Second Life* and social networking sites (SNSs) like *Facebook*, self-organizing consumers are (re)producing consumer culture through individual and multi-level group interactions. In many instances, brands and other marketplace symbols can play important roles in developing and reinforcing individual consumer identities, and in providing substance for online consumer community formation. Current consumer practices in the virtual world create new opportunities for marketers and their brands to activate consumers and engage them in brand-consumer relationships beyond the existing website-based brand communities.

Changing Socialscapes as the result of the Intersection between Offline and Online Reality

Since the emergence of the Internet we have seen a steady extension of consumption into new digital domains as consumers are living more and more of their lives online. Tremendous amounts of time online are spent on activities such as shopping, social-networking, gaming, socializing, dating and working. Social networking sites (SNSs) such as *Facebook*, *Myspace* and *Bebo*, and virtual worlds such as *Second Life*, have in recent years grown to become some of the most important sites for consumer interactivity (largely self-organized) on the web. Many online consumer activities are now being enacted on the burgeoning range of virtual worlds and SNSs, which have become powerful vehicles for self presentation, impression management, friendship performance and relationship management (boyd and Ellison 2007). We explore how consumers use different digital cultural resources in SNSs and virtual worlds to such ends, as well as to investigate how they facilitate the continuous convergence of online and offline consumer social relationships. As these sites have become an indispensable part of our society, we seek to illustrate how the boundaries between offline and online realities merge.

EXTENDED ABSTRACTS

"I Get by with a Little Help from My Friends: Consumer Creativity in Virtual Communities"

Aron Darmody, York University, Canada

Eric P. H. Li, York University, Canada

The market offers myriad opportunities for consumers' creative expression, from how they appropriate cultural and marketplace resources for their identity projects (Holt 2002; Holt and Thompson 2004), how they actively localize the global (e.g. Kjeldgaard and Askegaard 2006) to how they re-imagine consumption spaces and play within them (Kozinets et al. 2004). However, the topic of consumer creativity has not been the core focus of these studies. Instead, the majority of extant consumer creativity research has been focused on consumer creativity in problem-solving contexts (e.g. Burroughs and Mick 2004; Hirschman 1980).

In one of the first and most enduringly influential studies on the topic, Hirschman (1980) defined consumer creativity as "the problem-solving capability possessed by an individual that may be applied toward solving consumption-related problems" (p.286). Subsequent consumer creativity studies have closely adhered to that early conceptualization, wherein consumers are creative when they are required to respond to an impediment in a problem-solving context: when a problem arises, and no preexisting solution exists, the consumer must creatively construct a solution (Burroughs and Mick 2004; Dahl and Moreau 2002; Hirschman 1983; Moreau and Dahl 2005; Ridgway and Price 1994). Recent contributions in this vein include depiction of how analogical thinking by consumers facilitates originality in concept ideation and design (Dahl and Moreau 2002), and how input constraints influence the way in which consumers process information during a creative task and

can lead to instances of increased creativity (Moreau and Dahl 2005). Additionally, Burroughs and Mick (2004) investigated antecedents to and consequences of creative consumption. Their findings showed that two person-based antecedents (metaphoric thinking ability and locus of control) and two situation-based antecedents (situational involvement and time constraints) influence creative consumption, and the consequence of higher levels of creativity in response to a consumption problem leads to increased positive affect, including feelings of increased accomplishment, satisfaction, pride and confidence (Burroughs and Mick 2004).

Although varied in focus and scope extant consumer creativity studies share two other interrelated features beyond the common problem-solving perspective. Firstly, the overwhelming focus in consumer creativity is on consumers' cognitive processes during the creative undertaking (Dahl, Chattopadhyay and Gorn 1999; Moreau and Dahl 2005). Secondly, the overarching focus of this research stream has been on the single consumer as a creative individual, and analyses within it concentrated on the inputs and outcomes of a consumer's particularized creative endeavors (e.g. Burroughs and Mick 2004; Moreau and Dahl 2005).

In our present study we seek to extend the notion of consumer creativity beyond that which is conventional in consumer research as we move from a predominantly individual-focused view of consumer creativity to one that more adequately accounts for dynamic and social aspects of the creative process (Berkun 2007; Csikszentmihalyi 1996, 2006; Gruber 1974; John-Steiner 1997). Indeed sociocultural approaches to examining creativity and creative lives are commonplace in other disciplines as "[researchers] became increasingly constrained by theories that limited them to an individual focus (John-Steiner 1997, p. xviii). As Csikszentmihalyi (2006) highlights, psychologists tend to see creativity exclusively as a mental process, but creativity is as much a cultural and social as it is a psychological event, and what we call creativity is not the product of atomized individuals, but of social systems making judgments about individual's products.

In a departure from individual-centric consumer creativity research, we focus on creativity as manifest in more interactive social settings to investigate how consumer creativity is expressed at a communal level in the rich social contexts of the virtual world *Second Life*. In so doing, we also demonstrate that consumer creativity transgresses reactively responding to encountered obstacles (Collins and Amabile 1999). *SecondLife* is a site of immense creativity in which consumers are actively encouraged and enabled to create their own applications and experiences through the provision of user-friendly creative tools and templates. Creativity is no longer the sole purvey of those with highly developed web design skills (Ondrejka 2007), but is notionally available to all users. Users create the entirety of the world in action. Moreover, collaboration is commonplace within this virtual spaces as consumers collectively generate information and create digital artefacts (Evans 2007; Ondrejka 2007).

In this study we draw on Csikszentmihalyi's (2006) theory of creativity. In his conceptualization, creativity is a process that can be observed where individuals, domains (a cultural, or symbolic, aspect of the environment) and fields (social aspects of the environment) interact. By adopting this perspective we seek to address some of the following: what constitutes consumer creativity within interactive virtual worlds; what motivates consumer creativity within these worlds; what are the consequences of this altered conceptualization of creativity for understanding consumer behavior; and what are the implications of these creative consumer networks to companies in general (e.g. Tapscott and Williams 2006).

In pursuing the goal of this study, we employ netnographic methods (Kozinets 2002) which examines consumer creative practices online. Netnography necessitates an ongoing deep engagement within the context of study (Kozinets 2002). Data used for this project comprised Blog postings on the official *Second Life Forum* and more than six months of in-world participant observation.

Through this study we hope to stimulate discussion and present a research agenda for those interested in consumer creativity and virtual communities from a sociocultural perspective, as well as to shed some insight on the adoption of SNSs and virtual worlds play in consumer creativity.

"Mapping Out Digital Materiality—Insights for Consumer Research"

Richard Kedzior, HANKEN, Finland

Theorizations of materiality are central to the cultural understanding of consumer behavior, thus much of researchers' interest has been devoted to studying subject-object relations in different contexts such as material possession attachment (Schultz Kleine and Mezel Baker 2004), extended-self (Belk 1988), or object meanings (Richins 1994). The importance of materiality for consumer research is hinging on the notion that objects take active part in a subject's identity construction, therefore consumer selves can be transformed, created, expressed, or emancipated in relation to objects and contexts in consumer culture (Borgerson 2005). In other words, the consumer 'self' emerges through consumption practices and the objects involved in them, and consumption is a process through which human beings materialize or objectify values and meanings, resolve conflicts and paradoxes (Miller 1987).

To date, however, theorizations of materiality in consumer research have predominantly assumed the physicality (tangibility) of the object of consumption neglecting growing dematerialization of consumables accompanied by the development of technology (Slater 1997). This is a considerable omission given that the advent and proliferation of the internet has resulted in digitized equivalents of books, photographs and music encroaching on the realm of everyday consumption and exposing consumers to a new regime of materiality. Many goods which were once tangible have now lost their physical referent and become accessible solely as representations. With few exceptions (e.g. Siddiqui and Turley 2006) consequences of such process for consumer research remain largely unexplored. As also noted in the previous literature, an inquiry into materiality must expand to encompass various dimensions of change brought about by technology (Sherry 2000). Therefore, this paper introduces and problematizes the notion of digital materiality as an altered regime of materiality observable in a virtual world.

In building an understanding of digital materiality this conceptualization benefits from evidence gathered during a netnographic study (Kozinets 2002) conducted in *Second Life* over the period of four months. *Second Life* is an online three-dimensional virtual world where elements of reality merge with fantasy and its residents live their virtual lives through animated represen-

tations called avatars. Being highly immersive, this environment represents a lively consumption space that is home to all possible manifestations of consumerism such as consumer activism, resistance and consumer creativity. Existence in *Second Life* can be conceived of as an exemplar of hyperreality where members of the culture realize, construct and live the simulation (Firat and Venkatesh 1995). The distinctive value of *Second Life* as a site of this inquiry stems from the fact that it epitomizes the idea of digital materiality, as not only is the object of consumption is digitized and intangible, but the consuming subject as avatar is also an intangible representation in the virtual world.

This paper delineates the concept of digital materiality in three steps. First, in order to position the concept within the context of consumer research, it reviews other consumption phenomena that entail a non-material object of consumption such as consumer fantasies (Holbrook and Hirschman, 1982; Martin 2004), consumption dreams (d'Astous and Deschênes 2005) and vicarious exploration (Stell and Paden 1999). Research, in which the tangibility of consumption objects has been transcended, has conventionally looked at symbolic aspects of consumption or aspects of consumer fantasy and imagination. In those cases, however the non-material object of consumption usually has a physical referent that can act as a locus for the meaning. Objects in digital materiality differ significantly, as even though they might have their physical referents, they do not require them in order to exist.

Second, in order to illustrate the significance of digital materiality for consumers this study adopts a symbolic interactionist view of material identity while analyzing the meaning of consumption practices and experiences in *Second Life*. In this perspective, possessions as material symbols of identity can exist in three types of social reality (Dittmar 1992). Objective social reality is conceptualized as the objective world existing outside of the individual, i.e. objects possess 'hard' quantitative and various qualitative characteristics. Next, symbolic social reality consists of any form of symbolic expression of the world in which we live in and encompasses three important symbol systems of language, non-verbal communication and material objects (which can symbolically communicate the personal qualities of individuals). When both objective and symbolic worlds are internalized a subjective social reality is created and represented as each individual's awareness and understanding. Simplifying, it can be said that symbolic social reality represents a societal level of analysis while subjective social reality corresponds to an individual level.

Finally, by bringing in evidence from other fields such as library studies (Manoff 2006) and visual arts (Sasson 2004) this investigation exposes "the tactile fallacy". This is the logical fallacy to treat objects of consumption within digital materiality as being immaterial instead of intangible. Data gathered *in situ* also support the deconstruction of false dichotomies such as virtual versus real in terms of consumption experiences in *Second Life*. One of the major findings indicates that consumers perceive their consumption in *Second Life* as real because they interpret this lived experience within the context of the virtual world. In other words, their subjectivity moved along the confines of digital materiality.

This study addresses recent concerns in conceptualizing materiality in consumer research which resulted from the proliferation of the internet and information technologies in consumers' daily lives. By introducing and delineating the notion of digital materiality as an alternative regime of materiality as experienced by consumers in a virtual world, this research aims to sensitize researchers to careful conceptualizations of different aspects of non-material consumption.

"Virtually Me: Youth Consumers and Their Online Identities"

Natalie Wood, Saint Joseph's University, USA
Lan Nguyen Chaplin, University of Arizona, USA
Michael Solomon, Saint Joseph's University, USA

Identity exploration is an essential developmental task for adolescents (Erikson 1963; Harter 1999; Marcia 1993). Tradition-

ally, it was family and friends who served as a reference for identity exploration. Today, the internet affords adolescents many new and exciting opportunities to experiment with their identities (Katz and Rice 2002; Rheingold 1993; Smith and Kollock 1999; Stern 2004; Subrahmanyam, Smahel and Greenfield 2006; Turkle 1995). Online experimentation often occurs both in the presence, and with the aid of people they have never, and may never meet in the real world. Technologies like social networking sites (e.g. Facebook), chat rooms and blogs receive the majority of attention. However, much of the real action actually takes place in sophisticated virtual worlds such as MTV's *The Virtual Hills*, *Gaia Online* and *Kaneva*.

Individuals enter virtual worlds in the form of *avatars*—online digital personas that they create. In these worlds they socialize with each other, play games, watch videos, shop and tryout different personas. Participation rates are staggering—*Habbo Hotel* targets 13-18 year olds and boasts over 100 million registered users and over 10 million unique users each month (Sulake Corporation 2008). *Gaia Online* attracts more than 5 million unique visitors each month with 500,000 of their members logging in for an average of *two hours per day* (Gaia Interactive Inc 2008). By 2011 an estimated 53% of children and teen internet users will be experimenting with their virtual selves in these environments ("*Kids*" 2007).

As today's youth effortlessly move back and forth between their real and virtual environments, we can only imagine the ramifications for identity formation. These virtual playgrounds allow for experimentation and self exploration at an extraordinary level of realism. Experimenting with possible selves (see Markus and Nurius 1989) can be undertaken in a short period of time, in a relatively safe environment, with minimal effort and little or no expense.

To date a small number of researchers have investigated the relationship between online identity and offline social comparison and self concept, but with mixed results (see Caplan 2005; Harman, Hansen, Cochran and Lindsey 2005; Matsuba, 2006). The most recent study by Valkenburg and Jochen (2008) examined adolescents who use the internet for chat or instant messaging. Their findings revealed that 50 percent of users are motivated to engage in internet-based identity experiments to satisfy their desire for self-exploration (to investigate how others react), social compensation (to overcome shyness) and social facilitation (to facilitate relationship formation).

The purpose of this study is to examine, motivation for in-world participation, the potential impact and influence these virtual playgrounds have on youth identity formation (real and virtual) and how the residents of these worlds function as a reference group. To explore these issues we choose to complete a netnographic (online ethnography) study (see Kozinets 1998, 2002) of popular teenage virtual worlds. Our first step involved developing a list of specific research questions and identifying appropriate virtual environments for investigation. *MTV Network* currently operates eight teenage virtual worlds. We selected two worlds that exhibit high levels of traffic and between member interactions—*Virtual Laguna Beach* and *The Virtual Hills*.

The second step was to have our researchers join and fully participate in both of these worlds on a regular basis. Three researchers engaged in over 5 hours of virtual world familiarization/orientation. They then spent over 16 hours (1 hour per day, at various times of the day and night over a 2 month period) observing in-world behavior and taking reflective/introspective field notes and photographs. Finally they completed 7 in-world interviews with in-world residents. The reported age of respondents was 15-21 and each interview lasted 45-60 minutes. Data was first analyzed independently by each researcher and then jointly to identify major

findings based on frequency of occurrence (between and within subjects).

Motivation for participation included meeting real and virtual friends, to escape real life or find a better one, and to behave in a way that they cannot, or do not feel comfortable doing in real life. We observed a significant amount of role playing with many people owning more than one avatar, sometimes with different personas. Residents verbally and behaviorally adopt the persona of their avatar. For instance, one person was dressed in "country" attire (wearing denim and boots) and started a conversation with "Hey ya'll." Five of the seven people interviewed indicated that their avatar appearance was partially based on acceptance—the need to belong. Furthermore, screen names are commonly used to express a desirable aspect of the self (e.g. *Nakedsurfgod*)

In terms of identity formation possessions (virtual cars, clothing etc) are used as signals and symbolic representations of real or ideal selves. Groups of similar looking avatars tend to hang out together and are generally less friendly than groups of avatars with diverse appearances. It appears that a unified appearance acts as a code signifying membership to a specific group and members of these "in-groups" are very intolerant of new people (referred to as *Noobs*) who are usually recognizable by their standardized appearance and wardrobe. Furthermore, they use ridicule (bullying) as a way of setting boundaries for group membership.

All of the residents interviewed alluded to the fact that they are less confident in the real world and the environment gave them the confidence to express themselves. Several commented that they see themselves as being more outgoing in-world and in some cases this virtual confidence gives them real life confidence.

In conclusion we find that in virtual environments identity and acceptance is very important and owning the right assortment of virtual possessions is essential for fitting in. Just as in the real world a social ranking system exists and virtual bullying is common. These virtual worlds give people greater freedom and confidence to act out without any serious repercussions. Future research should 1. Explore the role of brands and how products are used to form and manage impressions of the self 2. Examine how in-world relationships are developed, how they differ from, and how they impact relationships found in the real-world, 3. Examine the relationship between identity formation via virtual worlds and psychological well-being.

"Pursuit of the Sacred in the Era of Infantilization: A Multi-sited Ethnography of Online Gaming in China"

Jeff Wang, City University of Hong Kong, China

Xin Zhao, University of Hawaii at Manoa, USA

Gary Bamossy, Georgetown University, USA

Most studies of online gaming and virtual communities have focused on identities issues and examined how the virtual world has offered unprecedented opportunities for reconstructing identities (Castronova 2005, 2007; Meadows 2008). In this paper, we take a different approach and examine how online gaming has contributed to and reflected the infantilization of society, through a netnographic inquiry of the sacred and profane in online gaming (Belk, Wallendorf, and Sherry 1989; Barber 2007). From American *kidults*, German *Nesthocker*, Italian *Mamoone*, Japanese *Freeter*, to Indian *Zippies* and French *Tanguy*, a rising infantilist ethos that encourages and legitimizes childishness is gaining momentum around the world. This market-generated infantilization induces puerility in adults and preserves a sense of childishness in children trying to grow up. An infantilist culture prefers play over work, instant gratification over long-term satisfaction, feeling over reason, picture over word, easy over hard, simple over complex, and fast over slow. The infantilization of society is tied closely to the demands of a global economy and its ethos has become the major ideology sustaining consumer capitalism (Barber 2007). However, the nature, causes, and consequences of infantilization have only been examined

within Western societies. China's rise toward the most populated consumer society offers an unprecedented opportunity to examine this thesis, especially when the one-child policy has left hundreds of millions of families with their focus on the needs of little emperors (Jing 2000).

One of the most significant findings in consumer research is the sacred and profane evoked by consumption (Belk, Wallendorf, and Sherry 1989). The sacred is the opposite to what is ordinary and part of everyday life, and it refers to what is extraordinary and significant. The sacred is often beyond rationalization and can only be comprehended through devotion. It evokes momentary ecstatic experiences, in which one temporarily feels he or she stands outside his or her self. Anything could become sacred and sacredness is an investment process, in which consumers actively seek to separate ordinary objects from the world of the profane and to create sacred meanings in their lives (Belk, Wallendorf, and Sherry 1989). A material object can be sacralized through ritual, pilgrimage, quintessence, gift-giving, collecting, inheritance, and external sanction. However, these previously studied processes of sacralization focus on the transformation of existing material objects or places into the sacred. They emphasize having and being as a mode of experiencing the sacred. Although it has been noted that the investment of labor plays an important role in transforming the ordinary into the sacred, and how such experiences can become sacred is not explored. It is also unclear whether or not consumers' gaming experiences in the virtual world can be sacred and if so, whether or not the sacralization of intangible virtual possessions takes similar trajectories. We seek to address these theoretical gaps with netnographic inquiries of the online gaming in China, and within Barber's framework of an infantilized society (Barber 2007).

We conducted depth-interviews with both experienced and amateur gamers in urban China during our multisited ethnographic fieldwork from December 2006 to December 2007. We talked to gamers in Internet Cafes, their homes, game sweatshops, and cafes where they often gathered. We interviewed thirty five informants, including not only gamers, but also game developers, reporters covering the game for newspapers, and managers of Internet Cafes. Our research sites covered a wide region in both southern and northern China, and both coastal areas and inner cities, including Beijing, Changchun, Guangzhou, Nanjing, Shanghai, and Shenzhen. Our informants ranged from fifteen-year old teenagers and to adults in their late 40s. Some were affluent young consumers whereas others were poor and played the game in order to sell virtual possessions to make a living. This diversity of different gamers helps to enrich our understanding of what it means to participate in the game world. The interviews started with grand tour questions about personal background, interests, history of online gaming, life objects, and then were followed by questions about gaming experiences (McCracken 1988; Thompson 1997). The interviews lasted from forty-five minutes to three hours. All interviews were digitally recorded and supplemented by extensive field notes, photographs of gamers playing in Internet Café, and videos of on-site observation. They were then transcribed and analyzed through a systematic and iterate process (Arnould and Wallendorf 1994; Spiggle 1994). Each individual interview was taken as an idiographic illustration of a culturally shared system of meanings, similar to previous research (e.g. Holt 2002; Mick and Buhl 1992; Thompson 1997). Initial analysis has generated rich insights about the virtual world of online gaming that we will present at the symposium.

The marketplace has long been associated with a carnivalesque atmosphere, fantastic and sensuous experience, and with the possibility of magical self-transformation through purchase in a fluid and anonymous social setting (Lears 1994). In China, the popularity of

online gaming has contributed to the creation of a carnivalesque culture (Twitchell 1992), in which communist creed that represses play in the name of self-sacrifice and hard work has been replaced with the new consumerist ethos that encourages playfulness and an obsession with youthful spontaneity and rebellion as also seen in Western society's theme parks, shopping malls, urban architecture, and advertising (Barber 2007). Accompanying the rise of consumerism there is often a sense of loss (Giddens 1991), and a yearning for the sacred (Ritzer 1999), for which consumption is celebrated as a form of compensation. Online games provide an ideal arena in which gamers can experience an idealized past and the sacred lost. Different games emphasize different values and offer a wide range of psychological remedies for everyday problems faced by Chinese gamers. The variety of experiences sought after in online games goes well beyond excitement, novelty, and relaxation. Although appearing profane and unimportant to others, the avatar's sacredness undoubtedly manifests itself to its creator and many gamers we interviewed. Online gaming is a play of conflicting values that offer psychological remedies for a lost sense of achievement and other desirable values in real world. Online games constitute a liminal space through which gamers seek a transcendental sacred experience and in which the rite of passage of identity cultivation takes place in the new tribal society (Maffesoli 1996).

SYMPOSIUM SUMMARY

Justification and Choice

Aner Sela, Stanford University, USA
Jonah Berger, University of Pennsylvania, USA

SESSION OVERVIEW

Justification, namely, the use of accessible reasons for resolving the conflict and guilt associated with choice, is important to understanding consumers' behavior and their ensuing satisfaction. However, while research has demonstrated the significance of justification-based processes in consumer choice (e.g., Simonson 1992; Kivetz and Simonson 2002; Kivetz and Zheng 2006), we still know relatively little about the factors that moderate and inform these general processes. The present session seeks to provide an in-depth look at justification-based processes by examining their situational and motivational antecedents as well as the different ways in which they shape choice and satisfaction. How do features of the choice-set, prior beliefs, and emotions both provoke and moderate justification processes? Can the same justification be used in different contexts to arrive at different choice outcomes? How much are good justifications worth to consumers? The session will address these and related questions as it works to deepen our understanding of the role of justification in choice.

Khan, Dhar, and Fishbach (paper 1) examine the motivational role of guilt in indulgent choices and justification processes. Unlike past research which has generally assumed that people who feel guilty should abstain from indulging, this research suggests that guilt can sometimes increase rather than decrease indulgence. Three studies demonstrate that priming guilt creates a motivation to feel not-guilty, leading people to interpret their mundane choices as virtuous and use these virtuous choices as justifications to relapse and indulge.

Sela, Berger, and Liu (paper 2) develop a justification-based framework to understand how assortment size influences the type of options consumers select. More options make choice more difficult which, in turn, increases reliance on available justifications for choice. Six studies illustrate that increasing the number of options often increases the choice of utilitarian options because these tend to be easier to justify. However, when situational factors provide an accessible justification to indulge, increasing the number of options can have the opposite effect, leading to increased selection of indulgences.

Botti and Burson (paper 3) examine how consumers justify successful and unsuccessful decision outcomes and propose that consumers' satisfaction can be influenced by a belief-based justification process. Three studies document instances in which participants are either more or less satisfied with expert-made choices than their own, even when the two outcomes are the same. The findings suggest that satisfaction with choice is not only due to the outcome or to who has made the choice. Beliefs about the decision-maker's ability to find the option that best matches preferences also determines consumers' ability to justify the choice's outcome.

Keinan, Kivetz, and Netzer (paper 4) examine consumers' motivated tendency to overvalue certain justifications. This research demonstrates how adding a small utilitarian feature to a luxury good can serve to justify the indulgent purchase and reduce the associated guilt. Six studies suggest that consumers tend to overvalue such minor product features that serve to justify indulgent choices. This overvaluation is found to be mediated by guilt and is more likely to occur when the purchase seems wasteful and frivolous.

Taken together, the four papers in this session extend and deepen our understanding of choice justification processes and how they interact with features of the choice set (e.g., assortment), beliefs (e.g., about choice competence), and affect (e.g., guilt). The session would be of interest to researchers and marketers interested in consumer judgment and decision making, choice theory and assortments, affect and emotions, and the effect of the choice process on preference and satisfaction.

EXTENDED ABSTRACTS

"Guilt as Motivation: The Role of Guilt in Choice Justification"

Uzma Khan, Stanford University, USA

Ravi Dhar, Yale University, USA

Ayelet Fishbach, University of Chicago, USA

Guilt plays an important role in consumer choices and self-control (Khan et al. 2005). However, to this point, it is unclear whether guilt only influences choice through emotional experience when people *feel* guilty, or whether it can also be a motivational state whereby people strive to *avoid* experiencing guilt. Whether guilt is an emotional or a motivational state further determines what affect guilt-primes have on indulgence. Past research has generally treated guilt as an emotion that steers consumers away from indulgence. According to this research, priming guilt-related words reduces indulgence by inducing guilty experience (Giner-Sorolla 2001; Zemack-Rugar et al. 2007). The underlying assumption is that guilt-primes create an affective state through direct assimilation with the prime. That is, people actually *feel* guilty when primed with guilt-related concepts and this feeling prevents them from indulging.

An alternative view explored in current research is that guilt acts as a motivational state. We propose that guilt-primes increase the motivation to avoid guilt, which guides the interpretation of means to achieve this goal state. For example, imagine Jane, who after picking up a diet-coke and is choosing between an unhealthy pizza and a healthy salad for lunch. We argue that she will interpret her choice of a diet-coke differently depending on her level of motivation to avoid guilt. If she is primed with guilt, she is more likely to use the diet-coke as a justification to have pizza (due to heightened motivations to avoid guilty) than if she is not primed. More generally, we suggest that guilt-primes motivate consumers to interpret their decisions as virtuous in order to avoid guilt and feeling virtuous can paradoxically lead to MORE and NOT less indulgence.

Formally, we propose that 1) guilt-primers can create a motivation to avoid guilt 2) higher motivation to avoid guilt promotes interpretation of mundane choices as virtuous 3) these virtuous choices then serve as guilt-reducing justifications for further indulgence. Three studies support our theory. In Study 1 we primed participants with neutral (control) or guilt-related words (guilt-prime condition) in a scrambled-sentence task. Next, they consumed chocolate as part of a taste-test. Half of them were given a diet-coke to be consumed after the taste-test. We assumed that diet-coke can serve as a guilt-reducing justification when motivation to avoid guilt is high and can justify chocolate consumption. Consistent with our theory, ANOVA of chocolate consumption yielded a 2 (Guilt-Prime: Yes vs. No) x 2 (Diet-Coke: Present vs. Absent) interaction; i.e., participants primed with guilt consumed more chocolate when they were given a diet-coke ($M=51\text{gm}$) as compared to when they were not ($M=28\text{gm}$). However, in control condition chocolate consumed was not significantly different when diet-coke was present ($M=28\text{gm}$) or not ($M=37\text{gm}$). Results support the notion that a diet-coke is interpreted as a guilt-reducing justification and allows greater indulgence when the motivation to avoid guilt is strong (i.e., when guilt is primed) but not in absence of such motivation.

Building on the motivational view of guilt, we further predict that virtuous choices in presence of a guilt-prime can directly reduce experience of guilt. Study 2 demonstrated this effect of guilt-prime on experienced guilt for a fixed amount of indulgence. We predicted that individuals primed with guilt would experience less guilt than those not primed if they are given a guilt-reducing justification (e.g., diet coke). Again we employed a 2 (Guilt-Prime: Yes vs. No) X 2 (Diet-Coke: Present vs. Absent) design. Instead of measuring consumption, all participants ate one donut and indicated their experienced guilt. ANOVA of guilt-ratings yielded the predicted *guilt-prime X diet-coke* interaction. Further analyses revealed that when diet-coke was offered participants primed with guilt experienced less guilt than those not primed with guilt.

Recent research has shown that initial virtuous choices serve as guilt-reducing justifications and lead to indulgence in subsequent decisions (Khan and Dhar 2006). Study 3 shows that an initial choice is more effective as a justification when guilt is primed. Specifically, participants made two choices 1) between two high-brow magazines and 2) between highbrow and lowbrow movies. Prior to the choices, half of the participants were primed with guilt. As predicted, those primed with guilt were more likely to choose a lowbrow movie (50%) than those not primed (26%). We explain that an initial virtuous choice is more likely to be viewed as a justification and lead to more indulgence when the motivation to avoid guilt is strong.

Our findings add to justification research by showing how guilt-primers can increase indulgence through a motivation to avoid guilt, which leads to interpretation of mundane decisions as virtuous justifications. Secondly, we contribute to priming research (e.g., Bargh et al. 2001) by suggesting a motivational role of guilt-primers, which is significantly different from an affect-assimilation account. This also provides a mechanism to distinguish between goal-related vs. semantic primes. We suggest that priming a motivational state can strengthen or inhibit a goal depending on the level of goal attainment experienced.

- "Variety, Vice, and Virtue: How Assortment Size Influences Option Choice"**
Aner Sela, Stanford University, USA
Jonah Berger, University of Pennsylvania, USA
Wendy Liu, University of California, Los Angeles, USA
- Recently, there has been a resurgence of interest in how variety influences consumer choice (Iyengar and Lepper 2000) and satisfaction (Schwartz 2004). This research has offered an important corrective to the notion that more choice is always better by demonstrating that too many options can lead consumers not to choose at all, and to feel less satisfaction and more regret about the options they do choose. But while this work has provided insight into how the number of available options affects choice likelihood, could assortment size also influence the *type* of choices consumers make?
- To address this question, we develop a justification-based framework that examines how assortment size influences the choice between vice and virtue. Specifically, we argue that because choosing from greater assortments is often more difficult, it may lead to greater reliance on accessible reasons and justifications. Because some options may be easier to justify than others, this in turn should affect the type of options consumers end up selecting. Prior work has demonstrated that people generally find virtues easier to justify than vices (e.g., Kivetz and Simonson 2002; Kivetz and Zheng 2006). Consequently, we propose that choosing from larger assortments should often lead people to select relatively virtuous or utilitarian options. However, when situational factors provide accessible justifications to indulge, choosing from larger assortments should lead people to select more hedonic options.
- Six studies, involving both hypothetical and real choice, support these hypotheses. Compared to people choosing from a relatively small set of options, those choosing from an enlarged set were more likely to choose reduced fat ice-cream over regular ice cream (Experiment 1A), select fruit over cookies as a lunchtime snack (Experiment 1B), and use a gift-certificate to obtain a printer rather than an mp3 player (Experiment 2). The studies also provide insight into the mechanism underlying these effects. Consistent with the notion that the effect of assortment size was driven by increased effort and conflict, it was found to be mediated by experienced choice difficulty (Experiment 3). In addition, the effect depended on whether the overall number of options was increased rather than which option category saw the increase. Thus, increasing the number of just the hedonic or utilitarian options in the choice set was sufficient to increase the choice likelihood of the utilitarian options.
- Moreover, consistent with the notion that variety influences choice through reliance on accessible justification, manipulations

that provided accessible reasons to indulge reversed the effect (Experiments 4 and 5). People who were given false feedback that they had exerted a great deal of effort on a task, and thus had an accessible “excuse” for selecting vice, were actually more likely to select a hedonic consumer good over a utilitarian one when choosing from an enlarged choice set than when choosing from a small choice set. In contrast, people who were told they had exerted relatively little effort were more likely to choose the utilitarian consumer good when choosing from the larger choice set. Similarly, people who felt “licensed” to indulge due to a virtuous choice they had made in an unrelated task were more likely to select a hedonic product rather than a utilitarian equivalent when choosing from a larger set, but people who did not make the “licensing” choice were more likely to select the utilitarian product from the enlarged set.

Taken together, these studies illustrate that variety not only influences whether consumers make a choice, but also what they end up choosing. Furthermore, they highlight the key role of justifications in these effects. Thus, the effect of variety on option choice was contingent on what *type* of justifications was available to people at the time of choice.

“Choice Satisfaction Can Be the Luck of the Draw”

Katherine A. Burson, University of Michigan, USA
Simona Botti, London Business School, UK

In this research, we explore how consumers justify both successful and unsuccessful choice outcomes depending on whether they or an expert has made the decision. We show that self-expert differences in satisfaction with choice outcomes depend on how consumers justify these outcomes. Two studies document instances in which participants’ satisfaction with expert-made choices relative to their own varies even when the choice outcomes are the same. The results of these experiments show that satisfaction for the same outcome is not only due to the outcome itself or the decision maker, but on how consumers explain the outcome. When consumers justify the outcome with the decision maker’s ability to make the best choice, perceived good (poor) ability generates more (less) satisfaction. However, when outcomes are justified by factors external to the decision maker’s ability, there is no effect of outcome on satisfaction.

Prior research suggests that ultimate satisfaction with choice outcomes depends on the extent to which that outcome can be justified by the chooser’s capability to make the best choice (Weiner 1985). Thus, factors that influence the way in which these abilities are assessed will also influence eventual outcome satisfaction. The correspondence bias (Jones & Nisbett 1972) is one of these factors. When a choice outcome can be explained entirely by context, consumers consider this fact and are likely to temper their

perceptions of the role of their own ability in the outcome. However, they are likely to persist in crediting that outcome exclusively to an expert’s ability. Consequently, participants will tend to be more satisfied with an expert’s positive choice outcome than their own because they can justify it more readily with the expert’s ability to make good choices, even when self and expert achieve identical choice outcomes. In contrast, participants will tend to be less satisfied with an expert’s negative outcome than their own because they justify it more readily with the experts’ *lack* of ability to make good choices.

The first study examined perceptions of abilities and subsequent choice satisfaction in the domain of medical treatment choices. Participants either chose their own treatment from a choice set or were assigned a treatment by an expert and then given feedback that the treatment had succeeded or failed. Consistent with our expectations, participants were more likely to temper their own ability assessments than an expert’s when the outcome was negative. This led to more middling satisfaction for self-chosen than expert-chosen outcomes. Mediation analyses confirmed that the self-expert difference in outcome was the result of perceived choice ability.

In the second experiment, we test these predictions in an investment domain. Participants either personally chose a mutual fund or had one assigned by an expert. Half of participants were then given feedback that the fund had either increased or decreased. They were also provided with feedback about the unchosen funds. The unchosen funds increased when the chosen fund increased and decreased when the chosen fund decreased, by the same percent as the chosen fund. When feedback was absent, self and expert ability assessment did not differ. When the feedback suggested that the market explained the choice outcome, self-ability assessments were middling while expert-evaluations were inflated for good outcomes and deflated for bad outcomes. Despite this unequivocal feedback about the market, participants were biased in their incorporation of this situational explanation for the outcome. Mediation analyses show again that the self-expert differences in outcome depends on perceived choice ability.

Taken together, these two studies show that assessments of an expert’s choice ability depend mainly on the choice outcome, while self-evaluations are often tempered by contextual information if it is available. Because satisfaction depends on participants’ opportunity to justify choice outcomes with choice ability, participants are frequently more satisfied with a positive choice outcome produced by an expert than by the same outcome resulting from their own choice. When the outcome is negative, participants are less satisfied with the expert-chosen outcome than the identical self-chosen outcome.

“Functional Alibi”Anat Keinan, *Harvard Business School, USA*Ran Kivetz, *Columbia University, USA*Oded Netzer, *Columbia University, USA**“Every vice has its excuse ready” (Publilius Syrus)*

Marketers of luxury products face two major challenges. Marketers have to first appeal to consumers’ desire and imagination, and create a demand for something which is not really needed. Accordingly, marketing scholars and practitioners have stressed the importance of appealing to consumers’ fantasies and senses, connecting with their hopes, wishes and dreams, and satisfying their emotional desires (Holbrook and Hirschman 1982; Schmitt 1999; LaSalle 2003; Danziger 2005).

However, creating a desire or a craving for the luxury product is not enough; consumers may desire such products but still feel guilty spending money on non-practical luxuries and avoid purchasing them (Kivetz and Simonson 2002; Kivetz and Keinan 2006; Keinan and Kivetz 2008). Since luxuries are “by definition superfluous” and “neither beneficial nor useful” (Thomson 1987), the purchase and consumption of such products seems wasteful and even immoral, and consequently is difficult to justify.

Thus, a second important challenge that luxury marketers need to overcome is appealing to consumers’ conscience and providing them with an excuse or an “alibi” that would justify their profligate purchase, and make the purchase seem “rational” and logical. Such alibis can help consumers overcome their guilt, and view their purchase decisions as influenced by product functionality rather than by non-practical considerations and desires.

In the present research, we demonstrate how righteous consumers rationalize their frivolous behavior by inflating the perceived value of minor functional features or aspects of the luxury product. We argue that small utilitarian aspects of a seemingly wasteful product or service can serve as “functional alibis.” For example, consumers whose cars never touch a dirt road often justify the purchase of an extravagant SUV by its performance in extreme driving conditions. Similarly, consumers often mention a protective cell phone pocket to justify the purchase of the multi-hundred dollars Coach or Louis Vuitton purses.

We demonstrate that consumers tend to overvalue features (or products) that serve as a functional alibi. Such small utilitarian additions to a hedonic luxury are often valued more than their standalone value since they provide additional utility from serving as a functional alibi and justifying the purchase. Accordingly, the willingness to pay for a luxury product connected to a utilitarian product (or feature) will be higher than the WTP for each product sold separately:

$$\text{WTP (Luxury + utilitarian addition)} > \text{WTP (Luxury)} + \text{WTP (utilitarian addition)}$$

Six studies explore the effect of adding a functional alibi on consumers’ willingness to pay, purchase intentions, choices, and emotions of guilt. We show that the overvaluation of the added utilitarian product (or feature) is mediated by feelings of guilt associated with purchasing the hedonic luxury. Moreover, we demonstrate that such functional alibis are valued more when the purchase seems wasteful and induces guilt. We show that consumers who view luxury purchases as wasteful will be more likely to overvalue small utilitarian features that are attached to luxury products. Additionally, we demonstrate that small utilitarian additions are valued more when they are attached to hedonic rather than utilitarian products.

We explore the effect of the functional alibi in a variety of marketing contexts (and across the 4Ps of marketing planning),

including product upgrades, product positioning, new products features, product bundling, pricing, cross selling, advertising, and sales promotions. Moreover, we examine the effect of connecting a variety of functional alibis to various products and services including personal luxuries (clothing and apparel, fashion accessories, watches, cosmetics and fragrances), home luxuries (consumer electronics, hi-tech gadgets, and luxury furniture) and experiential luxuries (hotels and vacations, travel, and entertainment).

SYMPOSIUM SUMMARY

Moving Beyond the Rabbit's Foot: Superstition and Magical Thinking in Consumer Behavior

Eric Hamerman, Columbia University, USA

SESSION OVERVIEW

Merriam-Webster defines superstition as “an irrational belief that an object, action, or circumstance not logically related to a course of events influences its outcome”. While a great deal of established consumer behavior literature has focused on violations of rational choice, superstition is unique in demonstrating that consumers may base their choices on magical thinking, *even while recognizing and acknowledging that this is irrational*.

As a phenomenon, superstition has tremendous impact in the business world. ABC News reports that people's reluctance to tempt fate results in losses of \$850 million each time a Friday the 13th occurs in the calendar. More personal examples abound; almost half of all collegiate track athletes used some sort of clothing ritual such as “lucky socks” to help their performance (Bleak and Frederick, 1998). From a consumer behavior perspective, individuals who score higher in superstitious belief are more suspicious of genetically modified foods (Mowen and Carlson, 2003), and Taiwanese students were more likely to purchase a portable radio when it was priced at TW\$888–8 is lucky in Asian culture—than at the lower figure of TW\$777 (Kramer and Block, 2008).

Several psychological paradigms underlay the phenomenon of superstition, although there has been little investigation of these principles as they relate to marketing. First, sympathetic magic (Rozin et al, 2007) encompasses the laws of contagion and similarity. The former states that objects that have been in contact with each other will forever remain linked, even after being physically separated. The latter posits that an item which is related to another by imagery or association may take on properties of the second item. Consistent with the definition of superstition, such beliefs are acknowledged as irrational, but still manage to hold sway over behavior.

The idea of “illusory control” (Wegner and Wheatley, 1999; Wegner, 2002) identifies three principles by which individuals may be tricked into believing that they exert control over an event: priority, consistency, and exclusivity. When an action occurs prior to an outcome, when the outcome is consistent with one's intent, and when the action is the exclusively available explanation, then one is more likely to believe that he or she caused it to occur. Pronin et al (2006) demonstrated that when individuals insert needles into a voodoo doll, they are more likely to believe that this action caused a headache in an experimental confederate when the confederate previously acted rudely; the outcome (headache in a rude individual) was consistent with subjects' intent (to hurt the confederate). Again, these beliefs are often recognized as irrational by the same individuals who use these cues to direct their actions.

A culturally ingrained idea that individuals should not “tempt fate” is the third block on which the symposium rests. While there is no rational reason why discussing an uncertain event (or a string of successes) should impact its outcome (or this “hot streak”), there are many examples in which individuals believe that such discussions will bring negative consequences.

Each of the papers in this seminar addresses at least one of these psychological components of superstition in varying ways, but with the common theme that irrational beliefs about sympathetic magic, control, or tempting fate regularly influence consumer behavior, despite being acknowledged as unreasonable by their perpetrators. In Paper 1 (Kramer and Block), individual differences in intuitive processing are examined as a moderator of sympathetic

magic. The authors found that college students were more likely to purchase a used textbook from an individual with a high grade-point-average (GPA) than from someone with a low GPA, but only for highly intuitive processors. In a second study, the authors demonstrated that magical thinking can actually impact academic performance. Subjects were given a study guide to prepare for a test, and were informed that the guide had been previously used by other students. Subjects who were highly intuitive processors and who believed that their intelligence was malleable (Dweck et al, 1993) performed better when they believed that the guide had been previously used by high-GPA rather than low-GPA students.

In Paper 2, Hamerman and Johar demonstrated that when conditions were in place for individuals to perceive an ability to control outside events (based on Wegner's three principles of illusory control), they were more likely to deploy superstition as a purchase strategy. In Study 1, subjects indicated that protagonists were more likely to stay with a non-preferred brand of beer after their alma mater's performance in a basketball tournament improved, compared to when the team's performance declined. This difference only occurred when the protagonist was framed as a big fan of the basketball team. In Study 2, subjects engaged in a simulated “Trivia Night” at two hypothetical restaurants. Participants disregarded their existing preferences (based on restaurant quality) and used their trivia scores as a factor in deciding which restaurant to patronize, even though they were explicitly informed that the location of the match had no bearing on their likelihood of scoring well. Despite this result, participants still reported that their score on the trivia quiz was less important than restaurant quality in making their decision. In Study 3, subjects were given Snickers bars while watching their school perform well in an intercollegiate academic competition. When any of the principles of illusory control were violated (e.g., the broadcast was tape-delayed, individuals were not rooting intently for the school), respondents were more likely to switch their preferences away from Snickers at the close of the match.

In Paper 3, Risen and Gilovich examined the idea that “tempting fate” elevates the accessibility of negative outcomes, which in turn increases the perceived likelihood of these outcomes. In one study, a protagonist “tempted fate” by wearing a t-shirt from a university to which he applied; subjects determined that this individual was less likely to be accepted after wearing the t-shirt. In a second study, subjects who were primed with a belief in tempting fate were less optimistic and displayed a lower level of overconfidence in their abilities. A third study indicates that subjects who “tempt fate” by exchanging a lottery ticket for one with new numbers are more likely to purchase insurance against losing the drawing. The presentation also includes a hierarchical cluster analysis that identifies “hubris” and “needless risk” as behavior clusters that are associated with the concept of “tempting fate”.

In Paper 4, Kruger et al extend this research with the idea that commenting on success invites failure. In two studies, they demonstrate that subjects are more likely to predict future negative outcomes for both hypothetical protagonists (Study 1) and themselves (Study 2) after a string of successes has been mentioned compared to when success has not been referenced. Study 3 shows that the mechanism for this phenomenon is a failure to recognize “regression to the mean”. At the precise time when a string of successes is noticed, regression to the mean predicts that events are

likely to begin evening out. As expected, participants believed that an alteration in the background screen of a video game—put in place after a string of successes—made the game more difficult.

Taken together, the four papers investigate how people apply superstitious decision-making strategies in their everyday life, even while acknowledging that these strategies are not rational. In addition to investigating several manifestations of superstition (e.g., tempting fate, inviting failure, conditioned behavior, and culturally ingrained beliefs) across a wide variety of domains, we attempt to demonstrate that superstition and magical thinking have a strong impact on actual behaviors, including consumption.

EXTENDED ABSTRACTS

“The Impact of Thinking Style on Sympathetic Magical Thinking”

Thomas Kramer, Baruch College, USA

Lauren Block, Baruch College, USA

Would you be reluctant to drink juice previously touched by a dead, sterile cockroach? How about eating a piece of chocolate fudge shaped to look like dog feces? Psychologists and anthropologists have studied these and other examples of “sympathetic magical thinking” since the turn of the 20th century (Rozin, Millman, Nemeroll 1986). As the examples illustrate, magical beliefs follow one of two laws of magical thinking. The law of contagion holds that objects that have been in contact (e.g. a cockroach in juice) remain in contact even after being physically separated. The law of similarity states that if items that are related by imagery or association, one item may take on properties of the second (e.g. chocolate dog feces).

Despite acknowledging that magical beliefs are irrational, even well-educated adults fall prey to thinking that touching an object transfers his or her qualities (or “essence”) to it, which subsequently can get passed on to another person (Rozin et al. 2007). However, the effects of magical thinking do not only result in negative attitudes, such as reluctance to consume or touch, but also have positive manifestations. For example, a building at 165 University Avenue in Palo Alto has a reputation for magical qualities, having housed PayPal, Logitech, and Google (Helft 2007), on which the owners capitalize when renting out space. Likewise, objects previously owned by celebrities maintain a distinct price advantage on the secondary market. For example, Pope Benedict’s 1999 Volkswagen recently sold for over \$282,000.

Recent work has brought the positive effects of magical thinking into the consumer domain. Argo, Dahl and Morales (forthcoming) show that product evaluations are higher when shoppers believe they have been previously touched by an attractive other. In general, there are only a handful of published studies in marketing that explore contagion in a consumer product domain, and these are all limited to the effects of contagion on attitudes or motivation (Argo, Dahl and Morales 2006, 2008; Morales and Fitzsimons 2007). We extend this literature by demonstrating that magical thinking can have profound effects beyond attitudes and beliefs. In a series of studies, we demonstrate behavioral manifestations of magical thinking, from purchase likelihood intentions to actual increases in performance on reasoning tasks. Importantly, in doing so, we are the first to demonstrate that achievement is a property capable of being transferred through magical thinking. We also contribute to the literature by demonstrating that the impact of magical thinking depends on consumers’ thinking style (Epstein et al. 1996).

Study 1 was a 2 (prior owner’s academic success: high vs. low) x 2 (intuitive processing: high vs. low) design, in which 124 undergraduate subjects were told to imagine that they were major-

ing in music and were looking for a used textbook for a class at the beginning of the semester. Next, subjects in the high (low) academic success condition were presented with the following ad: “This text is in excellent, like new condition. Great shape, with just a little bit of writing on it. Used it just last semester. Got an A (D) in the class; kept my GPA at 3.98 (2.34). Price: \$59.99.” Then, subjects indicated their purchase likelihood, followed by intuitive thinking style measures ($r=.83$; Epstein et al. 1996). Results showed a significant main effect of prior owner’s academic success [$F(1, 120)=12.23, p<.001$], which was qualified by the expected thinking style X prior owner’s academic success interaction [$F(1, 120)=4.16, p<.05$]. Planned contrast showed that high intuitive processors were significantly more likely to purchase the textbook from a prior student high versus low in academic success [$M=6.26$ vs. 4.07 ; $F(1, 56)=12.63, p<.001$]. However, there were no differences for low intuitive processors.

The objective of Study 2 was to provide evidence that high intuitive processors believe that achievement can be transferred through magical thinking, which would be obtained if the effect depends on perceptions about the malleability of one’s own intelligence. Importantly, we also sought to show the impact of magical beliefs on actual performance. One hundred and sixteen undergraduate students participated in a 2 (thinking style) x 2 (prior users’ success) x 2 (intelligence perceptions) design, were told that the study tested analytical reasoning abilities of undergraduate students, and received two sets of materials. The first set, which constituted the manipulation of prior user’s success, was a study guide to help subjects in term of how to solve the analytical reasoning problems. Subjects were informed that given limited budgets for graduate student research, each study guide was designed for use by multiple respondents to reduce costs. Each study guide ostensibly had been completed by six previous respondents, and that their GPA was either relatively high or relatively low. In fact, there were no previous respondents, and the GPAs had been completed by the experimenters’ research assistants. Subjects wrote down their own GPA, completed ten analytical reasoning problems, followed by thinking style and intelligence perception measures (Dweck, Hong, and Chiu 1993).

Analyses on the number of problems solved correctly yielded a main effect for prior users’ success [$M=3.89$ vs. 4.71 for the low vs. high GPA conditions; $F(1, 106)=5.10, p<.05$], and the hypothesized 3-way interaction between thinking style, prior user’s success, and intelligence perceptions; $F(1, 106)=4.35, p<.05$. The interaction between prior owner’s success and intuitive processing was significant for those subjects who believed intelligence to be malleable [$F(1, 51)=5.75, p<.01$] but not for those who believed intelligence to be fixed ($F<1$). Furthermore, actual performance on the analytical reasoning tasks of high intuitive processors who believed that intelligence was malleable was significantly greater when exposed to the study guide of high versus low prior users’ success [$M=5.58$ vs. 3.21 ; $F(1, 26)=10.12, p<.001$]; however, performance did not differ for low intuitive processors ($M=4.21$ vs. 4.23 ; $F<1$).

“Can Switching Brands Help Your Favorite Team Win the Big Game?”

Eric Hamerman, Columbia University, USA

Gita Johar, Columbia University, USA

A large stream of literature in psychology has demonstrated that individuals are often susceptible to the illusion that they can affect certain events through actions that—by all rational accounts—should have no impact on the event in question. This illusion of control is likely to occur when pre-requisites of priority, consis-

tency, and exclusivity have been fulfilled (Wegner, 2002). Priority states that an action must occur before the event. If an individual orders a beer after watching a football game, he is unlikely to believe that his beverage choice had any impact on the outcome. Consistency is fulfilled when the outcome is consistent with the individual's intent. If a fan roots hard for his team to win by wearing a "lucky shirt", he is likely to believe that his wardrobe choice impacted the game only if his team won. Exclusivity holds true when there does not appear to be an alternative explanation. If the first-place team beats a last-place team, someone who roots for the winner could easily attribute the victory to the relative strength of the two teams, rather than to the intensity of his support.

In this paper, we suggest that consumer purchases may be viewed in certain situations as instruments to control an outside event, rather than as an attempt to purchase the "best product for the money" based on an evaluation of item attributes. Therefore, consumers will be said to use "superstitious strategies" to inform their purchase behavior when their perception of control over an outside event influences their buying decisions. We demonstrate that this phenomenon occurs even when individuals are aware that this control is merely an illusion.

In our first study, we examined lay theory beliefs about the use of superstition in purchase behavior. Participants read a hypothetical scenario about an individual who is either a big fan of—or indifferent towards—a basketball team. After ordering a non-favored beer—the favorite brand is temporarily out of stock—the team begins to immediately play either better or worse.

The principle of consistency held true only when the team began to play better (vs. worse) after placing the beverage order. In all conditions, priority and exclusivity were held constant. Therefore, this was a 2x2 between-subjects design, with factors of motivation (fan/not a fan) and consistency (team plays better/worse).

Respondents predicted that avid fans of the basketball team would vary their beer orders based on whether the outcome was consistent with their intent; they were more likely to stay with their non-favored brand when the team played well (vs. poorly). When the protagonist was not a fan, the outcome of the game was not expected to impact their choice.

In a second study, individuals participated in a simulated "trivia night" event that was described as taking place at two separate restaurants that differed in quality. Respondents were explicitly instructed that they had the exact same chance of winning at either establishment. After reporting initial preferences for each restaurant, subjects participated in four rounds of trivia: two at each locale. False feedback was distributed; scores either differed between the two restaurants or were equal at both establishments. For the fifth round, half of the subjects were given the opportunity to earn an additional cash prize by scoring well on the quiz (high motivation condition); all subjects were then asked to re-rate their relative preferences for each restaurant.

The principles of priority and exclusivity were both held constant during this experiment. Those who received scores that differed between locations were considered "high" in consistency, because there was a clear restaurant choice that was consistent with their intentions (to score well on the quiz). The experiment therefore included two between-subjects factors—consistency and motivation—each manipulated at the "high" vs. "low" levels. Subjects' relative preferences for the two restaurants prior to the practice quizzes—versus after the four practice rounds—served as a within-subjects factor ("time").

A main effect was discovered for the preference ratings over time. This was qualified by a significant interaction between Time

and Consistency: Results suggest that respondents allowed the feedback regarding their performance in the first four rounds (i.e., consistency between intent and outcome) to change their preference of restaurant venue over time, regardless of their level of motivation. However, participants reported that the "score on the trivia quiz" influenced their decision significantly less than "quality of the meal", "location", and "ambiance".

In a third study, participants ate Snickers bars while watching what they believed to be either live or tape-delayed updates of their school's Intercollegiate Quiz Bowl Championship match. During this session, their school performed well. After the updates, the score was either listed as tied (so the outcome was uncertain) or lopsided (the outcome was no longer in doubt). Respondents were then given an opportunity to choose another chocolate (either Snickers or KitKat); the DV was the relative preference for each brand.

Unlike in the previous experiments, the principle of priority was manipulated through live or delayed updates of the match. Consistency was measured based on intensity of rooting interest; the school's strong performance was most consistent with those who were rooting intently for this to occur. Respondents were thought to be more motivated to impact the match when the score was tied (vs. when it was lopsided). This study is a 2x2x2 experimental design, with factors of consistency (rooting intensity: high or low), priority (live or time-delayed updates), and motivation (score of the match: close or blowout). An interaction was found between consistency, motivation, and priority, suggesting that when any pre-requisite for illusory control is met, individuals believe that they can impact the outcome of an outside event through their purchase behavior.

Taken together, these studies suggest that superstition is regularly deployed as a strategy during purchase decisions in order to impact the result of outside events. This occurs even as its users admit that the idea of such control is irrational.

"Causes and Consequences for the Belief in Tempting Fate"

Jane Risen, University of Chicago, USA

Thomas Gilovich, Cornell University, USA

It is an irony of the post-Enlightenment world that so many people who don't believe in fate refuse to tempt it. Whether due to culture, age, or stress, the magical thinking literature has traditionally stressed deficits in cognitive capacities. We contend that a complete understanding of magical thinking requires that one not only understand why the absence of cognitive capacities gives rise to magical beliefs, but also why the presence of certain psychological tendencies gives rise to magical beliefs among intelligent, emotionally-stable adults, well versed in the rules of logic.

The studies presented here provide evidence for an unexplored magical belief—the belief that it is bad luck to tempt fate. First, we demonstrate that people have the intuition that tempting fate will increase the likelihood of a negative outcome. Second, we argue that actions that tempt fate elevate the perceived likelihood of misfortune because such painful possibilities are automatically called to mind and, once entertained, they gain fluency and are seen as more likely to occur. Finally, we demonstrate that when the belief in tempting fate is made salient, people avoid the types of behaviors that are thought to tempt fate.

In order to document the magical belief, Study 1 used a between-participant scenario and measured subjective likelihood. The protagonist ("Jon") either tempted fate by being overly confident and presumptuous about the future or did not. We find that people are more likely to predict a negative outcome when fate has been tempted than when it has not. Specifically, participants be-

lieved that Jon was more likely to be rejected from Stanford if he wore a Stanford t-shirt while waiting for the school's decision than if he stuffed the shirt in a drawer while waiting.

Study 2 used the same scenario to test whether negative outcomes are more accessible following behaviors that tempt fate and whether accessibility predicts likelihood judgments. Participants were asked to read stories on the computer and indicate as quickly as possible whether a one-sentence ending made sense or whether it was a non sequitur. If the ending made sense, they rated the likelihood of the ending. Replicating Study 1, we found that participants who read that "Jon" wore the t-shirt thought he was more likely to be rejected than participants who read that he did not tempt fate. In addition, the rejection ending was more accessible for those who read that he tempted fate, and accessibility mediated likelihood judgments.

Studies 3 and 4 were designed to examine the conceptual structure of this culturally-shared belief and to examine how the notion of tempting fate can influence behavior. In Study 3, we find using hierarchical cluster analysis that "hubris" and "needless risk" composed the initial behavior clusters associated with the term tempting fate. In Study 4, we find that when people are primed with the shared belief in tempting fate, they avoid those behaviors associated with the belief. For example, we find that after participants filled out a tempting fate scale, they displayed less presumptuousness and hubris compared to those not primed; they made less optimistic predictions for their future and less over-confident claims about their traits and abilities. The tendency to "restrain" displays of hubris was similar for those who indicated an explicit belief in tempting fate and those who did not.

Although the belief in tempting fate is typically considered an example of irrational, superstitious thinking, this work suggests that this "irrational" belief results from very basic cognitive processes and may promote positive, pro-social behaviors such as humility and moderation.

"Why Calling Attention to Success Seems to Invite Failure"

Justin Kruger, New York University, USA

Jane Risen, University of Chicago, USA

Thomas Gilovich, Cornell University, USA

Ken Savitsky, Williams College, USA

"Bragging about one's good fortune is to invite misfortune. To say, 'I haven't had a cold all winter' is to wake up the following day snuffling."

— Ferm (1959/1989)

Calling attention to an ongoing streak of success is widely believed to invite failure. Commenting on a "no-hitter" before a baseball game is over, for example, is thought to "jinx" the pitcher and undermine his success. Recalling his legendary no-hitter in the 1956 World Series against the Brooklyn Dodgers, New York Yankees pitcher Don Larson noted that "Nobody would talk to me, nobody would sit by me, like I had the plague. . . . Some of the guys didn't want to say anything, afraid they'd put a jinx on it" (Aubrecht, 2002).

The present research empirically documents and partially explains this superstition. In Study 1, participants read one of three hypothetical scenarios about two lucky individuals or groups of individuals: two gamblers who had each won six consecutive hands of blackjack, two sports car owners who had each managed to avoid hail damage to their treasured vehicles, or two rainforest expeditions that had each avoided snakebites, mudslides, and a variety of other dangers lurking in the jungle. In one version of the scenarios,

the streak of luck was pointed out by someone (the casino dealer, the car-owner's wife, or the expedition guide), and in the other it was not. As expected, participants indicated that the streak was more likely to come to an end if it was verbally mentioned than if it was not.

Study 2 examined the superstition in a non-hypothetical situation involving real behavior. Participants played a series of gambles, with the outcomes determined by drawing from three urns ostensibly made up of winning (blue) and losing (yellow) pieces. The experimenter explained that he would draw three times from the first urn, twice from the second urn, and once from the third urn, and that the number of winners and losers drawn would determine the participant's final payment.

Participants were given a form to keep track of the outcome of each draw and to estimate the composition of the urns. After making sure that participants understood the rules, the experimenter started to draw pieces from the first urn. Unbeknownst to participants, the urns contained exclusively winning (blue) pieces. After drawing 3 winning pieces from the first urn and 2 winning pieces from the second urn, he either commented on the streak by saying, "Wow, that's five in a row. You're on quite a streak. If this keeps up, you could win more money than anyone else," or he did not comment on the streak and simply said, "Blue." After making their estimates about the composition of the final urn participants were given the option of having the experimenter draw from the third urn or having the experiment end without the final draw. The experimenter explained that if participants stopped, they would leave with \$4. If they continued, they would earn \$6 if a blue piece were drawn and \$2 if a yellow piece were drawn.

As expected, when the experimenter verbally noted participants' streak of five consecutive wins, participants expressed less confidence that they would win on the sixth trial and thought the objective odds of winning were less in their favor. As well, they were more likely to take the experimenter's offer to stop playing and take a sure \$4 rather than risk losing (or gaining) \$2 by drawing from the third and final urn.

What causes the superstition? One possibility is a misunderstanding of regression to the mean. Because calling attention to success by definition only occurs after a run of good fortune, subsequent performance is likely to regress towards the overall mean. Commenting on a pitcher's ongoing perfect game, for instance, is likely to be followed by someone getting on base in the next inning—not because the pitcher has been cursed, but because teams, on average, get at least one person on base in most innings. More generally, comments about on-going success are correlated with diminished outcomes because exceptional performance at one period (which tends to elicit such comments) is followed, on average, by less exceptional performance the next. To the extent that people mistake this correlation for cause, the superstition is borne.

Study 3 was designed to test this explanation by creating a novel superstition in the lab. Participants played numerous rounds of a simple videogame. Unbeknownst to them, the outcome of each trial was random—that is, $p(\text{success})=p(\text{failure})=.5$. In addition, the background of the game changed after three hits, which, given the number of trials involved and the probability of a hit, was virtually guaranteed to occur at least once for each participant. Also virtually guaranteed was the fact that, on average, this change in background would be associated with a relative decline in performance, since a run of three hits in a row is unlikely to be followed by a similarly successful streak. We then asked participants to describe what influence, if any, the background had on the difficulty of the game (as well as a control background that occurred after

three misses). Despite the fact that outcomes were unrelated to the background (i.e., the probability of a hit on a particular trial was .5 regardless of the background), we found that participants tended to view the background that appeared after a string of hits as a bad omen. Of key importance, participants not only thought that the background change tended to be followed by a decrease in performance (which it did), but that it *caused* that decrease in performance (which it did not).

Taken together, this research suggests that people believe that calling attention to success is bad luck, and traces the superstition to a misunderstanding of statistical regression (sometimes known as the regression fallacy). Discussion focuses on the scope and everyday implications of these findings.

SYMPOSIUM SUMMARY

Social Networks and Consumer Behavior

Andrew Stephen, Columbia University, USA

Jonah Berger, University of Pennsylvania, USA

EXTENDED ABSTRACTS

“Opinion Leadership and Social Contagion in New Product Diffusion”

Raghuram Iyengar, University of Pennsylvania, USA

Thomas Valente, University of Southern California, USA

Christophe Van den Bulte, University of Pennsylvania, USA

We investigate the role of network position and opinion leadership in social contagion. Our study combines actual network data on advice and patient referral ties among physicians in three cities, demographic data on those physicians as well as a measure of self-reported opinion leadership, individual-level prescription data for the new drug as well as two other drugs launched earlier for treatment of the same medical condition, and individual-level sales-call data for the new drug. This data set allows us to perform a modified replication of the classic study *Medical Innovation* as extended by Van den Bulte and Lilien, with the additional benefit that the marketing effort variable varies not only over time but across physicians as well. Hence, we are able to investigate the presence of contagion dynamics in real market settings in which more traditional marketing efforts are being deployed as well, a question that is of great importance to both practitioners and researchers.

Another key feature of our study is that we use both sociometric and self-reported measures of opinion leadership. Physicians who are often nominated by their peers as people they turn to for expertise and discussion about disease management are likely to be true sources of influence. Physicians, who perceive themselves to be influential, in contrast, may indeed be so but may also have an inflated sense of self-importance. As a result, not everyone who believes is an opinion leader will actually be at the cutting edge of medical practice due to above-average expertise and clinical judgment. On the other hand, early adoption may be affected more by how one perceives oneself than by one's true status. This raises the possibility that sociometric leaders and self-reported leaders do not adopt equally early, but leaves the sequence in doubt.

A final distinctive feature of our study is that we observe not only time of adoption but also the number of prescriptions (usage volume) in each subsequent month. This allows us to shed further light on who is influential when. Prior research indicates that opinion leadership is associated with product involvement, suggesting that it is also associated with usage level. Someone who is using the product extensively is likely to be more enthusiastic and credible than someone who is not. To the extent that peers' product usage affects the amount of contagion exerted on potential adopters, heavy users are more influential and hence more attractive seeding points in a viral campaign, over and above their greater “stand alone” customer value.

We address three research questions. First, is there social contagion operating over social ties such that better connected adopters exert more influence than less connected ones, over and above the effect of marketing efforts and system-wide influences that vary over time? Second, to what extent does sociometric and self-reported opinion leadership overlap, and do they have the same influence on the time of adoption? Finally, is contagion emanating from prior adopters a function of their product usage, i.e., is their social influence affected by their usage status or volume rather than simply by their having tried the product?

We find evidence of social contagion even after controlling for marketing effort and controlling non-parametrically for any other changes over time. This justifies the deployment of network-based marketing strategies with the hope of accelerating new product diffusion. It further suggests that the dyadic social influence between individuals that is often observed in the lab can aggregate into broad social phenomena such as trends. In addition, we find that the influence of prior adopters is moderated by their prescription volume of the new drug, suggesting that heavy users are attractive viral seeding points over and above their greater “stand alone” customer value. Finally, the results indicate that sociometric and self-reported leadership are different constructs. Not only are their measures only weakly correlated, but they behave differently in the theoretical or nomological network we study. Sociometric leadership has a direct, main effect on time of adoption but does not moderate the sensitivity to social contagion. Self-reported leadership, in contrast, not only has a main effect but is also associated with a lower sensitivity to social contagion.

Taken together, these results provide insight into how social networks and actual product experience influence diffusion.

“Social Hubs: Do They Exist and What is their Role?”

Jacob Goldenberg, Hebrew University, Israel

Donald Lehmann, Columbia University, USA

Sangman Han, Sungkyunkwan University, Korea

Growth processes are important to marketing in general, and new product adoption in particular, where the diffusion of an innovation is governed, among other things, by word of mouth. In social systems, growth processes are thought to be strongly influenced by individuals who have large number of ties to other people. Although recent work by Watts and Dodds (2007) suggest that this influence was overrated, a heated debate about their existence and magnitude of impact of influentials exist.

In the social network literature, such people are called influentials, opinion leaders, mavens or sometimes hubs. Somewhat surprisingly, however, until recently there has been relatively little attention paid to these individuals in the marketing literature. Further, when the marketing literature does address such individuals, the focus is typically not on how they influence the overall market, but rather on either assessing their influence on people they are in direct contact with or identifying their characteristics. Broadly speaking, influential people are thought to have three important traits: 1) they are convincing (maybe even charismatic), 2) they know a lot (i.e., are experts), and 3) they have large number of social ties, they know a lot of people.

We focus on the third trait and present empirical findings on social hubs—individuals who maintain a large number of ties to other people—and their influence on the overall process of innovation adoption. We argue, somewhat contrary to recent suggestions, that social hubs adopt sooner than other people not because they are innovative but rather because they are exposed earlier to an innovation due to their multiple social links. We examine this argument using a mapped network and data on diffusion processes. Although social hubs have a higher adoption threshold, thus making them less “innovative,” they adopt sooner than less connected individuals because their exposure exceeds this threshold sooner.

We further distinguish between innovator and follower hubs. We show that the first influence mainly the speed of the adoption in

a network while the latter influence mainly the number of people that eventually adopt the innovation. The reason for the difference is consistent with dual market theories: innovative hubs adopt sooner and they turn on the process. If they adopt later the entire process will be slower. However, innovators are not trusted by the majority so innovative hubs have less influence on the market size. Follower hubs however are more reliable and their adoption can influence people to consider adoption as well. Hence they have a small influence on the speed of growth but a strong influence on market size. We also show that a small sample of hubs can be used to make an early forecast of the entire diffusion process.

Finally, we examine the advice and recommendation interaction from a point of view of an advice seeker. We focus on case in which advice providers can be people with high or low technical expertise (high in technical knowledge) and/or high or low socially connection. Somewhat contrary to intuition, information sources who are high on social connectivity are hypothesized to be relatively more attractive for more innovative products in case of a low innovativeness individuals. Consistent with this, a meta-analysis indicates that the correlation between knowledge and opinion leadership is indeed lower for more innovative products. Our studies also show that innovators consistently prefer to consult with people who are high on technical expertise, while those who are less innovative prefer to consult with socially connected individuals for more radical new products. For incremental products they prefer the experts. Finally, we show that while even less innovative consumers prefer to consult with experts about technical performance attributes for radical innovations, they still prefer to talk to a socially connected person for information about attributes that require skill to use.

Overall, this research provides an array of findings about social hubs and their role in diffusion and social contagion.

“Creating Contagious: Cascades in Spatially Dispersed Social Networks”

Andrew Stephen, Columbia University, USA

Jonah Berger, University of Pennsylvania, USA

What drives social epidemics? Cultural information and practices (e.g., products, websites, songs, or ideas) often spread like viruses across social ties between people. This diffusion is a key process through which consumers learn about new products. Further, it can be responsible for a product’s amazing success (or dismal failure) with relatively little, if any, investment in conventional marketing communications or promotion strategies. But what drives these situations where products spread like wildfire through a population? How does (a) the number and network position of the early adopters and (b) characteristics of the cultural item being shared influence whether the item catches on?

This paper explores these questions by studying how information spreads across a realistic social network. People belong to physical communities (e.g., geographic centers) and are socially tied to other people both within and outside their communities. We use a stochastically generated social network of 1,000 people and an agent-based simulation model to consider the diffusion of a new product across a range of conditions. In this model, information about an innovation spreads over social network ties, and consumers are “infected” on a continuous scale. Consumers who have higher infection levels can be seen as more aware or enthusiastic about the innovation, and thus more likely to influence other consumers. Every period, one of each consumer’s friends is randomly chosen as a potential influencer. We then use a simple influence model where consumers’ influence one another based on their own level of awareness or infection.

We examine how characteristics of the early adopters and of the innovation itself determine how widely and quickly a product catches on. Regarding early adopters, we vary the proportion of the population that is initially infected (via advertising, for example). We also vary how the early adopters are spatially distributed over the network (i.e., where they are positioned) and their connectivity characteristics (e.g., are they well-connected with many friends or less connected but within reach of many others?). The positions of the early adopters can also be thought of in terms of the “seeding strategy” that a marketer might use to try to initiate a cascade (e.g., select the well-connected people, randomly select people). Regarding the innovation itself, we vary how conducive it is to spreading. Some products or information spread easily while others are more difficult to diffuse. Specifically, some innovations are easy to try whereas others require much greater interest. Thus, we vary the trial (or adoption) threshold. Also, while products or ideas may be top of mind right after a person hears about them, their accessibility, or how enthusiastic people are about the innovation, soon declines. We therefore vary the rate at which this decline or decay occurs, with higher decay rates meaning that the innovation is harder to remember over time.

We then examine how these factors influence product adoption. In particular, how quickly and broadly the product catches on. We find that the network positions of early adopters can dramatically impact diffusion outcomes, particularly in cases that are not conducive to diffusion (e.g., information being hard to remember or adoption requiring high awareness or enthusiasm). Even when the innovation’s characteristics are well suited to it catching on the network positions of the early adopters influences adoption outcomes. Interestingly, when early adopters are well-connected (the traditional definition of a social hub or an opinion leader), the innovation does not diffuse widely and does not take-off. However, when early-adopters are positioned between many other people (i.e., social intermediaries) the innovation is much more likely to achieve widespread success. In fact, even when the early adopters have few connections, but are randomly dispersed throughout the network, more people eventually adopt the product than when early adopters are well-connected. This suggests that how well-connected early adopters are is largely inconsequential; rather, where they are positioned in the network is what influences whether they trigger a successful cascade. We also find evidence of some compensatory effects between the characteristics of the innovation. In particular, the adoption-dampening effects of high adoption thresholds can be mitigated by low decay rates (although the reverse is not true: high decay rates are not offset by low adoption thresholds).

In contrast to recent findings (Watts and Dodds 2007) our results suggest that easily influenced people are not necessary for cascades to occur. Rather social epidemics depend on the positions of the early adopters. In fact, cascades can still occur “against all odds” (i.e., when conditions are not conducive to diffusion) provided that the early adopters are positioned throughout the network. Overall, these results provide insights into how different initial conditions and micro-level behaviors influence macro-level outcomes in social contagion processes. They have direct implications to research on word of mouth, social influence, and diffusion more broadly.

SYMPOSIUM SUMMARY

The IAT in Marketing

Claude Messner, University of Basel, Switzerland
Joachim Vosgerau, Carnegie Mellon University, USA

SESSION OVERVIEW

The Implicit Association Test has become a popular tool for measuring implicit attitudes, presumably because the IAT is characterized by a unique combination of impressive effect size and effortless implementation. The IAT attracted massive media attention (e.g., in “Blink” by Gladwell 2005), and was featured on TV shows (e.g. “The Oprah Winfrey Show” on 06/06/2007) as a tool to uncover implicit racism. Originally introduced to social psychology, the IAT has been extended to clinical psychology, organizational psychology, the law, and marketing. Marketing research companies have started to use the IAT as a measure of “true” preferences and brand associations.

Despite the huge interest sparked among academics and practitioners, critical examinations of the IAT’s methodology and predictive validity have received only limited attention. A notable exception are Brunel, Tietje, and Greenwald (2004) who discuss some of the methodological issues surrounding the IAT in marketing. However, the two most important issues, order-effects and assumptions behind the measurement model of the IAT, have not been investigated. Because methodologies developed in clinical research settings should undergo thorough critical examination before being used in applied disciplines such as Marketing, the symposium is aimed at investigating the role and consequences of order-effects and violations of IAT assumptions.

In the first paper, Messner and Vosgerau explain the logic of the IAT design and empirically demonstrate a procedural effect (an order effect of the IAT-blocks) and its impact on correlations of the IAT with predictor criteria. Counterbalancing or keeping order constant are shown not to alleviate the problem. In the second paper, Blanton explores the underlying measurement model and assumptions for the interpretation of IAT-effects. Stuetgen and Boatwright argue in the third paper that these assumptions (as identified by Blanton) are likely to be violated in marketing contexts, and examine via simulations how violations of the IAT-assumptions impact the validity of the IAT.

Concluding, order-effects and measurement assumptions are crucial determinants for the validity of the IAT in marketing research. The three papers explore the consequences of order-effects and violations of measurement assumptions for IAT-effects, and suggest solutions to overcome these issues.

EXTENDED ABSTRACTS

“Order Effects in the IAT”

Claude Messner, University of Basel, Switzerland
Joachim Vosgerau, Carnegie Mellon University, USA

Marketing researchers are becoming increasingly interested in non-conscious influences on consumer behavior. A central concept of non-conscious influences are implicit attitudes, which are defined as “...introspectively unidentified (or inaccurately identified) traces of past experience that mediate favorable or unfavorable feeling, thought, or action toward social objects” (Greenwald and Banaji 1995, p. 8). Implicit attitudes are thought of being potentially better predictors of behavior than explicit (self-reported) attitudes, because consumers might be unwilling to reveal their attitudes when the attitude concerns stigmatized behavior (e.g., racists atti-

tudes), or because they are unable to reveal their attitudes as they might lack the ability for correct introspection (Brunel et al. 2004).

The Implicit Association Test (IAT) has become the most popular tool for measuring implicit attitudes, presumably because the IAT is characterized by a unique combination of impressive effect size and effortless implementation. The IAT was initially introduced to social psychology (Greenwald, McGhee, and Schwartz 1998), and has since been applied in clinical psychology, organizational behavior, the law, and marketing. Outside the academic realm, the IAT has attracted massive media attention as a tool to uncover implicit racism, and is used by marketing research firms as a measure of “true” preferences and brand associations.

We focus on an internal validity problem of the IAT that has not been investigated to date, so called order-effects. Consider an Coca Cola versus Pepsi IAT in which participants favor Coke over Pepsi. In the ‘compatible’ block participants learn to exploit the association between Coca Cola and the positive words, but in the subsequent ‘incompatible’ block must respond in the opposite direction, that is Coca Cola and negative words. Switching from applying one categorization rule to applying an opposite categorization rule is cognitively demanding and requires time and practice. So, *ceteris paribus*, cognitive inertia leads to slower responses in the second block, no matter whether it is ‘compatible’ or ‘incompatible’. Order-effects now accrue from the interplay of cognitive inertia (slower responses in the second block) and the IAT-effect (faster responses in the ‘compatible’ block). When the faster ‘compatible’ block comes first, cognitive inertia slows down responses in the subsequent ‘incompatible’ block, thereby augmenting the difference in response latencies between the two blocks (i.e. enlarging the IAT-effect). In contrast, when the ‘incompatible’ block precedes the faster ‘compatible’ block, cognitive inertia slows down responses in the faster ‘compatible’ block (i.e., decreasing the IAT-effect).

In study 1 we conducted an Coca Cola versus Pepsi IAT and counterbalance the order of the blocks. As expected, when the ‘compatible’ block came first an IAT-effect in favor of Coca Cola was found ($t(24)=4.41, p<.01$), but no IAT-effect was found when the ‘incompatible’ block came first ($t(25)=0.05, p=.96$). Learning within blocks confirmed that the order-effect was due to cognitive inertia. Learning in the second block was always slower than learning in the first block, no matter which block came first and which second.

In study 2, we show that cognitive inertia can be so strong that it reverses the IAT-effect. We chose positive and negative stimuli such that Coca Cola was more strongly associated with either than Pepsi. The stronger association of Coca Cola with positive and negative words implied no IAT-effect at the aggregate level (neither in favor of Coca Cola nor Pepsi). However, an IAT-effect in favor of Coca Cola was found when the *Coca Cola & positive words* block came first ($t(22)=2.91, p<.01$), but an IAT-effect in favor of Pepsi was found when the *Coca Cola & negative words* block was administered first ($t(24)=3.66, p<.01$). And as in study 1, learning was always slower in the block that came second.

IAT-effects crucially depend on the selection of the positive and negative stimuli. Thus, the previous cognitive inertia effects might be a result of the positive and negative stimuli that were used.

We therefore conducted study 3 with the original positive and negative stimuli from Greenwald et al.'s (1998) study 1 and 2. The targets were coffee versus black tea. As in study 2, no IAT-effect was observed on the aggregate level. However, in accordance with cognitive inertia, an IAT-effect in favor of coffee was found when the *coffee & positive words* block came first ($t(29)=3.34, p<.01$), but an IAT-effect in favor of black tea was found when the *coffee & negative words* block was administered first ($t(29)=2.68, p<.01$). Again, learning was always slower in the block that was administered second.

Order-effects introduce so much noise in IAT-scores that they can wipe out (study 1) and reverse IAT-effects (study 2 and 3). Order-effects thus distort individual IAT-scores and render correlations with predictor variables almost meaningless. The common practice of counterbalancing block-order between-subjects cancels out order-effects on the aggregate level, but on the individual level IAT-scores are still contaminated with cognitive inertia effects.

We eliminate cognitive inertia-effects in study 4 by manipulating block-order repeatedly within- instead of between-subjects, using the same stimuli as in study 1. One group was administered the block-sequence CICIC where C denotes the block in which Coca Cola is paired with the pleasant stimuli, and I denotes the block where Coca Cola is paired with the unpleasant stimuli. The other group was administered the complementary block-sequence ICICI. When the first two blocks were used to compute IAT-effects, we found the same order-effect as in study 1, that is an IAT-effect in favor of Coca Cola when the compatible block came first ($t(26)=5.33, p<.01$), and no IAT-effect when the incompatible block came first ($t(25)=0.46, p=.65$). In contrast, when the last two blocks were used to compute IAT-effects, no difference in the IAT-effects was observed between the two block-sequences ($F(1, 51)=0.67, p=.42$).

Concluding, when block-order is manipulated between-subjects IAT-scores should only be interpreted on the group level. When individual IAT-scores are of interest, for example when IAT-scores are to be correlated with predictor variables, block-order should be manipulated repeatedly within-subjects.

“Looking Past the Claims: A Psychometric Analysis of the Implicit Association Test”

Hart Blanton, Texas A&M University, USA

The past decade has seen a dramatic increase in the use of implicit attitude measures, and the most popular measure by far has been the Implicit Association Test (IAT). Despite evidence of weak IAT-criterion relationships across many behavioral domains, strong claims have been made regarding the validity of this measure and its ability to improve our understanding and prediction of important social behaviors. Despite the excitement surrounding this new measure, closer inspection reveals a lack of psychometric justification. To date, no formal psychometric model has been published that can justify its scoring conventions. In my talk, I examine the theory, methods and analytic strategies surrounding the IAT to determine the psychometric model that a researcher embraces (knowingly or unknowingly) whenever this measure is used.

I will begin by presenting empirical data showing that the IAT has a misspecified measurement model. The equivalent in traditional questionnaire development would occur if a researcher were to incorporate a multi-dimensional scale into his or her research program and then incorrectly interpret results as though the scale were unidimensional in nature. This type of error pervades the IAT literature.

As I show, IAT scores are influenced by three latent factors. Two of these factors assess distinct and empirically uncorrelated association strengths. The third assesses a person's general process-

ing speed. Despite the complex factor structure of the IAT, researchers commonly interpret even very small correlations between the IAT and psychological criteria as evidence of validity. Interestingly, however, the IAT's previously unexamined factor structure can help explain why (1) the IAT rarely provides strong criterion prediction and (2) IAT scores are often independent of explicit self-reports.

I next show that researchers who use the IAT impose a restricted causal model into their studies, one that typically is not germane to their research questions. The causal model built into the IAT results from its construction as a measure of *relative* implicit attitudes. Specifically, association strengths for two attitude objects are assessed simultaneously (e.g., attitude towards smoking and attitudes towards candy). Further, this assessment is done in such a way that researchers cannot justify treating one “attitude object” as the focal object being evaluated and the other as the “scale” or “metric” against which this object is evaluated. These features require a researcher to adopt strict causal assumptions that, when not met, can cause one to unwittingly model relationships that are not of theoretical interest. As I will show, failure to consider this fact has likely resulted in faulty inferences regarding the nature of implicit attitudes and the types of influences they exert on behavioral decisions (Stuettgen and Boatwright in this symposium present simulation results that quantify the consequences of embracing such faulty assumptions).

I present a study where we assess (1) attitudes towards apples and (2) attitudes towards oranges. We show that (1) the IAT measurement strategy quite literally mixes apples with oranges (along with general processing speed), (2) the IAT measurement strategy cannot be used to represent a person's true “fruit attitude structure,” and (3) the IAT causal model can cause researchers to draw faulty inferences about the influence of apples and oranges in the liking of apples sauce, orange marmalade and fruit salad. Although this study was conducted somewhat tongue and cheek the implications for consumer research are quite serious.

I then review more traditional data on the IAT, including its low test-retest reliability and its responsiveness to social context and laboratory manipulations. I also explore the implications of these features for past claims that the IAT assesses stable trait constructs that influence behavioral criteria.

Finally, I turn my attention to attempts to address shortcomings by IAT researchers. IAT researchers recently have introduced a new IAT scoring algorithm, termed the “D Score” that ostensibly addresses many of the problems highlighted here. I explain how this method works and show that it not only fails to address the above but actually introduces new confounds and further undermines the measurement model.

I close by suggesting new measurement techniques that can begin to address the limitations in the IAT and that will provide marketers with a clearer guide to testing theories about consumer behavior.

“Assessing the Assumptions Behind the IAT”

Peter Stuettgen, Carnegie Mellon University, USA

Peter Boatwright, Carnegie Mellon University, USA

Imagine you go to a restaurant with your friends. One of your friends orders Coke, but the waitress tells him that they only have Pepsi. She asks him whether he would like Pepsi instead. What do you think your friend would do? Order Pepsi or order a different soft drink? What would you do in this situation?

We asked \$130\$ undergraduate students enrolled in a marketing class these two questions (“What do you think your friend would do”, and “What would you do?”). 88% expected their friend to order Pepsi instead, and 84% would also choose Pepsi them-

selves (both ratios are significantly different from 50%, chi-square >12.90, $p < .001$; we ran these scenarios also in the opposite direction, Coke being substituted for Pepsi. Results are similar).

While it is hardly surprising that most consumers are happy to substitute Coke with Pepsi or vice versa, consumer researchers have to assume exactly the opposite when using the IAT. The calculation of the IAT-effect requires the following relationship to hold: if Coke is someone's favorite choice, Pepsi should be one of her/his *least* preferred options (cf. Blanton's talk). In the IAT, averaging the within-block response latencies assumes a positive correlation between the two association strengths measured within one block, and subtracting the two blocks from each other assumes that the blocks are negatively correlated. Combined, this means that the more a consumer associates one of the target constructs (e.g., Coke) with one of the evaluative poles (e.g., positive), the more s/he should associate the other target construct (e.g., Pepsi) with the opposite evaluative pole (e.g., negative). In the example in the beginning, this assumption would imply that the consumer switched to a different soft drink altogether rather than substituting it with Pepsi.

This assumption on the relationship between the attitudes towards Coke and Pepsi is (1) never observable (since implicit attitudes are not directly observable) and (2) likely to be violated in marketing contexts where two products or brands are compared. In the case of Coke versus Pepsi, the more a consumer associates Coke with positive the more s/he also associates Pepsi with positive. The reason is that attitudes toward Coke and Pepsi are mainly driven by attitudes toward the product category "cola-drinks". The more a consumer likes cola-drinks, the more s/he will like Coke, and also Pepsi. This is illustrated in the opening scenario where, even though a consumer might prefer Coke over Pepsi (or vice versa), s/he is happy to substitute one for the other. Given these two problems with this assumption, we examine via simulations its importance for the IAT's validity.

In particular, we define 8 variables: four variables which represent the implicit association strengths to be measured in the IAT (e.g., Coke/positive, Coke/negative, Pepsi/positive, and Pepsi/negative), and another four variables that represent the IAT-measurements of these implicit attitude strengths as reaction times. We then simulate random draws from the 8x8 correlation matrix with a Gibbs sampler. By implementing constraints in the simulations of the correlation matrix we can therefore control for whether the assumption is satisfied or not. We derive a formula to calculate a measure for the IAT's validity from these correlation matrices. This measure is simply the correlation between the IAT-effect as calculated from the observed reaction times with the IAT-effect as calculated from the simulated implicit attitudes. If the IAT was a perfect measure, this correlation should be equal to 1.

The results confirm the intuition that the IAT is on average as good a measure for the relative attitude between the two target constructs as response latencies are for each individual association strength (which are measured by the correlation between the observed reaction times and the simulated implicit attitudes).

However, the IAT assumption determines crucially whether the IAT is a better instrument than the individual response latencies, or a worse instrument. In particular, when the assumption is satisfied (i.e., the correlation between the two implicit attitudes is negative), the validity of the IAT is relatively high, even if response latencies are only a crude measure of implicit attitudes. This is because in this case the calculation of the IAT-effect combines the observed measures in a way to minimize the measurement errors contained in each measure individually. In contrast, when the assumption is violated, the validity of the IAT drops to low levels even if response latencies are very good measures of implicit

attitudes. Thus, in this case interpreting the IAT-effect in the standard way is questionable.

These results suggest that the question of whether the assumption behind the IAT is satisfied or not may be more important for the validity of the IAT than the currently highly debated issue of whether response latencies are an accurate measure of implicit attitudes. Concluding, we offer advice on how to use the IAT in marketing in order to ensure its validity. In particular, whether the assumption is satisfied or not is not necessarily an inherent feature of the two target constructs to be compared, but may differ with the sample taking the IAT. For instance, in Maison et al.'s (2004) study of consumer preferences between Coke and Pepsi, the IAT performed well in predicting subsequent choice for those participants who could clearly distinguish and had clear preferences between the two brands. We conclude with the demand that IAT studies in marketing should include a discussion about how likely this crucial assumption is to be satisfied for a given sample and target categories.

SYMPOSIUM SUMMARY
New Perspectives in Global Branding
Carlos Torelli, University of Minnesota, USA

SESSION OVERVIEW

One of the most difficult choices that multinational corporations face is deciding whether to standardize their communication strategy or to customize it to the taste of consumers in different cultural settings. As new global markets emerge, and existing markets become increasingly segmented along ethnic or subcultural lines, the need to market effectively to consumers who have different cultural values has never been more important (Shavitt, Lee, and Torelli 2008). Linking a brand to the multiple, and sometimes dissimilar, valued states and identity concerns of consumers in multi-cultural environments is becoming an increasingly complex task. To succeed in this endeavor, branding professionals need to identify the types of brand associations that are more likely to appeal to consumers in global markets. What brand characteristics do consumers with different cultural orientations prefer? What brand signals are more likely to positively impact brand credibility in multi-cultural settings? Do some consumers have a more positive attitude toward global brands than others? And if so, who are these consumers? This symposium unites under a common theme of providing insights on some of the factors that impact brand preferences and the formation of brand attitudes in globalized economies.

The first paper by Torelli et al. examines the relationships that multicultural consumers establish with their brands. The authors integrate past research on the human characteristics associated with brands (Aaker 1997) with that on the universals of human values (Schwartz 1992) and on cross-cultural differences in the relative importance of values (Triandis and Gelfand 1998), to develop a measure of the values that multi-cultural consumers associate with their brands (brand values scale or BVS). Based on the notion that consumers prefer brands with characteristics congruent with those that describe them (Malhotra 1988), they further predict cross-cultural patterns of brand preferences. Results from four studies, using multi-country samples of consumers, show that the BVS is a reliable and cross-culturally general measure of brand value associations. The findings also suggest that the cultural dimensions of vertical-horizontal, individualism-collectivism predict consumers' preferences for brands associated with culturally-congruent values. This research not only provides a cross-culturally general measure of brand representations, but shows the effect of cultural factors on brand preferences.

The second paper by Erdem, Swait, and Valenzuela explores cross-cultural differences on the antecedents of brand credibility. The authors suggest that in cultures that legitimize status differentials among their members (i.e., high-power distance), brand investments may be relatively more important for creating brand credibility. This is because the commitment that is signaled by this type of branding effort can help to mitigate the general distrust of authority in these cultural environments. In contrast, in cultures that foster the subordination of individual goals to the goals of the ingroup (i.e., collectivism, Triandis & Gelfand, 1998), or in those in which their members exhibit high-levels of risk aversion (i.e., high uncertainty avoidance, Hofstede 1980), consistency in the marketing mix (e.g., price and distribution) may lead to higher levels of brand credibility. This is because brand consistency reduces ambiguity and increases the strength of brand-group connections. A survey including brands from two different product categories (juices and PCs) and administered in 5 different countries provided empirical evidence for the predicted relationships.

This stream of research provides further insight into the effects of cultural factors on the formation of brand credibility judgments.

The final paper by Zhang and Khare enhances our understanding of the effects of the self-identity concerns of global consumers on brand preferences. Arnett (2002) proposed that, in globalized economies, consumers can develop both a local identity, characterized by identification with people in one's local community, and a global identity, characterized by a view of the self as a global citizen. Building on this pioneering work, Zhang and Khare argue that the chronic or temporary accessibility of a given identity leads to preferences for identity-congruent products (e.g., local products in the case of an accessible local identity and viceversa). In three studies, the authors develop a reliable scale to measure consumers' local-global identity and provide evidence for the hypothesized patterns of brand preferences. This research reinforces the notion that consumers appropriate brand meanings for constructing their individual identities (Escalas and Bettman 2005), and that these identities can include a more homogeneous view of the world. It also helps to reconcile the debate on whether consumers prefer global or local products and whether markets should adopt a globalized or localized marketing strategy.

This session discusses very important issues in global branding and has a great potential to inform branding researchers about the factors that impact brand preferences and the formation of brand attitudes in globalized economies. We anticipate this session will attract not only those interested in global branding issues, but those interested more generally in cross-cultural consumer behavior. Debbie John, an expert in branding, will integrate the implications of the three streams of research and provide a roadmap for future research about the effect of cultural factors on branding decisions.

EXTENDED ABSTRACTS

“A Measure of Brand Values: Cross-Cultural Implications for Brand Preferences”

Carlos Torelli, University of Minnesota, USA
Aysegul Ozsomer, Koc University, Turkey
Sergio Carvalho, University of Manitoba, Canada
Hean Tat Keh, Peking University, China
Natalia Maehle, Norwegian School of Economics and Business Administration, Norway

Globalization is perhaps the most important macro trend affecting marketing (Goldsmith 2004). As new global markets emerge, and existing markets become increasingly segmented along ethnic or subcultural lines, the need to market effectively to consumers who have different cultural values and who pursue contrasting self-identity goals has never been more important (Shavitt et al. 2008). Past research suggests that one fruitful approach for identifying the types of brand representations that are more likely to appeal to consumers with different value priorities is studying the degree to which consumers' enduring human characteristics match those that describe the brand (Malhotra 1988). Within this approach, it is critical to understand the human characteristics that consumers associate with their brands.

Consumers frequently think about brands as entities associated with a set of human characteristics (e.g., personal values or traits, see Aaker 1997), and as relationship partners with whom they establish and maintain social interactions that resemble in many

respects those between social partners (Fournier 1998). Understanding which consumers like which brand characteristics better is a key issue when trying to position brands in the right spot in consumers' minds. Past research has tried to identify a set of personality dimensions that can capture the different traits that consumers attach to brands (e.g., sincerity, excitement, competence, sophistication, and ruggedness, Aaker 1997) and to use these dimensions for identifying the kind of people who prefer brands associated with different traits (e.g., Aaker 1999). In this research, we extend existing work in brand personality and argue for studying the human values that people with different cultural values associate with consumer brands.

Traits and values are two distinct elements of personality and each can predict different sorts of behavior (McClelland 1951). Values are enduring goals that people wish to pursue. Extensive research has established a theory and measurement of values in over 200 samples in more than 60 countries from every inhabited continent (Schwartz 1992). Consumer values play an important role in understanding behavior in the marketplace and models linking product attributes to values are widely used by marketing practitioners (e.g., means-end chain, Gutman 1982). In the four studies reported here, we developed a reliable measure of the human values that people from different cultural settings associate with their brands, or the *brand values scale* (BVS). These studies also show the validity of this measure to predict cross-cultural patterns of brand preferences. To develop our framework, we integrate past findings in brand personality research with those from research about the universals of human values (Schwartz 1992) and about cross-cultural differences in the relative importance of values (Triandis and Gelfand 1998).

In study 1, we explored the structure and reliability of the BVS using data from a multi-country sample of consumers (from Canada, the U.S., China, and Turkey) who rated a variety of local and foreign brands in terms of the values associated with these brands. The findings, using both exploratory factor analysis and multidimensional scaling, suggested that the same 10 value dimensions identified in past research on the importance of human values can be used to describe the values associated with consumer brands (power, achievement, hedonism, stimulation, self-direction, universalism, benevolence, tradition, conformity, and security).

Study 2 was set up to further assess the psychometric properties and structure of the BVS by performing a confirmatory factor analysis on data from a second multi-country sample of consumers (from the U.S., China, Norway, Brazil, and Turkey) who rated the values associated with a variety of brands. The results suggested that a model with 10 intercorrelated factors offered the best fit to the data. Although the BVS did not show the same circular structure of relationships found using ratings of the importance of values as guiding principles in people's lives (e.g., Schwartz 1992), there was evidence that a structure of opposing individual (self-direction, stimulation, hedonism, power, and achievement) and collective values (universalism, benevolence, tradition, conformity, and security) offered a reasonable fit to the data. Congruent with past findings about the importance of personal values, brands that are perceived high in 'individual' concerns such as 'power' or 'achievement' tend to be perceived low in 'collective' concerns such as 'universalism.' However, we did not find evidence for the moderate correlation between contiguous value dimensions representative of 'individual' and 'collective' concerns that a circular structure would suggest (e.g., between universalism and self-direction, or between power and security). This may be attributed to brand images in memory that blend elements from different value domains without the rigid constraints that emerge from value priorities.

Studies 3 and 4 showed the validity of the brand values scale for predicting cross-cultural patterns of brand preferences. Using a multi-country sample of consumers (from the U.S., Canada, Norway, Brazil, Turkey, and China), we found that the cultural dimensions of vertical-horizontal, individualism-collectivism predicted consumers' preferences and attitudes toward brands associated with culturally-congruent values. For instance, horizontal collectivism predicted a higher preference for brands associated with universalism values and a more positive attitude toward brands that embody these values.

This research introduces brand values as an important construct to better understand the relationships that multicultural consumers establish with their brands. The findings here are invaluable for branding professionals interested in assessing the degree to which brand associations match intended positionings congruent with culturally-important values in a particular market. The findings here also carry important implications for brand extension research. Parent brands associated with values that may be incongruent with those needed to succeed in a different category (e.g., a benevolent brand trying to launch a hedonistic product) may be better off by avoiding the launch of a brand extension, as this could cause dilution of the associated values. These are just some illustrations of how brand values can be used to extend our understanding of global branding phenomena.

“A Cross-Cultural Study of the Antecedents of Brand Credibility”

Tülin Erdem, New York University, USA

Joffre Swait, University of Florida and Advanis Inc., USA

Ana Valenzuela, Baruch College, USA

Brand credibility is a key concept in understanding consumers' behavior towards brands, as well as the formation and management of brand equity (Erdem and Swait 1998). Erdem, Swait and Valenzuela (2004) studied the impact of brand credibility on consumer choice in a cross-cultural setting and found that although the existence of brand credibility effects is seemingly generalizable, the mechanisms through which brand credibility operates have some differences across countries with different 'macro' cultural characteristics. In this paper, we focus on the antecedents of brand credibility in such a context. More specifically, our theoretical framework suggests that there are two exogenous antecedents to brand credibility: Consistency among the marketing mix elements and absolute brand investments. Clarity, on the other hand, affects brand credibility as a mediator for both brand investments and consistency. Specifically, this research answers the empirical question of whether the relative total impact of brand investments versus consistency on brand credibility vary depending on the cultural constructs of collectivism/individualism, uncertainty avoidance, and power distance.

We conducted our analysis using survey and experimental data from two different product categories: orange juice and personal computers. We chose these product categories because they represent categories that are respectively low and high in involvement, search costs, and risk. Data on consumer brand perceptions, brand credibility judgments, and cultural dimensions were collected from subjects in Brazil, Germany, India, Japan, Spain, Turkey, and the United States. We chose these countries to vary along Hofstede's (1980) cultural dimensions of individualism/collectivism, power distance, and uncertainty avoidance, that past research has linked to cross-cultural patterns of brand perceptions and choices. We investigated the role of these cultural dimensions as potential moderators of the process that underlies the formation of brand credibility judgments. All subjects in our studies were undergraduate students in business schools (except for about half of

the Brazilian sample, who were undergraduate students in engineering) who participated in exchange for course credit. The results provided strong empirical evidence for the conceptual framework proposed by Erdem and Swait (1998) across countries.

More specifically, we investigated the impact of uncertainty avoidance, collectivism-individualism, and power distance on the relative importance of consistency and brand investments on the formation of brand credibility judgments. We expected the impact of consistency on clarity and, as a result, on brand credibility to be relatively more important in collectivistic cultures that foster the subordination of individual goals to the goals of the ingroup. This is because brand consistency reduces ambiguity and increases the strength of the connection between the brand and the reference group. We also expected the impact of brand consistency on clarity to be more important in cultures whose members exhibit high uncertainty avoidance since lack of ambiguity reduces consumers' perceived risk when they use the brand to make inferences. In contrast, we expected that in cultures that legitimize the existence of status differentials among their members (i.e., high-power distance cultures), brand investments may be relatively more important for creating brand credibility. This is because the commitment that is signaled by this type of branding effort can help to mitigate the general distrust of authority in these cultural environments. On a side note, heavy brand investments may also create a signal of status or prestige (Steenkamp, Batra and Alden 2003), which is also highly valued by consumers from cultures that rate high in power distance.

Overall, empirical results supported our expected patterns. First, results were consistent across the two product categories under study (PC and juice). Second, Germany and U.S. usually formed one cluster, while Brazil, Spain, and Turkey formed a second cluster (except in the case of power distance where the second cluster included India, Brazil, and Spain). In other words, Brazil, Spain, and Turkey represented both the high collectivism and high uncertainty avoidance cluster, with a higher percentage-wise consistency effect, whereas, Germany and US represented the high individualism/low uncertainty avoidance cluster, with a lower percentage-wise consistency effect. In the case of power distance, country-clusters changed slightly: Japan, the U.S., and Turkey represented the high power distance cluster, with a higher percentage-wise investment effect, whereas India, Brazil, and Spain represented the low power distance cluster, with a lower percentage-wise investment effect (Germany being an outlier).

These findings have important managerial implications. First of all, companies have to understand what elements in their branding strategy have the higher effect on consumers' perceptions of whether the brand signal is clear or not and, as a result, credible or not. Consumers who need brands to become unambiguous signals of either group identity or just risk-less inference making would heavily base their credibility judgments on how consistent the branding strategy is. In contrast, when brands are generally not trusted, strong brand investments may be necessary to establish the commitment of the company to the brand. In this context, companies should adjust their branding strategies by country according to overall cultural differences in consumers' brand credibility formation processes. Companies could also execute communication campaigns that reinforce the consistency over the years of brand messages (e.g., using a "now and forever" type of message) or the company's commitment to support the brand with strong investments (e.g., using a "commitment to excellence" type of message) in order to match cultural beliefs and values in their markets. Finally, the consistency of brand extensions should be very carefully assessed in categories where either risk or collective identity matters.

"Consumers' Local-Global Identity: Measurement"

Yinlong Zhang, University of Texas at San Antonio, USA

Adwait Khare, Quinnipiac University, USA

With rapid globalization, local and global products are routinely pitted against each other. While global products are growing stronger (Alden, Steenkamp, & Batra 1999), local products are also successfully competing against global products (Parmar 2004; Rigby & Vishwanath 2006). Consider for instance the success of two local colas, Mecca Cola in France and Fei-Chang Cola in China, against the two global colas, Pepsi and Coke. There appear to be both local and global leanings in consumers' product judgments. Mindful of such influences, marketers have tried to devise suitable positioning strategies for their products. Take for example GM's marketing of its Buick Minivan in China as a local rather than a global product (Fairclough 2006), or P&G's marketing of its products as global in Asia and Europe stressing that consumers around the world are being offered the same products (Sexton 2004).

These market trends mirror prior research results that are divergent. While some authors (e.g., Alden et al. 1999; Batra et al. 2000) indicate that consumers like a global product more than a local product, others find just the opposite effect (e.g., De Mooij 1997; Shimp & Sharma 1987). We believe that an unexamined factor in these studies may be the degree to which consumers identify as local versus global citizens, which may help to explain the divergent findings. For instance, in the survey conducted by Batra et al. (2000), it is possible that the global identity of participants from urban regions may have been salient and led to preferences of global over local products. Similarly, in the survey conducted by Shimp and Sharma (1987) among consumers from small- to medium-sized U.S. cities, it is possible that a salient local identity led to preferences of local over global products.

Based on Arnett's (2002) research on the psychology of globalization, we reason that the accessibility of consumers' local versus global identity is a key factor for understanding their preferences for local versus global products. Throughout the discussion, we consider local products as those tailored-made for local markets, and global products as those made with the same specifications for consumers from around the world (see Steenkamp et al. 2003). We build on the notion that consumers tend to evaluate identity-consistent information favorably (e.g., Reed 2004, Wheeler, Petty, & Bizer 2005) and suggest that consumers with an accessible global identity should prefer a global (vs. a local) product more as it may reinforce their sense of being cosmopolitan. In contrast, consumers with an accessible local identity should prefer a local (vs. a global) product more as it may reinforce their sense of being connected to their local community.

In a series of three studies, we developed a reliable and valid scale to measure the construct of local-global identity, and demonstrated its ability for explaining consumers' preferences between local and global products. More specifically, our findings provide evidence for identity-consistent product preferences such that consumers high on local (global) identity scores tend to prefer a local (global) product over a global (local) one.

In study 1, using a sample of adult consumers in a Southwestern city of the U.S., we show that local-global identity is a two-dimensional construct. The corresponding sub-scales that measure local and global identity also show satisfactory reliabilities. A global identity is distinct from, and yet correlated with, attitudes toward global companies.

Study 2 further assessed the test-retest reliability and discriminant validity of the local-global identity scale. Both sub-scales show satisfactory test-retest reliabilities. Results also suggest that local identity is distinct from, and yet correlated with, consumer

ethnocentrism (Shimp & Sharma 1987). Both local and global identity measures are uncorrelated with measures of chronically accessible independent and interdependent self-construals (Singelis 1994). Finally, our findings suggest that local and global identities are two independent dimensions that measure distinct, yet possibly competing, desirable identity states.

In study 3, we show the predictive validity of the local-global identity scale and show that it can be used to predict consumers' preferences for global or local products. Participants completed the local-global identity scale. In a separate session, they were primed with either a local or a global identity and subsequently indicated their favorability toward a local and a global version of a palm pilot (order of presentation was counterbalanced). The results showed that both a temporarily and a chronically accessible identity predicted favorable attitudes for identity-congruent (vs. incongruent) products (e.g., more favorable attitudes toward local over global products when a local identity was accessible).

We believe that our research offers key theoretical contributions for globalization research and important implications for branding professionals. First, we advance the emerging literature on the psychology of globalization by empirically measuring the local-global identity construct. Extending the pioneering work by Arnett (2002), we developed a reliable and valid scale to measure the temporarily or chronic accessibility of consumers' local and global identities.

Our findings also provide a theoretical explanation for the contrasting findings about the preferences for local over global products (or viceversa). We show that when a local (global) identity is more accessible consumers prefer a local (global) product to a global (local) one. Thus, our study provides a more parsimonious explanation for reconciling divergent patterns of brand preferences reported in past research. Lastly, our results have key implications for branding decisions. By understanding consumers' accessibility of local-global identities, marketers may be better able to choose between local or global positioning strategies.

SYMPOSIUM SUMMARY

An Examination of the Complex Relationship Between the Self and Consumer Contexts

Lan Nguyen Chaplin, University of Arizona, USA

SESSION OVERVIEW

Objective, Topics, and General Orientation

The objective of the proposed symposium is to stimulate discussion and encourage research on the dynamic relationship between the self and consumer contexts. Researchers have argued that consumers evaluate and choose brands on the basis of whether they express aspects of the self to others, or fulfill some self-enhancement or self-verification goal. Although research has clearly shown that consumers evaluate and choose brands based on these self-related motivations (thereby forming self-brand connections (SBC), several research questions remain unanswered—Are there important moderators to consider that would further illuminate the relationship between the self and consumption? Additionally, research has explored the influence of brand evaluations on SBC, but to what extent might SBC affect brand evaluations? Finally, a major assumption is that consumers bring salient and relevant self-concepts to the brand consumption context, however to what extent might the consumption context influence consumers' self-concepts? The aim of this session is to shed some light on these research questions.

Paper #1, by Escalas and Bettman, questions the simple manner in which researchers currently view how consumers' views of the self drive consumption and present findings on how self-enhancement goals and brand symbolism moderate the influence of brand meaning on self-brand connections. Paper #2, by Cheng, White and Chaplin, challenges the unidirectional assumption that brand evaluations/attitudes determine SBC, and present results that suggest a feedback effect. Specifically, the authors suggest that when consumers make a SBC, brand-evaluation will become an important component of self-evaluation, and therefore, is likely to be affected by whether consumers make SBC. Paper #3, by Forehand, Perkins, and Reed II, add another dimension of complexity to the relationship between the self-concept and consumer contexts by questioning whether consumers always bring their identities to the context. The authors present evidence to show that social identities are automatically influenced by contextual information about others. Each paper moves away from the simple way in which researchers currently view the role of the self-concept in consumer contexts and provides empirical evidence to shed some light on the dynamic nature of this relationship (e.g., introducing moderators and challenging assumptions).

In summary, this session presents a dynamic view of the relationship between consumers' self-concepts and consumption activities. That is, while consumers' views of the self drive consumption, these views are also constantly being shaped by the consumption context itself. This perspective paves new avenues for research, such as the potential for consumption activities to transform consumers (via transformation of self-concept) and for contextual factors to determine the self-consumption relationship. The proposed session will serve as a good platform for researchers who are interested in the relationship between the self-concept and consumption as well as those interested in advertising and branding, to communicate and develop possible future research.

Theoretical Contribution

Together, these three papers provide a fresh perspective to study the relationship between the self and consumer contexts. The

current view is that individuals' self-concepts shape their consumer behavior. The emerging view from these papers is that while the self certainly drives consumption, it is more complicated than we think (as paper #1 suggests). Moreover, the directional relationship between the self and consumption may also be more complicated than we think (as paper #2 suggests). Finally, the self may not always drive consumption, but rather be driven by consumption (as paper #3 suggests). Each paper makes additional contributions. First, Escalas and Bettman provide an empirical demonstration of the ideas in McCracken's (1989) theory of meaning movement by demonstrating that brands endorsed by celebrities are a source of symbolic brand meaning. In doing so, they provide additional evidence that consumers use brands to communicate their self-concept. Cheng et al., merge the brand extension/dilution and the self-concept literatures to show how SBC can have a feedback effect and influence brand evaluations. Forehand et al., contribute to the advertising literature by showing that ad exposure has a profound effect on not just changes in brand attitude or purchase intentions, but also social identities.

EXTENDED ABSTRACTS

“Celebrity Endorsement and Self-Brand Connections”

Jennifer Edson Escalas, Vanderbilt University, USA

James R. Bettman, Duke University, USA

People engage in consumption behavior in part to construct their self-concepts and to create their personal identities (Richins 1994; McCracken 1989; Belk 1988). We examine one aspect of this construction process, namely the appropriation of the symbolic meanings of brands derived from celebrity endorsement. Building on McCracken's (1989) theory of meaning movement, we propose that the symbolic properties of the celebrity become associated with the brands the celebrity endorses. These symbolic meanings can then be transferred from the celebrity to consumers as they select brands with meanings congruent with their self-concept. When the symbolic properties associated with brands via celebrities are used to construct the self or to communicate the self-concept to others, a connection is formed with the brand. Our first study provides empirical support for the notion that brands endorsed by celebrities are connected to consumers' self-concepts as they use these brands to define and create themselves. Our second study supports the hypothesis that the self-construction process is moderated by brand symbolism, that is, the degree to which the brand communicates something about its user. Our third study is designed to test the hypothesis that the self-construction process is driven by self-enhancement motivations in consumers (cf. Escalas and Bettman 2003).

Our paper provides an empirical demonstration of the ideas in McCracken's (1989) theory of meaning movement by demonstrating that brands endorsed by celebrities are a source of symbolic brand meaning. Consumers form associations between the symbolism associated with the celebrity and the brands they endorse. These meanings are in turn transferred from the brand to the consumer as consumers actively construct themselves by selecting brands with meanings relevant to an aspect of their self-concept. Consumers form connections to brands that become meaningful through this process, and self-brand connections are intended to measure the extent to which individuals have incorporated brands into their self-

concept (Escalas 2004). A critical distinction in terms of such construction processes is that between brand associations derived from celebrities with whom consumers identify or feel an affinity and associations derived from celebrities that consumers do not like or do not perceive as being similar to themselves. Consumers are likely to accept meanings from brands associated or consistent with a celebrity whom they perceive as similar to themselves or whom they aspire to be and to reject meanings associated or consistent with a celebrity who does not represent either who they are or who they would like to become. We propose that when consumers appropriate or distance themselves from brand associations based on celebrity endorsement, they do so in a manner that is consistent with self-related needs, such as self-enhancement (Escalas and Bettman 2003).

Results from our first experiment show that the degree to which celebrity usage influences self-brand connections is contingent on an individual's perceived similarity with a celebrity. In this study, we measured the extent to which 52 undergraduate student participants felt that seven popular celebrities were likely to use the product they endorsed and the extent to which the participants perceived themselves to be similar to the seven celebrities (both averaged multi-item scales, with continuous variables used in the within subjects analyses). We find a significant celebrity-use by similarity-to-celebrity interaction ($F(1, 1194)=7.61, p<.01$), where there is a stronger positive influence of celebrity endorsement when the participants perceive themselves to be similar to the celebrity.

Results from our second study, run with 361 eLab participants, replicate the finding that the degree to which celebrity endorsement influences self-brand connections is contingent on celebrity type (here, operationalized as most vs. least favorite celebrity) and match between celebrity and brand image, with a significant celebrity-type by image-match interaction ($F(1, 318)=10.31, p<.01$). Furthermore, we find this effect is moderated by the degree to which the brand is symbolic, i.e., able to communicate something about the user, with more symbolic brands having stronger effects than less symbolic brands (Escalas and Bettman 2005). We find a significant three way interaction, with steeper slopes for symbolic brands ($F(1, 314)=4.76, p<.03$). The positive effect of celebrity endorsement on self-brand connections is stronger for brands that are perceived to communicate something symbolic about the brand's user compared to brands that do not. On the other hand, symbolic brands are more likely to be rejected when endorsed by non-similar, disliked celebrities.

Our third study, run with 311 eLab participants, examines whether self-enhancement needs moderate the influence of celebrity endorsement on self-brand connections. Research on reference groups has found that consumers with strong self-enhancement goals tend to form self-brand connections to brands used by aspiration groups, that is, groups for which the consumer wishes to become a member (Escalas and Bettman 2003). We find a similar process is at work with celebrity endorsement. In this study, we threaten self-esteem for half the participants, thus activating self-enhancement goals. This activation increases the extent to which celebrity endorsement positively influences self-brand connections for celebrities who have characteristics that the consumer aspires to possess, while lowering self-brand connections in the case of celebrities whom the consumer does not aspire to be like ($F(1, 310)=4.62, p<.05$). With this third experiment, we show that self-enhancement motivations drive the process by which consumers build connections to favorable celebrity images or distance themselves from unfavorable celebrity images.

"When Poor Brand Extensions Result in Favorable Brand Evaluations"

Shirley Y. Y. Cheng, *University of Illinois at Urbana-Champaign, USA*

Tiffany Barnett White, *University of Illinois at Urbana-Champaign, USA*

Lan Nguyen Chaplin, *University of Arizona, USA*

An impressive body of research demonstrates that individuals use products to create and communicate their self-concepts (e.g., Belk 1988; Sirgy 1982; Solomon 1986). Particularly interesting in this regard are consumer brands, which are ideally suited to this process given the wide availability of brands and the range of distinctive brand images they reflect (e.g., Fournier 1998; Muniz and O'Guinn 2001; Schouten and McAlexander 1995). Consumers can appropriate associations belonging to brands, such as user characteristics or personality traits, and incorporate them into their self-concepts, thereby forming self-brand connections (SBC; Escalas and Bettman 2003).

The prevailing view of how brands are related to the self-concept is that consumers have certain beliefs and evaluation of a brand, which affect whether consumers make SBC (i.e., Brand-evaluations → SBC). Is it possible that a feedback effect might be operative (i.e., SBC → Brand-evaluations)? In other words, once consumers have made a SBC, how resilient are their brand evaluations when, for example, the brand's favorable image becomes questionable? Are consumers likely to defend their brand-evaluations given their strong SBC? Or, are they likely to change their brand-evaluations given the obvious challenges to the brand's image? More research is needed to address questions of this nature.

This research investigates the role that self-brand connections play in brand evaluations. Of particular interest is the question of how high SBC consumers evaluate the parent brand when it launches a poor brand extension. To date, the brand extension literature has found that the effect of extension performance on parent brand evaluations depends upon the perceived typicality of the extension. Negative performance of a typical brand extension leads to brand dilution but negative performance of an atypical brand extension does not (Loken and John 1993). Our research investigates how this process could be moderated by consumers' existing SBC. We argue that when consumers make a SBC, brand evaluation becomes an important component of self-evaluation. We know from the psychology literature that individuals are

predisposed to try to maintain positive self-evaluation (Tesser 2000; Brown, Collins and Schmidt 1988). Therefore, in order to maintain a positive self-evaluation and avoid a potential threat to the self, it is likely that consumers with high versus low SBC will evaluate the parent brand favorably, even when the brand extension is objectively poor on multiple dimensions.

In study 1, we test the effects of extension typicality and extension performance on brand evaluations for consumers with high versus low SBC. We successfully replicated the typicality effect on brand dilution for those with low SBC. Specifically, we found a significant typicality by performance interaction on brand evaluation. In face of negative extension performance, low-SBC participants evaluated Apple (i.e., the target brand) less favorably when the extension is a printer (i.e., typical) than when it is a watch (i.e., atypical). As predicted, however, this effect was attenuated for high-SBC participants—parent brand evaluations were equally favorable regardless of extension typicality. As previously alluded to, we suggest that two factors set the stage for this effect. First, individuals are predisposed to maintain positive self-evaluation. Second, when consumers make SBC, brand-evaluations contribute to self-evaluations. Consequently, high-SBC consumers view poor extensions as a threat to their self and therefore evaluate poor extensions favorably in order to maintain a positive self-evaluation. To further explore this account, we look to Tesser's (2000) study, which showed that when the self is threatened, people seek to self-affirm. Following this notion, we should expect the effect of SBC on brand-evaluation to be attenuated when consumers are given the opportunity to self-affirm.

In study 2 we test whether self-affirmation attenuates the effects shown in study 1 in a 2 (SBC: high versus low) x 2 (Self Affirmation Task: Present vs. Absent) factorial. Our results show that the otherwise positive influence of high SBC on parent brand evaluations was indeed eliminated when respondents were given the opportunity to self-affirm in another domain. After completing a task in which participants described the values that are most important to them, high SBC participants evaluated the parent brand less favorably than high SBC participants who do not self-affirm, and equally favorable as those low in SBC. Studies 3 and 4 further explore the proposed mechanism and rule out important alternative explanations for the SBC effect. Study 3 demonstrates that negative brand extensions more adversely affect high versus low SBC participants. High SBC participants exhibited a greater need to self-affirm than low SBC participants. In Study 4, we directly measure negative feelings generated in response to negative brand extension performance and show that high SBC participants report significantly more negative feelings than do low SBC participants. However, as expected, this difference is attenuated when high SBC participants are able to self-affirm in another domain.

Taken together, these results provide mounting evidence in support of our account of why and how SBC affect brand evaluations. In so doing, we augment existing literature on the influence of SBC as well as research in the brand extensions literature, which has not examined the influence of SBC on parent brand dilution.

"The Shaping of Social Identity: Assimilation/Contrast Responses to Ad Exposure"

Mark Forehand, *University of Washington, USA*

Andrew Perkins, *Rice University, USA*

Americus Reed II, *University of Pennsylvania, USA*

Social identity has been found to influence a wide variety of consumer behaviors and attitudes. Consumer social identity is especially powerful to the extent that the identity is salient in the immediate social or contextual environment. In these situations, the activation of a social identity motivates the consumer to actively engage in social comparison, to express identity-consistent beliefs, and to select products that reinforce the desired social identity. Although understanding the influence of social identity on consumer behavior is clearly important, the extant research within consumer behavior has largely studied the phenomenon as a unidirectional process. That is, research has started with the belief that consumers bring certain social identities to consumption contexts and that these identities influence judgment to the extent that they are salient and relevant. Although it is certainly true that consumers do bring a variety of social identities with them into consumer contexts, past research downplays the dynamic nature of social identity. Social identities do not spontaneously appear within consumers—rather, they are shaped by a lifetime of experience, social interaction, and self-expression. Research on this phenomenon has largely argued that consumers choose brands in an attempt to express aspects of the self to others, or fulfill some self-enhancement or self-verification goal. Although these motivations do drive much of consumer social identity-formation, it is also clear that social identities are automatically influenced by contextual information about others. It is this latter automatic influence on consumer social identity that we focus on in this project. Specifically, we explore the influence of advertising exposure on the association strength between depicted social identities and the consumer's sense of self, independent of any explicit attempt at self-presentation. We argue that the influence of advertising exposure on consumer social identity is greatest when the advertising makes direct use of identity-relevant cues or generally targets specific identity groups. Exposure to such advertising can activate the relevant social identity dimension in a consumer's self-concept, and this activation can lead to either assimilation toward or contrast with the depicted identity.

Following an assimilation/contrast model, we assess the extent to which ad exposure directly influences the strength of association of basic social identity dimensions in the self-concept. Moreover, we identify two factors that determined whether consumer self-concept shifted toward the presented user imagery (assimilation) or away from the presented user imagery (contrast): (1) the discrepancy between the objective age of the characters in the advertisement and the consumer's own chronological age, and (2) the relevance of this self vs. user imagery comparison. It was hypothesized that assimilation is the likely response to others that are moderately discrepant and contrast is the likely response to others that are extremely discrepant, but that these effects would only occur when the comparison was deemed relevant.

To test the effects of self-concept discrepancy and relevance on consumer assimilation/contrast responses to advertising, three experiments were conducted. In experiment 1, consumers were exposed to advertising that featured individuals who were either similar in age (college-age users), moderately older (30-something users), or extremely older (senior citizen users) than the consumers themselves. After viewing this focal age-targeted advertisement, half of the participants then evaluated the advertising and how targeted they felt while the other half evaluated the advertising but not how targeted they felt. It was hypothesized that the evaluation of targeting status would increase the relevance of the user imagery as a comparison standard. Finally, participants completed an Implicit Association Test (IAT) that measured how strongly they self-identified with youth as part of their self-concept. Consistent with this hypothesized pattern of results, an interaction of ad type and target market evaluation was observed on subsequent self-youth association: subjects assimilated their self-concepts toward the moderately discrepant targets, but contrasted away from the extremely discrepant targets. In addition, these assimilation and contrast responses only occurred when comparison relevance was high (when the consumers initially assessed their target market status).

Experiments 2 and 3 investigated the process underlying the comparison relevance moderation effect in experiment 1. Instructions to evaluate target status were expected to heighten comparison relevance by drawing attention to characteristics that might make one a member of the target market. This proposed process was tested in experiment 2 by adding a manipulation of whether participants evaluated their similarities or dissimilarities to the presented user imagery. To simplify the design, experiment 2 only included congruent user imagery (college-age users) or extremely discrepant users (senior citizens). As in experiment 1, a significant self-concept contrast effect was observed when participants evaluated their target market status or when they evaluated their similarity to the depicted users. However, when participants evaluated their dissimilarity to the user imagery and did not evaluate their target status, no contrast effect was observed. Experiment 3 extended the findings of experiment 2 by demonstrating that the elicited effects of user imagery on the self-concept carried over to the evaluation of subsequent age-targeted stimuli. Specifically, participants with heightened self-youth associations reported more favorable attitudes toward youth-targeted films than did participants with unaffected self-youth associations.

SYMPOSIUM SUMMARY

Bettering Business: When and How Consumers Value Pro-Social Marketing Efforts

Nicole Verrochi, University of Pennsylvania, USA

SESSION SUMMARY

With increasing consumer interest in pro-social causes such as environmental protection and human rights, corporations are undergoing a shift in their charitable directions. Specifically, firms are increasingly relying on pro-social actions to increase positive evaluations and product preferences. These pro-social actions can take many forms, from donating a portion of profits to a charitable cause to sponsoring fundraising races/walks to creating new products that are tailored to a particular cause (e.g. "green" products, ethically manufactured goods). In all forms, pro-social business activities are those that take into account the interests and concerns of society.

In the marketing literature, there has been growing interest in such activities, especially those classified as corporate social responsibility (CSR), which has been defined as the overall status and activities an organization undertakes with regards to its perceived societal obligations (Brown and Dacin 1997). The prevalence of these CSR efforts has been encouraged by the growing evidence that consumers prefer to patronize businesses that share their own values and ethics (Menon and Kahn 2003; Sen and Bhattacharya 2001). In addition, socially responsible corporate activity may be a source of competitive advantage, in that it can augment the overall reputation and identity of the company. As this area of corporate activities grows, there are two questions consumer researchers may ask: how do consumers perceive these pro-social activities, and, in turn, how do those perceptions impact attitudes toward the corporation?

The three papers in this proposed special topic session address these two questions, using a variety of methods and contexts. Specifically, the lens through which the issues are examined is the comparison of self-focused versus socially-focused consumer perspectives. Bennett and Chakravarti conceptualize this comparison as the signals a person can send via consumption of CSR-related goods. Specifically, these authors find that attitudes toward these CSR-associated products are strongly correlated with their ability to not only signal to others socially desirable traits about the consumer, but also by their ability to self-signal to the consumer themselves. Goldsmith and Dhar examine the self- versus social-focus comparison via mindsets which emphasize either benefits to the self or benefits to the greater good. These researchers find that the positioning of "green" products can highlight either the match between the self and concrete benefits or the greater good and abstract benefits. When there is a mismatch between the benefits and the consumers' mindset, attitudes and willingness to pay for such "green" goods are undermined. Finally, Verrochi, Reed and Tong suggest that there are individual and cultural differences in the emphasis of self- versus social-focus in moral acts. These authors capture these differences using Moral Identity, and propose that consumer perceptions of CSR activities are driven by attributions of the corporation's intrinsic motivation to do good, which are, in turn, impacted by individual differences in perceptions of the motivations for moral action.

While these three papers build upon the burgeoning literature on socially responsible business practices, they contribute to this stream in several important ways. Bennett and Chakravarti expand on the literature regarding the ability of charitable behavior to signal the benevolent identity of consumers (Glazer and Konrad 1996), to demonstrate that it is not only the social signal that consumers are

concerned with, but also the ability to tell themselves (self-signal) about their socially desirable traits. Often when confronted with a charitable behavior, consumers are forced to trade off self-focused benefits (e.g. lower price) for socially-focused benefits (e.g. low emissions gasoline) (Bishop 2008). Goldsmith and Dhar demonstrate that the difference between these benefits is not only the target of the benefit, but also the mental level at which they are construed. Finally, Verrochi, Reed and Tong draw from the social identity literature (Reed 2004) to demonstrate that the reason why consumers reject or accept products that match their moral identity is determined by the attributions the consumer makes about why the company has engaged in prosocial behavior. It is this mediating process which is controlled by internal and social values of moral action (Moral Identity) that ultimately establishes the attitude toward the product.

The current consumption environment, characterized by extensive options in terms of product quality and pro-social business affiliation, increasingly puts consumers in situations where they must choose to satisfy their own needs, the needs of society, or some combination of the two. As well as consumers facing this decision, firms too must decide how to shape their offerings to meet the demands of both the socially conscious consumer and the mainstream shopper. Reflective of this trend, this proposed special topic session offers a timely and relevant examination of how to conceptualize and understand the intersection of these underlying issues. The results of these three papers not only deepen our current understanding of socially responsible actions, but also expand the viewpoints used to examine the process by which consumers ultimately evaluate each option.

EXTENDED ABSTRACTS

"The Self And Social Signaling Explanations For Consumption of CSR-Associated Products"

Aronte Bennett, New York University, USA

Amitav Chakravarti, New York University, USA

Consumers frequently encounter, and buy, products that have a corporate social responsibility (CSR) association (e.g., cell phones giving a portion of proceeds to cancer research). It is well documented that products with a CSR-association are extremely popular among consumers and consumers may even be willing to pay a premium for these products. However, the research on CSR-associated purchase decisions has focused on antecedents that influence evaluations and purchase decisions (Brown and Dacin 1997, Sen and Bhattacharya 2001); less attention has been paid to the specific motivations that drive the decision to purchase a CSR-associated product.

We address this gap in the literature through several studies in which we find that consumers like CSR-associated products for two distinct reasons. First, consumers like the fact that these products send out highly visible, *social signals* regarding their benevolence. Second, consumers also like the more private, *self-signaling* potential associated with the purchase of these products. In sum, we find that the valuation of a CSR-associated product is jointly determined by its social and self-signaling potential. Brief descriptions of the supporting theory, specific studies we conducted, and the corresponding results, are provided below.

Signaling refers to the act of conveying information about oneself in an implicit fashion, by engaging in behaviors that reveal one's traits and preferences to observers. Glazer and Konrad (1996) examined the role of social signals in the realm of charitable behavior. Their model implies that charitable donations are observable signals, and consumers are more willing to donate when there is an increased potential for signaling. We apply this theory to CSR-associated products, a specific type of charitable donation, and hypothesize that the evaluations of CSR-associated products will be positively related to the social signaling potential of the product.

Besides sending out social signals to observers, behaviors also have the capacity to *self-signal* to the individual in question. Quattrone and Tversky (1984) showed that people often engage in behaviors in order to signal to themselves that they possess a particular desirable trait, even when there are no social incentives. Thus, we posit that CSR-associated products also allow for self-signaling. These two hypotheses were investigated in the studies described below.

In the three studies that we conducted, all participants were first presented with an advertisement for a target product, and then asked several follow up questions about the target product, which served as key dependent and process measures of interest to us. We manipulated the social and self-signaling potential of the target product by altering various elements of the ad copy.

In study 1, social signaling potential is manipulated by varying the visibility of the product via color and the CSR-association was manipulated by the presence-absence of a CSR affiliation. Study 2 replicates study 1, replacing the social signaling manipulation with a more subtle manipulation of location of consumption (private vs. public). Study 3 considers the role of self-signaling; self-signaling potential is manipulated by the presence/absence of a reminder about how the purchase of the CSR-associated product would remind participants of their benevolence.

Results across these studies indicate that products with greater social signaling potential derive more benefit from CSR associations. Although evaluations in the low social signaling condition remained constant across CSR conditions, evaluations of products with high social signaling potential increased significantly when CSR-associations were added. This difference further increased when a self-signaling reminder was added. Our findings suggest that consumers generally reward CSR-associated products that have the ability to serve as social signals. Interestingly, in order for self-signaling potential to influence the evaluations of CSR-associated products, these products must also have social signaling potential.

Two more studies, which are currently in progress, are aimed at lending further credence to the fact that social and self-signaling play an important role in the purchase of CSR-associated products. In study 4, using a design that parallels Tversky and Quattrone's (1984) cold-compressor task, we investigate the potential for consumers to derive self-signaling benefits from the purchase of a CSR-associated product, even when (a) explicit reminders about its self-signaling potential are absent, and (b) a strong social signal is not plausible. In study 5, we look at individual level traits that should predispose people to differentially value the social (versus self) signaling potential of CSR-associated products.

These five studies, using disparate manipulations and dependent measures, provide convergent findings. Our findings suggest that consumers generally reward CSR-associated products for their ability to serve as social signals and are willing to punish and devalue similar CSR-associated products that do not offer the same signaling potential. Interestingly, we find this preference even when the product's social signaling potential is very subtly cued.

Furthermore, if consumers are provided with explicit self-signals, the difference between high and low social-signaling potential products is augmented. In sum, we address a gap in the literature on corporate social responsibility by showing that the valuation of a CSR-associated product is jointly determined by its social and self-signaling potential. Our findings also extend the literature on signaling by offering an addition to the relatively modest extant stream of research related to self-signaling, especially in the consumer behavior domain.

"Getting Gold by Going Green: The Importance of Fitting the Message to the Mindset"

Kelly Goldsmith, Yale University, USA
Ravi Dhar, Yale University, USA

Firms today are ever-increasing the number of "green" products they offer. These products are typically positioned in terms of an associated pro-social benefit. For example, purveyors of shade grown coffee may stress how their coffee is farmed with minimal damage to the environment. Thus far, the goal of offering green products has been to cater to consumers who value these pro-social benefits; however, industry leaders have recently noted that many consumers still weigh their own personal needs above those of society when making purchase decisions. Such critics have questioned how to position green products such that mainstream consumer interest can be cultivated and product success will not remain limited to the "green ghetto" or the minority of socially conscious consumers (Bishop 2008).

As no academic research to date has explored how consumer decision processes may influence purchase considerations of green products, the current research proposes and tests how consumer mindsets and the positioning of product benefits affect interest in green goods. When positioning a green product (energy efficient light bulbs), benefits along at least two distinct dimensions can be emphasized: the product can be described in terms of the benefits to the *self* ("reduce your home energy costs") or benefits to the *greater good* ("reduce global warming"). Benefits to the self can be seen as more concrete, as they are more psychologically proximal and are associated with lower level goal attainment. Conversely, benefits to the greater good are more abstract, as they are associated with higher order, more general goals. Recent research has demonstrated that consumers' mindsets (abstract vs. concrete) can systematically influence the importance of product benefits. Consumers in a concrete mindset have been shown to prefer products offering more tangible, personal benefits (Meyvis, Goldsmith and Dhar 2008); whereas consumers in an abstract mindset prefer products whose benefits meet higher order goals (Fishbach, Zhang and Dhar 2005). As such, we argue that consumers in a concrete mindset will

be persuaded by appeals for green goods promising more concrete benefits, such as benefits to the *self*. Conversely, an abstract mindset, which focuses attention on higher order goals, will cause consumers to be more persuaded by appeals for products promising benefits to the *greater good*. Thus we predict that a consumer's mindset (abstract vs. concrete) and how the product is positioned (offering benefits to the self vs. the greater good) will have an interactive effect on consumer preferences for green goods.

This proposition is tested in three studies. In Study 1, participants' read a vignette about a green product (solar panels) that they may purchase in the near future (two weeks) or distant future (six months). Temporal distance has been shown to systematically affect the level of abstraction at which consumers' process information: more distal time frames correspond to more abstract representations (Trope and Liberman 2003), thus the time frame manipulation was used as a manipulation of mindset. The green product was positioned either as offering benefits to the self ("reduce heating costs") or benefits to the greater good ("reduce global warming"). Finally, all participants indicated their willingness to pay for the product. In support of our hypothesis, the results demonstrated that consumers in an abstract mindset showed a greater willingness to pay when the product benefited the *greater good*; whereas consumers in a concrete mindset showed a greater willingness to pay for a product associated with personal benefit (interaction: $p=0.028$).

Study 2 was designed to extend the ecological validity of Study 1, by using a different manipulation of mindset and a different green product. The first study may have obtained the effect of mindset on willingness to pay only for a product where consumers were relatively unfamiliar with standard prices (Coupey, Irwin and Payne 1998). To address this concern, in Study 2 we used a product whose standard price was well known (a gallon of gasoline) and measured not only willingness to pay but also purchase intent. Participants first underwent a mindset manipulation then read a vignette about a green product (ethanol gasoline) that was positioned either as offering benefits to the self ("preserve the life of your engine") or benefits to the greater good ("preserve our environment"). Finally, all participants indicated the likelihood that they would consider purchasing the product on 1–9 scale (1=definitely yes, 9=definitely no), and their willingness to pay per gallon. In support of our findings from Study 1, the results demonstrated that consumers in an *abstract* mindset were more interested in purchasing the product when it offered a pro-social benefit as opposed to a personal benefit ($M_{\text{self}}=4.36$; $M_{\text{pro-social}}=3.07$); whereas the opposite was true for consumers in a *concrete* mindset ($M_{\text{self}}=2.80$; $M_{\text{pro-social}}=3.36$). This interaction replicated and was significant for willingness to pay ($p's<0.04$).

Finally to extend the findings of Studies 1 and 2 into the domain of choice, Study 3 tested for the moderating effect of mindsets and product positioning on choices with actual financial consequences. Participants underwent a mindset manipulation then were told that to thank them for their participation they would be entered into a lottery for a reward of their choosing. Their choices were a cash reward, described as "Ten dollars in cash that you can spend any way that you choose," or a green battery charger described as "one way for anyone to help reduce global warming and preserve the environment." In support of our hypothesis, we find that participants in an abstract mindset were significantly more likely to choose the green product over cash ($P_{\text{abstract}}=53.8\%$; $P_{\text{concrete}}=25\%$; $p=0.038$).

At present, this research achieves several goals: we demonstrate that consumer mindsets and the positioning of a green product can have an interactive effect on consumer purchases. Further we demonstrate that this effect carries over to actual choice decisions.

As many firms today feel compelled to offer green products and wish to do so successfully, we believe this research addresses an important practical question and makes a meaningful theoretical contribution.

"Moral Identity and Attributions of Corporate Social Responsibility"

Nicole Verrochi, University of Pennsylvania, USA

Americus Reed II, University of Pennsylvania, USA

Jennifer Tong, Singapore Management University, Singapore

Recent research has developed an instrument for measuring both the content and intensity of a person's moral identity. Moral identity has been defined as a self-conception organized around a set of collectively shared, higher-order values, principals or beliefs (Aquino and Reed 2002). While research on consumer perceptions of socially responsible corporate actions (e.g. charitable donations, foundations, etc.) have primarily focused on the either the fit between the corporation and the charity or the form of the action (e.g. Menon and Kahn 2003), we propose that individual differences in moral identity can predict consumer reactions to corporate social acts.

Two studies demonstrate that while fit and CSR form impact some types of attributions consumers make about the firm's motivations for engaging in socially responsible action, it is moral identity which predicts those attributions that ultimately determine attitudes toward the firm. In both studies, participants first filled out a "personality test" containing the Moral Identity scale (Aquino and Reed 2002) as well as other various individual difference scales. After completing these measures, participants engaged in a filler task, and then were presented with the experimental stimuli. Each participant saw one of four advertisements; either high or low on corporation-charity fit, and either a promotion format or advocacy format as per Menon and Kahn (2003).

Study 1 demonstrates that American participants' scores on the Internalization dimension of moral identity, or the degree to which moral characteristics are self-important, predicts ratings of Values-Driven attributions. This specific class of attributions, which relate to how much a firm cares about the adopted cause, predicts attitudes toward the firm. When participants' attributions are entered into the regression, we observe full mediation of the effect of Internalization on ratings of CSR. In contrast, study 2 shows that Singaporean participants' scores on the Internalization dimension of moral identity neither predict Values-Driven attributions nor ratings of CSR. Rather, Singaporean participants' scores on the Symbolization dimension of moral identity, which captures

sensitivity to the moral self as a social object, predict ratings of Values-Driven attributions, which in turn predict CSR. We also observe full mediation of the effect of Symbolization on ratings of CSR when Values-Driven attributions are included in the regression.

These results are consistent with the characterization of American consumers as possessing a relatively independent self-construal; while Singaporean consumers have a more interdependent self-construal. To this extent, independent (US) consumers follow the norm of expressing one's unique attributes (Markus and Kitayama 1991), which maps onto the Internalization dimension's conception of the *self*-importance of moral behavior. Opposing this, consumers holding an interdependent self-construal (Singapore) follow the norm of "seeing oneself as part of an encompassing social relationship" (Markus and Kitayama 1991: p. 227), evidenced by the Symbolization dimension's sensitivity to the *social* value of moral behavior.

These findings have implications beyond the realm of individual difference scales. We find that fit between the company and charity, as well as the form of the socially responsible action are less predictive of ratings of CSR than are feelings that the firm cares about the cause, regardless of cross-cultural differences. Although different dimensions of moral identity carry more or less weight in different cultures, Values-Driven attributions consistently predict CSR evaluations. With this in mind, managers should reconsider the strategies used to select between different corporate social actions. Rather than selecting those that are the best "match" with corporate identity, firms would be better served to choose activities that they are visibly passionate about, to encourage these Values-Driven attributions. Not only would attitudes toward the firm increase, but the charities themselves would be better served by engaged corporate partners.

SYMPOSIUM SUMMARY

Freedom and Constraint: The Interplay of Consumer Agency, Social Relations, and the Market

Michelle Barnhart, University of Utah, USA

Lisa Penaloza, Ecole des Hautes Etudes Commerciales du Nord, France

SESSION OVERVIEW

This session on consumer agency—that is, one’s ability to fully engage in all of the various aspects of consumption—is positioned as a follow up to last year’s ACR epistemic panel on consumer freedom. In that session Tom O’Guinn, Rob Kozinets, and Lisa Penaloza joined organizer David Mick in addressing the nature, extent, up/downsides, and changes in consumer freedom over time. This topic tapped a major artery running through consumer culture theory (CCT) in conveying the powerful and creative force of this social construction. As historical artifact, freedom has inspired revolutions, wars, and civil rights struggles. As modern idealization, freedom traverses a complex web of meanings interwoven in everyday and spectacular consumption practices at home and in the marketplace, with implications to larger social and government institutions. As such, the concept of freedom merits much further work.

In the spirit of such further work, this session on consumer agency is organized to contribute understanding to the micro dynamics through which consumer agency is exerted and constrained. Western ideas of agency are rooted in the tradition of philosophers such as Descartes and Hume who emphasized an autonomous, rational subject capable of individual thought. The ability to think independently and understand one’s subjectivity and self interests is necessary for agency, which has been understood in terms of action and the potential for action, as in one’s capacity to act in his/her own interests. When cast in the consumption domain, consumer agency is exercised in consumption practices.

In this session, we problematize consumption practices and discourses of consumer agency. In doing so, it is important to anchor our studies in relation to representations of the consumer and the social expectations held for consuming agents by significant others—family, friends, and market agents. Questions raised include: What does agency entail in the consumption domain? How do market institutions convey agency to their consumers? How does ownership of consumption artifacts enable and constrain agency? And, how is consumer agency differentially configured in the three contexts on which we focus: a family making use of their dining room table, as we get old, and when we move? These contexts allow us to bring forth various contours of personal independence and autonomy in social relations and in the market as consumers employ products and services in relation to their family and friends and with firms.

Writers such as Adam Smith and David Ricardo have positioned the market as a source of freedom from oppressive social and religious traditions, casting consumer agency as a means of liberating ourselves from social constraints. Yet previous research has shown that the market places its own constraints on individual freedom (e.g. Bernthal, Crockett, and Rose 2005; Penaloza 1994; Penaloza 2001), with some consumers finding the market so oppressive that they attempt to escape to an idealized, liberating social space (Kozinets 2002). In this session we examine the tension between freedom and constraint that exists in both the market and the social realms, and consider how engaging in one realm can influence the freedom/constraint balance in the other. Furthermore, this session illuminates the ways in which consumer agency is affected by significant others, the market, and one’s own body.

A common thread running through each of the three papers is an emphasis on the interplay between social relations and consumer agency. In its investigation of identity construction and the use of a family’s dining room table, the first paper challenges us to reconceptualize agency as something that is articulated in the practices of individual, relational and collective identity bundles rather than being manifest only by individuals. This work also uniquely contributes to this session in its emphasis on how an object, the table, may exert a constraining force over human agency. The analysis and write-up of this paper are complete. The second paper considers how consumer agency can be shared by family, paid providers, and elderly consumers when an older person is no longer able to consume independently. In this context, the focus shifts from an inanimate object to our own bodies as a source of constraint. Additionally, this research considers how the market can perpetuate an idealized concept of freedom and independence in old age. One round of data collection and analysis for this paper is complete, and the authors expect to be in the final stages of analysis by the time of the conference. Finally, in the context of house moving, the third paper analyzes the interplay and tensions between individual consumers and their social networks of family members, friends and acquaintances. Like the other papers of the session, this research questions the individualistic view of agency by focusing on how people negotiate the social expectations and relational obligations of the gift economy. More importantly, it examines how people may sometimes seek to escape the gift economy by turning to the market. As such, this paper looks at how the market helps to reconcile consumers’ desire to belong to a social network and their need for freedom and autonomy. Analysis and write-up are expected to be completed by the time of the conference.

This session is expected to appeal to those interested in consumer agency and freedom, the family, identity construction, elderly consumers, materiality, and the socially embedded nature of consumption. Implications for individuals include how they can use consumption to balance personal life goals with social and market benefits and challenges. Implications for service providers such as movers and elder care services relate to how they might position themselves relative to competitors and in anticipating future market development. Finally, implications for social theory include providing insight into how consumption impacts social groups of family and friends.

EXTENDED ABSTRACTS

“Agency, Identity and Materiality: The Storied Life of a Family and their Table”

Amber M. Epp, University of Wisconsin-Madison, USA

Linda L. Price, University of Arizona, USA

Eric J. Arnould, University of Wyoming, USA

“Figured worlds, like activities, are not so much things or objects to be apprehended as processes or traditions of apprehension which gather us up and give us form as our lives intersect them,” Holland, Lachicotte, Skinner and Cain 2003

Prior research in material culture studies has sought to “transcend a simple dualism in which agency is seen as a possession of

persons or society, and objects merely that which is passively worked upon” promoting instead an approach based on networks of agents that “include both animate and inanimate forms” (Miller 2001, p. 119). Consistent with this evolving perspective, we view consumer agency as improvisations and potentialities that come from the interplay of individual, relational and collective identities, material objects, other cultural resources, and situations in practice (Holland et al 2003). As such, agency is socially instanced in identities produced through collective practices that are spread across the material world and located in specific times and places (Cetina 1997). Within a socio-historical or “figured world” of semiotic meanings, objects are instruments of agency, recipients of the acts of others’ agency and also act as agents to transform and displace individual, relational and collective identities and practices (Miller 2005). Hence, at contrast with views of agency as individualistic, purposeful control; we emphasize how other social units (such as couples, children and families); objects; and spaces exert semiotic agency as they interplay in identity practices (Epp and Price 2008). In particular, our study illustrates “the positive blending of social and material relations” (Miller 2001, 115) that can occur at the intersection of object and personal biographies.

Our paper is based on a two-year ethnographic case study we conducted that describes linkages between the biography of the Erikson family (a pseudonym) and the biography of their kitchen table, a highly singularized object (Kopytoff 1986). Using a life-history approach (Denzin 1978), we interviewed five family members, including a mother, father, two children, and the mother’s mother. We uncover how contextual shifts and constellations of objects and spaces propel and alter the uses of the table, and how the table in turn alters key family identity practices. We produce depth of understanding and triangulation across informants and events by drawing on multiple family members and collecting data at multiple time points (Yin 2003; Wallendorf and Arnould 1991). Over the two-year period one of the researchers made multiple visits to the family’s home and photographed the table in various roles. Fortunately, this case tracks a family during a transitional period (moving to a new house), making identity issues salient (Otnes, Lowrey and Shrum 1997; Schouten 1991) and allowing us to assess contextual changes that challenge the object’s role in family identity.

Our research reveals that a highly singularized object can be propelled into periods of inactivity by a convergence of forces including 1) other singularized objects with complementary and/or competing biographies; 2) other complementary and/or competing individual, relational or collective identity performances; 3) shifts in contextual elements such as spaces, life events, and so on. In the case of a highly singularized object, periods of inactivity are marked by incorporation attempts and contemplation about possible futures for both object and family biographies. Objects are moved back into activity by 1) possible futures the family envisions, which create new opportunities for object-family interactions; 2) object indexicality that demands that particular identity practices require the use of THIS particular object; 3) the complementary iconicity of objects and spaces (as dining table; contamination of the object by the space and vice versa; sometimes just needs to be a big table); and 4) shifts in contextual elements.

Object movements have unprompted and unintended consequences such as displacement of identity practices, other objects, and spaces. By focusing on the consequences of movements of singularized objects in and out of activity, we are able to account for paradoxical behaviors. For example, we explain why and how individual, relational, and family identity practices are altered or abandoned in order to reincorporate singularized objects into their

performances. We also show how a singularized object, as it exits and re-enters the family’s social space, can precipitate a new vision of family identity. Our research provides examples of objects exerting constraining force over human agency as seen in the dramatic efforts made by two generations of family to accommodate the table, including remodeling three houses and moving the table in and out of the current house in order to provide a key prop to particular identity performances. In addition, we highlight the agency of multiple identity bundles, not just the individual, in the improvisations that unfold in the “figured world” of the Erikson family. In the Erikson family, convergent and overlapping identity practices are more prominent than divergent and competing practices. However, divergence and competition between identity bundles emerge in the family’s move to a new home with new objects and spaces potent with competing identities that ultimately displace the table to the garage. In this move we see how individual, relational and collective identities collide, compete and interplay to exert agency over the next moment of activity.

“Negotiating Agency in the Elderly Consumption Ensemble”

Michelle Barnhart, University of Utah, USA

Lisa Penalzoza, Ecole des Hautes Etudes Commerciales du Nord, France

While improvements in health care have greatly increased life expectancy over the last century, they have not eliminated many of the physical and mental limitations that often accompany old age. Age related changes leave many older consumers unable to consume independently. In 2005, 6.4% of Americans between the ages of 65 and 74, and 18.3% of those over the age of 75 required assistance with at least one of the following consumption activities: using the telephone, traveling outside the home, shopping, preparing meals, doing housework, taking medications, and managing money (Census 2008).

Assistance may include private, informal help from family members or friends as well as paid in-home services, and is likely to be a complex and dynamic process involving multiple people in changing configurations over time (Waldrop 2006). We refer to this group as the *elderly consumption ensemble (ECE)* and define it as an elderly consumer and one or more others who together engage in consumption activities of that elderly person. The ECE is analogous to a jazz ensemble in which members possess different competencies and are more or less engaged in activity at any particular moment.

This research investigates how consumer agency operates within ECEs that include both unpaid family or friends and paid providers. In so doing, it strives to understand how agency is constrained, enhanced, protected, contested, relinquished, and shared in consumer behavior. For example, an older person’s consumer agency may be constrained by physical limitations, enhanced by adaptive devices, protected as they insist on “doing it myself,” contested by family members worried about an elder’s physical safety, relinquished when they ask others to do something for them, and shared when they are able to engage in a consumption activity only with assistance. For our theoretical framework, we draw eclectically from previous work on elderly consumers, family, joint consumption, and commercial friendships. Methodology includes depth interviews with members of six ECEs, each consisting of an elderly consumer, at least one family member or friend, and at least one paid care provider. Questions elicit oral histories beginning with informants’ first recognition that assistance was needed, and including how levels and types of assistance and ensemble members’ relationships changed over time. Additional questions explore informants’ reflections on their experience as an older person,

family member/friend, or caregiver; their own aging; and what it means to be old in American society. Of interest is how older consumers' agency is influenced by their own aging bodies, family members, and market providers.

While cognition has received greater attention in studies of aging consumers (Cole and Balasubramanian 1993; Yoon 1997; John and Cole 1986; Law, Hawkins, and Craik 1998), changes in the body can also make it difficult or impossible for older consumers to exercise agency. For instance, Richard (89) has macular degeneration. He is no longer able to drive and reads only with great difficulty using a special machine that he has at home. While he has experienced no marked decline in his cognitive abilities, his is unable to act independently as a consumer in a marketplace that demands a certain degree of mobility and literacy.

Family members or friends may attempt to enhance or protect the agency of an older consumer by gifting adaptive devices, such as Richard's reading machine or Jane's (82) new walker. Yet these items may also be seen as threatening markers of age that imply a gradual loss of freedom and independence. Alternatively, family/friends may attempt to limit an older person's agency as they try to protect the older person or to advance their own self interests. When family members engage in consumption activity with an older person who previously acted alone, agency must be negotiated in consumption behavior as the elderly consumer moves into and acts from an elderly subject position.

Finally, the market both frees and constrains older consumers. Advertising images of independent, active seniors legitimize old age in ways that are gratifying but can also create unrealistic expectations of perpetual independence and autonomy. Service providers make it possible for older consumers to live independently from their families. However, this social independence is counterbalanced with increasing dependency on the market. Assisted living centers and paid caregivers are examples. At the level of the individual service provider, we conceptualize paid care providers as ECE members engaged in consumption with elderly consumers while supporting an ideal of independence. Like family members, paid care providers negotiate agency and subject position with the elderly consumer through consumption behavior. However, in this case the relationship between an older consumer's agency and the ECE member's interest is more immediately obvious. The paid provider's employment is the direct result of the older consumer's constrained agency. If the older person could act alone, the provider would not be needed. Thus, while the paid provider may out of genuine friendship or love wish to enhance the older person's agency, he/she also has a vested interest in continued or increasing constraints.

This research seeks to contribute to the consumer behavior literature by elucidating how changes in the body and changes in family and market relationships that accompany advanced age impact the nature of consumer agency. Furthermore, by asking how agency is shared by ECE members, we challenge the concept of individual consumer agency and add to previous work on the socially embedded nature of consumption. In increasing our understanding of the ECE, this work has implications for family members, marketers, and policy makers interested in maintaining and enhancing the quality of life of elderly consumers and their families.

“Moving Across the Gift Economy and the Market”

J.S. Maroux, University of Montreal, Canada

In consumer research, the gift economy has usually been considered as a sphere of exchange that is distinct from the market. The two are not only analyzed separately, however. They are also

often organized into a hierarchy of values in which the gift is privileged.

Researchers like Cheal (1988), Giesler (2006) and Thompson and Arsel (2004), for instance, have analyzed the gift and the gift economy extensively. These researchers have described gift-giving as a social activity in which a humanizing logic is applied at an interpersonal level. They have also projected this idea up to the level of the gift economy (see for example Kozinets 2002; Thompson and Coskuner-Balli 2007). Few of these researchers have questioned, however, the ennobling view of the gift economy. Notwithstanding the work on the darker sides of the gift (see for example Belk 1976, 1979; Ruth, Otnes and Brunel, 1999; Sherry, McGrath and Levy, 1993), which has unveiled the emotional and relational constraints of gift-giving behavior, consumer researchers have usually failed to explore the implications of the dark side of the gift in relation to the market. In other words, they have often ignored how people may seek to escape the constraints of the gift economy, and how they may turn to the market as a result.

This presentation examines how people negotiate the social expectations of the gift economy and the relational obligations (like social indebtedness) that such a context of exchange entails. It unveils the micro-dynamics of consumption that leads people to either comply to the norm of the gift economy, subvert it, or escape it through the market. The notion of agency is useful for understanding this process. If freedom is a notion in which the choice is sometimes idealized, agency is understood for its part as a means of expressing volition and intentions within a set of norms. In this case, we can speak about the norms of reciprocity prevailing inside the gift economy. As such, turning to the market becomes a means of asserting agency.

This presentation is grounded in an ethnographic study of house moving in Montreal (Canada). In line with Arnould and Thompson (2005), moving is used here as a privileged context for accessing reciprocity relations and for revealing the tensions that may make the gift economy unattractive, and that may lead people to escape it as a result. In Montreal, using family, friends, acquaintances and social networks for the purpose of moving is the norm. Moving is a social event particularly appropriate for the emergence of reciprocity relations. During a move, members of primary support networks—and also more distantly related persons—give, swap, exchange and trade services and resources in a fringe zone of social activity that lies between the gift economy and the market. Many people who decide to move view calling upon the market as a complement to, a substitute for, or an exit from the gift economy. Thus, the analysis of moving, with this activity seen as a point of passage between the gift economy and the market, can help us to think beyond the literature on reciprocity and gift-giving.

This presentation does not only challenge expectations of specific CCT researchers. It also goes against some of the fundamental tenets of consumer research on the gift. It shows how people may subvert the hierarchy of values that underlies most of our field's research on the gift.

SYMPOSIUM SUMMARY

Understanding Hedonic Misprediction: The Role of Lay Beliefs

Jane Ebert, University of Minnesota, USA

SESSION OVERVIEW

Research shows that consumers often spontaneously consider and are influenced by their anticipated feelings about consumption experiences, both in the choices they make and in how they feel about these experiences. However, people also commonly get these hedonic predictions wrong, leading them to make suboptimal or unwanted choices (e.g., see review by MacInnis, Patrick, and Park, 2005). This symposium combines 4 papers and a discussant that advance our understanding of why and how hedonic mispredictions occur, by focusing on a relatively new and unexplored explanation: the role of lay beliefs. Beyond simply providing a laundry list of lay beliefs that result in misprediction, the juxtaposition of these papers provokes thinking on when and how lay beliefs can result in misprediction.

First, misprediction can occur if consumers hold consistent, but incorrect lay beliefs. This occurs in two of the present papers, resulting in larger predicted differences in hedonic reactions than are observed in experience. In the Ebert/Meyvis paper, subjects expect the psychological distance of an experience (e.g., reading about a recent versus a distant past event) to impact both processing of the experience and its direct hedonic impact resulting in overprediction of the impact of psychological distance. In the Zhang/Hsee paper, subjects expect that differences between products that are hard to evaluate (such as the resolution of a digital camera) will affect their preferences more than they actually do. Second, consumers may hold lay beliefs that are incorrect but inconsistent across consumers or ones which lead consumers to (incorrectly) expect no impact on their hedonic reactions, resulting in no systematic effect on prediction. This is seen in the Galak/Kruger/Loewenstein paper, where subjects' enjoyment of repeated listening to songs or drinking beverages is strongly affected by the spacing of consumption, though their predictions show no effect of spacing. Third, consumers may hold accurate lay beliefs, but fail to apply them. This is the case in the Wang/Novemsky/Dhar paper, where consumers mispredict their product enjoyment over time because they fail to apply their accurate lay beliefs on adaptation—beliefs that are easily cued and moderated through subtle changes in product features.

We expect that these four papers, tightly linked around the role of lay beliefs in affective forecasting, will lead to an interesting and thought-provoking symposium. We intend that each presentation will last for 15 minutes, with an additional 15 minutes where the discussant will highlight session themes and moderate audience questions and discussion. The papers contribute to a developing research area relevant to the interests of many ACR members, notably those interested in hedonic consumption, information processing, and judgment and decision making.

EXTENDED ABSTRACTS

“Anticipating Adaptation to Products”

Jing Wang, Singapore Management University, Singapore

Nathan Novemsky, Yale University, USA

Ravi Dhar, Yale University, USA

Many consumer products deliver their value over extended periods of time. However, the level of this utility often diminishes over time due to waning novelty, shifting reference points and expectations, and various other mechanisms. Moreover, this pro-

cess of *hedonic adaptation* seems to catch people by surprise (Schwartz 2004). For example, imagine that after much thought, a person chooses to spend \$500 extra to buy a high-end stereo with many cutting-edge features instead of a basic model. A few months later, the initial thrill of the new stereo fades, enjoyment falls dramatically, and the person may get caught up in remorse, wondering why he chose the expensive stereo.

The purchase decision for a product with temporally extended enjoyment requires consideration of the product's utility profile integrated over its life (Kahneman and Snell 1990; Kahneman, Wakker, and Sarin 1997; Nowlis, Mandel, and McCabe 2004). In the current research, we demonstrate that when faced with such purchase decisions, consumers often fail to predict diminishing product enjoyment over time and explore the antecedents and consequences of this prediction error. We show that this failure to predict hedonic adaptation to products arises not because of erroneous beliefs about how experienced utility changes over time, but rather because of a failure to spontaneously consider adaptation and incorporate largely correct beliefs about adaptation at the moment of choice. As a consequence, consumers may over-purchase products and spend excessively on product features even when they have correct intuitions about hedonic adaptation for those products and features.

In a pilot study, we find that there is a prevalent belief in adaptation for a range of products that are consumed over time. In study 1, we show that people's predictions of future enjoyment with a product fail to reflect diminishing enjoyment observed in actual experience despite the fact that they expressed a belief in adaptation for that item in the pilot study. In study 2, we demonstrate that intuitive beliefs about adaptation can be cued by prompting people to consider enjoyment with a product at both near and distant points in time, thereby producing better hedonic forecasts. In subsequent studies we show that consideration of adaptation has important consequences for purchase intentions and choice. Specifically, study 3a shows that cuing beliefs about adaptation significantly decreases purchase intent for products whose enjoyment people believe will quickly dissipate over time. Study 3b shows that cuing beliefs about adaptation influences product feature choices, shifting preferences away from products containing features that people believe they will quickly adapt to. In studies 4 and 5 we provide evidence that salience of prospective duration of product ownership rather than direct attention to diminishing enjoyment is responsible for the effects demonstrated in our preceding studies. Specifically in study 4, we simply ask participants to imagine using a product at different points in time without asking for any hedonic predictions and obtain a similar pattern of results on choice as shown in study 3. In study 5, we show that making multiple product enjoyment predictions over a very short time period (where no adaptation is expected) is sufficient to draw attention to duration and thereby bring beliefs about adaptation to mind. And finally, study 6 examines a boundary of people's beliefs about adaptation for products. In this study, we test the idea that people may not believe in diminishing enjoyment for products that offer highly variable experiences. We show that very subtle changes in the description of a given product can influence the perceived variability of the product consumption, which in turn moderates the effect of making prospective duration salient on purchase decisions.

In summary, the present research explores how and why predictions of enjoyment with products over time may diverge from experiences even when consumers hold valid intuitive beliefs about adaptation. Moreover, we examine the consequences of this divergence for purchase decisions. Our findings offer important insights for the study of affective forecasting, overspending, and long-term satisfaction. It is important to note how our findings contrast with prior work on affective forecasting. Specifically, previous research suggests that people often hold inaccurate beliefs about affect progression, which in turn leads to prediction errors and suboptimal choices (e.g., Kahneman and Snell 1992; Nelson and Meyvis 2006; Novemsky and Ratner 2003; Wilson et al. 2000). The present research finds that even when intuitive beliefs are accurate, predictions may still diverge from actual experiences, as people frequently fail to incorporate these accurate beliefs into judgments and choices. Our findings also offer insights into issues such as consumer overspending (e.g., buyer's remorse) and Scitovsky's "Joyless Economy."

"Too Much of a Good Thing: Insensitivity to Rate of Consumption Leads to Unintended Satiation"

Jeff Galak, New York University, USA

Justin Kruger, New York University, USA

George Loewenstein, Carnegie Mellon University, USA

Repeated consumption of hedonic experiences is ubiquitous. Consumers eat their favorite foods repeatedly, listen to their favorite songs time and time again, and socialize with the same close friends regularly. Such repetition can lead to satiation. In one study, participants listened to a 45-second sample of a favorite song 15 times in quick succession, rating their enjoyment of the experience along the way. What began as an enjoyable experience became downright unpleasant after only 6 repetitions (Ratner, Kahn & Kahneman, 1999, Expt 1). Indeed, the notion that repetition decreases enjoyment of pleasurable experiences is a central tenet both of psychological and economic theories of taste (Helson, 1947; 1964; Mas-Colell, Whinston & Green, 1995; although see Zajonc, 1968 for an important exception).

Satiation, however, is not inevitable. A delay between exposures, for instance, can attenuate (and even halt altogether) satiation. Whereas the same song might grow tiresome if repeated in quick succession, a space between exposures reduces satiation. Are consumers aware of the impact of rate on satiation? Do they maximize satisfaction by choosing a sufficient inter-consumption delay between consumption? The present research addressed these questions.

Participants in Study 1 listened to a novel but (initially) well-liked song. Some participants went on to listen to the song 6 more times (experiencers), rating their enjoyment of the song after each iteration. Other participants merely imagined listening to the song repeatedly and predicted these ratings (forecasters). Orthogonal to this manipulation, one condition had a short break between iterations, whereas in the other condition consumption was back-to-back. Rate had a considerable influence on actual satiation, but had no influence on anticipated satiation. Participants enjoyed the song considerably more if there was a delay between consumption, but showed no difference in predicted enjoyment.

One implication of the results of Study 1 is that consumers may choose inter-consumption intervals that fail to maximize their satisfaction. If consumers do not realize the extent to which an inter-consumption delay can prolong liking, then they may not optimally space consumption. The next two studies were designed to test this hypothesis.

In Study 2, participants consumed a well-liked drink (Starbucks Mocha Frappuccino) while watching a 10-minute television pro-

gram. In one condition, participants drank the beverage as quickly (or slowly) as they wished. In the other condition, participants were limited to one-sixth of the beverage at six evenly spaced intervals throughout the duration of the 10-minute program (i.e., every 100 seconds). Not surprisingly, participants consumed more quickly when left to their own devices than when an inter-consumption delay was imposed upon them. Also as predicted, participants enjoyed the beverage more when consumption was spaced than when they consumed at their own (faster) rate.

Of course, one explanation for the results of Study 2 is that instead of failing to realize that they would enjoy the beverage more if they slowed their consumption, they simply lacked the self-control to do so. After all, there is no shortage of studies that attest to the occasional difficulty people have in avoiding temptation, even with full awareness that they are doing so (Loewenstein, 1996). Would participants choose a similarly sub-optimal rate of consumption if they made their choices in advance, prior to the influence of immediate temptation? Our third and final study was designed to find out.

Participants once again were offered the opportunity to repeatedly consume a well-liked stimulus while watching a television program. This time, however, participants who chose their own rate of consumption did so prior to the experiment. Specifically, participants were told they would be given 6 Hershey's Kisses during a 20-min television program and asked to choose their inter-consumption interval (from a minimum of 10 to a maximum of 200 seconds). Importantly, participants were instructed to select the interval they thought would maximize their enjoyment of the chocolates. As in Study 2, another group of participants had no such choice and consumed the Kisses at the maximum possible inter-consumption interval (200 sec). As in Study 2, participants who chose their own rate of consumption consumed the chocolates more rapidly than those who were assigned the maximum inter-consumption interval. Also as in Study 2, this resulted in decreased enjoyment.

Taken together, the results of these studies suggest consumers underestimate the impact of rate on satiation, and consume more rapidly than is optimal. In studies 2 and 3, paradoxically, participants asked to maximize their utility were less satisfied than those who had their rate of consumption decided for them. It appears that insensitivity to rate of consumption can lead to unintended satiation.

"Affective Forecasting and Psychological Distance: The Surprising Impact of Distant Events"

Jane Ebert, University of Minnesota, USA

Tom Meyvis, New York University, USA

Would you prefer to see a film based on a true story or a similar film that is entirely fictional? Does it matter if the true story occurred recently or 10 years ago? A growing literature shows that, when making experiential consumption decisions such as these, consumers are influenced by their anticipated feelings about the experience (see MacInnis, Patrick, and Park, 2005, for a recent review). Research also finds that these hedonic predictions tend to be inaccurate. In particular, consumers tend to overestimate the enduring hedonic impact of an experience. This impact bias has been demonstrated for a broad range of positive and negative hedonic experiences, such as relocations, winning prizes, receiving gifts, failing to lose weight, and electoral defeats (see reviews Kahneman and Snell, 1992, and Gilbert, Driver-Linn and Wilson, 2002). Explanations of this bias have focused on the *lack of consideration* by predictors of the internal and external context around the focal hedonic experience, such as how feelings will change or the effects of experiences that occur subsequent to the

focal hedonic experience (Gilbert et al. 1998; Gilbert and Wilson 2000).

In contrast to this work, we explore a process by which people mispredict the impact of a hedonic experience by *overconsideration* of the context around the focal hedonic experience. In particular, we demonstrate that people overestimate the dulling impact of contextual factors that increase the psychological distance of a target event. As a result, people underestimate the intensity of their emotional reaction to reading fictitious or historical stories, and to winning a prize that will only be made available later.

In 4 studies, we compared people's predicted versus actual hedonic reactions to events that were either psychologically close or distant. In studies 1-3, participants read emotion-inducing newspaper stories (e.g., about a student dying from meningitis). Experiencers were first given information about the story context. Psychologically distant experiencers were told the story was "fictitious" (Studies 1 and 3) or about an event that "happened 10 years ago" (study 2), while psychologically close experiencers were told the story was "real" (studies 1 and 3) or about an event that "happened recently" (study 2). Experiencers then read the story and rated their affective reactions. Predictors read the story and then predicted their reactions if they had first been given the information about the story context. Finally, in study 4, we use a new emotional experience and psychological distance manipulation: receiving a prize in 6 weeks (psychologically distant) or immediately (close).

Across all studies, predictors predicted a greater influence of psychological distance on their emotional reactions than experiencers actually experienced. Most often, predictors accurately predicted emotional reaction to the psychologically close experience and underestimated emotional reaction to the psychologically distant experience. Furthermore, study 3 rules out a differential salience or demand explanation for this effect. Indeed, the effect persists even when participants in the experience condition are explicitly reminded of the manipulation immediately prior to the dependent measures, ruling out an account based on a greater salience of the manipulation in the predictor condition. Furthermore, when the psychological distance information was said to be presented after the story, the predictors were reliably less sensitive to this information (than when it was said to be presented before the study), showing that predictors only relied on the information when they thought it would influence the processing of the story—and were not merely reacting to experimental demand.

These results suggest that, when choosing between options that vary on attributes related to psychological distance, consumers will be influenced by these attributes more than they should, e.g., preferring films based on stories that are true and occurred recently when, in actual fact, they would be equally happy with films based on fictional or older stories. More generally, this approach connects the affective forecasting literature to work in judgment that examines unwanted or over-correction, such as work on mental contamination (Wilson and Brekke, 1994). Given the frequency of these effects in judgment, we suspect that this process may prove a common source of systematic error in hedonic prediction.

“Inconsistency Between Predicted and Actual Sensitivity of Evaluation or Liking to Attribute Values”

Jiao Zhang, University of Miami, USA

Christopher Hsee, University of Chicago, USA

Will a consumer watching TV in her home have a better experience if the TV has a 50-inch screen or a 42-inch one? More important, can she accurately predict the difference in her experience between the two alternative scenarios? Overprediction may lead the consumer to buy the 50-inch TV without having better

experience she believes she will. Building on previous research (Hsee & Zhang, 2004), in the present research, we further examine the question of whether consumers would overpredict how sensitive their evaluation of or liking for an outcome is to the value of that outcome when they face it alone in consumption.

In Study 1, conducted in China, most participants believed that by smelling a sample of a perfume they could tell whether the perfume was from an expensive brand or a cheap brand and accordingly their liking for that perfume would be high or low. The participants were then randomly assigned to three groups, in which they smelt a piece of tissue paper scented with a drop of an expensive perfume (Chanel No. 5, 500 RMB a bottle), or one scented with a drop of a cheap perfume (a local brand, 50 RMB a bottle), or simply a piece of ordinary scented tissue paper (about 2 RMB a pack). Contrary to the participants' belief, there was no significant difference in how much they liked the perfume across the three groups. Liking for the expensive perfume was higher than that for the cheap perfume, though only slightly, for another group of participants who tried all of three samples. The results suggest that although an expensive perfume may be more pleasant to the nose than is a cheap perfume, the difference is likely to be exaggerated in consumers' belief.

In Study 2, also conducted in China, a group of "white-collar" employees in a big company were asked to indicate whether they would buy a 5-megapixel, 3000 RMB digital camera rather than a 1-megapixel, 500 RMB one, assuming that the other features were identical between the two cameras. Most of the participants chose to buy the 5-megapixel camera. The participants were also asked to indicate whether they believed that if they were presented with an 8"x10" size photo (the largest size they said they would ever use to print photos) they would be able to tell, according to the sharpness of the photo, whether it was taken by a 5-megapixel or a 1-megapixel digital camera. Most of them believed they could. Then, the participants were presented with either a photo with a 5-megapixel resolution or one with a 1-megapixel resolution and asked to rate the sharpness of the photo; the content of the two photos was identical. It turned out that the two photos received a similar rating. Considering the fact that the participants' average monthly salary was 4000 RMB, the finding is quite dramatic.

Such misprediction is less likely to happen for consumers who are knowledgeable about the attribute under evaluation and consequently have the relevant reference information to evaluate the desirability of a value on that attribute even when facing it alone. This idea was tested in Study 3, conducted in the U.S. A group of students from a large Midwestern university was randomly assigned to be predictors or experiencers. The experiencers were presented with either a 1-megapixel or 5-megapixel photo and asked to rate its sharpness; the photos had the same content and size (8" x 10"). The predictors were presented with both photos and told that each photo would be viewed by a separate student who was similar to them. The predictors were asked to predict the sharpness rating each photo would receive. All the participants were asked to report their knowledge about photography on a five-point scale ranging from 1 (*not knowledgeable at all*) to 5 (*very knowledgeable*). Participants who gave a rating of 4 or 5 were classified as experts and the rest, novices. As we expected, among novices, predictors overpredicted the impact of photo resolution on experience of photo sharpness; among experts, no overprediction occurred. Experts were sensitive to photo sharpness even when viewing a photo in isolation.

In sum, the findings of the three studies suggest that consumers tend to believe that a higher value on a positive attribute will translate into better experience. Unless they have acquired knowl-

edge from past experience with values on that attribute or relative reference information is provided at the time of consumption, systematic overprediction often occurs.

SYMPOSIUM SUMMARY

“Roll Your Own” Religion: Consumer Culture and the Spiritual Vernacular

Linda Scott, University of Oxford, UK
Pauline Maclaran, Keele University, UK

SESSION OVERVIEW

Consumer researchers have long questioned the traditional separation between sacred and secular that typifies other thought in the social sciences (Belk, Wallendorf, and Sherry 1989). In this symposium, we will build on this work in several ways.

The most salient difference will derive from the focus of place: all the sites here are European, while previous study in the stream has been in America. Our three sites—Italy, Ireland, and England—not only represent a geographic departure consistent with the theme of the conference, but also represent fundamentally different circumstances for studying the approach to spiritual experience. All three countries have historically been what James Twitchell called “single-supplier” societies in his recent book, *Shopping for God* (2007), where the church is closely intertwined with, if not indistinguishable from, the state. Consequently, these countries, especially Ireland and Italy, have traditionally allowed considerably less of the religious pluralism that Twitchell argues had led to a market-based approach to spiritual practice in America, where consumer choice and church competition are the order of the day.

Nevertheless, in all three cases, we will demonstrate a clear trend toward what Twitchell has also called “vernacular religion”—in which consumers either produce ritual objects themselves, re-purpose traditional religious props, or shop “off the shelf” from other religious traditions—to use for their own inventive, often empowering, spiritual practices. In this way, we will also be building further on the work by previous scholars in consumer behavior, who have focused primarily on the “sacralization of the secular”—where consumers imagine or treat everyday objects in a manner that echoes, but does not attempt to constitute, a religious practice (e. g., Muniz and Schau 2005).

In other work, consumer researchers have examined the commercialization of religious spaces and objects within the American experience, but framed by an existing official church (e.g., Belk and O’Guinn 1989). Again, the geographic setting makes a difference: all three of the sites examined here are places with long religious histories, reaching back hundreds of years into the pre-Christian era—yet the cultural memory of the pagan past is still manifest in practice and the places themselves are fundamentally hybridized, thus arguably more open to consumer reinvention. At the same time, these three settings are no less open to the influences of globalization than any American site; consequently, the consumers and the places both often invoke or reflect contemporary media. As a result, a layering of past knowledge and practice with presently accepted doctrine, as well as with new tropes and needs, is present at these sites in a more transparent and conscious way. Thus, our symposium will also marry the approach to religious practice with Thompson and Tian’s recent work on the cultural memory of place (2008).

We will add an important methodological layer to that originally proposed by Belk, Wallendorf and Sherry (1989): we not only tack between the field and the sociological literature for insights and analysis, we also consult the sacred texts and myths invoked by the practices under study, as well as the actual religious histories of the sites—and incorporate the layering provided by contemporary texts from *Buffy the Vampire Slayer* to *Harry Potter*.

Finally, our work demonstrates poignantly that humans are still spiritual seekers, even in a consumer society that so many

critics say leads to apathy and meaninglessness. Far from abandoning the thirst for meaningful existence, our subjects show an irrepressibly hopeful and creative search for the sacred.

EXTENDED ABSTRACTS

“Bidding Brigid: Objects of Petition and the Euhemerized Goddess”

Darach Turley, Dublin City University, Ireland

Often referred to as “Mary of the Gael,” St. Brigid holds pre-eminent and emblematic status among Irish Catholics. Though her reputation is not confined to Ireland (there are 40 dedicated sites in Brittany, as well as 10 pre-Reformation dedications in England, the most prominent at Glastonbury), it was probably due to her popularity in this strongly Catholic country that Brigid was spared in the Vatican’s recent purge of the saintly pantheon.

Brigid, like most who were thus swept away, lived in the transition period when the pre-Christian was being assimilated into Christian orthodoxy. St. Brigid is said to have died in 524AD; the Church’s first life of this saint was written soon thereafter, in the 7th century. Yet even this early biography includes attributes of a Celtic, pre-Christian goddess of the same name. Indeed, there is increasing evidence that the Christian St. Brigid is in fact an euhemerization and thus an artefact of an astute and far-sighted sixth century Papal stratagem, in which pagan sites and objects were reinvested with a Christian connotation, instead of being destroyed and replaced. Attributes of the tutelary Celtic goddess appear to have been appropriated and grafted on to her saintly virginized namesake. And while the persona of the Celtic goddess has obviously been obscured in this process, there are sufficient similarities and parallels between both to posit a composite of what constitutes a Celtic goddess. Thus, an examination of surviving Brigidine festivals and lore suggests that the cult of St. Brigid represents a perfect exemplar of this pagan-Christian syncretism. For instance, the pre-Christian Brigid was a goddess of fertility and growth and the guardian of livestock; St. Brigid’s feast day is celebrated on February 1st, the first day of Spring. Miracles attributed to Brigid are characterized by lavish abundance and fecundity. Her life story depicts her very much as a transitional, hybridized figure. For example, she has a noble (married) father and a slave (unmarried) mother; she is born at sunrise, a transition between night and day; on the threshold of her mother’s home in Irish folklore a symbol of the penumbra between inner and outer worlds. Later in life, Brigid becomes an abbess—thus she attains the hierarchical status of a male bishop. A superordinate female member of the Celtic pantheon, the pagan Brigid was creator of both natural land formations and the great megalithic structures of the British Isles. In keeping with the Celtic predilection for triads, she was also a poet, healer and artisan.

Today, popular devotion to the Christian St. Brigid resonates with her pre-Christian ancestry. At St. Brigid’s Holy Well in County Clare, Irish consumers marshal an array of objects and possessions to both reflect and shape religious and mythological beliefs. The well itself is situated at the back of a stone grotto. Shelves along the entrance to the grotto are bedecked with a dizzying assortment of objects left by pilgrims: romantic religious artifacts such as rosaries, Italianate holy pictures and statuary

together with an array of what appears to be tawdry everyday household bric a brac: pins, buttons, combs, biros, walking sticks, eyeglasses, rags, and scarves. Pilgrims leave these objects after traveling to the well to drink its waters on designated holy days—and often attach explanatory written messages to the objects they leave behind.

The aim of this paper is to examine how the pagan-Christian syncretism discussed above is refracted through this array of possessions and texts left by devotees. A key theme to emerge in this analysis is the performative roles of these goods. Unlike their counterparts in Latin Catholic countries, the objects left here do not appear to function as votive offerings, brought to a saint or Madonna in thanksgiving for favours received. Instead, pilgrims at this well, come to St. Brigid *seeking* a favour, physical or spiritual, and the good left behind appears to function more as a material metaphor enabling the supplicant to visualize in a concrete manner what they wish the saint to accomplish on their behalf. Thus, the old way of life, the illness, is ‘deposited’ in the rags, walking stick or eyeglasses. Obviously, this works best if the possession holds some cathetic relationship with the disease. This theme of cathexis, detachment or unfastening was further underscored by the nature of many of the possessions deposited on the shelves: buttons, pins, nails.

A second performative role was evidenced in the way many of the items—biros, combs, pins—were deliberately bent or broken. Local lore has it that this is to underscore the fact that these items are no longer intended for use in this world. For these believers, the efficacy of the material in the non-material sphere does not appear to be an issue, a fact that challenges the modernist notion of agency and embodiment as coextensive. Indeed on a wider tableau, the mindset of those who deposit possessions at the well suggests a need to re-conjugate the relationship between agency, embodiment and self. The dominance of empiricism and positivism has had ramifications for consumer behaviour that extend beyond choice of requisite methodologies; on a metaphysical level it has also perpetuated the elision of agency, empowerment and bodily incarnation. It is hoped that this paper may contribute to an exploration of alternate boundaries between embodied and disembodied agency and a metaphysics that can accommodate a world where possessions can simultaneously contribute to making a site sacred, solicit saintly intervention, and carry a semantic payload for both human and otherworldly audiences. In this regard, Brigid’s euhemerized status gives the debate an added theoretical twist.

Reflexive observations will also feature, among them a discussion of the need to revisit the notion of sociality in consumer research. A fresher, more accommodating metaphysical stance might permit a more inclusive appreciation of the role of disembodied beings, saintly and not so saintly, as significant others for the consumer behaviour of their earthly, embodied, counterparts.

“Living a Magical Life’: Sacred Consumption and Spiritual Experience in the Italian Neo-Pagan Community”

Diego Rinallo, Bocconi University, Italy

Neo-paganism is “an umbrella term for various religions, or spiritual movements, whose practitioners are inspired by the indigenous, pre-Christian, traditions of Europe ... to evolve satisfying and respectful ways of celebrating human relationships with the wider, other-than-human world” (Clifton and Harvey 2004: 1). In the 1950s, early British exponents of the movement claimed to be initiates of a nature-based witchcraft religion that had secretly survived Christian prosecutions (Gardner 1954; 1959). In the US, neo-pagan traditions have been assimilated since the 1970s to the women’s spirituality movement as feminist exponents (e.g.,

Budapest 1976; Starhawk 1982) popularized the emancipating idea of a Goddess immanent in nature (as opposed to a transcendent male God detached from creation), adopting at the same time the witch as a symbol of independent female power oppressed by patriarchy (Hutton 1999).

In Italy, the neo-pagan movement is still in an embryonic phase as only in the 1990s Internet enabled the constitution of the first pagan groups and associations. Most Italian neo-pagans were raised by Catholic families and adopted neo-paganism as a religion in later phases of their lives. As Italy is predominantly a Catholic country, Wiccan and other neo-pagans are often confused with devil worshippers and face considerable level of stigma, ridicule and social ostracism. My study is based on two years of ethnographic fieldwork within the neo-pagan community in the areas of Northern Italy and Sicily. Data collection consisted of formal and informal interviews and participant observation of neo-pagan gatherings, festivals, rituals, social events, workshops and online forums in 2006-2007.

Neo-pagans are avid consumers of goods such as ritual costumes; jewelry (e.g., pentacles, Goddess figurines); ritual tools like ceremonial knives, cups, incense burners, candles, incenses; Goddesses and Gods statues; CDs of neo-pagan music; and books. Many of these items are employed in the context of rituals to create a sacred space where communication between the human and Divine is made possible. To this aim, neo-pagans learn esoteric knowledge on the inherent properties of material objects for spiritual and magical purposes. The idea that objects and elements of the physical world are mystically connected to spiritual realms and entities is age-old. In the Renaissance, Cornelius Agrippa’s *Philosophia Occulta* (1533) reported extended tables of correspondences between spiritual entities and herbs, metals, stones, animals and other natural phenomena. Variations of these correspondence tables are widely available through countless books and websites, and are currently employed as reference tools for magical activities. Ritual practice among the neo-pagan community is also shaped by selective readings of scientific disciplines, including history, archeology, religious studies, psychology, folklore, anthropology and even physics. As a spiritual movement, neo-paganism has been disproportionately influenced by folklore and anthropology, and works such as Sir James Frazer’s *The Golden Bough* (1922), Margaret Murray’s *The Witch Cult of Western Europe* (1921) and Marija Gimbutas’ *The Language of the Goddess* (1989) feature prominently in the bookshelves of many neo-pagans. While the ideas reported by some of these scholars are now discredited among academic circles (see Hutton 2000), they act as “scientific” fundament for widely circulated counter-cultural mythologies that foster a sense of shared past and shape sacred consumption practices.

In this respect, another major source of influence consists of mass-mediated representations of magic, including fantasy books (e.g., Marion Zimmer Bradley’s *The Mists of Avalon*, J.K. Rowling’s *Harry Potter*) and popular movies or TV shows (e.g., *Harry Potter*, *Charmed*). By selectively leveraging esoteric knowledge and resonant science, history and popular culture, members of the neo-pagan community ideologically shape subcultural practices and consumption. During a ritual, incense recipes may derive from a medieval grimoire; hand-made ceremonial dresses may be inspired by the Lord of the Rings; a magic wand may be crafted after Harry Potter’s, and earrings and other ceremonial jewelry may reproduce Celtic patterns found in archeology books. The same sources also shape transcendent experiences. Eclectic neo-pagans may see Divinities in popular culture characters. Buffy may thus be invoked as a Goddess of fire and passion, while the sinister pantheon of H.P. Lovecraft’s *Chtulhu Mythos* may be adopted for more gothic

rituals. During meditations or dreams, neo-pagans may remember past lives when they were Avalon priests, Siberian shamans or Tuscan witches. Such vivid images, at least to a certain extent, may be influenced by their readings in history, anthropology and fiction.

This paper contributes to literature on sacred consumption. While magico-religious metaphors have been widely employed in consumer behavior, most studies have been concerned with the sacralization of the secular rather than the use of consumption goods to seek transcendent experiences. In particular, this paper explores the interplay of science and fantasy in the shaping of counter-cultural mythologies and consumption practices. As they engage with alternative spirituality and magical activities, members of the pagan community expose themselves to selected body of scientific knowledge and inspiring images from popular culture that shape their experience of the spiritual otherworld. Consumer researchers have highlighted the role of mass-mediated culture and selective readings of history in shaping of consumer ideologies and fantasies (Belk and Costa 1998; Thompson 2004; Thompson and Tian 2008). These same sources may also affect spiritual experiences.

"Spiritual Tourism: Mystical Merchandise and Sacred Shopping in Glastonbury"

Pauline Maclaran, Keele University, UK

Linda Scott, University of Oxford, UK

Set in the heart of England's countryside, Glastonbury town has become the main centre in England for what Bowman (2004, 273) describes as "spiritual tourism". Dominated by Glastonbury Tor, a distorted coneshaped hill with a ruined 14th century church tower on top, the area, that is also known as the Isle of Avalon, "generates and guards a powerful magic" (Roberts 1977). The history of the area stretches far back into the mists of time with many contested stories that change according to the spiritual orientation of the teller. It is generally agreed that the ancient Isle of Avalon was a site of prehistoric worship and mystical tradition that, arguably, can be traced as far back as the Atlantean era of 10,000 BC (Mann 2004) when the Atlanteans are said to have used the Tor as a natural temple after their own temples had been destroyed by the sea.

The area's key spiritual attractions are brought together in the concept of Glastonbury Zodiac which is claimed to have been created by a race of prehistoric astronomers (Malthood 1935). They are accredited with shaping patterns of mythical and astrological significance around the natural contours of the landscape (Roberts 1971). Estimated to be 10 miles in diameter and 30 miles in circumference, the sites that make up the Zodiac harness the Isle's potent celestial and terrestrial energies and are closely lined to the Arthurian legends that surround the Isle of Avalon and that have spiritual significance for both Pagans and Christians alike. King Arthur was allegedly taken there to heal after his last battle and his body is claimed by Christians to be buried in Glastonbury Abbey (Bowman 2004). The Chalice Well at Glastonbury is supposed to be where Joseph of Arimathea hid the Holy Grail after the crucifixion. The arrival of St Joseph brought Christianity to Glastonbury and is still celebrated in the Holy Thorn Ceremony that takes place there each December (Bowman 2006).

Yet, the Chalice Well's history, going back over 2000 years, predates a Christian era. It is thought to have been built by the Druids who came to the area in 600 BC and who founded a Druidic university in the area. They believed in the healing properties of the water and the well's powers as an entrance to the other world. Because the water is reddish in colour it has also been claimed by modern Neopagans as symbolizing the menstrual blood of the Goddess and a representation of the divine feminine. The story of the sorceress, Morgen Le Fay, an important icon in Goddess

culture, has its origins in Arthurian legend. Known as "Lady" or "Priestess" of Avalon, she was half-human and half-faerie. Morgen attempted to bring about the downfall of Camelot and was continually thwarted by King Arthur. In recent times she has been brought to the fore through Marion Zimmer Bradley's classic novel, *The Mists of Avalon*, that was made into a film in 2001, and which retells the story of Camelot from a goddess perspective, recasting Morgen as a gifted woman demonized by patriarchal legend (Jones 2006). Her eight sister Morgens, representing the changing cycles of nature, have also become an integral part of Goddess worship.

The many contested spiritual overlays that co-exist in Glastonbury are perhaps best exemplified by Glastonbury's high street with its astonishing array of small shops that are devoted to mystical merchandise. These New Age shops—e.g. Speaking Tree Bookshop, The Celtic Thread, The Goddess and the Green Man, The Psychic Piglet, Yin Yang, Gothic Image—sell esoteric ranges of mystical symbols, jewellery, books, tarot cards, clothing, furniture, soft furnishings and arts and crafts. Together they present a veritable spiritual bricolage that is manifested through what we have termed "sacred shopping", a shopping that reflects the rich mosaic of myth and legend that surrounds the region and enables a "pic n' mix" approach to a personalised spirituality. In the heart of this shopping lies the Goddess Temple where effigies of the Nine Morgens depict the creative power of nature and the divine feminine. In a strange juxtaposition, just around the corner stands Glastonbury Abbey, built in 37 AD, and reported to be the first Christian Church in Britain. Indeed, both Christian and Goddess communities continue to stake their claims to Glastonbury's spiritual heritage in annual processions through the town (Bowman 2004).

Drawing on a vernacular religious approach that emphasizes the role of material culture, in our presentation we will argue that Glastonbury's spiritual shopping plays an important role in carving out sacred space for New Age religious beliefs, and helps legitimize their claims in the face of more traditional Christian appropriations of sites in and around Glastonbury.

SYMPOSIUM SUMMARY
Comforting Social Presence, Depleting Social Influence
Anne-Laure Sellier, New York University, USA

SESSION OVERVIEW

We know that the presence of others affects consumers' product evaluations and their purchase behavior. Past research has demonstrated that consuming with others is a different experience than consuming alone, whether social presence is real or imagined (e.g., Argo, Dahl & Manchanda 2005; Ramanathan & McGill 2007). Of particular interest, recent research showed that consuming with others favors a similar pattern of emotional experience between consumers and others (Ramanathan & McGill 2007). Our objective in this session is to examine this "togetherness" aspect of consumption. In particular, the three presentations in this symposium generally document how social presence (real or imagined) can be comforting, thereby shaping evaluations and directing choices, while social influence—in contrast—appears taxing.

Two presentations present instances of how social presence can be comforting to consumers: Loveland, Smeesters, and Mandel show that social presence motivates consumers to choose nostalgic products over recent ones. They find that this preference is mediated by consumers' desire to feel close to others. Sellier and Morwitz find that when consumers perceive time as limited, they evaluate ads picturing a supportive social cue more positively than one presenting an achievement cue or a neutral, non-social cue; a reflection of emotion-related goals (e.g., feeling close to others) taking precedence over achievement-related goals (e.g., getting a degree to bank for a future perceived to be long). Conversely, they find that when consumers perceive time as expansive, they evaluate an ad containing a social cue signaling achievement more favorably than an ad containing a social cue signaling support. Also of interest in these two presentations is the link between valuing togetherness and managing time via consumption. In Loveland et al., social presence makes consumers value options related to the past rather than the present; in Sellier and Morwitz, social presence leads to more positive evaluations when it is congruent with the social goals activated by consumers' time horizon perspective. In contrast to this first set of findings suggesting a comforting role of social presence, Sellier and Morwitz also find that social presence hurts persuasion when it is incongruent with consumers' activated social goals, observing that a non-social cue not related to either emotion goals or achievement goals leads to more persuasion than a social cue incongruent with consumers' activated social goals. Vohs, Dennis, and Janssen present an instance of the harmful impact of social influence. Their research demonstrates that when the social context involves having one individual seek compliance from another (e.g., Cialdini 1993), it is ego-depleting for the consumer who is asked to comply. Together, these findings shed further light on the importance of investigating consumer behavior in the presence of real (Loveland et al.; Vohs et al.) or represented others (Sellier & Morwitz). In particular, this symposium stresses the implications of social presence and influence on the self. Consuming with others not only feels different (Ramanathan & McGill 2007): the findings in Loveland et al. suggest it may be self-enhancing; those in Sellier and Morwitz suggest that it can be helping or harming persuasion, while those of Vohs et al. show it can be ego-depleting.

EXTENDED ABSTRACTS

"Still Preoccupied with 1985: The Effect of Imagined Interaction on Preference for Nostalgic Products"

Kathleen E. Loveland, Arizona State University, USA

Dirk Smeesters, Erasmus University, The Netherlands

Naomi Mandel, Arizona State University, USA

We sometimes have an increased interest in products that we enjoyed in the past. The successful resurrection of nostalgic brands such as Pabst Blue Ribbon, Ford Mustang, and Converse shoes suggests that many consumers are interested in products that generate favorable childhood memories. Surprisingly, little attention has been paid to the concept of nostalgia in the consumer behavior literature. This research examines potential antecedents to an increased preference for nostalgic products. We define nostalgic products as products that were popular when one was younger and are no longer in current production.

Prior research has shown that nostalgic recollections often involve interaction with close others (Wildschut et al. 2006). Additionally, Wildschut et al. (2006) found that loneliness leads to higher nostalgic tendencies and that nostalgic recollection bolsters social bonds. These findings suggest that nostalgia serves the social functions of easing loneliness and fostering social interactions. Therefore, we hypothesized (and found) that preference for nostalgic products would increase when social, as opposed to private, aspects of life were activated in consumers' memory. We also tested the underlying mechanism for this effect, and found evidence that the increased preference for nostalgic products occurred when consumers felt emotionally closer to others, as measured by the Inclusion of the Other in the Self Scale (IOS; Aron, Aron & Smollan 1992). In addition, we examined the moderating role of life transition.

We conducted three experiments that provide empirical support for our hypotheses. In Experiment 1, participants were randomly assigned to either write about activities they engage in with other people (social), or activities they do on their own (private). Next, they chose a 10-minute video clip to watch from a set of four television shows, all of which were pretested and found to be equivalent in overall liking among individuals in the participants' age group. Specifically, they chose either a television show that is currently on the air (*The Office* or *Grey's Anatomy*) or a clip from a show that is no longer in production and first aired in the early 1990s (*Saved By the Bell* or *Fresh Prince of Bel Air*). We found a significant main effect of social interaction, with 61% of participants in the social condition choosing to watch a nostalgic show and 17% of participants in the private condition choosing to watch a nostalgic show ($\chi^2=12.06, p<.01$).

Experiment 2 replicated the first experiment with the addition of the IOS as a possible mediator for the relationship between social interaction and preference for nostalgic products. We found evidence that IOS mediates this relationship ($z=2.58, p<.01$), suggesting that people prefer nostalgic products when thinking about interacting with others because such thoughts lead them to feel emotionally closer to others, and the consumption of nostalgic products can prolong this feeling of emotional closeness.

In Experiment 3, we tested the moderating role of life transition on the preference for nostalgic products. Individuals may be more likely to experience nostalgia during times of transition (i.e., discontinuity hypothesis, Davis 1979). Consumer researchers have found that symbolic possessions tend to take on greater importance during times of transition as they can help ease the psychological difficulties associated with transition (Belk 1992). In support of the discontinuity hypothesis, we found that the increased preference for nostalgic products when thinking about social (as opposed to private) aspects of life was stronger when a life transition was salient. We used a 2 (social vs. private) x 2 (current vs. transition) between-participants design in which participants wrote an essay about either their *current* life, or what they think their life will be like after graduation from college (*transition*) while focusing on either the social or private aspects of that life. Participants again chose between watching either a nostalgic or a current television show. We replicated the main effect of social interaction on the preference for nostalgic products. Additionally, there was a significant interaction between life transition and social interaction, such that the preference for nostalgic products was more pronounced when the social aspects of a life transition were made salient ($Wald=3.28, p=0.05$). This finding is consistent with the idea that since periods of transition are marked by the adoption of new roles and relationships (Lee, Moschis, & Mathur, 2001), individuals will seek means, such as nostalgic products, to create a sense of social and identity continuity.

In Experiment 4, we replicated and extended our earlier findings by manipulating participants' self-construal (interdependent vs. independent). We found that individuals whose interdependent self was activated had a higher preference for nostalgic movies, cars, and television programs than individuals whose independent self was activated. Further analyses indicated that the effect of self-construal on the preference for nostalgic products was mediated by feelings of interconnectedness.

Importantly, our participants demonstrated an increased preference for products from the past when they wrote (in experiments 1-3) about interacting with others in the *present* and the *future*, as compared to when they wrote about solitary activities in the *present* and *future*. Therefore, it is unlikely that participants are merely matching their thoughts about friends from the past with activities associated with close others from the past. Instead, these findings support the notion of nostalgia as a socially driven phenomenon on a more general level.

This research contributes to the literature in several ways. First, while earlier research has hinted at the idea that nostalgia is social in nature, to date this issue has not been tested explicitly. We are able to add to this literature by demonstrating that individuals experience an increased preference for nostalgic products at the mere thought of interacting with others, regardless of whether those interactions are positive/negative, past/present. Second, this is the first study to examine behavioral preferences for nostalgic products as the dependent variable. Other works that have sought to investigate triggers of nostalgia have either used "attitudes towards the past" as the dependent variable (Wildschut et al. 2006), or have only considered individual differences in nostalgia proneness (Batcho 1998).

"The Impact of Social Cues on Message Persuasiveness: The Role of Time Horizon Perspective"

Anne-Laure Sellier, New York University, USA

Vicki Morwitz, New York University, USA

While the question of *whether* social presence influences consumers' evaluations and behavior has received much attention

in consumer research, less research has examined (1) whether different *types* of social presence (e.g., the mere presence of another person, social presence that signals the provision of emotional support, social presence that signals what can be gained from others, etc.) have different effects on consumers' evaluations, (2) how these effects may differ across different types of consumers, for example how it would differ across consumers who hold different perceptions concerning the amount of time they have ahead of them in life, and (3) when the absence of any social cue is preferable to its presence (in contexts other than the obvious case of low social desirability). This research explores these three questions. In particular, building on socioemotional selectivity theory (SST) (Carstensen et al. 1999), we suggest that the value that consumers will place on one particular type of social presence cue, namely cues that signal emotional support from others, will vary with their perception of how much time they have ahead of them; more precisely, it will vary with whether time is perceived as limited or expansive.

SST posits that time perception determines the relative importance of two broad categories of social goals: *knowledge-related goals*, defined as goals aimed at optimizing the future, (e.g., getting a University degree), involving a focus on achievement; and *emotion-related goals*, defined as goals related to feelings, involving a focus on emotion regulation, whereby one attempts to maximize positive emotional experiences, in particular through love and caring social interaction (e.g., interacting with people in a deep rather than a superficial manner) (Carstensen et al. 1999). SST's key predictions are that when time is perceived as limited, emotion-related goals receive priority over knowledge-related goals. That is, they pay more attention to how supportive a social interaction is than to what opportunities this interaction might open up for them. In contrast, when time is perceived as expansive, knowledge-related goals are perceived to be more important than emotion-related goals.

We hypothesized that when consumers perceive time as limited [expansive], they will evaluate a message containing a social cue signaling emotional support [achievement] more positively than a message containing a social cue signaling achievement [emotional support]. We propose that goal congruence is the process generating this effect. Further, we hypothesized that when the social cue is incongruent with the activated social goal (e.g., a social cue signaling emotional support presented to a consumer with activated achievement-related goals), it is devalued compared to a neutral cue (defined as a non-social cue that is neither emotion- nor achievement-related). In other words, an incongruent social cue is disinstrumental to the activated social goals, and offers a case where social absence is preferable to social presence (disinstrumentality hypothesis).

Importantly, in our experiments, we made sure that our messages containing a support cue and those containing an achievement or a neutral cue were equally focusing participants on thoughts and on emotions, to avoid replicating prior research contributions (particularly Williams & Drolet's 2005).

Four experiments test these predictions. In Experiment 1, we found support for our hypothesis that an emotional support [achievement-related] social cue embedded in an ad for a hotel should lead to more positive evaluations of the hotel when consumers perceive time as limited [expansive]. Participants' time horizon perspective and the social cue they were exposed to were both manipulated in a storyboard.

In Experiment 2, we manipulated participants' time horizon perspective by asking them to write about events in their life for which they perceived they had limited time versus all the time in the world to achieve them. Subsequently, participants were exposed to

a storyboard for a travel agency that either contained an emotional support social cue or a neutral cue, and then evaluated the storyboard. As predicted, we found that participants perceiving time as limited evaluated the storyboard containing a support social cue more positively than the storyboard containing a neutral cue. However, participants perceiving time as expansive only tended to evaluate the storyboard containing a neutral cue more favorably, failing to support our disinstrumentality hypothesis.

Experiment 3 provides a test supportive of our goal congruence explanation. We show that a limited (versus an expansive) time horizon perspective activates social goals of love and caring (versus knowledge and achievement), which in turn drives the effect observed in Experiment 2.

Experiment 4 had two purposes: to provide further support to our goal congruence account via a stronger test of our disinstrumentality hypothesis, as well as a boundary condition of our effect. Participants with a limited or an expansive time horizon perspective viewed a storyboard eliciting negative emotions. The storyboard either contained a support social cue or a neutral cue. In addition, to test for a boundary of our effect, we instructed participants to (1) let their emotions flow naturally or (2) suppress their emotions while viewing the storyboard. We reasoned that consumers with a limited time horizon, whose focus is on maximizing positive emotional experience, may choose to suppress negative emotions. When participants let their emotions flow naturally, we found a more positive evaluation of the storyboard containing a social cue compared to a neutral cue when participants perceived time as limited; we found *the reverse* when participants perceived time as expansive. This provides further support to our goal congruence account, by showing that using an incongruent social cue is not only inefficient, but disinstrumental compared to a cue unrelated to the activated social goal. In contrast, for participants who suppressed their emotions, we found a reversal of the effect in Experiment 2, thereby providing a boundary for our effect.

This research shows that social presence embedded in persuasive messages can shape evaluations, but only when consumers' focus is on congruent social goals. When the focus is on incongruent goals, social absence leads to more favorable evaluations. This work also stresses the relevance of different types of social cues depending on how much time consumers perceive they have ahead of them.

“Why Do People Fall Prey to Social Influence Techniques? A Limited-Resource Account of Compliance”

Kathleen D. Vohs, University of Minnesota, USA

Bob Fennis, University of Twente, The Netherlands

Loes Janssen, University of Twente, The Netherlands

Documenting and studying social influence techniques has fascinated scholars for over forty years. According to Cialdini (e.g., Cialdini 1993), all influence techniques aim to lure targets into a state of automaticity or “mindlessness”. In these states, targets are prone to employ norms that increase compliance rates. We propose that such mindlessness comes about because the initial stage of an influence technique triggers one underlying psychological mechanism: self-regulatory resource depletion.

We present a two-stage model, in which the first step involves draining the self's finite self-control resources via consciously attending and responding to the requestors' inquiries during the initial requests of an influence technique. A meta-analysis on the most prominent influence procedure, the foot-in-the-door (FITD) technique, revealed that its effectiveness hinges on the initial request being highly involving. A closer look suggests that highly involving requests entail either (a) active self-presentation or (b) demanding cognitive operations, or both — processes that are

known to elicit self-regulatory resource depletion (Schmeichel, Baumeister and Vohs 2003; Vohs, Baumeister and Ciarocco 2005).

In the second step, self-regulatory resource depletion fosters the use of norms, which increases the odds of yielding to the target request. Influence agents use norms of reciprocity, liking, and authority to compel the person to comply. These norms are more likely to be relied upon when people pay more attention to the peripheral aspects of a message and less to the message context — a pattern that is seen among people with depleted self-regulatory resources (Wheeler, Briñol, & Hermann 2007).

Hence in six studies, we examined whether influence techniques induce self-regulatory resource depletion and then whether self-regulatory resource depletion leads to a reliance on norms and hence enhances compliance. All six experiments supported our hypotheses.

In Experiments 1 and 2 we gathered evidence to test Stage 1 of our model by examining the initial request-phase of a typical foot-in-the-door ploy. We show that yielding to the initial part of a foot-in-the-door technique, which involved answering a series of self-disclosing (Experiment 1) or cognitively demanding questions (Experiment 2) induces self-regulatory resource depletion. Experiment 1 mimicked traditional foot-in-the-door technique questions while also connecting with the notion that self-regulatory resources are needed to engage in high-order thought processes and intelligent responding (Schmeichel et al 2003). Experiment 2 also borrowed questions from the foot-in-the-door literature and connected this process to the notion that self-regulatory resource depletion emerges after impression management attempts (Vohs et al 2005). Moreover, both were field studies, which enhance our claims about the generalizability of the effects.

In Experiments 3a and 3b, again field experiments, we ruled out alternate explanations that the prior results were due to emotion changes, type of interaction, or norm-violation by the agent. We asked participants to not only respond (or not) to the initial requests of a compliance technique, but we asked them to complete a mood scale to rule out the potential confounding role of negative emotions; we switched experimenters (i.e., requestors) between the initial request and the dependent measure of self-regulatory resource depletion so as to rule out violations of the norm of reciprocity; and we also added a condition in which participants on the street were simply engaged in a conversation that did not resemble anything like the initial steps of an influence technique to rule out the possibility that the effects were due to the simple act of unanticipated conversation with an unacquainted person. Across all measures in both studies, we found that no indicators of these alternate explanations prevailed; instead only self-regulatory resource depletion after being a part of a scripted social influence technique emerged.

In Experiments 4 to 6, we tested Stage 2 of the model. In this series of lab and field studies, we assessed whether self-regulatory resource depletion fosters the use of heuristics in decision making, thereby increasing the chances of compliance. In Experiment 4, self-regulatory resource depletion was manipulated, as was the salience of a norm—in this case, the norm of reciprocity). Subsequently, compliance with a request was measured. We predicted and found that when participants were self-regulatory resource depleted and were presented with a norm of reciprocity, they showed a clear tendency to comply with the request. We extended the generalizability of our theorizing in Experiments 5 and 6 to include other operationalizations of self-regulatory resource depletion. These studies also demonstrated the effect in both field and lab settings involving different norms (e.g., liking and authority) and other forms of compliance. Moreover, Experiment 6 obtained converging evidence by investigating trait self-control. In this case,

we found that low—but not high—trait self-control participants were induced to comply with a target request, but only when there was a norm in place.

The present findings point to a previously unexplored “theatre of operations” of principles involved in effortful self-regulation: that of dyadic social influence. Previous research has neglected instrumental dyadic interactions in which one party tries to persuade the other party into behaving in a specific manner. Our work is an exciting step forward toward understanding how, when, and why people agree to requests that perhaps even result in behaviors they did not wish to perform.

SYMPOSIUM SUMMARY

Revisiting Consumer Confidence: New Findings and Emerging Perspectives

Zakary Tormala, Stanford University, USA

SESSION OVERVIEW

Psychological confidence—that is, the general existential state of certainty or uncertainty—is a fundamental aspect of human judgment and thought. Indeed, considerable research now suggests that the confidence or certainty with which one holds one's thoughts, beliefs, and attitudes plays a crucial role in guiding the impact of those thoughts, beliefs, and attitudes on other outcomes. For instance, the more certain one is of one's attitude, the more resistant that attitude is to attack, the more stable that attitude is over time, and the more influence that attitude has over one's behavior (see Tormala and Rucker 2007). Nevertheless, despite the importance of certainty and the extensive body of research exploring its antecedents and consequences in other fields, it has been relatively understudied in the consumer domain. This symposium revisits the notion of consumer confidence by exploring new perspectives on attitude certainty and intuitive confidence. Three papers highlight the importance of these metacognitive assessments for understanding, predicting, and shaping consumer behavior.

The first paper, by Tormala and Clarkson, puts forth a new perspective on attitude certainty. These authors propose that whereas attitude certainty traditionally has been viewed as a strengthening agent, making attitudes more resistant to persuasion and more predictive of behavior, it might be more accurate to think of attitude certainty as an *amplifying* agent. In other words, rather than inevitably strengthening an attitude, certainty might accentuate the dominant effect of that attitude on thought, judgment, and behavior. In three experiments, the authors test this hypothesis by orthogonally manipulating attitude certainty and attitude ambivalence. Across experiments, they find that when ambivalence is low, becoming more certain of an attitude makes the attitude more resistant to change and more predictive of behavior. When ambivalence is high, however, becoming more certain of an attitude makes the attitude *less* resistant to change and *less* predictive of behavior. Thus, certainty has markedly different consequences depending on the structure of the underlying attitude. This research alters existing views of attitude certainty, painting a more dynamic picture of its implications for consumer thought and action.

The second paper, by Rucker and Dubois, explores a different aspect of attitude certainty. In particular, these authors examine the interpersonal transmission of certainty. Based on the logic that attitude certainty is a metacognitive assessment of an attitude and, thus, secondary to the attitude itself, they posit that certainty assessments should be less accessible than attitudes and more likely to be lost in interpersonal transmission contexts. In three experiments, participants are given favorable attitudes toward a product, with either high or low attitude certainty. When asked to write a message about the product for another individual, participants are shown to transmit their attitudes but not their attitude certainty. Consistent with the accessibility account, however, interventions that increase the accessibility of the certainty information (e.g., a certainty priming task) boost transmission. These effects have important implications for consumer behavior, particularly given the increasing prevalence of interpersonal transmission (e.g., web reviews, WOM) in real world consumer contexts.

The final paper by Nelson, Simmons, and Galak also touches upon interpersonal aspects of confidence. Specifically, these authors apply the notion of intuitive confidence to the projection, or false consensus, effect. They propose that when people form

preferences, they project these preferences onto others to a greater extent when they feel confident rather than doubtful. They further hypothesize that preference confidence can be affected by the valence of the options at hand. Two experiments provide support for this hypothesis, showing that preference confidence and projection are increased when consumers choose between positive rather than negative stimuli. A third experiment reverses this effect when participants are asked to reject, rather than choose, an option. This research enhances our understanding of projection, highlighting the role of judgment confidence in guiding perceptions of other consumers.

Taken together, the papers presented in this session highlight exciting new directions in an area that has received far too little attention in consumer research. We anticipate that this session will attract researchers interested in attitudes and persuasion, metacognition, information processing, and preferences. John Lynch, an expert on consumer decision making and the roles of accessibility and diagnosticity in guiding the impact of beliefs/attitudes on other judgments/behaviors, will provide a discussion of these three lines of inquiry, addressing their implications for consumer research and identifying potential questions for future study.

EXTENDED ABSTRACTS

“An Amplification Perspective on Attitude Certainty”

Zakary Tormala, Stanford University, USA

Joshua Clarkson, Indiana University, USA

People hold their attitudes with varying degrees of certainty. For example, two consumers might report liking a new restaurant, book, movie, or pillow to the same degree, but differ in how certain they are of that evaluation. Over the years, attitude certainty has stimulated considerable research interest (for a review see Tormala and Rucker 2007). This interest stems, at least in part, from the fact that attitude certainty is thought to have a number of important consequences for attitude-relevant outcomes. In particular, the more certain one is of one's attitude, the more predictive that attitude is of behavior (e.g., Fazio and Zanna 1978) and choice (e.g., Bizer, Tormala, Rucker, and Petty 2006) and the more resistant that attitude is to persuasion (e.g., Wu & Shaffer, 1987; Tormala and Petty 2002). These findings have been interpreted as indicating that attitude certainty inherently strengthens attitudes, making them more durable and impactful. This “crystallization hypothesis” is the dominant, if not only, view of attitude certainty in classic and contemporary research.

The Amplification Hypothesis. The current research challenges the notion that attitude certainty acts only as a strengthening agent, arguing instead that it can function as an *amplifying* agent. That is, we posit that rather than invariably strengthening an attitude, attitude certainty amplifies the dominant effect of the attitude on thought, judgment, and behavior. If the dominant effect of an attitude is to be resistant to change, for instance, increasing attitude certainty should increase that attitude's resistance, as in past research. If the dominant effect of an attitude is to be susceptible to change, however, increasing attitude certainty might increase that attitude's susceptibility.

Consider the distinction between univalent attitudes (attitudes that are primarily positive or negative in valence) and ambivalent attitudes (attitudes that consist of both positive and negative reac-

tions). It is well-documented that univalent attitudes are more resistant to persuasion than ambivalent attitudes (e.g., Armitage and Conner, 2000; Visser and Mirabile 2004). Thus, univalent and ambivalent attitudes differ in their dominant effects on attitude change. The amplification hypothesis holds that increasing attitude certainty should accentuate this difference, making univalent attitudes even more resistant to persuasion and ambivalent attitudes even less resistant to persuasion than they were to begin with. We tested this hypothesis in a series of experiments.

In our first experiment, we orthogonally manipulated ambivalence and attitude certainty by giving participants evaluatively congruent (univalent) or incongruent (ambivalent) information about a target person from a high or low credibility source. As intended, participants were more ambivalent when they received incongruent compared to congruent information, and were more certain when they received the information from a high compared to a low credibility source. Of greatest importance, later in the session we presented participants with a persuasive message about the target person and we assessed attitude change in response to this message. As predicted, there was an interaction between information congruence (univalence/ambivalence) and source credibility (high/low attitude certainty) on attitude change. When participants had univalent initial attitudes, they showed greater attitude change when the credibility manipulation gave them low rather than high attitude certainty. When participants had ambivalent initial attitudes, they showed greater attitude change when the credibility manipulation gave them high rather than low attitude certainty.

In Experiment 2, we sought to replicate these findings in a consumer setting. We presented participants with evaluatively congruent or incongruent reviews of a new department store from a high or low credibility source. Following this information, we examined the consequences of attitude certainty by presenting participants with a persuasive message about the store. As predicted by the amplification hypothesis, there was an interaction between information congruence and source credibility on attitude change in response to this second message. When participants had univalent initial attitudes (congruent information condition), they showed greater attitude change when they had low as opposed to high attitude certainty. When participants had ambivalent attitudes (incongruent information condition), this effect was significantly reversed.

In Experiment 3, we explored a different consequence of attitude certainty—the correspondence between attitudes and behavioral intentions. As noted, it is well-established that attitudes are more predictive of behavior when they are held with high compared to low certainty. The amplification hypothesis suggests that this effect might be confined to univalent attitude conditions; under ambivalent attitude conditions, attitudes might be less predictive of behavior when they are held with high compared to low certainty. To examine this issue, we presented participants with evaluatively congruent or incongruent reviews of a new department store and manipulated attitude certainty using a confidence/doubt priming task. Later in the session, participants reported their likelihood of shopping at the store. As predicted by the amplification hypothesis, greater certainty was associated with higher attitude-intention correspondence under univalent attitude conditions, but lower attitude-intention correspondence under ambivalent attitude conditions. Experiment 3 also revealed that the attitude change effect from the first two experiments was the result of thoughtful information processing.

Discussion. The current research offers support for a new conceptualization of attitude certainty. Contrary to the traditional (crystallization) view of attitude certainty as an inherently strength-

ening agent, our findings suggest that attitude certainty has dynamic effects on attitude strength that vary according to the attitude's underlying ambivalence. Specifically, increasing attitude certainty strengthens attitudes (makes them more resistant to persuasion and more influential over behavioral intentions) when those attitudes are low in ambivalence, but *weakens* attitudes (makes them less resistant to persuasion and less influential over behavioral intentions) when those attitudes are high in ambivalence. Taken together, these findings have numerous and important implications for our understanding of attitudes and attitude strength in consumer contexts.

"The Failure to Transmit Certainty: Causes, Consequences, and Remedies"

Derek Rucker, Northwestern University, USA

David Dubois, Northwestern University, USA

Consumers often share information in face to face exchanges, over email, or by leaving feedback for products on websites, such as Amazon.com or online forums. The present research examines consumers' propensity to transmit the degree of certainty associated with their attitudes when sharing their attitudes with others. Based on prior work showing that certainty is an important catalyst in motivating consumers to act on their attitudes (e.g., Basilli, 1996; Berger and Mitchell 1989; Fazio and Zanna 1978; Rucker and Petty 2004), we submit that it is important to understand how certainty is communicated from one consumer to another. Specifically, knowing whether another consumer is certain or uncertain should have an effect on a recipient's certainty.

Although not studied empirically, we believe there is reason to postulate that information regarding one's certainty or uncertainty is less likely to be expressed and thus is often lost in transmission. Whereas attitudes are primary beliefs (e.g., I like this car), attitude certainty is a metacognition or a secondary belief (e.g., how certain am I of my attitude towards the car). Compared to attitudes, we

propose that certainty, as a metacognition, is less likely to be communicated by consumers. Specifically, we suggest that because the monitoring of one's certainty requires additional effort and direction, consumers' certainty might be less accessible and thus less likely to be transmitted at the time of a communication. Indeed, work on metacognition suggests that such processes tend to operate under high levels of thinking (Tormala and Petty 2004; Rucker, Petty, and Briñol 2008). For this reason, we propose that in consumer to consumer communications, such as word of mouth, consumers' attitude certainty should be less likely to be expressed compared to their attitudes. As a result, information related to attitude certainty is likely to be lost in transmission.

That is, even when consumers hold favorable attitudes of which they are highly certain, the certainty underlying that attitude might get lost during the transmission process. Because subsequent consumers (i.e., receivers) are less likely to be aware of the certainty of the communicating consumer (i.e., sender), they might in turn be less certain of their own attitudes. More specifically, they would lack the information that the attitude is supported by a strong degree of conviction. In addition, we propose that this loss of certainty can be prevented by either alerting consumers' sending communications to their certainty or by making the senders' certainty more obvious to subsequent recipients.

Experiment 1 tested whether certainty is indeed lost in transmission more so than favorability of one's evaluation. The experiment was conducted in several phases. Participants in phase 1 read a message about a hotel. The message was positive or negative and the certainty expressed by the source of the message was either low or high. This produced initial differences in favorability and certainty among phase 1 participants. Subsequently, phase 1 participants wrote a message about the hotel that was read by another participant. This procedure was repeated until we obtained a chain of four consumers who had received a prior message and written their own message. Results indicated that although differences in expressions of favorability were stable across the chain of participants, expressions of (un)certainty decreased over time, suggesting information related to certainty was lost in transmission.

Experiment 2 tested whether the observed loss of certainty was due to its lower accessibility. A priming manipulation was used to subtly activate individuals' attention to their certainty. If the loss of certainty stems from senders not thinking about their certainty at the time of transmission, increasing consumers' awareness of their certainty before sending the message should increase its likelihood of transmission. Participants in phase 1 received an initial message from a source inducing high or low certainty about a hotel, but equally favorable attitudes. Subsequently, participants in phase 1 completed an ostensibly unrelated crossword puzzle that contained words related to certainty and uncertainty or filler words. Participants then wrote a message about the hotel that was received by participants in phase 2. Results showed that when consumers' certainty was not accessible, there was little transmission of certainty. However, when participants in phase 1 were primed with certainty/uncertainty words, they were more likely to transmit certainty. Consequently, participants in phase 2 were more certain (uncertain) when the prior participant had been certain (uncertain). Importantly, across all conditions, attitudes were positive and equivalent, suggesting an asymmetry in the transmission of attitudes and certainty. Finally, although attitudes did not differ, in both phases, participants with high certainty reported greater purchase intentions than those with low certainty.

Experiment 3 provided a further test of the asymmetrical relation between attitudes and certainty, and proposed a potential remedy to prevent the loss of certainty. Participants in phase 1 received an initial message promoting a brand of toothpaste from a

source inducing high or low certainty, but equally favorable attitudes. These participants then wrote a message about the toothpaste and reported their attitudes and certainty. Subsequently, participants in phase 2 either received a message and attitude score of one prior participant, or received the message, attitudes, and certainty scores of one prior participant. We found that participants in phase 2 were more likely to show a difference in certainty and behavior as a function of the prior participant's certainty when that certainty was explicitly provided. Put simply, a practical response to the loss of certainty in online venues, for instance, is simply to encourage consumers to report both their attitudes and certainty to be shared with others.

Conclusion and Contributions. The present research provides a first examination of how attitude certainty is shared and transmitted. In particular, as a secondary cognition, certainty is less accessible than attitudes and is thus more susceptible to being lost in transmission. The failure of initial consumers to communicate certainty has consequences for subsequent consumers' certainty and behavior. This work explores this failure via moderation and offers remedies regarding the loss of certainty.

"Intuitive Confidence and the Effect of Option Valence on Preference Projection"

Leif D. Nelson, University of California, San Diego, USA

Joseph Simmons, Yale University, USA

Jeff Galak, New York University, USA

People tend to project their own preferences and choices onto others. For example, when people choose whether or not to engage in an embarrassing act, they tend to think that other people will make the same decision (Ross, Green, & House, 1977). Although this *projection effect* (which is also known as the *false consensus effect*) has received considerable research attention, much of that attention has focused on investigating the implications of projection for judgmental accuracy (Dawes 1989; Hoch 1987; Hsee, Rottenstreich, and Tang 2008) rather than on understanding the psychological processes governing the projection process.

In this research, we propose that predicting the choices of others takes the form of a dual process (cf. Hoch, Davies, and Ragsdale 1986). First, people form an *intuitive judgment* by project-

ing their own preference onto others. Then, they adjust this inference on the basis of *constraint information* (e.g., knowledge of base rates; knowledge that other people may be dissimilar) that suggests that others may not share their preference. Simmons and Nelson (2006) have shown that people rely more heavily on their intuitions, and less heavily on constraint information, when they are confident in their intuitions. Following from that research, we propose that a stronger projection effect will emerge for easy, high-confident choices than for difficult, low-confident choices. This effect should emerge even when the choice options themselves are held constant.

We investigated these hypotheses by manipulating the valence of the choice options. Past research suggests that although choosing between two good options feels like an easy thing to do, choosing between two bad options feels like a difficult thing to do (Higgins 2000; Miller & Nelson, 2002). Thus, people should have greater confidence when choosing between two good options than when choosing between two bad options, and a stronger projection effect should emerge when choosing between two good options than when choosing between two bad options.

Study 1 tested this hypothesis by asking people to make choices between a certain outcome and a risky outcome (e.g., a 10% chance at \$200 or a certain gain of \$20) that offered equivalent expected values. On half of the trials, participants chose between two outcomes with positive expected values and, on the other half of trials, participants chose between two outcomes with negative expected values. After each choice, participants were asked to estimate the percentage of other participants they thought would make the same choice. As expected, people predicted that a greater percentage of others would make the same choice when they were choosing between two potential gains than when choosing between two potential losses.

In Study 2, we sought to generalize this result to a different choice scenario, and we measured decision confidence to assess whether it in fact differed between conditions. Participants were shown pairs of attractive or unattractive faces, and they were asked to choose between them. For each pair, participants rated how confident they were in their decision and they were asked to estimate the percentage of others who agreed with them. As predicted, participants were more confident when choosing between the attractive faces than when choosing between the unattractive faces. Moreover, the projection effect was stronger for choices between attractive pairs than for choices between unattractive pairs.

Studies 1 and 2 provide strong evidence for our hypothesis, but they suffer from a potentially important confound. Specifically, the positive stimuli presented on the high confidence trials were different than the negative stimuli presented on the low confidence trials. To eliminate this confound, we manipulated choice confidence by manipulating the framing of the choice task. Although asking participants to “choose” between two options makes it harder to select between two negative options than between two positive options, asking participants to “reject” one of the options may make it easier to select between two negative options than between two positive options (Higgins 2000).

In Study 3 we once again asked participants to express a preference between two attractive faces or between two unattractive faces. However, some participants were asked to “choose” which one they preferred whereas others were asked to “reject” the option they did not prefer. When participants were given the “choose” instruction, they once again expressed greater confidence and exhibited stronger projection when choosing between attractive than unattractive faces. However, when participants were given the “reject” instruction, these results reversed: Participants were more confident rejecting between two unattractive faces, and

they exhibited a stronger projection effect when choosing between unattractive faces. These results emerged even though task instruction had no effect on which options participants actually chose.

Finally, Study 4 extended this effect by manipulating the valence and extremity of the choice stimuli. On each trial, participants chose (or rejected) between two extremely positive words, two moderately positive words, two moderately negative words, or two extremely negative words. In the choice condition, decision confidence, and the projection effect, increased as the positivity of the choice set increased. In the reject condition, decision confidence, and the projection effect, decreased as the positivity of the choice set increased.

Together, these results provide strong support for the effect of intuitive confidence on projection. People more strongly project confident choices than uncertain ones. Moreover, this effect can account for a novel finding that we have presented here—namely, the effect of option valence on projection. Because people are often more confident when choosing between two positive options, they are more likely to believe that others would have made the same choice.

SYMPOSIUM SUMMARY

Does Authenticity Matter? The Importance and Interplay of Authenticity and Inauthenticity

Tandy D. Chalmers, University of Arizona, USA

Linda L. Price, University of Arizona, USA

SESSION OVERVIEW

Authenticity is argued to be the new business imperative and 'buzz word' of the 21st century (Gilmore and Pine 2007) and "consumers' search for authenticity is one of the cornerstones of contemporary marketing" (Brown, Kozinets, and Sherry Jr. 2003 p. 21). Consuming and communicating authenticity are recurrent themes in academic research and consumer research approaches the topic in several ways. First, consumer research has examined the authenticity of referents such as objects, persons, and experiences (Arnould and Price 1999; Grayson and Shulman 2000; Schouten and McAlexander 1995). Second, consumer researchers have examined authentic representations of objects, persons, and experiences, such as photographs, reenactments, and ads (e.g. Belk and Costa 1998). In both cases, research examines how to create authentic referents and representations of referents (e.g. Holt 2004) and how these are viewed by observers (Rose and Wood 2005). An important underlying assumption of this work is that authenticity is an important and positive outcome.

This privileging of authenticity has resulted in the neglect of an equally important construct: inauthenticity. Trilling (1972) notes authenticity is a polemical concept, usually only thought about when called into question, with the focus on something being either authentic or inauthentic. Much of consumer life, however, is represented by situations where both authenticity and inauthenticity co-exist (Benjamin 1969; Grayson and Martinec 2004). The purpose of this symposium is to explore the interplay between authenticity and inauthenticity.

First, Markus Giesler and Marius Luedicke discuss how consumers paradoxically create an authentic self by enhancing their physical selves with market offerings, such as Botox, that are often perceived as creating an inauthentic self. Next, Tandy Chalmers and Linda Price show how consumers negotiate authenticity and inauthenticity in an advertisement context and demonstrate a complex interplay between the two, uncovering how this authentication process is linked to ad liking. Finally, Jay Handelman and Robert Kozinets present work showing how consumers' desire to create authentic identities often overrides the negative aspects of inauthentic production techniques. They also highlight how corporations actively try to restore an image of authenticity while activists work to debunk these efforts. In each of these papers, consumers negotiate between seemingly inauthentic aspects of consumption (e.g. artificial body enhancement, blatant reproductions with a persuasive purpose, and mass production) in reaching conclusions about authenticity in their consumption choices and evaluations.

The objectives of this session are three-fold: to examine (1) the paradoxes inherent in how authenticity operates in consumers' lives and marketers' practices, (2) the different manifestations of authenticity and inauthenticity in the marketplace, such as self-authenticity, advertisement authenticity, and brand and product authenticity and, (3) how these authenticity domains all benefit from an analytic perspective highlighting the interplay between authenticity and inauthenticity as a co-production of meanings between the market and consumers.

Given the broad theoretical significance of authenticity and the multi-method focus of this symposium, it should appeal to a wide range of ACR attendees. These include CCT and other researchers interested in authenticity, inauthenticity, and its rela-

tion to identity, public policy oriented researchers interested in consumer resistance, and advertising and social identity scholars interested in the relationship between the self, authenticity, and advertising responses.

EXTENDED ABSTRACTS

"American Self-Enhancement Culture and the Cyborg Consumer: Consumer Identity Construction Beyond the Dominance of Authenticity"

Markus Giesler, York University, Canada

Marius K. Luedicke, University of Innsbruck, Austria

Why do Americans place so much emphasis on individual identity and self-fulfillment? Does the skyrocketing consumption of Viagra, Botox, Prozac, Propecia and countless surgical enhancements make them more true to a "real" self, or does it make them frauds? Social critics of American self-enhancement culture commonly charge that it indoctrinates individuals into a biomedical consumerism that frustrates the construction of a genuine self-identity (Elliott 2004; Kass 2004). Following this popular "lost authenticity" thesis, Americans today—members of the middle-class in particular—are replete with deep conflicts between the relentless pursuit of self-fulfillment and high performance and the insistent yearnings for authenticity and a genuine self. In one perspective, they worry that changing their bodies through biomedical intervention might make their body and their very identity inauthentic. But they also understand that they have a duty to pursue happiness and status by perfecting themselves according to the latest biomedical research and trends (Kass 2004). Sadly, Americans can look up to no authority to resolve this fundamental identity crisis. Their only escape from "anxious dislocation" is to "follow fashion" and "listen to the reigning experts" (Lawler 2005, 3).

However, reducing self-enhancement culture to pathological consumerism turns a blind eye to the potential to construct a coherent "narrative of the self" through the consumption of biomedical products and services. For example, consumer researchers have long recognized the creative role of consumption—including the use of aesthetic plastic surgery (Schouten 1991)—in people's quest for self-identity. In this perspective, Americans may partially and inconsistently transcend the entrenched dichotomy between artificial technology and the natural body to reach unprecedented levels of enhanced self, thereby challenging the modernist quest for authenticity. These heretical self-experiments and their underlying cultural incompatibility to authenticating appeals may inspire unprecedented agentic possibilities.

To give greater consideration to this alternative account, we present the concept of the cyborg consumer. Grounded in critical feminism and cultural studies (Haraway 1991; Hayles 1999; Davis 1999), the cyborg consumer illustrates how entrenched narrative dualisms—nature versus technology, authentic versus inauthentic—are partially and inconsistently transcended to construct hybrid stories of the self that challenge the modernist primacy of self-authenticity and instead aspire to an emerging ideal of unlimited agency through technological self-enhancement. From this standpoint, the social critics who are railing about consumerist inauthenticity may be expressing less of a relevant social comment than an emerging historical discontinuity between their cultural

lens and an emerging experimental cyborg episteme. For Botox consumers, being inauthentic is not the driving issue. As we will demonstrate, their ideological mandate is the duty for biomedical self-enhancement by any available means.

Our analysis is threefold. After reviewing the ideological groundwork of American self-enhancement culture, we analyze the self-narratives of individual Botox users. In distinction to the classic “lost authenticity” thesis, we build the case that Botox consumption is steeped in a complex ideology of the enhanced body and that Botox consumers’ routine confrontations with authenticity-inspired assessments of their bodies intensify and augment their experiences of enhanced self and its agentic possibilities. We then summarize our findings by documenting an emerging historical discontinuity between the modernist paradigm of authentic self-identity and the emerging cyborg consumer episteme and draw out implications of the cyborg consumer model for dualism-inspired theoretical debates on the body (Thompson and Hirschman 1995), and consumer identity construction (Holt and Thompson 2005; Kozinets 2002; Arnould and Price 2000). We also develop the implications of our cyborg consumer model for the critical cyborg model, as pioneered by Donna Haraway (1991).

This analysis is part of a larger ethnographic research exploring self-enhancement consumption using the Botox biomarket as an empirical context (www.doingbotox.com). We conducted depth interviews with 20 Botox consumers (6 male) in Chicago, New York, Buffalo, and Toronto. Informants hailed from a range of middle-class backgrounds and had received up to 9 cosmetic Botox shots. With the exception of two telephone and one Skype conversation, all interviews were held either at the informants’ homes, in coffee shops, or during and after a Botox injection at the dermatologist’s practice. To ensure that interview narratives had a broader resonance, we compared them to user entries on online Botox forums (Kozinets 2001). In addition to these netnographic procedures, one author also analyzed introspective journal notes on a Botox injection he received “in situ” during a Botox party (Gould 1991). The complete data set was analyzed using a hermeneutical process (Thompson 1997). Interpretations were formed, fed back to our informants through the research website and via email, and revised in relation to a broader network of theoretical concerns until sufficient interpretive convergence was achieved.

“Perceptions of Authenticity in Advertisements: Negotiating the Inauthentic”

Tandy D. Chalmers, University of Arizona, USA

Linda L. Price, University of Arizona, USA

Advertisements are a powerful tool through which companies can communicate authenticity to stakeholders. Successful communication of authenticity is presumed to be linked to positive downstream responses such as brand identification, loyalty, and sales (Botterill 2007), with authenticity viewed as a key mechanism for seducing consumers. Despite this rhetoric of importance, little is empirically known about how consumers respond to advertisements designed to communicate authenticity, or if authenticity even matters in an advertisement context.

The purpose of this study is to explore consumer perceptions of and reactions to ads designed to be authentic. Stern (1994) defines authentic ads as those that “convey the illusion of the reality of ordinary life in reference to a consumption situation” (388). The key premise of Stern’s conceptualization of ad authenticity is a link between everyday experiences and ad content: implying a self-referencing process where consumers relate their own experiences to an ad when evaluating it (Burnkrant and Unnava 1995). The consequence of this process should, theoretically, be increased ad liking. In contrast, if an ad is deemed inauthentic, it can be presumed

that consumers will dislike the ad. The paradoxical nature of authentic ads, however, convolutes this linear relationship: an ad, a representation by definition, cannot be something authentic or real, even if it creates a convincing illusion of something that is real (Stern 1994). Thus, even ‘authentic’ ads contain elements of inauthenticity (Benjamin 1969; Stern 1994).

Rose and Wood (2005), for example, find that reality television viewers negotiate between authentic and inauthentic elements of shows, with viewers deciding the entertainment value of the show is worth forgoing some aspects of authenticity. In the case of reality television, consumers are motivated to enjoy the show and seek out reasons to overlook the inauthentic. In the case of ads, however, consumers may approach the representation with skepticism (Friestad and Wright 1994) and be less willing to overlook inauthentic elements. Thus, the question of how consumers negotiate between authentic and inauthentic elements of advertisements remains unclear: do consumers seek out reasons to reject the representation as inauthentic or instead look for ways they can affirm the advertisement’s authenticity? And how do consumers’ general attitudes toward advertising influence these authenticity judgments?

These questions are explored in a two-study, multi-method inquiry into consumer perceptions of ad authenticity and inauthenticity. The first study, consisting of stimuli based in-depth interviews with 28 distance runners, examines if and how authenticity perceptions emerge naturally in consumer assessments of ads. Running was chosen as the study’s context as there are an abundance of ads in this area depicting everyday life. During the interviews, informants were shown 15 running themed ads, each of which fit Stern’s ‘authenticity’ requirement, and were asked what they thought of the ads. The second study consisted of a survey administered to 88 undergraduate students enrolled in an upper-level marketing class. Participants responded to one of four advertisements that seemed realistic (and therefore authentic) but also contained unrealistic undertones and elements of the outrageous. For example, an Axe Body Wash ad depicts a young man standing outside a shower with a towel showing a picture of a woman’s legs around his waist, creating the illusion of a real woman straddling the man. Participants assessed the authenticity and their liking of the ad. Afterwards, both authors engaged participants in a discussion about the ads to gauge their more nuanced reactions.

The findings from both studies contribute to our understanding of authenticity and inauthenticity in an advertisement context. A clear negotiation between authentic and inauthentic elements of the ads emerged. Informant discussions in study 1 show consumers naturally evaluate ads in terms of both authenticity and inauthenticity, with these evaluations linked to ad liking. In addition, discussions show an interesting interplay between authenticity and inauthenticity perceptions when ads contained elements of both. Sometimes, ads were viewed as being simultaneously authentic and inauthentic, with informants jostling between the two sets of perceptions when making final evaluations of the ads: moving between thinking the ad is authentic to thinking it is inauthentic, and vice versa. Throughout these authentication processes, consumers engage in both self- and other-referencing. A series of counterintuitive findings also emerged were consumers deemed an ad to be authentic, related to it, but did not like the ad. This occurred when consumers engaged in ‘looking-glass self’ referencing where they disliked how imagined others would view them based on what is depicted in the ads (Cooley 1902/1922).

Study 2 findings confirm the importance of authenticity and inauthenticity perceptions in ad liking, but also give rise to an additional authenticity structure: advertisements viewed as authentically inauthentic. In some cases, vastly exaggerated claims are

viewed as having a reflective legitimacy in relationship to the advertised product that engenders ad liking without strong links to self- or other- referencing. That is, ads may be paradoxically high in both authenticity and inauthenticity. Combining the findings from the two studies, we illustrate a set of relationships between authenticity, inauthenticity, self-, other-, and looking-glass self-referencing, and ad liking. These relationships highlight the importance of ad authenticity and inauthenticity perceptions, demonstrate the complexities and nuances of the advertisement evaluation process, and illustrate how the authentic and inauthentic are negotiated by consumers.

“The Cultural Privileging of Personal Authenticity: A Critical Postmodern Perspective”

Jay M. Handelman, *Queen’s University, Canada*

Robert V. Kozinets, *York University, Canada*

The quest for personal authenticity stands as an appeal to one’s potentiality for self-cultivation, self-direction, creativity, identity, and individuality—a type of human re-enchantment whereby the individual is able to find meaning in life, creativity, playfulness, sensuality, and morality (Berman 1970; Firat and Venkatesh 1995). In their quest for personal authenticity, consumers are deemed to be sovereign in their creative, playful, artful employment of branded products as core ingredients in their self-identity projects (Firat and Venkatesh 1995). The consumer dissolves the illusory separation between the physical product and the imaginary as mass produced products are transformed into symbolic meaning systems, freeing the consumer from the hegemony of the marketplace (Firat and Venkatesh 1995).

However, this postmodern privileging of consumers’ imaginative, creative, hedonic play conceals the fact that the physical product and its material consequences still exists. News stories about tainted products, documentaries and film clips such as *Mardi Gras Made in China* and *The Story of Stuff*, and amateur YouTube video footage revealing abhorrent working conditions in the factories that produce the products we consume, remind consumers that Taylorism is alive and well; that the physical resources extracted to produce consumer goods are becoming scarcer and more costly; that the environmental consequences associated with the production, use and disposal of these goods are becoming graver.

Far from a natural, inevitable evolution, our cultural privileging of consumer personal authenticity over the consequences of production occurs in the context of a socially constructed ideological framework (Berman 1970). In this paper, we examine the paradoxical essence that seems to cut to the core of our consumption-based society. In this paradox, the act of being a consumer comes to be associated with all things moral-human and economic development, re-enchantment, aesthetic experience, knowledge, skills, and even activism and social change (Heath and Potter 2004). Yet, the potential human and environmental denigration associated with the often out-sourced production feeding our consumption is downplayed or outright ignored.

We draw on Critical Postmodernism to capture a glimpse into the social construction that comes to privilege consumer personal authenticity over the material consequences associated with consumption. Critical postmodernism is the unlikely combination of critical theory and postmodernism (Alvesson and Deetz 1996), providing a potent lens through which to examine the hybridity of contemporary consumer life characterized by the interpenetration of modernist production and postmodern consumption practices (Boje 2006). By examining the interplay between marketers, activists and consumers, we present the cultural privileging of the

aesthetic nature of consumption as a hotly contested and problematized social phenomenon.

Method: We draw on three empirical sites for our data collection. First, we examine a variety of tactical maneuvers deployed by consumer activists from three different activist movements (anti-advertising, anti-brand, and anti-toxin activists). Through our participation in activist organized protest events, in-person meetings, and telephone interviews with activists from across North America, we report on the depth interviews with thirteen consumer activists who stood out as highly engaged in their protest against consumer society over the decade (1996–2006) that we examined them. Second, providing insights into marketer responses, we report on in-person (five) and telephone (six) depth interviews with eleven corporate marketers. These senior marketers were drawn from eleven different North American based multinational companies that had all been the target of consumer activist campaigns. Finally, we deployed the method of netnography to study a variety of controversy-laden online consumer discussion forum (such as <alt.politics> and <misc.activism.progressive>) and corporate blogs. In total we examined over 5,000 postings that ran from April 1999 to June 2006.

Theme 1-De-Sanctifying the Consumer: Activists rework consumer brands by recoupling them with their physical, production origins. Activists associate production, and the ensuing human and environmental consequences, with the “true” source of ethics and morality. Here, activists de-sanctify, or de-privilege, the consumer’s quest for personal authenticity as an immoral, self-indulgent endeavor completely decoupled from its production origins. As such, decoupling of production does not only conceal the commercial motives of the company, but it also serves to sanctify, or privilege, the consumer as removed from the product’s controversial human and environmental consequences. *Theme 2-Sanctifying the Consumer Through Corporate Social Responsibility (CSR):* Faced with a threat not only to themselves, but also to the sanctity of their consumers, marketers work to re-sanctify, or re-privilege, the consumer through acts of CSR by infusing consumption with claims of morality, ethics, and community well-being. *Theme 3-Mutual De-Sanctification:* Corporate blogs foster a type of mutual de-sanctification where consumers and companies inadvertently de-sanctify, or de-privilege, each other by recoupling the brand to its production sources. This mutual de-sanctification emerges as an enactment of the critical postmodern perspective whereby symbolic meanings of brands are celebrated, but tempered by a challenge to the power relationships that have come to privilege the consumer’s authenticity desires over the material consequences associated with production.

Discussion: The paper concludes with a discussion around two particular issues. First we explore the implications of branding in a critical postmodern context. Second, we discuss consumer re-enchantment not through consumption, but through *Consumer Social Responsibility*. Traditional *Corporate Social Responsibility* is critiqued as an ideological veil that works to maintain the extant power balance that privileges consumers and the companies that market to them. We reveal a type of consumer enchantment that comes through embracing the production consequences underlying the products that are consumed.

SYMPOSIUM SUMMARY

Emotions, Social Comparison, and Deception in Interpersonal Interactions

Eduardo Andrade, University of California, Berkeley, USA

SESSION OVERVIEW

Consumers' daily activities usually rely on interpersonal interaction: a car shopper who tries to avoid the unfair offer from a car dealer, two consumers who after a quick chat realize they have gotten different deals on the same product, or a patient who exaggerates his symptoms in order to increase the chances of getting an early appointment.

In a series of three papers we address those phenomena using standard games developed in experimental economics. We hope to contribute to our understanding of the role of interpersonal interactions in consumer behavior as well as to demonstrate how incentive-based games can shed light into this realm of research.

In paper 1, Andrade & Ho address what the authors call "emotional gaming"—i.e., people's willingness to either conceal a current emotional state or display an emotional state which diverges from the true state, in a strategic attempt to optimize the chances of success in a given social interaction. Examples of such phenomenon are widespread in consumer behavior: a waiter who, in an attempt to get a bigger tip, smiles to the customer when he hands her the check; a poker player who hides his emotional expressions to avoid providing unwanted information to competitors; and an HMO patient who exaggerates his reported level of pain to the doctor as to increase the chance of getting an early appointment with a specialist. In a series of three experiments, the authors show that during a given social interaction (e.g., ultimatum games and trust games) people deliberately conceal (experiment 1) or misrepresent (experiments 2 and 3) their emotional state in an attempt to succeed in the negotiation process.

Also using a game format, the role of emotions in interpersonal interaction is also addressed in paper 2. Ho & Su argue that in many consumption-related situations, people get upset when they receive a worse deal than their peers, which limit the extent of price discrimination. For instance, Apple has recently faced this problem after their decision to significantly reduce the price of the iPhones just a few months after the launching. Angry consumers, who had bought the product previous to the price reduction, forced the company to provide "retroactive" discounts to avoid further boycotting and damage to company's brand image. Ho & Su tested such concern for peer-induced fairness in the context of two independent ultimatum games played in sequence by a leader and 2 followers. Their results show that the leader does formulate the second offer based on the second follower's expectation of what the first offer is. In addition, the second follower is more likely to reject when she believes that the first follower receives a high offer.

As already pointed out, Andrade and Ho address the extent to which people misrepresent their feelings (e.g., inflate how happy or angry they are) for purely strategic reasons. Such willingness to convey "cheap talk" in a social interaction is certainly not constrained to emotions. In paper 3, Wang, Spezio, & Camerer point out that such phenomenon is common to many companies and consumers. Companies might be tempted to inflate earning prospects, MBA students might inflate course evaluations to improve school rankings, and HMO patients might inflate whatever symptoms they might have in order to get more quickly to the specialist. To test the extent to which participants "inflate the truth," when they have an incentive to do so, the authors rely on sender-receiver games. Moreover, they use eyetracking measures to assess the potential costs of deception. Among other findings, the authors

show that people indeed convey untruthful information. Moreover, deception can be tracked at the physiological level. Right before and after the message is sent, senders' pupils dilate more when their deception is larger in magnitude. This suggests that subjects feel guilty for deceiving, or that deception is cognitively difficult.

In short, all three papers attempt to understand a few of the multiple nuances consumers and companies face in any given social interaction (Do people inflate emotions [Andrade & Ho] or other types of information [Wang, Spezio, & Camerer]?, How do they physiologically react to it [Wang, Spezio, & Camerer]?, How does information about peers influence one's decision making [Ho & Su]?). Moreover, all papers adopt a similar methodology (i.e., economic games) to help us better understand how consumers and companies might interact when actual incentives are at stake.

EXTENDED ABSTRACTS

"Gaming Emotions"

Eduardo Andrade, University of California, Berkeley, USA
Teck-Hua Ho, University of California, Berkeley, USA

A car shopper pretends to feel angry in an attempt to reduce the chances of an unfair offer from a car dealer. A teacher hides his anxiety in front of students to avoid showing lack of confidence, which in turn, could reduce students' receptivity to the lectures. By wearing appropriate apparels (e.g., dark sunglasses), professional poker players hide both bad *and* good feelings from their competitors to avoid revealing any clues about their cards. Waiters smile when they hand customers the check in an attempt to get a bigger tip. Finally, parents pretend to be very angry at their kids' misbehavior just to make sure the children behave appropriately.

In short, knowing that one's expressed affective state can influence other's decisions, people are usually tempted to *game emotions*—that is, to either conceal a current emotional state or display an emotional state which diverges from the true state, in a strategic attempt to optimize the chances of success in a given social interaction.

Survey and observational-based evidence have suggested that individuals do display non-experienced emotions, especially when their jobs require them to do so. This so-called *emotional labor* literature has addressed (a) the extent to which the workplace demands specific emotional expressions and (b) how much such requirements influence employees' wellbeing. This research stream shows that employees have frequently been obliged either by implicit social norms or by explicit company policies to display, and usually fake, specific emotional states. The service industry has numerous examples. Amusement parks, airline companies, and fast food chains, to mention a few, usually suggest—or request—their employees to continuously display positive feelings when they interact with their customers.

Nevertheless, it is possible that people, when given the opportunity, may deliberately choose to game emotions on their own in an attempt to succeed in a given negotiation and, as a result, *improve* their overall wellbeing. This paper investigates this emotion gaming hypothesis experimentally. In a series of three experiments, we show that people deliberately conceal (experiment 1) or misrepresent (experiments 2 and 3) their emotional state in a negotiation setting. When given the opportunity to either hide or express their current emotions before playing an ultimatum game, receivers who

have reported low (vs. high) level of anger are more likely to conceal their emotion right before the proposers decide on the division of the pie (experiment 1). When the procedure allows participants to change their previously reported emotion, receivers choose to inflate their reported level of anger prior to proposers' decision (experiment 2 & experiment 3). Moreover, gaming emotions is financially beneficial as long as the partner does not realize that the one might be misrepresenting their feelings (experiment 3).

"A Theory of Peer-induced Fairness in Games"

Teck-Hua Ho, University of California, Berkeley, USA

Xuanming Su, University of California, Berkeley, USA

A long-standing assumption in economics is that people are purely self-interested. This assumption has been challenged recently by accumulating experimental evidence based on the so-called ultimatum game. Behavioral economists propose several models of distributional fairness to relax the self-interest assumption. In this paper we introduce the concept of *peer-induced fairness* because people have a drive to make social comparison.

That is, they look to similar others as a reference in order to form their opinions and evaluate their endowments. We investigate peer-induced fairness by considering two independent ultimatum games played in sequence by a leader and two followers. In the first ultimatum game, the leader makes a take-it-or-leave-it offer to the first follower. Before the next ultimatum game is played, the second follower obtains a public signal of this offer. Then, in the second game, the leader makes an offer to the second follower. The second follower infers what the first follower receives, uses this inference to form a reference point, and is averse to accepting offers that falls short of this benchmark. This generalized model nests the standard and several existing models of fairness. This model makes two sharp predictions. First, the leader's offer to the second follower

should be non-decreasing in the common belief of what the first offer is. Second, condition on an offer, the second follower's likelihood of acceptance is inversely proportional to the reference point derived from the signal. We test both predictions experimentally and find strong support for them. We structurally estimate the model and show that peer-induced fairness is 2.5 times larger than distributional fairness. We incorporate heterogeneity by allowing subjects to be either purely self-interested or fairness-minded. Our estimation results suggest that half of the subjects exhibit peer-induced fairness. We show how peer-induced fairness might influence the occurrence of labor strikes, explain low variability in CEO compensation, and limit the extent of price discrimination.

"Pinocchio's Pupil: Using Eyetracking and Pupil Dilation To Understand Truth-telling and Deception in Sender-Receiver Games"

Joseph Tao-yi Wang, National Taiwan University, Taiwan

Michael Spezio, California Institute of Technology & Scripps College, USA

Colin Camerer, California Institute of Technology, USA

During the tech-stock bubble, Wall Street security analysts were alleged to inflate recommendations about the future earnings prospects of firms, in order to win investment banking relationships with those firms. They usually gave two separate 1-5 ratings for short run (0-12 months) and long run (more than 12 months) performance. Henry Blodget, Merrill Lynch's famously optimistic analyst, "did not rate any Internet stock a

4 or 5," while privately admitting some were "POS [piece of shit]." He was later banned from the security industry for life and fined millions of dollars.

This case is an example of a sender-receiver game with divergent preferences (sometimes called a "cheap talk" or strategic

information transmission game). Sender-receiver games are simple models of economic situations in which one agent has an incentive to exaggerate the truth to another agent. The central issues in these games are how well uninformed players infer the private information from the actions of players who are better-informed, and what informed players do, anticipating the inference of the uninformed players.

Incentives for strategic information transmission are common. Besides the Blodget case mentioned above, similar dramatic accounting frauds in the last few years, such as Enron, Worldcom, and Tyco, might have been caused by the incentives of managers (and perhaps their accounting firms) to inflate earnings prospects. Expert advisors in consumer markets might also be tempted to paint a rosy picture when presenting in front of their clients. In universities, grade inflation and well-polished recommendation letters help schools promote their graduates. Other examples of incentives for strategic information transmission include government-expert relationships in policy making, doctor-patient relationships in health care choices, teacher cheating on student tests and the floor-committee relationship in Congress.

This paper reports experiments on a sender-receiver game. In the game, a sender learns the true state (a number S) and sends a costless message M to a receiver who then chooses an action A . Payoffs only depend on S and A so the message M is "cheap talk." The receiver prefers to choose an action that matches the state, but the sender wants the receiver to choose an action closer to $S+b$, where b is a known bias parameter. The value of b is varied across rounds. When $b=0$ senders prefer that receivers choose S , so they almost always just announce S (i.e., $M=S$), and receivers believe them and choose $A=M$. When $b>0$ senders would prefer to exaggerate and announce $M>S$ if they thought receivers would believe them.

Besides measuring choices in these games, our experiment uses "eyetracking" to measure what payoffs or game parameters sender subjects are looking at. Eyetracking software records where players are looking on a computer screen every 4 milliseconds. These data are a useful supplement to econometric analysis of choices, when decision rules which produce similar choices make distinctive predictions about what information is needed to execute these rules.

The eyetracking apparatus also measures how much subjects' pupils "dilate" (expand in width and area). Pupils dilate under stress, cognitive difficulty, arousal and pain. Pupillary responses have also been measured in the lie-detection literature for many years. These studies suggest that pupil dilation might be used to infer deceptive behavior because senders find deception stressful or cognitively difficult.

The experimental choices, eyetracking, and pupil dilation measures generate four basic findings:

1. Overcommunication in sender-receiver game is consistent with L0, L1, L2, and equilibrium (Eq) sender behavior produced by a level-k (cognitive hierarchy) model of the sender-receiver game in which L0 sender behavior is anchored at truth-telling.
2. Eyetracking data provide the following justifications for the level-k model of overcommunication:
 - a. Attention to basic structure: Sender subjects pay attention to important parameters (state and bias) of the sender-receiver game.
 - b. Self-centeredness: Sender subjects look at their own payoffs more than their opponents'.
 - c. Incorrect beliefs: Sender subjects focus too much on the true state payoff row.

- d. Strategizing from a truth-telling anchor: Sender subjects focus on the payoffs corresponding to the action $a=s$, as well as actions up to $a=s+b$.
3. Right before and after the message is sent, senders' pupils dilate more when their deception is larger in magnitude. This suggests that subjects feel guilty for deceiving (as in Gneezy, 2005), or that deception is cognitively difficult (as the level- k model assumes).
4. Prediction: Based on the eyetracking results, we can try to predict the true state observed by the sender using lookup data, messages, and pupil dilation. This prediction exercise suggests it could be possible to increase the receiver's payoff (beyond what was earned in the experiments) by 16-21 percent. Finally, this study shows the possible relevance of psychology and neuroscience to economics. Douglas Bernheim (2008) suggests that Neuroeconomics will be successful if it can show how new non-choice data can solve a prediction or normative problem that could not be solved by standard choice data. Our data satisfy this criterion because lookups and pupil dilation enhance prediction of the true state beyond the predictions derived simply from observed messages (choice) and equilibrium theory.

This is the first study in experimental economics to use a combination of eyetracking and pupil dilation, and is, of course, exploratory and is therefore hardly conclusive. But the eyetracking and pupil dilation results by themselves suggest that the implicit assumption in theories of "cheap talk" in games with communication—namely, that deception has no cost—is not completely right. Mark Twain famously quipped, "If you tell the truth, you don't have to remember anything." The corollary principle is that if subjects want to misrepresent the state to fool receivers, they have to figure out precisely how to do so (and whether receivers will be fooled). This process is not simple and seems to leave a psychological signature in the form of looking patterns and pupil dilation. Future theories could build in an implicit cost to lying (which might also vary across subjects and with experience) and construct richer economic theories about when deception is expected to be widespread or rare.

SYMPOSIUM SUMMARY

Novel Approaches to Understanding Context Effects in Choice and Judgment

Anastasiya Pocheptsova, University of Maryland, USA

SESSION OVERVIEW

A major theme of a large body of research in psychology and consumer behavior has been that judgments and choice are influenced by temporary incidental context. The sources of these contextual effects are “as varied as the sources of information that can serve as input into evaluative judgment” (Schwarz and Clore 2007). Despite the wealth of empirical evidence on the topic, many interesting questions remain unanswered. For example, how can physical context (such as temperature) influence psychological judgments and change preferences? How does context cross modality; how do simple visual cues affect higher order processing? Finally, do context effects have a long-term influence on judgments or are they only capable of affecting immediate evaluations? Answering these questions will help consumer behavior researchers as well as marketers make better predictions about when context effects take place and provide a more integrative framework for this area of research.

By looking beyond a traditional examination of context effects, the current session provides a richer analysis of consumer behavior by proposing novel approaches to understanding context effects. In particular, the papers in the session examine the nature of context effects by looking at the role of metaphorical relationships, the interaction of perceptual fluency and attention, psychological buffers, memory effects and lay theories. Furthermore, the session expands our understanding of context effects by examining two novel context effects: psychological warmth and perceptual boundaries.

In the first paper in the session, Williams & Bargh direct our attention to a novel under researched context effect of physical warmth. They find that physical warmth that is unrelated to the stimuli being evaluated systematically affects judgment and choices. The authors hypothesize that physical warmth is capable of producing feelings of psychological warmth and thus have downstream effect on preferences. Such a metaphoric relationship between fundamental aspects of human life and psychological concepts is proposed to be a cause of this as well as other context effects.

In the next two papers, the authors examine a different context effect of perceptual boundaries. Zhang & Labroo find that perceptual boundary (a simple box) added to stimuli affects judgments of the stimuli. Further, the authors examine the mechanism underlying the effects and find that the perceptual boundary has differential influence on visual vs. verbal stimuli through its effects on perceptual fluency. Continuing this topic, Galak, Kruger & Rozin show that arbitrary perceptual boundaries can create an illusion of distance, reducing risk perceptions and one's motivation to cross those boundaries. The authors further show that observed effects are not limited to visual spatial representation, but are rather driven by the creation of the sense of isolation that serves as a psychological buffer.

Finally, Pocheptsova & Novemsky look at the mechanisms of context effects from a different angle by examining whether these effects are long-lived. The authors examine this question by looking at a well-established incidental mood effect. They find that in general the effect of context dissipates with time. However, context effects can be prolonged through the use of immediate evaluations and application of consumers' lay theories.

Taken together the research papers in this session investigate context effects in choice and judgment from multiple, yet related,

theoretical perspectives with different conceptualizations of context effects. The authors of the papers span marketing and psychology offering an interdisciplinary view on the topic. As such the session will offer a novel perspective on the ways in which context affects the behavior of consumers and is expected to attract a broad audience at ACR.

EXTENDED ABSTRACTS

“Tactile Experience with Warm Objects Alters Judgments and Decisions”

Lawrence E. Williams, University of Colorado at Boulder, USA

John A. Bargh, Yale University, USA

Over the past 25 years, nonconscious priming research has demonstrated how environmental cues shape people's thoughts, feelings, and behaviors, often in a direct, literal fashion. This research examines new routes through which the external world influences people's judgments, via the metaphorical relationship between fundamental aspects of the physical environment (e.g., physical temperature), and psychological concepts (psychological warmth). A consideration of the ways in which the physical environment influences higher-order judgments and decisions increases our understanding of just how deep context effects run.

Psychological warmth is a ubiquitous feature of people's psychological realities. However, relatively little is known about the experiential basis of the concept of warmth. Based on recent treatments of concept development via metaphor, we tested the hypothesis that physical warmth is a core psychological concept capable of producing feelings of psychological warmth. To do this, we examine the effect of incidentally exposing people to warm or cold temperatures on personality impressions and social choices in two studies. In Study 1, participants who briefly and incidentally hold a hot coffee cup rate an ambiguous person as being nicer and more generous, compared to people who hold an iced coffee cup. Participants were primed with temperature by briefly holding either a cup of hot coffee, or a cup of iced coffee. To do this, a confederate blind to the study's hypotheses met participants in the lobby of the psychology building, carrying a cup of coffee, a clipboard, and two textbooks. During the elevator ride to the fourth floor laboratory, the confederate casually asked participants if they could hold the coffee cup as she recorded their name and the time of their participation. After the confederate wrote down the information, she took back the coffee cup. The temperature of the coffee cup (hot versus iced) was the only between-subjects manipulation. When participants arrived to the experimental room, they all received a packet containing a personality impression questionnaire modeled after the Solomon Asch's classic study on personality judgments. We find that this coffee cup manipulation altered people's judgments without their awareness, such that people who held the hot coffee cup judged this ambiguous person to be warmer. In Study 2, we find that people who briefly hold a hot therapeutic pad choose a gift for a friend more often than people who hold a cold therapeutic pad, extending these temperature priming effects into the realm of decision-making. Under the guise of product evaluation, participants held either a hot or cold therapeutic pad. After participants rated the effectiveness of either the hot or cold pad, they were asked to choose between a Snapple beverage and a \$1 gift certificate to a local ice cream shop as a reward for participating in the study. For

half of the participants, the Snapple option was framed as a personal reward for themselves, and the gift certificate option was framed as a social gift for a friend. For the remaining participants, the Snapple option was framed as a social gift for a friend, and the gift certificate option was framed as a personal reward for themselves. Consistent with our expectations, participants who held the hot pad were significantly more likely to choose reward framed as a social gift for a friend, regardless of whether it was a gift certificate or a Snapple.

These results highlight the importance of sensory experiences on higher-order psychological phenomena, improve our knowledge of how external cues can alter people's judgments, and provide marketers and managers with a new set of levers for influencing consumer behavior.

“Perceptual Boundaries: Helping You See Better but Making You Think Less”

Yan Zhang, University of Chicago, USA

Aparna A. Labroo, University of Chicago, USA

Four studies demonstrated that adding a perceptual frame (or boundary) around a stimulus improves visual processing of the object but interferes with verbal processing of the object. Building on research suggesting that visual processing relies on narrowing of attention whereas verbal processing relies on elaboration, we proposed that a perceptual boundary can help narrow attention. As a consequence, narrowed attention results in increased perceptual fluency towards a visual stimulus, making it appear more eye-catching and attractive and improving its evaluation. However, when the target object is verbal in nature, then the salience of a perceptual boundary can constrain elaboration and interfere with the ease of understanding the object, making the target appear less fluent conceptually. As a consequence, a perceptual boundary (simply adding a box) around a visual target can improve evaluation of the target but can reduce evaluation of a verbal target. A stronger positive effect of perceptual frame is observed on visual processors processing of visual objects, and a stronger negative effect of perceptual frame is observed on verbal processors processing of verbal objects.

Experiment 1 tested this basic premise. Non-Japanese speakers were informed that they would be evaluating Bank of Japan's new logo. The logo was presented either in Japanese, and was therefore not conceptually fluent to any participant, or was presented in English. In addition, for roughly half of the participants, a box was added around the logo while no box was added for the remaining participants. The data indicated the logo was evaluated more favorably when presented in Japanese and contained a frame vs. not. In contrast, when presented in English, the logo was evaluated less favorably when it contained a frame vs. not. Process measures indicated that for the Japanese logo, the improved evaluation was mediated by increased eye-catchingness of the logo. However, for the English logo, the reduced evaluation was mediated by reduced ease of understanding and elaboration. Variables such as need for cognition or need for closure do not impact the results, nor was there a reliable effect of self report measure of explicit attention to the target. A post test that manipulated perceptual salience in an alternative way by simply highlighting the Japanese and the English logo resulted in similar effects as a frame.

Experiment 2 extended these findings by showing that visual processors who presumably process a painting visually demonstrate an increased liking of an abstract painting comprised of a box vs. no box around it, presumably because the frame facilitates perceptual processing of the painting. In contrast, verbal processors who prefer to elaborate demonstrate reduced liking, presumably because the frame interferes with elaboration about the picture.

Experiment 3 replicated these findings in the context of an unfamiliar consumer product, Lanza Shampoo. It demonstrated that only among visual processors, liking was higher when the image was framed by a box (vs. not). In a final experiment, participants were asked to rate a verbal target — the description of a statement describing a psychological effect. High elaborators demonstrated reduced liking and importance rating of the theory when it contained a perceptual frame rather than not. In contrast, low elaborators demonstrated the reverse effect.

Taken together, these experiments add to our understanding of perceptual context effects. They demonstrate that a perceptual frame can serve as a context for evaluation of a target object, but its effect on evaluation diverges based on whether the target object relies on visual or verbal processing and whether people are more inclined to process information visually or verbally. Whereas perceptual frames facilitate visual processing by narrowing attention and making the visual objects appear more eye-catching, they also constrain elaboration and interfere with verbal processing when they are salient.

“Not in My Backyard: The Influence of Arbitrary Boundaries on Consumer Choice”

Jeff Galak, New York University, USA

Justin Kruger, New York University, USA

Paul Rozin, University of Pennsylvania, USA

The present research suggests that symbolic barriers such as political borders act as psychological buffers. Specifically, we show that the context that is defined by the presence or absence of a symbolic barrier affects the decisions that consumers make. Participants in Study 1 played a simple videogame in which the goal was to navigate an automobile to a virtual store as quickly as possible. Several routes were possible, some of which necessitated crossing a political boundary, some of which did not. Participants tended to choose routes that did not require crossing a town border, even though doing so did not result in a shorter (or quicker) route. This was true despite the fact the arbitrary nature of the border was clear (that is, the border was clearly unassociated with any geographical features such as lakes, rivers, etc.).

What, then, caused this reticence to cross borders? The results of Study 2 suggest that one reason is that the presence of a political border increases the perceived distance between locations. Participants were asked to imagine that they were in the market for a new guitar and to select which of two hypothetical music stores they would visit. The location of each store relative to the participant was depicted on a map. The map was drawn such that the two stores were in fact equidistant from the participant, but whereas one store was located in the same town as the participant, the other was not. Participants were not only more likely to choose the store that did not require crossing the border (replicating the results of Study 1), but also indicated that they were more confident in their decision when the store was “in the same town”. This effect was replicated in a third study involving a non-visual border manipulation, indicating that the effect is not unique to visual spatial representations.

The results of Study 4 suggest that there is more to the buffering effect of borders than the illusion of distance, however. Participants were asked to imagine that an oil refinery was to be built a few miles from their home. A map was provided that depicted the location of both the participant's home and the proposed refinery, which in one condition included a political boundary separating the two. Participants were less bothered by the threat of toxic waste if the refinery resided on the other side of a border. Of key importance, this was true even after statistically controlling for perceptions of distance. This effect was replicated in our fifth and

final study involving the proposed construction of a nuclear power plant. Here, too, participants were less concerned about the threat of contamination, despite the fact that a political border presumably offers little protection against airborne contaminants (and despite the fact that the arbitrary nature of the border was clear).

Taken together, these results suggest that arbitrary symbolic boundaries such as political borders act as a psychological buffer. Although part of this effect can be traced to the fact that borders make objects seem further away, it is also the case that borders provide a sense of isolation (from desirable objects) and protection (from undesirable ones). It appears that just as symbolic connection can convey the feeling of contamination (Morales and Fitzsimons, 2007; Rozin and Nemeroff, 2002; Rozin, Millman and Nemeroff, 1986), so too can symbolic *disconnection* serve as a psychological buffer. Discussion focuses on the relation between these findings and other findings from the judgment and decision making literature, including work on categorization (e.g., Parducci, 1965; Tajfel and Wilkes, 1963), context effects (Payne, Bettman, and Johnson 1993) and pricing (e.g., Thomas and Morwitz, 2005; Stiving and Winer, 1997).

“The Effect of Context on Memory-based Judgments”

Anastasiya Pocheptsova, University of Maryland, USA

Nathan Novemsky, Yale University, USA

Much research suggests that incidental situational factors (e.g., a transient mood) can affect immediate evaluations (Schwarz and Clore 1983, Schwarz 2004), but less is known about how such factors affect memory-based evaluations. Many (if not most) real-life consumer decisions involve memory-based judgments, where the decision is based on the evaluation of earlier experiences. For example, when consumers decide whether to come back to the restaurant they visited last week or heard about from a friend or buy a DVD based on their own or others' movie theater experience a couple of months ago, they have to rely on memories of past experiences. In the present research, we strive to expand our understanding of mood effects on memory-based judgment in two important ways. First, we investigate the effect of incidental mood present at the time of an experience on judgments made after the mood has dissipated. We propose that memory-based judgments are generally unaffected by context that is present during an experience. However, evaluations made during experience result in the “lock in” of context effects, leading to biased memory-based judgments and choices.

Consistent with these propositions, in the first two studies we found that mood had an influence on memory-based judgments when participants evaluated target stimuli in real time. This led to higher memory-based ratings for people who encountered the target in a positive mood and lower ratings for those who encountered it in a negative mood. However, the assimilating effect of mood disappeared in the absence of real-time evaluations. In the next study we extend our findings to a real choice setting. Because the choice task requires a comparison of several options, it can be argued that individuals might be motivated to recall the attributes of the experience rather than relying on the stored overall evaluation. In contrast, we show that being in a negative mood at the time of product consumption lead participants to prefer other options over the one they experienced last time, but only if they evaluated the experience at the time of consumption.

Next, we examine lay beliefs that people hold about the effect of incidental mood on memory-based judgments. In study 3 we show that people are not sensitive to time delay in their beliefs about the effect of incidental mood on memory-based judgments. Additionally, we find that real-time evaluations do not play a role in lay

theories and as a result people believe that their memory-based judgments are biased by incidental mood regardless of whether real-time evaluations were made. Finally, next two studies show that when reminded about the context of an experience, participants corrected for the perceived bias in their memory-based judgments consistent with the lay theories uncovered in study 3. This led to context-dependent judgments for participants who held context-free memories of the experience.

Since a multitude of situations involve judgments based on recollections of prior experiences, this line of research sheds some light on when such judgments will be context-dependent or context-free. Our research suggests that people are more likely to make context-free memory-based judgments when 1) there is no immediate evaluation of the experience and 2) context is not brought to the individual's attention while making a memory-based judgment.

SYMPOSIUM SUMMARY

Beyond 2x2x2: Methodological Advances in Uncovering Consumer Decision Processes

Siegfried Dewitte, Catholic University Leuven, Belgium

SESSION OVERVIEW

This symposium presents four methodological advances for illuminating the psychological processes underlying consumer decision making. The methodologies address two main problems. First, process data are often collected via static self-reports that distort what researchers wish to unveil, as is sometimes the case in mediation studies. Second, processes are often assumed instead of inferred from process data, which is often the case in behavioral decision theory.

The converging message of the papers in this symposium is that while reality is more complex than standard measures admit, the appropriate methodologies can both capture and clarify psychological processes. Each paper presents feasible and accessible tools that promise to provide significant leaps over conventional methods used in the consumer behavior literature. The first two papers highlight the dynamic nature of decision making. Willemsen and Johnson designed the MouselabWEB methodology and illustrate how the rich information coming out of such studies may help to set apart theories about well-known phenomena (in this case context effects). Ramanathan illustrates the wealth of information that the measurement of moment-to-moment affective changes, as measured with a joy stick, may reveal about processes underlying well-known effects. Dewitte identifies criteria that a moderation-by-process design should meet before a moderation interaction can be interpreted as evidence for the hypothesized underlying process. Goldstein introduces an interactive, graphical tool for risk preference assessment that, compared to earlier techniques, allows one to more useful process information in less time.

The symposium may be of interest to experimental researchers who, because of the phenomena they tackle, struggle to find accurate process measures. Willemsen and Johnson's contribution may help decision researchers to illustrate the process underlying an emerging decision. This insight may help to put conflicting decision theories to the test. Ramanathan's contribution may help affect, goal, and social interaction researchers to illuminate the dynamics underlying affect, motivation, and decisions in a social context. Dewitte's contribution helps researchers to clearly specify and identify the process without measuring it. Goldstein's contribution will help risk researchers to model more complex risk decisions. The symposium may also inspire consumer researchers to apply the proposed methods to new domains in our field.

Eric Johnson will lead the discussion. Several methodological contributions to our field (e.g. Johnson 2001, *JCR*; Lohse and Johnson 1996, *OBHDP*) attest to his seminal role in the methodological advance of our field. He will critically weigh the contributors' suggestions against his experience as an experimentalist interested in processes. Individual presentations will take 14 minutes, which leaves 19 minutes for discussion.

EXTENDED ABSTRACTS

"The Why and When of Context Effects"

Martijn Willemsen, Eindhoven University of Technology, The Netherlands

Eric J. Johnson, Columbia University, USA

Several accounts have been proposed to explain context effects like the compromise effect and the attraction effect. Though these accounts all predict choice, they differ strongly in the underlying cognitive mechanisms. To distinguish between the accounts, we look at the process predictions that can be derived from them. Process tracing tools (like MouselabWEB (Willemsen & Johnson, 2008), the tool we used in this study) allow us to gather information acquisition data that provides us with process measures on attention (acquisition frequencies and time), comparisons (transitions between information units) and dynamics (how information search changes over time). In two studies about Loss Aversion (Willemsen et al., 2008) we have applied these tools, showing that process data can help to distinguish between alternative accounts for loss aversion (reference dependence and gain-loss framing). In the current paper, we apply a similar methodology to get more insight into the cognitive processes underlying context effects.

We focus our analysis on theories that explain *both* attraction and compromise effects. In terms of process predictions, current accounts for context effects can be classified into two broad categories: biased and unbiased information search. One series of models predict a largely unbiased information acquisition process consisting of a large number of attribute-based comparisons. Some of these are based on loss aversion, such as the relative advantage model of Tversky and Simonson (1993) and the LAM model (Kivetz et al., 2004) which we extended to account for attraction effects. Recent sequential sampling models provide a computational modeling approach to explain context effects, such as Multi-alternative Decision Field Theory (Roe et al., 2001) and the Leaky Accumulator model (Usher & McClelland, 2004). These process models also predict an unbiased sequential sampling process, and are either based on lateral inhibition (Roe et al.) or on loss aversion (Usher and McClelland).

Another series of models predict context effects by means of a biased process. Emergent-value models explain the effects in terms of justification (Petibone & Wedell, 2007; Simonson, 1989), an option gets extra (emergent) value by means of a qualitative argument. Recently our own work on loss aversion (Willemsen et al., 2008), suggests that decision makers show an information acquisition process that is predominantly alternative-focused, and that over time attention is directed towards the option that is preferred (i.e., sampling is biased towards the chosen alternative). Studying the phenomenon of loss aversion, we showed that a 'Decision by Distortion' account could best account for the process data (information acquisition patterns) we observed. We also observed significant presentation order effects on the choice data, which is predicted by a decision by distortion account because early preferences might affect direction of search and likewise final preference.

We tested these accounts using process data gathered online from a group of 374 ordinary US citizens, ranging from 18 to 65 years of age, and from all educational levels. Each participant made

several choices for different product classes (DVD-players, cell phones, printers and small TVs), including a compromise choice, and attraction effect choice and a two option choice (control). Additional individual measures were gathered (such as importance ratings, demographics, loss aversion for money).

An important contribution of the current paper is that we present new, more advanced, methodologies to analyze and test the process data we collected. Rather than looking at global search indexes, we look in detail to attention given to each attribute/alternative, and how this changes over time. Data was analyzed using multilevel regression to account for individual differences and repeated observations, and to include time dynamics. New representations (Icon Graphs) were used to provide a detailed qualitative view of the process measures in our data.

The choice results replicated the compromise and attraction effect. Effects of presentation order on choice proportions were observed (as predicted by a Decision by Distortion account) and some effects of individual characteristics, such as gender and age and relative importance of the attributes. Furthermore, process data was closely linked to choice, showing that process data indeed captures part of the cognitive process responsible for the construction of preference.

Secondly, the process predictions from the models were tested by contrasts within the multilevel models on attention, comparison and search dynamics. The data revealed a biased information acquisition process, showing strong shifts in attention towards the chosen option over time. This data supported an alternative-based account, and the decision by distortion account in particular. Little evidence was found for the unbiased acquisition processes such as predicted by current models like the Relative Advantage Model and current Sequential Sampling models.

The present paper demonstrates how new methodologies of analyzing process data can be used to more rigidly test processes assumptions underlying models of decision making behavior, which might help us to distinguish between models in terms of their process validity. Furthermore, insights gained from these processes might allow us to build better specified models of decision making behavior, and those insights might also inform current computational models of context effects on what assumptions underlying these accounts might be most plausible from a psychological perspective.

“Understanding Dynamic Processes in Consumer Behavior”

Suresh Ramanathan, University of Chicago, USA

Consumer behavior researchers are very familiar with the use of between-subjects cross-sectional designs wherein participants provide data on their thoughts and feelings on a single occasion. Yet, psychological processes rarely tend to be static—they are subject to substantial internal and external influences every moment. Consider a person left alone in a room with a stranger for one hour. If one were to measure the mood of the person just before entering the room and again after a few minutes, the data may reveal both an internal variability (e.g., the person may have just had an argument with a friend leading to moods becoming more negative or may have just received an A on an exam, leading to moods becoming more positive) and external variability (due to the social influence of the stranger). One common way of looking at longitudinal measures is to use repeated measures ANOVA. However, this assumes that any intrinsic dynamics within a particular variable apply in the same way to all individuals in the sample in the interval between measurements, so that intra-individual variability may be mis-represented as measurement noise (Boker and Nesselroade 2002). Put simply, each individual or class of individuals may have a unique signature pattern of psychological dynamics. In this paper,

we present two different ways of modeling intra-personal and inter-personal dynamics in two contexts—self-control and social interaction.

In the first illustration, we discuss the dynamics of ego-depletion and how depleted individuals respond to temptations on a moment-to-moment basis. Subjects were asked to suppress their emotions in response to a very sad video clip in the depletion condition (vs. no instruction in the control condition). Following this, they were presented with a tray filled with tempting desserts and instructed to move a joystick up and down (towards themselves if they felt like taking the dessert and away from themselves if they felt like pushing it away) continuously for 3 minutes. The following measures were computed from the resultant time series: a) distance from mid-point—positive if approach, negative if avoid, b) velocity computed as the first derivative of the time series and c) acceleration, computed as the second derivative of the time series. A non-linear dynamic model was fitted with acceleration being modeled as a function of distance and velocity. The interpretation of the coefficient for distance is that it represents the frequency of oscillations in emotions, with higher absolute values implying greater cyclicity in feelings towards the temptation. The coefficient for velocity is indicative of regulation or excitation—negative values suggest that the individual is dampening the feeling towards the temptation, positive values indicate that the individual is experiencing increasing desire. Results indicated that depleted individuals had both a greater frequency of oscillations and an increasing desire compared to non-depleted individuals.

In the second illustration, we discuss the dynamics of social interaction and how people’s emotions change in response to the presence of others, both friends and strangers. Using a technique called cross-spectral analysis that decomposes the time series into different frequencies, we show that interacting friends who can see each other exhibit greater synchrony (as revealed by the covariation in the time series at specific frequencies) in their moment-to-moment reactions to a video clip compared to those who cannot see each other. The same is true for strangers who can see each other. However, we show that friends expect to experience this synchrony and discount it in their retrospective evaluations of the video clip while strangers misattribute the synchrony to the video clip and hence tend to use it as a heuristic to evaluate the clip.

“Good Practice in Experimental Moderation Designs”

Siegfried Dewitte, Catholic University Leuven, Belgium

The field’s favorite way of gaining insight in the processes underlying an association between variables, either causal or descriptive, is by means of statistical mediation tests. Spencer, Zanna, and Fong (2005) list six concerns associated with this technique and propose two alternatives. In this paper I focus on the moderation-of-process designs, in which the process, rather than measured, is experimentally manipulated, orthogonally to the independent variable manipulation. The typical design is a two-by-two design in which the independent variable, for which a main effect has been established, further called the basic effect, is crossed with a manipulation of the process. An ordinal interaction between the two manipulations in which the main effect is either (partially) suppressed or augmented is taken as evidence for the mediating role of the process in the basic effect.

However, an ordinal interaction does not invariably indicate moderation of the process. I distinguish three ways in which a researcher could mistake an interaction as evidence for a moderated process. The moderation manipulation may not (only) affect the target process, but (also) the independent variable itself. In that case the process underlying the basic effect is not suppressed but sabotaged from the start (‘the sabotage trap’). The moderation

manipulation may also influence the dependent variable directly. In that case the process underlying the basic effect is not suppressed but overruled at the end ('the sledgehammer trap'). The moderation manipulation may, finally, also initiate an alternative, artificial process. In that case the process underlying the basic effect is not suppressed but replaced by another process ('the introspection trap').

I will present a set of simple checks that researchers can implement to make sure that they exclusively affect the natural process. In addition to the actual dependent variable, the researcher needs (1) a measure *I* that reliably reacts to the independent variable but not to the hypothesized process. The moderation manipulation should not interact with the independent variable on this variable (upstream criterion). Sabotaged processes will not pass this criterion. The researcher also needs (2) a measure *P* that reacts to the process but is not inherently related to the actual dependent variable. The design is safe for the sledgehammer and the introspection trap if the independent and the moderation manipulation also interact on *P*, provided that the partial correlation between *P* and the dependent variable (controlling for the experimental manipulations) is zero (= downstream criterion).

To the extent that the additional measures are sensitive to other measurements, they should be measured in separate samples. To the extent that they are intrusive, they should be measured at the end of the procedure. The rationale is generalizable to the case (1) of individual differences as moderating factors, (2) of multiple steps in the causal chain, and sheds new light on the concept 'boundary condition'.

"Measuring Consumer Risk-Return Tradeoffs"

Daniel Goldstein, London Business School, UK

Consumer choice occurs over multiple products and services, each having multiple associated risks. The numerous outcomes and probabilities facing consumers may be unknown, or as we shall explore, be known but be too numerous and interdependent for the unaided mind to process. Product and service risks cause consumers anxiety as they worry about matters such as automotive breakdown, computer failure, drug toxicity, and fund underperformance. Marketing managers have similar worries from the sell side, along with additional concerns about predicting risk attitudes in order to design promotions, loyalty programs, and sales contests.

Despite the importance of risk to marketing, the measurement of risk preferences has lagged behind the swift progress made in the measurement of riskless, attribute-level preferences. Specifically, conjoint analysis has rocketed from its humble roots in mathematical psychology to become the marketing's chief methodological export. The lack of a risk measurement method in the marketer's toolbox might limit the impact that marketing research can have on insurance, financial services, and medicine, in which risk is an inextricable component. This paper presents a new market research technique for measuring consumer preferences over complex multiple-outcome risks.

How do people think about risk and return? Since the Enlightenment, theories of risk preference have been based on choices between simple gambles. In the last century, choices among gambles have been used to show violations of Utility Theory, and motivate subsequent alternatives, such as Subjective Expected Utility Theory, Rank Dependent Utility Theory, Cumulative Prospect Theory, Reference-Dependent Subjective Expected Utility Theory, among many others. In recent years, alternative models to the alternative models have been motivated by choices between gambles as well.

With the most notable exception being the estimation of consumer utility functions, why has consumer research had so little

to say on risk preference? One possibility might be that simple prospects, while analytically tractable, are not realistic descriptions of the risks consumers regularly face. First, real product and service risks have multiple outcomes, not just two: An investment can return any percentage of its principal, and an insurance policy can be worth any percentage of its cost. Second, unlike simple prospects, consumer choice often occurs over far more than two alternatives. A consumer shopping for funds with Fidelity has over 4,500 investment products from which to choose. Each fund has a continuous distribution of outcomes, and each can be combined with other funds to create more portfolios than could be enumerated in a lifetime. As Lopes (1987) puts it, simple prospects "occur most frequently in the context of formal gambling and psychology experiments." Measuring risk in the domain of multiple-alternative, multiple-outcome prospects seems warranted.

We focus on investing for retirement, one of the largest decisions many people ever make, and certainly one of the consequential consumer decisions for which researchers have been hearing the call. Most employees in the United States, upon starting a new job, are taken down the hall to the human resources department where they are shown a list of investment products, and asked to allocate 100 percentage points of their retirement contribution between them. Many employees spend less than an hour deciding how to allocate assets for retirement, which is surprisingly little time considering that as many as 90% or more will never change their initial choice and that the decision could impact their well-being for one third of their lives or more.

We present a new market research technique for studying preferences over multiple-outcome risks. We first describe the method, present its psychological and analytical motivations, and then report the results of empirical tests of its reliability and validity both within testing sessions and across the span of one year. Empirically, we use this method to estimate the coefficient of relative risk aversion and the loss aversion parameter for a sample of working adults who have been saving for retirement for 5 to 30 years. To foreshadow our results, the method passes tests of reliability and validation and captures individual differences based on age and income. It also identifies two sub-populations, one best fit by the classical economic theory of risk preference, and the other by a behavioral model incorporating loss aversion. We conclude by discussing how the new methodology can impact research on risk and consumer decision-making.

SYMPOSIUM SUMMARY

Experiential and Informational Perspectives of Consumer Preference Consistency

Leonard Lee, Columbia University, USA

Marco Bertini, London Business School, UK

SESSION OVERVIEW

The notion of preference consistency lies at the roots of understanding, predicting, and influencing consumer behavior. Most marketing activities such as market segmentation, new product development, marketing communications, and customer management are based on the premise that consumers behave in somewhat consistent patterns. A substantial body of research in preference construction (see Lichtenstein & Slovic 2006 for a recent collection of work in this literature) has established that consumers do not always have stable preferences; in contrast, their preferences can be susceptible to a host of context effects such as changes in the number (Iyengar & Lepper 2000) or composition (e.g. Huber, Payne, & Puto 1982, Simonson 1989) of the choices they have.

This session brings together a series of three papers that examine how thinking about one's consumption experiences and given product information in different ways can differentially affect the consistency and stability of one's preferences. Specifically, the degree of consistency in consumers' preferences can change as a result of how consumers think about their related retrospective consumption experiences, the given attribute information of the products to be consumed, and the associations between these products and consumers' self identities.

Using a series of four experiments in three distinct domains—food, social interaction, and music—Galak, Redden, and Kruger demonstrate that making more salient related (vs. unrelated) intervening experiences since the last consumption episode can reduce the degree of product satiation and enhance the consistency of preferences over time. Simply having a wide variety of experiences might not be enough for consumers to recover from satiation since consumers tend to experience “variety amnesia;” rather, for consumers to “restore” their preferences to the products they most preferred and to maintain consistent preferences over time, *thinking* about the variety of their past related experiences might be essential.

On the other hand, Lee, Bertini, and Ariely find that how consumers think about the given product information can also influence the consistency of their preferences. In particular, they examine how the availability of price information can impact consumers' preference consistency given the inherent imprecision of mapping between monetary assessments and predicted utility. The results of a series of five experiments converge toward the same conclusion: when consumers think about prices during their purchase decisions, their choices are less consistent and transitive. Interestingly, price conscious consumers who are chronically more adept at thinking about how prices can affect their utility are less susceptible to such a negative effect of price consideration on preference consistency.

Nonetheless, the consistency of consumers' preferences over time depends not only on how consumers think about given product attributes but also the relationships between these products and their self identities. Through a series of three studies, Amir and Mazar show that consumers' preferences for products or experiences that are closely associated to consumers' self identities, when these identities are formed (e.g. during adolescence) or significantly changed (e.g. due to a life changing event such as marriage), will remain relatively stable throughout consumers' lives. Such

preference consistency does not apply to products that are not associated with consumers' identities and does not depend solely on the consumers' age or the novelty of the products.

Overall, given the fundamental relevance of these papers' topics to consumers' every day lives, this special topic session should be of great interest not only to marketing researchers and psychologists, but also to anyone who is fascinated by the factors that determine how consistent our preferences are over time.

EXTENDED ABSTRACTS

“The Construction of Satiation: Recalling Related Intervening Experiences Accelerates Recovery from Satiation”

Jeff Galak, New York University, USA

Joseph Redden, University of Minnesota, USA

Justin Kruger, New York University, USA

Consumers typically enjoy something less as they have more of it. Although such satiation is often inevitable, it does not last forever. For example, listening to a song several times in a row will get tedious, but presumably will not affect one's enjoyment of that song a year from now. We explore this temporal aspect of satiation, and show how consumers can recover from satiation more quickly.

In a process termed “spontaneous recovery” (Thompson and Spencer 1966), people seem to recover from satiation and once again enjoy their favorites with the simple passage of time. Likewise, satiation also seems to dissipate as people have other intervening experiences. For example, people salivate less from a taste of lemon after 10 trials, but a novel taste can immediately restore their salivation (Epstein et al. 1993). It seems that either the passage of time or the presence of different experiences helps people recover from satiation. We focus on how satiation depends on the salience of intervening experiences from the past.

The recall of past consumption plays an important role in determining satiation. People eat less candy if the wrappers from each piece remain visible (Polivy et al. 1986), and consume less food when they more fully account for how much they have already had (Wansink 2004). Remembering past consumption episodes seems to increase satiation for an item. We ask the complementary question of whether focusing on past episodes that were different has the inverse effect of reducing satiation for a particular item.

It is unlikely that recalling all past experiences accelerates one's recovery from satiation. We examine the distinction between

the recall of related and unrelated experiences. Specifically, we predict that thoughts of unrelated experiences should have little impact on recovery. For example, thinking about music likely won't make one feel less satiated with respect to sushi, as music has little to do with food. In contrast, thinking about things related to sushi, such as other types of cuisines, should help the recovery process. More generally, thoughts of other experiences will accelerate recovery only when they fall within the same consumption context.

Finally, we distinguish between thinking about *any* episodes and thinking about *intervening* episodes. When consumers decide what to consume, thoughts of related experiences play a role in determining the amount of satiation felt. However, these thoughts can be of any experience that a consumer *has had* (intervening) or *may have* (future). We predict that that much like actual dishabituating experiences (Rolls, Rowe, and Rolls 1982), which necessarily occur since the last time a stimulus was consumed, only thoughts of intervening experiences will accelerate recovery. For example, when deciding what song to listen to, a consumer may think about songs he has recently heard or songs that he will potentially hear in the future. Thoughts of the former should decrease satiation, while thoughts of the latter should not. More formally, we predict that feelings of satiation should decrease when intervening experiences are made salient.

We find support for these predictions across four empirical studies. The first study finds that people had a greater preference for a flavor of jelly bean that they had satiated to when they were reminded of other jelly beans that they had also consumed. The second and third studies extend and replicate this effect in the domains of social interaction and music. When participants thought of "all the other music they listened to" or "all the other friends they hung out with" during the past two weeks, they wanted to hear their favorite (and presumably most satiated) song and hang out with their close friend more so than when no such thought generation task occurred. The third study also finds that this recovery from satiation appears only when listing friends they have spent time with in the past two weeks (i.e., it broke up the repetitive experience), and not for friends they expected to see in the upcoming two weeks. The fourth and final study rules out some alternative explanations in a controlled longitudinal study related to music consumption. Three weeks after being satiating to a preferred song, participants enjoyed that song again more when they thought of all the other musical artists they had heard in the intervening time, as compared to when they thought of other unrelated experiences. Importantly, this difference was only present for a satiated song, and not for another unsatiated song that they also preferred.

Many see satiation as an inevitable, but temporary, negative consequence of consumption. Although seeking out variety likely helps counter satiation, this research suggests that simply having variety is not enough. People seem to forget about this variety when they once again think about and focus on their favorite. Despite the fact that consumers work hard and pay a price to surround themselves with a great deal of variety, they seem to succumb to some sort of "variety amnesia" and forget the abundance that they live in. It seems that people construct and recover from satiation in the moment based on past episodes that easily come to mind. We find that the simple act of recalling related intervening experiences reduces satiation.

"Money Muddles Thinking: The Effects of Price Consideration on Preference Consistency"

Leonard Lee, Columbia Business School, USA

Marco Bertini, London Business School, UK

Dan Ariely, Duke University, USA

Price is an integral part of every buying decision. Consumers not only interpret prices as signals of product/service quality (Gerstner 1985) but can also be influenced by prices in their degree of involvement with the purchase process (Wathieu and Bertini, forthcoming) and their subsequent post-purchase consumption experience (Shiv, Carmon, and Ariely, 2005).

More fundamentally, in this work, we explore consumers' ability to use this important attribute—price—in their decision making. Specifically, we examine the effects of prices on the reliability and consistency of consumers' preferences, or consumers' capacity to consider prices and interpret them the same way every time they make a purchase decision. Prior research has consistently demonstrated the general dissociation between monetary assessment and predicted utility and the ill-defined hedonic representation of money in the minds of consumers (Amir, Ariely, and Carmon, forthcoming). Based on the inherently imprecise mappings between price evaluations and predicted utility, we hypothesize that price considerations can deteriorate the consistency of buying decisions.

To test this hypothesis, we investigated whether the availability of price information for a set of ten differentiated products (t-shirts) affects the consistency of sequential choices in pair-wise comparisons. As a measure for preference consistency, we computed the number of transitivity violations (i.e. for any a, b , and c , $a \geq b$, $b \geq c$, $c \geq a$, where \geq denotes relative preference) across experimental conditions (Kendall and Babington Smith 1940; Lee, Amir, and Ariely, forthcoming). Across five experiments, we consistently found that when consumers considered prices in their decision making, their preferences were more intransitive.

In *Experiment 1*, participants ($N=103$) were randomly assigned to one of two conditions: in the *price* condition, both the pictures and prices of the t-shirts were presented to participants, while in the *no-price* condition, only the pictures of the t-shirts were available. Consistent with our basic hypothesis, the results revealed that participants in the *price* condition made significantly more intransitivity errors than those in the *no-price* condition ($p=.01$).

This result was replicated in *Experiment 2* ($N=43$) in which we used a different preference elicitation method—a ten-point relative preference rating scale—instead of binary choice. Additionally, we modified the experimental procedure to test an alternative explanation: in *Experiment 1*, participants in the *no-price* condition were never given the t-shirts' prices; thus, differential learning across conditions could have contributed to the different degrees of

preference consistency. To test this account, in Experiment 2, we showed all participants (in *both* conditions) the prices of all ten t-shirts before the choice task. (We used this modified design in all subsequent experiments.) Similar to Experiment 1, participants in the *price* condition made significantly more intransitivity errors than those in the *no-price* condition ($p < .05$), demonstrating that the negative impact of price on preference consistency is the result of differential availability of price information *during* choice and does not depend on how preferences are elicited.

One alternative account of the above results is that participants in the *price* condition had “more” information than those in the *no-price* condition during choice, and the salience of this additional information could have made it more difficult for participants in the *price* condition to integrate different attributes in their decision making. We rule out this alternative account in *Experiment 3* ($N=174$) by demonstrating that it is the *type* of information, and not the availability of *more* information, that influences the stability of consumers’ preferences. Specifically, participants were randomly assigned to one of three experimental conditions: in the *price* condition, participants were asked to consider how much they thought each t-shirt would cost when making their choices, whereas in the *experience* condition, participants were asked to consider how it would feel to wear each t-shirt; in the *no-info* (*control*) condition, participants were simply asked to choose the t-shirt they preferred within each pair without any specific instructions to consider any particular decision factor. Thus, unlike the earlier experiments, the t-shirts’ prices were *never* displayed on the screen in all three conditions. The results revealed that participants in the *price* condition made significantly more transitivity errors than participants in both the *experience* condition ($p=.03$) and the *no-info* condition ($p=.03$), indicating that, rather than the mere availability of prices during choice, it is the active consideration of such prices that deteriorates preference consistency over time.

The results of Experiment 3 were conceptually replicated in *Experiment 4* ($N=194$) using a 2 (Price: present, absent) \times 2 (Quality Rating: present, absent) between-subjects design: participants were shown both the prices and quality ratings of the t-shirts, one of the two pieces of information, or neither during choice. A 2X2 ANOVA returned a main effect of price on preference consistency [$F(1, 190)=4.065, p=.045$]; however, neither the main effect of quality ratings [$F(1, 190)=.332, p=.57$] nor the interaction effect between price and quality ratings [$F(1, 190)=.773, p=.38$] was statistically significant, providing further evidence that the negative effect of price consideration on preference consistency cannot be adequately explained by an information complexity account.

Finally, in *Experiment 5* ($N=50$), we further tested our hypothesis by using an individual difference factor—price-consciousness (Lichtenstein, Ridgway, & Netemeyer 1993). We posit that price-conscious consumers chronically focused on paying low prices should find it easier to map between prices and predicted utility; thus, the availability of price information should be less likely to degrade their preference consistency, compared to consumers who are less price-conscious. Indeed, a 2 (price vs. no-price) \times 2 (price-consciousness: high, low) ANOVA revealed a significant main effect of price [$F(1, 46)=4.193, p=.046$], a significant main effect of price-consciousness [$F(1, 46)=7.271, p=.009$], and a significant interaction effect between both factors [$F(1, 46)=6.152, p=.017$] on preference consistency. Planned comparisons further revealed that whereas the availability of price information led to greater preference inconsistency among relatively non-price-conscious participants [$t(23)=2.532, p=.019$], it did not affect the preference consistency of price-conscious participants [$t(23)=.482, p=.63$].

“The Most Influential Age Hypothesis: Does the Self Cause Predictable Preferences?”

On Amir, University of California, San Diego, USA

Nina Mazar, University of Toronto, Canada

Preferences are formalized as the basis for behavior ranging from our everyday actions to the most significant choices in life. One of the traditional assumptions of many social sciences is that such dispositions are relatively stable throughout our lives. Life after all, demands some stability in our motivations to survive, procreate, and belong (Maslow 1943). The hallmark of this stability assumption has been the ability to predict or forecast behavior, which in turn enables the modeling of human behavior—a necessity in disciplines such as economics or public policy aiming at increasing social welfare. In this paper we attempt to shed light on the situations in which this crucial assumption is more likely to hold and its antecedents.

A growing body of research in psychology and decision making has accumulated evidence that preferences are often unstable and dependent on transient aspects of the situation. For example, preferences for risk and reward are reference dependent (Kahneman & Tversky 1979) and thus, depend on the framing of the situation (Epley et al. 2006; or McKenzie 2004; Ariely, Loewenstein, & Prelec 2003). Even preferences for high involvement decisions, such as how much to pay for real estate (Simonsohn & Loewenstein 2005) or which university to pick, may depend on recent, albeit less relevant experiences. Choosing whether to accept an offer for undergraduate studies, for example, may depend on the weather during the admissions visit (Simonsohn 2007). Moreover, even the valence of experiences may be shifted based on an initial less relevant anchor (Ariely, Loewenstein, & Prelec 2006). Termed “the Tom Sawyer Effect”, Ariely and colleagues (2006) show that people categorized the experience of listening to poetry as either enjoyable or aversive depending on whether they were asked to pay for this experience or offered to be paid for it. In sum, there are many examples for which people do not seem to have well-defined predictable preferences.

Yet, at the same time, there exists evidence that some preferences are predictable. Most notably, Holbrook and Schindler (1989) contrasted people’s age with their ratings of songs and find an inverted-U shape peaking at the early twenties (23.47 years old).

Their results suggest that “People seem to develop preferences for popular musical styles (typically those which prevail among their current circle of friends) during late adolescence or early adulthood, and these preferences over other styles of music tend to prevail for the rest of their lives.” The mixed evidence about the stability of preferences begets questioning what mechanism might lead to their development and what may be the resulting domains in which we might expect relatively stable preferences.

In this work we investigate one theory implying the development of such stable preferences: “The most influential age hypothesis”. Emerging from a vast stream of research in social and developmental psychology, this theory builds upon the idea that identity is a rather stable trait, which is formed during late adolescence (Baumeister 1998; Erikson 1968; Kroger 2000;). To the extent that some preferences are driven by one’s identity, the formation of one’s self may not only influence downstream attitudes (Lord, Ross, & Lepper, 1979; Visser & Krosnick, 1998) but also preferences. Based on this idea and Holbrook and Schindler’s (1989) findings about the influence of the early adulthood age on preferences for popular music, we suggest that similar to moral principles, social schemas, and languages, preferences for products or experiences that are closely associated to one’s identity, when it is formed or significantly changed, will remain relatively stable throughout our lives. We report three studies in support of our theory.

We begin by looking at movies and asking experts (Study 1) as well as lay people (Study 2) two simple questions: What are their favorite movies, and at what age did they see those movies? Our data does not support a recency effect story. In contrast, we find that both, experts as well as lay people have very strong preferences for movies they have seen as early adults. We show that our results cannot be explained by age of the participant, age of the movie, nor any other movie attribute. We therefore conjecture that products or experiences that are somehow linked to one’s identity-formation will be more likely to make a long lasting, predictable impression, and consequently lead to rather stable preferences. In our final study we explicitly compare the preferences for products related to one’s identity (e.g., movies) versus products not related to one’s identity (e.g., portable music players) to show that only preferences for the former, when linked to identity-changing events such as marriage or becoming a parent, leave a lasting impression.

SYMPOSIUM SUMMARY

Self-Expression and Brand Identity in Consumer Choice

Alexander Chernev, Northwestern University, USA

SESSION OVERVIEW

Building on the existing literature, this session contributes to a better understanding of the role of brands in consumer decision processes. Research papers presented investigate the impact of brands from multiple theoretical perspectives, offering a broader view of the role of brands in consumer choice. The findings of the individual papers are unified into a general framework which examines the role of brands as a means of self-expression.

Given the relevance of the proposed topic to central issues in consumer behavior, this symposium adds to the identity research and, in particular, the role of brands as a means of self-expression. Apart from providing theoretical insights into how brands influence choice, the proposed symposium contributes to the understanding of several context areas that are of great interest to ACR conference attendees, including attitudes, self-image, and conspicuous consumption. Specifically, the session addresses the following issues:

Research presented by Chernev and Gal explores the antecedents of the recent decline in the power of many brands. Building on the view of brands as a means of expressing one's identity, they argue that the decline in brand power could be attributed to the increase in alternative means of self-expression. They posit that the proliferation of brands, as well as other non-brand means of self-expression, has diminished the personal relevance of individual brands — a phenomenon referred to as “brand saturation”. They show that the self-expressive value of a given brand is subject to diminishing returns as the number of alternative means of self-expression increases.

Research by Berger and Ward examines the role of inconspicuous brand consumption in consumer choice. Conspicuous consumption suggests that branded products help explicitly display wealth and sophistication. In contrast, they argue that inconspicuous consumption, or using subtler signals unrecognizable to most consumers, can sometimes be more effective to insiders. Eight studies demonstrate that a) certain categories show an inverted U relationship between price and explicit branding; b) mass consumers prefer high-end products with explicit branding and misidentify those that use subtle brand signals; and c) insiders or experts prefer less explicit branding and can correctly identify subtle-signal products, which implies that subtle signals can sometimes provide more effective identity signals.

Finally, research by LeBoeuf and Simmons investigates the influence of branding on attitude functions. They show that branding predictably alters the degree to which products give rise to attitudes that serve self-expressive, as opposed to utilitarian, functions. Specifically, products that support utilitarian attitudes at the category level support less utilitarian, more symbolic attitudes at the brand level, whereas products that support symbolic attitudes at the category level support more utilitarian, less symbolic brand attitudes. They further demonstrate the implications of this finding for persuasion: Whereas utilitarian appeals are best for “utilitarian” products (and symbolic appeals are best for “symbolic” products) at the category level, this advantage does not arise at the brand level, in part because attitude functions change with branding.

The individual presentations were integrated by the discussion leader Rohit Deshpande into a more general framework, facilitating a broader understanding of the role of brands as a means of self-expression.

EXTENDED ABSTRACTS

“Brand Saturation in Consumer Choice”

Alexander Chernev, Northwestern University, USA

David Gal, Northwestern University, USA

There is a growing belief among many marketers that brands are losing their power and have “run out of juice.” Prior research has attributed the diminishing power of national brands to factors such as the increased degree of commoditization of the underlying products, the transparency of the product information available online, the proliferation of intelligent agents, and the deployment of new business models such as Priceline.com, which make brands invisible to consumers.

In this research, we advance a novel explanation for the recent decline in brand power. Building on the view of brands as a means of expressing one's identity, we argue that the role of brands as a means of self-expression is contingent on the availability of other means of self-expression. We posit that the proliferation of brands, as well as other means of self-identification, has diminished the personal relevance of individual brands — a phenomenon we refer to as “brand saturation.”

We propose that brand saturation can be caused by a variety of available means of self-expression, including other self-expressive brands in the same category and in unrelated product categories, and by non-brand means of self-expression. For example, we argue that the relevance of the Budweiser brand is a function not only of the strength of its intrinsic associations, but also the strength of other beer brands such as Miller and Coors. Furthermore, we argue that relevance of the Budweiser brand is affected by non-beer self-expressive brands such as Apple, Swatch, and Whole Foods, as well as by non-brand means of self-expression, including involvement in online communities such as MySpace.com, Facebook.com and LinkedIn.com. In this context, we posit that the self-expressive value of a given brand is subject to diminishing returns as the number of alternative means of self-expression increases.

We examine the impact of identity saturation on consumer brand preferences in a series of four experiments. The first study aims to demonstrate that merely asking consumers to identify their favorite brands weakens their brand preferences in unrelated product categories. Consistent with our theory, respondents who were asked to articulate their most preferred brands displayed greater indifference between the available brands in subsequent choices.

Building on the findings from this study, the second experiment documents that non-brand means of self-expression—such as identifying favorite books, movies, songs, sports teams, and hobbies—are likely to decrease perceived differentiation of the target brands. We show that the brand-saturation effect holds even in the presence of non-brand means of self-expression, such that respondents who were asked to articulate personally relevant items displayed weaker brand preferences in subsequent choices.

Experiment 3 documented identity-saturation effects naturally occurring in the context of brand choice. Thus, unlike the first two experiments in which identity saturation was achieved by explicitly asking respondents to state their preferences, in this experiment identity saturation was manipulated by having respondents merely make a choice in several product categories. This manipulation was based on the notion that choice itself can serve a

self-expressive function, such that making multiple selections in personally relevant categories is likely to lead to identity-saturation, which in turn will decrease consumer preferences for the subsequent brands.

Building on the first three studies, experiment 4 provides more direct evidence of the processes underlying the brand saturation effect, documenting the role of self-expression in brand saturation. In this experiment we manipulated individuals' need for self-expression by providing a feedback that was either consistent or inconsistent with their self-image, and examined its impact on subsequent brand preferences. The data lend further support to the notion that the strength of individuals' brand preferences is a function of their need for self-expression. In particular, we show that decreasing the need for self-expression (e.g., by validating individuals' unique identity) tends to weaken their brand preferences, whereas increasing their need for self-expression (e.g., by threatening their identity) has the opposite effect, strengthening their brand preferences. This experiment documented the impact of self-expression on the strength of individuals' brand preferences using three different measures: personal brand relevance, perceived brand similarity, and willingness to pay. The data show convergence across all three measures—a finding that enhances the validity of the observed effects.

From a theoretical standpoint, this research contributes to the literature of self-identity by furnishing evidence in support of the notion that individuals' need for self-expression is finite and that there are diminishing returns on increasing the variety of means of self-expression. We show that the need for self-expression is not domain-specific but rather occurs across categories and consumption occasions. In this context, we show that brands compete for a share of a consumer's identity, such that the self-expressive value of a given brand tends to decrease as the number of alternative means of self-expression (brand and non-brand) increases.

“The Subtle Signals of Inconspicuous Consumption”

Jonah Berger, University of Pennsylvania, USA

Morgan Ward, The University of Texas at Austin, USA

Branding varies across products. While some products use explicit branding (e.g., Armani Exchange emblazoned across a shirt front), others do not. The literature on conspicuous consumption suggests that price differences might drive signal explicitness. People often use products to communicate identity, and in particular to signal wealth and/or expertise to others. Consumers might want to broadcast their purchase of an expensive Lacoste polo shirt because it signals high status. They might be less interested in letting people know they purchased a generic polo shirt from Wal-Mart. Consequently, one might imagine that explicit branding might increase with price.

The data, however, display a distinctly different pattern. In Study 1, we randomly selected more than 120 pairs of sunglasses (both men's and women's) from major sunglass websites (e.g., Sunglass Hut). We then gave coders an image of each pair, and had them rate whether each pair explicitly identified the brand (i.e., the brand name or logo appeared) or not. In contrast to what would be predicted by conspicuous consumption, we found an inverted U relationship between price and brand identification. Regressing price and price squared on brand identification indicates that while brand identification increased with price, brand identification was negatively related to price squared. While only 21% of sunglasses under \$50 bore brand identifiers, 84% of sunglasses between \$100 and \$300 identified the brand. Brand identification decreased, however, among higher priced options. Only half the sunglasses over \$400 identified the brand. In Study 2, a category analysis of

handbags replicated these results. These findings provoke an interesting question. If consumers care about signaling status, why would they pay more for a product whose brand is harder to identify?

We argue that certain consumers may prefer high-end products with subtle signals because they ensure differentiation. Consider two populations: mass consumers (the general population) and insiders (those with special knowledge). If being seen as an insider carries value among the masses, then some mass consumers may attempt to “poach” or borrow insider symbols so other mass consumers will treat them like an insider. This will dilute the product's value as a marker of insider group identity, and insiders will diverge, developing new symbols to mark their group boundaries. Insiders may be able to maintain group identifiers, however, by adopting subtle signals that are only recognizable to other insiders. Because mass consumers want most others to regard them as insiders, they prefer explicit signals recognized by mass consumers. Consequently, insiders may migrate to subtle signals because they provide such differentiation.

Six additional studies support this perspective. Studies 3A-3C demonstrate that people typically misidentify products with subtle signals. Participants viewed different shirts, both low- and high-priced, which varied in their brand-signal strength from subtle (e.g., a small logo) to explicit (e.g., a large brand name). Results indicated that participants a) were more likely to misidentify the brand on shirts that used subtle brand signals; b) could not differentiate between generic and expensive shirts displaying subtle brand signals; and c) inferred no price difference between an expensive subtly marked and a generic, subtle-signal shirt. This shows that most people would misidentify someone who bought an expensive shirt with a subtle brand signal.

The data provided by Study 4 show, however, that insiders can identify products with subtler signals. For example, though members of the general college population could not differentiate between expensive and inexpensive handbags with subtle brand markings, members of a fashion school were able to identify such bags correctly.

Insider knowledge also moderated the inferences people made about others carrying subtly vs. explicitly branded bags, as well as the preferences of both groups. Study 5 showed that while members of the general population thought people with explicit bags knew more about fashion, insiders thought that people who carried more subtle (and actually, more expensive) bags, knew more. Further, Study 6 showed that given the choice between expensive bags at similar price points, members of the general population preferred explicitly branded bags while insiders preferred bags with subtler signals.

Overall, these studies indicate the utility of subtle signals. Though members of the general population prefer high-end products with explicit signals because they facilitate recognition by the general public, insiders prefer products with subtler signals that can be recognized only by their in-group of savvy insiders. Thus, while explicit signals facilitate broader recognition, subtle signals may be useful in maintaining group boundaries.

“Branding and Attitude Functions”

Robyn LeBoeuf, University of Florida, USA

Joseph Simmons, Yale University, USA

Attitudes serve different functions. Some serve a utilitarian function of maximizing rewards, whereas others serve a symbolic, value-expressive function. Prior research has shown that particular product categories are associated with particular attitude functions: Whereas some products (e.g., aspirin) typically support utilitarian

attitudes, others (e.g., flags) typically support symbolic attitudes. However, such research has focused almost exclusively on product categories, and has not considered how branding might alter associations between products and attitude functions.

We propose that branding alters these associations. First, although the associations between product categories and attitude functions are often clear, brands might be less directly associated with the category's attitude function. Spreading-activation models of knowledge suggest that knowledge is often represented hierarchically, with properties associated with the entire category being stored at the highest applicable level and not necessarily re-stored for each subsidiary instance (e.g., "can fly" would be stored with "bird," but not necessarily with each bird). Thus, the links between category-level functions and subsidiary brands may be indirect, with branded products being relatively weakly associated with the category's dominant function. Second, brands may often emphasize how they differ from the generic category: brands in utilitarian categories may build symbolic associations, and brands in symbolic categories may build utilitarian associations. Because of this, consumers may expect brands in utilitarian (symbolic) categories to be more symbolic (utilitarian) than the category itself.

Thus, we predict that products that give rise to utilitarian category-level attitudes will give rise to brand attitudes that are less purely utilitarian, but that products that give rise to symbolic category-level attitudes will give rise to brand attitudes that are less purely symbolic.

We further predict that branding will alter appeal persuasiveness. Typically, "function-matching" appeals are more effective than "mismatching" appeals: for utilitarian products, appeals emphasizing tangible benefits are superior, but for symbolic products, value-laden, symbolic appeals are superior. However, because attitude functions may differ for categories and brands, appeals that match a product's category-level function may not match the product's brand-level function as clearly. As a result, an appeal that is more persuasive at the category level (because of this function-matching advantage) may not be more persuasive at the brand level. For example, for a utilitarian product, a utilitarian appeal's advantage may be smaller at the brand level, precisely because brand attitudes for the product may be less strictly utilitarian.

We first examined whether branding alters attitude functions. In Study 1, participants evaluated the attitude functions they associated with an array of utilitarian (e.g., toothpaste) and symbolic (e.g., class rings) products. Half evaluated category-level products (e.g., vitamins) and half evaluated branded products (e.g., One-a-Day vitamins). As predicted, products that supported utilitarian category-level attitudes supported somewhat more symbolic attitudes when branded, but products that supported symbolic category-level attitudes supported less symbolic attitudes after branding.

Study 2 replicated this procedure, but participants in the branded condition evaluated hypothetical, unnamed brands. Even when the brands were unnamed, branding made attitudes towards utilitarian products more symbolic but attitudes towards symbolic products more utilitarian.

Study 3 examined the implications of this effect for persuasion. Participants considered appeals for paper towels and college t-shirts, which support utilitarian and symbolic (respectively) category-level attitudes. Participants were randomly assigned to a 2 (appeal level: brand, category) x 2 (appeal type: matching or mismatching the category-level attitude) design. For paper towels, the utilitarian (matching) appeal discussed cleaning, whereas the symbolic (mismatching) appeal discussed how paper towels, made of recycled paper, symbolize conservation. For t-shirts, the utilitar-

ian (mismatching) appeal emphasized a discount associated with wearing the shirts, whereas the symbolic (matching) appeal emphasized school spirit. As predicted, matching appeals reliably outperformed mismatching appeals when delivered for the category, but this advantage disappeared—and non-significantly reversed—when the same appeals were delivered for brands. Study 4 replicated these results, using different products, appeals, and brands.

In study 5, participants evaluated an advertisement for greeting cards. Between participants, we manipulated whether the ad was symbolic or utilitarian, and whether it was a category-level or brand-level appeal. We also measured the function served by each participant's attitude towards the category of greeting cards; this allowed us to define for each participant whether the assigned appeal was a "match." Indeed, for those with utilitarian (symbolic) attitudes, the utilitarian (symbolic) appeal had an advantage at the category level, but not at the brand level. Thus, the very same appeal's success depended upon whether it matched the individual's attitude function, thereby confirming attitude functions' role in these effects. Even with appeals held constant and "matches" defined idiosyncratically, matching appeals outperformed mismatching appeals for categories, but not for brands.

Finally, in study 6, participants evaluated actual magazine advertisements, rating them on either (a) how effective each advertisement seemed, (b) the degree to which each advertisement made symbolic and utilitarian claims, or (c) the degree to which each advertised product supported utilitarian or symbolic category-level attitudes. Advertisements for branded products were more favorably evaluated to the degree that the appeals were incongruent with the attitude function associated with the product category (i.e., mismatching appeals had an advantage). This finding converges with the more controlled experimental evidence provided by the other studies, showing that the main conclusions hold even with a much broader set of appeals. Strikingly, even with these "real" stimuli, there was no evidence that the category-function-matching advantage emerged for branded products.

These results give us insight into what brands communicate about products. Branding alters attitude functions, with predictable consequences for persuasion: "Function-matching" appeals that are superior at the category level lose their superior status at the brand level, in part because appeals that are incongruent with categories are more congruent with brands. This has potentially important managerial implications, especially because most advertisements are for brands (rather than categories). It seems that the mere fact that a product has been branded can strikingly alter not only how it is perceived, but also how attitudes towards it can best be changed.

SYMPOSIUM SUMMARY

Perspectives on Shopping Involvement

Kathleen O'Donnell, San Francisco State University, USA

SESSION OVERVIEW

With the exception of Bergadaa, Faure, and Perrien (1995), previous research has framed involvement within the context of the consumer's involvement with a particular product or product class (see for example Richins, Bloch and McQuarrie 1992). While the link between product involvement and purchase behavior is clear, we propose in this session to extend Bergadaa, Faure, and Perrien's work by bringing together three different, though interrelated, perspectives on consumer involvement with shopping in general. By focusing on involvement at this level, we hope to provide additional insights into consumers' shopping motivations that will impact retailers' sales promotion, advertising, and pricing strategies.

This session considers shopping involvement within the context of a new typology that addresses the inadequacy of the traditional distinction between situational and dispositional factors in motivation. In the new typology, involvement ranges from situational excitement, through enduring enthusiasm, to obsessive fixation and beyond.

In our first paper, Schindler updates his previous work on consumers' bargain hunting games (situational involvement), and concludes with recommendations for eliciting game play, as well as a tentative framework for how games may motivate consumers.

In our second paper, O'Donnell and Strelbel identify a segment of consumers—the sport shopper—whose shopping prowess goes beyond the situational context of bargain hunting games, and over time becomes an integral part of their self identities (enduring involvement). This research provides a profile of sport shoppers' unique motivations, attitudes and involvement with shopping.

Finally, Albanese, Jewell and Murtha describe a typology that distinguishes between four categories of shoppers who vary in their degrees of shopping involvement from situational to enduring to obsessive. Within the framework they provide, game players and sport shoppers would be categorized in the normal to neurotic ranges of shopping behaviors, while those exhibiting more extreme or abnormal shopping involvement would be found in the compulsive or psychotic ranges of behavior.

These papers bring together disparate lines of research to provide a richer and more comprehensive examination of shopping involvement and to extend our understanding of consumer motivation.

EXTENDED ABSTRACTS

“Games Bargain Hunters Play: An Update”

Robert Schindler, Rutgers University, USA

Considerable work on the marketplace effects of price promotions has shown that discounts and other forms of price deals have a marked ability to influence consumer choice (e.g., Blattberg and Neslin 1990; Pauwels, Hanssens, and Siddarth 2002). Past research has also suggested that “smart-shopper feelings” and other experiential variables play an important role in these effects (e.g., Schindler 1998; Chandon, Wansink, and Laurent 2000; Bardhi and Arnould 2005). To further explore how these experiential variables have a motivational impact, a sample of consumers who are highly involved in activities designed to obtain price discounts and a sample of consumers who enjoy shopping on the Internet were interviewed in depth. A total of 37 consumers were interviewed. The resulting

transcripts of over 38 hours of interviews were then analyzed by interpretive methods (e.g., Thompson, Locander, and Pollio 1989).

It was apparent that the concept of the game plays a key role in how deal-prone consumers experience their bargain-hunting activities, and that the games involved can be systematically described (as in Berne 1964). There appears to be at least two types of bargain-hunting games. The first is a solitary game, against an impersonal seller. The goal is to obtain a valued item at a price lower than what you would have otherwise paid. The second is a social game, played with or against other consumers. A common goal of this second type of game is to have your bargain-hunting successes recognized by other consumers. A consumer is likely to play a complex mixture of these two types of games.

A common game of the first type could be called, “Wait.” In this game, the consumer identifies a particular desired item, and then waits for its price to decrease substantially, hoping that this will occur before the item becomes unavailable. After describing successful play of this game concerning a pair of boots, one informant described the thrill of the experience: “I guess it's like bungee jumping ... scary but exhilarating.”

A common game of the second type could be called, “Guess What I Paid For This.” In this game, the consumer shows a second player (e.g., a friend or family member) a recent purchase and asks this second player to indicate what one would expect to pay for the item. Since responding with a low price disparages the quality of the purchase, most second players respond with a high price, to which the first player responds with delight. Play of this game can become quite involving since it invites the second player to play again later, with the tables turned.

Numerous other games were identified in these interviews. For example, in “Diamond in the Rough,” the player purchases an item that is discounted because of an apparent defect, and then attempts to show the defect to be inconsequential to the benefits provided by the item. In “Radar,” the player systematically scans for bargains by repeatedly carrying out a predetermined sequence of shopping activities, thus working to defeat retailers' efforts to make discount offers unpredictable. In “Tag Team,” the players clip coupons or finds discount ads for friends or relatives to use, thereby enjoying the bargain vicariously and avoiding the inconveniences of actually obtaining the items. In “Santa Claus,” the player purchases numerous items on deal for the purpose of giving them away, expecting to stimulate conversation about the source of this generosity.

The interviews provided some insight on how consumer game-playing behavior is elicited and maintained. At the current point in this research, it seems that there are at least three important aspects of everyday game elicitation:

1. *Actions with intrinsic appeal.* For many people, searching advertisements and/or stores for discounts are easy and pleasant activities.
2. *A goal that seems attainable.* The desired outcome of these price-search activities—to pay less for something for which you would have otherwise paid more—seems, for many people, to be easily within their reach.
3. *Clear feedback as to how well you do.* Because a retail price is so specific and objective, even a small gain or loss becomes not only readily apparent, but also publicly observable.

The descriptions of these shopping games also suggest a tentative framework of how games may act to so effectively motivate consumers. The motivational mechanisms include (1) the ability of game play to set the agenda for one's actions, (2) the ability of a game to recruit energy, both mental and physical, and (3) the ability of a game to affect one's evaluations, both by distracting attention and by bending perceptions.

“Sport Shoppers: An Important New Segment”

Kathleen O'Donnell, San Francisco State University, USA

Judi Strebel, San Francisco State University, USA

Marketers have long realized that the majority of retail shoppers are motivated by more than simply the acquisition of goods and services. In an effort to extend the previous research that has examined the dual role of economic and hedonic motives on retail shopping behaviors (Bellenger and Korgaonkar 1980, Westbrook and Black 1985, Schindler 1998, Arnold and Reynolds 2003, Bardhi and Arnold 2005, Guiry, Magi and Lutz 2006), this study explores a unique retail shopper whom we have christened the “sport shopper”. For this segment, shopping is similar to sports participation in that the shoppers compete for great deals, they train to improve their performance, they experience a “high” when they perform well, and they are able to recreate that feeling both by continuing to compete and by sharing the tales of their successes with others.

This exploratory research suggests that sport shoppers are unique from other shoppers in terms of the type and nature of the competitiveness they exhibit in the shopping arena, their desire to tell others about their shopping behaviors, and the trait-like nature of the positive affect they experience from self identifying as sport shoppers. Based on our interpretation of the cognitive responses provided by 94 students at a large western university, who were asked to share their thoughts and feelings about bargain shopping (Lincoln and Guba 1985), we find that sport shoppers take great pleasure and pride in their ability to uncover exceptional bargains by carefully combing the racks of department, specialty and discount stores. Unlike recreational shoppers, sport shoppers do not enjoy all shopping, just shopping for great deals. The thrill of victory they experience with each find reinforces their motivations to shop and to boast about the bargains they've uncovered. For them shopping is an arena in which they can compete, not against other shoppers per se, but against the retail system and their own past performance. Each shopping trip brings with it the opportunity to refine and improve their bargain shopping skills, thereby motivating them to continue participating in their “sport” (Ryckman and Hamel 1995).

In order to increase the likelihood of “winning”, sport shoppers develop a set of skills which includes the creation and maintenance of a vast body of knowledge about both the products (e.g. current fashion trends, brand popularity and pricing) and retail stores in the marketplace (e.g. assortment, quality and layout of each location), as well as “pre-game” strategies based on products of interest at the time, budget and time available for shopping.

Unlike their thrift-shopping counterparts, sport shoppers compete to find the best deals on new products in a wide array of retail environments including discount retail stores (e.g. T.J. Maxx, Nordstrom Rack and Marshalls), traditional department and specialty stores (e.g. Macy's, Nordstrom, Anthropologie), and online venues (e.g. eBay and Bluefly). While they may enjoy shopping in the occasional thrift or consignment store, new products are the gold standard for sport shoppers, as they allow for the most objective determination of the savings earned.

Unlike other bargain hunters, sport shoppers compete to save more, rather than to spend less. While no particular skill is neces-

sary to buy a \$20 pair of jeans at Target, the sport shopper prides herself on being able to find the coveted \$300 designer jeans for \$100. Though she's paying more for her jeans on a relative basis, her \$200 savings and the prestige of the premium label make her feel competent, talented and happy. Sport shoppers make a game out of shopping, perceiving the great deal as a victory over the system. They obtain greater pleasure from bragging about their bargain-hunting prowess than they would from letting others believe they paid full price for the item.

Sport shoppers are motivated to share the tales of their triumphs with others because doing so allows them to prolong or relive the positive affect they experienced at the time of the purchases, but it also earns them the additional positive feelings resulting from the admiration of the people they tell. Because they are motivated by the amount of money they save, sport shoppers tend to remember with exceptional vividness, the details of the various purchases they make.

Rather than experiencing smart shopper feelings only on those occasions when they feel responsible for getting a deal (Schindler 1998), the intensity, duration and frequency with which sport shoppers experience positive affect over their shopping “careers” creates an ongoing involvement with bargain shopping that becomes more trait-like over time. The ongoing nature of their involvement with sport shopping allows them to stay motivated and to continue identifying as sport shoppers, even when they have not gotten a great deal, or shopped lately. Unlike compulsive shoppers (O'Guinn and Faber 1992), they do not need to make a purchase on each outing, and they are able to rationalize an unsuccessful trip as either an information gathering opportunity or another form of savings.

Based on our preliminary research, we believe that this previously ignored shopper segment is unique, formidable and deeply committed to its sport, and as such it is important for both academicians and retailers to better understand the motivations and behaviors they exhibit. Using the insights gained thus far, the second phase of our research will include field observation, video ethnography and in-depth interviews, with the long-term goal of developing a sport shopper scale.

“A Typology of Four Qualitatively Different Patterns of Shopping Behavior”

Paul J. Albanese, Kent State University, USA

Robert Jewell, Kent State University, USA

Katie Murtha, Corbett Accel Healthcare Group, USA

What has been missing from the rich literature on compulsive buying is a theoretical framework that differentiates between qualitatively different patterns of shopping behavior. Without a substantive theoretical foundation it has been difficult to differentiate true compulsive buying from other problematical patterns of shopping behavior that appear similar from the descriptive or observable aspects of the buying behavior when considered in isolation. This article contributes a theoretical typology of four qualitatively different patterns of shopping behavior based on the Personality Continuum (Albanese 2002, 2006). The Personality Continuum is an integrative framework for the interdisciplinary study of consumer behavior (Albanese 2002, 2006). The Personality Continuum is divided into four qualitatively different levels of personality development that are hierarchically arranged in descending order from highest to lowest level: normal, neurotic, primitive, and psychotic (Albanese 2002). With respect to shopping behavior, the qualitatively different patterns based on the Personality Continuum are the normal consumer, neurotic shopper, compulsive buyer, and psychotic spender. Normal Consumers spend less than they earn, save for future purchases they cannot afford in the present, and

prudently plan consumption activities. Neurotic Shoppers spend an excessive amount of time shopping for just the right purchase, exhausting anyone who shops with them, often not buying anything, and when a purchase is made, it is sometimes returned. They typically spend money they have and do not seriously impair family and social relationships. Compulsive Buyers are driven to spend money they do not have on things they do not need in repetitive buying binges, and then hide their purchases away, often in the original packaging with the price tags left on. The shopping behavior impairs family, social and professional relationships, and results in serious financial problems. Psychotic Spenders engage in episodic spectacular spending sprees that result in serious financial and legal problems that severely impair family, social, and professional relationships, and sometimes result in hospitalization or incarceration.

The purpose of imposing the Personality Continuum onto compulsive shopping is to allow critical evaluation of shopping categories uncovered via the various existing compulsive buying scales. Without a theoretical framework as a foundation, there is no way to evaluate the output of the various scales in other than psychometric terms. The results are presented for five instruments designed to measure compulsive shopping behavior: 1. Compulsive Buying: Original Measurement Scale developed by Valence, d'Astous, and Fortier (1988) consists of thirteen items rated on a five-point Likert scale; 2. Clinical Screener for Compulsive Buying developed by Faber and O'Guinn (1992) consists of seven items rated on a five-point Likert scale; 3. Edwards (1992, 1993) Compulsive Buying Scale consists of 13 items rated on a five-point Likert scale; 4. Questionnaire about Buying Behavior developed by Lejoyeux and Ades (1994) consists of 19 dichotomous items; 5. The Yale-Brown Obsessive-Compulsive Scale—Shopping Version developed by Monahan, Black, and Gabel (1996) consists of ten items rated from 0 to 4. The five measurement instruments were administered to a convenience sample of 128 college students (68% female; 95% between the ages of 19-23) at a large Midwestern university using an online survey to explore to what extent the four qualitatively different patterns of shopping behavior would emerge in the two-stage cluster analysis. The results demonstrated that only the Questionnaire about Buying Behavior (Lejoyeux et al. 1994, 1996) yielded three different groups that represent the normal consumer (41 subjects or 33.6%), neurotic shopper (45 subjects or 36.9%), and compulsive buyer (36 subjects or 29.5%). No psychotic subjects completed the survey; therefore, we were unable to assess whether this instrument would capture the psychotic spenders. The four remaining instruments divided the subjects into two broad groups—non-compulsive and compulsive shoppers, respectively: Valence, d'Astous, and Fortier (1988) 50% and 50%; Faber and O'Guinn (1992) 44.9% and 55.1%; Edwards (1992, 1993) 30.2% and 69.8%; and Monahan, Black, and Gabel (1996) 58.7% and 41.3%.

The failure to differentiate between qualitatively different patterns of shopping behavior is problematical because the shopping behavior of neurotic shoppers and psychotic spenders are lumped together with true compulsive buyers. This makes understanding etiology and motivation for compulsive buying behavior difficult. While the prevalence of psychotic shoppers may be relatively small quantitatively, it is important to understand this level of personality development to delimit the lower boundary of true compulsive buying behavior. The challenge now is the refinement of the measurement of the four qualitatively different patterns of shopping behavior by combining items from the existing instruments, modifying existing items, and adding new items to reflect the full typology of shopping behavior.

SYMPOSIUM SUMMARY

To Deal or Not to Deal: Exploring the Boundaries of Dynamic Inconsistency

Xianchi Dai, University of Chicago, USA, and INSEAD, France

SESSION OVERVIEW

One of the most robust findings over decades of research in intertemporal choice is that people are dynamically inconsistent; they are more patient for future trade-offs than for near trade-offs (e.g. Ainslie 1975; Strotz 1955; Thaler 1981). Previous research has provided different theoretical explanations (e.g., Hoch and Loewenstein 1991; Liberman, Trope and Stephen 2007; Loewenstein 1996; Zauberman and Lynch 2005), examined its boundary conditions, e.g., in the domain of consumer behavior (e.g., Malkoc and Zauberman 2006; Malkoc, Zauberman and Ulu 2005; Soman 1998) and investigated consumers' coping strategies (e.g., Ariely and Wertenbroch 2002; Wertenbroch 1998).

Despite the extensive research done in this field over the years, this session demonstrates that it remains a fertile area for continued research. The session presents three papers, each focusing on different aspects of the dynamic inconsistency problem. In particular, they demonstrate that (1) dynamic inconsistency might not be as serious a problem as previous research has suggested. It might be even reversed when consumers are moving from distant to near choices. (2) Sophisticated consumers are willing to adopt commitment strategy even with the prospect of real financial losses, which is proved to be very effective in solving dynamic inconsistency problem. (3) Concern for dynamic inconsistency might lead consumers to be overly prudent, which systematically drives consumer preferences and decisions.

Dai and Fishbach demonstrate in four studies that the actual movement towards the options can increase consumers' patience, which is contrary to the prediction based on models of dynamic consistency. They show this pattern of results in hypothetical as well as real waiting and monetary consequences, with cash and consumer products. They also show that this is because consumers infer from their wait experience that they value the category more, which in turn leads to greater preference for larger later reward.

Giné, Karlan & Zinman examine consumers' precommitment strategy in a field experiment in a Philippine bank. Substantial proportion of smokers sign up to a savings account (CARES) designed to help them quit smoking. They deposit money into the account and agree to let the bank forfeit their entire balance to charity if they fail a urine test six months later. Compared with those in the control condition, those who signed up to the CARES program were about 30% more likely to pass the test. The result suggests that sophisticated consumers are willing to pay premium for such commitment products, and that these commitment products are effective in helping achieve self control.

In the third paper, Kivetz and Keinan argue that consumers often suffer from a reverse form of dynamic inconsistency problem, namely excessive farsightedness ("hyperopia") and future-biased preferences. It shows that consumers (a) require special entitlement justifications to indulge (e.g., through hard work or perceived excellence); (b) perceive themselves as suffering from insufficient indulgence, and consequently, correct this imbalance in their lives by pre-committing to future hedonic experiences; and (c) regret (in the long-run) their supposedly farsighted acts of choosing virtue over vice.

Overall, the three papers were chosen for this session because (1) they center on the same dynamic inconsistency problem, and

examine new boundary conditions, which greatly enrich our understanding of intertemporal choice and self control. (2) In terms of methodology, the session represents both behavioral and economic approaches. Different approaches complement each other and can potentially inspire new insights for future research. Together, the three papers form a cohesive set of explorations into some fundamental issues of intertemporal choice.

EXTENDED ABSTRACTS

"History Matters: When Waiting Increases Patience in Intertemporal Choice"

Xianchi Dai, University of Chicago, USA, and INSEAD, France
Ayelet Fishbach, University of Chicago, USA

An underlying assumption in the literature of intertemporal choice is that people are better able to commit to larger-later reward over a smaller-sooner reward a long time in advance compared with a short time in advance (Ainslie and Haslam 1992; Frederick, Loewenstein, and O'Donoghue 2002). It follows that people become more impatient as they get closer to making a self-control choice between a smaller-sooner reward and a larger-later reward. For example, research on the common difference effect (Frederick et al. 2002) attests that a person prefers a smaller-sooner reward (e.g., one apple today over two apples tomorrow) when the options are presented in the near future, but prefers the large-later reward when the options are presented in the distant future (e.g., two apples in 101 days over one apple in 100 days). However, whereas previous research compared distant and near futures, it is less clear how the actual movement from distant to near choices influences preference. For example, would waiting for 100 days before making a choice make one more or less likely to prefer two apples tomorrow over one apple today?

We predict that the wait experience as a person moves closer to making a choice increases patience such that people are more likely to choose the larger-later reward than before, or compared with people who face a near future choice. We propose that this happens because people learn about their preference by observing their own behavior and the wait experience signals to a person that the category of items (e.g., apple) is desirable. This heightened value inferred from wait further leads to increase in preference for larger-later reward (per magnitude effect, Frederick et al. 2002).

We tested this proposition in four studies. The first three studies compared intertemporal choice in 1) near future condition (e.g., a small reward today vs. a large reward in 20 days) 2) distant future condition (e.g., a small reward in 30 days vs. a large reward in 50 days), and 3) near future + wait condition (e.g., the above near future choice + the person has waited 30 days before making the choice). Study 1 examined the effect of waiting use monetary reward. We found that in the wait condition, the choice share of the large-later options was higher than in the distant future condition, which was higher than the near future condition. Study 2 replicated the same effect with products (MP3 player). Furthermore, it also showed that this increased patience is associated with increase in liking for MP3 player in the wait condition than in the other two conditions. The same finding was demonstrated in study 3 with real waiting experience and real monetary reward (\$50 vs. \$55 lottery):

the choice share of the large-later option was the highest in the wait condition, then the distant future condition, and lowest in the near future condition. We further found that increased patience in the wait conditions was associated with an increase in the perceived importance of money.

In the final study, we tested whether perceived wait, similar to actual wait, increases patience. In addition, this study examined whether wait experience signals that the product is valuable (value inference), rather than that wait is less costly to the individual (cost inference). We manipulated waiting by asking half of the participants their waiting experience since the last time they had Godiva chocolate (for the other half we didn't ask this question, which served as control group). Similar to study 1-3, we found that for choice between smaller sooner reward (i.e., 12 pieces of Godiva chocolate in 6 days) and larger later reward (16 pieces of Godiva chocolate in 48 days), salience of wait increased patience and thus preference for the larger-later option. Whereas for choices between getting the same reward for free later (e.g., 16 pieces of Godiva chocolate in 48 days) or sooner (paying \$3 premium to get the same option in 6 days), wait increased preference for expediting, which suggests a decreased patience. This later result is noteworthy because value inference would predict preference for expediting (due to increased value) whereas cost inference would predict preference for postpone (due to lower cost estimation of waiting). These results suggest further that consumers infer from wait that they value a category more, rather than that they are the type who can wait (or that waiting is not that painful).

“Put Your Money Where Your Butt is: A Commitment Savings Account for Smoking Cessation”

Xavier Gine, The World Bank, USA

Dean Karlan, Yale University, USA

Jonathan Zinman, Innovation for Poverty Action and Sticck.com, USA

The use of cash incentives, generally referred to as conditional cash transfer programs, to alter behavior in health and anti-poverty programs is becoming more common, as evidenced by the spread of PROGRESA-type anti-poverty campaigns. One less-utilized method for applying cash incentives to behavior modification is the commitment contract. A commitment contract is essentially a contract on one's own behavior, made with one's own money—if a behavior benchmark is met, the individual gets his money back; if it is not met, the individual forfeits his money.

Green Bank of Caraga in the Philippines, together with Innovations for Poverty Action and the World Bank, recently tested a commitment contract to help Filipino smokers quit. Under the contract, participants deposited money into a bank savings account and agreed to forfeit their balance if six months later they failed a urine test to detect nicotine (failure to take the test was equated with failure to quit). Bank marketers offered the product by approaching smokers in public places. The marketers administered a short survey, provided a standard pamphlet with information on smoking's harmful effects and how to quit, and then made one of three randomly assigned offers: 1) the commitment contract; 2) aversive “cues”: graphic, pocket-sized pictures of the negative health effects of smoking modeled on Canada's cigarette packaging mandate; 3) nothing.

Six months after marketing the bank team returned and administered urine tests to participants from all three groups. Subjects offered the commitment contract, regardless of whether they accepted or not, were 3.1 percentage points more likely to pass the test than the control group (a 38.8 percent increase). Those offered the contract who had previously reported a desire to quit smoking at

some point in their lives were 4.3 percentage points more likely to pass. The impact was even more substantial among those who signed a commitment contract. Signers overall were 29 percentage points more likely to pass the test than the control group; signers who'd stated their intention to quit at some point were 33 percentage points more likely to pass. Acceptance rates for the contract were almost double the acceptance rates reported from previous randomized controlled trials for smoking cessation aids such as the nicotine patch or gum. Success rates of those who accepted the commitment contract in this study were double reported rates of success achieved with the help of the patch or gum. (The impact of the cards was about the same as the reported impact of patches or gums.)

This product is motivated specifically from models of time inconsistency. Clearly someone with no inconsistency, no “dual-self” model of behavior, would opt in to such a contract. Hence, the mere preference for the contract is itself evidence supporting such models, and the success of the contract in changing behavior further reinforces the theoretical motivation behind the contracts.

The study also found that acceptance of the commitment contract was heavily dependent on the ease with which participants could make subsequent deposits. Some participants offered contracts were also offered a deposit collection service by the bank; all others would have been required to go to a bank branch to make deposits. Uptake of the contract without deposit collection was so low that the offer was dropped, and everyone subsequently offered the contract was also offered deposit collection. Success in quitting, unsurprisingly, was also strongly correlated with the number of deposits made.

There is still much to learn. Would a commitment contract that offers a better return be more popular, and possibly more effective, than the one designed for this study? Do those who quit using a commitment contract take up smoking again after the contract ends? Did the bank staff who came to collect weekly deposits provide a de facto reminder that was a major element in quitting success? Despite these outstanding questions, the results suggest that non-profits and policy-makers should experiment with commitment contracts in addition to conditional cash transfers in their health and anti-poverty programs.

“Hyperopia: A Theory of Reverse Self Control”

Ran Kivetz, Columbia University, USA

Anat Keinan, Harvard University, USA

Our religions, mythologies, and fables admonish us to overcome temptation, exercise self-discipline, and heed the future (see Adam and Eve, Odysseus, and the Ant and the Grasshopper). Social scientists, too, offer helpful strategies for increasing willpower and avoiding indulgence (e.g., Ainslie 1975; Trope and Fishbach 2000). The seemingly universal espousal of prudence and farsightedness as noble goals is reflected in the voluminous literature in the social sciences on self-control. This body of research is premised on the notion that people are short-sighted (myopic) and easily tempted by hedonic “sins,” such as overbuying (oniomania), splurging on tasty but unhealthy food, and indulging in luxuries (e.g., Prelec & Herrnstein 1992; Thaler 1980).

The current paper advances an alternative approach. Specifically, the universality of myopia is challenged and it is proposed that people often suffer from a reverse self-control problem, namely excessive farsightedness (“hyperopia”) and over-control. Such hyperopia leads people to deprive themselves of indulgence and instead overly focus on acting responsibly, delaying gratification, and doing “the right thing.” The present research examines the processes underlying hyperopia (e.g., guilt, justification), the way

people cope with hyperopia (e.g., by pre-committing to indulgence), and the consequences of over-control (e.g., long-term regret).

The paper begins by reviewing and integrating the empirical evidence regarding the antecedents and consequences of hyperopia, including the findings that people (a) require special entitlement justifications to indulge, relying on such justification cues as hard work or perceived excellence (Kivetz and Simonson 2002a; Kivetz and Zheng 2006); (b) perceive themselves as suffering from insufficient indulgence, and consequently, correct this imbalance in their lives by pre-committing to future hedonic experiences (Kivetz and Simonson, 2002b); and (c) regret (in the long-run) their supposedly farsighted acts of choosing virtue over vice (Kivetz and Keinan 2006; Keinan and Kivetz 2008).

The paper also reports new direct evidence for hyperopia and supports the notion that hyperopia involves time-inconsistency and preference reversals due to variations in the intensity of guilt. Specifically, a series of studies demonstrates that people select pleasurable consumption and vices when the consequences of their decisions are psychologically distal (e.g., temporally delayed, hypothetical, improbable, abstract, or self-irrelevant) but reverse their decision when the consequences are psychologically proximal (e.g., temporally imminent, real, vivid, or self-relevant). Such reversals are more pronounced among people with a chronic tendency to experience guilt. Finally, the presented paper attempts to generalize the self-control construct by reconciling myopia and hyperopia using a distinction between self-control lapses and self-control dilemmas.

SYMPOSIUM SUMMARY

Attentional and Inferential Effects of Point-of-Purchase Marketing

Ana Valenzuela, Baruch College, USA
Pierre Chandon, INSEAD, France

SESSION OVERVIEW

Recent trends in marketing have demonstrated an increased focus on in-store marketing with the hope that it will generate incremental sales at the point of purchase. Despite the importance of this topic, there are still two important unresolved issues: 1) does P-O-P marketing actually work? and, if yes, 2) how exactly does it work?

Although we know that end-of-aisle displays have large effects on consumers, the evidence about the effects of less conspicuous P-O-P activities changes that keep total category shelf space constant is less conclusive. For example, while industry reports claim that the number and position of shelf facings matters, Drèze, Hoch, and Purk (1994, p. 324) concluded that “the benefits from additional facings are non-existent” and that shelf position only has a limited influence on sales. There is also no consensus on what is the best location on a shelf, with prior findings supporting an extreme position advantage (Nisbett and Wilson 1977) or a middle position advantage (Christensen 1995; Shaw 2000). Even if P-O-P marketing works, we don’t know how large its effects are compared to the well-known memory-based effects created by advertising and branding.

P-O-P marketing can influence consumers through an attentional and an inferential route. First, P-O-P marketing ensures that the brand is noticed, a necessary condition for purchase. Even then, it is important to determine how much of a brand’s salience is due to bottom-up perceptual features (e.g., packaging color, number and position of shelf facings) and how much is due to top-down memory-based effects (e.g., consumer search goals, past brand usage). Second, the position of a brand on the shelf could affect the inferences consumers make about the product itself. This would be likely if, for example, consumers believe that retailers position brands on the shelf according to general, meaningful criteria but it could also occur outside consumers’ awareness.

Despite the importance of understanding in-store marketing effectiveness and the growing theoretical interest about position effects in consumer psychology (e.g., studies showing the association between vertical position and concepts such as power and God), relatively little research work examines the effect of in-store product position and marketing support on an option’s visual search, consideration and choice. The three papers in this special session are a step forward in the empirical investigation of how in-store marketing affects visual attention and inferences about products. All the three papers are interdisciplinary in the sense that the underlying theoretical questions involve both the economic and psychological aspects of consumer decision making, combine experimental interventions and verbal reports with state-of-the-art eye-tracking data and statistical models, and examine a variety of behaviors (attention, visual search, consideration, choice, and inferences about brand attributes) for existing and fictitious brands.

In the first paper, Chandon, Hutchinson and Bradlow examine the effects of important in-store factors (the number and position of shelf facings) and out-of-store factors (past brand usage, the regular and actual price of the brand, its market share, and the shopping goal of the consumer), on attention, recall of attention, consideration, and choice. They find strong effects of the number and position of facings on attention but that not all attention improvements lead to

choice. They also find that recall of attention is not a good proxy for visual attention.

In the second paper, van der Lans, Pieters and Wedel go deeper into measuring the bottom-up and top-down components of brand salience. Drawing on a framework of competitive salience and a model of the visual search process, they estimate the effects of perceptual features (color, luminance, edges) and how these are influenced by consumers’ search goals using eye-movement data. They identify two key sources of brand salience: *i*) the bottom-up component is influenced by in-store activity and package design; *ii*) the top-down component is influenced by out-of-store marketing activities such as advertising.

In the third paper, Valenzuela and Raghuram propose that, people hold underlying schemas associated with the position in which options are presented that lead to inferences about the desirability of the options and formation of preferences. They find that consumers believe (inaccurately, as we show) that retailers place brands in decreasing order of price from top to bottom rows and from right to left rows, thus, showing preference for options holding center positions in both orientations as they represent a balanced price/quality tradeoff. Preferences for the middle product are moderated by shopping goals, especially for the vertical orientation, and can be temporarily attenuated through priming, but are robust in the longer term.

Xavier Drèze, the author of the seminal and award-winning paper on the effects of P-O-P marketing, and an authority on retailing, led the discussion.

EXTENDED ABSTRACTS

“Does In-Store Marketing Work? Effects of the Number and Position of Shelf Facings on Attention, Consideration, and Choice at the Point of Purchase”

Pierre Chandon, INSEAD, France

Wesley Hutchinson, University of Pennsylvania, USA

Eric Bradlow, University of Pennsylvania, USA

Marketers are diverting a growing proportion of their promotional budgets from traditional out-of-store media advertising to in-store marketing and retailers are responding by adopting increasingly sophisticated shelf layout and management tools. We already have strong evidence that end-of-aisle displays and large increases in shelf space have strong effects on brand sales (Bemmar and Mouchoux 1991; Curhan 1974; Inman, McAlister, and Hoyer 1990; Wilkinson, Mason, and Paksoy 1982; Woodside and Waddle 1975). The evidence about the effects of less conspicuous in-store marketing changes that keep total category shelf space constant is less conclusive. While industry reports claim that the number and position of shelf facings matters, Drèze, Hoch, and Purk (1994, p. 324) concluded that “the benefits from additional facings are non-existent” and that shelf position only has a limited influence on sales. A related stream of research has shown that the position of a brand in a vertical or horizontal retail display influences price and quality expectations and hence brand choice (Christenfeld 1995; Valenzuela and Raghuram 2008). However, these results have only been demonstrated for non-familiar brands or for choices among identical options. More importantly, prior research has not exam-

ined the effects of in-store marketing on visual attention and brand consideration and has not compared its effects with those of out-of-store factors such as past brand usage, shopping goals, or the market share and price of the brand.

The objective of this research was to examine the interplay between in-store and out-of-store factors on consumer attention, consideration, and choice among brands displayed on supermarket shelves. Drawing on research on shelf management effects and on eye movements in scene perception, we developed a framework of the effects of important in-store factors—the number and position of shelf facings—and out-of-store factors—past brand usage, the regular and actual price of the brand, its market share, and the shopping goal of the consumer—on attention and purchase-related behaviors. We tested the predictions derived from this framework in an eye-tracking experiment in which we manipulated or measured all these factors for established as well as for new brands of two categories. The experimental design was a between-subjects fractional design with two within-subject replications (soap bars and pain reliever tablets). We manipulated the number of a facings of each brand (4, 8, or 12), its vertical position (first, second, third, or bottom shelf), its horizontal position (far left, center left, center right, or far right of shelf), and its shelf price (regular vs. discounted). The participants were 348 adult shoppers recruited in shopping centers. They were either asked say which of the 16 brands of soap or of pain relievers they would buy (choice goal condition) or which brands they would consider buying (consideration goal condition). We tracked the movement of their eyes while they were making these decisions and measured their recall of attention and brands past usage.

We find that in-store attention is limited. One quarter of the 16 brands were never looked at and another quarter was only fixated once. Recall of visual attention was a poor indicator of actual attention, as participants forgot 58% of the brands that they had fixated at least once. Only one quarter of the brands was included in the consideration set. We also found that eye fixations increased consideration and choice for the two new brands inserted in the shelf layout. Because participants had never seen these brands before the study, this analysis showed that in-store eye fixations can cause consideration and choice, and are not just driven by memory-based out-of-store factors.

Regression analyses showed that both in store and out-of-store factors influence attention, consideration, and choice, although in-store factors primarily influence attention whereas out-of-store factors primarily influence consideration and choice. Specifically, we found that the number of facings had a strong but marginally diminishing impact on attention, that it had a positive and linear effect on purchase decisions, and that the influence on choice was particularly strong for regular users, for low market-share brands, and for consumers with a choice rather than with a consideration goal. We also found: a) that placing the brand near the center of a shelf (vs. on its extreme ends) and on the top shelves (vs. the bottom shelves) improved attention and purchase decisions, b) that being on the left or right-hand side of the shelf made no difference, and c) that a being on the middle shelves (vs. the top or bottom shelves) helped attention but neither consideration nor choice.

These findings provide insights into four of the five issues identified as important areas for future eye-tracking research in Wedel and Pieters's (2008) review: 1) studying the interplay between bottom-up salience and top-down informativeness in guiding attention, 2) examining eye movements to other marketing stimuli besides print ads, 3) testing different attention metrics, and 4) investigating the relationship between attention and downstream marketing effects such as purchases. Finally, these findings have methodological implications. Specifically, our findings that not all

attention improvements lead to choice and that recall is not a good proxy for visual attention, underscore the importance of combining eye-tracking and purchase decision data to obtain a full picture of the effects of in-store and out-of-store marketing at the point of purchase.

“Competitive Brand Salience”

Ralf van der Lans, Erasmus University, The Netherlands

Rik Pieters, Tilburg University, The Netherlands

Michel Wedel, University of Maryland, USA

Competitive clutter at the point-of-purchase is intense due to SKU proliferation, brand extensions, me-too products, private labels and copycats. As a consequence, searching brands on supermarket shelves is a daily challenge for consumers. Clutter causes consumers to accidentally pick-up the wrong brands or not to find their favorite brand at all. Therefore, manufacturers and retailers try to make the SKUs of their brands visually salient among competitors through improved package design and advertising. They seek an optimal level of differentiation of their brands and SKUs by balancing the visual salience of each SKU relative to competitors with a unique identity of the entire line of SKUs, at the same time needing to obey established codes about the visual appearance of the category. To support this management task, the visual salience of SKUs and brands needs to be assessed but how to accomplish this is far from obvious: there is no academic literature addressing this problem, but related literatures exist on variety perceptions of assortments and on the overlap within product portfolios.

We intend to fill this gap and afford a detailed analysis of visual competition between brands based on the few seconds that consumers search for them on the shelf. Using eye-movement data collected in a brand search experiment, we develop a model that allows us to assess competitive salience, establish its effects on search performance, and show improvement through marketing.

We assess brand salience using a model of eye-movement recordings, collected during a brand search experiment. During a computer-mediated brand search task for laundry detergents eye-movements were collected for a random sample of 109 regular consumers in the Netherlands (47 males and 62 females between 16 and 55 years of age). Participants were individually seated behind 21-inch LCD computer screens (1,024 x 1,280) on which a shelf with six brands of laundry detergent was shown, four brands with three SKUs each and two brands with two SKUs each (16 SKUs in total). Multiple replications (facings) of SKUs were present to mimic regular shelves at the point-of-purchase. Participants were randomly assigned to one of five conditions of a one-factorial between-subjects design, in which they searched for one out of five different brands. In all cases, the search goal was directed at a specific SKU of a brand (the “tablet” SKU). The sixth brand is the market leader and serves as a baseline. Placement of the brands in the display was rotated across conditions and consumers to eliminate possible location effects, with the same number of facings in all conditions. Participants had a maximum of 10 seconds to find the target brand, and indicated having found the target brand by touching it on the touch-sensitive LCD screen, after which the brand search task ended. Eye-movements, and latency and accuracy of search were recorded.

We propose a conceptual framework of competitive salience and a model of the visual search process, which enable diagnostic analysis of current levels of visual differentiation of brands and SKUs at the point-of-purchase. We develop a brand search model that (a) includes the effects of image features, (b) includes the effects of systematic search strategies on eye-movements, (c) assumes two unobserved states reflecting the localization of brands, respectively their identification through re-fixations. We separate

top-down from bottom-up salience through a combination of experimental design and model formulation. We integrate the effects on search accuracy and latency in the model. Together, this makes it possible to comprehensively assess competitive salience and its effects on search performance.

We thus estimate brands' salience at the point-of-purchase, based on perceptual features (color, luminance, edges) and how these are influenced by consumers' search goals from the eye-movement data. We show that the salience of brands has a pervasive effect on search performance. We identify two key sources of brand salience. The bottom-up component is influenced by in-store activity and package design. The top-down component is influenced by out-of-store marketing activities such as advertising.

Our study reveals that about one-third of salience on the shelf is due to out-of-store and two-thirds due to in-store marketing. This underlines that the integration of advertising with packaging strategies should be a key concern. The relatively small top-down influences on salience that we found for some brands in our study may well be attributable to a lack of integration of packaging and advertising strategies for some brands. Although salience of brands has a pervasive effect on search performance, it appears that consumers use only one or two basic features at the same time when trying to find a brand rapidly and accurately. This has important implications for package design and for advertising that has the purpose to increase brand salience on the shelf. Such advertising would need to establish strong associations in memory with a limited number of unique features.

“Center Of Orientation: Effect of Vertical and Horizontal Shelf Space Product Position”

Ana Valenzuela, Baruch College, USA

Priya Raghubir, University of California, Berkeley, USA

Does placing a product in a central, peripheral, or extreme-end position, or a top or bottom position systematically affect consumers' attitudes toward the brand? Surprisingly, this issue has received scant attention from consumer psychologists despite the importance of shelf placement in consumers' brand choice decisions, a manufacturer's distribution decisions, and a retailer's shelf space pricing decisions. Prior research on product placement showed that the spatial positioning of products affects consumers' inferences about prices (e.g., Inman, McAlister and Hoyer 1990), their allocation of attention across brands (e.g., Chandon, Hutchinson, Bradlow and Young 2007), the number and type of product choice comparisons (e.g., Breugelmans, Campo, and Gijbrecchts 2007), the level of exposure and physical interaction with a good (e.g., Folwell and Moberg 1993), as well as brand sales (e.g., Desmet and Renaudin 1998).

This paper investigates whether, how, and when consumers extract meaning from the position of products in both horizontal and vertical shelf space arrays, and how these inferences translate into their preferences. We test three basic hypotheses: consumers believe products are placed in decreasing order of price from top to bottom rows (H1: verticality) and from right to left rows (H2: horizontality), leading to preferences for center positions in both orientations as they represent a balanced price/quality tradeoff (H3: centrality). Study 1 finds evidence that consumers have shared shelf layout schemas regarding retail practice for verticality and centrality, but not for horizontality: premium brand are on top rows, cheaper brands are on the bottom rows, promoted brands are on the extremes and popular brands occupy central positions. Study 2 shows that verticality and horizontality beliefs do not universally reflect retailers' pricing practice. Study 3 shows that these schemas affect product inferences: consumers infer that products placed on the top (and on the right) have higher prices and higher quality than

those placed on the bottom (or on the left). Accordingly, they prefer positions in the center of both orientations as these represent price-quality compromises.

The next two studies examine moderating conditions for the use of vertical and horizontal shelf space schemas. They test the schema interference hypothesis, which argues that the use of these schemas will be attenuated when accessible information interferes with the schema that is held (H4). They also test the schema diagnosticity hypothesis, which argues that spatial position is used as a function of its informativeness (H5). Each of these hypotheses is examined for both the vertical and horizontal orientation. Results show asymmetric effects for the horizontal and vertical schema: schema interference eliminates verticality effects and attenuates horizontality effects (Study 4), while schema diagnosticity only has an effect on verticality-based inferences (Study 5). The center effect remains robust at an overall level, because even if the specific meaning associated with order changes, the center position may still represent a compromise option. However, the preference for the center of an array is stronger in the horizontal orientation than in the vertical orientation. Finally, mediation analyses demonstrate that verticality effects are perfectly mediated by schematic inferences, while horizontal effects are not. This implies that the use of the vertical schema is contingent on its accessibility and diagnosticity, reflecting that it is a controlled and conscious process (Feldman and Lynch 1988), whereas the use of the horizontal schema may be contingent on its mere accessibility, an effect shown to reflect automatic processes in judgments (Menon and Raghubir 2003). Finally, Study 6 finds that when consumer purchase goals move towards a higher quality/higher price alternative, choice patterns move from the center to the extreme.

SYMPOSIUM SUMMARY
Marketing Issues in Politics
Akshay Rao, University of Minnesota, USA

EXTENDED ABSTRACTS

“Marketing of Political Candidates and Voter Choice”

Jon Krosnick, Stanford University, USA

Josh Pasek, Stanford University, USA

Voting behavior

A great deal of research has explored the determinants of citizens' vote choices in elections and the psychological processes by which citizens make those choices. In fact, voting behavior has been one of the central topics of social science research on mass political behavior. Empirical research on voter decision-making began in the late 1940's and has progressed through four stages of development, as we shall review below. During the first three phases, research focused primarily on identifying the determinants of citizens' vote choices. In the fourth stage, interest has shifted to understanding the psychological processes involved.

Social Structure

During the first phase of voting research, studies focused on the impact of social structure on vote choices. This approach was best exemplified by the classic book, *The People's Choice*, by Lazarsfeld, Berelson, and Gaudet (1948). These researchers examined data from repeated survey interviews of a panel of citizens and found that their candidate preferences were a function of their memberships in various social groups. Specifically, three demographic variables were found to be particularly strong determinants of citizens' preferences: place of residence, social class, and religion. Living in a rural area, being middle-class, and being Protestant enhanced the likelihood of voting for Republicans, whereas living in urban areas, being working-class, and being Catholic enhanced the likelihood of voting for Democrats. Citizens who belonged to social groups with conflicting tendencies (e.g., an urban, working-class Protestant) were “cross-pressured” and were found to have unstable political preferences, selected a candidate late in the election, and frequently did not vote at all.

Party Identification

During the second phase of voting research, the emphasis shifted from a sociological one to a psychological one that emphasized attitudes (See also: ATTITUDE THEORY AND RESEARCH). This new perspective was advanced by University of Michigan researchers Campbell, Converse, Miller, and Stokes (1960) in *The American Voter*. The Michigan approach acknowledged both long-term attitudinal influences on voting by party identification and political IDEOLOGY, as well as short-term influences of attitudes on specific policy issues and attitudes towards specific candidates.

The Michigan approach emphasized party identification as the key determinant of vote choice. A citizen's party identification was presumed to be a result of his or her place in the social structure as well as the interpersonal influence of family members, especially parents. Adopted early in life, party identification was hypothesized to be a highly stable orientation that directly influenced voting. Additionally, party identification was thought to function as a perceptual screen that shaped short-term influences on voting.

Although a great deal of research has consistently demonstrated that party identification is a stable and powerful predictor of

vote choice, the relation between party identification and short term influences on voting has turned out to be more complex than originally thought. Specifically, in addition to influencing short term forces, party identification appears to be influenced by them as well. For example, although party identification has been found to influence citizens' perceptions of economic conditions and their preferences on policy issues, the latter seem to influence the former as well. Thus, the relation among party identification and short-term influences is reciprocal in nature. Consequently, it appears that party identification may reflect other determinants of vote choices rather than being the single, primary engine driving voters' decisions.

Additional Determinants of Voting

During the third phase of voting research, researchers maintained the psychological emphasis and have expanded the list of vote determinants. One major body of work focused on the impact of attitudes on specific policy issues. In contrast to the *American Voter's* presumption that such attitudes play relatively peripheral roles in vote decisions, more recent work has shown that policy attitudes do indeed have significant impact when the issue is considered personally important by a voter. But when an issue is considered personally unimportant, it appears to have little or no impact on candidate preferences.

Other phase-three research has focused on retrospective judgments of the past performance of the candidates and parties in handling national problems. Judgments in domains such as the economy and foreign affairs have been shown to exert substantial influence on vote choices (e.g., Abramson, Aldrich, & Rohde, 1991).

Finally, voters' perceptions of candidates as people have been found to influence voting. Specifically, perceptions of candidates' personality traits (i.e., competence, integrity, leadership, and empathy), as well as the emotions candidates elicit (e.g., anger, pride), shape the impressions voters form of candidates and thereby determine voting in part (Kinder, 1986).

Psychological Processes

Most recently, research has moved beyond specifying the determinants of voting and has focused on the processes by which these determinants are combined. It has been suggested that this is a relatively simple process, in which voters simply add up the number of things they like and dislike about each candidate and choose the candidate with the most positive net score. However, Lodge, McGraw, and Stroh (1989) have proposed a more complex psychological process model that distinguishes between on-line and memory-based decision-making. Rather than waiting until the end of an election campaign to integrate information from memory about the candidates to formulate a vote choice (as the memory-based perspective would suggest), voters appear to form evaluations of the candidates early on and continually update these attitudes on-line as new information is encountered. This sort of on-line updating seems especially prevalent among citizens who are political experts rather than political novices.

Conclusion

This summary touches on just a very small set of the research to be reviewed in this presentation regarding the determinants of

who a citizen will vote for. New work on the role of the mass media and the impact of advertising is especially interesting and has clear applications for the understanding of consumer behavior broadly.

“Mere Measurement, Implementation Intentions, and Voter Turnout”

Daniel Goldstein, London Business School, UK
Kosuke Imai, Politics, Princeton University, USA
Anja Goritz, University of Erlangen-Nurnberg, Germany

Since World War II, in over 1,600 national elections in 170 independent states, voter turnout rates have averaged about 65% of the voting age population. Policy makers in 18% of these democracies have deemed electoral participation important enough to justify compulsory voting laws, under which non-voters can face fines and other punishments. Recently, the US Congress authorized 3.9 billion dollars for the Help America Vote Act, and state governments have invested in expanding early-voting methods, which accounted for roughly 20% of the votes cast in the 2004 election. Worldwide, rewards for voters have included tax breaks, job opportunities, scholarships, and even high-stakes lotteries.

What drives voter turnout? Political theory speaks of the costs and benefits of voting and the slight probability that one's vote will be decisive. In practice, these and other variables appear in policies that target two causes of weak participation: low motivation and high obstacles. Motivation-focused initiatives aim to impart the desire to vote by invoking the importance or closeness of an election, a voter's sense of duty, rewards, punishments, or social comparisons. Obstacle-focused policies aim to make voting easier, such as by introducing same-day or automatic registration, voting by mail, or early in-person voting. If voting is largely influenced by motivations and obstacles, policy makers might take inspiration from psychological research on goal attainment, which has revealed the strong effects of two simple treatments. We attempt to demonstrate that simply asking people if and how they intend to vote can increase turnout.

The technique of asking people if they intend to vote comes from research on attitude accessibility and self-fulfilling prediction. In what is called the mere measurement or question-behavior effect, people become more likely to perform certain actions if they are first asked whether they expect to perform them. That is, merely measuring intentions changes behavior. One surprising study found that asking people whether they intended to buy an automobile increased their chances of doing so.

Why does mere measurement work? One important literature suggests that people who make forecasts about the future may alter their behavior to make the predictions come true. An emerging and complementary view is that when people answer questions about

intentions, their underlying attitudes become concrete and readily accessible. For this reason, questions can be polarizing. If attitudes toward electoral participation are generally positive, assessing intentions may turn voting into a goal.

Eighty years of research has looked at the effect of polls, questions, and surveys on voter turnout with some promising findings but leave an unclear picture due to mixed results and some methodological controversies. Part of the variation in results may be due to the variety of populations, instruments, and historical periods studied. Additional variation may be due to the way experiments have mixed mere measurement treatments with related political questions and even practical information on voting.

The second technique, asking people how they intend to vote, comes from research on implementation intentions, which are simple plans that help people overcome obstacles en route to goal attainment. The effects of implementation intentions have been estimated in over 100 policy-relevant studies on exercising, recycling, smoking, and beyond, however, the link to voting has not been investigated in the literature.

How do implementation intentions work? These plans are hypothesized to lead one to direct resources (such as time and attention) toward a target goal, and away from competing goals when they inevitably arise. Furthermore, implementation intentions might make one aware of goal-realization opportunities that would otherwise go unnoticed (e.g., noticing registration offices near work), and help automate responses to foreseeable obstacles (e.g., identifying a means of backup transportation to the polls).

We illustrate the application of mere measurement and implementation intentions through experiments, analyzed in order to estimate causal effects on voter turnout in two national elections: the 2006 US Midterm Election and the 2005 German Federal Election.

In the US study, 1,968 participants were invited to take part in a brief survey approximately two months before the election. In it, a mere measurement group was asked about intentions to vote, and an implementation intentions group was additionally asked to formulate simple plans to vote. The crucial difference with the German study, which involved 1,426 people, is that it took place 1 to 4 days before the election, presumably leaving treatments fresh in the minds of participants.

The experiments pose novel theoretical and applied questions. Will implementation intentions have an effect above that of mere measurement? Will the two treatments be effective on one-shot goals that can be realized only on one day (e.g., voting on Election Day) and open-ended goals that can be realized on many possible days (e.g., early and postal voting)? For both types of goals, do mere measurement and implementation intentions treatments fade over periods of days or months?

For the open-ended goal of early (e.g., postal) voting, mere measurement treatments given two months in advance (US study) had moderate positive effects on turnout, a finding consistent with studies showing that mere measurement treatments can impact the probability of undertaking an action (such as purchasing a computer) on any day within a window of several months. For early voting, estimated implementation intentions effects were similar to those of mere measurement.

For the one-shot goal of election-day voting, mere measurement was only effective when it was administered days (Germany), but not months (US) in advance. Implementation intentions treatments, in contrast, held their effectiveness for both near and distant races.

Our study contributes to a growing body of research demonstrating that policies can benefit from working in concert with psychological mechanisms. People's preference for default op-

tions, for instance, can lead to increased membership in organ donor pools, and participation in retirement savings plans. While some policies benefit from a tendency toward inaction, others must help people to act. To construct effective campaigns and messages, policy makers might consider addressing voting as a goal, one that is aided by stating intentions and making plans.

“Facial Similarity between Voters and Candidates Causes Influence”

Jeremy Bailenson, Stanford University, USA

Shanto Iyengar, Stanford University, USA

Nick Yee, Stanford University, USA

Voters identify with political candidates in many ways, from agreeing with their positions on issues, holding the same party affiliation, belonging to the same social categories such as race or gender, or even having common physical traits such as height and facial appearance. Political scientists typically focus on candidates' policy positions, performance records, and party affiliation as the fundamental determinants of voter preferences. With a few notable exceptions nonverbal cues are conspicuously absent from the list of “usual suspects”. The cognitive paradigm so dominates voting studies that even when researchers detect the effects of similarity based on a candidate's physical traits (most notably, race and gender), they typically attribute the propensity to support same-gender or ethnicity candidates to voters' tendency to infer agreeable policy positions from these traits.

On the other hand, an extensive literature across the social sciences demonstrates that people are often drawn to others perceived as similar. In the current work, we examined the relative effects of different forms of similarity on candidate evaluations by using an experimental design that manipulated the degree of candidate-voter facial similarity. We were particularly interested in how facial similarity compares to other forms of similarity such as partisanship or policy agreement and with other non-verbal cues including gender and candidate familiarity.

In Experiment One, we examined the effect of facial similarity among unfamiliar political candidates and hypothesized that the effect of facial similarity would be significant due to the lack of other cues or pre-existing biases. One week before the 2006 Florida gubernatorial election we presented a national random sample of voters with photographs of unfamiliar candidates (Charlie Crist and John Davis) that had been morphed either with the voter filling out the survey or with an unfamiliar person. In other words, Experiment One allowed us to examine, as a first step, whether facial similarity could be used to sway political outcomes in the least restricted scenario.

In Experiment Two we replicated the design with familiar candidates (George W. Bush or John Kerry) one week before the 2004 Presidential election. Our hypothesis was that the effect of facial similarity among familiar candidates would be significant, but minimal, due to the presence of pre-existing biases and other information surrounding a presidential election. The effect of facial similarity would also be minimized because the study was administered so shortly before the actual election and many voters may have already made up their minds. Thus, Experiment Two tested the effect of facial similarity in the most conservative and realistic way possible.

In Experiment Three we combined different aspects of Experiment One and Experiment Two by using a set of potential candidates (some familiar, some unfamiliar) for the 2008 presidential election. In the study, we also directly pitted forms of similarity (e.g., facial similarity, gender similarity) against candidate familiarity. We also manipulated the gender of the candidate and pitted the effects of facial similarity against the effects of attitude similar-

ity on salient political issues. Thus, Experiment Three builds upon the first two studies by allowing us to understand the relative importance of facial similarity among other cues typically present in a political election.

In these three studies we demonstrated a moderate but consistent effect of facial similarity on evaluations of actual candidates. In all three studies the effect of facial similarity was heightened when other competing identity cues were less salient. In Experiment One, we examined similarity in the least restrictive situation and demonstrated that similarity increased support for unfamiliar candidates across the board. In Experiment Two, in a high information election in which voters were invested in the outcome, facial similarity increased support for familiar candidates only among weak partisans and independents. Experiment Three directly tested the relationship between familiarity and similarity and demonstrated that facial similarity proved effective only when the candidate was relatively unfamiliar. Furthermore, the effect of facial similarity was smaller than cognitive similarities such as issues and party membership.

These results convey clear implications for the study of voting behavior. While other scholars have demonstrated that candidates who look more “competent” win elections, they have not identified the characteristics of faces that make voters evaluate a candidate more favorably. Our work demonstrates that facial similarity is one such characteristic. Increasing the facial resemblance between candidates and voters can alter electoral results, especially when the candidate is unfamiliar. The effects persist on a limited basis even when the information is conveyed about familiar candidates, one week before a closely contested presidential election. Given the revolution in information technology, we have no doubt that political strategists will increasingly resort to transformed facial similarity as a form of campaign advertising.

“Reference Dependence When Tastes Differ”

Neil Bendle, University of Minnesota, USA

Mark Bergen, University of Minnesota, USA

Behavioral decision scholars have made great strides in showing that decisions can be influenced by context and references (Kahneman and Tversky 1979, Thaler 1985, Highhouse 1996). In marketing this work has developed a much deeper understanding of behavior given the decision context (Huber Payne & Puto 1982, Hedgcock, Rao & Chen 2007), and has explored areas such as reference prices (Winer 1986, Hardie, Johnson & Fader 1993) and product line strategy (Orhun 2007).

The bulk of this work typically concentrates on vertical attributes; i.e. attributes that have a clear ordering on any single dimension and a directionality which is consistent amongst people. For example all other things being equal, people prefer high to low quality, and lower prices rather than higher prices.

There are, however, many situations where attributes cannot be easily classified as vertical. For example, in political marketing voter preferences are often modeled as horizontal differentiation, such as the classic left to right continuum. This is true of many product characteristics such as color, and taste. For example, there is no commonly agreed “ideal” car color. In these situations, consumers will not all make the same choice even when they are faced with identical alternatives and all have the same information. Not only does horizontal differentiation characterize a wealth of consumer decision contexts, it allows us to consider more complex markets where tastes must be aggregated to assess the outcomes and implications of reference dependence and marketing activities.

We use the classic Hotelling model to explore “horizontal” reference dependence, introducing reference effects that are not direction specific, i.e. the references represent a consumer's atti-

tude about the distance to the product they experience and not an attitude to the location of the reference as such. The work horse model of competition research, the Hotelling (1929) line, parsimoniously captures both a consumer's personal preference and the market outcomes incorporating other people's preferences. We develop "horizontal" reference dependence in a manner faithful to horizontal differentiation and prospect theory, using non-direction specific effects which show diminishing sensitivity to gains and losses. The reference effect is a function of both the consumer's distance to the reference and to the product being considered. We apply reference effects to utility additively (Koszegi & Rabin 2004); a parameter sets the relative power of reference effects compared to "actual" distance.

This adds discreteness which greatly complicates the Hotelling model. To maintain a manageable scope of this work we take a partial equilibrium approach. We explore the implications of reference points not the process of setting reference points. To solve the model we analyze all possible permutations of gains and losses, 65 cases. We show that although references influence the relative strength of preferences, references don't change choice under horizontal differentiation in this model. However, extending the model to contexts where strength of preference matters, we show that choices can be substantially influenced by "horizontal" reference dependence. These choices move in reasonable ways given loss aversion and diminishing sensitivity which allows specific advice to be generated as to the location managers of any given product want consumers to use as a reference.

We apply this to political marketing, which is a natural market in which to consider taste differences. In politics, despite controversy about the prevalence of coherent ideology (Converse 1964, Jost 2006), many people are willing to categorize politicians and their policies on a single taste dimension (Gigerenzer 2007). The left-right continuum that is widely used in political research (Morton 1999, 2006) represents taste differences because there is no objectively agreed upon reason for the superiority of left to right or right to left. The policy position that each voter prefers depends upon where they stand on the policy continuum.

We examine primary elections. Both the primary and predicted general election choices are captured on a Hotelling line. We show that in a general election reference effects don't change the voter's choice. However we also show that when electability and uncertainty matter, references can influence voter choice in primary elections. This allows us to develop marketing advice; campaign managers shouldn't necessarily aim to anchor potential voters' references around their own candidate's position. Specifically more electable candidates, those expected to be stronger in the general election than their primary election opponents, want voters' references far from the primary contest while less electable candidates want voters to concentrate on their specific policies, they want voters concentrating on the primary election at hand.

Thus, we provide an explanation of how reference dependence can sometimes be a very powerful influence on certain political decisions and yet have no effect on others. We explore why Howard Dean's 2004 communications strategy may have helped John Kerry noting that the conventional wisdom—that the "scream" cost Dean the election is incomplete, Dean's fall in the polls and loss in Iowa preceded the scream. In 2004 Howard Dean was relentlessly attacking George Bush not his opponent in the election John Kerry. This attention to the President reinforced a focus on ousting George Bush minimizing the policy differences between John Kerry and Howard Dean. Where voters' references are focused outside the specific primary contest this is an advantage for candidates perceived as more electable like John Kerry. This work also helps

explain why in 2008 republican voters confounded expert's predictions that they would choose a candidate more in tune with their core beliefs instead choosing John McCain, the candidate seen as more electable.

SYMPOSIUM SUMMARY

Brand Symbolism and Reference Groups: Perspectives on the Identity Value of Brands

Carlos Torelli, University of Minnesota, USA

SESSION OVERVIEW

People buy products not only for what they do, but also for what the product means; thus brands can be symbols that become part of the individual identities of consumers (Levy 1959). McCracken's (1988) model of meaning transfer states that such meaning originates in the culturally constituted world and moves into brands through several instruments such as advertising, the fashion system, and reference groups. In particular, reference groups shape brand meanings via the associations consumers hold regarding the groups of individuals who use the brand (Muniz and O'Guinn 2001). These meanings can move to consumers, as consumers appropriate brand meanings for constructing their individual identities (Escalas and Bettman 2005). How do brands achieve the highest levels of symbolism and become icons of a group? How do consumers use iconic brands for signaling their identity? When do consumers feel more motivated to seek connections among fellow brand users? How do group norms impact the identity value of brands? This symposium unites under a common theme of providing insights on the dynamic processes underlying the transfer of brand meanings via reference groups and the appropriation of these meanings for constructing consumers' self-identities.

The first paper by Torelli, Chiu, Keh, and Amaral examines how brands become icons of a cultural group and how consumers use iconic brands to manage their social identity. Adopting a shared reality perspective (Hardin and Higgins 1996) to the study of the cultural significance of brands, these authors define brand iconicity as the degree to which a brand symbolizes the values, needs, and aspirations of the members of a particular cultural group. They further reason that for these brands to become culturally influential their symbolic meanings should be widely and durably distributed in the culture (Sperber 1996). Through the sharing of these meanings in an ongoing, dynamic process of social verification, they become a shared reality. In five studies, the authors develop a reliable and cross-culturally general measure of brand iconicity. They show that consumers may use preference for iconic brands over non-iconic ones as a self-symbolizing strategy. They also show that for likable brands, if their cultural significance is widely known in the community, they are more likely to become cultural icons. This research not only provides insights into the social verification process by which symbolic group meanings get transferred to iconic brands, but show how consumers use iconic brands to manage their social identity and use social information to judge the level of iconicity of brands.

The second paper by Cheng and Chiu explores how brand patronage can facilitate perceptions of group interconnectedness and homogeneity. Cheng and Chiu suggest that knowing that one's brand choice was favored only by a few people motivates individuals to seek connections among fellow brand users. They further argue that this need to seek connections motivates minority (vs. mainstream) brand users to perceive fellow brand users to be a homogenous and desirable group, and to emphasize commonalities when they talk among each other. Minority brand users would therefore be more likely to have a shared representation of who they are and what they are like. In five experiments, they found that both the need to seek connections and ingroup communication are critical for individuals to form shared representation of group members. This stream of research provides an important insight

into how brand-group associations get established and how abstract group meanings can get transferred to a brand.

The final paper by Ng and Lau-Gesk enhances our understanding of the dynamic processes underlying the appropriation of brand meanings via reference groups. Ng and Lau-Gesk suggest that the identity value of a brand can be diminished by highlighting the conflict between individual identity-signaling desires and important group values. In three experiments, the authors find that when the conflict between consumers' desire to signal status through brand usage and the group norms disapproving such behavior are made salient, consumers are less likely to choose products that feature (vs. not) brand logos prominently. This effect is particularly strong for brand choices that are made in public (vs. in private), and even extend to situations involving counterfeit products.

This session discusses a very important topic that has amazing potential to both inform consumer researchers about the antecedents of self-brand connections and help branding professionals make better decisions. We anticipate this session will attract not only those interested in branding issues, but those interested in group-processes and the cultural meanings of brands. Jennifer Escalas, an expert in the study of consumer narrative processing and brand symbolism, will integrate the implications of the three streams of research and provide a roadmap for future research about the dynamic processes underlying the transfer of brand meanings via reference groups and the appropriation of these meanings for constructing consumers' self-identities.

EXTENDED ABSTRACTS

"Brand Iconicity: A Shared Reality Perspective"

Carlos Torelli, University of Minnesota, USA

Chi-yue Chiu, University of Illinois at Urbana-Champaign, USA

Hean Tat Keh, Peking University, China

Nelson Amaral, University of Minnesota, USA

That certain brands reach an iconic status in society is a notion widely accepted by marketing practitioners and consumers alike. Although recommendations to build iconic brands are not uncommon, very little research has been devoted to basing these recommendations upon any theoretically grounded conceptualization of brand iconicity. Recently, Holt (2004) conceptualized iconic brands as consumer brands that become "consensus expressions of particular values held dear by some members of a society" (p. 4). Iconic brands carry a heavy symbolic load for consumers, who frequently rely on them to communicate to others who they are or aspire to be. For these brands to become culturally influential, their symbolic meanings should be widely and durably distributed in the culture (see Sperber 1996). Through the sharing of these meanings on an ongoing, dynamic process of social verification, or shared reality (Hardin and Higgins 1996), their symbolism becomes an objective reality. It is precisely this shared understanding of the symbolic meaning of an iconic brand that facilitates the communication of ideals and aspirations to others through brand usage or consumption.

We define brand iconicity as the degree to which a brand symbolizes the values, needs, and aspirations of the members of a particular cultural group. Brands high in iconicity have the power to connect diverse elements of cultural knowledge and can act as reminders of culturally-relevant values and beliefs. In the five

studies reported here, we developed a measure of brand iconicity and provided evidence for its reliability and validity. These studies also show how consumers use iconic brands to manage their social identity and use social information to judge the level of iconicity of brands.

In study 1, we developed a scale to measure brand iconicity (BIS) and provided evidence for its reliability and cross-cultural generality using samples of American and Chinese consumers. Brand iconicity was shown to be a construct that is distinct from, and yet correlated with, involvement. Although iconic brands are very familiar ones, brand iconicity is uncorrelated with brand familiarity.

In studies 2 and 3, we demonstrated the validity of the BIS. In study 2, we asked American participants to write a story describing American culture. Participants were further instructed to use brands either high or low in iconicity as an aid in writing the story (a control condition, in which no brands were mentioned, was also included for comparison purposes). They subsequently rated the fluency in idea generation. Results showed that including iconic brands identified through the BIS when writing about their associated culture increases fluency in idea generation and the number of important cultural values mentioned in the essay. These effects remained even after controlling for participants' level of involvement with the brands. In study 3, participants were either reminded of a recent ban on a symbolic marker of their group identity (University mascot) or completed a control task. They subsequently evaluated brands with varying levels of iconicity. Results showed that consumers preferred iconic brands over non-iconic ones as a self-symbolizing strategy. They used this strategy to compensate for a tarnished group identity upon the reminder of the ban on the University mascot.

Finally, studies 4 and 5 investigated the shared reality processes that underlie judgments of brand iconicity. Participants were led to believe that a majority (vs. a minority) of fellow participants associated either a likable or a dislikable brand (in this case a celebrity name) with culturally-relevant values. They subsequently rated the brand in terms of iconicity. Results showed that for likable brands, if their cultural significance is widely known in the community, they have an increased likelihood of becoming cultural icons. However, for dislikable brands, public awareness of their cultural meanings does not increase their iconicity scores.

Findings from this research suggest a relationship between brand evaluation, public awareness of the brand's cultural significance, and brand iconicity. At least for likable brands, it is possible to increase their iconicity by strengthening its associations with important cultural values and broadening the public awareness of such associations. This idea is congruent with Holt's (2004) assertion that brands that are successful in addressing the collective desires of a cultural group are the ones raised to an iconic status. In contrast, for dislikable brands, even when the consumers know that these brands are widely known to embody important cultural values, they do not consider these brands to be iconic. This finding is consistent with theories of intergroup behavior (e.g., Tajfel 1982), which posit that people adopt a certain group identity to fulfill their need for positive distinctiveness of the self. Thus, it would be unlikely that consumers would accept a dislikable brand as an icon of their culture, as doing so may contrast with the perceived positivity of the culture.

Findings in this research carry important implications for global branding. Consumers who are aware of the symbolism of a foreign brand in its associated culture might bring to mind its attendant cultural meaning. For example, a Chinese consumer may think about the individualist values characteristic of American culture while passing in front of a Starbucks outlet in downtown

Beijing. If the consumer values an independent self-identity, the activated cultural associations upon seeing the iconic American brand may increase purchase intention.

In combination, the studies in this research not only provide insights into the social verification process by which symbolic meanings associated with a group get transferred to iconic brands, but show how consumers use iconic brands to manage their social identity and use social information to judge the level of iconicity of brands. The present paper offers a framework to better understand the impact of the cultural meanings associated with consumer brands on brand perceptions and the fulfillment of identity goals.

"Emergence of Shared Representation of Brand Users"

Shirley Y. Y. Cheng, University of Illinois at Urbana-Champaign, USA

Chi-yue Chiu, University of Illinois at Urbana-Champaign, USA

One major feature of brand communities is the "consciousness of kind" (Gusfield 1978), which is the "intrinsic connection that members feel toward one another, and the collective sense of difference from others not in the community" (p. 413, Muniz and O'Guinn 2001). Intrigued by the observation that many brand communities are centered at minority brands (e.g., Apple-Mac or Harley Davidson) instead of mainstream brands, we looked into how being in a minority group may contribute to forming a shared representation of fellow brand users.

Specifically, we examined how brand users become aware of some distinctive characteristics that are shared among fellow brand users. These distinctive characteristics *define* the group, and differentiate members from non-members of the community. We proposed that the motivation to seek connections among fellow brand users and the opportunity for in-group communication contribute to the emergence of the shared group representation.

Minority brands and the motivation to seek connections. Optimal distinctiveness theory (Brewer 1991) posits that people need to see themselves as being different from others and being connected to others at the same time. For minority brand users, knowing that their brand choice is shared only by a small group satisfies the need to be different more than the need to connect, which would motivate to seek connections to others in order to restore the optimal level of distinctiveness. Motivation to seek connections would lead minority brand users to perceive commonalities among fellow brand users. For majority brand users, knowing that a majority shares their brand choice heightens the need to be different. They are motivated to perceive differences instead of commonalities among fellow brand users.

Communication as a critical mechanism. Communication is an important mechanism for forming shared representation (Latané 1996). We maintain that communication among brand users is responsible for crystallizing distinctive group characteristics. Minority brand users (because of the heightened need to connect) would be more likely to emphasize commonalities when they talk about fellow brand users. Majority brand users, however, would be more likely to emphasize the differences among fellow brand users. Therefore, we hypothesize that minority (vs. majority) brand users would be more likely to form a shared group representation.

Experiments 1 and 2—Emergence of distinctive group characteristics. In these experiments, we manipulated group membership by giving participants a choice between two brands. They were told that their choice was either popular (majority condition) or unpopular (minority condition) among previous participants, which would lead to relatively lower versus higher levels of need for connections respectively. Next, participants read information about "the most enjoyable activity of 20 other participants who made the same choice." These activities varied in the degree to which they repre-

sented openness to experience, and there was a slightly higher number of activities high (vs. low) in openness. Using this information, participants wrote an essay to communicate their impression of these participants (referred thereafter as the target group) to another participant who would also choose the same brand. Two independent coders classified each essay in terms of whether it captured a global impression of the target group or not, and in terms of whether this global impression reflected openness to experience as the main theme. As predicted, participants in the minority (vs. majority) condition were more likely to communicate a global impression of the target group and to characterize it as high in openness.

Participants also rated the target group on group homogeneity and openness. Again as predicted, participants in the minority (vs. majority) condition rated target group members as being more similar to one another and as being more open to experience, although participants in the two conditions rated openness as equally desirable. To rule out an alternative interpretation based on information representativeness, experiment 2 replicated the findings of experiment 1, but using this time a smaller target group (i.e., information about five instead of 20 participants).

Experiments 3 and 4—Testing the proposed model. These experiments were designed to show that the need to seek connections and ingroup communication are critical for forming shared group representations. In experiment 3, participants performed the same tasks but without making the initial brand choice, which presumably prevented them from associating with the target (i.e., taking an outsider's perspective). They were simply instructed to read the same 20 most enjoyable activities of participants who chose either a minority or a majority brand and wrote an essay about these participants. As expected, participants who wrote essays about such groups did not perceive a minority group to be more homogeneous or open. In fact, reversing the pattern found in previous studies, minority (vs. majority) users were perceived to be less homogeneous and less open. These results suggest that the need to connect with fellow group members may be a prerequisite for forming a shared group representation. In experiment 4, participants made the same brand choice as in experiment 1, but were prevented from communicating their impressions (i.e., they did not write an essay describing the target group) before rating the group. Congruent with the notion that ingroup communication is necessary for forming shared group representations, participants in the minority (vs. majority) condition perceived the target group to be equally homogeneous, and even perceived it as being less open.

Experiment 5—Crystallization of distinctive group characteristics. This experiment studied serial communication as an antecedent of the crystallization of brand user representations. Participants here followed the same procedure used in experiment 1, but read a sample of the essays written by the participants in experiment 1 instead of the 20 most enjoyable activities. As predicted, participants in the minority (vs. majority) condition perceived the target group as being more open, homogenous, cohesive, and trustworthy.

Results here show that minority (vs. majority) brand users perceive and talk about fellow brand users with a greater emphasis on the commonalities among them. This contributes to forming a shared representation of the distinctive group characteristics. Existing reference group research mostly focuses on how perception of a reference group affect consumers' brand choice (e.g., Escalas and Bettman 2003). Extending this stream of research, our findings show that brand choice can affect the perceptions of the reference group by group members, which might subsequently impact the meaning of being a brand user.

“One Trait, Two Images: Impact of Impression Management Goal Conflict on Brand Choice”

Sharon Ng, Nanyang Technological University, Singapore

Loraine Lau-Gesk, University of California, Irvine, USA

Consumers frequently use brands as a means to express a desired self image. Brands, indeed the more successful ones, tend to be associated with images that consumers would like to be associated with in order to help managing the impressions they make on others (Escalas and Bettman 2005). To highlight these associations, most branded products are designed such that the brand logo is prominently featured on the product (e.g., the monogram bags sold by Louis Vuitton, the logo featured on all Ralph Lauren apparels, etc). One purpose of these logos is to highlight the brand and fulfill the impression management purpose of its users.

Many brands in the marketplace, however, possess complex trait associations where more than one meaning can develop and evolve over time. A brand may possess a conflicting image through a single trait. Take prestige, for example. On the one hand, the prestige of a brand may in itself entice consumers to purchase it in view of its associated meaning of personal success and status. On the other hand, consumers may find prestige as undesirable if they think about negative group perceptions of being overly materialistic and shallow as opposed to modest and grounded. These multiple meanings associated with a single brand trait can lead consumers to experience tension balancing personal desires (e.g., showing success) with societal values (e.g., demonstrating modesty, Goffman 1959, Leary and Kowalski 1990).

Though many brands with conflicting meanings exist in the marketplace, the literature remains silent about how brand conflict could impact brand choice. To address this gap in the literature, the present research examines situations where a single brand trait arouses oppositely-valenced responses, forcing consumers to choose between satisfying personal identity-signaling desires or fulfilling important group values. We examine how this type of conflict affect consumers' choice between products that feature the brand logo prominently and those that do not feature the logo. Our findings will help firms better understand how conflicting brand image and societal norms affect consumers' choices. In addition, we extend our theory to understand consumers' purchase of counterfeit products.

Specifically, drawing from the impression management literature, we propose that saliency of the conflicting associations triggered by the purchase or use of a brand would make people more hesitant to use the brand for impression management purposes, which would ultimately impact brand choice. To test this hypothesis, study 1 manipulated the degree to which the conflict between consumers' desire to signal status through brand usage and the group norms disapproving such behavior were made salient. Those in the low conflict condition were told that signaling status through brand usage was a widely accepted behavior in their groups, whereas those in the high conflict condition were told that such behavior was in conflict with group norms. As predicted, we found that people were less likely to choose products that featured the brand logo prominently (vs. those without the brand logo) when the conflict was made salient.

We further propose that the impact of conflicting associations on one's brand choice is moderated by the extent to which the decision is made in the public or the private domain. When the decision is made in the public domain, the conflict would take on greater weight in affecting one's decision. To test this hypothesis, study 2 adopted a 2 (Evaluation Condition: Private vs. Public) X 2 (Conflict: Low vs. High) between subjects design. As expected, we found that when the decision was made in the public domain,

participants were more likely to choose products that did not feature the brand logos prominently (versus those that featured the brand logos prominently). In the private domain, there was no significant difference in the choices made. Thus, findings from studies 1 and 2 supported our contention that making salient the conflict between individual identity-signaling desires and important group values do affect consumers' choices, and this effect is particularly evident when the decision is made in the public domain.

Building on studies 1 and 2, study 3 examines how conflicting associations would affect people's attitudes towards counterfeit products. Very little research has been devoted to understanding the psychological processes underlying the purchase of counterfeit products. We propose that our findings can shed light on some of these processes. Consumers may buy counterfeit products in an attempt to signal status through brand usage without having to pay a higher price. However, these consumers may also perceive that the usage of counterfeit products is a practice that is not accepted by their groups and may negatively impact how group members perceive them. This conflict between personal goals and important group values (i.e., to leverage the brand's image to impress others and societal disdain on the purchase of counterfeit products) should affect attitudes toward counterfeit products. Specifically, we argue that when such conflict is made salient to the consumers, they would exhibit a less favorable attitude towards counterfeit products. Furthermore, this effect will be stronger when the decision is made in the public (vs. the private) domain. To test this hypothesis, we conducted a 2 (Evaluation Condition: Private vs. Public) X 2 (Conflict: Low vs. High) between subjects experiment in a counterfeit product context. Results supported our prediction.

In summary, findings from three studies suggest that the use of brands for impression management purposes may be more complex than it was previously known. Brand attributes that satisfy individual identity-signaling desires may be in conflict with values that are important for the group. Making this conflict salient can impact consumers' attitudes and choices.

SYMPOSIUM SUMMARY

Multifaceted Consumer Welfare: Broadening the Perspective

Behice Ece Ilhan, University of Illinois at Urbana-Champaign, USA

SESSION OVERVIEW

Current Perspectives on Consumer Welfare: In his ACR presidential address in 2006, David Glen Mick stresses that “transformative consumer research is not something new, nor has it been dormant” (page 2). Yet, the proliferation of scholarly studies and special session journals indicates consumer behavior scholars’ growing interests on the topic. To date, existing consumer welfare studies have primarily examined whether a particular consumption practice enhances or impairs consumer welfare. Consumer welfare has generally been treated as a dependent variable in association with consumption practices such as eating habits (Moore 2007, Chandon and Wansink 2007), alcohol consumption (Creyer et al 2002), gambling (Wijnholds and Little 2002), and consumption of product information (Balasubramanian and Cole 2002, Wansink and Chandon 2006). Balasubramanian and Cole (2002), for example, have tested how consumers benefit from product labels that include more negative attributes (such as sodium and fat where less is better). Reiterating the product labels-consumer welfare relationship, Wansink and Chandon (2006) pointed out the negative role of ‘low-fat’ nutrition labels for consumers. These welfare studies in relation to consumption have largely been guided by the question ‘how does consumer behavior impact consumer welfare?’ The *Journal of Consumer Research*’s Call for Papers for Transformative Consumer Research Special Issue also summarizes the scope of these studies as: “consumption that has positive or negative externalities is a way to study consumer welfare”.

Broadening the Construct of Consumer Welfare: Consumer behavior scholars have learned substantially from these previous consumer welfare accounts. While these prior elaborations are most relevant to our understanding of the consumer welfare concept in association with different consumption practices, they are limited in their scope and insufficient in their elaboration of what consumer welfare is and how broadly it could be studied. Consumer welfare analysis is limited to the one-step and somewhat deterministic assessment of the concept—as a dependent variable. Also, the consumer welfare concept is used interchangeably with other consumer behavior constructs such as subjective well being, consumer satisfaction, and quality of life and is also equated with higher levels of quality of life, overall happiness with life, absence of ill being, and greater social welfare (Sirgy, Lee, and Rahtz 2007). However, accepting the face-value of consumption practices for their consumer welfare implications, consumer researchers inevitably fail to notice the complex and profound layers of the consumer welfare concept.

The session *builds on* existing consumer welfare studies by exploring multiple faces of this complex and multi-layered concept. The session papers do not deem consumer welfare only as a dependent variable that is directly associated with a consumption practice but rather try to address the amorphous nature of consumer welfare that might be compromised and enriched at the same time for the same practice. The session also *extends* existing scholarship by pointing at some boundary conditions where the existing consumer welfare frameworks fall short of offering elaborate explanations and understandings. Assumptions about consumers, contexts, and units of analysis are challenged by the session papers to broaden the frameworks. Thus, the session has been designed to contribute

to an attempt to theory development of consumer welfare by furthering the existing frameworks and identifying their limits.

Papers: The three papers are united in their exploratory perspective as each of them seeks to broaden the existing consumer welfare frameworks and challenge at least one assumption related to existing discussions on the topic.

Ilhan and Tumbat attempt to extend the existing studies on consumer welfare by introducing an alternative consumer choice prospect. To challenge the face value of counterfeit consumption as lessening consumer welfare, they introduce a context that offers new choice scenarios where the consumer choice is between having a counterfeit product versus not having anything. They argue that the choice dichotomy of having an ‘authentic’ versus a ‘counterfeit (inauthentic)’ product—imposed by the existing Western lenses—is an impediment to explore possible positive consumer welfare implications of counterfeit consumption. Their findings challenge the anti-counterfeit consumption discourse and propose a novel conceptualization of consumer welfare based on this alternative choice prospect.

Askegaard and Kjeldgaard, in their study of consumption of personal coaching, challenge the validity of the assumption underlying the coaching phenomenon: that it is possible to perform oneself to better consumer welfare. Starting at the self-actualization level, they formulate a framework for investigating consumption of self-improvement therapy, exemplified by personal coaching. They then, discuss both the potential, negative macro-level consequences of the self-actualization and coaching techniques for consumer welfare in spite of the positive phenomenological experience and also the legitimacy of such macro-level critiques in the face of positive consumer experiences.

Finally, adopting a different theoretical perspective, Gau and Viswanathan re-examine the concept of consumer expertise and discuss counterintuitive implications on traditional notions of consumer welfare. Using problem solving frameworks, they suggest that traditional notions of consumer welfare should be reconsidered in light of the unique cognitive tendencies observed in low-literate consumers. Challenging the assumptions about consumer expertise, they assert that a more complete understanding of the low-literate consumer experience would include a more complete incorporation affective considerations, as well as further distinctions of literacy, perhaps into individual components of literacy and numeracy. In their paper, they iterate how this greater understanding would reveal a clearer picture of what consumer welfare could be.

This special session is very up to date with the recent transformative consumer research direction that guides the consumer behavior field. As it seeks to build on, challenge, and extend prior consumer welfare frameworks and literature, this symposium appealed to a broad cross-section of ACR attendees, particularly to the ones who are interested in and in search for new and broader directions on consumer welfare. David Glen Mick, as one of the initiators of transformative consumer direction in the field and expert in the area, was the ideal discussion leader who is well positioned to comment on research that seeks to broaden the existing frameworks.

ABSTRACTS

“Counterfeit Consumption: Consumer Welfare Perspective”

*Behice Ece Ilhan, University of Illinois at Urbana-Champaign
Gulnur Tumbat, San Francisco State University*

Previous studies suggest that counterfeit consumption, regarded as an illegal and unethical practice, has undesirable consequences for markets, firms, and also for consumers. The focus of consumer studies on the topic is limited to the motivations for or symbolic meanings of counterfeit consumption. Yet, the potential positive consequences of counterfeit consumption on consumer's welfare haven't been explored. We argue that the Western contexts used in existing studies bring in a specific choice dichotomy—between having an ‘authentic’ versus a ‘counterfeit (inauthentic)’ product—that acts as an impediment to explore possible consumer welfare implications of counterfeit consumption. We use an alternative context where the consumer choice may be between having a counterfeit product versus none to explore consumer welfare implications of counterfeit consumption. Our findings challenge the anti-counterfeit consumption discourse and propose a novel conceptualization of consumer welfare.

“Coaching for Capacity or Incapacity? Self-Actualization and Consumer Welfare”

*Søren Askegaard, University of Southern Denmark, Odense
Dannie Kjeldgaard, University of Southern Denmark, Odense*

Consumption of personal coaching is growing rapidly. Based on a utopian and a dystopian vision on the contemporary culture of self-actualization, we formulate a framework for investigating consumption of self-improvement therapy, exemplified by personal coaching. Sixteen consumers were interviewed about their motivations for engaging in as well as their experiences of personal coaching and its consequences for their lives before, during and after the therapy. We analysed the results of the interviews in the light of its contribution to consumer welfare using insights from positional economy, the ideology of performance, and critical perspectives on the self-help ideology and industry.

“Consumer Welfare Considerations Across Literacy and Resource Barriers”

*Roland Gau, University of Illinois at Urbana-Champaign
Madhu Viswanathan, University of Illinois at Urbana-Champaign*

Our research on low-literate, low-income consumers in the U.S. and India finds a variety of behaviors indicative of concrete thinking (e.g., buying based on a single attribute, often price, buying based on immediate need), often resulting in poor marketplace decisions (e.g., buying incorrect items, buying items with higher unit prices, foregoing substitute items). However, some low-literate consumers exhibit consumer expertise, a seemingly surprising result, given extant expertise perspectives. Our experience with educational interventions also suggests some counter-intuitive results, given our understanding of literacy. Thus, aspects of consumer welfare (e.g., consumer education, communication of product information) should be reconsidered for low-literate consumers.

SYMPOSIUM SUMMARY

Building an Understanding of What Makes Consumer Behavior Transformative

Eric J. Arnould, University of Wyoming, USA

SESSION OVERVIEW

The purpose of this session is to create a discussion of what makes consumer behavior transformative (Mick 2006), and through presentations and discussion, to show how participatory approaches, as well as top down approaches adopted in social marketing, can be effective in accruing positive change to individual consumers and to society. More specifically, this session explores transformative consumption experiences that consumers create by appropriating marketplace resources for their own purposes. While considerable excitement has been generated by the emergence of more participatory models of market relationships, little attention has been directed to the market transformative potential of participatory consumer behavior, although evidence for these sorts of presumptive behaviors has been reported (Craig-Lees and Hill 2002; Thompson and Coskuner-Balli 2007).

Grass roots social innovation (Young Foundation 2006) in marketing systems provides an important complement to the more top down approaches espoused by some proponents of transformative consumer research. Social marketing seeks to change behavior through marketing programs that help individuals understand and embrace prescribed positive behaviors. By contrast, participatory research approaches facilitate learning by actively engaging consumers in ways that help them define consumer-driven solutions to problems (Ozanne and Saatcioglu 2008). Both social marketing and grass roots social innovation in market systems can and should co-exist within the Transformative Consumer Research vision.

Increasingly consumers are insisting on building or reformulating markets that implement, amplify and promote principles and ideals marginalized, attenuated, or neglected by mainstream commercial interests (Thompson and Coskuner-Balli 2007, 138). Consumers are interested in systemic market change; they have become active producers of their own consumption requirements. Unlike historic or classic countercultural approaches that emphasized utopian self-sufficiency or do-it-yourself models, today, consumers are becoming adept at developing marketing-informed solutions to create beneficial systems, often incorporating non-commoditized goods and/or local connectivity, as well. In other words, consumers are investing in qualitative improvements in need satisfying systems, in some cases incorporating the goal that net benefits to the society and the environment should be higher than the full systemic costs (Mont 2008, 253).

Sometimes attributed to the collective intelligence fostered by the Internet, and the democratization of digital media technologies, a paradigm shift in consumer behavior may be occurring (Jenkins 2006; Lévy 1997). Consistent with this idea of paradigm shift, the consumers described in the current session do not passively accept the dominant marketplace conditions with which they are presented, as Melea Press shows in a paper casting Consumer Supported Agriculture as a risk management strategy. Nor do consumers in marginalized socio-economic contexts passively accept resource constraints and external policy mandates that seek to define their consumption options as Baker, Hill, and Hunt demonstrate. Nor as Rosa and Geiger-Oneto illustrate, do resource constrained consumers passively accept resource deficits that lead some to characterize them as marginalized non-consumers. In effect, this session also builds directly on a past ACR session critical of TCR and CCT (Ozanne and Dobscha 2006). Our innovative approach will show how focusing on the market transforming

capabilities of consumers may help us understand how to alter markets in the consumer interest, and concurrently destabilize inadequate theoretical binaries like mainstream vs. marginalized market actors. Moreover, the consumer strategies described here may represent a middle ground between the opt-out strategies promoted by some consumer downshifters and voluntary simplicity advocates, the legitimacy of which is contested, and the more acquiescent orientations to consumption of those in mass markets (Bekin, Carrigan and Szmigin 2005; Mont 2008; Ottman 1995; Schorr 1998).

Professor Julie Ozanne, who has long championed both participatory approaches to policy-oriented consumer research and critical approaches to consumer research generally, will provide a synthesizing discussion of the papers and lead the audience in a discussion of the implications of these papers for developing the theory and practice of transformative consumer behavior research (Murray and Ozanne 1991; Ozanne and Dobscha 2006; Ozanne and Saatcioglu 2008).

EXTENDED ABSTRACTS

“Co-Creating Alternative Markets: Consumer Efficacy in Risk Abatement”

Melea Press, University of Wyoming, USA

Many consumers are disappointed with the current food marketing system, and are concerned by the risks they feel they take and the compromises they make with preferred values by engaging with a system they do not fully trust (Rampton and Stauber 2001). In an attempt to mitigate their feelings of risk, some consumers engage in marketplace activities that lie outside of the mainstream (Beck 1992). Community Supported Agriculture (CSA) is highlighted here, as an example of how consumers are driving change in the marketplace by choosing to purchase products through non-mainstream channels.

Transformative consumer research (TCR) takes the approach that research should shed light on consumer issues, and help to improve consumers' lives (Mick 2006). In this paper, the consumer is not painted as a marginalized figure that lacks efficacy; rather, the exemplary consumers in this paper are proactive and engaged members of a community who are able to make choices that affect their own wellbeing, as well as the marketplace itself. In the case of CSA, the idea of TCR is turned on its head, as we look to consumers to show us how they engage in alternative market activities, and advocate for their own needs.

CSAs are programs through which consumers can purchase produce (and sometimes meat and dairy products) directly from a farm. Farms that offer CSAs typically meet organic growing standards, and express concern for the environment, the local food system, and the local economy (DeMuth 1993). These values and concerns are communicated through the marketing materials of the CSA, so that consumers are able to assess the level of values congruence (Posner and Schmidt 1993) between themselves and the CSA.

For many CSA members, buying food is not a low involvement purchase. Many of these consumers want to know where their food comes from, the growing practices that are used, their food production's carbon footprint, and information about how farm workers are treated, values that are shared with CSAs. These

concerns are often phrased in terms of risks that consumers are taking for themselves, their families, communities, and planet earth. The desire to manage these perceived risks, coupled with the lack of trust in the industrial agricultural system, and emergent beliefs that this system imposes sub-optimal outcomes on them, have led some consumers to seek out alternative purchasing opportunities (Thompson 2005). These consumers recognize their desires as well as their efficacy in the market system and seek out, find, and/or create purchasing opportunities that suit their needs.

CSA members balance risks by trading those they feel they cannot monitor for risks that are more manageable or at least closer to home. For example, when choosing to buy produce from a CSA rather than a grocery store, they trade uncertainty about how the produce was grown, and where it really came from, for the uncertainty that the weather in their region will be good enough during the growing season so that the farmer can actually grow produce to give to them. Other CSA members may choose to pay for the "hidden costs" of their food rather than live with the lack of information about how much petroleum has been used in the growing and transport of their produce (environmental concerns). By engaging in these activities to manage and control risk, consumers take a proactive and participatory role in creating a marketplace that fits their needs. They show themselves as able to leave the dominant social paradigm for an alternative that is a better fit for their needs and their personal values, and they show that they are able to participate in transformative activities on their own, outside the mainstream marketplace. CSAs are participatory market structures insofar as they are highly responsive to consumer concerns, and in turn, use their consumers as drivers of CSA marketing materials.

The value of the product purchased from the CSA goes beyond the produce itself, to include the emotional properties ("feel good" effects), the fit with their personal values (value congruence, see (Kalliath et al. 1999)), and the linking value of the product (Cova 1997) that joins the consumers with each other, and with their broader communities. The CSA is then positioned as an organization that fulfills a variety of needs for the consumer, from minimizing risk, to reinforcing personal values, to being a connection through which the consumer can participate in the immediate community. At no point do these consumers give up their efficacy for getting what they want from the marketplace. In fact, through their experiences with the CSA community, consumers find even more opportunities to engage in alternative purchasing behavior.

Interviews with 35 CSA members illustrate how these consumers use this alternative market mechanism, and what they gain from it. These consumers do not accept that their only option for food purchasing is their local grocery store, or even that the best option is the organic selection available at the grocery store. Rather, they have joined a grass-roots subculture, built on co-creation between producers (farmers) and consumers (CSA members). CSA members have opportunities to go to the farm and see the actual place where their food comes from, which allows them to assess the "hidden costs" of their food, as well as to learn about growing practices the farm uses. These consumers also take home extremely fresh produce (often harvested less than 24 hours before they receive it), which they highly value for perceived taste differences, improved storage quality, and the belief that the food is not only good for them, but also helps keep money in their local economy and is good for the planet.

Unlike traditional views of values and value congruence, values in CSAs are not static systems (Schwartz and Bilsky 1987). CSA members demonstrate an iterative evolution in their personal values, and in the importance they place on the products they receive from the CSA and the market structure. By going outside of the mainstream market and purchasing produce from farmers who

they know, from a farm they can actually visit, CSA members assuage several of the risks that come with mass-produce food (Rampton and Stauber 2001). What is perhaps most interesting, though, is the personal transformations that CSA members experience, which seem to be strongly influenced by the co-creative process of the community, coupled with the evolution of values. These changes include differences in eating habits, thinking about food and health, preparation of food, the way food is consumed (i.e. with other people vs. alone), and the role of food preparation and meals in the household.

Community Supported Agriculture (CSA) is just one example of ways in which consumers can change the marketplace by choosing not to be involved in typical options. Through this assertion of their needs, consumers drive change, and create new market opportunities that better address their concerns about the products they are buying. CSAs provide us with an opportunity to enrich our understanding of the role of the consumer in TCR.

"Rising from the Wreckage: Personal Responsibility vs. Social Welfare in Tornado Recovery"

Stacey Menzel Baker, University of Wyoming, USA

Ronald Paul Hill, Villanova University, USA

David M. Hunt, University of Wyoming, USA

This paper explores the competing consumption ideologies of personal responsibility and social welfare and shows how these constructs are not on opposite ends of a continuum, but instead are multi-faceted and domain specific. This theoretical argument extends beyond the specific empirical context we explore here, namely rural community recovery after a disaster, to show how conflict over consumption ideologies is a necessary condition for community recovery.

In August of 2005, a tornado hit a rural community (pop. ~1500) in the Mountain West. Two people died, 25 percent of the population was left homeless, and the disaster was declared a state and national emergency. Focus group and depth interview data gathered from January through November 2006 serve as the primary data for analysis, while newspaper accounts and other written materials since the time of the tornado are used to illuminate the context. Our discovery-oriented approach was guided by a desire to employ and extend theory (Wells 1993) and by a desire to improve human welfare (Ger 1997; Murray and Ozanne 1991). The theory developed here illuminates competing consumption ideologies and describes how the nature of a market mediates the disaster recovery process.

Data show that residents of this community did not just passively accept external mandates and consumption constraints; instead, they actively and constructively resisted the domination of (1) the tornado and (2) the disaster relief procedures, often referred to as the second disaster (Myers 2008). Guiding residents' grassroots recovery efforts were two competing consumption ideologies. A consumption ideology is a system of meaning reflected in attitudes and behaviors that aim to maintain the interests of dominate groups in society (Hirschman 1993). To understand the competing ideologies, we must first understand the form and content of each ideology and then see how these ideas are reflected in the actions guiding recovery efforts. In this situation, competing ideologies were evident in (1) specific consumption behaviors that helped move people toward a changed state of existence, (2) conscious decisions to deviate from the expected (e.g., breaking rules set by FEMA), and (3) in the rhetoric of the conflict between the victims and policy-setting groups in the community.

The central assumption of the ideology of personal responsibility is that individuals should take care of their own problems, or "Cowboy Up" as locals would say. This ideology was reflected in

the rhetoric and actions witnessed during the recovery process: a quick clean up conducted almost entirely by resources available within the community; beliefs about whether people should have had or should now have insurance; taking storm spotting classes to empower one's self to spot tornados; and so forth.

The ideology of social welfare is to take care of your neighbor and those less fortunate, as reflected when the locals say, "we may be out here in the middle of nowhere, but we're out in the middle of nowhere together." In tornado recovery, this ideology was reflected in perceptions that those who were more victimized (less fortunate) needed more care and illustrated when community members came together to account for victims; help reunite families with their belongings; help sort valuable from valueless objects; dispose of rubbish; donate goods; volunteer time; etc.

Consumption ideologies address problems of identity construction and reconstruction and guide decisions on how to resolve conflicts (Arnould and Thompson 2005). In this community, solutions to problems about identity reconstruction at both the individual and community level and about conflict between victims and policy makers were developed at the grassroots level, which is consistent with FEMA's guiding principle that disasters are local. To understand how solutions evolved and how competing ideologies were operationalized, it is important to understand the nature of the market in Wright. Wright is a relatively isolated community with limited services including one general contractor and one grocery store. Wright residents were already in the habit of going elsewhere to have their consumption needs met. In addition, most community members are employed in mining and ranching and possess the skills and equipment common to those industries (e.g., disaster training, heavy equipment such as tractors and dump trucks). In other words, Wright has a mobile population with mobile resources. The nature of the market in Wright mediates the lifestyles of the 'hunters and gatherers' who reside there. In some ways, these market conditions facilitated recovery because people were not dependent on the market to provide their necessities. In other ways, these market conditions mandating independence detracted from recovery, as people thought they should be able to take care of themselves, which is difficult when one is in a fog and has limited resources (85% of victims were uninsured).

When one compares this community's experience to what we know about recovery in larger communities, we can understand why recovery is so difficult. For example, Hurricane Katrina hit New Orleans two weeks after this tornado struck. Though people in this community are relatively recovered, at least from a market and consumption stand point, residents in New Orleans appear to continue to struggle. People are still undecided about purchasing or leaving FEMA trailers, etc. The difference in recovery is in part explained by the nature of the market. In New Orleans, people were totally dependent on the market to provide for their needs; whereas in this community, residents were used to employing market resources as inputs to the process of fending for themselves. Thus, from a theoretical standpoint, not only does the market mediate the lifestyle, it mediates the ideologies underlying that lifestyle and the way in which individual and community identity construction and reconstruction occurs.

"Social Strain as an Antecedent of Innovativeness among Subsistence Consumers"

Stephanie Geiger-Oneto, University of Wyoming, USA

Jose Antonio Rosa, University of Wyoming, USA

Transformative consumption and innovativeness are virtually inseparable. That is to say, consumers involved in transformative consumption creatively extract meaning and benefit from products or services and transform both themselves and the product in the

process. We can consequently think of transformative consumption as depending on 1) consumers recombining past knowledge and experience into novel arrays and 2) on those arrays producing valued outcomes, i.e., on consumers being innovative (e.g., Amabile 1996). Moreover, transformative consumption and innovativeness do not have to be discontinuous and occur more frequently than most people imagine. To recognize the ubiquity of transformative consumption we need look no further than the behaviors of consumers in resource constrained environments, noting how they create beneficial artifacts from what others discard, and transform their lives through the process.

Inquiry into consumer innovativeness has a long history in consumer research (e.g., Hirschman 1980, Ram and Jung 1989 and 1994, Price and Ridgway 1983, Ridgway and Price 1994, Burroughs and Mick 2004, Moreau and Dahl 1995), and has given us valuable insight into the process and its antecedents and consequences. Recurring themes are that innovativeness is draining and risky. Consumer innovativeness involves taking products and services beyond the uses for which they were engineered. In addition, consumers that engage in the innovative redefinition of artifacts work outside their domains of expertise, and learn about the possibilities and boundaries of their novel arrays through experimentation. All innovative consumers engage in such risky concerted efforts; and in the case of resource constrained consumers the risks may be more pronounced. Driven by survival needs and resources constraints, many poor consumers engage in creative endeavors daily. Moreover, they often place a higher proportion of their limited resources at risk in innovative experiments than more affluent consumers.

In order to gain a better understanding of innovativeness among subsistence consumers, we conducted exploratory ethnographic studies in several countries, in both rural and urban contexts. Participants were first asked to identify members of their communities who they felt engaged in innovative behaviors. Once identified, we interviewed those considered to be innovative and documented both their creations and their development process. We also inquired into what inspired them, what they sought to accomplish, and the general history surrounding their innovations. We learned much about the trial and error process by which they develop products to sell in the marketplace and services to augment their products, and how they persist in innovative behaviors to sustain or improve their businesses. We also learned much about their feelings, triumphs, disappointments, and aspirations.

One lens through which to view the innovativeness of subsistence consumers is Agnew's General Strain Theory (1992). The theory argues that consumers who engage in innovative behavior do so to cope with negative emotions caused by social inequality and disappointment or frustration with their own social position. Although individuals may experience many types of strain (i.e. economic, environmental, and emotional) during the course of their lives, innovative behavior is more likely to be observed from individuals who believe their current undesirable state is due to circumstances beyond their control. For example, subsistence consumers who adopt specific goals (i.e. financial stability, education for children) may resort to innovative behaviors that push existing technologies in new directions because they see themselves as having no other options (Agnew 1992). They work around the system because they believe the system will not provide them with opportunities to advance their social status. In modern societies, moreover, the strain can be exacerbated if consumers are exposed to media images that suggest the consumption of certain products will lead to more idyllic lifestyle. A gap between the culturally-induced aspirations of the poor and their opportunities for achieving them forces innovative subsistence consumers to develop their own

methods of obtaining or approximating (through do-it-yourself concoctions) the branded consumer goods shown in the media. Unfortunately, they often do so without awareness of the dangers of product misuse or abuse, or the toxicity of the ingredients used to create the goods.

At the level of the individual level, we find that engaging in addition to the transformations that innovativeness in consumption can entail, innovative behaviors can provide relief from negative affect such as status frustration. According to Agnew (1992), consumers experience status frustration when they recognize a gap between status expectations and actual achievement, and the frustration (negative affect) triggers pressure for corrective action as an avoidance mechanism. The pressure can in fact be a stronger motivator for consumer innovativeness than their desire for transformative outcomes. One informant, for example, compromised his successful all-purpose cleaner business by experimenting with and distributing a "new" recipe to customers who favored the old one. When asked why he experimented in this manner the response was "just in case this one works better, despite the fact that his new innovation led to a loss of customer loyalty, and ultimately impacted his family's income and well-being." It seems plausible that the process by which his innovations were created provided him with a release from status frustration that was more valuable than the product itself. More than one of the subsistence consumers we encountered engaged in similar behavior, and we continue to distill the factors that influence whether or not innovative behavior as a coping strategy can become dysfunctional.

At a macro level we also find that not all instances of transformative consumption and innovativeness are positive, in part because the innovation process among poor consumers is inextricably social. Most poor consumers engage in innovation to benefit their families directly or to create transformative experiences they can sell to others, and the boundaries between being a producer and a consumer are fuzzy. To improve their creations, innovators rely on a continuous flow of conversation with customers. These conversations may be used to discuss existing products, possible new products, or to generate transformative problem solutions. One unfortunate consequence of this informal process is that experimentation with existing products is seldom conducted in controlled environments and therefore lacks the necessary safeguards. Suggestions arising from conversations are quickly tested but seldom documented, and the outcomes are better remembered than the process that yields them. In addition, when new product concepts prove to be ineffective or harmful, it is those closest to the innovator who may pay the price because they are often the guinea pigs used to test them. Moreover, the disposal of experiments gone awry is often done with the same abandon as the experimentation, contaminating their home environments and those of neighbors and further eroding the subsistence consumers' already fragile health.

SYMPOSIUM SUMMARY

Consumer Perceptions of Value and Price

Leif D. Nelson, University of California, San Diego, USA

SESSION OVERVIEW

There is a (deeply hypothetical) world in which the link between price and value is simple and intuitive. In this world, marketers set prices that reflect some combination of the amount of money they need and the amount the customer is willing to pay. Customers look at a product on the shelf, decide how much they want it (in currency), and if the price is below that level, they decide to buy. Consumer research has suggested that this simple and intuitive world is a mediocre proxy for its complex and confusing reality. This symposium presents four papers investigating the relationship between value and price in an effort to further the understanding of how these factors play into the perceptions of consumers.

In a hypothetical pricing world, people first evaluate a product and then ponder that value in relation to its price. In reality, the price can influence evaluation. Numerous studies have found that increased prices increase evaluations. The first paper (Gneezy, Carmon, and Nelson) shows that even this peculiar finding is more complicated than it seems. When prices are raised to particularly high levels, they find, perceptions of quality are reduced. A cookie that was tasty at one price is spontaneously a lot less palatable at a higher price.

Intuitively, fees should reduce consumption. The second paper (Lee and Norton) challenges this assumption, by showing that fees can increase consumption. The authors consider the influence of membership fees and find a surprising result: fees increase subsequent spending. People assume that fee-requiring stores must offer low prices and so go on to buy with the belief that they are finding great deals. Paying for the privilege to shop may seem like a deterrent to customers, but the company that charges such a fee may benefit not only from revenue from membership, but also from increased sales.

If nothing else, marketers should have some mastery of consumer price sensitivity. The third paper (Hsee and Shen) suggests that this is not true either. Marketers, because they are jointly evaluating multiple price possibilities, generate fundamentally different prices than their separately evaluating customers. Joint evaluation necessarily leads to extreme price sensitivity, whereas separate evaluation (in the absence of more knowledge of price distributions) should lead to general price insensitivity. For new and unfamiliar products, marketers tend to set prices too low.

Perhaps the most well known pricing peculiarity is the *endowment effect*, in which randomly assigned ownership produces systematically higher selling prices. Classically, this has been interpreted as consistent with loss aversion and prospect theory. The fourth paper (Weaver and Frederick) offers a new account. Consumers compare trades to market prices (which typically exceed consumer value), and increase their reservation prices to a point where they think they would be getting a good deal.

These four papers take very different approaches to a related problem, so we are lucky to have an expert on the dynamics of pricing and value as our discussant. Dan Ariely is an expert in experimental psychology and consumer research, and has authored numerous articles on related topics, and recently published a best-selling book about some related research.

EXTENDED ABSTRACTS

“Getting Less Than You Pay For: Very High Prices Lead to Inferences of Very Low Quality”

Ayelet Gneezy, University of California, San Diego, USA

Ziv Carmon, INSEAD, Singapore

Leif D. Nelson, University of California, San Diego, USA

Consumers often lack the time, training, or inclination to judge the actual quality of a product or service. Accordingly, to infer quality they seek simpler alternative signals (cf. Aaker 1991) like the product's country of origin, how heavily it was promoted, or its price (Huber and McCann 1982; Rao and Monroe 1989). As a result, considerable evidence demonstrates that higher priced products are judged to be higher quality (see e.g., Gerstner 1985; Riesz 1979). One step further, price and brand name, for example, can influence actual consumption experience (e.g., Allison and Uhl 1964; Levin and Gaeth 1988). Finally, prices have been shown to produce placebo effects, as products identified as price-reduced are less effective than products identified as full price (e.g., Shiv, Carmon, and Ariely 2005; Waber, Shiv, Carmon, and Ariely 2008).

Do higher prices always lead to inferences of higher quality? In this paper, we illustrate that truly high prices actually reduce perceived quality. In a pilot study, three groups of participants were given an unfamiliar cookie to taste and rate. To create a slightly negative experience for participants we served cookies that we had strategically allowed to become stale in the week prior to the experience. Participants were informed that the cookies were now being sold on the market, and were told one of three possible prices (low, medium high). Replicating past research, the moderately priced cookie was judged to be tastier than the lower priced cookie. But most notably, participants tasting the high-priced cookie judged it to be *lower* quality than participants in either of the other conditions.

In our next study (Study 1) we wanted to see if variation in actual product quality moderated this effect. We employed the same three price levels as in the pilot, but this time we presented only approximately half of the participants with a stale cookie whereas the remainder received a cookie taken from a freshly open package. Replicating the pilot results, when participants tasted a stale cookie a moderate priced cookie was judged more favorably than a low priced cookie, but the high priced cookie was judged more negatively than both. For the comparatively tasty cookies, there was a linear relationship between price and inferred quality: moderate priced cookies tasted better than low priced cookies, and high priced cookies tasted better than both. When prices are vaguely in line with actual quality we found a standard price-quality link, but when prices were more obviously out of line, the price-quality link was reversed.

Perhaps consumers are merely drawing on an unusual theory of the relationship between price and quality? If so, then people should predict the above results regardless of actual consumption. A follow up study (Study 2) then distinguished between two possible causes of the effect: (1) judgments of the quality of the high priced product as lower than that of the moderately priced product, reflect lower quality expectations; (2) an alternative cause could be that these judgments reflected contrast between expectations and the consumption experience. Our results support the latter cause—

high priced cookies were assessed as being of significantly higher quality.

Finally, we sought to investigate how higher prices influence perceived quality (Study 3). Lee and his colleagues (Lee et al. 2007) have argued that information can operate on experience only if it is presented prior to consumption. With that in mind we replicated the moderate and high priced conditions from the previous study, while manipulating whether price information was presented prior to consumption or after consumption (but before reporting a quality measure). If the earlier findings are due to an explicit rescaling effect or a recasting of quality relative to expectation, then the manipulation should have no effect. If, on the other hand, high prices fundamentally change the experienced flavor of the product as we predict, then we should only replicate our effects when the price is presented before consumption. We found strong support for the latter: if people were told the price before tasting, the expensive cookie tasted much worse than the moderately priced cookie, but when told the price afterwards this effect was entirely eliminated.

Significantly, within the same experiment, participants sampled two much more familiar product categories (water and tissue paper). We predicted that product novelty would be crucial to our effects, but though much smaller in magnitude, the effects persisted for these product categories as well. Perhaps even the consumption of well known products can be enhanced or undermined by mere price perception.

“The “Fees → Savings” Link, or Purchasing Fifty Pounds of Pasta”

Leonard Lee, Columbia University, USA

Michael I. Norton, Harvard University, USA

Discount membership clubs have a large and growing presence in retail—one recent survey reported that Costco sells to 1 in every 11 people in the United States and Canada, and warehouse clubs are estimated to be a \$120 billion industry today in the United States alone. As a result, more and more people have had the experience of entering one of these popular clubs and leaving hours later with more goods than can fit in their car and enough pasta to outlast a nuclear winter; at minimum—as is the case with at least one of the authors—many are familiar with a family member who engages in this kind of behavior.

One rational reason for such behavior is that membership clubs offer lower prices (due to volume discounts and lower overhead), but we suggest that the presence of membership fees alone—independent of the actual savings on any given product—spurs this increased spending, due to perceptions of “good prices.” What might account for this generalized belief in the savings offered by discount clubs? We suggest that membership fees required for the consumption of a brand or service signal dominance on the dimension most salient to the particular brand or service: for country clubs, higher fees might signal greater exclusivity; for health clubs or healthcare plans, fees may signal higher service quality; for discount stores such as Costco or Sam’s Club, where the most salient dimension is cost savings, fees may signal greater price discounts. The presence of fees at membership stores thus may instantiate an implicit norm with consumers (see Grice 1975): “We wouldn’t charge you this fee if we weren’t making it worth your while,” leading consumers to infer a “fees → savings” link.

In a series of studies, we created our own membership clubs and sold goods to participants in our stores. Some participants were allowed to purchase whatever they liked; other participants, however, were informed that the store charged a fee, which they were required to pay before making a purchase. We show that 1) the presence of fees increases spending and overall store profitability

(despite people’s predictions to the contrary); 2) fees serve as a signal of price, such that stores that charge fees are perceived as offering better deals.

In addition, another study showed that the mere presence of fees may drive choice of retail outlets: when we presented participants with newspaper advertisements for stores that mentioned membership fees, such stores were preferred to stores which did not mention fees—even when both stores offered similar goods at similar prices. Finally, we explore the impact of fees on memory: several field studies show that reminding people of membership fees paid in the past (for health insurance and gym memberships) lead them to remember having used those services more. In sum, fees lead retailers to make more money both on increased sales and, ironically, on collecting the fees that cause these increased sales, and also lead customers to see themselves as more frequent users of that outlet, a potentially important precursor to customer loyalty.

Our results seem to suggest that consumers behave irrationally in response to membership fees, attributing low prices to the perceived savings offered by retailers that charge fees, and then trying to capitalize on these seeming savings by buying more than they otherwise would. At the same time, however, the feeling of getting a good deal—whether erroneous or not—likely has positive (transaction) utility for these consumers (Thaler 1985), which would only be increased the more items placed in one’s shopping cart. In addition, this transaction utility gained from perceived savings is unlikely to be offset by regret upon encountering a better deal, given the difficulty of comparing prices at other retailers. Although some utility may be offset by the vocal displeasure of the shopper’s loved ones when forced to lug groceries into the house for 30 minutes, consumers may on average come out ahead despite their overgeneralized perception of the link between fees and savings.

“Marketers Mispredict Price Elasticity”

Christopher Hsee, University of Chicago, USA

Luxi Shen, Fudan University, China

Price elasticity is a key concept in economics and marketing. It reflects how consumers’ demand for a good varies as the price of the good varies, and thus reflects consumers’ sensitivity to price variation. What determines price sensitivity? Can marketers accurately predict consumers’ price sensitivity?

We propose that an important determinant of consumers’ price sensitivity toward a good or service is their familiarity with the distribution information (including reference, range, etc) of the price of the given good or service. Consumers are more price sensitive when they have more price information (e.g., the price of a can of Coke) than when they have less (e.g., the price of a newly-introduced soft drink).

Marketers know much more about price distributions than do ordinary customers, and for this reason systematically overestimate consumer price sensitivity. Specifically, marketers, when pricing a product, must jointly evaluate (JE) alternative possible prices by juxtaposing those possibilities. However, consumers, when deciding whether to purchase a product, are usually confined in the single evaluation mode (SE) in which they only see the finally offered price. Consumers know much less about price ranges than do the marketers who set the price.

This mismatch in evaluation mode should lead marketers to overestimate consumers’ price sensitivity with unfamiliar products, and as a result, should lead them to systematically underpricing their products or services.

Our research is important for at least four reasons: First, it addresses a fundamental issue in economics and marketing: price

elasticity or price sensitivity. Second, this is the first research showing that the mismatch in evaluation mode between marketers and consumers would not only lead marketers to mispredict consumers' price sensitivity, but also leads to reduced profit. Third, we identify that product familiarity serves as a crucial moderator of this mismatch. Finally, we show that the effects we described above occur not only when marketers are 'placed' in the JE mode (that is, they are shown alternative prices), but also when marketers are naturally in the JE mode (that is, they are simply asked to set the price for the target good). We assume that to set a price, marketers would naturally consider alternative prices and naturally found themselves in the JE mode.

We tested our ideas in six studies involving different contexts (ranging from taxi ride, coffee beans, puzzles, etc.), different dependent variables (willingness to pay, and purchase intention), and involving both hypothetical scenarios and real purchasing behavior.

In one study, for example, some participants assumed the role of marketers and some assumed the role of consumers. The marketers either set the price of a taxi ride (familiar) or of a horse ride (unfamiliar). Consumers were resented with these prices and asked whether they would purchase the service at that price. As predicted, marketers overestimated consumers' price sensitivity and therefore underpriced the horse ride but not the taxi ride.

In another study, the target product was a set of psychological tests. As in the horse-ride/taxi study, we also asked some research participants to assume the role of marketers and to make a price decision on the tests, and asked other participants to assume the role of consumers and to make a purchase decision regarding the tests. For half of the marketers and consumers (the familiar condition), there was a reference price for the target product for both marketers and consumers; for the other half participants (the unfamiliar condition), there was no reference price to either marketers or consumers. Unlike the horse-ride/taxi study, this study involved real consequences to both the marketers and the consumers, that is, marketers could earn profit by selling the tests and consumers had to pay to get the tests. Again, the study confirmed our predictions: In the price-unfamiliar condition but in the price-familiar condition, marketers overestimated consumers' price sensitivity, set too low a price, and consequently made less profit than they otherwise could had if they had set a higher price.

This research has both theoretical implications for what influences price elasticity, and prescriptive implications for how to improve profitability by improving marketing prediction accuracy.

"Transaction Disutility and the Endowment Effect"

Ray Weaver, Harvard University, USA

Shane Frederick, Massachusetts Institute of Technology, USA

Buying and selling are different expressions of the value one places on a good, with money as the medium for this expression. Accordingly, the minimum amount an owner requires to relinquish an item should correspond closely to the amount a non-owner is willing to pay for it. In fact, however, this presumption is often violated: in a review of 59 studies involving market goods, Horowitz and McConnell (2002) found that minimum selling prices exceeded maximum buying prices by a factor of nearly three. This *endowment effect* is commonly attributed to loss aversion (Thaler, 1980): people are assumed to compare potential trades to the status quo, and to feel losses from their current holdings more keenly than gains. According to this model, selling prices exceed buying prices because owners charge a premium to offset the psychological pain they expect to feel when they give up possessions.

We propose an alternative explanation: the endowment effect is caused not by the anticipated pain of losing possessions, but by

a reluctance to trade on terms that are perceived to be disadvantageous or unfair — an experience Thaler (1985) calls *transaction disutility*. Stated maximum buying or minimum selling prices are based on the value consumers expect to get from ownership, but can be influenced by concerns about making "bad" deals. Consumers judge potential deals against some reference price (r), and experience transaction disutility whenever trading at their valuation would be unfavorable with respect to that price. That is, non-owners dislike stating reservation prices that are greater than r , and owners dislike stating reservation prices that are less than the r . In this way, transaction disutility tends to distort buying prices downward and selling prices upward, away from underlying values.

The degree of transaction disutility depends on the relationship between a consumer's valuation and r , and therefore may affect buyers and sellers asymmetrically. Suppose, for example, that valuations for a coffee mug vary uniformly between zero and ten dollars. If the mug's reference price is eight dollars, transaction disutility will have a large influence on potential sellers because for most people, selling at their valuations would be a bad deal. Conversely, it will have little effect on potential buyers, most of whom could pay their valuations without making a bad deal.

Reference prices are usually based on market prices, which typically exceed the value most consumers place on products: consumers turn down the opportunity to buy most goods in the marketplace. Supermarkets, for example, carry tens of thousands of items, but each shopper buys at most a few dozen on a given trip and repeatedly declines to purchase almost everything else in the store. Like the pain-of-losing account, our account of evaluation disparities implicates sellers rather than buyers. That is, we argue that buying prices closely mirror underlying valuations, whereas selling prices significantly exceed them. In contrast to the pain-of-losing explanation, however, we attribute this to the incidental fact that reference prices are generally high, rather than to a fundamentally different consideration on the part of sellers, namely an aversion to parting with possessions.

In four experiments, we test our model. Study 1 shows that reducing r from a high (typical) level to a more moderate level alleviates sellers' transaction disutility, shrinking the endowment effect. Consumers were assigned to the role of either buyer, then asked the maximum they would pay for a box of "movie theater" candy; or given a box of candy and assigned to the role of seller, then asked the minimum they would demand to sell it. The ratio of selling prices to buying prices was greater among subjects who were suggested a high r ("the Harvard Square Theater sells this candy for \$4.00") than among those given a moderate r ("Target sells this candy for \$1.49").

Our model predicts that very low values of r (i.e. below most consumers' underlying valuations) will induce transaction disutility in *buyers*, causing a disparity driven by a reluctance to buy, not to sell. Study 2 confirms this prediction. Consumers were randomly assigned to the role of either buyer or seller, shown a picture of a 1925 buffalo nickel, and told, "A randomly chosen person who took this survey before you would [pay at most] [sell for as little as] \$ x ," where x varied from \$0 to \$20. Consistent with our model, we found that the magnitude of the endowment effect was a U-shaped function of r . When r was low, the gap was large because of deflated buying prices; when r was moderate, the gap was small because neither buying nor selling prices were severely distorted; and when r was high, the gap was again large, this time because of inflated selling prices.

In Study 3, we show that internally-generated r 's function similarly as externally-provided ones. We asked consumers for maximum buying or minimum selling prices for two domestic airline tickets. We then asked them to estimate the market price of

those tickets. Among people who estimated a high market price, the endowment effect was substantial. But there was no endowment effect among people whose market price estimates were similar to their valuations.

The pain-of-losing account of the endowment effect suggests that owners who value a good most highly will anticipate the most psychological pain from its loss, and therefore that the gap between buyers and sellers will be largest among these “fans.” Our transaction disutility model, however, predicts the opposite: given a relatively high r , selling prices will be similarly inflated among both fans and non-fans. But buying prices, which more closely reflect underlying values, will be higher for fans. Study 4 confirms our account. We categorized people as video game fans or non-fans according to how often they play and whether they own home video game systems. For a Nintendo Wii system, the endowment effect was larger for fans than for non-fans.

Our experimental evidence supports our hypothesis that an aversion to bad deals, not an aversion to losing possessions per se, causes buying and selling prices to diverge. The results also suggest that marketing efforts designed to make favorable reference prices salient will be more effective than those that try to instill a sense of ownership in potential customers.

SYMPOSIUM SUMMARY
Positive Emotions–Theory and Application
Michal Herzstein, University of Delaware, USA

SESSION OVERVIEW

Positive emotions have been gaining more empirical attention in the last decade. The objective of this symposium is to examine the theory and application of the effects positive emotions, both specific and general, have on a range of contexts, such as motivation, choice, assessment, and risk propensity. The research presented contributes to the emotions and decision making literature by examining new effects of important specific emotions, investigating the influence of the source of the emotion on choice, and investigating applications in health care.

The first paper shows that specific positive emotions, joy and contentment, lead to different outcomes: individuals who experience joy are more likely to use approach motivation, find gain-framed messages more compelling (and change actual behavior), and be more risk seeking; individuals who experience contentment are more likely to use avoidance motivation, find loss-framed messages more compelling, and be more risk averse. The second paper focuses on attribution of one's positive mood, either to the self or to the environment. If happiness is attributed to the self, individuals are more likely to focus on internal sources of happiness (one's behavior) rather than external sources of happiness (e.g., chocolate). The reverse is true for unhappiness. The third paper shows that physicians who experience positive emotions (vs. neutral emotions) toward their patients (empathy and sympathy) tend to overestimate the risk associated with high severity diseases and offer a larger range of treatments.

EXTENDED ABSTRACTS

“All Positive Emotions Are Not Created Equal: The Case of Joy and Contentment”

Michal Herzstein, University of Delaware, USA

Meryl Gardner, University of Delaware, USA

Positive emotions, with happiness as their representative, have been shown to promote approach behaviors because the enhanced feelings of energy and vigor increase the subjective perception that one is capable of performing these behaviors (Cacioppo et al. 1993). In this paper we investigate two distinct positive emotions, joy and contentment, and find that they have a different influence on individuals' choice of motivation and consequently their behavior. We focus on these emotions because while both are positive, they are distinct and therefore easy to manipulate and measure (Fredrickson and Branigan 2005). Building on previous literature (Fredrickson 1998) we suggest that joy is consistent with the approach system because it is a high arousal positive emotion that creates the urge to be playful, involves exploration, invention, and prompts individuals to be more willing to experience new things. We further suggest that contentment is more consistent with the avoidance system because it is a low arousal positive emotion that prompts individuals to savor their current life circumstances and recent successes, which prompt a mood regulation behavior.

We test our predictions in four experiments, in which we manipulated emotions using two short clips (c.f., Fredrickson and Branigan 2005), one elicits joy and the other contentment. A pretest and manipulation checks in all experiments show a significant difference in the levels of joy, contentment, and activation reported by participants, and no difference in pleasantness level.

In experiment 1A we wished to create a situation that encourages avoidance behavior (participants expected to be punished for sub-performance); in experiment 1B we wished to create a situation that encourages approach behavior (participants expected to be rewarded for good performance). The main dependent variables were nervousness level (in 1A) and happiness level (in 1B), because according to Carver and White (1994) these emotions are indicators of avoidance and approach behaviors respectively. As expected, in experiment 1A we found that participants in the contentment (vs. joy) condition reported a higher level of nervousness, indicating that when individuals experience contentment they are more likely to use avoidance motivation. Similarly, in experiment 1B we found that participants in the joy (vs. contentment) condition reported a higher level of happiness, indicating that when individuals experience joy they are more likely to use approach motivation. Next we explore whether joy and contentment lead to the downstream consequences prescribed by the approach and avoidance systems.

Sherman et al. (2006) show that when a health message is congruent with individuals' motivation, it is more effective in promoting health behaviors. Specifically, approach motivation was found to be congruent with gain-framed messages while avoidance motivation is congruent with loss-framed messages. Experiment 2 employed a 2 (emotion: joy vs. contentment) x 2 (framing: gains vs. losses) between subject design to test the prediction that participants who experience joy will find a gain-framed message more appealing, and participants who experience contentment will find a loss-framed message more appealing. Participants read an article about flossing, which either stressed the benefits of flossing or the negative outcomes of not flossing. Results show that there were no main effects of emotions or framing, but there was a significant interaction of emotions x framing on article effectiveness (measured during the experiment) and actual behavior (# of times participants flossed in the week following the experiment.)

The aim of experiment 3 was to test the influence of joy and contentment on risk propensity. Previous research (Friedman and Förster 2002; Dweck and Legget 1988) suggests that when individuals use approach motivation they tend to be more risk seeking because they welcome challenge and use explorative processing; when individuals use avoidance motivation they tend to be more risk-averse because they use systematic and perseverant processing to avoid negative outcomes. We hypothesize that in the gain domain joy leads to risk seeking while contentment leads to risk avoidance, and the reverse in the loss domain. We are currently collecting data to test our hypothesis. Initial results are in the direction hypothesized.

In experiment 4 we tested whether there is a differential effect of our target positive emotions on variety seeking, a behavior more congruent with the approach system. Kahn and Isen (1993) show that positive emotions, with happiness as their representative, lead to variety seeking. We suggest that this holds for joy but not for contentment, because individuals who experience joy are more likely to use approach motivation and be more risk seeking—trying different known and unknown brands, while individuals who experience contentment are more likely to use avoidance motivation and be more risk averse—confining their choices to a small set of familiar and liked brands. We tested this hypothesis by asking participants to make choices from a list of brands of crackers, some were known American brands and the other were fake brands.

Results show that compared with participants in the contentment condition, those in the joy condition chose more brands, more unfamiliar brands, and switched more.

In sum, our research shows that not all positive emotions were created equal. While we find that joy leads to consequences similar to those found in the literature for happiness (approach motivation, congruency with the gain-frame, risk seeking (in the gain domain), and variety seeking), contentment leads to a different set of consequences (avoidance motivation, congruency with the loss-frame, risk avoidance (in the gain domain), and the choice of a small number familiar brands). Our findings imply that these are two distinct, equally strong, while equally positive emotions. Implications of our results will be discussed.

“Do You “Work to Live” or “Live to Work”? The Role of Mood and Confidence in Causal Agency”

*Aparna A. Labroo, University of Chicago, USA
Nidhi Agrawal, Northwestern University, USA*

Take a trip to the Workaholics Anonymous website (<http://www.workaholics-anonymous.org/knowing.html>) and take their test on whether you are a workaholic. You will probably discover that you are a workaholic. ABC news reports that a growing number of Americans are discovering that they live to work rather than work to live. Recent research also suggests that for the most part, people are likely to over-engage in activities that presumably better them in the long term at the cost of activities that help them feel better in the moment. Are people working harder because this will provide material wellbeing that will allow them to indulge in the moment, or do they derive happiness from engaging in activities usually associated with immediate effort and negative feelings?

We investigate when and why people might demonstrate a tendency to over-engage in actions that are in their long-term interests over those that might improve their immediate feelings. Our basic proposition is that there are two modes of happiness—internal happiness which results from feelings of personal development, including things that are in our long-term interests, and external happiness which results from the consumption of material goods that immediately make us feel better—and one is the default of the other. People’s choice of internal rather than external modes of happiness depends on their confidence in the self as the agency responsible for their happiness. In contrast, the choice of external rather than internal modes of happiness depends on their confidence in the environment as the agency causing their happiness.

High confidence in the self as an agent of happiness increases actions that result in personal development and investing effort in things in ones long-term interest. This is because seeing the self as responsible for happiness leads people to believe that unless they invest in their self growth and work they cannot be happy. In contrast, high confidence in the environment as an agent of happiness increases indulgent actions because happiness is seen to result only from external sources such as the consumption of hedonic or material goods. As a consequence, happy people are more likely to engage in activities that lead to long-term personal development rather than external happiness from indulgent actions when they are confident that the self (vs. environment) causes happiness. On the other hand, people feeling unhappy who are confident that the self (vs. environment) is the cause of unhappiness look externally for happiness and reduce long-term actions over indulgent ones. Additionally, confidence in the environment as agent of unhappiness would imply a need to work to resolve the problems caused by the environment. When confidence in agency is low and people doubt that the self (vs. environment) is the agency of ones happiness, their

reliance on the environment as the cause of their happiness increases and they engage in increased hedonic consumption consonant with seeking external sources of happiness. The reverse is true when people doubt that the self (vs. environment) is the agency of ones unhappiness. These predictions are tested in a series of experiments.

Experiment 1 employed a 2 (mood) x 2 (high confidence in internal vs. external agency) between-subjects design to see the effects of these factors on self-control in choice. We find that that happy participants making attributions to internal (vs. external) agency are more likely to make choices that are consonant with their long-term personal development (i.e., dieters choose an apple) rather than seek external happiness (i.e., choose a chocolate). The reverse is true for unhappy participants making attributions to internal (vs. external) agency.

Experiments 2a and 2b employ a 2(mood) x 2 (low confidence in internal vs. external agency) between-subjects design to test our predictions but use different manipulation of confidence in agency. It is demonstrated that that when participants in a positive mood make attributions to internal (vs. external) agency but are low in confidence in agency, they are less likely to make choices endorsing personal development and long-term benefits (e.g., say they will get tested for herpes even though they think they are less likely to have the disease). The reverse is true for negative participants who have low confidence in an internal (vs. external) agency as responsible for feelings.

Experiment 3 employs a 2 (attribution of happiness to internal vs. external agency) x 2 (confidence in agency) between-subjects design to demonstrate that happy participants with a high confidence in an internal (vs. external) agency are more likely to endorse activities that result in long-term personal development even if they involve short-term effort. In contrast, happy participants with a low confidence in an internal (vs. external) agency are less likely to endorse activities that result in long-term benefits and more likely to endorse indulgent activities that conflict with long-term personal development.

Experiment 4 studied these effects while focusing on an external agency. In a 2 (mood) x 2 (high vs. low confidence in external agency) between-subjects design, it demonstrates that happy participants who are high (vs. low) in confidence in external agency are more likely to make material choices that reflect seeking external modes of happiness. Unhappy participants who are high (vs. low) in confidence in external agency show reversed effects. Across these experiments, confidence in agency is manipulated in a variety of ways, by instructions, by ease of attribution manipulations such as generating one versus seven instances implicating the agency and using dominant versus non dominant hand writing about agency, and by employing emotions that naturally vary in confidence (e.g., happiness vs. hope).

The literature has suggested that wanting to feel good leads to short-term oriented indulgent choices. We suggest that attributing happiness to the self moves individuals from focusing on external sources of happiness (e.g., chocolates) to internal sources of happiness (e.g., one’s behavior resulting in personal development). Such liberation of the self from external sources of happiness facilitates behaviors that increase personal development and including those beneficial in the long-term. Thus, agency attributions determine whether an external or internal mode of happiness governs behavior. Implications for the literatures on emotions, self-regulation, and consumer welfare will be discussed.

“Physician, Heal Thyself: Positive Affect, Risk, and Treatment Decisions in Health Care”

Lisa A. Cavanaugh, Duke University, USA

Christine Moorman, Duke University, USA

James R. Bettman, Duke University, USA

Mary Frances Luce, Duke University, USA

Imagine you are a physician and the decisions you make each day have implications for the health and well-being of twenty to thirty patients. As a medical practitioner, your primary vehicle for improving patient health is the treatment recommendations that you make. In reviewing a course of treatment, patients often ask you about their treatment options and the risks that are involved. Clearly you want to make the best decisions possible for your patients.

Your extensive medical education (medical school, internship, and residency) has taught you a great deal about standard courses of care and the culture of medicine. You have been taught both explicitly and implicitly not to allow your emotions to cloud your clinical judgment (Landro 2005; Hafferty and Franks 1994; Smith and Kleinman 1989). Recent advances in health care have exacerbated this “affect-free” view of medical decisions by fostering increased specialization by physicians and reliance on technology, allowing doctors to provide consultations from afar without ever seeing the patient face to face.

While affective neutrality may help protect physicians from the negative affect and significant stress they face, this practice also potentially carries with it some critical costs, particularly the loss of positive affect, empathy and the benefits they offer to patient and physician. The hidden curriculum in medical culture has marginalized humanism in favor of the transmission of technical skills and ignores the most human aspects of care (Apker and Eggly 2004; Hafferty and Franks 1995) that help people heal.

We argue that some important benefits of positive affect identified in the psychology literature (Fredrickson 1998, 2001; Isen 2003) may be forgone by physicians when they employ a strategy of affective neutrality. When physicians deny feelings and fail to see their patients as people, they may be unable to fully appreciate the stakes and possible treatment risks posed to the patient, and there may indeed be costs associated with practicing affective neutrality.

The potential to experience negative affect is omnipresent in a clinical setting, where physicians deal with sick patients and communicate bad news daily. The purpose of this research is to determine if and how the introduction of positive affect (i.e., positive feelings toward patients) will influence physicians’ judgments. Building on the relevant literature on positive affect, dual-process models of information processing, and risk, we identify key factors influencing physicians’ judgments. We look at the interaction between mode of patient presentation (affect-rich/affect-poor) and disease severity (low/high) in influencing treatment considerations and perceptions of risk.

In study one, physicians were asked to either imagine that their hospital was considering using a new medical record keeping system or that the Susan B. Komen Foundation was considering the use of a new fundraising appeal (between subjects). Physicians were shown a sample photograph of a breast cancer patient and then asked to report the extent to which seeing a picture like this would influence their own judgment, other doctors’ judgments, and nurses’ judgments. Physicians reported that the photograph would influence their donation judgments but not necessarily their own medical judgments.

In study two, physicians were asked to evaluate a breast cancer patient. We conducted a 2 (mode of patient presentation: affect-rich/affect-poor) x 2 (disease severity: low/high) between subjects

experiment. Physicians were presented with identical patient information but mode of patient presentation was varied using a procedure similar to Hsee and Rottenstreich (2004). Specifically, physicians saw either a picture of the patient with her two children (affect-rich) or a picture of a female symbol with two smaller symbols representing her children (affect-poor) in conjunction with the same patient file. We manipulated disease severity to be either low (Stage 0) or high (Stage IIIB). Physicians were then asked to make a series of judgments about the treatment options they considered and the risks that the treatments posed to the patient.

We found a two-way interaction of mode of patient presentation and disease severity for both dependent measures—breadth of consideration and perceived risk. As predicted, physicians in the affect-rich condition who evaluated a patient with a high severity disease demonstrated greater breadth of consideration in treatments. Most importantly, these same physicians also showed greater willingness to recommend the use of non-traditional therapies. These results suggest that positive affect plays an important facilitative role in the breadth of treatment options that physicians consider for severe cases of disease.

In the case of risk assessments, consistent with our prediction, physicians who evaluated a patient with a high severity disease in the affect-rich condition saw more risk than the participants in the affect-poor condition. Yet, when evaluating a patient with a low severity disease, physicians in the affect-rich condition actually saw less risk than those in the affect-poor condition. Physicians’ reports of sympathy and empathy offered evidence that may help in gaining additional insight into our pattern of results. In sum, the pattern of risk seems to be driven by physicians’ reliance on either risk as feelings or risk as analysis.

These findings have potentially important implications for consumer health and welfare; they also raise the question—under what circumstances are these physician behaviors desirable? We are conducting additional studies to determine how these influences on consideration and risk may ultimately affect clinical practice and patient care. We hope to illuminate two key questions: 1) When will an affect-rich mode of patient presentation be helpful versus harmful to physicians’ judgments and patients’ outcomes? 2) When might physicians be underestimating or overestimating risk, and which estimates are most appropriate?

Our findings offer insight into the conditions under which positive affect influences judgments of consideration and risk. Equipped with additional knowledge about the interactive effects of affect and disease severity, patients may be able to receive and physicians may be able to provide improved care, as the Hippocratic Oath suggests: “promote health and healing, reduce suffering, and not act contrary to the well-being of their own patients.”

SYMPOSIUM SUMMARY

Cognition and Sensory Perception: The Impact of Input from Sensory Modalities on Imagery, Memory, Information Processing, and Sensory Perception

Aradhna Krishna, University of Michigan, USA

SESSION OVERVIEW

Inputs and interactions among multiple sensory modalities affect what we imagine, what we remember, and how we process new information. The goal of this symposium is to introduce current research in the domain of cognition and sensory perception to marketing, and to inspire further exploration of this promising area. The presentations in this session will address the complex interactions of cognition and sensory perception as it applies to consumer behavior. Each of the four papers focuses on a different sensory modality, allowing for a broad, yet coherent exposition of research in the area.

The first paper by Elder and Krishna examines the impact of sensory stimulation on taste perceptions. Perceived taste is formulated from the inputs of multiple sensory modalities, including smell, touch (texture), sight, and even sound. The authors draw upon physiological and neuroscience literatures to propose that food advertisements which include multiple senses in the verbal copy can result in higher perceived taste, compared to advertisements that focus on taste alone. The effects are driven in large part by increased sensory stimulation, which is shown to mediate the process. Further, adding to the cognitive component of taste, the authors show that restricting working memory attenuates the effects.

The second paper by Peck and Barger further exhibits sensory imagery capabilities of the human mind. The endowment effect, which states that consumers value objects more highly if they own them, also arises from psychological ownership of the object. Psychological ownership, in turn, can stem from simple physical contact with the object. The authors posit that touch (haptic) imagery can act as a surrogate for actual touch, thereby increasing psychological ownership of the object and its subsequent valuation. They show that the effects of touch imagery are similar in magnitude to having consumers actually touch the object.

The third paper by Krishna, Morrin, Lwin, and Wirtz examines the impact of product-embedded scent on subsequent recall of product information. This paper presents a large body of evidence for the heightened recall effects of scented versus unscented products. In particular, across three studies the authors show that both unaided and aided recall of product information is higher for scented versus unscented products, regardless of if the scent is congruent or incongruent with the product. These effects hold even after a delay, suggesting their storage in long-term memory. In addition, the authors show that scent is more effective at enhancing memory than the visual cue of product color.

The fourth paper by Stamatogiannakis, Chattopadhyay, and Gorn examines the impact of visual processing capacity on aesthetic response. The authors show that violations of “holistic” properties of visual stimuli (e.g., symmetry, unity, simplicity, prototypicality) results in a less positive aesthetic response when ability/opportunity to visualize is low. However, when capacity to visualize is not constrained, either because the person’s inherent ability to visualize is sufficiently high, or because the person has the time to fully process the stimulus, then violations do not affect aesthetic response. Additionally, the authors identify the mechanism through which these effects operate.

The underlying constructs across each of the four papers present a cohesive representation of the interaction of cognition and

sensory perception. The symposium will prove beneficial not only to researchers interested in sensory perception, but also to those interested in better understanding perceptual processes and their impact on imagery, memory, and processing. The session will conclude with a discussion moderated by Priya Raghubir, seeking to increase general understanding within the area, and to encourage future research in this exciting domain.

EXTENDED ABSTRACTS

“The Effect of Advertising Copy on Sensory Stimulation and Perceived Taste”

Ryan Elder, University of Michigan, USA

Aradhna Krishna, University of Michigan, USA

Despite our seemingly constant exposure to food, we have remarkable difficulty in discerning one taste from another when other senses are inhibited. For instance, if one cannot smell or see the food, it is difficult to tell apart the taste of a potato from an apple, or red wine from coffee (Herz 2007). Part of this ineptitude stems from the limited number of distinct tastes that we can detect.

Ambiguity in taste experiences is reduced in large part by our ability to incorporate multiple sensory inputs into our ultimate taste perceptions. The primary accompanying sense for taste is olfaction (how the food smells). Taste is further affected by vision (how the product looks, including aesthetic appeal, color, shape), as well as auditory aspects (primarily the sound the item makes when bitten or chewed). The convergence of these sensory inputs occurs in the orbitofrontal cortex, labeled as a secondary taste cortex (Rolls 2005). Interestingly, sensory activation in their respective regions of the brain can occur simply by reading verbal depictions of sensory experiences. Therefore, we posit that advertising copy that address multiple-sensory inputs will result in higher taste perceptions due to increased sensory stimulation. Results across five studies, utilizing different taste stimuli add support to our hypothesis, and also delineate the underlying process of sensory stimulation on taste perceptions.

In study 1, we created multiple- and single-sense verbal ads for potato chips. Our results show that participants that read multiple-versus single-sense ads more highly evaluated the perceived taste of potato chips. This finding was replicated in study 2, where participants evaluated the perceived taste of popcorn. Study 2 also explored a potential moderator of the ad-taste effect—cognitive resource availability. Cognitive constraints that limit the availability of working memory should reduce the ad-taste effects, since construction of sensory perception depends on available working memory (Jonides, Lacey, and Nee 2005). That is, we should see an attenuation of the effects of multiple- versus single- sense ads on taste perceptions. We do obtain this attenuation of effects in Study 2; that is, participants rated the perceived taste of the popcorn higher than those exposed to the single-sense ad. Further, within the multiple-sense ad condition, participants in the no load condition rated the taste higher than participants in the high load condition.

In studies 3 and 4, we test for the processes driving the ad-taste effect. Study 3 examines the impact of “attention” to multiple-versus single-sense (taste) on perceived taste. Participants were given instructions to either focus on all five senses (multiple-sense) or on taste alone (single-sense) when eating a cookie. We found that

attention to all five senses resulted in higher taste perceptions of the cookies than the focus on the sense of taste alone. Study four looks more directly at the cognitive responses from participants as a measure of sensory stimulation, using gum as the product category. In particular, we measure the number of positive sensory thoughts elicited by participants about the gum after exposure to the ad and after tasting the gum. The relationship between multiple- versus single-sense ads and taste perceptions was mediated by the number of positive sensory thoughts.

The fifth study explores a more managerially relevant consequence of our theory, showing that willingness to pay for a novel product (Incan hot chocolate) is higher in the multiple-sense ad condition than in the single-sense condition. In sum, these five experiments support our theory that multiple-sense ads will lead to more positive taste experiences than single-sense (taste) ads.

Our research makes important contributions to both the consumer behavior and sensory perception literatures. Our contribution to marketing is an explication of the effects of ads on taste perception. This extends the impact of advertising beyond variables such as awareness and purchase intentions to perceived taste. We also contribute to perception research by providing evidence for the impact of verbal stimuli on sensory evaluations. More specifically, we show that multiple-sensory stimulation can enhance single-sense perceptions. Lastly, we make an attempt to bridge the gaps between physiology, neuroscience, and consumer behavior, showing promising potential for future research.

"In Search of a Surrogate for Touch: The Effect of Haptic Imagery on Psychological Ownership and Object Valuation"

Joann Peck, *University of Wisconsin-Madison, USA*

Victor Barger, *University of Wisconsin-Madison, USA*

Previous research has shown that consumers value objects more highly if they own them, a finding commonly known as the endowment effect (Thaler, 1980). This effect is not limited to legal ownership; psychological ownership, characterized by the feeling that something "is mine," also produces the endowment effect. One antecedent of psychological ownership is the ability of an individual to control an object by touching it. Shu and Peck show that when individuals are given the opportunity to touch an object (versus not), they report a greater sense of psychological ownership and value the object more highly.

If touch is not available, could the act of visualizing touch act as a surrogate? According to MacInnis and Price (1987), imaging is a resource demanding process in which sensory information is represented in working memory. Bone and Ellen (1992) conjecture that imagery "may involve sight, taste, smell and tactile sensations" (p. 93). Although research on imagery and the tactile system is limited (Klatzky, Lederman & Matula, 1993), there is some evidence for the interdependence of touch and visual imagery (Katz, 1925).

Since imaging requires cognitive resources and the effects of imagery are mediated by resource availability (Bone & Ellen, 1992; Unnava, Agarwal & Haugtvedt, 1996), blocking out perceptual

distractions during imaging may enhance its effects. Unnava et al. (1996) found that when imagery and perception compete for the same resources, the positive effects of imaging are reduced. Similarly, Petrova and Cialdini (2005) found that difficulty in imagery generation can reverse the positive effects of imagery appeals. In some instances, consumer behavior researchers have instructed participants to close their eyes when imaging (e.g., Bone & Ellen, 1992; Keller & McGill, 1994 (Experiment 1); Petrova & Cialdini, 2005 (Study 3)), although this was not the focus of these studies. We hypothesize that closing one's eyes while imaging touching an object leads to greater psychological ownership and valuation than imaging touching an object when one's eyes are open.

An experimental study was designed to examine the effect of touch imagery on both psychological ownership and valuation. The design was a 4 (imagery/touch: imagery eyes closed, imagery eyes open, no touch no imagery, touch with no imagery) x 2 (product: Koosh ball, blanket), with the first factor manipulated between subjects, and the second factor varied within subjects. Three hundred and twenty-six individuals participated in the study.

Our first hypothesis predicted that when participants imaged touching the product with their eyes closed, both psychological ownership and valuation would be greater than when participants imaged with their eyes open. We found a main effect of touch/imagery for both psychological and valuation. For psychological ownership, both the touch condition and the touch imagery with eyes closed condition resulted in a significantly stronger sense of ownership than the touch imagery with eyes open condition and the no touch-no imagery condition. Interestingly, there was no significant difference in either psychological ownership or valuation between the touch imagery with eyes closed condition and the condition where actual touch was possible. For valuation as the dependent measure, the results were similar.

We next conducted a second study in order to examine the process in more detail. We hypothesized that when a person closes their eyes to imagine, they are focusing their cognitive resources which results in similar effects to actual touch. In the second study, we had participants imaging touching a product (as in Study 1) but we manipulated whether haptic interference was present and also whether the interference "fit" with the imagined object. The design of this study was a 2 (vision: eyes open, eyes closed) x 3 (haptic stimulus: none, congruent, incongruent) with both factors manipulated between subjects. Three hundred and eighty seven individuals participated and we were able to replicate our first hypothesis. We also found that when a person imagines with their eyes closed, the presence or absence of a haptic stimuli does not significantly impact haptic imaging unless the stimulus is incongruent with the product being imaged.

"Beyond the Proustian Phenomenon: The Effect of Product-Embedded Scent on Memory for Product Information"

*Aradhna Krishna, University of Michigan, USA
May Lwin, Nanyang Technological University, Singapore
Maureen Morrin, Rutgers University, USA
Jochen Wirtz, National University of Singapore, Singapore*

Research in psychology suggests that humans have the ability to recognize scents previously smelled, even after long periods of time. There has been relatively little research in the marketing discipline on the relationship between scent and consumer memory, particularly when the scent is embedded within the product itself, rather than coming from the surrounding environment (i.e., ambient scent). The major goal of this paper is to explore how product-based scent impacts memory for product information, and the extent to which such memory resists decay and interference. We also explore whether the effects of product-based scent are moderated by scent's perceived congruency with the product. Further, for benchmarking purposes, we compare the effectiveness of product-based scent to product-based color (i.e., a sensory modality comparison of olfaction versus vision).

We conducted two pretests to choose the stimuli and then conducted a series of three main studies designed to explore the major issues of interest. In study 1 (n=151), we infuse a pencil product with either a congruent (pine) or incongruent (tea tree) scent and measure unaided and aided recall for brand attributes after different times from exposure (no delay, 24 hour delay, two week delay). A significant time delay by scent condition interaction emerged for both unaided and aided recall. Recall was higher when the pencils were scented, especially true after a time delay, and the congruent scent was sometimes better than the incongruent scent at enhancing memory.

In study 2 (n=448), we compare the effects of scent with those of color. Versus a white, unscented control moisturizer, we infuse either a congruent (rose) or incongruent (anise) scent and either a congruent (beige) or incongruent (dark red) color. We again measure unaided and aided recall after no delay, a 24 hour delay, and a two week delay. We obtained a significant time delay by scent condition interaction for both unaided and aided recall. Recall was higher when the moisturizers were scented versus unscented, this was especially true after a time delay, and the congruent scent was sometimes better than the incongruent scent at enhancing memory.

In study 3 (n=86), we test the effects of competitive interference on memory for scent-encoded product information. All participants are exposed to an orange-scented moisturizer. Later, those in the interference condition are subsequently exposed to a different brand with the same scent, whereas those in the control condition are not. Four weeks after initial product exposure, memory for brand information is tested. With no interference, recall for the

scented product is better than that of the unscented product; however, when there is interference from a second product with the same scent, recall for the original product falls to the level of the unscented product. Thus, interference negated the memory-enhancing effects of product scent, suggesting a boundary condition for this phenomenon.

One of the most intriguing results of this research concerns the effect of time delay on memory for product information associated with scent-infused (versus unscented) products. For most types of information that is learned, retrieval performance declines over time as it becomes more difficult to distinguish cues that were experienced more recently versus more distantly. The greatest decline is typically observed shortly after exposure. However, in the case of scented products, we find that memory for scent-based information does not exhibit the same rapid drop off. Instead, information encoded with scent persists over time, exhibiting a much more gradual decline over time.

Nearly all of the research on scent reintroduces scent at the time of retrieval to test its effects on memory (called Proustian effects). In our research, we examine the ability of scent to produce strong associations in memory that later manifest regardless of whether or not the scent cue is re-encountered by the consumer, i.e., going beyond the Proustian phenomenon. A key focus is therefore on the ability of product-based scent to create strong memory traces at the time of encoding, as well as the extent to which these memory traces are resistant to decay over time and interference from competing information.

"Can You Fix It?: Effects of Visual Processing Capacity on Visual Aesthetic Response"

*Antonios Stamatogiannakis, INSEAD, France
Amitava Chattopadhyay, INSEAD, Singapore
Gerald Gorn, Hong Kong University of Science & Technology, China*

In a recent review chapter of the role of aesthetics in consumer psychology, Hoegg and Alba (2007) stress the need to understand how perceptual processing affects product design evaluation and choice. This research is a step towards such an understanding. Several properties of visual stimuli are assumed to contribute to a positive aesthetic response (e.g. symmetry, unity, simplicity, prototypicality). We investigate one specific characteristic that is likely to influence response to violations of these properties and aesthetic response, namely visual processing capacity.

Several properties of visual stimuli, properties that emanate from Gestalt psychology principles (e.g. Katz, 1950), have been found to lead to increased liking of visual stimuli in both psychological and consumer behavior research. For example visual stimuli properties such as unity and prototypicality tend to induce a positive aesthetic response (Veryzer and Hutchinson 1998). The same for symmetric vs. asymmetric patterns, with people tending to complete unfinished ones in symmetric ways (van Lier and Wagemans, 1999). Also in general, relatively simple patterns tend to be preferred over more complex ones at sufficiently high levels of complexity, but not in low levels of complexity. (e.g. Berlyne, 1974).

Consumers do not always visually process the products they see fully. There may be too many products to process as for example in a large department store. The person may be thinking of other things, or they may be making the purchase impulsively and hence only briefly scanning the package or packages in the store. Researchers have proposed that when cognitive resources are limited (e.g. Hutchinson and Alba 1991) people tend to process information more holistically than analytically. We draw on this research and

suggest that when people have a lower visual processing capacity, symmetry, unity (any aspect of visual display that connects its parts in a meaningful way, Veryzer and Hutchinson 1998), simplicity, and prototypicality will be crucial for liking. When however visual processing capacity is higher, liking will be less affected by whether or not these properties are violated.

In experiments one and two we investigate visualizing capacity in different ways. In experiment one we look at capacity using an individual difference approach, namely comparing the responses of those lower or higher in visual processing ability. In experiment two we do so by manipulating exposure time. In our first study, we used individual differences in visualization ability to capture the effect. We used a 2X2 mixed factorial design, with pattern (full or broken) as the between participants factor and shape (3 squares and 3 octagons) as the within participants factor. Participants saw each figure for 3.5 seconds, and then rated it for liking, symmetry, simplicity and prototypicality. We also had measures of visualization ability and preference for visual processing. We found a pattern X visualization ability interaction: People low in visualization ability liked full patterns much more than broken patterns, but people high in this ability preferred the two almost equally. A similar effect was found for preference for visual processing. Interestingly, visualizing preference and visual ability were not significantly correlated. The interaction effects obtained were driven by the fact that the “lows” liked the full patterns much more than the broken ones. This difference was driven by a similar difference in symmetry ratings.

In our second experiment we used a 2X2X2X2 mixed factorial design. Time (.5, 2.5 and 3.5 seconds) and pattern (full or broken) were varied between participants, while shape (circles or squares) and number of shapes (one or three) within participants. Each participant was exposed to four figures one after the other (in random order) on a computer screen: A square, a circle, three concentric squares and three concentric circles. Half the participants saw full shapes, and half saw these same figures, but broken by two gaps randomly placed on two different spots. Also, a third of the participants saw the figures for .5 seconds each, a third for 2.5, and the other third for 3.5 seconds. After each figure was presented, participants rated it on four dimensions: liking, simplicity, symmetry and unity. Liking was always first, but the other three ratings were randomized. There was a significant interaction between pattern (full vs. broken) and time short (.5 seconds) or long (2.5 or 3.5 seconds). In the short time condition full patterns were liked more than broken ones, but in long time condition there was no such difference. Overall, these results supported expectations that the more “holistic” stimulus properties examined would be crucial for a positive aesthetic response only when visual processing capacity is limited. The drop was mediated by a similar drop in the unity ratings, indicating that in this case, unity violation was the crucial one.

In our third study we use more realistic stimuli and try to manipulate orthogonally symmetry and unity and thus resolve the different results regarding the driving mechanism in the first two studies. We further manipulate visual processing ability by cognitive vs. visual load. This helps us understand whether our effects are driven by low levels of visual processing ability, or processing ability in general. In our fourth study we manipulate visual processing ability by loading the visual context to mirror a large store context where many products are simultaneously visually perceived.

SYMPOSIUM SUMMARY

Compensatory Consumption: How Threat Directs Consumers' Product Preferences

Derek Rucker, Northwestern University, USA

SESSION OVERVIEW

Classic research on consumption proposes that products are often purchased for their symbolic qualities (Belk 1988; Levy 1959; Solomon 1983). Indeed, consumer products can communicate information both to oneself (Bem 1972; Solomon 1983) and to others (Belk, Bahn, and Mayer 1982). For example, an individual who notices she enjoys artwork might conclude to herself that she values creativity; an individual who drives a Lexus might be perceived by others as wealthy and having status. Based on the idea that products have such signaling value, the present session poses the question of whether consumers' product preferences and purchases are used to cope with threat. This proposition is examined with respect to threat in three different domains: one's self-worth, one's self-views, and one's sense of power. Each paper puts forth evidence supporting the idea that threat leads consumers to prefer and select products that compensate for the dimension under threat. As a whole, the session sheds new light on the nature of consumption and the conditions under which threat produces compensatory consumption.

The first paper, by Dalton, proposes that a threat to consumers' self-worth leads to compensation by choosing products that allow for self-expression. Three experiments are presented to test the effect of threats to one's self-worth on consumption in the context of choosing whether to trade up for a higher priced item in a category. Dalton finds that a threat to one's self-worth does indeed increase consumers' propensity to trade up and choose the higher priced option in a choice between two options. Importantly, however, Dalton finds that this occurs only when the decision to trade up occurs in a highly self-relevant domain. In a less self-relevant domain, consumers showed a reduced propensity to trade up. In addition, further supporting the idea that consumers trade up on products in response to threat, Dalton finds that buffering participants prior to the threat reduces their tendency to trade up on self-relevant products.

Wheeler and colleagues examine how consumers' confidence in their self-views can be threatened via apparently innocuous tasks that stir compensatory consumption in their decision-making. In four experiments, consumers' confidence in their views of themselves is shaken either by having participants use their non-dominant (versus dominant) hand or priming doubt (versus confidence). Wheeler and colleagues find that these simple manipulations have a significant impact on consumers' choice such that they choose products that will offset the characteristic of which there is doubt. Thus, if consumers' self-views (e.g., excitement, intelligence) are threatened by doubt, they are more likely to choose consumer products that display these characteristics. Wheeler and colleagues further demonstrate that such threats can be prevented via direct or indirect methods that bolster the self-concept.

Rucker and Galinsky present three experiments suggesting threats to consumers' power evoke compensatory consumption in an effort to regain their sense of power. Based on the notion that status provides one means of signaling one's power, Rucker and Galinsky suggest and find that experiencing a psychological state of powerlessness fosters a preference for attributes related to status, leads to an emphasis in status when developing an advertisement, and leads to more positive attitudes towards products associated

with status. Importantly, when the product attributes are described in terms of performance, the effect reverses. Compared to the powerless, the powerful evince a stronger preference for attributes related to performance, emphasize performance in developing an advertisement, and hold more positive attitudes towards products associated with performance.

As a whole, these three streams of research converge on the point that people often consume in a compensatory manner. Furthermore, each stream of research goes beyond this initial premise by demonstrating that threats do not simply provoke greater consumption. Dalton demonstrates consumers trade up when the product is relevant, but not when the product is irrelevant. Wheeler and colleagues demonstrate that consumers do not exhibit compensatory consumption if they first engage in an affirmation of the self. Finally, Rucker and Galinsky demonstrate that if a product confers performance, rather than status, threatened individuals are less favorable towards it. Thus, these findings push our thinking on several fronts.

EXTENDED ABSTRACTS

"Look on the Bright Side: Self-Expressive Consumption and Consumer Self-Worth"

Amy Dalton, Hong Kong University of Science & Technology, China

It is widely held that people who spend money to compensate for negative feelings of self-worth do so in vain; thus "retail therapy" has been relegated to the dark side of consumption. But in fact, little is empirically known about the relationship between consumption and self-worth. First, when the going gets tough, do the tough always go shopping, or might they sometimes become thrifter instead? And second, is retail therapy inevitably a hollow pursuit, or do conditions exist in which it can be an effective way to repair consumers' feelings of self-worth? In addition to addressing these two questions, the current research explores the substantive issue of trading up—what drives consumers to pay premium prices for goods and/or services in some situations and not others?

According to the current framework, events that threaten self-worth do not uniformly increase consumption, but increase a particular type of consumption: *self-expressive consumption*. *Self-expressive consumption* is consumption that is consistent with (expresses) a consumer's self-concept, his or her values and beliefs about who he or she is. Several experiments document this effect and, in doing so, highlight that retail therapy does in fact have a bright side.

First, in this framework, while self-expressive consumption can sometimes result in an increase in consumer spending (here, trading up), it can also have the opposite effect depending on consumption self-relevance. That is, material objects and consumption domains vary in the extent to which they are important to a consumer's self-concept, a dimension referred to as self-relevance. For instance, both trading up in a highly self-relevant domain and not trading up in a domain that is low on self-relevance are forms of self-expressive consumption. The basic prediction across studies was that, in response to an event that threatened their self-worth, participants would be more likely to trade up (or trade

up more) in a consumption domain that was high on self-relevance and less likely to trade up (or trade up less) in a consumption domain that was low on self-relevance.

This hypothesis was tested in experiment 1 by examining how an academic failure impacted students' willingness to trade up when choosing between two t-shirts that were high on self-relevance (i.e., two Duke t-shirts) or low on self-relevance (i.e., two white t-shirts). In each choice set, the t-shirts were priced at \$14 and \$19. Results showed that threat did not increase trading up in both choice contexts; rather, the tendency to trade up increased only for the self-relevant choice set. For the less self-relevant choice set, threat decreased the tendency to trade up. These results are consistent with the theory that threat impacted self-expressive consumption.

Experiment 2 sought to conceptually replicate these findings. Rather than manipulating threat, this study manipulated whether the threat experience was buffered or not by having participants write about a personally important value (or a value important to others; Steele and Liu 1983) before the academic failure. Second, rather than manipulating self-relevance, it was measured as an individual difference variable. Participants completed a questionnaire that assessed their chronic perception that possessions are part of their self-concept (Sprott, Czellar, Spangenberg 2007). Finally, rather than trading up being a hypothetical choice, it was a real choice. Following the academic failure, participants were led to believe the experiment was over and were told that the lab was conducting a draw for prizes. They were asked how they would allocate \$100 to two different gift cards should they win the draw. The gift cards were for the stores Nordstrom (a more expensive store) and Macy's (a less expensive store).

Results showed that compared to buffered participants, non-buffered participants engaged in higher levels of self-expressive consumption. Thus, the conceptual pattern of experiment 1's results was upheld: when self-worth was threatened (here, because a threat was not buffered against), consumption became more self-expressive, with consumers who considered material objects important to their self-concepts trading up more (allocating more money to an expensive store), and consumers who did not consider material objects important to their self-concepts trading up less (allocating less money to an expensive store).

The results of a third experiment explored how individual and choice set differences interact to predict trading up in response to threat. The findings suggest that individuals with chronically strong links to possessions responded to threat by trading up in a variety of consumption contexts, whereas individuals with weaker links to possessions responded to threat by trade up in a more restricted range of consumption contexts. Simply put, people with strong (vs. weak) links to possessions perceive more (vs. fewer) consumption contexts to be self-relevant, and therefore trade up more (vs. less) in response to threat. These findings bolster the overall argument that threat triggers self-expressive consumption.

As alluded to earlier, this research also addressed the impact of trading up on self-worth. That is, can the decision to trade up or not assuage consumers' negative feelings of self-worth? It was predicted that trading up could repair self-worth, but only in a self-relevant domain. Experiment 1 tested and supported this hypothesis and also showed that self-worth could be repaired in less self-relevant domains by *not* trading up. Thus, not only can consumer decisions repair self-worth, but consumers apparently respond to threats by consuming in a way that immediately makes them feel better about themselves.

These findings support the theory that threats to self-worth trigger self-expressive consumption: consumers trade up more (or less) when consumption domains are more (or less) relevant to who

they are. Moreover, engaging in self-expressive consumption in turn repairs the self-worth of threatened consumers. These findings highlight the bright side of the relationship between consumption and self-worth: consumers respond to threats adaptively—sometimes spending more and sometimes spending less—and functionally—by making *consumption decisions that repair self-worth*.

“Products as Compensation for Self-Confidence: Subtle Actions Affect Self-View Confidence and Product Choice”

Leilei Gao, The Chinese University of Hong Kong, China

Christian Wheeler, Stanford University, USA

Baba Shiv, Stanford University, USA

It has long been postulated that consumers should choose products with brand personalities that are congruent with their own self-views (e.g. Levy 1959; Birdwell 1964). For example, Birdwell (1964) showed that automobile owners' perceptions of their cars match their self-perceptions. However, despite some promising findings such as these, extensive reviews failed to find consistent evidence that people choose products congruent with their perceived self-characteristics (Kassarjian 1971; Sirgy, 1982).

In the present research, we suggest that a key determinant of product-self congruency in choice is self-view confidence. We show that individuals' confidence in their self-views can be shaken by seemingly inconsequential actions, such as writing about their self-characteristics with the non-dominant hand, and that this lowered confidence can increase the likelihood that they will choose products congruent with the shaken self-views.

Self-view confidence refers to the certainty that one's self-view is truly characteristic of one's actual characteristics (Pelham 1991; DeMarree, Petty, and Briñol 2007). Highly confident self-views can result from consistent and coherent evidence about one's self-characteristics drawn from the environment and from one's past experiences (Campbell 1990; Pelham 1991). In this research, we suggest that self-view confidence can also be affected by very subtle situational factors, such as performing routine actions in unusual ways (e.g., writing with one's non-dominant hand) as well as by subtle priming tasks. Individuals generally desire to hold confident self-views, and evidence suggests that a lack of such confidence can be aversive, resulting in negative psychological outcomes such as low self-esteem (Baumgardner 1990; Campbell 1990), unhappiness and anxiety (Rosenberg 1979). As a result, people seek to bolster confidence in self-views that are threatened. They can do so through both direct and indirect means.

A direct bolstering strategy would involve taking actions that directly restore the shaken self-view. One direct strategy is selecting products that symbolize the dimension on which one has lowered self-confidence. Products are frequently chosen for their symbolic qualities (Belk 1988; Levy 1959; Solomon 1983), and usage of these products can indicate that one has certain self-characteristics both to oneself (Bem 1972; Solomon 1983) and to others (Belk, Bahn, and Mayer 1982). An indirect strategy, by contrast, would involve restoring overall self-views without bolstering the self-characteristic directly. For example, people can cope with self-threats by affirming unrelated self-views (Steele 1988). This affirmation process can eliminate feelings of threat without directly repairing the challenged self-view.

In the present studies, we predicted that people who experience momentarily lowered confidence in a given self-view would be more likely to select products that bolster that self-view. We also predicted that this shift in product choices would be eliminated when participants first had the opportunity to bolster their self-views through either direct or indirect means. A series of four studies provided support for these predictions.

In experiment 1, participants wrote about their excitingness before choosing between exciting products (e.g., Apple computers) or competent products (e.g., IBM computers). They were randomly assigned to write about their excitingness with either their dominant hands or their non-dominant hands. Based upon prior research (Briñol and Petty 2003), we predicted that writing about a self-view with one's non-dominant hand would lower confidence in that self-view, because doing so would be difficult and the writing would look shaky and unconfident. Participants who wrote about their excitingness with their non-dominant hands were more likely to choose exciting products than those who wrote with their dominant hands, consistent with the idea that exciting products were chosen to restore the self-views shaken by writing with the non-dominant hand.

In experiment 2, we replicated and extended these results by testing the effects in another domain (intelligence) and by testing the effect of a direct bolstering opportunity. Participants were first randomly assigned to write about their intelligence with either their dominant or non-dominant hands. They then chose among a series of products from sets containing either intelligence-related products (e.g., bookstore gift certificate) or no intelligence-related products. At the conclusion of the session, they were offered a choice between a pen (intelligence-related) and M&M's (not intelligence-related). We predicted that participants who wrote about their intelligence with their non-dominant hand would be more likely to choose the pen, but only when they did not first have the opportunity to bolster their self-view through prior choice of intelligence-related products. This is what we found.

Experiment 3 generalized these results to another domain and tested the indirect bolstering strategy. Participants were first assigned to write about their health-consciousness with either their dominant or non-dominant hands. They then engaged in a self-affirmation task, in which they wrote about an important value, or an unrelated filler task. Last, they chose between a healthy snack (apple) and an unhealthy snack (M&M's). Results indicated that those who wrote about their health-consciousness with their non-dominant hands were more likely to choose the apple, but only if they did not first have the opportunity to engage in self-affirmation.

In our final experiment, we use another means of shaking self-confidence, fully crossed our design to test for trait-specific confidence, and tested for confidence mediation. The experiment had a 2 (Prime: confidence vs. doubt) x 2 (Trait: excitingness vs. competence) design. Participants were first primed with confidence or doubt before writing about their excitingness or competence. They then chose between a series of products with exciting or competent brand personalities. Results indicated that participants chose more exciting products when primed with doubt and writing about excitingness and chose more competent products when primed with doubt and writing about competence. Moderated mediation analyses showed that these choices were mediated by participants' confidence, but that the effect of the reduced confidence depended on the trait that was activated.

“Lifestyles of the Powerless and Powerful: Compensatory and Non-compensatory Consumption”

Derek Rucker, Northwestern University, USA

Adam Galinsky, Northwestern University, USA

Power is an omnipresent force in consumers' social world. Throughout the day consumers are likely to have experiences of feeling both powerful and powerless. For example, meeting with one's boss, defending a thesis, or submitting a job application might evoke the psychological state of feeling powerless. Conversely, interviewing a potential employee, giving advice, or setting curfew for one's child may evoke the opposite state of feeling powerful.

How does power affect consumption? We propose that psychological states of low and high power have qualitatively different effects on consumers' preferences.

Powerlessness and Compensatory Consumption. On the one hand, powerlessness, or a low power state, is associated with an aversive psychological experience that consumers are motivated to reduce. One means of reducing such a state would be to consume in a manner that gives one a sense of power. In particular, past research suggests that status is one form of power (e.g., French and Raven 1959), and that consumer products serve the function of communicating information about one's status (e.g., Belk et al. 1982). Belk and colleagues note, “It may be that concern with *demonstrating* status to others comes to dominate other consumption message interests sometime after the eighth grade and that this concern then continues.” Consequently, due to a motive to compensate for their lack of power, we hypothesize that low power consumers are likely to have a preference for products and product attributes associated with status. In fact, recent work by Rucker and Galinsky (2008) suggests consumers in a state of powerlessness are willing to pay more for status-related products. We suggest this increased willingness to pay should extend to consumers' general preferences.

Having Power and Internal Focus. On the other hand, being powerful, or a state of high power, is typically associated with having control. As control is often desirable, we hypothesize that such consumers should not have a compensatory motive activated. However, we believe there is reason to suspect that experiencing a state of power should be more likely to orient consumers towards performance and obtaining products associated with exceptional functionality and performance. Specifically, prior research has shown that when people are focused on their internal states they tend to focus on the quality of the product (Snyder and DeBono 1985). And, prior research suggests that feeling powerful leads to an increased focus on their own attitudes and desires (Briñol et al. 2007; Chen, Lee-Chai, and Bargh, 2001). For example, Briñol et al. (2007) found that the powerful were less likely to process information about a persuasive message because a state of power suggested their own attitude was correct and listening to others was unnecessary. Given that a focus on one's internal desires produces a focus on quality (Snyder and DeBono 1985), and power focuses people internally, we proposed that high power should intensify a focus on the quality of the products and lead to a preference for products that emphasize quality.

We tested the different preferences resulting from states of low and high power in a series of three experiments. In experiment 1, we manipulated participants' power using a role manipulation adapted from past research (Briñol et al. 2007). Specifically, participants were informed they would be participating in two separate experiments. In the first experiment participants were randomly assigned to either a high power role (Boss) or a low power role (Employee). After the role assignment, as part of a supposedly unrelated task, participants were asked to generate a slogan to accompany a picture of a BMW that they thought would be persuasive. Participants' slogans were coded with respect to whether they emphasized status or performance. Participants assigned to the low power condition generated more slogans related to status than high power participants. In contrast, participants assigned to the high power condition generated more slogans related to performance than low power participants.

Experiment 2 tested our hypothesis by measuring, rather than manipulating, participants' general sense of power and examining their preference for a product advertised as associated with status or performance. Participants were subsequently asked to report their purchasing intentions towards the product. We found that as participants' general sense of power increased they had *more* favorable

purchasing intentions for the product associated with performance. Conversely, as participants' general sense of power increased they had *less* favorable attitudes towards the product emphasizing status.

Experiment 3 examined the role of power in consumers' response to ads emphasizing the status or performance aspect of a product and experimentally manipulated power. In addition, a control group was added to demonstrate that low and high power both exhibited effects relative to a control condition. Participants were assigned to control, low, or high power conditions by having them recall a past event (see Galinsky et al. 2003). Participants then read an advertisement for an executive pen and provided their attitude towards the pen. The advertisement was varied to either emphasize the status conveyed by the pen or the performance of the pen. When the pen emphasized status, low power participants held more favorable attitudes towards the pen than both high power and control participants, which did not differ from one another. In contrast, when the pen emphasized performance, high power participants held more favorable attitudes toward the pen compared to both low power and control participants.

Conclusion and Contributions. The present research provides evidence for both compensatory and non-compensatory processes in consumer behavior. Specifically, states of powerlessness foster a desire to compensate for the loss of power, which manifests itself in a proclivity to focus on, and prefer products associated with, status. In contrast, states of power invoke a preference for products associated with performance. Theoretical and practical implications of this work in understanding power in consumer behavior are discussed.

SYMPOSIUM SUMMARY
Legitimation in the Marketplace
Ashlee Humphreys, Northwestern University, USA

SESSION OVERVIEW

This goal of this session is to examine the role of marketplace structures (e.g. brands, products, retailers) in the creation and maintenance of legitimacy, the congruence with dominant norms, values, and institutions. Previous research on legitimacy in consumer research has studied the acceptance of brands (Fournier 1998; Holt 2002; Kates 2004), subcultures (Kozinets 2001), and business practices (Deighton and Grayson 1995), pointing to mechanisms that range from explicit manipulation of legitimacy through social cues and actions (Kates 2004; Kozinets 2001) to implicit manipulation of affective attachment through integration into daily life (Fournier 1998) and the use of cultural scripts (Holt 2002) and discourses (Thompson 2004). Although this previous work has admirably tackled a number of disparate phenomena under the rubric of legitimacy, a clearly articulated theory of the legitimation process and its relationship to market-oriented behaviors has yet to be posed and developed by consumer researchers. By bringing together several approaches to the study of legitimacy, the aim of this session is to theorize the legitimation process through both explicit and implicit cultural forms, to examine the role of larger institutions such as legal or market structures in the legitimation process, and to debate the particular role that market-oriented behaviors play in the legitimation process. Through what process does a practice or identity become stigmatized or destigmatized? How can legitimacy be constrained or enabled by the marketplace? Lastly, how can market structures be used to gain or deny legitimacy?

The session will contribute to our understanding of consumer behavior in three ways. First, the study of legitimation helps us better understand the normative structuring of consumer practice. Many consumers have stopped smoking, started gambling, or refused to buy products made with child labor, all because these practices have gained or lost legitimacy, its congruence with other values, institutions, and social norms. By understanding these normative and institutional structures, we gain insight into the ways in which consumer behavior is constrained in some domains and enabled in others. Second, because legitimation is a fundamental social process (Johnson et al. 2006), it can be used to understand a diverse set of phenomena in consumer research. Understanding legitimation as a distinct social process can shed light on the acceptance of brands, products, practices, and marketplace ideas. In turn, it can also make clear the ways in which the market is used by consumers to attain legitimacy. Finally, a study of the legitimation process can help us better understand the interactions between consumer groups, as they vie for legitimacy in the marketplace and in the social world at large.

Three papers will examine the relationship between legitimation and market structures. First, Gokcen Coskuner-Balli and Craig Thompson will provide an analysis of the creation and legitimization of a non-traditional gender identity through marketplace performances. Ashlee Humphreys will present an institutional analysis of the legitimation of casino gambling in the United States that examines the relationships between regulative, normative, and cultural legitimacy in their interaction with marketplace institutions. Next, Marius Luedicke will examine the contestation and legitimation of brand meaning through an examination of the acculturation process. Finally, John Deighton will tie together the

presented empirical work and, drawing from his previous research on the topic, will offer some guidance for further research on legitimacy.

EXTENDED ABSTRACTS

“Legitimizing an Emergent Social Identity Through Marketplace Performances”

Gokcen Coskuner-Balli, University of Wisconsin-Madison, USA
Craig Thompson, University of Wisconsin-Madison, USA

This paper explores the creation and legitimization of a non-traditional gender identity in the market place. Over the past twenty years, consumer research has explored a variety of ways consumers use market resources for identity construction and communication (Arnould and Thompson 2005). While previous research has recognized the market as a legitimating institution for consumer identities (Penaloza 1994), it has not provided an in-depth understanding of how consumers use the marketplace to legitimize new and unconventional social identities.

To explore these issues we focus on the consumption practices of Stay-at-Home Dads (SAHD from here on) and adopt multiple methods of data collection. Data from in-depth interviews, participant observation at SAHD play groups as well as annual SAHD convention, data collected through netnography (Kozinets 2002), and textual data gathered through compilation of texts/books written for SAHDs, newspaper articles all contribute to our emergent theoretical account.

Our analysis highlights key relationships between consumers' collective efforts to legitimate a new social identity and their efforts to co-create product/brand meanings that facilitate a legitimating or successful performance of this identity. These social actors undertake contextually nuanced social performances and strategically adapt these performances in response to different audience reactions. To better understand these legitimating performances, we identify the cultural scripts from which SAHDs seek to cultivate a new way of performing fatherhood (and masculinity) and the role of the market in providing social, cultural, economic resources which are employed in their legitimating project. We then present the individual and collective consumption strategies (communal, political, entrepreneurial and masculinizing domesticity) SAHDs adopt as they simultaneously seek to legitimize a new social identity while also coping with the feelings of stigma and isolation that are routinely invoked by negative social reactions to their divergence from more culturally established models of fatherhood and masculinity.

The theoretical contributions of our analysis are threefold: First, it addresses the social and cultural barriers that consumers have to negotiate in the process of legitimating new social identities through market-mediated social performances. While the previous CCT literature has repeatedly shown that consumers creatively adapt market resources to construct identities that transcend gender, age and ethnic identities (e.g. Schouten and McAlexander 1995) or to construct hybrid ethnic identities (e.g. Penaloza 1994; Oswald 1999), it has given little attention to the ways in which audience expectations, social conventions, and a paucity of marketplace resources, can impede and/or significantly complicate the performance and legitimization of a new social identity. Second, our

analysis reveals that legitimization performances are often embedded in collective struggles and mobilization of market resources in these performances are done in communication with others. As the forces of globalization and postmodern detraditionalization create new spaces for identity experimentation and transformation, various consumer groups will continuously seek to rework their collective identities to better align with these dynamic socio-cultural conditions and to make new claims for social and political rights, as in the case of poor migrant women seeking to lead a middle-class consumer lifestyle (Ustuner and Holt 2007), Greenlandic consumers seeking to forge a connection with global youth culture as a means to transcend the legacy of colonial stigmas (Kjeldgaard and Askegaard (2006), or immigrant consumers seeking to create a new hybrid identity (Peñaloza 1994). Extending this line of theorization, we highlight that a consumer group, who possesses more social and economic resources, can actively accentuate particular postmodern trends—such as the loosening of traditional gender norms—attempt to transform social perceptions and interaction rituals through their performative innovations. Third, this study further demonstrates that consumers can use market resources not only for therapeutic gain but also to create and legitimate a new social identity that diverges from dominant gender norms. SAHDs employ communal, political, entrepreneurial and masculinizing strategies to mobilize market resources towards this goal. As such this analysis suggests that the marketplace is a political forum for creating a social script that supports emergent identity project and negotiating the impediments for attaining successful performances. In sum, SAHDs' practices of product and brand meaning co-creation are embedded in a societal dialogue over the terms of an effective performance and involves legitimating new performative role and social identity; reducing or refuting social stigmas that accompany violations of conventional performative scripts; adopting market place resources and pushing market to provide more fitting resources; contesting and transforming audience expectations.

“Legitimacy and the Cultural Diffusion of Casino Gambling, 1976-2006”

Ashlee Humphreys, Northwestern University, USA

This paper will examine the legitimation of consumption practices, as it is mediated through social, cultural, and regulative institutions. In 1976, casino gambling in the United States was a marginal consumption practice, legal in one state and undertaken by only about one in ten people in United States. Today, casino gambling is a thriving industry that exists in 28 states and is a consumption practice in which one third of consumers the US participate every year. What explains the shift in gambling from marginalized practice to thriving industry? More generally, how do new industries come to be accepted in the marketplace? How does this acceptance, in turn, destigmatize certain consumer behaviors?

This article explores stigma at the macro-cultural level by evaluating the semantic shifts in discourse about casino gambling in the United States from 1980 to 2006. Previous research on consumer stigma has studied the pathology of shopping behaviors (O'Guinn and Faber 1989), the role of stigma in formations of fan community (Kozinets 2001), and the perceived pressures and consumer enactments toward normalization in response to stigma (Thompson and Hirschman 1995), all with an eye toward the consumer experience of living with stigma. While previous research has studied stigma from this lived perspective, it has not fully taken into account the larger political and social institutions in which stigmatized consumption practices change. How and why does stigmatization of consumption practices change over time and what institutional factors facilitate this change? This article will

evaluate destigmatization through the theoretical lens of legitimation, as it is theorized by institutional theory (Johnson et al. 2006; Suchman 1995).

Legitimation is social process of making a practice congruent with the configuration of other values, institutions, and social norms. It occurs on three levels, regulative, normative, and cognitive (Scott 1995). Regulative legitimacy is the degree to which a practice conforms to rules and regulations set forth by a superordinate organization, usually the government. Normative legitimacy is the degree to which the practice is accepted by social actors, irrespective of legal status. Cognitive legitimacy is the degree to which the practice is “taken for granted” and can be categorized and understood according to existing cognitive schemas and cultural frameworks. All three types of legitimacy, however, draw from the same semantic repertoires. As members of a shared social world, politicians, journalists, consumers, and casino owners, work with the same basic concepts that are used to frame casino gambling. On the one hand, the meanings of casino gambling are “out there” as social facts for actors to cite (Husserl 1900/1970). On the other hand, the social meaning of gambling is actively constructed and changed by social actors, especially those with economic and political resources (Sewell 1992). Through this change in meaning, casino gambling can be legitimated or delegitimated. Evaluating this universe of shared meanings and associations, then, is crucial for understanding how legitimacy is achieved.

The data for this chapter comes primarily from a stratified random sample from the population of all newspaper articles with “casino” in the headline or lead paragraph from three periodicals, *New York Times*, *Wall Street Journal*, and *USA Today* from 1980-2006, found using the Factiva database. Several other sources of data including seven interviews and six months of participant observation provided the context with which articles were interpreted.

I find that discourse about casino gambling is structured by semantic binaries that are mobilized by journalists and their sources to frame casino gambling along the dimension of purity and filth (Douglas 1966) and the dimension of wealth and poverty. Employing the Gremsian square (Greimas 1983; Jameson 2005), I show how a number of concepts structurally align along these two semantic poles to orient the ways in which discussions about casino gambling are enacted. The concepts of purity and filth in discourse about casino gambling are evoked not only literally to describe the state of communities where gambling occurs, but are also, and perhaps more often, used figuratively to activate reader associations with crime, prostitution, rot, and decay in the case of filth or cleanliness, integrity, transparency, heroism, and integrity in the case of purity.

Wealth and poverty orient discourse about casino gambling in terms of success and failure. The image of wealth, as it's embodied in high roller clients, wealthy companies, and resort locales, implies unambiguous success. Poverty, in any form, signals failure. The concepts of wealth and poverty are complimentary to the concepts from purity and filth, but they are by no means identical with them. A broader capitalist ideology may associate wealth with purity and poverty with filth, but this view is valid only within a very particular ideological framework. From a religious ideology, for example, poverty is associated with purity and wealth with impurity. Because of the commercial nature of gambling and the American business context, however, the semantic poles of wealth and poverty take on a special role in orienting discussions of gambling and are complimentary to the poles of filth and purity.

Further, I show how these basic semantic materials evolve over time, becoming linked through narratives of contamination, disillusionment, and redemption. For example, in the case of

gambling run by Native American tribes, cultural narratives of redemption can be harnessed understand and articulate the transition from poverty to wealth and thereby judge success or failure of these social-structural changes. I examine how these semantic polarities are also synthesized over time into concretizations used to describe the state of the world. Lastly, I more closely examine the ways in which these particular concepts are used to support cultural, normative, and regulatory legitimacy, and assess the degree to which these types of legitimacy are mutually reinforcing.

These findings contribute to consumer behavior in several ways. First, the findings here contribute to our knowledge of the interaction between frames, ideologies, and discourses (Ferree and Merrill 2000). Cultural binaries are the building blocks with which social actors construct frames (Gamson 1992; Gamson and Modigliani 1989). Frames, in turn, are driven by ideologies, the oppositions of which are negotiated within a discourse. Conceptually, these semantic networks are important because they unite multiple levels of analysis, from cognitive structures (i.e. individual conceptualizations of casino gambling) to social structures (i.e. norms that govern when and where one should gamble) to regulatory structures (i.e. laws that govern the enactment of casino gambling). Second, we learn more about the basic process by which consumption practices become destigmatized. Through associations with deeply resonant metaphors and meaning, proponents of casino gambling are able to normatively construct a story and identity that valorizes gambling practices to individuals and to communities. Finally, we gain greater insight into the interaction between types of legitimacy. Specifically, legitimation occurs through more than mere “talk.” Rather, it is achieved through a mutually reinforcing system of explicit structural change (regulations, market growth) and more implicit normative and cultural shifts in discourse.

“Host Culture Responses to Brand-related Acculturation: Legitimation Struggles Between German and Turkish BMW Owners in Germany”

Marius K. Luedicke, University of Innsbruck, Austria

Markus Giesler, York University, Canada

Consumer acculturation is a challenge. Global migrants today must not only cope with foreign languages, diverging cultural habits, and alternative market systems (Peñaloza 1995, p. 92), but also with multiple “ascriptive identities” (Horowitz 1975) and multifaceted national discourses and practices that result from swapping between home and host cultures (Oswald 1999; Askegaard, Arnould and Kjeldgaard 2005). Particularly for consumers who lack sufficient capital to participate in the dominant cultures’ desired modes of consumption, migration more often than not results in shattered identities (Üstüner and Holt 2007) and ideologically and physically segregated existences (Davis 2006).

By providing platforms for shared social experience and community, brands are commonly held to play an integrative cultural role (Kates 2004; Muñiz and O’Guinn 2001; Oswald 1999; Peñaloza 1995). As Üstüner and Holt (2007) amply illustrate, for migrating Turkish consumers the experimentation with the dominant-culture’s favorite brands presents a viable option for familiarizing with the consumption patterns of their new social environment. Consumers that are capable and ideologically attuned to delve into these new consumption practices are found to enter the new culture by consuming status-relevant goods and services in ways particular to their original culture (Peñaloza 1994). In this perspective, host cultural brands are theorized as integrative resources, a unifying *lingua franca* of the marketplace that bridges cultural gaps through creative consumption. By combining their own cultural meanings and codes with the host culture’s favorite

status brands, (immigrant) consumers attempt to gain social legitimacy while, at the same time, regenerating the national brand’s established system of meanings.

However, when we studied the brand consumption practices of German and Turkish-immigrant BMW drivers in Germany, this optimistic protocol of brand-based acculturation revealed several theoretical incongruities. First, we found the relationship between these two ethnic consumer groups to be mostly antagonistic rather than synergistic. Second, we found that, by way of constructing competing interpretations of BMW driving, particularly German consumer groups fostered ethnic reservations and stereotyping to deny Turkish-German consumers legitimate status gains through BMW ownership rather than bridging cultural gaps. Third, we found that, through BMW consumption, tropes of innovative engineering, Christian virtue, and social achievement were generalized as German national identity traits that were either consumed (Turkish) or consumed and defended against ethnic intrusion (German). Finally, we found that these brand-based attempts to gain social legitimacy in the German culture more often than not served to intensify ethnic segregation ideologies rather than advancing cultural integration.

The goal of our paper is to document these empirical findings and discuss their theoretical, public policy, and marketing implications. We develop a dialectical theory of consumer acculturation and brand consumption that profiles the market-mediated process of acculturation as a mutually competitive legitimation struggle. Specifically, we revise the laudable, yet in parts unrealistic, goals of the brand-based acculturation model in favor of a more nuanced theory of consumer acculturation that draws from symbiotic co-optation dynamics (Thompson and Coskuner-Balli 2007; Giesler 2008) in a multi-ethnic marketplace context. We will illustrate this alternative model on microscopic practice and market-system levels. We will show that the most laudable policy goals of homogenizing national integration will inevitably collide with the ideological segregation forces of a multi-ethnic consumer culture. Yet, at the same time, we will explain that the same competitive consumption processes that hamper national homogenization foster a multi-ethnic national market of hybrid consumer segments.

Methodologically, this analysis is part of a larger ethnographic and netnographic (Kozinets 2002) investigation of German and Turkish immigrant BMW drivers in Germany. Our German BMW drivers are between 18 and 65 years of age, have German family roots of at least three generations and belong to the German middle class. These consumers drive BMW cars including new and pre-owned 3, 5 and 7 series models as well as the Z sports cars and the X sport utility types. With currently more than two million people, the Turkish immigrant community is the largest, most visible group of immigrants in Germany and has a 35+ year cultural history in Germany. Comprising of 15 Turkish-German BMW drivers, our data set consists of 20% first generation Turkish-German consumers who were born in Turkey and immigrated to Germany and 80% second generation Turkish-Germans who were born and raised in Germany but carry forth a distinct Turkish cultural and religious heritage. These consumers drive the entire range of BMW vehicles but tend to own more used and older models than the German group. To ensure trustworthiness of our findings and the representativeness of our German national sample we used data sets from Austria and Switzerland as comparison contexts with similar socio-cultural features. We solicited informants in Berlin and Frankfurt (Germany), Innsbruck (Austria) and Zürich (Switzerland) on the streets as well as through websites and analyzed our in-depth, semi-structured interviews using the established interpretive toolkit of hermeneutical analysis (Thompson 1997).

SYMPOSIUM SUMMARY
Patience, Attention to Time, and Consumer Cognition
Christopher Olivola, Princeton University, USA

SESSION OVERVIEW

Many important consumer decisions involve time. Decisions about saving money, maintaining a diet vs. splurging, or making a payment by credit card vs. with cash are just some of the numerous situations in which people must tradeoff between consumption in the present and consumption in the future. Given the importance of intertemporal choice, then, understanding how time and patience factor into the decision making process is an important goal if we are to properly understand consumer behavior. In line with this goal, the purpose of this symposium is to explore how perceptions of time and individuals' patience-levels interact to impact consumer decision making. The papers in this session explore the impact of attention to time on consumer cognition as well as some important determinants of people's discount rates (an economic measure of patience).

The first paper (Krupka) examines the relationship between patience and access to financial resources (i.e., benefits and credit) among welfare recipients and finds that discount rates increase as access to these resources decreases. The second paper (Olivola & Wang) introduces two novel incentive-compatible methods for eliciting discount rates. A comparison of these methods reveals that discount rates vary, depending on whether attention is focused on the temporal or monetary dimension of delayed rewards. The third paper (Day & Bartels) demonstrates that temporal distance impacts perceptions of similarity, with some events seeming more similar when considered in the near future (or past), while others increase in similarity as temporal distance increases. Finally, the fourth paper (Frederick) demonstrates that two intertemporal choice "anomalies" (the magnitude effect and the sign effect) are actually more pronounced when discount rates across conditions are directly compared or when respondents are encouraged to think more deeply about their pattern of responses. This last paper also considers how these results undermine the normative (rather than descriptive) validity of the discounted utility model.

The papers in this session highlight novel and important features of the interaction between patience, attention to time, and decision making. This research demonstrates that normatively irrelevant factors can impact patience and intertemporal choice (i.e., discounting). The discount rate is shown to depend, dynamically, on access to financial resources (Krupka) and varies depending on whether consumers are focused on the monetary or temporal dimension of delayed payoffs (Olivola & Wang). In fact, attempts to reduce these inconsistencies can actually aggravate them (Frederick). Additional interesting and counterintuitive results include the finding that attention to time increases patience (Olivola & Wang) and alters perceptions of similarity (Day & Bartels).

These papers also adopt creative approaches to the study of intertemporal choice, which include the use of field experiments (Krupka) and experimental auctions (Olivola & Wang). Some papers also compare two or more methodological approaches to the elicitation of discount rates, such as between-subjects vs. within-subject designs (Frederick) and hypothetical vs. real-money incentive-compatible procedures (Olivola & Wang).

In summary, the four papers in this symposium provide both original methods for studying intertemporal choice and novel findings concerning the relationship between patience, attention to time, and consumer cognition. Collectively they demonstrate interesting and surprising phenomena, as well as important theoretical

constructs to the study of intertemporal choice. This symposium should appeal to a diverse research audience for several reasons. First, research into intertemporal choice has implications for understanding the beneficial behaviors (e.g., saving for retirement), as well as the adverse choices (e.g., accumulation of credit card debt) that seriously impact the well-being of many consumers. It therefore contributes to a growing interest in transformative consumer research. In addition, a number of important areas are considered in these papers, including intertemporal choice, time perception, psychological distance, and consumer welfare.

EXTENDED ABSTRACTS

"Eliciting Subjective Discount Rates: Monthly Patterns of Impatience Among the Very Poor"

Erin Krupka, Institute for the Study of Labor (IZA), Germany

The very poor are important targets for US government policies and financial transfer programs. Broadly speaking, individual time preferences have a fundamental role to play in explaining consumption and financial decision making (eg. Angeletos et al. 2001), but some have specifically highlighted the relationship between impatience and financial decision making among the very poor (Meier and Sprenger 2007, Shapiro 2005). It has been suggested that an important source of vulnerability for the poor stems from tight financial constraints which may turn small mistakes, like over-spending at the beginning of the month, into big problems (Caskey 1994, Bertrand, Mulinathan and Shafir, 2004, Eckel et al. 2004). Several papers have found evidence for a monthly pattern in consumption and in time preferences (Shapiro 2005, Wilde and Ranney 2000). This later group of papers suggests that there is a link between rising financial desperation and changing time preferences over the course of a benefit month and the former set of papers suggests that financial constraints play a role in determining monthly patterns of behavior.

Using a sample of 975 married male welfare recipients participating in the Seattle Income Maintenance Experiment (SIME), this paper examines the relationship between rates of subjective time preference (ie discount rates elicited using hypothetical scenarios) and the timing of benefits among welfare recipients. The income maintenance experiments, from which the data for my analysis come, were conducted in the 1970's to examine the effect of negative income tax welfare programs on work behavior. In this paper I use two different and common measures of impatience to explore the relationship between elicited impatience and benefit check receipt.

This paper exploits variation in the interview date of the "Time Horizon and Planning" module, which is orthogonal to the welfare benefit disbursement date, to demonstrate a 'daily discount rate' that is increasing over the course of the benefit month while controlling for socio-economic variables and economic behaviors collected as part of the larger study. The correlation between monthly benefit receipt (or the timing of pay checks) and behavior among welfare recipients (and those with low income) has received some empirical support. In economics, Shapiro (2005) analyzes caloric intake of food stamp recipients and finds that intake declines by 10 to 15 percent over the food stamp month. Wilde and Ranney (2000) find similar patterns for food spending and energy intake after food stamp receipt. Using a sample of mostly retired US

workers and a separate sample of UK households, Stephens finds that consumption expenditures are excessively sensitive to monthly receipt of social security checks and paychecks respectively (Stephens 2003, 2006). This literature has focused on the ways in which consumption varies with the timing of welfare benefits and has suggested that the ‘excessive sensitivity’ to monthly payments stems from credit constraints and or poor financial management. In this paper I show a similar sensitivity of subjective discount rates to the timing of benefit payments.

Using the “Attitudes to Credit” module, I can create a subjective perception of credit constraint and examine whether the increase in the daily discount rate I observe can be accounted for by controlling for perceived credit constraints. I find that those who believe themselves to be credit unconstrained have significantly lower discount rates but that the daily discount rate remains significant and increasing over the benefit month.

The design of the Seattle Income Maintenance experiment also allows me to test whether exogenous variation in the size of the monthly transfer affects the daily discount rate. In the Seattle Income Maintenance Experiments, benefit levels (and other sources of non-work related income) were replaced by the experiment at 95%, 120% or 140% of pre-experimental benefit levels for 3 and 5 years (depending on treatment status). Thus, I can examine the effect of higher benefit levels on impatience and on the monthly impatience trend. I find no significant differences between daily discount rates elicited for controls and for those receiving larger benefits, the coefficient on the daily discount rate remains significant, and is, in some cases, larger.

This paper’s final contribution is an empirical one to the growing interest in the study of impatience, and its correlates, among the very poor (Lawrence 1991, Bertrand et al 2004, Eckel et al. 2004). While the data used here are from the 1970’s, my main finding of an increase in the daily discount rate over the benefit month is consistent with estimates of the relationship between subjective impatience over the benefit month using more recent data. The main result of my paper resonates with a policy recommendation for distributing welfare payments in smaller installments so that households may be assisted in smoothing consumption. Further, the results would caution against simply raising benefit levels without changing how they are administered.

“Patience Auctions: Novel Mechanisms for Eliciting Discount Rates and the Impact of Time vs. Money Framing”

Christopher Olivola, Princeton University, USA

Stephanie Wang, California Institute of Technology, USA

How do people trade off consumption in the future with current consumption? Measuring discount rates or discount functions is crucial to answering this question, but such measurements pose many methodological challenges. The majority of current measurement methods, such as matching tasks or hypothetical choice, suffer from important weaknesses (Frederick, Loewenstein, & O’Donoghue, 2002). Either they only provide bounds on the discount parameter rather than a point estimate or they are not carried out with real payoffs, thus giving participants no incentives to provide accurate answers and possibly limiting their external validity. In contrast, auction-based approaches can overcome these limitations by providing incentive-compatible mechanisms to elicit discount rates. For example, in second-price private-value auctions, the dominant strategy is for each bidder to bid his/her true value for the good regardless of what the other bidders do (Vickrey, 1961).

We introduce, test, and compare two novel auction-based experimental methods for eliciting discount rates. In these “patience auctions”, participants could either receive \$10 immediately or a payoff sometime in the future, as determined by the bidding process. The two types of single-round sealed-bid “patience auctions” that we used differed with regard to the dimension that participants could bid on: money versus time. We also compare the relative merits of using first-price auctions versus second-price auctions. In each money-bid auction, the length of delay for the future payoff was pre-set and participants simultaneously bid the monetary amount for that payoff. The lowest bidder obtained the bid-determined payoff at the end of the pre-set delay period and all other bidders received \$10 at the end of the session. In the first-price money-bid auction, the bid-determined payoff was the lowest bid whereas in the second-price money-bid auction, the bid-determined payoff was the second lowest bid. In each time-bid auction, the monetary amount for the future payoff was pre-set and participants simultaneously bid the length of delay for that payoff. The highest bidder obtained the pre-set payoff at the end of the bid-determined delay period and all other bidders received \$10 at the end of the session. In the first-price time-bid auction, the bid-determined length of the delay was the highest bid, whereas in the second-price time-bid auction it was the second highest bid. We discuss the important advantages these auctions have over other incentive-compatible methods of elicitation, including Becker-DeGroot-Marschak (BDM) and alternative auction designs. In particular, we show that patience auctions provide a more efficient method for eliciting discount rates from large numbers of participants than previous procedures, yielding significant savings of time and money.

In each of the four experimental auction sessions, fifteen participants bid in eight money-bid auctions and eight time-bid auctions, with different pre-set parameters for the delayed payoff or

the length of delay, depending on the bid type. All the auctions were first-price auctions in two of the sessions and second-price auctions in the other two sessions. Participants were given no feedback about others' bids or the outcome of each auction. They were paid based on the outcome of one of the sixteen auctions, chosen at random, after all auctions were completed, in order to avoid any incentive distortions. In addition to the auctions, we administered surveys to another group of participants. These surveys were designed to be the hypothetical matching-task equivalents of the auctions: the parameter values used and their orderings were identical to the ones used in the auctions. This allows us to compare the discount rates revealed through the incentive-compatible auctions to those obtained with the commonly used matching task method. Sixty Princeton undergraduate students participated in the experimental auction sessions and an additional thirty completed the hypothetical matching-task surveys.

Beyond their methodological advantages, these auctions allow us to examine new and important questions about the determinants of discounting. Using our within-subject bid type manipulation, we can compare how discount rates vary depending on whether the auction focuses participants' attention on the temporal or monetary dimension of delayed rewards. We find that people are more patient when they bid time than when they bid money—a difference not obtained with equivalent hypothetical matching surveys. Specifically, the estimated mean daily discount rate (DDR) was lower in the time-bid auctions than in the money-bid auctions. While this result supports a “constructed preferences” account (Lichtenstein & Slovic, 2006) of intertemporal choice, we also find a strong within-individual correlation between implied discount rates obtained under time and money bidding, suggesting that approximately half the variance is driven by stable underlying preferences for discounting. Our results are robust to varying assumptions about the curvature of the utility function (risk-aversion vs. risk neutrality), as well as the form of the discount function (exponential vs. hyperbolic). Finally, we find that, contrary to standard auction theory predictions, first-price auctions provide more coherent estimates of the discount rates than their second-price equivalents.

We discuss why standard models of discounting fail to account for the disparity we find in discount rates when people bid money versus time. We then consider how our results relate to other recent findings in psychology, regarding the way people value time versus money. We also discuss the implications of these experimental results for the design of economic mechanisms that involve intertemporal tradeoffs. One example is treasury auctions of bills and bonds that have a pre-specified payoff structure in the future. We consider the possible outcomes of alternative treasury auction designs that elicit time bids for pre-determined current prices and future payoffs rather than the existing money bid method.

“Event Representation, Similarity, and Preference in Temporal Context”

Samuel Day, Indiana University, USA

Daniel Bartels, University of Chicago, USA

Similarity is widely believed to play a major role in determining how entities, including choice options, are grouped and considered together, and how the consideration of one entity or event brings related knowledge to mind (e.g., Shepard, 1987). In three studies, we considered a novel factor that might affect similarity: this distance in time in which the comparison is considered. Previous studies had shown that similarity can vary widely with factors such as prior knowledge (e.g., Chi, Feltovich & Glaser, 1981) and the comparison context (e.g., Medin, Goldstone & Gentner, 1993).

It is notable that several theories in intertemporal choice theorize representational change over time (e.g., that negative information is discounted at a higher rate, that “affective” information is discounted at a higher rate, or that “low-level” information is less weighty at greater temporal distance), but with few exceptions, representational change is never tested. The current studies offer one such direct test.

Construal Level Theory (CLT; Trope & Liberman, 2003; Liberman & Trope, 1998) proposes that events in the distant future are likely to be construed primarily in terms of their abstract, central, goal-related features. Conversely, representations of events that are closer to the present are likely to contain more concrete, contextual information. These are referred to as high-level and low-level construals, respectively.

The current research draws on this theory, and asks whether these differences in which information is salient may influence how similar two events are perceived to be. For instance, events that share more high-level than low-level commonalities should seem more similar in the distant future, when the abstract goal information (which is shared) is highlighted, and contextual information (which differs between the two) is less available. An example would be the two events “going to the dentist” and “joining a health club”, which involve some obvious high-level similarities pertaining to long-term health goals, but are quite different in concrete and contextual details (the “low-level” features). Conversely, we should predict the opposite pattern for events that share primarily concrete features. For example, “going to the dentist” and “getting a tattoo” are surprisingly similar in terms of specific details (reclining on a chair, needles, discomfort, etc.), but seem quite dissimilar in terms of the larger goals that they reflect.

Contrary to the first pair, these sorts of events should seem more similar in the near than the distant future, since near future construals should emphasize their concrete commonalities.

In our first experiment, we asked participants to rate the similarity of event pairs such as these, which could share either high-level (abstract, goal related) commonalities, or low-level (concrete, contextual) ones. Additionally, these events were described as taking place in the near future (“this week”) or the distant future (“next year”). As predicted, there was a significant interaction between commonality level (low v. high) and temporal distance (near v. distant). Pairs sharing high level commonalities were rated as more similar in the distant future, while those sharing low-level commonalities were rated as more similar in the near future.

The first experiment contained a possible confound: two events that are near to the present are also necessarily near to each other, but distant events might not be. To address this issue, we ran a second experiment that included a “distant-close” condition, in which events are described as occurring in the same week next year. We replicated our basic effect: effects appear to be based on

distance from the present (not distance between events). The distant-close condition was virtually identical to the Distant condition, but significantly different from the Close condition.

In our third experiment, we replicated these findings for events described in the near and distant past. Again, we found a significant interaction, with high-level pairs rated more similar in the distant past, and low-level pairs more similar in the recent past.

A great deal of human cognition involves planning for the future, and considering and learning from the past. The current studies suggest that these temporal distances should have a significant impact on perceived similarities, and therefore have an important effect on how knowledge is organized, and which entities and events are grouped together. This, in turn, should have important consequences for people's judgments and decisions.

Similarity can impact the manner in which choice alternatives are grouped, the adoption of a reference point, and ultimately, the ranking of preferences. We plan to discuss the implications of our findings for context effects. Specifically, Dhar & Glazer (1996) found that context effects were produced by underlying changes in similarity between choice options. We will use temporal distance to induce changes in perceived similarity and make predictions about how to turn substitution effects (between alternatives that are perceived to be similar) into attraction effects (when alternatives are perceived to be less similar).

"Applications of the Savage Test to Intertemporal 'Anomalies'"

Shane Frederick, Yale University, USA

Daniel Read, Durham University, UK

In his classic *Foundations of Statistics* (1954), Leonard Savage discusses the criteria for judging the normative status of a decision principle. His focus was the Allais paradox, a pair of choices for which the modal responses (including Savage's) violate the sure-thing principle—an alleged tenet of rational choice. Savage decided that 'if, after thorough deliberation, anyone maintains a pair of distinct preferences that are in conflict with the sure-thing principle, he must abandon, or modify, the principle.' In other words, if preferences are robust to deliberative reflection by intelligent individuals—if they pass "the *Savage test*"—the principle they violate ought to be discarded as a requirement of rational choice. Slovic and Tversky (1974) applied the Savage test to the Allais paradox by exposing individuals to arguments for and against the sure thing principle. After reading arguments from both sides, most continued to make the choices that jointly violate the sure-thing

principle: they preferred a 10% chance of 5 million to an 11% chance of 1 million but rejected a 99% chance of 5 million, preferring the sure million. Thus, if one grants that the participants were "intelligent individuals" and that a hearing of the evidence allowed them to achieve reflective equilibrium, the Savage test dictates that the sure thing principle be jettisoned as an axiom of rational choice.

Variants of the Savage test could be applied to many problems in judgment and decision making literature. For example, Tversky and Kahneman (1983) show that the "conjunction fallacy" is diminished when the two critical items that are normally embedded among six unrelated items are placed side by side, the juxtaposition cues the logical rule of set inclusion for some respondents; they recognize that it *can't* be more likely for Linda to be a feminist bank teller than for her to be "just" a bank teller. That is, the reflective answers of statistically sophisticated respondents shows a recognition of the validity of that logical principle.

In this paper, we use a 'minimal' Savage test to examine the status of the major "anomalies" in *intertemporal* choice. Following the aforementioned logic, we reasoned that if people are required to make two discounting judgments side by side (or in close succession), then they must consider any differentiation between them as normatively correct—because they would otherwise capitalize on the opportunity to coordinate their responses. If, for instance, people believe they *should* apply a constant discount rate to all delayed outcomes, regardless of the magnitude, valence, or timing of the delay, then the main intertemporal choice anomalies—the "magnitude effect", "sign effect", and "hyperbolic effect" should diminish if discount rates were elicited in a manner that facilitates comparisons (e.g., the magnitude effect should be less pronounced if subjects evaluate "small" and "large" amounts side by side, than if they evaluate them separately). Conversely, if people believe that differences in discount rates *are* justified, the opportunity to consider multiple judgments side by side will not eliminate the effects, and might even increase them, by drawing attention to a factor that subjects consider to be normatively relevant.

We find that the tenets of the discounted utility model (DU) have little appeal to most intelligent adults. When experimental circumstances facilitate direct comparison of discount rates across outcomes differing in valence, magnitude, and delay, respondents did not coordinate responses. Indeed, two of the so-called "anomalies" (the magnitude effect and the sign effect) were *more* pronounced under these conditions. Thus, respondents apparently believe that it is legitimate to discount different goods differently. Admittedly, if discrepant discount rates are not reconciled by additional reflection, one could always counter that respondents were not encouraged to think hard *enough*. However, we show that respondents encouraged to think more deeply about their pattern of responses diverge *further* from the dictates of the theory. On the view that normative models draw support from the reflective equilibrium of intelligent individuals, these results undermine the *normative* validity of DU as well as its *descriptive* validity.

SYMPOSIUM SUMMARY

Taking It to the Streets: Methodological Challenges of Doing Transformative Consumer Research on Health

Julie L. Ozanne, Virginia Polytechnic Institute and State University, USA

SESSION OVERVIEW

A long tradition exists of bringing the expertise of consumer researchers to pressing social problems, such as Alan Andreasen's (1975) classic work on the disadvantaged consumer. Transformative consumer researchers are developing a multi-paradigmatic program of research that directly engages different stakeholders to help solve social problems and increase consumer well being. Consumer researchers stand in a unique position as informed brokers between the interests of business, consumers, and policy makers. Like other social scientists, we employ rigorous methods and theories and seek to alleviate social problems. Unlike other social scientists, our constituency is consumers, our domain is consumption, and we have a sophisticated grasp of businesses, their strategies, and techniques. Increasingly, the great social problems of our time, such as improving health, are tied to the practices of both businesses and consumers. This ability to converse intelligently with these different stakeholders gives us the potential to broker sustainable change. Nevertheless, practical challenges emerge when doing transformative research.

This special session brings together consumer researchers who are all engaged in programmatic research that examines health problems but employ different methods. Sonya Grier and Shiriki Kumanyika discuss findings from an on-going program of community-based social marketing. Their research examines marketing as a contextual factor on food practices and obesity among African-Americans (Grier and Kumanyika 2008; Grier et al. 2007). In their presentation, they discuss conceptual and methodological challenges related to assessing the marketing environments of African Americans, which occurs at a confluence of interests and generates significant media interest. Craig Andrews, Scot Burton, and Rick Netemeyer examine the effects of a statewide, anti-smoking media campaign on adolescents (Andrews et al. 2004) and adults (Netemeyer, Andrews, and Burton 2005) using telephone interviews. This study was taken to scale in this statewide effort that involved negotiations with researchers from public health and marketing and political decision makers, which had both positive and negative impacts on the research. Laurie Anderson and Julie Ozanne employ a community health approach to examine the health beliefs and cultural practices in a Mexican-American and Native-American town where diabetes rates are 23%. Engaging community members to participate in a research project required tremendous flexibility and time. A series of methods were employed as the project continued including participant observation, interviews, photography, and action methods (Anderson 2007; Ozanne & Saatcioglu 2008).

This session highlights that despite employing different methods, these field projects all examine complex social problems that invariably involve methodological ingenuity, complex trade-offs, and intricate negotiations among various stakeholders. These researchers bring insights from their field work to explore the construction of transformative knowledge that inescapably emerges within a web of social and political interests. While these researchers study health issues from different theoretical and methodological perspectives, a common set of issues and questions emerges in their field work, which offers a platform from which we can debate the challenges and opportunities of doing research aimed at improving consumer well being. This session would be relevant to re-

searchers interested in transformative consumer research, health care, social marketing, and at-risk consumer segments.

EXTENDED ABSTRACTS

"Methodological Challenges in Assessing the Food Marketing Environment of Target Segments"

Sonya Grier, American University, USA

Shiriki Kumanyika, University of Pennsylvania, USA

The extremely high rates of obesity have led researchers, government health organizations and advocacy groups to characterize obesity as an 'epidemic' (Institute of Medicine 2005a; Institute of Medicine 2005b; World Health Organization 2003). In the United States, although obesity is population wide, it is not equally distributed among socio-demographic groups. Ethnic minority status is associated with higher than average obesity prevalence among children and adults, particularly women (Ogden et al. 2006; Ogden et al. 2002). Researchers, policymakers and health advocates debate how food marketing strategies that encourage excess consumption of food and/or discourage physical activity create "obesogenic" environments (Hawkes 2004). A review of past large-scale public health efforts with elements similar to obesity prevention indicate that changes in the marketing environment will be a critical element for success (Economos et al. 2001; Koplan et al. 2005). Research has also described contextual differences in the type and nature of marketing exposures that may limit the effectiveness of health promotion initiatives aimed at preventing obesity among ethnic minority consumers (Grier and Kumanyika 2008; Kumanyika and Grier 2006).

The parallel discussions of the excess risk in minority populations and the importance of the marketing environment underscore the importance of understanding the marketing environments of specific target segments. However, discussion of specific conceptual and methodological approaches to assess the marketing environment of specific consumer segments have not been central to academic research or public policy discussions regarding obesity. For example, although government agencies recently recommended that food companies tailor their public education programs and market more nutritious foods to specific racial/ethnic minority populations, limited mention was made of the socio-contextual barriers these efforts may encounter (The Federal Trade Commission 2006). Although knowledge about the marketing environments of specific populations is limited, it is needed to inform such discussions (Grier et al. 2007; Kumanyika and Grier 2006). A focus on understanding marketing as a contextual variable becomes especially important given the focus on social marketing and transformative consumer research as social change mechanisms underlying public health, and public policy (Esperat 2005; Andreasen 2002).

We will discuss conceptual and methodological challenges related to assessing the marketing environments of specific target segments. We will draw from several projects related to an ongoing, grant-funded research program aimed at illuminating the marketing environment of African-Americans in light of disparities in obesity. In this community-based social marketing research, we examine marketing as a contextual factor on food-related attitudes, beliefs, norms and practices from both emic and etic perspectives.

Thus, we seek to have this research driven by realities facing the community (Esperat 2008).

In one project, we conducted field observations at three health centers that varied in their ethnic composition to inform the development of protocols to assess marketing as a contextual influence on childhood obesity. The observations allowed a qualitative assessment of context-specific marketing factors that may not emerge in standard survey questions. In another project, we conducted a systematic review of the available evidence about the food marketing environments in which African Americans live. We developed an analytical framework for defining the marketing environment of a population sub-segment, created a search strategy to identify relevant articles, and developed a coding scheme to assess the quality of identified articles. The assessment of the validity and reliability of the marketing variables across diverse studies presented key challenges for understanding the quality of marketing environment data. Issues arose with regard to making appropriate comparisons between target segments who may inhibit multiple overlapping contexts. Examples will also be drawn from other research in progress.

We will integrate across several projects to propose general and specific research strategies for assessing the marketing environments of target segments. We will also discuss issues relevant to translating the conceptual frameworks for the projects into the participatory involvement of the community. Finally, we will outline the types of future research that can address deficiencies in the current evidence base regarding how differences in the “street-level” contexts of target segments, including the marketing environment, may limit the generalities that can be drawn regarding population health interventions. The presentation aims to support the development of consumer research that generates practical solutions to contribute to the positive transformation of communities.

“Insights and Challenges in Studying the Effects of Anti-Smoking Ad Campaigns and Other Transformational Consumer Research”

J. Craig Andrews, Marquette University, USA

Scot Burton, University of Arkansas, USA

Richard Netemeyer, University of Virginia, USA

The use of tobacco is the foremost preventable cause of premature death, causing approximately 5.4 million deaths and currently responsible for the death of one in ten adults worldwide (World Health Organization 2008). Sadly, half of the 650 million global smokers will die prematurely (World Health Organization 2008). In the U.S. alone, smoking results in some 438,000 premature deaths each year and \$167 billion in total tobacco-related disease costs (Centers for Disease Control and Prevention (CDC) 2008). Given this level of human and financial cost, it is not surprising that advertising and marketing communication efforts aimed at reducing smoking rates are viewed as critical (Fiore et al. 2004).

In this session, we focus on a set of adolescent and adult studies based on a multi-million dollar, statewide anti-tobacco advertising campaign in Wisconsin. We examine many of the methodological difficulties and compromises involving negotiations among diverse stakeholders (i.e., ad agency creative and media professionals, public health officials, policy makers). The campaign was funded as a result of the national Master Settlement Agreement between the states and the tobacco industry. Specific ads used in the adolescent campaign were targeted at middle and high school aged youth in Wisconsin, for which smoking incidence levels were higher than national averages. These ads focused primarily on

industry deception/anti-imagery, with other themes addressing addiction and harmful effects of second-hand smoke. The campaign ads had been successfully tested and run in other states and were placed in youth television and radio spots in seven major Wisconsin markets over a six month period.

In this first study, telephone interviews were conducted with over 900 adolescents aged twelve to eighteen years. (One of the presenters had some input into the design and measures for the adolescent and adult studies.) Based on prior research, we examined predicted relationships among social influence (i.e., friends, siblings, or adult smoker in the home), prior smoking trial behavior, attitudes toward specific campaign ads, anti-smoking beliefs, and adolescent smoking intent. Two primary questions were addressed: (1) Do counter ad campaign attitudes directly impact anti-smoking beliefs and intent in a manner similar to that of conventional ads? and (2) Can ad campaign attitudes have a stronger effect on beliefs and intent for adolescents with prior smoking behavior and for those exposed to social influence? Findings show that ad campaign attitudes, prior trial behavior, and social influence all directly affect anti-smoking beliefs, and that ad campaign attitudes interact with prior trial behavior to strengthen anti-smoking beliefs (Andrews, Netemeyer, and Burton 2004). Importantly, our results indicate that attitudes related to the campaign, prior trial behavior, and social influence directly influence intent, and ad campaign attitudes interact with social influence and prior trial behavior to lessen adolescent intent to smoke. Overall, our study findings point to the importance of understanding key characteristics of the target population in the evaluation of counter-marketing campaigns. Studies examining general adolescent populations, while ignoring the measurement of important factors such as prior trial behavior and social influence, may be masking significant effects of the campaign.

In addition, separate ads in the Wisconsin Anti-Tobacco Campaign were targeted at influencing adult smoker beliefs (e.g., about the harmfulness of addiction, environmental smoke, and tobacco industry deceptive practices). In this second study, our findings for 327 adult smokers show that consideration of quitting is positively influenced by the interaction between the number of children living at home and beliefs about deceptive tobacco industry practices used to induce people to smoke (Netemeyer, Andrews, and Burton 2005). In general, implications for counter-marketing communications and for the design and understanding of future anti-smoking campaigns aimed at adolescents and adult smokers are provided.

We then discuss the many methodological challenges and problems inherent to field studies that limit the control of important factors that might differ among important political stakeholders (i.e., ad agencies, public health officials, policy makers) and can lead to non-optimal research designs. Based on our set of studies, this includes dealing with multiple advertisements in a campaign (rather than a single ad), different domains of social influence, varied levels of ad exposure, different types of relevant focal antismoking beliefs, lack of true control groups, unmeasured/omitted variables, single item and more ‘practitioner-based’ measures, lack of causal designs and related inferences, and use of multiple media. In addition, we discuss some of the challenges regarding the political process of dealing with different constituencies with widely varying perspectives in campaigns designed to promote consumer welfare via transformative consumer research.

More generally, we draw upon additional examples from our participation in important field studies involving market-based transformative consumer research. This includes participation with the Behavioral Change Expert Panel as part of the National Youth

Anti-Drug Media Campaign, as a Consumer Research Specialist with the Federal Trade Commission, and work for the Risk Communication Advisory Committee of the Food & Drug Administration. These positions dealt with important and difficult challenges involving campaign communications, design, assessment, and advertising copy testing and tracking. Our examples also include recent involvement in the Consumer Testing Group of the Keystone Center's Food and Nutrition Roundtable, which is charged with developing a simple, easily-understood, Front-of-Pack (FOP) Icon system that aims to identify the healthier choice for consumers within each category based on pre-established nutrition criteria. Finally, based on these examples and studies, general recommendations are provided about how to best proceed in the design and implementation of projects on consumer transformational research.

"Community Action Research on Diabetes"

Laurel Anderson, Arizona State University, USA
Julie L. Ozanne, Virginia Polytechnic Institute and State University, USA

Diabetes can be envisioned as a problem involving individual consumer decision making, such as choices to eat a healthy diet and get regular exercise (Moorman et al. 2004). Alternatively, diabetes can be conceptualized as a community problem in which social and cultural forces have a significant impact on community health (Kreuter et al. 2003). For example, diabetes is at near epidemic rates in many Mexican American and Native American communities (Giachello et al. 2003). In this study, we use participatory community action methods to examine diabetes within a town where 23% of its Mexican American and Indigenous American citizens suffer from diabetes. Health care professionals in the community felt that existing preventative programs and services were ineffective in stemming the rise in diabetes. Moreover, cultural beliefs, practices, and institutions have a significant impact on individual consumer's behaviors.

Participatory action research refers to a general methodological approach that seeks to generate knowledge that is rigorous and can be used for social action (Reason and Bradbury 2001). It is widely applied in community health research because this approach is based on the assumption that those people affected by a social problem should be meaningfully included in the research process

(Minkler and Wallerstein 2003). Community members are not merely polled for their opinion, but are actively involved in defining and shaping the research process (Ozanne and Saatcioglu 2008). It is assumed that when community members are involved in the research process they will gain new capacities, they will become more conscious and reflexive regarding the problem, and they will be more ready and committed to taking action that was guided by research based on the needs of their community (Lewin 1946).

We examine an ongoing research project that was first based on participatory observation within a local advocacy group and interviews with members of this community. After the initial exploratory stages of the research, the findings were presented to a group of health workers, social workers, and community members where it coincided with and sparked an interest in the development of a community-based intervention. Specifically, a program is being developed for *promotoras* who are lay health workers and educators that work and reside within the local community. Additional interviews with community members who had diabetes were then collected and the insights from these first-hand accounts were cycled back to help shape the *promotoras* program.

During the fieldwork a number of challenging issues had to be addressed including length of time required to conduct the research, requirements for different types of expertise (consumer, business, and medical), and the sustainability of the social interventions. For example, while traditional ethnographic work often requires time in the community to develop an understanding of local culture and build trust with potential informants, the length of time required to conduct community action research is significantly longer. This longer tenure is due to the need to forge alliances among many different stakeholders, develop high levels of trust needed to get people to participate actively in research and action, and identify the organizational and cultural capacities needed to actually implement programs of social change. The methodological challenges and empirical results will be explored in the presentation.

SYMPOSIUM SUMMARY

Unraveling Motivation: Affective and Cognitive Processes Underlying Consumer Goals and Choices

Monica Wadhwa, Stanford University, USA

SESSION OVERVIEW

"I have come to the conclusion that my subjective account of my motivation is largely mythical on almost all occasions. I don't know why I do things." -Anonymous

Introduction. Dating back to the ancient Greeks, scholars have attempted to elucidate the motivational factors underlying human behavior. Aristotle, who proposed one of the earliest theories of motivation, suggested human behavior to be motivated by a desire to achieve an imagined or a real appetitive outcome, and avoid an aversive outcome. Similarly, Freud suggested that individuals work toward seeking pleasurable experiences and avoiding pain. The importance of understanding what motivates goals and choices has been recognized by the consumer researchers as well. Behavioral researchers have examined motivation through a variety of lenses including hedonic versus utilitarian motives (Shiv and Fedorikhin 1999; Dhar and Wertenbroch 2000; Kivetz and Simonson 2002), motivation as a drive (Hull 1951), and the goal-systems theory (Kruglanski et al. 2002). The three papers in this session integrate some of these perspectives in presenting a dynamic view of goals and motivation.

Session Objectives and Overview. The broad purpose of this session is to present work that adds significantly to the growing body of research on motivational factors that drives consumption goals and choices. The more specific objectives of this session are to 1) to explore how affective and cognitive processes underlying an activated goal drive consumption momentum, and 2) to examine the role of exogenous irrelevant sources of motivation in energizing goal striving behaviors. To meet these objectives, three papers are included in this session, all of which are in advanced stages of completion. Keeping in mind the overall theme of ACR 2008 ("Port of Call"), and the diverse audience that ACR conference attracts, the papers in this session explore the factors that impact the motivation underlying consumer behavior from different, yet related perspectives. While the first paper examines how goal related attentional biases can energize momentum toward goal satiating stimuli, the second paper extends the focus of the first paper by exploring another factor—goal-compatibility—in energizing goal related actions. Finally the third paper complements the first two papers by exploring the role of exogenous motivational sources that are irrelevant to any specific goal in energizing subsequent goal striving behaviors.

The session will begin with a focus on goal-driven attentional biases among impulsives and non-impulsives that drive indulgent behavior. Suresh Ramanathan will present his work that focuses on how two types of attentional biases, an initial visual attention bias toward temptations and a bias related to inability to avert attention from such temptations motivate indulgent behaviors. His results demonstrate that while impulsive people exhibit both forms of goal-driven biases towards tempting stimuli, it is their inability to avert attention from such temptations that drives the extent to which they show approach reactions toward such consumption stimuli and subsequently indulge themselves.

Amar Cheema will then present his work with Nidhi Agrawal that builds on the first paper by examining the role of goal-compatibility in energizing momentum toward goal relevant con-

sumption stimuli. Specifically, their results show that compatibility between goals (hedonic versus utilitarian), frames (loss versus gains) and construal levels (low versus high) motivates action aimed at acquiring the goal-compatible consumption stimuli. They find the goal-compatibility motivated consumption action toward such consumption stimuli is independent of attitudes related to such consumption stimuli that when people are energized to achieve a goal (acquire the stimulus) on the basis of compatibility, attitudes towards the stimulus do not have a significant influence on action.

Finally, Monica Wadhwa will present her work with Baba Shiv, which complements the first two papers by examining the impact of brief experiences with hedonic cue (e.g., an appetitive taste) on subsequent goal pursuit. Wadhwa and Shiv demonstrate that a brief experience with a hedonic cue can activate a general motivation drive, which, in turn, enhances pursuit for a subsequently adopted goal (e.g., performance on an intellectual goal, dieting goal etc.). Moreover, they show that given a sequence of goals, the activated motivational drive enhances the pursuit for the more salient goal, that is, the goal temporally closest to experience with the hedonic cue. Finally, their findings demonstrate that the impact of experiencing a hedonic cue on subsequent goal pursuit is attenuated if the activated motivational state is satiated prior to the goal adoption.

In an effort to increase audience participation and provide insights about the three papers, the session will have the services of Baba Shiv as a discussant. Shiv has expertise in the area of the role of emotion in decision making, the neurological bases of emotion, and nonconscious motivational processes in decision making. As a discussant, he will contribute insights about the three papers and the general session theme from not only the field of consumer behavior, but also neuroscience, which is of great interest and appeal to many consumer behavior researchers. Each presenter will limit their talk to 15-20 minutes, to allow ample time for him to speak and to engage the audience into a discussion of the research ideas.

We believe that the features of this proposal suit the evaluation criteria for ACR 2008 symposium proposals. Notably, the session includes papers that are likely to have a broad appeal, yet maintain a coherent theme. We feel that this session brings together three papers that use innovative tools to provide cutting edge counterintuitive insights into the motivational processes that drive consumer behavior and decision making. In addition to attracting researchers interested in the domains of goals and motivation, we expect further interest from those who work within the application areas represented.

EXTENDED ABSTRACTS

"Why One Can't Stop Looking at that Temptation: Dynamics of Attentional Biases in Self-Control Dilemmas"

Suresh Ramanathan, University of Chicago, USA

Why do people over-indulge? What motivates a person not just to act on impulse but to do so repeatedly in a manner counter to one's self-interest? A variety of theories have been ventured in the literature. One view, held by behavioral economists, is that such acts of excessive impulsivity may be attributed to extreme hyperbolic discounting. While this may describe the extent to which

people may value the rewarding aspect of indulgence, it does not tell us much about the underlying psychological process. Two views have emerged in the literature in this regard. An affect-based explanation suggests that such indulgences may cause spontaneous activation of lower-order affective reactions that then guide behavior (e.g., Shiv and Fedorikhin 1999, 2002). On the other hand, a motivation-based explanation proposes that rewards carry high incentive value and activate hedonic goals that strengthen over time, leading to over-indulgence (e.g., Ramanathan and Menon 2006). In this paper, I provide additional support for an incentive-salience argument, showing that impulsive behavior and overindulgence are motivated by two different forms of attentional biases toward temptations—an initial visual attention bias toward temptations and bias related to an inability to avert attention from temptations. These biases emerge despite having healthier options that are rated as equally liked and are equally vivid and attractive.

In the first study, participants first completed a scrambled sentence task that was either neutral or designed to activate a hedonic goal. All participants then engaged in a visual probe task (Bradley et al. 2002), in which participants were required to respond as quickly as possible to a small dot probe which was presented immediately after the display of a pair of pictures. The pictorial stimuli used in the visual probe task consisted of 18 color photographs of tempting desserts (e.g., ice-cream, lemon meringue, chocolate cake), each paired with a photograph of a sweet but healthy option (fruit salads, cut fruits). Each picture pair was chosen on the basis of matched liking, vividness and attractiveness as well as size. Pictures were also matched as far as possible on colors. There were an additional 18 pairs of pictures of flowers and vacation spots that were rated as equally pleasant and likeable but had no immediate incentive salience. Eight pairs of neutral objects (e.g., shoes, ties) were used on practice rounds. Picture pairs were displayed side by side. Pictures were presented for either 100 ms or 1250 ms on the screen after a fixation cross that appeared for 500, 750 or 1250 ms at random. The pair of pictures was followed by the dot probe that appeared in the position of one of the two preceding pictures and remained on the screen till the respondent's response. The task consisted of 16 practice trials, followed by 64 experimental trials in two blocks of trials, presented in a new random order in every session. Each picture pair was presented four times, so that pictures and probes appeared equally often on the left and right sides. Attentional bias scores were computed for each participant by subtracting mean RTs to probes replacing the pictures of desserts from the mean RTs to probes replacing the pictures of fruits. Positive values indicate greater vigilance for temptations. Positive values at the 100 ms exposure level indicate an initial visual attention bias towards temptations, while those at the 1250 ms level indicate maintenance of attention and an inability to divert attention from desserts when the probe appeared in the position of the fruit. Next, participants completed a series of filler questions, followed by questions relating to their felt emotions and an assessment of their impulsivity on the CIS scale (Puri 1996). They were then dismissed and ushered one at a time into an adjacent room where they were left alone for 3 minutes (while waiting to complete an unrelated study) with a tray filled with chocolate cookies that the experimenter suggested were from a departmental meeting. The experimenter subsequently counted the number of cookies consumed. Results show that impulsive people showed a strong initial visual attention bias towards the desserts despite being presented with an equally vivid and attractive healthy option. There was no such bias towards either flowers or vacation spots, both of which were rated as equally liked and attractive. Interestingly, this bias did not affect the number of cookies picked up. Rather, it was the bias

related to an inability to avert attention at a more conscious level from the temptation that influenced the number of cookies taken, more so when impulsive people were primed with the hedonic goal.

In a second study, a similar visual probe task was followed by a task requiring participants to continuously move a joystick indicating whether they felt like picking up a tempting chocolate snack on a tray in front of them right at the moment or felt like pushing it away (Ramanathan and Menon 2006). Results once again indicate that impulsive people who were primed with a hedonic goal exhibited a strong attentional bias at the conscious level that prevented them from averting their attention from temptations, and that this bias resulted in more intense approach reactions towards the snack.

Together, these results provide evidence suggesting that motivational influences leading to over-indulgence is likely due to a goal-driven attentional bias that causes people to remain fixated on temptations despite having equally liked and vivid alternatives. Stated differently, these results, therefore, suggest that the motivation to indulge is likely to be based on pure incentive salience of the temptations (Berridge and Robinson 1998) rather than initial affective reactions.

“Compatibility-Driven Momentum in Redemption of Sales Promotions”

Amar Cheema, Washington University in St. Louis, USA

Nidhi Agrawal, Northwestern University, USA

In this paper, we bring together the literatures on choice between hedonic versus utilitarian options, gain and loss frames, and construal level to identify the influence of these factors on consumer decisions in response to price promotions. We identify factors related to the message (product category, frame) and the consumer (construal level) that might make the same promotion (e.g., \$5 off of \$25) more or less likely to be used by the consumer. In doing so, we aim to understand the process by which the compatibility of these factors affects behavior. Based on regulatory fit theory which argues that compatibility between factors generates momentum towards accomplishing the compatible goal (Higgins 2006), we propose that compatibility urges action (e.g., redemption of a coupon) towards compatible stimuli independent of product evaluations. In contrast, stimuli that are incompatible with the goal enhance the role of product evaluations in consumers' decisions to redeem the coupon for the featured product.

Theoretical Background. By examining the effects of compatibility between three factors (product category, frames, and construal level) on coupon redemption, we integrate two disparate streams of literature. First, past research in consumer choice has shown that gain framed choices are likely to favor utilitarian products over hedonic ones (Dhar and Wertenbroch 2000). In contrast, loss framed choices tend to favor hedonic rather than utilitarian options. This research suggests that hedonic items are compatible with a loss frame whereas utilitarian items are compatible with a gain frame. A second set of findings has suggested that factors that focus on losses (e.g., prevention focus) are compatible with a near time frame and factors that focus on gains (e.g., promotion focus) are compatible with a distant time frame (Förster and Higgins 2005). On the basis of these two sets of findings we propose that for products that are associated with a utilitarian goal (e.g., an energy bar), gain framed messages presented under higher levels of construal are most effective because of the enhanced compatibility. In contrast, for products associated with hedonic goals (e.g., a chocolate cake), loss framed messages presented under lower levels of construal are compatible. Compatibility, in turn, generates an enhanced momentum for action and increases redemption likelihood. Importantly,

we expect the effect of compatibility on redemption to be independent of product evaluations.

Overview of Results. In four studies, participants at higher or lower levels of construals are presented with gain or loss framed coupons. These coupons either feature a product associated with a hedonic or a utilitarian goal. Redemption likelihood, evaluations of the featured product, and other process measures are collected. Study 1 shows that for a hedonic product, redemption is highest under compatibility conditions (loss frame presented to low-level construers) than for the other three conditions. Providing further support for the proposed compatibility thesis, study 2 reveals that compatibility (utilitarian product, gain frame presented to high-level construers) leads to greater redemption than the other (incompatible) conditions. Interestingly, our results show that the effect of product evaluation on redemption is not significant in the presence of compatibility, suggesting that a stronger motivation to act, rather than evaluation drives redemption under conditions of compatibility. Consistent with this expectation, study 3 reveals that participants in compatibility (vs. incompatibility) conditions make the redemption decision faster and pay less attention to the product quality. In study 4, we find that redemption of an actual coupon offered by a local restaurant varied in accord with our predictions.

Conclusion. While previous studies on compatibility have focused on elaboration or fluency as explanations for compatibility effects on attitudes, our studies show a mechanism that links compatibility directly with behavior and suggests that compatibility might affect behavior independently of attitudes. Our findings support an explanation based on the strength of engagement—in other words, a process in which compatibility creates a momentum for action—might characterize the effects of compatibility on behavior. Higgins (2006) suggested that people experience greater strength of engagement when responding to goal-compatible (vs. incompatible) stimuli, which should fuel a momentum towards performing the compatible action. Incompatibility dilutes this momentum, lowering the propensity towards action, and increases the impact of product evaluations on redemption. On a broad level, these results contribute to increasing our understanding of consumer motivation underlying goal-directed behavior.

“Kindling the Motivation System: Impact of Incident Hedonic Cues on Subsequent Goal Pursuit”

Monica Wadhwa, Stanford University, USA

Baba Shiv, Stanford University, USA

Our consumption environment is abundant in cues that are high in hedonic value (i.e., cues that are desirable). A whiff of a fragrance, a sample of a refreshing drink or an advertisement picturing romantic images are some such cues that we commonly experience in our everyday lives. While, recent research on consumption motivation suggests that experiencing such high hedonic value consumption cues can lead to generalized reward seeking behaviors (e.g., Vanden Bergh, Dewitte and Warlop 2008; Wadhwa, Shiv and Nowlis 2008), relatively little is understood about whether and how experiencing such cues impact consumer’s subsequent goal related behaviors. Since arguably all of consumer choices and behaviors are goal driven (Bettman, Luce and Payne 1998), investigating how such experiences with hedonic cues impact subsequent goal related behaviors is consequential both from the marketers’ and consumers’ perspectives. Drawing upon the synthesis of research on consumption motivation (Van Den Bergh et al.; Wadhwa et al. 2008) and the recent evidence in neuroscience (Depue and Collins 1999; Berridge 2007; Salamone 2007), in the present research, we propose that the motivational drive activated by brief experiences with hedonic cues can enhance pursuit of a subse-

quently adopted goal. To illustrate, our proposition would suggest that if a consumer adopts an environmental goal following the consumption of an appetitive beverage sample, she should now be motivated to make a larger donation for an environmental cause (than if she had not sampled the appetitive beverage).

We address the aforementioned research proposition in a series of studies across an array of consumer goals and dependent variables. In study 1, we sought to explore the basic research question—whether or not a brief experience with a hedonic cue can enhance pursuit of a subsequently adopted goal. Our findings demonstrate that participants who had experienced a hedonic cue (romantic images) set a higher health goal (i.e., number of hours they were planning to work out), but only when they were primed with a health goal. In study 2, we sought to provide further support for our core research proposition. Specifically, we argue that when the motivational drive state activated in response to experience with hedonic cues is satiated, impact of hedonic cues on subsequent goal pursuit behaviors should get attenuated. To test this logic, we carried out the motivational drive manipulation by employing a sampling paradigm. All respondents sampled either Hawaiian Punch (motivational drive-induced condition) or a neutral water drink (motivational drive-not induced condition) presented to them in the disguise of a newly launched sports drink. Subsequently, we carried out the drive state satiation manipulation, which was adopted from Wadhwa et al. (2008). Specifically, participants who had experienced the hedonic cue either received a surprise reward (candy bar) after the hedonic cue experience but before the goal adoption (motivational drive -satiated), or they received the candy bar at the end of the study (motivational drive-induced). In this study, we measure actual persistence on a subsequent goal, which in this study was an intellectual goal that involved working on anagrams. We predicted that sampling a consumption cue high in hedonic value should enhance persistence on the subsequent intellectual goal involving unscrambling anagrams. However, when the induced motivational drive state is satiated (i.e., when participants received the surprise reward in an intervening task), the impact of hedonic cues on subsequent goal pursuit behaviors (persistence on anagrams) should get attenuated. Consistent with our propositions, we show that respondents who had experienced the hedonic cue (motivational drive-induced condition) persisted longer on the anagrams than those who had not experienced the hedonic cue (motivational-drive-not induced condition). Further, our results show when the induced motivational drive was satiated by giving a surprise reward in an intervening task, the impact of experiencing hedonic cue on subsequent goal persistence was attenuated.

In study 3, we provide further support for our activated motivational drive hypothesis. Further, study 3 shows that given a sequence of goals, the induced motivational drive enhances the pursuit for the more salient goal, that is, the goal temporally proximal to the source of activated motivational drive. To elaborate, in study 3, female participants were sequentially exposed to two goals (dieting and environmental goal), the two goals being separated by a five-minute filler task. However, in one set of conditions (goal salient-dieting), motivational drive was manipulated proximal to the dieting goal—that is, respondents sampled either an appetitive drink (motivational-drive-induced) or a neutral drink (motivational-drive-not induced) as soon as the dieting goal was made salient. In the other set of conditions (goal salient-environment), respondents sampled either an appetitive drink (motivational drive-induced) or a neutral drink (motivational-drive-not induced) proximal to when the environmental goal was made salient. Subsequently, respondents moved to another room where they made food (cookies) and drink (lemonade) choices. Finally,

respondents were asked to indicate the amount of money they were willing to pay for a charity devoted to an environmental cause. They were informed that the amount they indicate will be deducted from their study compensation. Our results show that participants showed enhanced pursuit for the dieting goal when the motivational drive state was activated temporally proximal to the dieting goal. Specifically, these participants chose to consume less of cookies and sweetened lemonade. In contrast, when the motivational drive state was activated proximal to the environmental goal, participants showed enhanced pursuit for the environmental goal—these participants chose to donate more money for the environmental cause. Across these studies, I also rule out alternative accounts related to factors such as mood and arousal.

In sum, our findings suggest that a brief experience with a hedonic cue can enhance pursuit of a subsequently adopted goal that is unrelated to the experienced hedonic cue. Implications for marketers and policy makers are discussed.

SYMPOSIUM SUMMARY

Context-Dependent Search

Kristin Diehl, University of Southern California, USA

SESSION OVERVIEW

While the notion of context-dependence has played a dominant role in the study of consumer decision-making, most research on consumer search has focused on internal or external search costs as search determinants (e.g., Urbany 1990), treating context effects mainly as determinants of consumers' search costs (e.g., Russo 1977). By focusing solely on search costs, past research fails to account for how today's complex decision environments may influence search strategies and for search in environments where search cost are inherently low (e.g., online). Addressing these gaps, this session presents novel perspectives on determinants of consumer search. The research presented investigates the role of different search contexts in the ways consumers search, ultimately linking search to the choices consumers make and the satisfaction they derive from these choices as well as the search process as a whole.

Findings presented in this session suggest that the context in which consumers search can subtly prompt different search strategies. In particular, more restricted or less expected contexts may cue greater search effort while contexts triggering withdrawal tendencies associated with task-related affect may cue truncated search. Further, this session also suggests that the extent of search consumers engage in may affect satisfaction with the process and the choice itself.

The work by Lin and Levav investigates how the structure of product configuration menus can trigger distinct mindsets and ultimately different search strategies. Encountering menus with relatively fewer options to start with, consumers find themselves in a maximizing mode, searching more exhaustively not only from the initial set but also from subsequent, larger selections. Starting off consumers with lots of options, however, triggers a satisficing mindset associated with more superficial search even among manageable sets. Ultimately deeper search leads to greater satisfaction short-term but not necessarily greater remembered satisfaction.

Relatedly, Poynor and Wood explore how different ways of structuring assortment sets affects information acquisition and choices. They compare grouping familiar products either into more conventional taxonomic sets or into less common thematic sets. Results show that for more knowledgeable consumers, thematic groupings act as newness cues that cause them to expend greater effort when deciding among options. Engaging with the decision context in a more effortful way leads to greater incidental learning among expert but not among novice consumers. Experts also seem to derive greater process satisfaction from the more effortful decision context.

Diehl, Morales, Fitzsimons and Simester investigate how the decision context, specifically purchasing a product that elicits task-related affect, can alter where and how much consumers search for and purchase other, unrelated products. Focusing on products that elicit disgust, an emotion associated with a tendency to pull away from one's surroundings, they show that in this context consumers truncate their search even for neutral products. Ultimately lack of search leads to smaller shopping baskets and is associated with lower evaluations of the overall experience.

These presentations address this area of research from diverse and novel perspectives but converge on a central theme: External search environments subtly cue different search strategies and

ultimately alter product choice. Taken together, this session will provide new insights that should be interesting to a wide range of researchers, for example, those studying context effects, assortment size and structure, or the effects of retail environments.

EXTENDED ABSTRACTS

“When Choice is Motivating: Using Product Configuration Sequence to Evoke Maximization”

Claire Lin, Columbia University, USA

Jonathan Levav, Columbia University, USA

Product configuration is an increasingly common consumer experience; consumers now customize a variety of products (such as shoes, computers, cars and pre-fabricated houses). Yet little is known about one crucial variable for designing the configuration process: the sequencing of choice menus. All else equal, how does the order of choice menus affect people's choice and satisfaction?

Consistent with research on consumer mindsets, we propose that the order by which people make a sequence of decisions may determine the overall approach they take in making these decisions. A mindset refers to a cognitive process or judgmental criterion that is triggered by a task and persists in subsequent tasks (Xu and Wyer, 2007). For example, once people learn a rule for solving an initial series of problems, they persist in applying this rule to later problems (Luchins & Luchins, 1959). The effect of mindsets has also been demonstrated in consumer settings. For example, in the shopping momentum effect (Dhar, Huber and Khan, 2007), after people make a purchase decision and get into the “which to buy” mindset, they are more likely to make subsequent purchase (Xu and Wyer, 2007). Similarly, in the context of product configuration, we expect that the mindset triggered by initial choice menus may also affect people's approach to later choice menus.

We hypothesize that the sequence of choice menus may determine people's tendency to maximize vs. satisfice, which we conceptualize as a mindset either to search exhaustively through all options in order to identify the best or to stop searching as soon as a satisfactory option is encountered. To test this hypothesis, we choose the number of options of each choice menu as a variable for sequencing the choice menus. Prior research has shown that a large number of options may be demotivating (Iyengar & Lepper, 2000). As a result, we expect that when product configuration begins with a choice menu that includes a relatively large number of options, people may be more likely to resort to a simplifying heuristic like satisficing. In contrast, when product configuration begins with a choice menu that includes a relatively small number of options, people may find it relatively easy to maximize, i.e. search through the options to identify the best one for them. Based on the concept of mindset, we expect that the maximizing or satisficing heuristic/mindset that is triggered by the initial choice menu will persist throughout the product configuration process. Further, the maximizing or satisficing mindset may affect people's satisfaction in a similar pattern observed among chronic maximizers and satisficers (Iyengar, Wells and Schwartz, 2006).

We tested our hypothesis in three experiments. Participants encountered a sequence of choice menus either with an increasing number of options (the increasing-sequence condition) or a decreasing number of options (the decreasing-sequence condition). In

Experiment 1, 49 participants configured a 10-song CD, which they could take home 2 weeks after the study. The 10 songs were chosen from 10 non-overlapping music collections. In the increasing-sequence condition, the number of song options increased from one music collection to the next (5, 10, 15, ..., 50), and vice versa in the decreasing-sequence condition. Our results showed that participants in the increasing-sequence condition engaged in a deeper search effort—they sampled about 50% more songs and spent 50% more time in making decision.

In Experiment 2, using a similar task, we measured the degree of self-reported “maximization tendency,” and found that the maximizing measure mediated the effect of sequencing on search. In addition, we ruled out an alternative explanation that participants who encountered a small choice menu first might search more because they mistakenly expected that all subsequent choice menus would have a similarly small number of options. We found that regardless of whether participants were informed of the actual numbers of options in all choice menus in advance, they followed the same search patterns. Apparently the mindset primed by the initial choice menu exerted a strong effect that was not overcome by the information provided to participants.

In Experiment 3, we measured participants’ satisfaction with their choices immediately and again two weeks after the experiment. The immediate satisfaction was measured on a scale of 1 to 7. The delayed satisfaction was operationalized as whether people were more or less likely to follow through on their earlier decisions by coming to claim their CD two weeks later. We found that participants in the increasing-sequence condition, who exhibited stronger maximizing tendencies, were more satisfied immediately yet were less likely to claim their CD gift two weeks later, reflecting lower long-term satisfaction.

Our research shows that the sequence of choice menus can determine people’s mindset for maximizing vs. satisficing. Overall, people spend more effort searching through options when they encounter a sequence of decisions in which the number of options increases from one choice menu to another. Self-reported degree of goal maximization mediates the effect of menu sequence on depth of search. Finally, the maximization vs. satisficing mindset triggered by menu sequence has a downstream effect on satisfaction: temporary maximizers are more satisfied in the short-term but less satisfied in the long-term.

“Designed To Learn: How Category Design Influences Consumer Learning, Satisfaction and Choice”

Cait Poynor, University of Pittsburgh, USA

Stacy Wood, University of South Carolina, USA

Given the proliferation of product information in the marketplace, consumers should be well-equipped to acquire knowledge and make good choices. However, due to a host of individual and contextual challenges (Alba and Hutchinson 2000, Camerer and Johnson 1991), even knowledgeable consumers may not learn information they encounter. This research suggests a novel means of improving consumers’ incidental learning, proposing that type of category structure used to group products in the retail environment can be adapted in ways which help consumers acquire more knowledge while shopping.

We focus on the effects of organizing an assortment in very familiar taxonomic groupings, where objects are grouped by type, or more abstract thematic groupings, a type of goal-derived structure. Two studies employing foods as our target stimulus show that category structure can impact consumers’ learning of nutritional information. However, the extent of learning generated by each design depends on consumers’ prior knowledge. Whereas low prior

knowledge consumers’ incidental learning is low and promoted by the highly fluent context of taxonomic sets (Alba and Hutchinson 1987), for highly knowledgeable consumers thematic category designs operate as a “newness cue” (cf. Poynor and Diehl 2008, Wood and Lynch 2002). For these consumers, thematic category structures prompt more effort during shopping. Increased effort leads to superior product information encoding for experts and raises expert consumers’ satisfaction with their shopping experience. In addition, we find that greater effort among experts is associated with objectively higher choice quality. For less knowledgeable consumers, however, these effects do not hold.

A pretest first identified thematic groupings which were less expected in the marketplace but equally plausible as taxonomic groupings for the same items, consistent with the nature of a “newness cue”. Participants (n=38) saw a menu containing the same 16 items organized either taxonomically (soups, sandwiches, finger foods, salads) or by cuisine theme (American, Chinese, Mexican, Italian.) Participants rated the menus as equally believable, but as expected, felt that the taxonomic groupings were more expected than were the thematic groupings.

Study 1 integrated these categories into a shopping situation to see if the less-expected thematic category structure would impact consumer learning as hypothesized. Participants (n=70) first completed a test of their prior knowledge of the nutritional content in foods. During the experiment, they were asked to imagine that they were working on a class project and decided to order lunch online. They were given the general goal of choosing a “nutritious” food and shopped a website containing 16 items organized either by the taxonomic or thematic structures identified in the pretest. Participants clicked on food names to review their nutritional information. After selecting a single food, participants completed a 10-item “surprise” quiz about the nutritional content of foods on the website, which provided our main dependent measure.

Analysis suggested that the thematic structures did, in fact, operate as newness cues for expert consumers. In the taxonomic structure, higher prior knowledge consumers did not outperform novice consumers on the quiz, consistent with a complacency effect (Wood and Lynch 2002). However, higher prior knowledge consumers showed significantly better recall for nutritional information in the thematic as opposed to the taxonomic sets. Experts also demonstrated significantly better recall in the thematic sets compared to novice participants shopping in the same structure, suggesting that their complacency was overcome. Interestingly, however, the thematic organization also created marginally significant *decreases* in incidental learning among lower prior knowledge consumers relative to the taxonomic set.

For thematic structures to be aptly characterized as newness cues, it was also important to establish that their effects occur at encoding, by increasing processing effort among experts, rather than at retrieval. Therefore, in study 2, we added an external incentive to process the nutrition information prior to shopping for some participants (n=76). For the remaining participants (n=64), the incentive was given prior to recall but after exposure to the website information. We hypothesized that study 1’s effects would replicate when the incentive was offered after exposure to the information, but not when the incentive occurred before encoding. In addition, we measured participants’ effort, shopping satisfaction, and choice quality.

As expected, study 2 replicated study 1’s findings when consumers had received external incentives after shopping. Once again, experts learned more from the thematic structures than they had in the taxonomic structures. By contrast, novices showed a significant decrease in learning in thematic as opposed to taxo-

nostic sets. Furthermore, the effect of category design on learning was mediated by the amount of effort expert consumers reported investing during search. In addition, the increase in effort seen among expert consumers led to higher, rather than lower shopping satisfaction ratings than in taxonomic sets. Finally, results show that expert participants chose significantly more nutritious foods when selecting from thematic as opposed to taxonomic sets. By contrast, when a processing incentive was received before exposure to the choice set, only prior knowledge predicted participants' learning and choice quality.

Data from a third study will be available for discussion at ACR 2008. Thus far, we have tested taxonomic categories which are more expected than thematic structures. However, thematic categories are becoming increasingly popular in the marketplace. Thus, our third study explores the question, what happens when taxonomic structures are unexpected, or when thematic structures become expected?

Taken together, our research suggests that a relatively subtle change in the retail environment can create positive outcomes in terms of consumer well-being and retailer success. However, findings also suggest caution: what operates as a "newness cue" for experts appeared to impede novices' encoding. Thus, retailers considering thematic structures should remain cognizant of consumers' knowledge level before adopting wholesale changes in assortment layout.

"Does One Bad Apple Spoil the Barrel? Carry-over Effects of Buying Disgusting Products on Consumer Search and Shopping Basket Decisions"

Kristin Diehl, University of Southern California, USA

Andrea C. Morales, Arizona State University, USA

Gavan J. Fitzsimons, Duke University, USA

Duncan Simester, Massachusetts Institute of Technology, USA

Trash bags, diapers, dog food, and cat litter—any one of these products is likely to be on a consumer's shopping list. Now imagine two consumers in a supermarket: X needs to buy trash bags while Y needs to buy sandwich bags. Would you expect these consumers to behave differently during the *remainder* of the shopping trip? Our research suggests that a difference in the decision context as subtle as having to buy trash versus sandwich bags can alter how much time consumers spend in a store, the types of products they buy, and their evaluations of the shopping experience as a whole. What would drive such effects? We suggest that buying products such as trash bags, diapers, dog food, etc. that elicit feelings of disgust (Morales and Fitzsimons 2007) can influence search behavior and purchase decisions not just for these disgust inducing products but, more importantly, for *other* products purchased on the same occasion.

As a first step we partnered with a national chain of convenience stores to gather actual shopping basket information. The resulting sample captured items purchased in more than 27 million baskets. We combine this data with survey measures of perceived disgust for the top 45 non-food product categories. Focusing on the 11 million baskets that included at least one item from these 45 categories we used the perceived disgust measures to categorize transactions according to the "most disgusting" item in each basket. For each category we then calculated the average percentage of food items in each basket. The findings reveal a clear relationship: baskets that contain items that are more disgusting tend to contain a smaller percentage of food items.

This data documents the relationship between purchases of disgusting items and the composition of the shopping basket. However, it yields limited insight on why exactly this might happen

and how the presence of disgusting items can lead to these findings. Disgust is associated with an appraisal of being too close to an offensive object (Lazarus 1991) and triggers an implicit action tendency to pull away from the cause of disgust and one's immediate surroundings (Rozin et al. 2000). Disgust can have powerful effects on consumer actions either due to its associated appraisal tendencies (Lerner et al. 2004) or due to perceived contamination through physical contact (Argo, Dahl and Morales 2006). Results from our transactional data could indeed be explained by consumers' reluctance to add food items to their baskets so as not to "contaminate" them. However, our laboratory findings support a slightly more complex process that does not require physical contact for a disgusting purchase to influence shoppers' behavior.

Where and how much consumers search in a retail environment can alter the kind of products considered and chosen (e.g. Moorman, Diehl, Brinberg, Kidwell 2004). In contexts that elicit disgust, we expect consumer search to be truncated based on the implicit distancing reaction disgust triggers. We also expect distancing tendencies to carry over to how consumers search in other, unrelated product categories and the store as a whole. We further test these predictions in two experiments and also rule out that it is simply negative affect that leads to these results.

In study 2 participants were given a list of ten product categories typically found in a drugstore and were asked to "purchase" one product from each category at one of two computerized stores. Lists differed only with respect to the *first* category on the list. This category was either a product prone to elicit feelings of disgust (diarrhea medicine) or a neutral product (ballpoint pens). In a third condition (disgust-branded) participants saw the same shopping list as in the disgust conditions but brand names rather than more generic category labels were used (i.e. Immodium A-D instead of diarrhea medicine).

As expected, participants in the disgust condition spent less time in the target category than those in the neutral condition. Interestingly, compared to the neutral condition, those in the disgust-branded condition also spent less time searching the target category. More importantly, purchasing a disgusting or a disgust-branded product also reduced time spent searching *other, unrelated* product categories and spent less time in the store as a whole.

We find that buying a disgusting product has pronounced effects on search behavior across unrelated product categories. As such our field results may not just be driven by consumers planning separate trips for disgusting items but may actually be due to differences in search *within* the same trip. In study 3 we rule out that our findings are driven merely by negative affect in general as opposed to the avoidance tendencies specifically triggered by disgust.

Study 3 varied the target product to be either disgusting (diarrhea medicine), neutral (Vitamin C supplement) or sad (sympathy card), holding all other products on the list constant. We replicate our prior findings that search in the target category as well as *other* categories during that trip is significantly lower for those buying a disgusting product compared to those buying a neutral product. In contrast, we find that participants purchasing a sad product spent significantly *more* time in the target category than those in the neutral condition, supporting the notion that it is the specific appraisals triggered by the target purchase, and not just the valence, that leads to these effects on search. Further, replicating findings from the field, we also show that participants who purchased a disgusting product were significantly less likely to buy a food item on the same trip than participants in the sad or neutral condition. A mediation analysis shows that purchase reductions are indeed driven by decreased search, further evidence that changes in

the search context can systematically alter purchase decisions across categories.

SYMPOSIUM SUMMARY

Through the Looking Glass: New Ideas about the Consumption of Beauty

Barbara Phillips, University of Saskatchewan, Canada

SESSION OVERVIEW

Then she began to look about, and noticed that what could be seen from the old room was quite common and uninteresting, but that all the rest was as different as possible. (Lewis Carroll, Through the Looking Glass)

Legions of consumer researchers have examined the concept of beauty from such diverse perspectives as aesthetic ideals, body image, self-concept, self-identity, and specific industries including clothing and cosmetics. Nonetheless, a review of the beauty literature reveals a certain sameness to this research endeavor. This sameness has resulted from applying a single root perspective, leading to an oversimplified view of the phenomenon of beauty consumption. We believe that it is time to step up to the looking glass. First, to mirror the conceptualizations of beauty as they are currently conceived. Second, to go through the looking glass and explore alternative ways of seeing beauty, and thus gain new perspectives for understanding the consumption of fashion advertising, body ideals, and cosmetics purchases.

The researchers participating in this symposium are not naive about previously published research in this area, nor do they seek to overturn it. Instead, they seek to build upon it to present a more complex, more elaborated, and more nuanced explanation of the consumption of beauty. The first presentation examines the idea of aspiration as the driver of fashion advertising, and finds it lacking. The authors combine interview, content analysis, and survey data to uncover what fashion ads are really like, and the diverse ways in which women actually choose to consume them. The second presentation explores women's embodied experiences of pregnancy and birth. Previous research implies that women are released from beauty ideals during pregnancy; but interviews with pregnant women suggest that body-image is much more multifaceted and mixed than a simple polarity between freedom or enslavement can explain. The third presentation investigates the common perspective that selling beauty products such as cosmetics subjugates women. A case study of the Avon lady in Africa suggests ways in which the cosmetic industry can be empowering for women, as it creates ties of economic health between them, while avoiding disastrous repercussions from the ruling powers.

All three presentations *reflect* current perspectives on beauty consumption and then go *through* the looking glass to reverse, expand, or embellish conventional wisdom and unexamined assumptions. Yet each addresses different areas of beauty consumption: fashion images, body ideals, and the cosmetics industry. In addition, each presentation relies on empirical data that have already been collected but not yet published. Consequently, these presentations form a coherent symposium containing new information of interest to a diverse audience of consumer behavior scholars.

EXTENDED ABSTRACTS

“The Aspiration Assumption: Women’s Consumption of Fashion Advertising”

Barbara Phillips, University of Saskatchewan, Canada

Edward McQuarrie, Santa Clara University, USA

Fashion is a process by which the latest aesthetic styles are introduced to the public through a system that structures the

reception and consumption of those styles (Entwistle 2000). The fashion process relies on continual, regular, and institutionalized changes in dress, adornment, and decorative design (Davis 1992). Ever since Richins (1991) demonstrated that women compare themselves unfavorably to the models portrayed in clothing ads, the preponderance of academic papers examining fashion advertising has focused on representations of women—both their appearance and their roles—and compared them to some standard of “reality” (for a review, see Lindner [2004]). One of the key assumptions underlying such research is that all fashion advertising is rooted in a straightforward aspirational message showing a model to be emulated. That is, fashion advertising presents an idealized image that women are taught to aspire to. Consequently, consumer response to fashion advertising is must be simple as well: a woman can accept the idealized image and strive for it, or she can reject the idealized image and define herself in opposition.

By contrast, previous research in consumer behavior has demonstrated that the reading of advertisements is a complex task nuanced by personal life themes, goals, and projects (Mick and Buhl 1992, Mick and Politi 1989, Scott 1994), and may be conducted for many non-purchase reasons (O’Donohoe 1994). We also know that clothing choices are used to build identity within a local group (Elliott and Davies 2006) using fashion discourses from the broader culture (Thompson and Haytko 1997) while attempting to avoid negative associations (Bannister and Hogg 2004). Given these perspectives, it is difficult to believe that a simple interpretive strategy, such as “accept/reject idealized image” can effectively capture the reality of consumers’ readings of fashion ads.

We contend that the reading of fashion ads has been so stigmatized and denatured that the larger project of studying fashion image consumption has stalled. Women are too often forced into the narrow categories of fashion object or fashion victim, ignoring the fact that fashion is a culturally-situated practice resulting from the intersection of complex social forces and individual negotiation (Entwistle 2000). This presentation uses the perspective of consumer culture theory (Arnould and Thompson 2005) to examine how consumers’ motivations and interpretations frame their consumption of mass-mediated fashion images. Under consumer culture theory, marketing scholars accept that individuals consume the symbolic meanings of products along with a product’s physical characteristics. A fashion brand is just such a combination of the physical and the symbolic (Rocamora 2002). However, little research exists on how branded and heavily imaged products such as clothing come to be infused with symbolic meaning. “Lacking such knowledge, we can at best only form conclusions without quite knowing how we derived them; this is something we often have to do in everyday life, but it hardly satisfies the requirements of a science” (Davis 1992, 4). It is our hope to advance consumer science in the domain of fashion.

We will present a content analysis of three decades of fashion advertising in *Vogue* and *Vanity Fair* to demonstrate that fashion ads are not simple vessels of aspiration. We add findings from two surveys of the readers of fashion magazines to examine *how* women consume fashion magazines. Finally, the presentation reports the results of an ongoing set of interviews with “fashionista women” to develop a theory of *why* women consume fashion advertising as they do.

“Mirror, Mirror on the Wall: Consuming Ideal Images? Celebrating the Pregnant and Postpartum Body”

*Margaret K. Hogg, Lancaster University, UK
Emma Banister, Lancaster University, UK
Mandy Dixon, Lancaster University, UK*

In this presentation we focus on the body as the basis for the “evaluation of self in the public arena” (Turner 1994) and explore women’s experiences of cultural ideals surrounding bodies, both during pregnancy and post partum. Pregnancy is often regarded as a state which frees women, at least temporarily, from their concerns with their slender ideal self, allowing them to gain weight and change shape without the risk of attracting adverse evaluation from others; or feeling inadequate in social comparisons with idealized images of women and beauty (Richins 1991, Wood 1989). Much consumer research has focused particularly on the psychological (negative) implications of cultural idealizations of beautiful and slender bodies, to the relative neglect of investigating occasions (e.g., pregnancy) when women experience positive feelings about their bodies. Pregnancy would seem to be an occasion when women can experience positive feelings about their bodies and celebrate their growing size. Our study links Duke’s (2002) consideration of consumption as a social and cultural process which involves the acceptance of, and aspiration to, the ideal, with the disciplinary gaze (Foucault 1979), that recognizes the individual as “his/her own agent of surveillance conforming to normative conventions” (Thompson and Hirschman 1995, 149).

We used phenomenological interviews to understand how the embodied self is articulated during pregnancy and early motherhood; and how expectant and new mothers respond to a variety of discourses from society and the media about what constitutes an ideal body. Firstly for many women pregnancy represented a time and space for ‘free play’ of the embodied self, i.e., the feminist argument which describes pregnancy as “an opportunity to ‘step outside’ of the tyranny of slenderness... [and] enjoy a more embodied, subjective and maternal state” (Earle 2003, 250). Our data indicated that some expectant mothers experience release from the disciplinary gaze and societal expectations, which constructs the ideal feminine body in ornamental terms, and enjoy their bodies’ physicality without feelings of stress or guilt. However, it could be argued that these women are not so much freed from the disciplinary gaze, but are subject to a different disciplinary gaze or a different set of ‘ideals’, which constructs the feminine mothering body as productive, fertile and large. This represents a development of Earle’s (2003) point. She argues that because the pregnant body is temporary it offers women no reprieve from societal expectations. It is simply that the emphasis switches to an (often unspoken) interest in women’s bodies as functional-producers rather than as ornamental-seducers and women are instead presented with an alternative range of conventions around pregnant bodies and consumption, promoted via public policy statements, media and maternity interest groups.

Secondly, the environment became a source of unwanted comparative ideals (Wood 1989). Expectant mothers can find themselves confronted with a different range of discourses, which are just as normative as those they experienced before pregnancy. During pregnancy, women face the challenge not so much about what they consume in order to create a sexually attractive body but rather how they discipline their appetites in order to develop and maintain their bodies as fitness machines for pregnancy and birth (e.g., eating the right foods; taking the appropriate supplements; giving up smoking and alcohol; avoiding smoky atmospheres). This theme suggests that women’s bodies are just as strongly policed within the context of pregnancy as in their non pregnant states where they feel themselves subject to another range of disciplinary discourses.

A third key theme revolved around retrieval and control, and social comparison plays a vital role here as women called on their past (pre-pregnancy) self as a source of comparison as well as the idealized images that abound in media and society. New mothers faced a difficult balancing act. As new mothers they are expected to retain the functional role of their body, including the strength to care for and nurture their child; whilst also regaining their past non-pregnant self. However, our participants did not lack agency in asserting their own independent views of their bodies, illustrated by these women’s construction of their bodies as a source of strength and control; and by their discussions which centered on regaining or retraining their bodies to be ‘fit’. Stories revolved around various constructions of ‘fitness’ in relation to various selves e.g., fit enough to be effective mothering selves (e.g., breast feeding: body finely tuned for production); fit enough to climb ladders and regain competence as the DIY self (body as agile machine); fit enough to power dress within the business world to regain the professional self (body as power engine); fit enough to regain a young, svelte-like feminine self (body as female).

“Avon in Africa: Cosmetics Consumption and Women’s Empowerment Through Trade”

*Linda Scott, University of Oxford, UK
Catherine Dolan, University of Oxford, UK*

Critics of consumer culture have often focused on cosmetics as the nadir of the wasteful, oppressive ethic of the market. Recent historical works have suggested that this view needs revision. One particularly contradictory aspect of the historical record is the way that the beauty industry has created opportunities for women with little education or capital to achieve economic autonomy. Big names like Elizabeth Arden, Estée Lauder, and Helena Rubinstein testify to the power a small investment, an entrepreneurial spirit, and a flair for style can have in a market for goods aimed at a female constituency. However, larger, less spotlighted groups have also been served by the trade between women as consumers and women as sellers. From the corner beauty salon to the local “Avon Lady,” history has given us many examples of the way cosmetics consumption can be parlayed into an economic empowerment tool for women.

The premise of this study is that the historical power of the beauty industry to quietly create incomes for women could be harnessed to fight poverty in developing nations. One of the oldest female trading networks in America, the Avon Company, has already experienced significant growth in the poor nations, with more than half of their sales now coming from developing markets. Surprising as it may seem today, Avon’s historical market was among factory girls and rural farmwives in the United States—so they have a long-established track record for building businesses among poor women’s existing trading relationships. Since the networks are female and the products feminine, the men in such settings seldom take notice of what can be a very healthy income stream. Indeed, anecdotal evidence coming in from Brazil or Thailand suggests that not only are Avon representatives building good incomes in unlikely places, but they may be doing it without the disapproval and even violence that often comes from patriarchal cultures when women are empowered. So, this line of goods may offer a potentially safer venue for women to improve their status, which, in turn, is now seen as a central key to developing national economies.

This presentation will report the first phase results of a three year, multi-site study in South Africa, being conducted under the auspices of the Department for International Development and the Economics and Social Science Research Council (United Kingdom). We are using several methods to examine the potential for trade of these manufactured cosmetics to alleviate poverty and

foster empowerment among African women. As unlikely as cosmetics may seem as a vehicle for development, direct sales of beauty products appear to offer low risk opportunities for women to become entrepreneurs, even in regions where capital, infrastructure, and institutional frameworks are weak.

First phase results suggest not only interesting findings on the practices and benefits for Avon representatives but surprising feedback from consumers of the product. Buyers of Avon are clearly imbedded in a web of trade relationships in which they not only buy cosmetics from a friend or relative, but also sell other goods to that "Avon Lady" in a reciprocal arrangement. Patterns of purchase reflect historical African aesthetics that focus on lotion and shiny skin, but also more recent and global aesthetics involving "glamour products" like lipstick and eye shadow. Further, consumers, especially in very poor areas such as the squatter's camps outside Johannesburg, show both a proclivity to reinvention and a shrewd attention to maintaining a balance between "necessities" (lotion, in this culture) and "luxuries" (mostly perfumes). Thus, the study presents some interesting learning about hybridization, global versus local culture, and consumer adaptation, in addition to contradicting most contemporary thinking about the political status of cosmetics.

SYMPOSIUM SUMMARY

Taking the Load out of Choice Overload: Strategies for Reducing Cognitive Difficulty in Choice from Extensive Assortments

Gergana Spassova, Cornell University, USA

SESSION OVERVIEW

Objective of the session. Choosing from a greater number of options can increase regret and reduce satisfaction with one's choice (Iyengar and Lepper 2000). Cognitive overload, or the extra effort needed to process information about multiple options, has been proposed as one of the mechanisms underlying the choice overload phenomenon. The objective of this symposium is to outline new strategies for reducing cognitive overload and enhancing people's enjoyment and satisfaction with choice in the context of extensive assortments.

Topics and issues. The first paper, by Isen and Spassova, proposes that mild positive affect or novelty mitigate the detrimental consequences of choice overload. Studies one and two showed that people who experienced positive affect or novelty prior to choosing from an extensive assortment were just as satisfied with their choice as people choosing from a small assortment. Studies three and four extended these findings to measures of post-sampling satisfaction and shed light on the underlying mechanisms. The authors propose that positive affect and novelty have beneficial effects on choice overload by enhancing cognitive flexibility and the ability to organize and integrate information. In the second paper, by Inbar et al., time is a resource that allows people to adequately evaluate their choice options and protects them from experiencing cognitive overload. The first study showed that when people are given ample time to make a choice, those choosing from a large array are as satisfied with their selection and experience no more regret than those choosing from a small array. The second and third studies showed that it is the subjective perception of available time that generates choice overload. Even after controlling for the time available to make a choice, feeling rushed fully mediated the impact of assortment size on regret and dissatisfaction with one's choices. The third paper, by Goodman and colleagues, investigates yet another factor that influences choice difficulty—the common retailer strategy of using recommendations such as a “best seller” sign. Results from four studies show that the extent to which consumers have developed preferences is a key moderator of the effect of best seller signage on choice from large assortments. For consumers possessing more (less) developed preferences, best seller signage in large assortments increases (decreases) the size of consideration sets and exacerbates (attenuates) decision difficulty and regret.

Potential contribution and importance. Previous research has suggested that the negative consequences of choice overload on consumer satisfaction can be reversed by factors that simplify the choice process. The papers in this symposium contribute to this research by proposing strategies that enhance consumers' cognitive resources and make the choice process easier, more manageable, and ultimately more satisfying, without changing the nature or the presentation of the options in the choice set. Furthermore, by investigating new moderators, the papers in this symposium shed light on the nature of the choice overload phenomenon and on the psychological mechanisms underlying it. Cognitive flexibility and the subjective perception of time are introduced as important elements of the choice process, and factors that influence the consumer consideration set are investigated. The scope of this symposium goes beyond research on choice overload; it has impli-

cations for judgment and decision making in general as it suggests mechanisms for reducing cognitive complexity and for promoting consumers' problem-solving abilities.

EXTENDED ABSTRACTS

“When Choosing is No Longer a Burden: The Mitigating Effect of Positive Affect and Novelty on Choice Overload”

Alice M. Isen, Cornell University, USA

Gergana Spassova, Cornell University, USA

Increasing the size of a choice set has been shown to have negative consequences, such as a greater tendency for consumers to defer choice (Dhar 1997; Tversky and Shafir 1992) or to feel frustrated, confused, and less satisfied with the chosen option (Huffman and Kahn 1998; Iyengar and Lepper 2000; Malhotra 1982). Researchers have argued that these negative outcomes occur because consumers experience “choice overload” (Iyengar and Lepper 2000)—they feel overwhelmed by the extra cognitive effort needed to process information about the numerous options in the choice set. Strategies suggested to decrease choice overload involve simplifying product information (Gourville and Soman 2005), presenting it in an attribute-based as opposed to alternative-based format (Huffman and Kahn 1998), or asking consumers to articulate their preferences explicitly (Chernev 2003).

This research identifies two new factors for reducing choice overload—positive affect and novelty—and explores the specific mechanisms through which they impact consumers' experience with large choice sets. We propose that positive affect may reduce the effects of choice overload because it enhances people's cognitive flexibility and their ability to process, organize, and integrate information (Isen 1993; Kahn and Isen 1993). The beneficial effects of positive affect are proposed to be mediated by increased brain levels of the neurotransmitter dopamine (Ashby, Isen, and Turken 1999). Because novelty is also related to increased levels of dopamine, we predict that novelty may also mitigate the effects of choice overload. We test our hypotheses in four studies.

Studies one and two provided initial support for the hypotheses. Participants chose from either a small (9 flavors) or a large (45 flavors) assortment of jams, all from the same brand. Black-and-white pictures of the jams, with the flavor indicated, were displayed on the computer screen. Participants indicated their choice of jam, how much they enjoyed the choice process, and how satisfied they were with the chosen jam. Prior to choosing, to induce positive affect, participants were asked to provide first associates to positive common words (study one), and participants in the novelty condition provided first associates to neutral uncommon words (study two), while controls in both studies provided first associates to neutral common words. Among controls, the effects of choice overload previously observed were confirmed. Controls choosing from the large assortment of jams reported feeling more frustrated and tired than controls choosing from the small assortment of jams and were less satisfied with their choice. Among positive affect participants, however, the effects of choice overload were not observed. People in positive affect choosing from the large assortment did not report more frustration or tiredness than people in positive affect choosing from the small assortment, and did not feel

less satisfied with the choice they had made. When choosing from the small assortment, people in positive affect reported the same degree of tiredness and frustration, and the same satisfaction with their choice, as controls. When choosing from the large assortment, people in positive affect reported feeling significantly less tired and frustrated than controls. They also enjoyed the choice process more and were more satisfied with the selected option than controls.

Novelty had a similar beneficial effect on participants' satisfaction with their chosen product, but not on their frustration or tiredness. In contrast to controls, participants who had experienced novelty did not feel less satisfied with the choice they had made from a large, relative to from a small, assortment. Furthermore, when choosing from the large (but not from the small) assortment, participants in the novelty condition reported enjoying the choice process significantly more than controls. Unlike positive affect, however, novelty did not reduce the experience of frustration and tiredness with the choice process. Participants in the novelty condition reported feeling as tired and frustrated when choosing from the large assortment as controls, and significantly more so than novelty participants who chose from the small assortment.

Studies three and four were designed to test if the observed effects of positive affect and novelty extended to measures of post-sampling satisfaction with real jams, and to shed more light on the underlying psychological mechanisms. We also reduced the number of jams in the two assortments to six (small assortment) and thirty (large assortment) to be more in line with previous manipulations of choice overload. As in the first two studies, positive affect (study three) and novelty (study four) were manipulated by asking participants to provide first associates to positive common (affect condition) or neutral uncommon (novelty condition) words. Participants were run individually. After completing the word-associates task, they were asked to choose from the designated assortment of jams and to complete measures assessing their experience with the choice process. After choosing, participants were given the option to taste the chosen jam and to indicate how much they liked it, how much they regretted their choice, and how many different flavors of this brand of jam they would like to purchase if they became available in a local store. Results were in line with our predictions. Controls choosing from the large assortment experienced more regret about their choice relative to controls choosing from the small assortment and also reported that they were likely to buy fewer flavors of jam. Positive affect and novelty mitigated the negative effect of assortment size on choice regret and purchase intentions. Additional process measures provided support for our hypothesis that positive affect and novelty have their beneficial effect on choice overload by enhancing people's ability to integrate and categorize information.

Overall, these results support the hypothesis that positive affect and novelty reduce the negative consequences of large assortment size on consumer satisfaction with choice. They confirm previous findings about the beneficial effect of positive affect on cognitive flexibility and problem solving abilities and suggest intriguing possibilities for future research on the impact of novelty on cognitive processes and decision making.

“Take It Easy: Removing Time Constraints Mitigates Choice Overload”

Yoel Inbar, Cornell University, USA

Karlene Hanko, University of Cologne, Germany

Simona Botti, London Business School, UK

Thomas Gilovich, Cornell University, USA

Although it has traditionally been assumed that more options can only increase satisfaction with a choice outcome, recent research has shown that choosing from large arrays of options can be

difficult, inducing choice “paralysis” and dissatisfaction with the chosen option (Iyengar and Lepper 2000). This choice overload effect has been attributed to several causes, including the cognitive difficulty involved in evaluating and comparing a large number of options and the emotional burden that this process entails, especially for consumers who are striving to make the best choice (Brenner, Rottenstreich, and Sood; Iyengar, Elwork, and Schwartz 2006; Kahn and Lehmann 1991). Prior research has identified several factors that reduce the cognitive burden created by larger choice sets and thereby mitigate the negative effects associated with too much choice. For example, clearly articulated preferences (Chernev 2003; Huffman and Kahn 1998) allow consumers to identify the best match between their preferences and the available options without engaging in extensive, and sometimes frustrating, processing of these options. On the other hand, suppliers can ease the burden on consumers by selecting options that are easy to evaluate and displaying them in a way that facilitates within- and cross-category comparisons (Broniarczyk, Hoyer, and McAlister 1998; Gourville and Soman, 2005).

In this research we focus on another factor that can reduce the cognitive effort of choosing: sufficient time and resources to consider the available options. We hypothesize that people facing large choice sets will be less satisfied than those facing smaller sets only when they do not have adequate time and resources to evaluate the available options. When time constraints are removed, we expect that people will be as satisfied when choosing from large sets as they are when choosing from smaller sets. Moreover, we argue that it is the subjective feeling of being rushed when making a choice that reduces satisfaction with the chosen options and increases regret for the forgone options. These hypotheses were tested in three studies.

Study 1 examined whether encouraging people to take their time when choosing would ameliorate the negative effects of choosing from a large set. Participants were assigned to choose and eat a Godiva chocolate from either a small (6 chocolates) or a large (30 chocolates) array, under conditions of low or high time pressure. In the *high time pressure (rushed)* condition, the experimenter remained in the room with participants and stood directly behind them while they chose. In the *low time pressure (unrushed)* condition, the experimenter encouraged participants to take as much time as they wanted and left them alone in the room while they made their choice. After choosing, participants consumed their chocolate and completed a questionnaire that measured their satisfaction, enjoyment, and regret with their choice. Consistent with prior research, participants under high time pressure were less satisfied with their choice and experienced greater regret when choosing from the large set than when choosing from the small set. However, as predicted, this difference was entirely eliminated among participants under low time pressure.

Study 2 expanded upon these findings by demonstrating that it is the subjective feeling of being rushed during the decision process that accounts for reduced satisfaction when choosing from large choice sets. Participants chose a DVD from a small (6 DVDs) or a large (30 DVDs) array, with the understanding that they had a 1 in 10 chance of winning the DVD they selected. They then completed the same choice enjoyment, satisfaction, and regret measures as in the previous study, as well as a measure of the extent to which they felt rushed during the choice process. Replicating prior research, participants experienced greater regret and lower satisfaction when choosing from a large set than when choosing from a small set. Participants also felt more rushed when choosing from a large set than when choosing from a small set. A mediational analysis revealed that the impact of set size on satisfaction with the decision outcome can be attributed to subjective feelings of time

pressure, as feeling “rushed” fully mediated the impact of set size on regret and dissatisfaction with one’s choices.

Study 3 bolstered the results of Study 2 by manipulating the actual amount of time participants had to make their choice. As in the previous study, participants chose a DVD from either a small (6 DVDs) or a large (30 DVDs) array. Participants in the rushed condition were given exactly 30 seconds to make their choice and were shown a timer which counted down how many seconds were still available to complete the choice task. Participants in the unrushed condition were given unlimited time and saw no timer. Supporting previous results, those who chose from a larger set under time pressure felt more rushed than other participants and subsequently felt less happy with their choice.

In conclusion, this research contributes to our prior knowledge by showing that one of the factors contributing to the greater psychological burden of making a choice from a large set, as compared to a small set, is the perception of not having enough time for making this choice. Our results suggest that it is the perceived feeling of being rushed through the decision process, rather than the objective amount of time available to consumers when making a choice, that induces lower satisfaction and greater regret when choosing from large choice sets.

“Simplify or Intensify? Best Seller Signage on Consumer Decision-Making from Large Assortments”

Joseph K. Goodman, Washington University in St. Louis, USA

Susan Broniarczyk, The University of Texas at Austin, USA

Leigh McAlister, The University of Texas at Austin, USA

Jill Griffin, Evansville University, USA

Despite the increased cognitive load required to process large assortments, consumers are attracted to such broad options (Arnold, Oum and Tigert 1981; Broniarczyk, Hoyer, and McAlister 1998); however, they experience negative consequences, such as greater decision difficulty and regret, when they ultimately must make a choice (Iyengar and Lepper 2000; Chernev 2003). In four studies we examine whether a common retailer strategy—the use of recommendations such as a “best seller” sign—attenuates or exacerbates these negative consequences in consumer choice. The studies show that the negative consequences in consumer choice in large assortments is exacerbated when signs create conflict in the decision making process.

The first study manipulated the presence of a best seller recommendation in a small assortment (6 chocolates) and a large assortment (30 chocolates). After making a choice, participants indicated their anticipated regret and difficulty with the decision across multiple measures taken from previous research. The study showed that instead of reducing the negative consequences associated with choice, best seller signs actually exacerbated decision difficulty and anticipated regret when consumers face large assortments.

The second study manipulated the location of the sign and measured participants consideration sets. The results replicated the findings from study 1 and showed that signs increased the number of signed and non-signed options in consumers’ consideration sets in large assortments. This increase in consideration set size mediated the effect of signs on decision difficulty and experienced regret. The study also shows that the findings only hold when signs are on a viable, high preference option that has the potential to conflict with consumers’ preferences.

The third and fourth studies provide additional evidence that the best seller signs lead to the increased difficulty and consideration set size due to conflict with consumers’ preferences. Generalizing the findings to other product categories (i.e., organic juices and designer chairs), Study 3 manipulated preference development

and the presence of a sign and found that participants with more developed preferences reported experiencing greater decision difficulty when choosing from a large assortment when a sign was present versus absent. On the other hand, participants with less developed preferences exhibited the opposite pattern of results and showed that signs reduced difficulty, regret, and the size of the consideration set.

Interestingly, signs have this effect on the choice process without changing the final option that is chosen; none of the three studies showed an increase in choice share of the signed options. Study 4 manipulated the number options that participants could choose by either having participants buy one chocolate or allowing consumers to buy multiple chocolates. Study 4 also measured preference development via subjective knowledge. We again find that best seller signage led participants with more (less) developed preferences to create larger (smaller) consideration sets, primarily due to greater consideration of non-signed options. If limited to a single choice from a large assortment, the number of options considered was related to regret, with participants with more versus less developed preferences more likely to experience regret when a best seller sign was present. However, if free to act on their larger consideration sets, participants with more versus less developed preferences were more likely to buy multiple options when a best seller sign was present in a large assortment. Implications for consumers and retailers are discussed along with avenues for future research.

SYMPOSIUM SUMMARY

Time: It's a Personal Thing

Cassie Mogilner, Stanford University, USA

SESSION OVERVIEW

Consumer behavior is fundamentally temporally situated. For example, consumption experiences are extended in time, and consumer choice is strongly influenced by temporal distance and sequence. Despite time's ubiquity in consumer behavior, the scientific treatment of time is psychologically naïve. Consumer behavior research on time typically focuses on manipulation and measurement of objective time (minutes, days, weeks, months, and years), to the neglect of subjective time. Just as merely measuring and manipulating decibels and lumens provides an impoverished understanding of people's judgments and decisions about loudness and brightness, respectively, merely measuring and manipulating objective time provides an impoverished understanding of consumers' judgments and decisions about time. The three papers in this symposium seek a more psychologically sophisticated understanding of the role of time's subjective, personal influence on consumer behavior.

First, Mogilner and Aaker highlight the personal value of time (vs. money) for consumers. They find that because consumers' expenditure of time carries a great deal of personal meaning, merely activating the construct of time (vs. money) boosts consumers' feelings of personal connection with the product and, in turn, their attitudes toward the product.

The next two papers examine subjective temporal distance as an output—rather than an input, as is typically the case—of emotional experience, demonstrating that subjective distance is imperfectly correlated with and can vary independently of objective time. Kim and Zauberger find that emotional arousal moderates the subjective distance between now and later. They find that individuals' preference for a lesser item now over a greater item later is partly caused by immediate emotions expanding perceptions of the temporal distance between now and later, in addition to the standard explanation that immediate emotions increase the value of immediate items.

Van Boven and colleagues argue that psychological distance generally, and temporal psychological distance in particular, is emotional in nature. They demonstrate that people report less psychological distance to events about which they feel more rather than less intense emotions, holding objective distance constant. This negative correlation between emotional experience and psychological distance is significantly reduced when people are given an alternative interpretation of their immediate emotions.

Finally, John Lynch leads a discussion of these findings and their relation to the scientific understanding of time as a psychological (rather than a purely objective) construct in consumer behavior.

EXTENDED ABSTRACTS

“Life's Riches: The ‘Time>Money Effect’”

Cassie Mogilner, Stanford University, USA

Jennifer Aaker, Stanford University, USA

As the most important resources consumers have at their disposal, references to time and money are pervasive in the consumer landscape. Consider, for example, the marketing campaigns of two brands of beer: Guinness's “It's worth the wait” commercials have appealed to consumers by guiding attention to time whereas Stella Artois's “Perfection has its price” campaign has appealed through focusing attention on money. Even Citibank, an institution

based on monetary transactions, brings focal attention to how one chooses to spend time (not money) in their “Live Richly” campaign (e.g., “There is no preset spending limit when it comes to time with your family”). In fact, a content analysis of ads in four very different magazines (*Money*, *New Yorker*, *Cosmo*, and *Rolling Stone*) revealed that, out of the 300 advertisements, nearly half of the ads (48%) integrated the concepts of time and/or money into their messages.

Despite the preponderance of marketers' decisions to integrate these constructs into their communications, little is known about the downstream effects of directing consumers' attention to time or money. Does the mere mention of time versus money change the way consumers evaluate products? And if so, why?

To address these questions, we conducted a series of experiments both in the field and in the laboratory. The results converge to reveal a robust “time>money effect.” Compared to activating money, activating time, in general, leads to more favorable product attitudes. This “time>money effect” appears to be driven by a differential focus on one's experience gained from using the product versus the value gained from merely owning the product. Whereas thinking about time fosters feelings of personal connection as consumers consider their experiences garnered with the product (Reed, Acquino, & Levy, 2007; Van Boven & Gilovich, 2003), thinking about money disconnects consumers from those same products they know and use (Vohs, Mead, & Goode, 2006). As a result, directing attention to time (rather than money) apparently helps consumers extract greater happiness from the products filling their lives.

Across four experiments, we found support for our hypothesis that activating time (vs. money) leads to more favorable product attitudes. And further, this “time>money effect” is driven by the distinct mindsets that each activates, with the temporal (vs. monetary) mindset evoking greater feelings of personal connection.

In experiment 1, student participants were first asked to report either the amount of *time* they spent on their iPod or the amount of *money* they spent on their iPod. Those who were led to think about their time spent subsequently reported more positive attitudes towards the product than those led to think about their money spent. Further, this “time>money effect” was mediated by participants' feelings of personal connection with their iPods.

Experiment 2 was conducted to examine whether the “time>money effect” is driven by increased feelings of personal connection with the product, or if a mere valence-based account could explain the results (e.g., differential attention to the monetary costs of purchasing the product versus the temporal benefits of consuming the product). Therefore, experiment 2 was conducted at an outdoor concert that was free of charge but for which some individuals spent extensive amounts of time waiting before the concert to ensure getting decent seats. Just prior to the start of the concert, participants were asked either how much time or how much money they spent in order to see the concert. The results revealed that even in instances where the expenditure of time represented a considerable cost, activating time led to more positive attitudes towards the product than activating money, and this effect was mediated by feelings of personal connection with the product.

Participants in experiment 3 were primed with either time or money using a sentence scramble task to determine whether the “time>money effect” occurs only when time and money are acti-

vated through an overt question, or whether it can also occur when the constructs are activated more subtly. Experiment 3 also offered further insight into the underlying process through a test of moderation. Specifically, if feelings of personal connection underlie the effect, we would expect it to be particularly strong for experiential purchases (those that “are made with the primary intention of acquiring a life experience”) compared to material purchases (those that “are made with the primary intention of acquiring a material good”; Van Boven & Gilovich 2003, 1194). Supporting our conceptualization that the activation of time (vs. money) boosts product attitudes by leading consumers to reflect on their purchase as part of their personal life experience, we found “the time>money effect” to be stronger for experiential purchases than material purchases.

Finally, in experiment 4, individuals were primed with either time or money using the same sentence scramble task as used in experiment 3 before entering a café. Upon leaving the café, those who had been primed with time reported more positive attitudes towards the café than those who had been primed with money, revealing that the “time>money effect” is strong enough to impact how individuals actually experience the products they consume.

“Deconstructing the Present Bias: Linking Visceral Factors and Mental Representation through Time Perception”

B. Kyu Kim, University of Pennsylvania, USA

Gal Zauberman, University of Pennsylvania, USA

Research on intertemporal decisions has shown individuals have a present-bias: that is, their preference for earlier outcomes over later ones gets stronger as consumption comes closer in time (O'Donoghue and Rabin 1999). This preference is often modeled using a hyperbolic discount function: the rate at which an outcome is discounted over time (delay discounting) decreases as the time horizon gets longer. Several lines of research on intertemporal choice have suggested that visceral factors (e.g., sexual desire, hunger, or alcohol; Loewenstein 1996) or concrete mental representation (Malkoc and Zauberman 2006; Zauberman and Lynch 2005) increase the degree of present-bias. While these factors are shown to drive present-biased preferences, it is not clear whether they change individuals' momentary valuation of outcomes or their sensitivity to time horizon (i.e., the duration of the delay).

Recently, in their time perception model of present bias, Zauberman, Kim, Malkoc, and Bettman (2008) showed that individuals discount the value of outcomes, as well as discount duration itself (e.g., non-linear time perception), and this combined effect results in hyperbolic discounting. In this paper, we investigate the link between affective and cognitive drivers of present bias and time perception. Specifically, we propose that some of the standard affective and cognitive drivers of the present bias operate, at least in part, through shifts in subjective time perception of the relevant time horizon such that individuals' perceived time is more contracted or non-linear when these drivers are active.

Study 1 demonstrates the impact of sexual attractiveness on sensitivity to time horizons. Participants rated the attractiveness of

15 portrait photographs of the opposite sex, which were taken from a public website (<http://www.hotornot.com>). About half of the participants were presented with ‘hot’ photos that received mean ratings of 9.5 (out of 10) or higher on the website, and the other half were presented with ‘not hot’ photos that were rated as 5 or lower. After viewing and rating the attractiveness of each photo, all participants indicated subjective feeling of duration between today and multiple time horizons (e.g., 3 months to 36 months). Next, they indicated how much they would have to be paid to wait to receive a gift certificate for multiple time delays (e.g., 3 months to 36 months).

Results showed that participants' subjective estimates of time horizon were less sensitive to changes in objective time horizons after viewing ‘hot’ photos than after viewing ‘not hot’ photos. Such non-sensitivity to time horizons corresponds to a greater degree of present bias according to the time perception model of hyperbolic discounting (Zauberman, Kim, Malkoc, & Bettman 2008). Supporting this, when discount rates were calculated using objective time horizons, participants in the ‘hot’ condition showed more deviation from exponential discounting than those in ‘not hot’ condition. When participants' subjective time estimates were accounted for (i.e., discount rates were calculated using subjective time estimates of objective time horizon instead of objective time horizon itself), however, discount rates in both conditions no longer decreased as a function of time delay. These results suggest that visceral factors impact perceived time horizon, and not just the valuation of the outcome itself. Moreover, these changes in time perception contribute to present-biased preferences when visceral factors are active.

Study 2 demonstrates the impact of concrete mental representation on time perception. Participants were randomly assigned to either a concrete representation or control condition. In the concrete representation condition, participants visualized the time when they would receive and spend a \$75 cash prize. They were asked to imagine and describe the occasion as vividly as possible including where to go and with whom to spend the money. Participants in the control condition did not complete this task. Next, all participants indicated how long they felt the duration between today and a day in 1 month or 3 months to be. They also indicated the delay premium if they were to delay the use of the cash prize by 1 month or 3 months.

Results showed that participants' subjective perception of time horizons were less sensitive to objective time horizons in the concrete mental representation condition than in the control condition. Participants in the concrete mental representation condition showed a greater level of present bias (i.e., decrease in discount rates over time) than those in the control condition when present bias was measured using objective time horizons. When subjective time perception was used, however, discount rates in both conditions were equal over time, supporting the time perception model of hyperbolic discounting. These results imply that concrete mental representation shifted participants' sensitivity to time horizons, causing a greater level of present bias. There was also a marginally significant main effect of mental representation on discount rates calculated using subjective time estimates, implying that concrete mental representation changed participants' valuation of outcomes as well.

In sum, this paper demonstrates an important way in which emotion and mental representation affect present-biased preference. We confirmed that affective and cognitive drivers influenced present bias (measured by declining discount rates), replicating the findings in past research. Importantly, these drivers changed individuals' sensitivity to time horizons. Taken together, these results support and extend the time perception model of hyperbolic dis-

counting (Zauberman, Kim, Malkoc, & Bettman 2008), showing that factors often assumed to operate through the valuation of outcomes, actually operate (at least in part) through changes in sensitivity to time horizons, leading to present-biased preferences.

"Feeling Close: The Emotional Nature of Psychological Distance"

Leaf Van Boven, University of Colorado at Boulder, USA
 Joanne Kane, University of Colorado at Boulder, USA
 A. Peter McGraw, University of Colorado at Boulder, USA
 Jeannette Dale, Denver, Colorado, USA

What can make an event psychologically close or distant? What can make high school graduation seem like "just yesterday" or "long ago?" What can make a conference presentation seem "just around the corner" or "ages away?"

Despite psychological distance's importance to everyday experience and behavior (James 1890/1950; Lewin 1951), it is not clear what psychological distance actually is. This is because psychological distance tends to be operationally equated with objective distance (e.g., Trope & Liberman 2003). This paper seeks to clarify the psychological nature of psychological distance.

We hypothesize that psychological distance is largely emotional in nature: events about which people feel stronger emotions are less psychologically distant than events about which people feel weaker emotions. Because factors unrelated to events' objective distance can influence how intensely people feel about those events, the same events can be more or less psychologically distant, independent of when they actually occur.

Psychological distance may be emotional in nature in part because emotional arousal typically signals events' importance and relevance to the self (Frijda 1988; Lazarus 1991; Neese 1990). Increases in emotional arousal are closely related to decreases in objective distance (Olson 1988; Savitsky, Medvec, Charlton, & Gilovich 1998). This naturally occurring inverse relationship between emotionality and objective distance may produce a subjective inverse association between emotionality and psychological distance that may become overgeneralized such that events of equal objective distance can be psychologically closer when people feel relatively intensely about those events.

Our analysis of the emotional nature of psychological distance yields the novel prediction that inducing people to feel more strongly about an event will reduce that event's psychological distance, holding constant the event's objective distance. We tested this prediction in four experiments

In experiment 1, people were asked to describe, either emotionally or dispassionately, positive or negative future events. People reported being psychologically closer (i.e., less distant) to emotionally (rather than dispassionately) described events. People also reported positive events to be more psychologically distant than negative events, probably because positive events are less emotionally evocative than negative events (e.g., Rozin & Royzman 2001).

In experiment 2, we sought to test whether emotional intensity would reduce psychological distance to both past and future events. Participants described either their last or next dentist visit. After estimating the number of days since or until their dentist visit, participants were asked to describe the visit, depending on random assignment, either emotionally or dispassionately. As predicted, people reported that emotionally regarded dentist visits were psychologically closer than dispassionately regarded dentist visits, independent of those events' tense (past or future) and of the number of days since or until the visit.

In experiment 3, we sought to manipulate whether people felt more or less intensely about a future event indirectly through assignment to social roles. Such an indirect manipulation helps avoid potential concern that explicit instructions to regard events more or less emotionally, as in experiments 1 and 2, elicit experimental demand or some other aspect unrelated to emotionality. People were randomly assigned either to engage in an embarrassing public performance—dancing to the Devo song, "Whip it"—or to evaluate others' performance. Dancers reported more emotional arousal than evaluators. As predicted, dancers also reported that the dancing was psychologically closer than did evaluators. In addition, the effect of being a dancer or evaluator on reported emotional intensity statistically mediated the effect of being a dancer or evaluator on psychological distance.

In experiment 4, we sought more direct evidence for the emotional nature of psychological distance, which implies that emotional intensity should reduce psychological distance to the degree that experienced emotions are attributed to emotional events, but not when experienced emotions are attributed to some other event. The negative correlation between emotional intensity and psychological distance should therefore be reduced if people are led to attribute their emotional experience to some source other than the target emotional event.

Participants were told that in 15 minutes they would dance to the Devo song "Whip It" for one minute in front of the experimenter and a video camera, and that their performance would be shown later to other students in a study of impression formation. During the wait, participants were asked to complete an unrelated "marketing" study concerning product evaluation and auditory stimuli. Participants donned a pair of headphones and listened to "New Age" whale songs while completing questionnaires. Depending on random assignment, participants were either told that the songs "did not influence cognitive performance" (control condition), or that the songs might make them feel "anxiety and fear" (misattribution condition).

Consistent with the emotional nature of psychological distance, the correlation between emotional intensity and psychological distance was more strongly negative in the control condition than in the misattribution condition. People's emotional intensity is associated with reduced psychological distance, but not when people attribute their emotions to an unrelated source. This finding indicates that emotional intensity does not reduce psychological distance of all future events, but only those events to which people attribute their emotions.

In conclusion, although psychological distance has conceptual prominence in behavioral science, the extant theoretical and empirical emphasis has been on objective temporal distance (minutes, days, weeks, months, and years) as an input to thinking, feeling, and behaving. Our studies shift focus to the subjective (rather than the objective) nature of psychological distance as an output (rather than an input) of emotion. Independent of objective distance, emotional intensity reduces events' psychological distance. Our findings highlight the importance of putting the "psychological" back in psychological distance.

SYMPOSIUM SUMMARY

The Effect of Conflicting Information and Natural Primes on Health Related Behaviors

Barbara Kahn, University of Miami, USA

SESSION OVERVIEW

It is becoming increasingly common for consumers to reach for a copy of *Newsweek* or some other mainstream publication and find information pertaining to health-related behaviors. Pharmaceutical companies are spending large marketing budgets to detail physicians and to advertise their products directly to consumers. Consumers are routinely bombarded with advice as to when to get tested, how much to eat, and which disease symptoms they should be on the look out for. With all of this information and natural priming in the marketplace, there are bound to be conflicting influences. This session looks specifically on the role that conflicting information cues have on health-related behaviors.

This session should appeal to researchers who are interested in how consumers process information from conflicting sources. In the past much of the research on conflict has focused on information from the same domain, e.g., one study says one thing, another study says another. In this session, we focus on the realistic environment where the sources of conflict frequently come from non-comparable sources of information, e.g., a scientific study reports one finding and the medical industry reports something different—or behavior indicates one kind of conclusion and physical appearances indicate another. We believe this session presents research that will make important contributions both to further our understanding of consumer behavior as well as to inform policy makers about consumers' potential reactions to conflicting sources of information in the environment.

In the first paper, "The Branded Physician's Office: Effects of Exposure to Small Pharmaceutical Promotional Items on Physician Treatment Preferences," the researchers examine how the conflicting cues offered by the pharmaceutical companies in their branding strategies and recent guidelines put into place by many universities that restrict pharmaceutical company activity in University hospitals affect medical students' implicit attitudes and decisions to prescribe. In the second paper, "Super Size Me: The Social Influence of Obese Consumers on the Food Choices of Others," the researchers examine the sometimes conflicting cues between what a person looks like (fat or thin), how much s/he eats (a lot or a little), and the interaction of those effects on what others eat. Finally, in the third paper, "Change, Change, Change: Evolving Health Guidelines, Preventive Health Behaviors, and Interventions to Mitigate Harm," the researchers examine the role conflicting information sources have on the effectiveness of various medical treatments and screening tests in affecting patient decision-making. Specifically, their focus is on providing appropriate interventions to counter possible avoidance tendencies that may occur as patients try to cope with the stress of the conflict.

Each of the papers in this session has several completed studies. The discussion leader, Punam Anand Keller is a noted expert in how consumers process information in general, as well as specifically in health-related behaviors.

EXTENDED ABSTRACTS

"The Branded Physician's Office: Effects of Exposure to Small Pharmaceutical Promotional Items on Physician Treatment Preferences"

David Grande, University of Pennsylvania, USA

Dominick Frosch, University of California, Los Angeles, USA

Andrew Perkins, Rice University, USA

Barbara Kahn, University of Miami, USA

The relationship between the pharmaceutical industry and physicians has received a great deal of attention in recent years. This attention is due in part to rapid growth in pharmaceutical spending in conjunction with significant increases in pharmaceutical marketing to both physicians and patients. Pharmaceutical companies focus a majority of their marketing efforts on "detailing"—visits to physicians' offices to encourage prescriptions of the company's product (IMS Health, 2006). Most of these visits include inducements in the form of branded gifts to physicians and their staff and free drug samples that can be given to patients. These relationships have raised concerns that pharmaceutical companies are inappropriately influencing physician decision-making and that these relationships represent a breach of medical professionalism and patient trust.

The concerns of the public, media and policymakers appear to be warranted based on a series of studies demonstrating that the pharmaceutical industry is effective at influencing physician prescribing through the use of financial inducements or gifts (Wazana, 2000). Much of the research is observational and focuses on gifts of relatively high value such as expensive meals or travel to conferences. This research along with a general belief that large gifts should be the focus of concern has led numerous professional societies and universities to adopt ethics guidelines that discourage gifts valued above a certain level, often in the range of \$100 (Coyle et al., 2002; AMA Code of Medical Ethics). Smaller gifts such as pens, branded prescription pads, and other office supplies are typically regarded as trivial and inconsequential.

While attention has primarily focused on gifts of relatively high value reflecting a belief that influence is proportional to economic value, little is known about the influence of smaller, less valuable branded promotional items on physicians' clinical preferences. Further, few physicians believe that small branded gifts can influence medical decision-making despite social psychology theory and evidence to the contrary. The goals of the current study are twofold. First we explore any potential influence these smaller marketing trinkets might have on physician decisions. In particular we are interested in measuring the unconscious effects that branded gifts of minimal economic value may have on implicit attitudes and physician prescribing behavior. Second the study will try and assess whether in-place educational policies with regard to pharmaceutical industry activity have any effect on attitudes toward the promoted brands.

To this end, we designed a randomized control experiment to measure the impact that exposure to these brands have on attitudes and how those attitudes affect physician decisions. 180 third and fourth year medical students and internal medicine and family medicine residents at the Penn's School of Medicine participated in the study. Participants were randomly assigned to either a control condition or a treatment condition where participants were exposed to promotional items for the brand Lipitor. Following exposure,

participants completed a series of vignettes requiring them to report their clinical preferences in lipid management in situations of varying cardiovascular risk and ambiguity. Participants then completed self-report measures and implicit measures of preference and attitudes. Implicit attitudes were measured using the Implicit Association Test (Greenwald, McGhee, and Schwartz 1998), a computer-based categorization task designed to uncover inaccessible or socially undesirable attitudes. The IAT assessed relative implicit attitudes between Lipitor (the promoted brand) and Zocor, a generic equivalent.

Interestingly, participants exposed to branded promotional items for Lipitor demonstrated *weaker* positive attitudes toward Lipitor compared to Zocor on the IAT ($p=0.05$). Further, significant differences reflecting the same paradox were found on the most ambiguous cardiovascular risk clinical vignette, with 42.1% of controls choosing to initiate Lipitor therapy compared to 26.1% of the subjects exposed to Lipitor promotional items ($p=0.03$). No significant effects were evident on the low and high cardiovascular risk clinical vignettes. Explicit preferences showed similar patterns among global attributes although not statistically significant (product superiority: 48% of controls and 36% of treated rated Lipitor over Zocor, $p=0.13$; product preference: 53% of controls and 41% of exposed rated Lipitor over Zocor, $p=0.10$).

These results suggest that trainees exposed to pharmaceutical branded promotional items exhibited a boomerang response with weaker preferences toward the marketed product when compared to controls. These findings were evident on implicit measures in the most ambiguous clinical decision. A similar but non-significant pattern on the explicit measures lends support to these findings. In this case, the observed boomerang effect is potentially explained by recent policies at the University of Pennsylvania that severely restrict pharmaceutical marketing on campus. This suggests that strong institutional policies may affect attitudes underlying behavioral responses to marketing. Overall, this study provides evidence that subtle branding within the environment can have significant effects on clinical decisions and treatment preferences, but not necessarily in the direction one would expect. Further studies are currently being conducted to assess responses at other institutions with less stringent policies.

“Super Size Me: The Social Influence of Obese Consumers on the Food Choices of Others”

Brent McFerran, University of British Columbia, Canada

Darren Dahl, University of British Columbia, Canada

Gavan J. Fitzsimons, Duke University, USA

Andrea C. Morales, Arizona State University, USA

Obesity and unhealthy food consumption are major public health issues, especially in North American society. Making healthy food choices is an important part of maintaining a healthy body weight. Consumers make over 200 food choices per day (Wansink 2006), and thus it is important to understand the antecedents to unhealthy food choices. However, little research in marketing has examined why consumers make the food choices they do. For instance, once inside a restaurant, what causes one to purchase the burger instead of the salad, or the large fries over the small ones? Such trivial decisions actually have large caloric consequences, as the difference between a 16 oz. McDonald's Swamp Sludge McFlurry and McDonald's Low Fat Ice Cream Cone is 560 calories (McDonald's USA 2006). Portion size has been linked to obesity (Young and Nestle 2002), as people who select larger portions tend to eat more than those given small portions, even if the food is of poor taste or consumers are not hungry (Wansink 2006).

Past research has shown that consumption decisions are influenced by those who are physically present. People are sensitive to

the behavior of others in a retail context (Bearden and Etzel 1982; Dahl, Manchanda, & Argo 2001), even if such a person is only physically present but does not engage the consumer in any way (Zhou & Soman 2003; Argo, Dahl, & Manchanda 2005). In a food context, studies have found that social influence can have either a facilitating or attenuating effect on consumption, depending on the context (see Herman, Roth, & Polivy 2003 for an excellent review). They argue that food choice is influenced by a desire to convey a certain impression or adhere to social norms (Leary & Kowalski 1990; Roth et al. 2001). Although, Herman et al. (2003) argue that making a good impression usually means eating less, other research has found that people may eat more, rather than less in the presence of another person (e.g. Conger, Conger, Costanzo, Wright & Matter 1990). Indeed, the social facilitation literature has found that the presence of others can lead to increases in consumption (e.g. de Castro 1990) because the duration of the meal is longer.

Another line of research has examined the impact of obesity on consumption. Priming people with overweight images leads to an increase in quantity consumed (Campbell and Mohr 2008). Christakis and Fowler (2007) found that a person's chance of becoming obese significantly increased when a close other (e.g., friend, sibling) became obese. Moreover, the effect persisted even if they were not living in the same city; rather, social distance was a better predictor than physical distance. Effects were not seen in neighbors in the same area.

The above lines of research have focused either on how much others eat, or on the social influence of obesity, but little research has examined the influence of the two jointly. In social influence work more generally, the effects of the social “other” have been shown to be moderated by whether the person is a member of an aspirational or dissociative group (Escalas & Bettman 2005; White & Dahl 2005, 2008). Since thin models are seen as an ideal standard in North American society (Durkin & Paxton 2002) and obesity—associated with unhealthy eating and over consumption—is a stigma that most wish to avoid (Johnson 2002), the body type of others should interact with their food choice (indulgent versus moderate) in forming evaluations of them. We propose that these frameworks can be reconciled by examining the person by situation interaction. In other words, we examine how eating with (or simply ordering in the presence of) those who are thin versus obese can impact one's food intake, but that such effects are moderated by the actual food choices of the other individual.

In Study 1, we test the joint influence of others' portion selection and their body type on consumption in a 2(thin vs. obese confederate) x 2(confederate takes little vs. takes a lot) between-subjects design. We find that if a confederate first selects a large quantity of snack food, participants chose and consumed more if the confederate was *thin* versus obese. In contrast, if the confederate selected a small portion, participants chose and consumed more if the confederate was *obese* versus thin. A sole confederate was employed across both the obese and thin conditions, and to manipulate body type a professionally-constructed obesity prosthesis was used. Identical clothes were tailored in both a size 00 and a 16 to ensure consistency.

In Study 2, a 2(thin vs. obese confederate) x 2(healthy vs. unhealthy food) between-subjects design was employed to examine whether the effect is driven by the pairing of obesity and unhealthy food, or whether it still holds for healthy food as well. We find that regardless of the perceived healthiness of the food, after seeing a confederate select a large amount of food, participants selected and consumed less when the confederate was *obese* versus thin. As such, evidence suggests that the effects generalize to foods perceived to be healthy, and thus the effects are driven by perceived over consumption, rather than by perceptions of unhealthy eating.

Study 3 used a scenario methodology where participants imagined they were ordering ice cream and overhear the person in front of them order an extra large ice cream cone. The design was a 2 (other person: obese vs. thin) x 2 (cognitive load: low vs. high) between subjects design that also included a continuous body image satisfaction measure. We tested whether cognitive load and body image satisfaction moderate the effects identified, and find a 3-way interaction such that the participants chose a smaller size when they were low in body image satisfaction and their processing resources were not impaired, suggesting that the process of food choice seems to have a conscious component and such social comparison effects are heightened among those less satisfied with their physical appearance.

“Change, Change, Change: Evolving Health Guidelines, Preventive Health Behaviors, and Interventions to Mitigate Harm”

Christine Moorman, Duke University, USA

Mary Frances Luce, Duke University, USA

James R. Bettman, Duke University, USA

Every day, newspapers, magazine, television, and the internet publicize new findings produced by medical researchers. As a result, consumers have become accustomed to learning which foods, dietary supplements, exercise behaviors, and work habits will affect their risk of cancer or cardiovascular disease. Studies are followed by even more studies, and consumers are left with a great deal of information, but also with doubt and confusion about what preventive behaviors are really best for them. Casual conversations reveal this confusion and consumers simply give up trying to find a health regime that fits within the conflicting stream of health guidelines delivered at their front door each morning.

Our research considers what types of changes to health guidelines cause consumers to have a negative reaction (Study 1, completed), what types of psychological processes and traits contribute to this negative reaction (Study 2, completed), and what types of interventions might attenuate these reactions (Study 3, currently in the field). All of our studies present health guidelines through mock newspaper articles to adults. Our guideline involves the cardiovascular effects of pyridoxine (Vitamin B6).

In Study 1, we observe that consumers react more negatively to a guideline that first communicates a positive effect (i.e., pyridoxine protects against cardiovascular disease) and then reverses to describe a negative effect (e.g., pyridoxine increases risk of cardiovascular disease) than to non-conflicting guidelines or guidelines moving from negative effects to positive effects. We also find three corresponding and troubling reactions to the guidelines. First, consumers reduced their intention to monitor pyridoxine, even though the guideline suggests, from either a positive or negative perspective, that monitoring would be helpful. Second, consumers reported less faith in health guidelines and health professionals. Third, consumers exhibited a negative spillover to healthy behaviors not implicated by the guideline change. Specifically, they reported reduced intentions to engage in unrelated heart-healthy behaviors (e.g., cholesterol monitoring).

Study 2 examined potential moderators and mediators of these negative reactions. In terms of moderators, we observe a guideline change x scientific literacy interaction. Scientific literacy refers to a consumer's understanding of the nature of science, its role in society, and an appreciation of what science can and can not do (Laugksch 2000). We find that consumers who score low on a scientific literacy scale exhibit the negative spillover effects described above, while consumers scoring high on the same scale actually have a positive reaction to changing guidelines. We sus-

pect this difference emerges because high scientific literacy consumers value new information because this reaffirms their faith in scientific progress. Low scientific literacy consumers overreact and exhibit the troubling spillovers. More specifically, we find that low scientific literacy consumers follow a process moving from the changing guideline to less faith in health guidelines and health professionals, which leads to less monitoring of cardiovascular threats. Tests for moderated mediation show that this pathway does not unfold for scientifically literate consumers. Similarly, consumers higher in objective health knowledge do not exhibit the negative spillover effects associated with changing guidelines. While the underlying processes for scientific literacy and objective knowledge seem similar, the two measures are not highly correlated in our sample. Finally, further additional tests show that an external (physician) health locus of control (Lau and Ware 1981) protects against the negative spillover effects. It appears that consumers who look to their doctors for medical advice show less erosion in faith in health professionals, and hence fewer spillovers following changing guidelines.

In Study 3, which is in the field at this writing, we test the effect of four interventions designed to attenuate these effects. All of these interventions are based on reasonable frames that will help consumers put the changing health guideline information into perspective, a process we believe some consumers may do naturally. The perspective may come from: (1) appreciating the larger body of scientific literature (relevant to our scientific literacy moderator in Study 2); (2) considering all of the factors that are important to cardiovascular health (relevant to our objective knowledge moderator in Study 2); (3) asking your doctor for assistance (relevant to external-physician locus of control in Study 2); and (4) understanding the goals and constraints of media. We designed these interventions not only to disrupt the negative effects of changing guidelines, but also with an eye toward their practical use in media reports of health research.

Subjects will receive one of five intervention treatments. Four groups will receive one of four “Before You Act” boxes that corresponding to one of the contexts described above. For example, box (2) notes, “Remember that your cardiovascular health is influenced by a number of factors, including genetic and lifestyle risks. Hence, you should consider how a change in behavior fits with all your heart-healthy behaviors in order to determine the best course of action. Keeping these behaviors in mind will help you put this one action in perspective.” Likewise, box (4) notes, “Remember that the news can only cover medical findings at a general level and can not cover all studies on a topic. Hence, you should be aware that they will choose to selectively report on findings they consider newsworthy. Keeping their goals and constraints in mind will help you put this information in perspective.” We expect each intervention, relative to the no-intervention control group, to dampen the spillover effects observed in Study 2. We also expect that the aforementioned interactions between changing guidelines and scientific literacy, objective health knowledge, and external locus of control will be weakened as a result of the interventions. If effective, these results will point to important remedies to the problem of changing health guidelines for consumers.

SYMPOSIUM SUMMARY

Welcome to the Jungle: Understanding How Environmental Cues Influence Consumption in “The Wild”

Lisa A. Cavanaugh, Duke University, USA

SESSION OVERVIEW

How do the various cues in a shopping environment affect consumer choice? Every day consumers are exposed to a myriad of sights and sounds—colorful displays, promotional stands, different store configurations, and music playing over the loudspeaker. While exposure to “primes” in the lab has reliably shown effects on consumers, considerable skepticism remains as to whether these environmental cues do much, if anything, in more complex, real world environments. The purpose of this symposium is to better understand the impact of such environmental cues on consumer behavior, though a mixture of well-controlled lab experiments and real world field studies.

While these environmental cues are recognized by consumers and marketers alike, the extent or the direction of their influence is not well understood. Do the places and people you just happen to pass on your way to the store influence the choices you make? Do crowded stores and narrow aisles influence the products you select? Does ambient music you hear influence the type of products you buy or the size of donation you make at the register? Does the sight of a prominent holiday display make you more likely to indulge yourself or more likely to indulge others? These and other questions will be examined by the papers in this symposium.

Together the three papers in this session address how a variety of sensory cues in the consumer’s environment influence product evaluation, selection, and donation behavior. More importantly, they uncover the underlying mechanisms that drive these effects. To this end, the first paper shows that products are evaluated more favorably and are more likely to be purchased when the surrounding environment contains more conceptually-related cues. The second paper shows that perceptions of physical confinement affect consumers’ variety-seeking behavior. The third paper shows that the imagery and sounds prevalent in store environments around popular holidays (e.g., Christmas, Valentine’s Day) can trigger very different emotional reactions among consumers with counterintuitive consequences for consumption.

Tanya Chartrand will connect the three papers and serve as the symposium discussant. Tanya is well known for her research on non-conscious goal pursuit and automatic processing of social environments. Her research suggests that much of our daily life is determined by mental processes put into motion by features of the environment, which may operate above or below consumers’ conscious awareness (see, e.g., Bargh and Chartrand 1999). Her comments will integrate the various papers while also encouraging discussion among the audience and suggesting interesting potential directions for future research.

EXTENDED ABSTRACTS

“Why Coastal Dwellers May Prefer Tide: The Effects of Conceptually-Related Environmental Cues on Product Evaluation”

Jonah Berger, University of Pennsylvania, USA

Grainne Fitzsimons, University of Waterloo, Canada

Every day, consumers’ environments bombard them with different stimuli. People see certain colors around particular holidays (e.g., orange on Halloween), may read a lot about Mars in the

news when a NASA mission is ongoing, and may see their neighbors walking dogs as they come home from work. Might these diverse cues influence people’s consumer preferences? We know that direct product exposure, through ads and point of purchase displays, should positively affect sales (e.g., Baker 1999; Zajonc 1968), but what about exposure to perceptually or conceptually linked stimuli? The more consumers see Tide advertisements, the more they should like and purchase Tide, but what about exposure to stimuli related to Tide? Might it be the case that the more consumers see stimuli like waves, the more they will like and purchase Tide?

This presentation investigates how exposure to simple cues in everyday environments can influence consumer behavior. Our hypotheses are based on psychological research regarding spreading activation. Situational cues or primes can automatically activate associated representations in memory, leading them to become more accessible (e.g., Higgins, Rholes, and Jones 1977). This accessibility can then spread to related constructs via an associative network (Anderson 1983; Collins and Loftus 1975; Neely 1977). According to this spreading activation account, priming (or activating) a given construct in memory leads to the spontaneous activation of related constructs in memory. Building on processing fluency research (Lee and Labroo 2004; Whittlesea 1993) we argue that this activation should lead to more positive evaluations. Consequently, we argue that exposure to everyday real world stimuli can have important downstream effects on perceptually or conceptually-related products.

Four studies examined how environmental cues prevalent in real-world environments influence the accessibility and evaluation of conceptually-related products. Our first study simply sought to establish that real-world environmental cues can activate—or make more accessible—related product representations. We took advantage of a natural temporary difference in the prevalence of certain environmental cues, by using the fact that exposure to the color orange varies greatly around Halloween. Either right before Halloween, or one week later (when all the pumpkins, etc. disappear), participants were approached outside a supermarket and asked to list the first brands of candy and soda that came to mind. Results indicated that the mere increased presence of the color orange in the natural environment was enough to influence product accessibility; consumer products associated with the color orange (i.e., Reese’s Pieces and orange soda) were more accessible the day before Halloween as opposed to a week later.

Field Study 2 investigated how exposure to conceptually linked environmental cues influences product evaluation. We again relied on the natural environment for stimuli exposure. Some undergraduates ate in dining halls that used trays, while others ate in dining halls that did not use trays. Consequently, participants varied in how frequently they were exposed to trays over our week long study. We also manipulated whether a digital music player (ePlay) was linked to this, versus another, environmental cue. At the onset of the study, half the participants learned a slogan that linked the music player to dining hall trays (“Dinner is carried by a tray, music is carried by ePlay”) while the other half learned a control slogan that linked the music player to a cue (i.e., luggage) that did not vary across groups (“Luggage carries your gear, ePlay carries

what you want to hear"). Thus in the 2 (slogan) x 2 (environment) design, only one group of participants was exposed to more frequent conceptually linked product cues. One week later, participants reported their product evaluations and indicated how frequently they had seen trays in the past week.

Results indicated that merely being exposed to conceptually linked product cues was enough to increase product evaluations. Participants who had learned a slogan linking the product to dining hall trays, and ate in dining halls which used trays, liked the digital music player more. A moderated mediation analysis further underscored our hypothesis that the effects were driven by differential exposure to conceptually-linked environmental cues. Another study (Experiment 3) found similar effects linking products to a different environmental cue (i.e., luggage). People who traveled during the study, and thus were exposed to luggage more frequently, reported higher product purchase likelihood and greater willingness to pay.

To further examine the role of conceptual fluency in producing these effects, Experiment 4 directly manipulated exposure to conceptually linked environmental cues. Participants were shown either zero, five, or ten pictures of dogs as part of a study on "brightness perception" and then, in an ostensibly unrelated experiment, reported their evaluations of various sneakers, including some from the brand Puma. The results indicated that frequent exposure to conceptually linked stimuli increased product evaluations. Participants who saw more pictures of dogs evaluated puma sneakers more favorably.

Taken together, these studies demonstrate how subtle, everyday environment cues can have an important impact on consumer behavior. Exposure to conceptually linked stimuli can increase product accessibility, which in turn can lead to increased evaluation and purchase likelihood. These findings deepen our understanding of conceptual fluency (Lee and Labroo 2004) by demonstrating the underlying role of processing ease and examining the effects of frequent (in addition to recent) exposure. They also answer calls from priming researchers (Bargh 2006) by beginning to examine how such effects play out in noisy real world contexts. Seeing dogs can increase evaluations of Puma sneakers and living near the beach (i.e., waves) might even lead people to purchase Tide...

"Physical Confinement and Variety Seeking"

Jonathan Levav, Columbia University, USA

Rui Juliet Zhu, University of British Columbia, Canada

How does physical confinement affect consumers' behavior? Imagine shopping in a grocery store with narrow aisles; will the feelings of confinement created by the narrow aisles affect your product choices? Building on reactance theory (Brehm 1966; Wicklund 1974), we argue that such physical confinement can lead to psychological reactance, and that one consequence of this reactance is variety seeking.

Reactance theory suggests that when an individual's freedom is curtailed, she will experience a state of psychological reactance, which in turn will evoke behaviors aimed at regaining her freedom. In the consumer behavior literature, reactance research has focused on the choice context that can induce reactance, such as when constraints are placed on choice sets (e.g., stock-outs, Fitzsimons 2000) or when consumers are offered unwanted advice (Fitzsimons and Lehman 2003). A commonly observed consequence of such reactance is that individuals tend to adopt or strengthen an attitude or behavior that runs counter to what was intended for or presented to them (e.g., Fitzsimons and Lehman 2004). Building on this line of research, in this paper we investigate an important yet novel source of reactance in consumer behavior: physical confinement. We propose that asking individuals to make choices in (relative) physical confinement will evoke reactance. We predict that a

unique consequence of this reactance is variety-seeking behavior because it is viewed as an expression of choice freedom (Kim and Drolet 2003). Three studies support our theorizing.

The first study tests our basic hypothesis that a relatively confining versus a relatively less-confining space will lead to more variety-seeking. We randomly assigned participants to one of the two conditions, Wide Aisle (7ft) or Narrow Aisle (3.5ft) using dividers placed in a large laboratory space. At the end of the aisle was a table with six bowls containing six different popular candy bars. Participants were instructed to proceed down the aisle and choose three candy bars of any kind, in any combination they pleased. As anticipated, participants in the Narrow Aisle condition chose a greater variety of candy bars than their Wide Aisle counterparts.

In the next study we test the implication of our finding in study 1 to the choice of lesser known brands. We reasoned that where people seek variety they would be more likely to choose brands that they are less familiar with. Another motivation of this study was to test whether aisle width affects overall category choice or only market share. We consider familiar and unfamiliar charities as our "brands" in this study. Seventy-five undergraduate students completed the study in exchange of \$10. We randomly assigned participants to a narrow or a wide aisle as in study 1. We placed a table at the end of the aisle where participants were asked to complete a short questionnaire. In the target task, participants were presented with a list and short description of six charities. Three of these were familiar charities to our participants and three were obscure. Participants were asked to indicate: 1) whether they would be willing to donate any or all of their \$10 to any of the charities; 2) if so, how much they would donate; and, 3) how they would allocate their donation among the six charities in the event that they elected to make a donation.

The results revealed a significant influence of aisle width on our participants' choices. We created two donation intention indices, one for the familiar charities and one for the unfamiliar charities. No treatment effect was found on donation intentions for familiar charities. However, we found a significant main effect of aisle width on intentions to donate to the less familiar charities, such that participants in the Narrow Aisle condition were more likely to donate to the less familiar charities than their Wide Aisle counterparts. Next we examined whether the amount of money people donated differed by condition. There was no treatment effect on total donation amount, which suggests that the overall category choice is not sensitive to aisle width. We did, however, find a difference in the amount of money donated to each cause. Specifically, those in the Wide Aisle condition donated slightly more to the familiar charities. In contrast—and most interestingly—Narrow Aisle participants donated significantly more money to the unfamiliar charities compared with participants in the Wide Aisle condition.

In our third study we examine whether *feelings* of physical confinement can have the same effect as *actual* physical confinement. We held constant the aisle width at approximately 5 feet, and evoked a sense of confinement (and reactance) by prompting participants think about how narrow the aisle was (confinement condition) or not (control condition). After completing a series of unrelated measures participants were presented with ten pairs of gambles, and asked to choose one gamble from each pair. Each pair included a high probability, low payoff bet ("P-bet") and a low probability, high payoff bet ("S-bet") of approximately the same expected value. We found that participants in the confinement condition were more likely to choose an equal amount of P and S bets, representing the highest degree of variety seeking, compared with control participants, who tended to prefer S bets.

Finally, in an in-progress study, we attempt to confirm that reactance is indeed driving our variety-seeking effect using a similar procedure to study 3 where we also measure individuals' chronic reactance tendency. We anticipate that highly reactive participants should seek more variety when they are asked to focus on the aisle's narrowness than participants who are not. However, such a difference should be reduced among those who are chronically low in reactance. Initial results seem to support this theorizing.

In sum, we demonstrate that physical confinement can evoke reactance and consequently lead to variety-seeking. Thus, we identify an important antecedent of reactance (i.e., physical confinement) and highlight a unique consequence (i.e., variety seeking). In addition, this research contributes to the study of how structural aspects of the physical environment affect behavior.

“Happy Holidays? How Sights and Sounds of the Holidays Cue Different Feelings & Consumption Behaviors”

Lisa A. Cavanaugh, Duke University, USA

Gavan J. Fitzsimons, Duke University, USA

How do emotional holiday cues affect consumer behavior in real shopping environments? Generally the holidays are expected to prime positive feelings and large scale expenditure by consumers, particularly around holidays with an emphasis on gift giving, such as Christmas and Valentine's Day. Each holiday season consumers are flooded with seasonal holiday imagery not only at the shopping malls but also at their local grocery stores. Consumers can rarely pick up a gallon of milk or loaf of bread without passing a colorful display or hearing music reminding them of the upcoming holiday at hand. How do these sights and sounds of the holidays influence consumption? We argue that seemingly small differences in how holidays are portrayed can trigger very different types of feelings and appraisals with important consequences for consumption. Our studies look at the impact on the selection of groceries, gifts, food choices, and charitable donations in a real store environment.

Holiday decorations and themed music are often thought to enhance the holiday shopping experience and make people feel happy. Building from the literature on environmental cues (Meyers-Levy and Zhu 2007) and differential response to primes (Wheeler and Berger 2007), we look at how holiday cues differentially affect consumers. We examine how personally relevant cues trigger emotional appraisals (i.e., stakes of the situation and options for coping) and hence lead to more or less indulgence. We argue that different types of cues around the same holiday will trigger different types of feelings and meanings with important consequences for consumption. Specifically we test whether different portrayals of the same holiday can shape the choices that consumers make in real store environments. For example, some environmental cues portray Christmas as a religious holiday with manger scenes and traditional music (e.g., Silent Night, Oh Come All Ye Faithful) while others portray Christmas as a non-religious holiday with emphasis on Santa Claus, reindeer, and non-religious music (e.g., Winter Wonderland, Silverbells). Moreover, Valentine's Day has traditionally been portrayed as a holiday for lovers, however, the greeting card industry and self-affirming singles have worked diligently to reframe Valentine's Day as a holiday for loved ones more generally (e.g., cards and gifts exchanged between girlfriends and siblings). Our series of studies show that the sights and sounds associated with different portrayals of these holidays can lead to very different choices and behavior at the register.

The Christmas Study I. The Christmas studies test our hypothesis that different portrayals of the same holiday will lead to more or less indulgent behavior. We randomly assigned participants to one of two Christmas imagery conditions: Religious or Non-

Religious prior to making product selections. Under the auspices of a greeting card evaluation task, those in the Religious condition were exposed to greeting cards with religious Christmas imagery and music. Those in the Non-Religious condition were exposed to cards with non-religious imagery and music. Participants then allocated a \$50 gift certificate between an indulgent and non-indulgent option. Religious affiliation (Christian/ Non-Christian) was a measured factor. We found that Christians who saw Religious portrayals were *less likely* to opt for indulgent products for themselves. Yet, Christians who saw Non-Religious portrayals of Christmas were significantly *more likely* to indulge than Non-Christians who saw the exact same portrayal.

The Christmas Study II. Participants who had been exposed to either Religious or Non-Religious Christmas imagery entered a store environment. As participants entered the store, either religious or non-religious Christmas music was playing. The key dependent measure was indulgence, specifically the number of store brands vs. national brands selected across a variety of household product categories. Those who had viewed the Religious portrayal of Christmas and heard religious music chose significantly more in-store brands (i.e., indulging the least for themselves and spending less overall). Yet, those who heard religious music were also most likely to choose more indulgent gifts for others. Notably participants did not believe that the music had impacted their choices. Our final dependent measure of interest was donation behavior. After making all their product selections, participants had an opportunity to donate to two different charities—a local charity and an international charity—at the cash register. We find that those who had seen religious imagery and heard religious music playing in store: a) donated the most money and b) donated significantly more money to the international charity than those who heard non-religious music playing in the store environment.

Valentine's Day Study I. The Valentine's Day study was designed to test the implication of Christmas study II within a different holiday context and with generation of different types of feelings. Non-partnered individuals sometimes refer to Valentine's Day as “Single Person's Awareness Day.” A prevalent stereotype consists of lonely singles home alone engaging in self-indulgent behavior, but we wondered whether this stereotype would hold across contexts. We hypothesized that consumers' relationship status would affect the way consumers respond to Valentine's Day cues and indulgence opportunities. In Valentine's Day study I, female participants were randomly assigned to one of two conditions: Romantic Valentine's Day imagery or Friendly Valentine's Day imagery via a greeting card evaluation task. Relationship status (single vs. partnered) was a measured factor. We found a significant interaction of imagery and relationship status such that non-partnered individuals who had viewed the Friendly Valentine's Day cards were less likely to indulge than those who had viewed Romantic cards.

Valentine's Day Study II. Female participants were exposed to either Romantic or Friendly Valentine's Day imagery and then entered a grocery store where they encountered a large Valentine's Day display (e.g. roses, giant teddy bear, chocolates) and seasonal music playing. Participants made a series of choices in store and checked out at the register. Our key measures of interest were self-indulgence, in the form of choices of foods and money spent on personal care products, and reported feelings. We find that imagery and relationship status influence self-indulgence in distinct ways. Non-partnered females resist tempting food but indulge more with personal care products. Our results show that while Valentine's Day undoubtedly increases individuals' awareness of their own relationship status, the effects on their consumption are sometimes counterintuitive but ultimately functional.

In sum, we show that holiday cues which reaffirm important goals can dampen self-indulgence while cues that may threaten goals lead to coping through indulgence.

SYMPOSIUM SUMMARY
The Psychological Consequences of Choice
Jinhee Choi, University of Chicago, USA

SESSION OVERVIEW

Choice has been a central topic in consumer research, and in recent years, choice researchers have been mainly investigating what people choose (i.e., preference) and how they choose (i.e., choice process) (e.g., Dhar 1997; Hsee et al. 1999; Payne, Bettman, and Johnson 1992; Shafir, Simonson, and Tversky 1993). To this day, however, there is still relatively little known about the psychological consequences of choice. For example, what are the affective residual consequences of choice? How does choice affect people's mental resources? And why are some choices experienced differently than others? The objective of this symposium is to bring together a group of researchers that study these questions. They will address the consequences of choice for consumers' affective experiences and mental resources. Specifically, the symposium includes papers on consumers' experiences of depletion, replenishment, satisfaction, and regret, as a result of making choice.

The first two papers will address choosers' general psychological experience after making a choice. The first paper by Vohs et al. demonstrates that making choices depletes self-regulatory resources and further suggests why this happens by showing the various conditions of choice. Specifically, these researchers find that making choices for the self (compared to choosing for others), making unenjoyable choices (compared to enjoyable choices), and making full choices (compared to only deliberating or only implementing choices) were more depleting.

The second paper by Choi and Fishbach identifies the conditions under which the process of making choices has replenishing (vs. depleting) effects. In contrast to broad range of research showing that making choices is hard and depleting, they demonstrate that choosing can even be replenishing when it is construed as an end rather than a means to get something. Specifically, when consumers make choice for its own sake without considering getting something, it is replenishing. In contrast, when consumers make choices to get something, it is depleting. Thus, this research suggests the positive consequence of choosing based on how it is construed.

Whereas the first two papers focus on choosers' general experience after making a choice, regardless of the chosen item, the following papers focus on choosers' experience of the selected option. The third paper by Iyengar et al. investigates the implications of choice for a chooser's experience of post-choice satisfaction. They demonstrate that merely providing a categorization of the options enhances chooser's satisfaction on the chosen item. For example, choosers were more satisfied with their selection of magazine or coffee when these products were divided into more (vs. less) categories, irrespective of the information contained in the category labels. They further show that this is driven by a sense that a greater number of categories signals greater variety among the available options, which allows for a sense of self-determination from choosing.

The final paper by Ratner et al. identifies the factors that cause choosers to regret their selections and how they react to this feeling afterwards. They show that consumers switch away from a dominant option to a dominated option in subsequent choice when they experience regret after choosing the dominant option. They further demonstrate that whether consumers' regret leads them to switch depends on how they think and make attributions about the previous options. Thus, they suggest a situation leading consumers to negative

affective experience (e.g., regret), which further causes switching afterwards, moderated by their cognition (e.g., attribution).

Taken together, these papers explore the psychological consequences of making choices, including depletion, replenishment, satisfaction, and regret. These different lines of research provide diverse insights on the study of choice consequences yet maintain a coherent theme.

We believe that choice is central to consumer research and therefore, this symposium will be of great interest and appeal to a large number of audiences in consumer research, including those interested in emotion, motivation, information search and processing, and consumer satisfaction. All the papers are in advanced stages of completion (two are currently in press) and at least one author from each paper has agreed to present their paper if the symposium is accepted. As this symposium includes four talks, there will not be a long discussion but Fishbach will provide a brief summarizing discussion at the end. The talks will be kept brief to allow enough time for Q&A. We believe that the presentations on the psychological consequence of choice will elicit active discussion and idea generation for future research on choice.

EXTENDED ABSTRACTS

"Why Do Choices Tax Self-Regulatory Resources? Three Tests of Candidates to Explain Decision Fatigue"

Kathleen D. Vohs, University of Minnesota, USA

Noelle Nelson, University of Minnesota, USA

Catherine Rawn, University of British Columbia, Canada

Although many studies now detail the deleterious effects of making many choices or having many options, few have investigated why the process of choice derails the self. The current research approached this question using the limited-resource model of self-regulation, which has been a fruitful context to study the taxing nature of making choices. The current research asked about three distinctive features of choice that may underlie the effect.

It is instructive to review previous findings on self-control deficits after making choices. A series of studies by Vohs and colleagues (Vohs et al. 2008) found that making choice led people to perform worse on a subsequent act of self-control, relative to conditions in which participants previously had not made choices. This research used multiple domains of decision making, including choices about products and courses for a university degree. The dependent measures of self-regulation included enduring painfully cold water and drinking a bad-tasting but healthy liquid. In all

studies, the pattern was clear: people who had made choices showed impaired self-control on a later task, relative to people who had not made choices.

Why would choice deplete the self's regulatory resources? We investigated three important aspects of the choice process in the current studies. Our model of how choice taxes the self was derived from Gollwitzer's (1996) Rubicon Model of decision making. Gollwitzer depicts choice as the move between two qualitatively different modes of thought: deliberate and implement. The first stage in a choice process is deliberation, in which options are analyzed and a rather even-handed evaluation of options occurs. The act of choosing, per se, comes when people select an option (or more than one) in a quasi-behavioral act that connects the self to the chosen option (Strack, Werth, and Deutch 2006). The second stage in the choice process is to implement the choice, which means to act upon the selected option. This stage is markedly different from the deliberate stage, insofar as it engenders a commitment to an option and a bolstering of positivity about the chosen option. Shifting from one mindset to a qualitatively different mindset ought to be taxing, given that the concept of a mindset entails a distinct orientation toward the world, manner of engaging with the world, and evaluations of incoming information due to differing standards.

The first study examined whether making choices for the self versus making choices for another differs in terms of the regulatory energy. Insofar as making choices ties the selected object to the self, making choices ought to be more taxing when it involves the self than when it is for another given that the tie between the object and selfhood is likely far weaker. Participants came to the lab and were assigned to a condition in which they made choices for the self, for a person with whom they were moderately acquainted (on a scale from 1-9, the closeness of the relationship with this person was a 5), or made no choices. Then participants completed math problems as a measure of self-control. In line with predictions about the specialness of the self in choice, participants who made choices for themselves performed worse than participants who made choices for a friend, which itself was equivalent to self-control after not making choices.

A second study tested whether making enjoyable choices was less taxing than making choices that were not enjoyable. We hypothesized that the pleasantness of the choosing process might reduce its deleterious effects. If depletion is caused by forcing oneself to do something, then a pleasant task would presumably be less depleting than an aversive one. There was also some reason to predict that choice quantity would interact with subjective enjoyment. The beneficial impact of enjoying the task will likely wane as time and exertion increases. Hence we predicted that people would be less depleted when they made only a few, enjoyable choices but that by the time they had made many choices, they would be depleted regardless of liking for the choice task. Participants who had made no choices performed the best on the subsequent act of self-control, and participants who had made many choices (12 minutes of choosing) performed the worst. In between were a group of participants who had made a moderate amount of choices (3 minutes), and in this group the effect of choices depended on enjoyability of the task. If participants enjoyed the choice task (in this case, using a gift registry), they were less depleted than if they did not enjoy the task. But again, when participants had made many choices, the effect of enjoying the task vanished.

A third experiment manipulated which part of the choice process participants completed. Some participants engaged in only the deliberate aspect of choice, whereas others followed pre-selected instructions to implement an already-chosen option (this is akin to locating the right kind of peanut butter on a grocery list

someone else wrote), whereas a third group performed the full choice process of deliberating and implementing. In line with our notion of switching mindsets, the full choice process of deliberating and implementing produced the most depletion; the other two conditions of only deliberating and only implementing were better at self-control and were equivalent to each other.

In sum, three tests of three candidates for why choice is depleting found that the self is integral to when choice is depleting; making enjoyable choices helps when making moderate amounts of choices but not when many choices are made; and that the full choice process is more taxing than either simply deliberating among options or implementing pre-selected options. This research helps move the field toward a fuller understanding of the nature of choice, by detailing when, for whom, and how choice harms self-regulation.

"Choice as an End versus a Means"

Jinhee Choi, University of Chicago, USA

Ayelet Fishbach, University of Chicago, USA

Past research has distinguished the activities derived from two distinct motivators: An extrinsically motivating activity that serves other goals and hence construed as a means to achieve these goals, and an intrinsically motivating activity that does not serve other goals and hence construed as an end in itself (Shah and Kruglanski 2000). In this research, we apply this distinction to the activity of choosing and propose two different choice modes: the one that starts with an external need to which the choice is an instrumental means versus the one where the choice is its own end and it is experiential.

Based on research attesting that the same activity is experienced as effortful when it is extrinsically motivating and as enjoyable when it is intrinsically motivating (Higgins and Trope 1990), we propose that the activity of choosing is experienced differently depending on how it is framed. When choosing is construed as a means and thus instrumental, choosing is experienced as effortful and results in post-choice depletion. Conversely, when choosing is construed as an end in itself and thus experiential, it is experienced as enjoyable and results in post-choice replenishment. Thus, whereas choice research has traditionally considered the act of choosing as effortful and depleting (e.g., Baumeister et al. 2008; Dhar 1997; Luce, Bettman, and Payne 1997), choosing can also be enjoyable and replenishing if conducted for its own sake rather than conducted to get the selected item. We also propose that the subsequent interest in getting the selected item differs based on this mental framing. When choosing is instrumental and consumers experience depletion, they should express lower interest in getting their selected item than when choosing is experiential and they experience replenishment.

Four studies explore these distinct consequences of choosing depending on whether it is instrumental or experiential. Study 1 (“chips choice”) manipulated choosing as instrumental or experiential by directing participants to consider the next step of purchase or not. After tasting a number of chips, those who chose chips they like most (experiential choice) were more persistent in drinking healthy but bad-tasting beverage than those who chose chips they would like to buy (instrumental choice) or those who did not make any choice (control). Study 2 (“vacation choice”) manipulated choosing by emphasizing the goal of choosing or not. We found that participants who chose a vacation package without a specific external reason (experiential choice) performed better in the subsequent cognitive task than those who chose a vacation package with an emphasized goal of vacationing (instrumental choice) or those who did not make any choice (control). We also found that those who made an experiential choice were more motivated to go on a selected vacation than those who made an instrumental choice. Study 3 (“book choice”) framed choosing differently by leading participants to think about the goals of choosing or the means to choose. “Thinking about the goals” frames choosing as instrumental to achieve these goals, whereas “thinking about the means” frames choosing as experiential that can be achieved by these means. We found that participants who chose a fiction book under thinking about the means (experiential choice) were more motivated to engage in effortful activities after choosing than those who did not make any choice (control), whereas those who chose a book under thinking about the goals of choosing (instrumental choice) were less motivated to do effortful activities afterwards compared to those in control condition. We also found that those who made experiential choice were willing to pay more for the selected book than those who made instrumental choice. Finally, Study 4 (“flower choice”) manipulated choosing by framing it as a need or want. We found that people who did flower shopping as what they want to do (experiential choice) felt more replenished than those who did not make any choice (control), whereas those who did flower shopping as what they need to do (instrumental choice) felt more depleted than those in control condition. We further found that those who made experiential choice were more motivated to purchase the selected flower than those who made instrumental choice.

Taken together, these studies provide convergent evidence that instrumental choice construed as a means makes people depleted and decreases the interest in getting the chosen option, whereas experiential choice construed as an end makes people replenished and increases the interest in the chosen option. It implies that the same choice activity has distinct consequences depending on how it is framed.

“The Mere Categorization Effect: How the Presence of Categories Increases Choosers’ Perceptions of Assortment Variety and Outcome Satisfaction”

Cassie Mogilner, Stanford University, USA

Tamar Rudnick, Columbia University, USA

Sheena Iyengar, Columbia University, USA

Imagine shoppers browsing the magazine rack of a supermarket. They study rows upon rows of glossy pages, colorful pictures, and splashy headlines. They wander the aisle among hundreds of publications grouped under different category headings. Picture the magazines on the rack: Under “Fashion” there is the ultra-thick issue of *Vogue*. Under “Current Events” there is a copy of *Newsweek*. Under “Music” there is the most recent *Rolling Stone*. Watch the shoppers pick magazines from a set of hundreds. Did the category labels—Fashion, Current Events, Music—influence the shoppers’ choices? Did the very presence of categories affect their satisfaction with their magazine selections?

We sought answers to these questions by observing customers as they shopped the magazine aisles of a Northeastern supermarket chain. The 10 branches of the chain where we conducted our observations varied in the number of magazine options (331 to 664, $M=575$) and the number of magazine categories (18 to 26, $M=23$), which were unrelated ($r(10)=-.26$, NS). Although each of the store displays identified such categories as “Fashion & Beauty,” “Health & Fitness,” and “Entertainment,” the retailer had flexibility in deciding whether to further categorize the display to include such categories as “Women’s General Interest,” “Sports,” and “Music.” We observed 391 shoppers as they exited the magazine aisle (50% women, ranging in age from 30 to 50 years old) and asked them to participate in a short survey. Shoppers reported on a 100-point scale their perceptions of the variety offered by the magazine selection and their levels of satisfaction with their shopping experience. The results showed that while the actual number of magazine options had little impact ($r=.04$, $t=.66$, NS), the number of categories used to partition the display positively influenced perceptions of variety ($r=.18$, $t=3.44$, $p=.001$), which in turn led to greater customer satisfaction ($r=.49$, $t=11.00$, $p<.001$).

Expanding on the observations from our exploratory field study, we conducted two experiments in the choice domains of magazines and gourmet coffee to more closely examine the relationship between the presence of categories and consumers’ subjective experiences of choosing. In particular, the experiments examined the effect of mere categorization, in terms of the number and content of category labels, on chooser satisfaction. The findings show that the mere presence of a greater number of categories leads to increased chooser satisfaction, irrespective of the information contained in the category labels. This “mere categorization effect” occurs by increasing choosers’ perceptions of variety, which increases their feelings of self-determination.

In experiment 1, participants were presented with a display of 144 magazines from which they were instructed to choose one. Holding the magazine options constant, the display was manipulated between subjects to either offer three broad categories (i.e., *Men’s*, *Women’s*, and *General Interest*) or 18 more specific categories (e.g., *Cooking*, *Auto*, and *Sports*). Although categorization did not influence participants who were familiar with their choice set, those participants who were unfamiliar with their choice set were

significantly more satisfied with their selected magazine when the display was divided into 18 categories than when the display was divided into three categories. This effect was driven by choosers' perceiving increased variety amongst the options when there were a greater number of categories.

In experiment 2, participants were presented with a menu of 50 gourmet coffee flavors from which they were instructed to choose one to taste. The coffee options were either uncategorized or divided into 10 categories with labels that were informative (e.g., "Complex," "Spicy," "Nutty,"), somewhat uninformative (e.g., "The Gathering," "Java Joe's," "Coffee Time"), or completely uninformative "Category A," "Category B," "Category C". The results showed that irrespective of the information contained in the category labels, categorization led to greater chooser satisfaction than no categorization, but only for those who were novice coffee drinkers. Mediation analyses showed that this "mere categorization effect" was driven by the sense of self-determination that choosers experience when choosing from an assortment that they perceive to offer variety.

Building on research on categorization (e.g., Schmitt and Zhang 1998), consumers' inferences from marketing communications (e.g., Carpenter, Glazer, and Nakamoto 1994), and self-determination (e.g., Ryan and Deci 2006), this research has clear implications for retailers and offers theoretical contributions to extant work on perceived variety (e.g., Broniarczyk, Hoyer, and McAlister 1998; Hoch, Bradlow, and Wansink 1999; Kahn and Wansink 2004) and assortment size (e.g., Chernev 2003; Iyengar and Lepper 2000).

"When Dominated Options are Chosen: The Interplay of Affect and Cognition in Repeated Risky Choice"

Rebecca Ratner, University of Maryland, USA

Kenneth Herbst, Wake Forest University, USA

Nathan Novemsky, Yale University, USA

Individuals often face repeated choices between the same risky options. For example, when choosing how to invest savings, there are classes of investments that offer different risk profiles that a single individual might choose among on many different occasions. We are interested in examining how the outcome from a previous choice influences subsequent choices in these situations. We focus on a choice where there is a dominant option in all rounds and examine when and why individuals will choose the dominated option following a disappointing outcome with the dominant option.

Previous research has examined switching behavior in this context and found that individuals experience regret following the negative resolution of uncertainty; and that this regret drives them to switch away from what they still believe is a dominant option (Ratner and Herbst 2005). Thus, emotional reactions seem to interfere with individuals' ability to make a rational choice (Shiv et al. 2005). We extend this prior research by trying to understand why individuals experience regret following the choice of a dominant option. Regret usually accompanies a sense that one should have taken a different course of action. In the present context, that means one wishes to have chosen a dominated option. Nevertheless, substantial regret does emerge in this situation. We also examine when individuals are prone to act on their feeling of regret and actually switch to a dominated option.

In all studies, we use a fixed paradigm following Ratner and Herbst (2005). In that general paradigm, all participants first choose between two risky options (e.g., stock brokers). The information given about the options is very simple and clearly points to one option as dominant over the other option: for example, participants are asked to choose between a broker with a past success rate of 54% vs. one with a past success rate of 43%. Therefore, although one option clearly dominates the other, even the dominant option includes a substantial chance of failure. Not surprisingly, almost all participants choose the dominant option on the initial choice occasion. They then receive feedback that the option they chose did not produce a positive outcome on this first occasion. Our studies focus on what participants think and feel about this outcome and how that impacts their choices on subsequent occasions.

In our first study, we find that if we do not provide information about how the foregone option fared, participants assume that it fared well. As a result, they feel regret about having chosen the dominant option despite believing that the chosen option has a better chance of success than the foregone option even after accounting for the results of the first round. This experienced regret led individuals in Study 1 to switch to the dominated option on the next occasion. In our next study, we find that although individuals feel regret whenever they believe their outcome was worse than the outcome of the foregone option, they do not always act on this regret by switching to the dominated option. That is, their affective response does not always produce a switch on the subsequent occasion. Whether their regret leads them to switch appears to depend in part on whether they expect that the unchosen option produced a qualitatively different outcome than the obtained outcome (e.g., that the foregone option would have produced an increase in the value of an investment whereas the chosen option resulted in a decrease in value).

To summarize, we examine a situation where individuals are taking substantial risks and choosing a dominant option. Neverthe-

less, they are experiencing regret following the negative resolution of the risk. These feelings are sufficient to cause individuals to choose what they believe is a dominated option in a subsequent choice. Our results also suggest situations in which experienced regret does not produce regret-driven switching behaviors. Together, the results suggest a complex interplay between affect (e.g., regret) and cognitions in situations in which consumers make repeated choices between options that do not guarantee successful outcomes.

SYMPOSIUM SUMMARY

“What Things Do”: Examining Things That “Matter” in Consumer Research

Elizabeth Parsons, Keele University, UK

SESSION OVERVIEW

In this symposium we attempt to re-assert the role that the object has to play in our understandings of the consumption process in exploring ‘what things do’. As such the symposium aims to open out recent debates surrounding materiality in consumer research (Bettany 2007, Borgerson 2005, Zwick and Dholakia 2006). While the role material objects play in meeting needs, wants and desires, and their centrality as resources for identity construction, has been discussed by consumer researchers in depth (i.e. Belk 1988), much less attention has been paid to matter and materiality. In his 2005 book ‘Materiality and Society’ Dant argues strongly for a closer focus on the ‘material stuff of life’ and observes that the mundane routine ways in which objects are taken up in everyday lives have been neglected. Of course such an approach regards the meanings of objects not as intrinsic to the objects themselves, but as socially and culturally (re)produced (see for example Miller 1998). We seek to take this one step further by exploring the agency that might be afforded the more-than-human world of objects, or in Borgerson’s words objects’ ‘*non-intentional capacity to facilitate alteration*’ (2005: 440).

Rather than offer a description of each of the papers here, it is perhaps more instructive to draw out key themes operating across the three papers. In seeking to explore object agency and intentionality (i.e. in thinking through ‘what things do’) all three papers unpack the capacity of objects to resist our attempts at meaning making. Lai and Dermody, and Brownlie both use the trope of ‘hybridity’ to explore the ambiguity of object intentionality. Lai and Dermody view the donor-cadaver as an ambiguous hybrid, which destabilizes the boundaries between (living) subject and (inert) object. Likewise, Brownlie observes that music is ‘simultaneously abstract and concrete, physical and mental, material and social, concept and ‘thing’’. For Parsons a focus on the aesthetics of antique objects similarly draws out the concomitance of the substantive and communicative dimensions of things.

Through this exploration of hybridity the authors also seek to problematise prevailing understandings of subject-object relations in consumer research. This is most obviously accomplished by Lai and Dermody in their exploration of donor-cadavers, ‘the living dead’ which achieve a liminal quality being neither fully subject, nor fully object. Brownlie similarly persuades us to reflect on the liminal quality of music, he argues that studying music as social interaction in material context has potential to destabilize tensions between the object-subject divide. Finally, the authors in the symposium all identify the importance of understanding the embodied, performative and staged elements of the consumption experience.. As Brownlie observes, there are ‘riches to be found in getting out of the object-subject divide and the production-consumption ghetto, into the area of materiality and embodied habituated social practice.’

EXTENDED ABSTRACTS

“The ‘Living Dead’: An Exploration of The Social Biographies of Donor-Cadavers as Intentional Objects”

Ai-Ling Lai, University of Gloucestershire, UK

Janine Dermody, University of Gloucestershire, UK

This paper seeks to advance the burgeoning interest concerning the role of the (material) object in consumer research. Bettany

(2007) observes that there has been an ontological departure within the discipline to accord greater agentic primacy to the consuming subject. This has been conceptualized most recently in Consumer Culture Theory, where consumers “*actively rework and transform symbolic meanings*” encoded within the marketplace as part of their identity-projects (Arnould and Thompson, 2005). Consequently, the object remains a passive *res-extensa* subordinated to the consuming subject (Merleau-Ponty, 1962). As such, consumer researchers are increasingly called to explicate the intentional (purposeful) orientation between the subject and object (Borgerson, 2005; Dant, 2005; Bettany, 2007; Lai *et. al.*, 2008).

The aim of this paper is to ‘recover’ the ‘agentic capability’ of things, by exploring how the embedded intentionality of objects is enacted through the intersubjective network in which they are situated (Merleau-Ponty, 1945/2002; Borgerson, 2005; Bettany, 2007). This paper will answer this special session call from an embodied perspective drawing from the existential philosophy of Merleau-Ponty (1945/2002) and Heidegger (1927/1962). We will focus our analysis within the context of organ transplantation to consider the extent to which donor-cadavers can be considered as intentional objects (*what do objects do*) and how these cadavers enter into a purposeful communion with various members of the transplant community (subject). Accordingly we will present key themes emerging from the embodied narratives of 14 potential female donors, aged 21-30, who claim to be ambivalent as they explore the ideas surrounding cadaveric organ donation (Lock, 2002).

Specifically, we analyze the way in which participants trace the ‘social biography’ (Kopytoff, 1986) of cadaver-donors, as they consider the social significance of the body in relation to the liminality of the machine-ventilated-cadaver in organ transplantation (Hogle, 1995). This is understandable as organs are generally donated by patients who suffer from brain stem death (BSD).¹ These machine-ventilated cadavers are occasionally referred to as heart-beating cadavers or *neomorts* (Hogle, 1995). As an ambiguous hybrid, its marginal identity destabilizes the boundaries that customarily mark the donor-cadaver as (living) subject and (inert) object. In particular, the lifelike appearance of the *neomort* (Hogle, 1995; Lock, 2002) raises panhuman controversies over its agentic status as a marker of subjectivity, which is constantly being negotiated, abolished and redefined within the intersubjective network of the transplant community. In short, the *neomort* exudes an ambiguous intentionality, which problematizes the cultural meanings surrounding the status of the body as a lingering site of the donors’ personhood and a biomedical production of routine cyborg (Hogle, 1995).

Our analysis of the biomedical narrative reveals that the *neomort* is stripped of its intentionality. The body is ‘staged’ by biomedical experts in an attempt to construct a boundary marker to reduce the ambiguity of the *neomort* (Hogle, 1995). Medical rituals and protocol are orchestrated around the body, where the ‘humaness’ of the donor-cadaver is eradicated. For instance, the body is

¹Brain Stem Death should not be confused with Persistent Vegetative State (PVS). BSD refers to the irreversible damage of the brain stem and PVS refers to injury to the higher brain while the brain stem remains intact.

chained to a paraphernalia of technical equipment to sustain its vegetative status, which transforms the embodied patient into a docile and disembodied object (Hogle, 1995). Yet the *neomort* is firmly located within the matrix of interpersonal relationship (Hallam *et. al.*, 1999), and as such continues to exhibit social intentionality, as it remains comported towards the intersubjective world. For the participants, the intervention of the life-support machine creates a tension concerning the agentic capacity of the neomort-as-subject. On the one hand, the neomort persistently displays an *ambiguous transcendence* in its lingering orientation to life (Hallam *et. al.*, 1999), and thus continues to project into the potentiality-for-being (Heidegger, 1927/1962). For some participants, preserving the life of the *neomort* becomes synonymous to preserving the endurance of the embodied self. As such, the neomort-as-subject is permeated with 'social agency' (Miller, 2005) which inhibits the decision of the potential donor and their family to consider organ donation. Other participants however, consider such *ambiguous transcendence* afforded by transplant technology as limiting. Here, the *neomort* is perceived to be 'engaging' with the world in an inhibited manner (*inhibited intentionality*), and as such hampers its 'experience' for 'being-in-the-world' (Heidegger, 1927/1962). In other words, the *neomort* is 'decapitated' in its agentic capacity to meaningfully transcend the immanence of its materiality (Merleau-Ponty, 1945/2002). Consequently, the neomort emerges as an alienated presence, whose 'experience' is disjointed from the surrounding world (lost quality of life).

Our analysis therefore illustrates how the meanings and agentic properties of the donor-cadaver come to be materialized/erased through the interpersonal narratives and rituals performed through and around the body. We also uncover a number of important ethical questions surrounding the 'ownership' the neomort and the extent to which death can be defined in relations to the materiality of the body—which we will consider within our discussion. In so doing, our paper has thematized the agentic capability of objects (donor-cadaver) in enhancing/resisting the meaning-making process surrounding the consumption practice of organ donation. The donor-cadaver is therefore an intentional object that 'objects'.

"Creating 'The Look': Staging Value in the Antique Shop"

Elizabeth Parsons, Keele University, UK

This paper adds to our understanding of the way in which value is 'staged' in the consumption experience through an exploration of the antique shop. Staging and dramatic metaphors have been widely explored in the context of services marketing (i.e. Grove and Fisk 1983, Arnould *et al.* 1998) and more recently developed through the emerging language of consumptionscapes (Ger and Belk 1996, Venkatraman and Nelson 2008). However, these accounts focus largely on the relations between consumers, employees and the consumption surroundings. Here objects often merely act as props to the business of consumption. The aim in this paper is to explore in more depth the role that objects themselves might play in the value staging process (taking centre stage as it were). Dealers typically choose, alter, repair and assemble their objects for sale to achieve a particular look. It is argued that the innate style of objects and their presentation on the shop floor to create a specific 'look' becomes a key communicator in the staging of value. The services marketing literature has identified a split between communicative and substantive modes of staging the service experience. The focus on object aesthetics in this paper (see Wagner 1999), suggests a rejoining of these two concepts. It is argued that communicative staging, in particular dealers' story telling around the histories of objects (Parsons 2008), cannot be separated from the substantive nature (physicality) of the objects themselves. In highlighting the

role of the object the paper applies a material culture perspective on consumer behaviour and markets (Gell 1992, Attfield 2000, Borgerson 2005, Dant 2005, Miller 2005, Bettany 2007). With a particular concern to further explore 'what things do' in the consumption process (Verbeek 2005).

The paper draws insights from a wider project involved with exploring the social and material dimensions of antique dealing. Discussion is based on 15 interviews with antique dealers in two UK locations: Glasgow in Lanarkshire and Leek in Staffordshire. In this paper two cases are drawn from this research population for further elaboration. In each of these cases the dealers are involved in creating and maintaining quite different and specific 'looks' in their showroom or shop floor.

The first look to be explored is '*Eccentric Englishness*'. Roger uses several freelance finders to source his unusual objects and then transforms them in his workshop for sale to dealers (mainly American). When asked if he is interested in a specific period of antiques he says 'not into a period no- more into a look, the whole look exactly'. When asked about the look he is creating he comments 'English and a bit of French'. For inspiration Roger refers to the American interior design magazine 'Veranda' which he has copies of around the showroom. The second look to be explored is '*Scandinavian Design*'. Steve has a shop and workshop in the same small town as Roger but is involved in creating this very different look. He underlines that his look is 'that sort of Scandinavian Gustavian look which is really quite strong at the moment—as long as it's not too distressed'. Similar to Roger, Steve relies on interior design magazines for inspiration and to get a feel for what is popular, he cites Homes and Gardens (a British interiors magazine) as influencing his look.

In exploring these two looks it becomes clear that while the look *represents* a style or theme within the antique shop, on a deeper level this style or theme also becomes *demanding* of the dealer in choosing and/or altering the right objects to complement, and fit in with, the look. Therefore it is argued that 'looks' operate right across markets, influencing the practices and processes of producers, designers, retailers and consumers (see Entwistle's 2002 work on modelling). In this sense the look might be more usefully conceptualised as an 'aesthetic regime' around which networks of these cultural intermediaries are organised. This concept is useful in that it allows a consideration not only of the way in which aesthetics directs the purchase and consumption of goods, but also their modes of production, distribution and presentation. Geographers have explored a 'commodity chain' approach to consumption (i.e. Hughes and Reimer 2003). But further research would explore how markets are mediated by 'aesthetic regimes' and how such regimes both direct, and place demands on, those involved in networks of dealers, retailers, interior designers and consumers. For consumer researchers the focus will undoubtedly be on the last of these, however it is argued that consumer cannot be studied in isolation of these wider networks of provision.

"On the 'Hybridity' of Music"

Douglas Brownlie, University of Stirling, UK

The paper will argue that the category of 'music' as 'culture in the making'-as social interaction in material context-is worthy of further consideration within the consumer culture research cannon.

As a provocation, the claim is offered on this basis: that examination of the current status of 'music' as analytical object within consumer research reveals widely held assumptions about the relationship between subjects and objects of consumption (Wallace, 1997; Heckler & Blossom, 1997). That 'music' as it presents itself is simultaneously abstract and concrete, physical and

mental, material and social, concept and 'thing'; that it simultaneously inspires ambivalence and clarity, detachment and solidarity, offers a convenient stage on which to explore distinctions between the phenomenal and the noumenal that, as Kuchler writes, "emerged from the Enlightenment to drive a theory of culture in which not things, but humankind, is at the helm" (2005: 205). She goes on to argue that "[as a result] the world as experienced and the world as ontologically framed remain in tension, despite a long line of scholarship devoted to situating thought at the heart of the individual and of culture" (2005: 206). The paper argues that such tensions are present, if apparently dormant, within the consumer culture research project too. An adequate treatment of 'music' as material culture has, we suggest, the potential to destabilise this tension, problematizing trains of thought whose architecture unwittingly draws upon essentialist ontologies and the credo of the object-subject divide they authorize.

There is something to be gained from stepping aside from the instrumental agenda that appears to have inspired previous consumer research studies—where music is often seen as way of socially engineering an atmosphere that is conducive to certain forms of behavioural outcomes. In seeking to 'reassemble' (Latour, 2007) studies of music as consumer culture, it is clear to me that the 'actant' potential of music (cf Latour, 1991, 1992; Law 1991) is not merely as another form of powerpoint adornment—i.e. playing rock anthems to lighten up the presentation and lend it fashionable capital. In its viscerality and materiality music can be experienced as a transformative agent (Sacks, 1985, 2007), a shapeshifter, having the power to transport us between worlds as a way of bringing forth altered states of consciousness (Law, 1994; Kuchler, 2005). In that sense it has things in common with witchcraft. Indeed there is a long line of musicology that investigates the important part played by music (and cuisine) in bringing forth materiality in the context of resisting colonial acculturation (oppression) and opening up spaces for alterity and emancipation. This is especially so in the history of 'code-switching', a subtle form of re-signification to be found around the rhythmic space of syncopation as a material site of identity work done on the musical and social self. This work is done on the body, constructed not only as 'other', the site of necessary distinctions and resistance to them, but in its embodied alterity, as a site of beauty, sexuality and pleasure. Social identity and musical experience are mutually constitutive and, as Negus and Velazquez argue, "the subject and collectivity are mediated through musical experience" (2002:134). In my view current discussions of music and consumers framed through the subject-object divide seem only to work through forcing upon us a rhetorical strategy which admits unnecessarily narrow views of 'music' as material sociality.

By considering the character of performance we will explore practices already inscribed on bodies (playing, dancing, clapping, participating, observing), drawing attention to the embodied and material features of social action, revealing for inspection art-world knowledge (Becker, 1974) through performing and constructing an empirical site for the observation of embodied praxiological skills. The overall idea is to explore the riches to be found in getting out of the object-subject divide and the production-consumption ghetto, into the area of materiality and embodied habituated social practice (making music as materiality). This, in my view, constitutes the contextual relevance of music as a site of materiality as embodied social action within consumer culture research. Hopefully we will also further excite interest in the materiality of social life (Appadurai 1986; Kopytoff, 1986; Latour, 1991, 1992; Dant, 2005; Miller, 2005).

SYMPOSIUM SUMMARY

To Indulge or Not to Indulge? Self-Regulation and Overconsumption

Alexander Chernev, Northwestern University, USA

SESSION OVERVIEW

Consumers often make choices among options representing conflicting goals. This session enhances understanding of various mechanisms to resolve goal conflict in consumer decision processes by investigating the impact of goal conflict and goal progress on choice from multiple theoretical perspectives, thus offering a broader view of the role of self-regulation in choice.

Apart from providing theoretical insights on how goal conflict and goal progress influence choice, this session contributes to the understanding of the domains of self-regulation, consumption, and choice. Specifically, the session examined the following issues:

Research presented by Chernev and Gal explores scenarios in which attempts by individuals to regulate their consumption is counterproductive, leading to overconsumption. In particular, they propose that when individuals face an option that represents one of two competing goals (e.g., a tasty but high-calorie steak), adding another option that favors the alternative goal (e.g., a low-calorie salad) will increase the preference for a combined option that represents both goals (steak and salad). The counterintuitive aspect of their prediction is that by choosing the combined option, individuals end up increasing their calorie intake, an outcome counter to their goal of consuming fewer calories. They theorize that individuals evaluate choice options based not only on the options' objective performance (e.g., amount of calories) but also based on their fit with the activated goal. In this context, they show that the calorie content of the combined "low-calorie" and "high-calorie" items (e.g., steak and a salad) is perceived as lower than that of the higher calorie option alone (e.g., steak only).

Research by Fishbach and Finkelstein examines how individuals infer their progress toward achieving a particular goal in the context of food consumption. They propose that healthful food labels (e.g., "low fat" or "fat free") cue people to feel hungry, which increases the consumption of unrelated food items. They assert that this effect is driven by a perception of progress towards a person's goal of being a healthy individual as a result of exposure to healthy food labels. Consequently, one feels that the competing motivation of satisfying hunger was neglected and increases food consumption. Fishbach and Finkelstein report five experiments that manipulated the exposure to healthy product labels and documented increased subjective feelings of hunger, perceived progress towards the health goal, and actual food consumption.

Finally, research by Chandon, Wansink, Werle, and Payne investigates the effect of calorie compensation after moderate changes in calorie intake or expenditures. In particular, their research seeks to answer the following question: "Even if people eat more or burn fewer calories, why aren't they restoring their calorie balance by adjusting their subsequent calorie intake and expenditures?" Homeostasis should lead people to compensate for overeating by eating less and compensate for exercising by eating more. In a series of studies involving analyses of consumption panels and laboratory and field experiments, they show surprisingly little amount of calorie compensation within and across meals. They also find that compensation is influenced by whether overeating involved healthy or tasty foods and whether people focused on the healthy or enjoyable dimensions of exercising.

At the end of the session, the discussion leader Baba Shiv integrated the individual presentations into a more general framework, facilitating a broader understanding of the role of self-regulation in choice.

EXTENDED ABSTRACTS

"When Self-Regulation Leads to Overconsumption: The Goal-Progress Illusion"

Alexander Chernev, Northwestern University, USA

David Gal, Northwestern University, USA

Consider an individual primarily concerned with calorie intake who is choosing between two meals: a steak and similar steak with a side garden salad. After some deliberation, she chooses the second meal although the combined meal contains more calories and, thus, is inconsistent with her primary goal of consuming fewer calories. This pattern of behavior is not unusual and is, in fact, consistent with anecdotal industry evidence. To illustrate, to increase sales by attracting additional traffic into its stores, McDonald's introduced to its menu healthy, low-calorie food items like salads and fruit. Yet, its sales grew not so much from increased sales of healthy, low-calorie foods but from selling more fast-food items like double cheeseburgers.

What motivates consumers to act in a way that ends up being counterproductive vis-à-vis their goals? We propose that when individuals face an option that represents one of two competing goals (e.g., a tasty but high-calorie steak), adding another option that favors the alternative goal (e.g., a low-calorie salad) will increase the preference for the combined option that represents both goals (steak and salad). This prediction is consistent with the notion that when faced with a choice among options representing two competing goals, consumers attempt to satisfy both goals by choosing outcomes that ensure progress toward both goals. The counterintuitive aspect of this prediction is that by choosing the combined option, individuals end up increasing their calorie intake, an outcome counter to their goal of consuming fewer calories.

To explain this pattern of behavior, we theorize that individuals evaluate choice options not only based on their objective performance (e.g., amount of calories) but also based on their fit with the activated goal. To illustrate, ordering a green salad is likely to be perceived as consistent with the weight-loss goal, whereas ordering a juicy steak is likely to be perceived as consistent with the goal of indulging oneself. Because the green salad in the above example fits the low-calorie-consumption goal, it is likely to be classified as a "low-calorie" item, whereas the juicy steak is classified as a "high-calorie" item. The interesting phenomenon here is that the calorie content of the combination of a "low-calorie" item and a "high-calorie" one (e.g., steak and a salad) is perceived as lower than that of the higher calorie choice (e.g., steak only).

In a series of three experiments, we examine the proposition that goal-consistent evaluations of decision alternatives can lead to counterproductive decisions. Our first experiment examines how adding a low-calorie option (e.g., a green side salad) to one of two similar high-calorie meals influences consumer choice. We show that even when the primary goal is to reduce calorie intake, adding the low-calorie option increases the preference for the combined meal, although it contains more calories.

In the second experiment, we directly test the proposition that consumers' reliance on goal-consistency to evaluate choice options leads to a biased estimation of the options' objective performance (i.e., calorie content). In particular, we ask respondents to estimate the amount of calories in individual components of a meal, as well as the number of calories in the meal as a whole. The data show that when evaluated separately options satisfying competing goals are

estimated to have a greater number of calories than when the same options are estimated jointly.

The third experiment examines the role of goal consistency in estimating options' performance on consumption quantity. In particular, we examine the amount of calories consumed as a function of consumers' choice from a menu. We find that when the menu includes a lower calorie item (such as a green salad or an apple) individuals end up consuming more calories (relative to those given a menu without the low-calorie option). We also show that when the menu includes a very high-calorie item (e.g., a 1000-calorie milkshake), the effect is similar to inclusion of a low-calorie item, such that individuals who selected to forgo the very high-calorie item ended up consuming more calories than those in a scenario in which the very high-calorie item was not on the menu.

Overall, our findings are consistent with the proposition that consumers evaluate choice options based on the options' fit with their active goals and that such evaluations can lead to counterproductive outcomes. In addition to its theoretical contribution, our research has important managerial and public policy implications. In particular, we show that consumers tend to underestimate the calorie content of combinations of healthy (virtues) and unhealthy (vices) products, a finding that casts a shadow on the recent attempts by many fast food restaurants to add healthy options to their menus. Thus, while providing a healthy alternative to individuals interested in a healthier lifestyle, the introduction of healthier options can paradoxically lead to overconsumption, which stems from biased estimation of the calorie content of the available options.

“When Healthy Food Makes You Hungry”

Ayelet Fishbach, University of Chicago, USA

Stacey Finkelstein, University of Chicago, USA

Research on the Dynamics of Self-Regulation (Fishbach & Dhar, 2005; Fishbach, Dhar, & Zhang, 2006) attests that in the course of pursuing multiple goals (e.g., saving and spending), whether the individual experiences commitment to or progress towards a goal influences the course of self-regulation over time. While an experience of commitment encourages goal-congruent actions because of an increased sense that the goal is valuable and attainable, an experience of progress towards one goal will result in relaxing one's effort and moving away to another, competing motivation that is presumably somewhat neglected. This second self-regulatory process, that of inferring progress, is more likely when individuals' behavior is under externally imposed control; as a consequence, they cannot infer based on their actions that the goal is important to them and that their commitment is high.

The current research documents effects of perceived progress in the domain of healthy eating. We propose that healthful food labels (e.g. “low fat” or “fat free”) cue people to feel hungry, which increases the consumption of unrelated food items. This effect is driven by a perception of progress towards the goal of being a healthy individual as a result of exposure to healthy food labels. Consequently, a person feels that the competing motivation of satisfying hunger was neglected and increases food consumption.

Five studies manipulate exposure to healthy products and product labels (versus tasty products or regular product labels) and show increased subjective feelings of hunger, perceived progress towards the health goal, and actual food consumption. In study 1, participants tasted a sample of a health bar that was presented as either “health bar” or “tasty bar” and then indicated how hungry they were. Those to whom the sample was framed as “healthy” indicated that they were hungrier compared with participants who did not taste any food sample or tasted a sample that was framed as “tasty.”

Study 2 extends these results by comparing participants' hunger level before and after eating a food sample. Participants who tasted a sample that was framed as healthy (tasty) showed an increase (decrease) in subjective hunger as a result of their consumption experience while participants in a third control condition that did not sample an item showed no change in hunger over time.

Study 3 investigates the link between healthy food sampling and consumption. Participants tasted a sample that was framed as healthy or tasty and were offered the opportunity to consume an unrelated snack afterwards. Participants to whom the food sample was framed as healthy consumed more of the unrelated snack – hence, they were hungrier – than participants to whom the sample was framed as tasty.

Study 4 tests the prediction that healthy food labels increase feelings of hunger when people do not experience free choice. This study manipulated the sample that people ate (healthy vs. tasty) and the nature of their consumption (free vs. imposed choice). We found that participants who were required to eat a sample framed as healthy indicated higher hunger levels than participants who were required to eat a sample framed as tasty. In contrast, participants who believed they had a free choice were similarly hungry after sampling food that was said to be healthy versus tasty.

Finally, in study 5 we tested the effect on hunger of merely being exposed to healthy labels, such as “low-fat,” versus regular labels. We predicted that the association between health and hunger is basic, such that people do not need to actually consume healthy food to infer that they have made progress towards their health goal. Merely seeing these healthy food labels can increase one's perception that progress has been made and intensify feelings of hunger. Accordingly, we expected an increase in consumption of unrelated foods. To test these predictions, participants were primed with food labels for products that were either healthy (e.g. fat-free American cheese) or regular (regular American cheese) in a “product evaluation survey.” We found that participants who merely viewed healthy food labels reported that they had made more progress towards their health goal compared to participants who viewed regular food labels. More important, mere exposure to healthful (vs. regular) food labels increased consumption of a neutral snack on a subsequent task.

In summary, across five studies we find that individuals who sample healthy foods or who merely see healthy food labels feel that they have made progress towards their health goals. This sense of progress, in turn, cues feeling of hunger. Thus, eating healthy food can actually whet the appetite.

“Can Healthy Eating and Fun Exercising Make Us Fat? Post-Intake and Expenditure Calorie Compensation”

Pierre Chandon, INSEAD, France

Brian Wansink, Cornell University, USA

Carolina Werle, Grenoble Ecole de Management, CERAG, France

Collin Payne, Cornell University, USA

It is clear that the simultaneous increase in calorie supply and decrease in calorie expenditures over the past decades help explain the current obesity epidemic. Still, these environmental effects leave one important question unanswered: Even if people eat more or burn fewer calories, why aren't they restoring their calorie balance by adjusting their subsequent calorie intake and expenditures?

Calorie compensation obviously occurs for very large changes in calorie intake or expenditures. Who hasn't vowed after a really big Thanksgiving dinner that “they will never eat again”? At this level, homeostatic mechanisms kick in and re-establish the nutritional balance that is necessary for our body to operate. In this

research, we examine calorie compensation after moderate amounts of changes in calorie intake or expenditures. Given that a weekly 67-calorie imbalance leads to a one pound weight gain over a year (Hill, 2003), even moderate amounts of changes in calorie intake can have big impact on obesity rates if people fail to compensate for them.

Our main hypothesis is that calorie compensation after moderate changes in calorie intake or expenditures is driven by perception of goal progress and not by homeostatic physiological mechanisms. Building on research on goal balancing (Dhar, 1999), we hypothesize that two conflicting goals are salient when making food consumption decisions: the hedonic goal of maximizing pleasure and the more utilitarian goal of maintaining good health. In addition, prior research has shown that people underestimate their calorie intake but overestimate their calorie expenditures (Livingstone, 2003). We therefore expect that perception of progress toward the “healthy living” goal is higher when a food is perceived as “healthy” than when it is perceived as “pleasurable” or “tasty.” Accordingly, we hypothesize that once the choice of the main course has been made consumers will choose side orders, desserts, and beverages containing more calories if the main course is positioned as healthy (and thus perceived to contain fewer calories) than if it is positioned as “tasty.”

We expect the opposite pattern of results for calorie compensation following calorie expenditures. Because of the overestimation of calorie expenditures, perception of progress on the “healthy living” goal will be lower when the calorie expenditures are perceived as contributing to health than when they are perceived as contributing to pleasure. We expect that consumers will realize that they are burning fewer calories than they thought when the calorie expenditure activity is positioned as “healthy” than when it is positioned as “pleasurable.” As a result, we expect lower compensation (i.e., smaller meals) after “healthy” exercising than after “pleasure” exercising. Note that by manipulating the perception of the food and the exercising while holding the actual food and the exercise constant, we isolate the effects of goal-driven compensation from those of physiological compensation.

In the first experiment, we provided participants with either a coupon for a burger perceived to be tasty (600 calories) or for a sandwich perceived to be healthy but containing, in fact, 900 calories. We then asked people to choose whether they would like to have chips, drinks, and cookies with the burger/sandwich. We found that people chose beverages, side dishes, and desserts containing up to 131% more calories when the main course was positioned as “healthy” compared to when it was positioned as “tasty,” even though the “healthy” main course already contained 50% more calories than the “tasty” one. As a result, meals ordered in the “healthy” condition unknowingly contained more calories than meals ordered in the “tasty” restaurant condition.

We replicated these results in a second experiment in which we manipulated the health positioning of the food by changing the name of the restaurant and the other types of items on the menu while holding the target dish constant. We also tested whether these effects could disappear when asking participants to consider arguments contradicting the health claims. We found that participants were more likely to order chips with a Bologna sandwich served by a “healthy” restaurant than with the same sandwich served by a “tasty” restaurant unless they were asked to consider whether the health claims of the restaurant actually applied to that particular sandwich.

In the third study, we analyzed consumption diary data from a panel of 1,800 households maintained by NPD Foodworld, Inc. Drawing on previous research (Wansink, 2006) showing that

people overeat “low-fat” snack food, especially when it is considered healthy (e.g., granola), we measured calorie compensation within and across meals among households eating low-fat granola and among households eating regular granola. We found that households eating low-fat granola for breakfast consumed more calories overall during that day. We also found that these extra calories came from food and not from beverages, showing that (spurious) compensation occurs only within the same type of food. Finally, consistent with prior work (Khare, 2006), we found that compensation occurred only during breakfast and lunch and had disappeared by dinner time.

The fourth study examined the effects of imagined exercising on subsequent calorie intake. We asked people intercepted in shopping centers to read a scenario describing a 30-minute walk. The scenario asked them to focus either on the music that they would be listening to during the exercising (pleasure condition) or on the amount of effort that it would require (health condition). People in the control condition did not read a scenario involving exercising. Participants were then given the opportunity to help themselves to as many snacks as they wanted. We found that people served themselves more snacks in the pleasurable-exercising condition than in either the healthy-exercising condition or in the control (no exercising) condition.

In the final fifth study, we asked people to walk for half an hour while focusing either on the amount of energy spent (health condition), on the music that they were listening to (pleasure condition), or on an unrelated task (control). We then weighed how much food they took at an all-you-can-eat buffet where they had lunch after the task. We found that people chose bigger meals in the pleasurable exercise condition than in either the health exercise or in the control conditions.

Our research seeks to make four major contributions. First, we show that exercise influences food intake differently if people just think about exercising – in which case there is compensation – or if they actually exercise – in which case the framing and the importance of staying fit will play a role. Second, we show that people focusing on having fun when exercising tend to compensate for the calories they have burned by eating more, while those focusing on exercise eat less. Third, we find that people concentrating on exercising eat less when the central objective of staying fit is very important to them. Fourth, we put forth potentially useful implications for public policymakers, health care professionals, and consumers interested in controlling their food intake.

SYMPOSIUM SUMMARY

Encoding, Remembering, and Using Numeric Information: Implications for Pricing

Manoj Thomas, Cornell University, USA

SESSION OVERVIEW

Price cognition plays a pivotal role in models of consumer behavior postulated in the economics as well as the psychology literature (Monroe 2003; Winer 2006). Both streams of literature concur on the following assumption: A buyer's subjective judgment of the magnitude of a price should be an important determinant in purchase decisions. However, the psychological processes that underlie price magnitude judgments and the strength of the association between price magnitude judgments and choice continue to be topics of debate. In this symposium, we present three new papers that offer novel perspectives on how consumers encode, process, and use price information. The first two papers draw on the numerical cognition literature and focus on how consumers encode and process price information, while the third paper examines factors that lead to a dissociation between price perceptions and choices.

The first paper by Thomas, Simon, and Kadiyali examines whether the precision or roundedness of numbers influence people's judgments of magnitude. This paper draws on the numerical cognition literature to examine how consumers encode the magnitude information from a string of digits in a multi-digit number. Specifically, drawing on previous research on the distribution of numbers and on the role of associative processes in everyday judgments, they suggest that that people nonconsciously learn to associate precise prices with smaller magnitudes, and that this association influences their price magnitude judgments and willingness to pay. They test this hypothesized precision heuristic in laboratory experiments as well as using data from real estate transactions.

The second paper by Vanhuele and Laurent examines why consumers are less adept with prices that are not rounded. They suggest that short-term memory constraints induce consumers to apply mathematical rounding, truncate price endings, or resort to approximations. Their conceptualization suggests that what typically are considered as recall errors may therefore actually be the result of adaptive simplification strategies. They analyze patterns of price recall errors to show that errors follow systematic patterns that reveal these strategies.

The third paper by Danziger, Gal, and Morwitz examines the influence of price magnitude perceptions on product and retailer choice in an environment where price discounts are sometimes offered and vary in their depth and frequency. Past research (Alba et al. 1999; Lalwani and Monroe, 2005) has studied the effects of depth and frequency of price discounts on price perceptions. In the present research, the authors challenge the implicit assumption of this past research, that price perceptions guide choices. They find that although respondents' price perceptions are lower for retailers offering deep infrequent discounts, they buy more often from retailers offering frequent shallow discounts. They discuss the implications of this finding for our understanding of how consumers encode, process, and use price information.

EXTENDED ABSTRACTS

“Do Consumers Perceive Precise Prices to be Lower than Round Prices? Evidence from Laboratory and Market Data”

Manoj Thomas, Cornell University, USA

Daniel Simon, Cornell University, USA

Vrinda Kadiyali, Cornell University, USA

Research on factors that affect consumers' magnitude judgments in general (see Krishna 2006 for a review) and price magnitude judgments in particular (Greenleaf 1995; Monroe 2003; Morwitz, Greenleaf and Johnson 1998; Wathieu and Bertini 2007; Winer 2006) has not only unveiled several new behavioral phenomena, but also has enhanced our understanding of the consumers' cognition processes. Given the centrality of perceived price magnitude in buyers' decision making, we examine a ubiquitous, yet hitherto unexplored, aspect of price magnitude judgments: Do consumers perceive round prices to be higher or lower than prices that are not rounded? Consider the following illustrative example: A seller of a house can list the house for a more round price \$365,000 or \$364,000 or a more precise price such as \$364,578. How would the precision in the price affect buyers' evaluation of the list price?

To explore whether people use precision as a cue in magnitude judgments, and if it does, in which direction, we ran a short online survey. Sixty nine students from a university were asked to respond to the following question: “Consider two six-digit numbers X and Y. The number X is rounded to the nearest thousand. The number Y is not rounded. Which number is likely to be smaller: X or Y?” A majority of the respondents (68%) said that the number that is not rounded (Y) is likely to be smaller, and this response rate was significantly different from chance ($p < .01$). This result suggests that people might be using precision as a cue for smaller magnitudes in their day-to-day numerical judgments. We refer to this decision rule as the “precision heuristic” in price magnitude judgments. In this article, we examine whether this heuristic can influence on buyers' behavior in high involvement purchases such as buying a house, and try to gain some insights into the psychological basis of the precision heuristic.

Two important clarifications about our approach are due right at the outset. First, our definition and operationalization of roundness is consistent with the extant literature (Sigurd 1988, Dehaene and Mehler 1992, and Rosch 1975). We consider the number of zeroes in a number as the measure of roundness of the number. Further, our operationalization of roundness is consistent with the notion that there can be gradations in perceived roundness of numbers; that is, some round numbers might be perceived to be more round than others (Jansen and Pollmann 2001). For example, \$364,500 is more round than \$364,578, but less round than \$364,000. Second, we note that our discussion of roundness is distinct from the well-established literature on nine-endings in pricing (e.g., Stiving and Winer 1997). A precise price can have a nine-ending (e.g., 364,999) or not (e.g., \$364,578). Comparing consumers' evaluations of a nine-ending precise price with that of the corresponding round price (e.g., 364,999 vs. 365,000) is problematic, because the effect of precision will be confounded with the nine-ending effect. Therefore, in our experiments we do not use prices that end in nine,

and in the analyses of the market data we find that our results are robust to controlling for the nine-ending effect.

We report four studies that test our hypotheses. We examine whether consumers systematically judge precise prices to be higher than round prices and whether this biased judgment influences their buying behavior. Our laboratory experiments provide evidence consistent with the precision heuristic and its effect on buyer behavior. Results from study 1 offer evidence for the effect of precision heuristic in price magnitude judgments. Specifically, we find that under conditions of uncertainty, buyers are more likely to judge the magnitude of a precise price (e.g., \$364,578) to be lower than the magnitude of a comparable round price (e.g., \$364,000 or \$365,000). Study 2 was designed to demonstrate (i) that it is possible to create an association between precision and subjective magnitude judgments, and (ii) that the activation of such an association could influence participants' judgments and decisions. The results from this study show that house buyers are likely to pay more for a house with a precise list price (e.g., \$364,578) than for a comparable house with a round list price (e.g., \$364,000 or \$365,000). Further, we show that this effect of list price precision on buyers' willingness to pay is mediated by the bias magnitude judgments. In study 3 we use responses from a nationwide sample comprising mostly homeowners and corroborate the external validity of our results. Finally, in study 4 we analyze the data from more than 27,000 residential real estate transactions to provide evidence that the precision heuristic influences buyers' behavior, even in what is likely the largest purchase that most buyers will make in their lives. We conclude with a discussion on the limitations of this research and directions for future work.

“What Recall Errors Tell Us About Price Memory”

Marc Vanhuele, HEC Paris, France

Gilles Laurent, HEC Paris, France

In order to buy at the right price many consumers verify prices, and make comparisons across products, across purchase locations, and over time. Memory plays an important role in these comparisons. When the to-be-compared prices are present at the same location, they have to be held in short-term memory. It is also often useful to call on long-term memory to retrieve prices from the past or from another purchase location.

A series of price knowledge surveys have shown that price memory is weaker than what prior research, for instance on reference price, suggested. In-the-aisle surveys (Dickson and Sawyer 1990) suggest that many consumers do not watch prices and, when they do pay attention, price information is easily erased from short-term memory. Vanhuele, Laurent, and Drèze (2006) examined the constraints of short-term memory. In experiments in which multiple prices have to be retained in short-term memory, a requirement for the price comparisons described above, they show that auditory short-term memory has a capacity constraint in terms of the time it takes to pronounce the to-be-remembered information. Two prices with decimals often surpass this capacity constraint which leads to loss of information.

We advance the thesis that consumers are somehow intuitively aware of the difficulty of retaining price information when prices become long to pronounce and adapt their price encoding by simplifying observed prices. They may apply mathematical rounding, truncate price endings, or resort to approximations. What typically are considered as recall errors may therefore actually be the result of adaptive simplification strategies. So-called recall “errors” should therefore follow systematic patterns that reveal these strategies.

The theoretical basis for our work is provided by the triple-code model of Dehaene (1992). This model is a synthesis of the key

research findings in numerical cognition, a sub-domain of cognitive psychology that examines how numbers are represented and processed in the cognitive system. Dehaene (1992) proposes that numbers can be mentally represented and manipulated in three different forms, in function of the task people are executing. The visual Arabic code represents numbers on a spatial visual medium on the basis of their written form in Arabic numerals (e.g., 35). The auditory verbal code is generated through a phonological representation in which each number is represented by a sequence of phonemes (e.g., /thirty/ /five/). Finally, the analogue magnitude code represents numbers as approximate quantities on an internal dimension termed the “number line” (e.g., about 35, slightly less than 40, or somewhere between 30 and 40).

Vanhuele, Laurent, and Drèze (2006) found evidence of all three codes, but also observed the dominance of the auditory verbal code. This observation highlights the importance of the verbal capacity constraint of short-term memory. Baddeley's (1992) work examined this constraint in detail. He postulates the existence of a phonological loop, which consists of a phonological store to hold speech-based information for the duration of 1.5 to 2 seconds and an articulatory control process to hold data within the phonological store through subvocal repetition. Vanhuele, Laurent, and Drèze (2006) found three types of evidence of the impact of the phonological loop: prices that are longer to pronounce (independently of the number of digits) are less well remembered, participants who use verbal shortcuts (e.g., pronouncing 245 as two four five instead of two hundred forty-five) have better price memory, and participants who habitually speak slower have poorer price memory.

To examine our thesis that consumers use adaptive simplification strategies, we ran new price recall surveys but also examined the data used for previous publications. For these publications, the probability of a correct response, or response within a certain error range, was taken as dependent variable. Here, we examine the types of errors that are made.

We have three types of data sets: (i) Immediate memory tests in which participants make a deliberate attempt to retain price information in short-term memory for a number of seconds, (ii) Store-exit surveys where supermarket shoppers are questioned on the prices of items they just paid for, and (iii) A store-entry survey that examines long-term memory for products consumers purchased on previous shopping occasions. As first step of our analysis we made a content analysis of the errors. Each recall response was compared to the correct price and the error was then labeled. After a couple of iterations we found that the following classification covers most of the errors: interference from other prices; rounding down one or more decimals (e.g. from 3.24 to 3.20 or 3). We reserve the word “rounding” for the mathematically correct operation of rounding down decimals below 0.5 and rounding up from 0.5 onwards; rounding up (e.g. from 3.79 to 3.80 or 4); simplifying down (e.g. from 3.79 to 3.70 or 3). Simplifying refers to a mathematically incorrect operation; simplifying up (e.g. from 3.24 to 3.30 or 4); approximations.

We then examined with statistical analyses whether the occurrence of the different types of errors had systematic drivers. Our main findings are the following:

- a. Price recall errors are not randomly distributed but fall instead into clear patterns because they often are the result of simplification strategies.
- b. Simplification strategies are in large part determined by the structure of the price. Whether a consumer will round or simplify is determined by the first digit(s) (euro in our case) and by the price ending (the cents part). In other words, a price of 1.XY euro will be treated differently than a price of

2.XY euro, just like a price of X.85 euro will be treated differently than one of X.99 euro. This suggests that consumers scan the most notable features of a price before registering a simplified version.

- c. Our initial analyses suggest that consumers with really good price recall do not use simplification strategies, but that consumers with poorer recall ability benefit from these strategies.

“Do Price Judgments Always Influence Choice? The Effects of Retailer Discount Frequency and Depth”

Shai Danziger, Ben-Gurion University, Israel

Sharon Gal, Ben-Gurion University, Israel

Vicki Morwitz, New York University, USA

According to economic and marketing theory, product price is a major determinant of consumer choice. When multiple retailers offer the same product or a single retailer offers very similar products, consumers who are aware of price differences usually purchase the cheapest product. Therefore, retailers offer various price discounts to influence consumers' perceptions of retailers' and products' prices, and ultimately their choices of which retailer to purchase from and which product to buy (Alba et al. 1999; Lalwani and Monroe, 2005). Two aspects of discounts that retailers manipulate are discount frequency (how often discounts are offered) and discount depth (the magnitude of the offered discounts). Past research has examined the effect of discount frequency and depth on consumers' perceptions of average prices, but has not examined how that in turn influences choice. In contrast our work focuses on the impact of type of discount strategy on choice and, importantly, finds a dissociation between perceptions of the average price and choice.

Alba et al. (1999) examined the effect of depth and frequency discounting on consumers' price perceptions. They presented respondents with the prices of two brands over multiple trials (simulating weekly purchases) and asked them to indicate on each trial the brand they would choose. After all trials, participants estimated the average price of each brand. The true average price was identical for both brands. They found that when each brand was priced at only two (multiple) levels, the depth (frequency) brand was perceived to have the lower average price. Lalwani and Monroe (2005) used similar procedures to test the hypothesis that relative salience determines which discount strategy yields lower perceived prices. They found that when discount frequency (depth) is more salient, a frequency (depth) effect is found. Thus, these studies demonstrate that discount frequency and depth influence perceptions of the average price and they determine conditions when one or the other strategy is more effective in lowering price perceptions. Importantly, both papers implicitly assume that perceived average price in turn influences retailer or brand choice. However, their procedures do not allow them to examine this because respondents always saw both product prices prior to choice. Under such conditions respondents can simply select the cheaper of the two prices shown. Therefore, it is likely that respondents in these studies estimated average price only when asked to do so after the choice phase and did not use it in choice. Also, their procedures only consider the case when full price information is available for both products. In many real world shopping situations, consumers must decide which retailer to visit based only on their price expectations, and not on the actual prices of retailers.

In our research, in contrast, we explicitly examine the effects of depth and frequency discounts on consumers' choice of retailer and on several price judgments. In two experiments respondents were instructed that they would be making multiple decisions

(simulating weekly purchases) regarding where to purchase a product that was available at two stores. They were also told that each store offered the product at either a regular price or at a discounted price, that they would make 100 choices, and that their goal was to minimize overall spending. An incentive compatible procedure was used. Critically, as is the case in actual retailer choice situations when consumers are not exposed to price advertising, respondents were told that their decisions would be made in the absence of current retailer price information. In other words, on each purchase occasion respondents' choices likely reflect their predictions about which store they thought was offering greater savings. In the 'chosen' feedback condition that most closely mimics many real world shopping experiences, in each trial, respondents saw only the chosen retailer's price after choice. In the 'both' feedback condition, for each trial, respondents saw the prices of both retailers after choice. This condition enabled us to examine risky choice under conditions of full price information. Following the choice phase, respondents estimated each retailer's average price, discount frequency and depth, and rated each retailer's price attractiveness and price fairness.

116 respondents participated in Experiment 1. The design was 2x2x2 with independent variables price feedback (chosen retailer only vs. both retailers; between subjects), frequency of depth discount (13% vs. 25%; between subjects) and type of discount (frequent and shallow vs. infrequent and deep; within subjects). The regular price for the three distributions was 9.89 and the average price was 8.89. In the frequent discount distribution the discounted price of 7.89 was offered on 50% of the purchase trials. In the 13% (25%) discount condition the discounted price of 2.19 (5.89) was offered on 13% (25%) of the trials.

190 respondents participated in Experiment 2. The design was 2x2x2 with independent variables price feedback (chosen retailer only vs. both retailers; between subjects), EDLP (discount vs. no discount; between subjects) and type of pricing (EDLP vs. infrequent and deep; within subjects). The regular price for the EDLP no discount distribution was 8.39, for the EDLP discount distribution it was 8.89 and for the infrequent and deep distribution it was 9.89. The average price of the three distributions was 8.39. In the EDLP discount (infrequent and deep) distribution the discounted price of 7.89 (4.89) was offered on 50% (30%) of the trials.

The same pattern emerged in both experiments. The retailer offering frequent but shallow discounts (Experiment 1) or the retailer offering every day low prices (Experiment 2) was chosen more often than the retailer offering deep but infrequent discounts even though perceived average price was lower for the latter. Also, retailer choice was more associated with perceived price fairness than with perceived average price. Thus, these results suggest that when retailers' prices are unavailable, as is often the case, choice is driven by internal price perceptions other than the perceived average price.

SYMPOSIUM SUMMARY

The Consumption of Reading

Cele Otnes, University of Illinois at Urbana-Champaign, USA

SESSION OVERVIEW

Surprisingly little attention has been paid in consumer research to the consumption of “everyday” hobbies and pastimes. A search for this topic in the *Journal of Consumer Research* reveals that hobbies have typically been understood as a dependent variable associated with issues such as materialism (e.g., Chaplin and Roedder-John; 2005, 2007), or have been mentioned but not really unpacked in studies of very specific consumer segments, such as people trying to be cosmopolitan (Thompson and Tambyah, 1999) or pursuing a particular masculine identity (Holt and Thompson, 2004). However, from a consumer welfare perspective, people are often encouraged to pursue hobbies and interests in order to relieve stress, engage in pleasurable activities, help them pursue self-identity and self-actualization, and escape from the mundane world. One activity that has implications not only for these outcomes, but also is linked to a more literate and skilled populace that possesses higher cultural capital, is the reading of books. Benefits of reading extend beyond merely potentially enhancing social mobility; one study finds adults who read books are likely to be more involved in cultural activities, volunteer or charity work, and sports (charityguide.org). And while U.S. sales of trade nonfiction and fiction trade publications (which excludes religious and text books) are projected to top \$27 billion in 2009 (Book Industry Study Group, 2006), in fact reading books is a hobby that faces increased competition for consumers’ time from other diversion (e.g., computers, in-home movies, portable music) and cultural challenges (e.g., that reading is a somewhat elitist enterprise for “eggheads.”). It is explicitly because book reading is an activity that either inspires great enthusiasm (Fineberg 2007) or increasing apathy (e.g., one in four adults read no books in 2006; Fram 2007) that the presenters in this session believed it important to turn our attention to the reasons people read (or do not), and the ways the marketplace enables them to pursue reading as a pastime in contemporary consumer culture. Clearly, understanding the consumption of books is important for scholars interested in public policy and education, but it also has implications for consumers of new technology, such as Amazon’s new “Kindle,” which encourages consumers to eschew traditional books in favor of downloadable, electronic versions.

Springboarding off of the recent *Consuming Books* (ed. Stephen Brown), this session features new or expanded work on how consumers pursue the pastime of reading in contemporary consumer culture. In “Never Tickle a Sleeping Booklover: How Readers Devour Harry Potter,” Anthony Patterson and Stephen Brown unpack the reading styles of consumers enraptured with the Harry Potter series. Pauline Maclaran and Rosalind Masterson, in “BookCrossed Lovers: Consumers and Their Relationships with Books” explore how consumers find new meanings in reading communities as they circulate books around the world through a book-sharing technology. “Reading Others’ Texts: Marginalia and the Inscription of Meaning in Collectible Books” by Janet Borgerson and Jonathan Schroeder explore the benefits of marginalia (notes made by the owners/authors) in books purchased in used or vintage outlets. Finally, in “Curling Up and Reaching Out: Meanings and Motivations for Passionate Readers,” Cele Otnes and Behice Ece Ilhan hone in on what passionate readers regard as the benefits and joys of reading, and unpack many active components to this “passive” hobby. All of the authors approach their topics from the

interpretive research tradition, and employ a variety of methods (e.g., netnography, depth interviews, observation) to explore their topic of interest.

This symposium was designed to appeal to a broad cross-section of ACR attendees, including scholars interested in issues pertaining to 1) consumer lifestyles and consumer identity, as reading is a hobby that is intertwined with these constructs; 2) consumer entrepreneurship and co-creation, as consumers create new ways of reading and new reading communities; and 3) “consumer culture theory”—particularly those interested in everyday consumption activities. And while public policy organizations such as Reading is Fundamental (www.rif.org) no doubt have a stake in understanding what makes various forms of reading attractive and engaging to consumers, the pervasiveness and evolution of reading make it a fascinating form of consumer behavior to study in its own right.

ABSTRACTS

“Never Tickle a Sleeping Booklover: How Readers Devour Harry Potter”

Anthony Patterson, University of Liverpool, UK

Stephen Brown, University of Ulster, UK

With 400 million copies of her books in print, J.K. Rowling’s Harry Potter series has turned an entire iGeneration on to the old-fashioned pleasures of reading “proper” novels. But how do her readers read the holy writ? Detailed analysis of a Harry Potter database, consisting of several hundred qualitative interviews, suggests that there are four Rowling reading styles: Gryffindor (enthusiastically competitive); Slytherin (unhealthily compulsive); Ravenclaw (forensically critical); and Hufflepuff (comfortably numb). After considering these magical reading modes, the paper compares them to G.P. Stone’s classic typology of consumer behavior.

“Curling Up and Reaching Out: Meanings and Motivations for Passionate Readers”

Cele Otnes, University of Illinois at Urbana-Champaign, USA

Behice Ece Ilhan, University of Illinois at Urbana-Champaign, USA

Although reading increasingly competes and is complemented by other entertainment activities, many consumers regard reading as one of their most cherished everyday activities. Our study, based on depth interviews with 15 self-identified adult passionate readers, explores the benefits these consumers derive from their hobby, and the ways they co-create and incorporate reading activities into their lives. We find that for passionate readers, this “passive” hobby contains many more active components than the passive nature of reading implies (e.g., by fostering book clubs, reading lists, actively becoming market mavens in the area of reading).

“BookCrossed Lovers: Consumers and Their Relationships with Books”

Pauline Maclaran, Keele University, UK

Rosalind Masterson, DeMontfort University, UK

Very few studies explore how readers feel about their books and how their involvement with books affects their lives. Following Fournier’s (1998) study on the relationships between consumers

and brands, this paper explores the diverse relationships between readers and their books. This study draws on book lovers' experiences of BookCrossing.com; a website that encourages and facilitates the circulation of secondhand books on a global basis. The research is based on a netnographic investigation which includes six months of observation and participant observation in the BookCrossing community.

“Reading Others’ Texts: Marginalia and the Inscription of Meaning in Collectible Books”

Janet Borgerson, University of Exeter, UK

Jonathan Schroeder, University of Exeter, UK

The popular value of used books reveals insights into the material pleasures of reading and collecting books. Focusing on a collectible book genre, we explore how material practices such as collecting, reading, and inscribing create meaning for consumers. We analyze the materiality of these used texts, including “inscriptions” and previous owner’s marginalia—written annotations, marks, and notes left in the pages. We explore the aesthetic and temporal dimensions of books via three key aspects of their appeal: 1) marginalia; 2) collectability; and 3) material pleasures.

SYMPOSIUM SUMMARY

The Impact of Psychological Distance on Charitable Fundraising

Christopher Olivola, Princeton University, USA

Wendy Liu, University of California, Los Angeles, USA

SESSION OVERVIEW

The purpose of this symposium is to explore how psychological distance impacts charitable giving and philanthropic fundraising. Charitable giving has turned into a competitive business in which charities compete to advocate their causes to consumers. Of all the social causes consumers encounter each day, which one's do they give to and which ones do they pass? What are the factors that determine when and to whom people give? This session seeks to shed light on these questions by focusing on one factor that plays a significant role in consumers' decision about charity choice and level of giving, namely, the psychological distance between the individual and the cause. Four papers, each from a different angle, demonstrate how psychological distance affects giving behavior. In doing so, this session significantly contributes to the understanding of the psychology of giving, bringing the self and the cause's relation to the self into focus, and broadening the factors to be considered when studying donation behavior. Specifically, the four papers illustrate that the motivation to contribute to a prosocial cause is heavily influenced by the extent to which consumers feel *involved* in the cause, and just as important, the extent to which they feel *separated* from the costs associated with contributing. Further, they explore the factors that mediate or moderate the impact of psychological distance on charitable giving.

The first paper (Kennedy et al.) demonstrates that social distance (self vs. other) and temporal distance (now vs. later) have parallel effects on consumers' willingness to contribute to a prosocial cause, and that these effects are moderated by the relative salience of the benefits vs. costs of contributing. When cost is salient, greater social and temporal distance fostered giving. When the pro-social benefit is salient, smaller psychological distance fostered giving. The second paper (Liu & Aaker) shows that people are more generous when they are first primed with a concept that makes them feel personally engaged in a cause (donating time; volunteering) than when they are primed with a concept that distances them from the cause (donating money). The third paper (Olivola & Shafir) takes this notion of engagement even further by showing that people are willing to donate more to a prosocial cause when they have to suffer pain and effort to contribute than when the contribution process is easy and enjoyable. Finally, the fourth paper (McGraw et al.) demonstrates the effect of literal temporal separation: people respond more strongly to the most recent humanitarian crisis they happen to encounter than equivalent events that occurred earlier.

This set of projects highlight several important aspects of psychological distance in the context of giving behavior. First, distance to the self is a key construct underlying giving, and this distance can be multiply determined. In particular, it can be determined by (a) the self-other dichotomy (Kennedy et al.), (b) a temporal gap, either in looking forward (Kennedy et al.), or in retrospect (McGraw et al.), and (c) the extent to which the person's affective system is engaged—considering spending time with a cause activates emotional thoughts about giving (Liu & Aaker), and suffering a little pain in the giving process engages the person more so than an activity that incurs no pain (Olivola & Shafir).

As supporting evidence, emotionality seems to underlie the effect of psychological distance on behavior. For example, in Liu and Aaker, greater focus on happiness and emotional benefit

occurred when time donation, rather than money donation is evoked, fueling donations. In McGraw et al., people rated the most recently viewed video clip about a crisis as more upsetting than a previously viewed clip, resulting in donating more to the more recent appeal.

Finally, the current set of papers highlights an insight that has received scant attention in previous charity literature. Specifically, distance relates to not only the benefit side of consideration (the focus of previous research), but also the cost side. For example, in Kennedy et al., when cost of helping is salient, large psychological distance is actually beneficial for donations. Related, in Liu and Aaker, asking people about their monetary donations intentions lead to less donations than if intentions were not first gauged, due to the distancing effect of money.

In summary, this symposium provides a novel view of the study of charitable behavior by examining the relationship between psychological distance and giving. In the process, intriguing new findings about charitable behavior is revealed. These results are worthy of discussion; moreover, they prompt important questions for future research. For example, what are the specific emotions that create greater psychological closeness (pain, guilt, upset, happiness)? Are all emotions created equal, and do negative affect create closeness or a distancing effect? Further, when feeling close to a cause, how does the act of giving to the cause impact a person's self construal and identity?

This symposium should appeal to a diverse research audience. In particular, research into the psychology of charitable giving contributes to a growing interest in transformative consumer research. In addition, a number of important areas are considered in these papers, including affect, motivation, consumption choice, and wellbeing.

EXTENDED ABSTRACTS

“Do We Give More of Our Present Selves or Our Future Selves? Psychological Distance and Prosocial Decision Making”

Kathleen Kennedy, Princeton University, USA

Christopher Olivola, Princeton University, USA

Emily Pronin, Princeton University, USA

This research investigates the types of decisions that individuals make for their present selves, their future selves, or for others. In a series of four studies, we demonstrate that individuals make uniquely different decisions for their present selves, compared to the choices they make for future selves and others, and that these differences seem to be a result of varying internal subjective experiences. Importantly, these internal experiences can affect individuals' behavior such that they are either more generous or more selfish. If the focus of the individual is on the charitable aspect of the situation, rather than the burdensome nature of the task, they may be more generous with their present selves than with their future selves or others. However, if the internal subjective experience is one of anxiety and concern over the costs, then present selves are often more selfish. Simple manipulations to remind individuals that their future self will likely resemble their present self seem effective in reducing differences in the decisions made for the two

selves (present and future). Also, asking them to make a decision for another person before choosing for themselves in the present tends to move them towards that initial commitment.

In Study 1, participants were told that they were part of an experiment that required them to consume some amount of a disgusting tasting liquid. Participants made what they believed to be truly binding decisions for themselves in the present or the future, or for someone else in the present. It was emphasized that the more they drank, the more it would help the study. Participants made unique decisions for their present selves, such that they volunteered to drink less of the liquid in the present-self condition than in the future self or other conditions. In this case, the prospect of drinking the disgusting liquid was very aversive, and the salient internal subjective experience was likely one of anxiety.

In Study 2, individuals were asked how much time they would donate to help struggling freshmen study for their exams. They were either asked to volunteer time to tutor “right now” (in the middle of midterms week), to volunteer their time for next midterms week (the next semester), or to decide how much time other students could tutor during their next midterm week. Participants volunteered less when choosing for their present selves, compared to future selves and others. A fourth condition also asked participants to make a decision for their future self, but this time they were reminded that they would likely be “the same person you are now”. In this reminder condition, the time volunteered on behalf of the future self did not differ from the time volunteered for the present self. Here, reluctance, on the part of the participants, to donate their time seemed to be due to a focus on the time pressures and stresses of their midterm exams, tempering the amount of time they volunteered.

In Study 3, individuals were approached in their dorm and asked how much money they would donate to a breast cancer charity. The decision was either on behalf of their present selves (how much money will you donate right now?), their future selves (how much money will you will pledge to donate next semester?), or someone else (how much money should the average student donate?). Participants were again less generous with their present selves than with future selves and others. In a fourth condition, participants were asked to decide how much someone else could donate, followed by a request that they themselves donate money in the present. In this present-self/other-first condition, participants offered more money than in the present-self condition where they did not make a commitment for the other person beforehand. In this case, participants’ decisions about how much someone else should donate seemed to relieve some of the reluctance they had about donating in the present.

In Study 4, participants were asked to receive emails that would benefit charitable organizations and help out a fellow student who was struggling to pay for college. Students made decisions for their present selves, future selves, present others, and future others. In this experiment, the negative aspects of the task at hand (receiving some annoying emails) were outweighed by the positive experience of helping (helping the charities and helping the needy student who was standing right in front of them). Under these circumstances, participants actually gave more of their present self (by agreeing to receive more emails) than they gave of their future self or another person in the present or future. In addition, participants reported that their primary internal subjective concern was the pro-social benefit of helping.

Altogether, these studies demonstrate that people’s immediate subjective experiences play an important role in shaping how generous they will be in the present vs. the future. If the experience is one of strong pro-social goals, they may actually be more

generous “in the moment” while those goals are subjectively stronger, but if the experience includes heavy costs, they may be more generous if they make a commitment for a future self instead. Finally, we found that some simple reminders (such as reminding people that they will be very much the same in the future as they are now, or that they’ve just committed someone else to a more generous amount) can work to make people more or less generous.

“The Happiness of Giving: The “Time-Ask” Effect”

Wendy Liu, University of California, Los Angeles, USA

Jennifer Aaker, Stanford University, USA

How to get people to give? This research proposes one source of influence on people’s response to a charity request is the mindset activated by the request—people give more when under an emotional rather than a transactional mindset. Further, we find that two commonly asked intention questions, namely, “how interested are you to volunteer” (a time-ask), versus, “how interested are you to donate money” (a money-ask), activate distinct mindsets, due to the different mental associations of these concepts. As a result, a charity request is more successful when the donor is first approached with a time-ask, rather than a money-ask.

Specifically, because spending time is inherently a personal action, thinking about time activates thoughts of personal emotions and goals; on the other hand, because money is a major accounting unit, thinking about money activates associations of economic value and exchanges. Thus answering a question about time activates an emotional mindset in which people interpret events based on their emotional meaning, whereas answering a question about money activates a transactional mindset in which people evaluate the utility of events. Consequently, because of the personal emotional meaning of charity, asking of time reduces psychological distance to the charity, and increases subsequent actual donations; on the other hand, a money-ask highlights the exchange nature of a donation, thereby distances the donor from the charity and thus decreases actual donations (compared to not asking about intentions at all).

We propose that time and money are social constructs associated with distinct concepts. Following the theory of construct activation and accessibility and research on the “question-behavior effect” (e.g., Morwitz, Johnson and Schmittlein 1993; Schwarz 1999; Sherman 1980; Spangenberg 1997; Sprout et al. 2006), we propose that asking people to consider their intention to spend time versus spend money in a certain way activates discrete goals and beliefs. We argue that thinking about time activates goals of emotional well-being, whereas thinking about money suppresses such goals by activating goals of economic utility (Brendl, Markman, and Messner 2003). As a result, considering donating time leads the individual to focus on the emotional implications of helping others, thereby bring the charity closer to the self. On the other hand, considering donating money diminishes the emotional implication, creating distance. Consequently, first asking people about their volunteering intentions, compared to first asking them about monetary donation intentions, leads to greater amount of charitable contribution—both in time, and in money.

Evidence for the time-ask effect is found in three studies. Experiment 1 contrasts two conditions: directly asking people for a monetary donation (money-ask) to the American Lung Cancer Foundation, versus prefacing this request by first asking people for volunteering (time-ask). This time-ask significantly increased subsequent amount of donation ($M = \$36.44$ vs. $\$24.46$, $p = .04$).

Experiment 2 is a field study conducted with HopeLab.org. HopeLab, a remarkable non-profit organization, uses innovative technology to help improve the quality of life for children with

chronic illnesses. At time 1, participants read information about HopeLab, and were asked “How interested are you to donate time?” and “How interested are you to donate money?” The key manipulation was the order of these two questions—when time-ask (money-ask) appeared first, it put people under an emotional (transactional) mindset for subsequent questions. A third group (control condition) read about HopeLab, but was not asked any intent questions. At time 2, the same participants were approached with an opportunity to donate money to HopeLab, and/or to volunteer for HopeLab. It is found when time-ask appeared first, donation was significantly higher than in the control condition ($M=\$5.85$ vs. $\$4.42$, $p=.04$); whereas when money-ask appeared first, donation was actually lower than in the control condition ($M=\$3.07$, $p=.05$). Time-ask condition also yielded more hours of volunteering.

Experiment 3 found that a stronger perception of the link between charity and personal happiness fully mediated the effect of measuring time intent on subsequent donation.

This research has significant implications for consumer research in the areas of charitable giving, the conditions for and implications of “hot” versus “cold” thinking, psychological distance, and happiness. Future research may further examine the effect of thinking about time versus money. For example, can a simple prime of time (e.g., thinking about a future time frame) have a similar effect in activating an emotional mindset? Can thinking about time versus money lead to greater subjective happiness in life in general?

“The ‘Martyrdom Effect’: When the Prospect of Pain and Effort Increases Charitable Giving”

Christopher Olivola, Princeton University, USA
Eldar Shafir, Princeton University, USA

Charitable giving is a puzzle for standard normative theories of motivation and choice for two reasons: First, the act of giving up personal wealth for the sake of others whom we may not know or ever see seems contrary to the assumption that we are primarily driven to maximize personal utility. Second, and even more puzzling, are the ways that people choose to raise money. Some of the most popular and successful fundraisers involve a good deal of pain and effort, such as charity marathons and charity fire-walks (walking over burning coals). But there is no a priori reason for this to be the case. From a rational point of view, it’s hard to see what individuals could gain from suffering or watching their friends

suffer to raise money. The same holds true for the charity organizations and the recipients of charity. Given that running or biking tens of miles is both painful, effortful, and, further, that it can be done for free, why are people paying to suffer? We consider this puzzling phenomenon, wherein the prospect of pain and effort actually increases our motivation to participate in an activity; a phenomenon we call the “martyrdom effect”. The name refers to the fact that people are choosing to suffer for a cause that they care about. Many theories, and lay intuitions alike, assume that making a task more painful and effortful should decrease its appeal. The implication, then, is that to maximize participation and contributions, fundraisers ought to be easy and enjoyable for donors. In contrast, we provide evidence that the prospect of pain and effort can promote charitable giving. Across a series of experiments, participants reported that they would contribute more to a cause when the contribution process was painful and effortful than when it was neutral or even enjoyable. Additional studies showed that this “martyrdom effect” could not be explained by a taste for painful-effortful donation activities, cognitive dissonance, social norms, or a cognitive attribute substitution heuristic.

Experiment 1 tests the hypothesis that making the donation process more difficult and painful will increase the amount that people are willing to donate relative to a pleasant control, while ruling out the simple possibility that people have a preference (whatever the reasons) for the painful-effortful fundraising event. Participants considered a hypothetical scenario in which they had to decide whether to donate some of their own money in order to participate in a charity fundraiser. The nature of the fundraiser was manipulated between participants. Participants who considered a fundraiser in which donating was contingent on performing a painful or effortful activity (running 5 miles) reported that they would donate more than participants who considered an enjoyable fundraising event (attending a picnic), suggesting that they valued painful-effortful fundraisers more. However, a third group of participants who jointly considered and compared the two fundraisers indicated (by a large majority) that they would prefer attending the pleasant fundraiser to the painful-effortful one, thereby ruling out a standard economic explanation based on a ‘taste for painful fundraising’.

Experiment 2 extended these findings by using real payoffs and actual pain. Participants played a Public Goods Game, in which they decided how to allocate a budget between themselves and the public pool (where money was doubled and redistributed evenly between the players). We found that players allocated more of their budget to the public pool when doing so would require enduring pain (a cold-pressor task) than did players in the painless control condition. We also found that this contribution increase was not related to beliefs about others’ allocation decisions.

Experiment 3 examined whether the ‘martyrdom effect’ could be attributed to beliefs about the relative popularity of painful-effortful vs. enjoyable fundraisers. Participants read about a hypothetical charity that was transitioning from using one kind of fundraiser to another (from a painful-effortful one to a pleasant one or vice-versa) and were asked to predict how this transition would affect attendance and donations. Results show that participants believed the pleasant fundraiser would be more popular, ruling out the possibility that the ‘martyrdom effect’ is the product of social norm beliefs (e.g., Prentice & Miller, 1993).

Experiment 4 tested whether the ‘martyrdom effect’ occurs because people rely on a simple cognitive attribute substitution heuristic (Kahneman & Frederick, 2002) that uses amount of pain-effort as a cue when deciding how much to donate. We show that, although participants are sensitive to the amount of effort and pain

involved in running various distances, they do not use this cue to determine how much they should donate to participate in a charity fundraiser.

In all of our experiments, participants decided how much to donate BEFORE experiencing any pain or effort, thereby ruling out standard dissonance theory (Festinger, 1957) as a possible explanation for our results. We discuss how the prospect of suffering for a cause may lead people to ascribe more value to their future contributions, thus motivating them to donate more and providing them with greater satisfaction.

"Whom to Help? Immediacy Bias in Humanitarian Aid Allocation"

A. Peter McGraw, University of Colorado at Boulder, USA
 Leaf Van Boven, University of Colorado at Boulder USA
 Michaela Huber, University of Colorado at Boulder, USA
 Laura Johnson-Graham, University of Colorado at Boulder, USA

Deciding how to allocate charitable resources toward minimizing human suffering is among the most important and most difficult decisions consumer face. Donation decisions are difficult largely because people are exposed to information about different sources of human suffering over time, in sequences that may reflect the whims of popular media (CNN) and pop icons (Bono and Angelina) more than genuine differences in the severity of human suffering. The question we examine is how consumers perceive different, emotionally arousing sources of human suffering presented over time, and how these perceptions influence consumers' decisions about humanitarian aid allocation.

Previous research indicates that people exhibit an immediacy bias in emotion perception such that immediate emotions seem more intense than previous emotions, all else equal (Van Boven, White, & Huber, 2008). This immediacy bias occurs for at least two reasons. First, immediate emotions attract and hold attention. Second, information about immediate emotions is more available in memory than information about previous emotions. Immediate emotions may therefore seem more intense than distant emotions to the degree that people use attention and availability to judge emotional intensity.

Judgment and decision making research indicates that affect strongly influences economic preferences, including preferences about allocating humanitarian aid (Kahneman, Ritov, and Schkade 1999; Slovic et al. 2002). People donate more money to victims who arouse more intense affect than to victims who arouse less intense affect, independent of, and sometimes in spite of, information about the mortality magnitude of human crises. For instance, people sometimes donate more money to single victims than to large numbers of victims because the large numbers of undermine affective reactions (Small, Loewenstein, and Slovic 2007).

Integrating research on the immediacy bias and on the affective basis of economic preferences, we hypothesize that consumers

perceive human suffering that happens to arouse immediate emotional arousal as more severe compared with human suffering that happened to have aroused previous emotional arousal. We also test whether this immediacy bias is associated with neglect of information about the crises' deadlines, and whether the immediacy bias decays over time as emotions decay.

In Study 1 participants watched two short films provided by Doctors Without Borders (DWB) regarding humanitarian crises in Sudan and Niger. Participants viewed the videos in random order, separated by 20 min. Directly after learning about the second crisis, participants were asked to allocate charitable money to DWB's activities in the two locations. Consistent with the immediacy bias, most participants (67%) allocated significantly more charitable funds to the crisis they happened to learn about second than to the crisis they happened to learn about first.

In Study 2 we sought to conceptually replicate the immediacy bias demonstrated in Study 1 with two extensions. First, we explicitly provided participants with (fictional) information about the deadlines of the two crises; this allowed us to test whether people would exhibit an immediacy bias in spite of information about the crises' deadlines. Second, we measured perceptions of human suffering and charitable actions both immediately after learning about the crises and after one day's delay, which allowed us to test whether the immediacy bias declined over time as emotions presumably subsided.

Participants watched two short DWB videos, in random order and separated by a 20 min delay, about malnutrition in Angola and Niger. Participants also read summaries of the circumstances of the two crises, which made clear that 60,000 more people were dying in one randomly determined crisis. Consistent with the immediacy bias, participants reported that they were significantly more upset while watching the second rather than the first video, and that the crisis they happened to learn about second was more deserving of humanitarian aid than the crisis they learned about first. When participants were asked to write a letter to their Senator calling attention to the suffering in one of the crises, 65% chose to write about the country they happened to learn about second. Importantly, people exhibited this immediacy bias even when it was clear that more people were dying in the first rather than the second crisis participants learned about. Finally, there was no hint of an immediacy bias when participants returned the following day, when their emotions had presumably subsided.

In our final study, we sought to replicate the immediacy bias, but with an extended sequence of four (rather than two) DWB videos of crises separated by minimal delay of 2 min (rather than 20 min). Doing so would minimize concerns that the immediacy bias is due primarily to memory decay. We also sought to reconcile an apparent inconsistency between our results and previous research suggesting that people allocate more funds to charitable causes that occur earlier rather than later in a sequence (Payne et al. 2000). We hypothesize that both patterns reflect an immediacy bias, rather than some other difference between our research (e.g., our focus on humanitarian suffering and the previous research's focus on environmental programs). Regardless of the type of pattern (immediacy or primacy) people respond to their immediate emotions, and these emotions are influential late in the sequence when allocations are made after viewing all the videos (i.e., post hoc) but emotions are influential early in the sequence when allocations after made after watching each video (i.e., sequentially).

Participants watched four randomly ordered videos about African humanitarian crises. When participants allocated funds after viewing all four videos, as in our previous studies, they allocated a disproportionately higher amount to the final crisis. In contrast, when participants allocated funds sequentially, as in

previous research on sequence effects, they tended to allocate more money to the first (rather than the last) crisis.

These studies document an important bias in people's judgments and decisions about allocating charitable resources toward mitigating humanitarian suffering. Integrating research on emotion perception and the affective basis of economic preferences, these studies demonstrate that people exhibit an immediacy bias in judgments and decisions about humanitarian suffering.

SYMPOSIUM SUMMARY

Effects of Supersizing and Downsizing Packages on Consumption: Marketing and Policy Implications

Pierre Chandon, INSEAD, France

EXTENDED ABSTRACTS

“Downsize in 3D, Supersize in 1D: Effects of the Dimensionality of Package and Portion Size Changes on Size Estimations, Consumption, and Quantity Discount Expectations”

Pierre Chandon, INSEAD, France

Nailya Ordabayeva, INSEAD, France

Marketers have significantly supersized package and portion sizes because it can increase consumer expenditures. However, supersizing has been under attack by regulators and consumer advocacy groups because it can lead to over-consumption. On the other hand, downsizing can help marketers hide unit price increases but is not liked by consumers. In addition, retailers are pushing manufacturers to change the shape of their packages (e.g., to switch to rounder bottles) to reduce the environmental cost of package waste. In these circumstances, the issue of how consumers respond to changes in both the size and shape of portions and packages has become important for marketers who seek to increase the purchase and consumption of their products, as well as for consumers and regulators who are concerned about improving size estimations and reducing overconsumption.

In this research, we examine how the dimensionality of changes in portion and package sizes influences consumers' estimations of product volume, size of resized doses that they produce for consumption, their preference for buying supersized or downsized packages and portions, and price discounts expected and offered for buying larger sizes.

Research in psychophysics (Stevens 1986) has shown that the subjective experience of physical intensities (e.g., weight, volume) follows an inelastic power function of their actual magnitude, which means that people underestimate the magnitude of size changes. Research has also shown that size estimations are even less elastic when estimating changes in volume (3D change) than when estimating changes in areas (2D change) or lengths (1D change) (Frayman and Dawson 1981). Drawing on these findings, we make the following hypotheses. First, size estimations are more elastic when packages change in one dimension (e.g., height) than when they change in two or more dimensions (e.g., height and diameter). Second, consumers' willingness to pay for larger package sizes—and hence their quantity discount expectations—are influenced by their biased size estimations and follow an inelastic function of actual size. Third, providing size information reduces but does not eliminate the effects of package dimensionality. Finally, this effect of dimensionality leads consumers to pour more product into and out of product containers when supersizing and downsizing a dose in 3D (vs. 1D) and to prefer packages supersized in one dimension and those downsized in multiple dimensions. Five studies provide support for our hypotheses.

Study 1 examined consumers' perceptions of package size when it changes in 1D vs. 3D. The study involved 2 between-subjects size change dimensionality conditions (1D vs. 3D) and 6 within-subjects package sizes (a candle of 50, 100, 200, 400, 800, 1600 grams). Participants saw the pictures of 6 sizes of a candle increasing either in 1D (height) or in 3D (height and diameter). Participants knew the size of the smallest candle (50 g) and had to

estimate the remaining 5 sizes. We found that size estimations followed an inelastic power function (with a power exponent b smaller than 1) and that estimations were even less elastic when size changed in 3D ($b=.63$) than when it changed in 1D ($b=.87$).

Study 2 examined the effect of size change dimensionality on willingness to pay for size increases and the effect of providing size information. The study involved 6 within-subject sizes, 2 between-subject dimensionality conditions (1D vs. 3D), 2 between-subject size information availability conditions (size info available vs. unavailable) and a control condition. The participants saw 6 sizes of two actual products (vs. pictures as in Study 1), wool and dishwashing detergent, which increased either in 1D or in 3D. Participants in the unavailable-information condition saw the products and provided both size estimations and WTP for each size of each product. Participants in the available-information condition knew the actual product sizes and only provided their WTP for each size. Participants in the control condition knew the actual sizes of the products but did not see them and only provided their WTP for each size. We found that, as in Study 1, size estimations were inelastic, especially when size increased in 3D ($b=.68$) vs. 1D ($b=.93$). Partly due to size estimations, WTP also followed an inelastic power function, with lower elasticity in 3D ($b=.56$) than in 1D ($b=.72$), and dimensionality influenced WTP even when the actual package sizes were available ($b=.69$ in 3D vs. $b=.83$ in 1D).

Study 3 examined the effect of resizing dimensionality on consumption dosage. The participants increased or decreased the doses of three products provided in three containers (a vodka glass, a cocktail glass, and an infant syrup cup). In the 1D condition, the participants used cylindrical containers, in which product volume changed only in height (1D). In the 3D condition, the participants used conical containers, in which product volume changed in height and diameter (3D). Because the participants were less sensitive to size changes in 3D than to size changes in 1D, they poured more of each product into and out of conical (vs. cylindrical) containers.

Study 4 consisted of two field experiments examining how the dimensionality of size change in real product packages affects people's supersizing (Study 3a) and downsizing (Study 3b) decisions. In Study 3a, participants made a choice between a control beer or cider in a 22 Cl mug and a target brand which was either in a similar 22 Cl mug (control condition) or in a 33 Cl mug, supersized in 1D (height) or in 3D (height and diameter). The choice share of the target brand was significantly higher in the 1D condition (100%) than in the 3D (68%) or the control (55%) condition. In Study 3b, consumers chose between regular-size packages of regular Coke (50 Cl) and popcorn (94 Cl) and smaller packages of diet Coke (33 Cl) and popcorn (63 Cl) downsized in 1D or in 3D. We found that participants were more likely to choose the downsized option in the 3D condition (69%) than in the 1D condition (48%).

The final study was a field survey of the prices of regular and large product packages supersized in 1D or in 3D. Across 70 pairs of regular and supersized packages in 4 product categories (cosmetics, sandwiches, beverages and snacks), we found that the elasticity of price to size change was lower for packages supersized in 3D (.55) than for packages supersized in 1D (.88).

In sum, we found that people underestimate the magnitude of package and portion size changes, especially when they occur in

3D. Providing size information helps consumers improve their price expectations and make better resizing decisions, even if it doesn't eliminate dimensionality effects. Finally, we showed that these effects explain why supersizing is more effective in 1D and downsizing is more effective in 3D.

"Packaging Cues that Frame Portion Size: The Case of the Red Potato Chip"

Brian Wansink, Cornell University, USA

Andrew B. Geier, University of Pennsylvania, USA

Paul Rozin, University of Pennsylvania, USA

What leads people to continue eating past the point of satiety (Rozin et al. 1998)? First, they might ineffectively monitor how much they have eaten (Chandon and Wansink 2007); second, they may simply eat what they believe is an appropriate amount for that situation (Geier, Rozin, and Doros 2006; Wansink 2004); third, they may be engaged in a semi-automated habitual activity, which simply continues until interrupted. A solution to all three of these problems could take the form of various types of markers which would call attention to food intake.

An increasing amount of research suggests that people use visual indications to tell them when to stop eating (Wansink 2006). A serving portion creates a consumption norm, which indicates to people when they should stop eating (Geier, Rozin, and Doros 2006). To some extent, this is what small-size portions (e.g., 100-calorie packages) do. When people reach the end of a small package they need to decide whether to continue eating by opening another package. This interrupts their hand-to-mouth behavior and forces them to consider whether they want more. Such interrupts reduce consumption of food and improve estimations of the food intake (Wansink, Painter, and Lee 2006). Less "intrusive" segmentation cues may not interrupt consumption, but simply call attention to norms and the amount consumed.

This research examines whether inserting "segmentation cues" within a package can reduce total intake of a snack within a single sitting. We propose that the use of consumption markers decrease intake of a food because: 1) they call attention to eating, 2) they provide consumption norm cues, and 3) they break the eating script by introducing a pause. Our study investigates whether visually segmenting snack food in a package will decrease how much a person eats in a single occasion.

The study involved a 3-level between-subject design where fifty-nine undergraduate respondents were randomly given one of 3 different tubes of 82 potato chips (of 11 grams each, 10 calorie/chip) while watching a documentary video. The consumption interrupt or segmentation-framing cue was a red-colored potato chip of the same size and composition as the ordinary yellow ones. Two pilot studies showed that the red chip was treated as a "regular" potato chip, except subconsciously with regard to its effect as a segmentation marker. The chips were emptied from the tube and then replaced. In one group, red-colored chips were used to mark every group of seven chips (i.e., every seventh chip was colored red) (7-marker group). In the second group, red-colored chips marked every group of fourteen chips (14-marker group). The control group had no red chips in the tube. Following the program, the respon-

dents estimated how many chips they ate, how many calories they consumed, and how many chips they usually ate when watching a one-hour show. Finally, they were asked to provide their gender, height, weight, and the number of hours since their last meal.

As anticipated, the inclusion of a divider had a dramatic influence on how many chips were consumed. Participants in the control condition on average ate 45 chips, those with 14-chip segments ate 24 chips, and those with 7-chip segments ate 20 chips. The simple use of any segmenting divider significantly reduced intake by about half, regardless of whether the dividers were present at intervals of 7 or 14 chips. There was no significant difference between the 7 and 14 dividers. The control group overestimated their actual intake significantly more than 7- and 14-marker groups, in which the participants were reasonably accurate in estimating their intake (33 vs. 19 vs. 24 chips, respectively, $p < .001$).

These results present evidence that segmentation cues and/or consumption interrupts may help reduce intake and improve estimates of calories consumed. The effects are substantial in size (around 50%). Further research is needed to determine what types of segmentation cues are most effective and in what contexts. Our results have important policy implications. Small reductions in food intake, maintained over months, can lead to substantial weight losses over years. If using consumption interrupt strategies cuts 200 calories out of a person's daily intake, it translates into the cut of 20 pounds in one year. Thus small interruptions to mindless eating can provide large aggregate results. Helping consumers understand and develop their own segmentation cues could be an effective way to reduce mindless eating.

"Consumer Usage of Ultra-Concentrated Products"

Maura L. Scott, University of Kentucky, USA

Stephen M. Nowlis, Arizona State University, USA

Naomi Mandel, Arizona State University, USA

Ultra-concentrated products, often offered in smaller packages with greater potency, are available in various categories including medications, detergents, and beverages. We explore when consumers overuse ultra-concentrated products, and which cues communicate potency.

Three factors influence consumption of ultra-concentrated products: prior usage behavior, package size, and product potency.

Consumers anchor on their prior usage and fail to adjust appropriately, leading to over-consumption (Tversky and Kahneman 1974). Consumers use more of a product when dispensing from larger packages than smaller ones (Wansink 1996). We propose that product potency changes exert a unique force that causes consumers to overuse ultra-concentrated products. We explore which cues signal potency changes, and examine how these cues translate to consumption.

Study 1 examined whether consumers overuse higher potency products, and which cues assist consumers in using the prescribed quantity. It was a 2 (bottle size: large, small) \times 2 (recommended regular-strength quantity: yes, no) \times 2 (ultra-concentrated defined: yes, no) between-subjects experiment, $N=338$. The dependent variable was the amount of ultra-concentrated detergent used, relative to regular-strength detergent usage.

Participants viewed a 200 oz. regular-strength detergent bottle, an ultra-concentrated detergent bottle, and a list of items in one laundry load. Bottle size was operationalized with the ultra-concentrated bottle as either large (200 oz.) or small (100 oz.); the regular-strength bottle was always 200 oz., and the regular and ultra-concentrated bottle caps were identical. Recommended regular-strength quantity reflected whether or not a recommended use amount was given for the regular-strength detergent. For example, in conditions providing a recommended regular-strength amount, an entire capful was identified as the amount required for the laundry load, and participants indicated how much ultra-concentrated detergent they would use for this load; otherwise, participants indicated regular-strength quantity and the corresponding ultra-concentrated quantity they would use to wash this load. Ultra-concentration was operationalized by either indicating that the "ultra-concentrated detergent is two-times as strong as regular-strength detergent", or the packages were labeled as ultra-concentrated with no definition. The dependent variable was the percentage of over-/under-usage of ultra-concentrated product, relative to usage of the regular-strength product. For example, if a participant used one cup of regular-strength detergent and three-fourths of a cup of ultra-concentrated detergent for the same load, the over-consumption rate would be reflected as 25%; if a participant used exactly half the amount of the regular-strength when using the ultra-concentrated detergent, the over-usage rate would be 0%. Under-usage is reflected in a negative percentage.

In the result, we found that participants over-consume the ultra-concentrated product relative to the regular-strength version ($M=12.24\%$). Participants over-consume by more from a large ultra-concentrated package ($M=16.70\%$) than a small one ($M=7.94\%$); however, participants significantly overuse both the large bottle size *and* the small bottle size. Hence, a bottle size reduction slows consumption, but does not eliminate the effect.

When the regular-strength recommended usage quantity is one full cup, participants use 8.25% more than one-half cup using the ultra-concentrated version. When participants indicate *both* the amount they would use of the regular-strength and ultra-concentrated detergent, they overuse the ultra-concentrated detergent by 15.99%. That is, when given freedom to demonstrate their usage behavior of both regular and ultra-concentrated strengths, participants overuse by significantly more. Verbally defining ultra-concentrated as '2 \times as strong as regular-strength' should help consumers use one-half as much ultra-concentrated detergent, relative to regular-strength. However, there was no consumption difference when ultra-concentrated was defined versus not defined, although both over-usage rates were significantly greater than zero ($M=10.97\%$ and 13.45%, respectively).

Study 2 examined how trust influences consumption. It was a between-subjects experiment with 2 trust conditions (high trust,

low trust), $N=386$. The trust factor manipulated the information source communicating "ultra-concentrated strength is two times as strong as regular-strength," *Consumer Reports* in the high trust condition and an advertisement in the low trust condition. The dependent variables were identical to study 1, plus measures of perceptions of regular and ultra-concentrated products.

In the result, participants significantly over-consumed the ultra-concentrated detergent in both the high ($M=9.7\%$) and low trust ($M=26.8\%$) conditions; and the directional difference in consumption rates ($p=.092$) indicates that consumers' trust in potency cues may influence their consumption. Participants trusted and believed *Consumer Reports* more than advertisements. Interestingly, even though participants perceived that potency levels of ultra-concentrated products are higher than regular-strength products; and that greater adverse effects are possible from using too much ultra-concentrated product relative to using too much regular product; consumers were not convinced that differences in effectiveness exist between ultra-concentrated and regular-strength products.

In these studies consumers persistently overused the more potent product. Understanding what factors drive wasteful consumption rates and what cues help consumers more accurately use products has marketing theory, practice, and public policy implications.

SYMPOSIUM SUMMARY

What Makes Ideas Stick? How Characteristics and Contexts of Messages Influence Their Success

Rebecca Ratner, University of Maryland, USA

Jonah Berger, University of Pennsylvania, USA

Jason Riis, Harvard University, USA

SESSION OVERVIEW

Most approaches to persuasive communication focus on aspects of people. Certain individuals are more credible (e.g., experts; Petty et al. 1983) or influential (e.g., opinion leaders; Rogers 1995) and consequently are important to increase persuasion or help messages diffuse. Rather than focusing on people, however, a new stream of research has begun to examine how characteristics of ideas or messages themselves influence their staying power.

This session showcases some of this emerging research and illustrates how focusing on characteristics of ideas or messages themselves provides insight into what sticks and succeeds. For example, when consumers are initially exposed to an idea, what characteristics lead the idea to be perceived as compelling? Over time, which ideas are more memorable, and how do message and environmental characteristics determine people's ability to recall the messages? And what additional factors might one incorporate to revisit the question of source credibility, such as to examine how the timing of source information impacts stickiness of information? Four papers and a discussant address these ideas.

Alter and Oppenheimer (Paper #1) investigate which ideas seem most compelling on initial exposure. How does the fluency of stock names and ticker codes influence their performance? Results of several lab and archival studies demonstrate the surprising impact of fluent stock names and ticker codes.

Ratner and Riis (Paper #2) investigate how message characteristics impact stickiness after a delay. They show that the relatively simple USDA MyPyramid guideline is not simple enough, and that an even simpler guideline is much easier to remember, is more motivating, and leads to better food choices a full month after a brief exposure. Such a sticky guideline could improve many of the myriad poor choices that contribute to an individual's obesity.

When are certain urban legends more prevalent and how can we use these findings to get people to eat more fruits and vegetables? Berger (Paper #3) examines how the prevalence of related stimuli in the environment influences stickiness and success. Four studies demonstrate that products are more likely to be chosen and messages are more likely to be successful when their habitats, or set of related environmental triggers, are more prevalent and lead the messages to be remembered.

Finally, Birk, Johar, and Sengupta (Paper #4) consider how the timing of source credibility information influences stickiness. They find that the impact of source credibility is particularly pronounced when source information is provided after the message. Bad news attributed to a low-credibility source is less sticky when provided after the message. Results suggest that the stickiness therefore can depend critically on the timing of source information.

Chip Heath (Stanford University), the discussant, will integrate the talks, provide his own insights, and suggest directions for future research. Taken together, this symposium addresses how message characteristics influence staying power, and how the environment can enhance or undermine the success of the message. The papers contribute to a research area that is relevant to the diverse interests of many ACR members, including those interested in what makes ideas catch on, attitudes, persuasion, decision making, memory, health behavior, and attitude-behavior consistency.

EXTENDED ABSTRACTS

“Easy on the Mind, Easy on the Wallet: Fluency Predicts Stock and Currency Valuation”

Adam Alter, Princeton University, USA

Daniel Oppenheimer, Princeton University, USA

Why do some items seem more valuable than others? Although people routinely assess the value of stimuli in the environment, the processes that underlie valuation estimates are not well understood. Across six studies, we found that processing fluency—the subjective experience of ease with which people process information—influenced valuation estimates for monetary currency and financial stocks.

We first examined the effects of fluency on currency valuation. In three studies, participants estimated how many of each of ten inexpensive items (e.g., thumbtacks, gumballs) they could purchase with one of two monetary instruments that shared the same nominal value, but differed according to their familiarity (and, therefore, the ease with which they were processed).

In Study 1, participants either estimated the purchasing power of a common (and therefore fluently processed) \$1 bill or a rare (and therefore disfluently processed) \$1 Susan B. Anthony coin, one of which was depicted at the top of the questionnaire. Participants presented with the \$1 bill believed they could purchase significantly more of the ten items than those who were presented with the rare \$1 coin. Supporting our proposed mechanism, participants' familiarity with the rare coin was positively correlated with their estimates of its purchasing power.

We were concerned that participants may have perceived less value in coins than bills, so participants in Study 2 estimated the purchasing power of two common (fluently processed) \$1 bills or a rare (disfluently processed) \$2 bill. As in Study 1, participants believed the two \$1 bills had significantly greater purchasing power than the rare \$2 bill. Again, participants who were more familiar with the \$2 bill assumed that it had greater purchasing power.

One concern with Study 2 was that participants may have overvalued the two \$1 notes merely because there were two notes compared with the single note in the disfluent condition. Accordingly, in Study 3 participants estimated the purchasing power of a common \$1 bill or a subtly altered \$1 bill that differed from the original in several barely noticeable respects. We were also concerned that disfluency might generally attenuate valuation estimates, so we included a third condition with a real \$1 bill in which the 10 items were printed in a difficult-to-read (disfluent) font. We expected participants to perceive the items as less valuable, thereby assuming the \$1 bill had greater purchasing power relative to participants in the other conditions. As in Studies 1 and 2, participants believed the real \$1 bill had greater purchasing power than the fake \$1 bill, despite failing to recognize that it was in fact fabricated. Furthermore, participants believed the real \$1 bill had greater purchasing power when the items were printed in a disfluent font. This result suggests that stimuli are valued according to how fluent they are specifically, and that disfluency does not generally depress the tendency to consume or perceive value in the environment at large.

Having shown that fluency influenced perceptions of purchasing power, we sought to show that fluently perceived purchasable commodities—in this case, financial stocks—seem more valuable than their disfluently perceived counterparts. In Study 4, undergraduates predicted how stocks with fluent (e.g., Barnings) and disfluent (e.g., Xagibdan) names would perform over six months. Participants anticipated appreciation in the stocks with simple names, and depreciation in the stocks with complex names.

Although Study 4 demonstrated a causal link between fluency and valuation, we were concerned that investors might ignore fluency when faced with many other cues. Accordingly, in Studies 5 and 6 we investigated the performance of real stocks shortly after they entered the New York Stock Exchange (NYSE) and American Exchange (AMEX).

In Study 5, undergraduates rated how easily they could pronounce the names of 89 companies that entered the NYSE between 1990 and 2004. We then compared these ratings to each stock's performance, and found that more fluently named stocks performed more strongly during their first week in the market.

The fluent names in Study 5 may have conveyed different semantic information from the disfluent names, so in Study 6, we examined whether 660 stocks with pronounceable ticker codes (e.g., LAM) outperformed stocks with unpronounceable ticker codes (e.g., HLY) in the NYSE and AMEX. Again, stocks with pronounceable ticker codes outperformed those with unpronounceable ticker codes over the first day of trading.

In sum, students and investors valued fluently processed currency and financial stocks more highly than their disfluently processed counterparts. These findings suggest that marketers benefit from creating simple, straightforward, and “sticky” products and advertising campaigns.

“What Good is A Guideline That People Can't Remember?: The Benefits of Extreme Simplicity”

Rebecca Ratner, University of Maryland, USA

Jason Riis, Harvard University, USA

Marketers provide consumer guidelines for many purposes, including product care and consumer well-being. Many such guidelines do not require stickiness, because written documents can be consulted when needed. Some guidelines, however, are needed so frequently that stickiness should be a high priority. Dietary guidelines are one example, as people make numerous food choices each day. The Department of Agriculture's (2005) customized MyPyramid nutrition guideline was designed to be simple enough to change consumer behavior. Its colorful display provides a visualization of the recommended daily consumption from each of 5 food groups. However, even this relative simplicity may be insufficient to make MyPyramid stick. With obesity levels rising, there is little evidence that consumers are following the guideline. Given the urgency of the obesity epidemic, the stickiness of nutritional guidelines needs to be better understood. We report several studies suggesting that only extremely simple guidelines have much chance of motivating consumers to adopt a more healthful diet.

Previous research has linked complex information and complex choice sets (Iyengar and Lepper 2000) with inferior decision making. Here, we suggest that even modest complexity in a guideline hampers both a consumer's ability to remember it and motivation to follow it. In one study, participants were presented either with a simple guideline (to eat fruits and vegetables as half of their food intake) or the more complex guideline from the USDA's interactive MyPyramid website. Immediately after the self-paced exposure to one of the guidelines, participants rated their interest in adhering to the guideline, the ease of remembering the guideline,

and the scientific rigor of the guideline. One month later, participants completed a food selection task and then were tested for recall of the guideline.

At Time 1, respondents reported greater motivation to adhere to the simpler guideline than to MyPyramid. Motivation to adhere to the guideline was predicted significantly by how accurately they thought they would be able to remember it (and only marginally by their perceptions of the guideline's scientific rigor). Most importantly, these same participants showed significant behavioral effects of the guideline manipulation after a delay of one month: participants in the simpler guideline condition selected significantly more fruits and vegetables than did the MyPyramid participants. Recall measures indicated that a majority who had been in the simpler guideline condition correctly recalled their guideline after one month, whereas less than one percent in the MyPyramid condition was able to recall all five recommended numbers after one month. These results are particularly noteworthy given that the MyPyramid participants spent an average of almost 30 seconds studying the guideline, compared to under 10 seconds for participants in the simpler guideline condition.

The results suggest that the compliance benefits of very simple consumer guidelines can be substantial. Consumers are more motivated to follow such guidelines, and they find them much easier to remember, although they believe these are based less on scientific research. We show that even a brief exposure to such a guideline has positive effects on dietary choices after a month-long delay. Future studies should include more extensive tests of diet change, and additional manipulations of guideline exposure. But given that obesity results from thousands of poor food choices over many years, it is encouraging that substantial improvements in the stickiness of dietary guidelines may eliminate some of those poor choices.

“Cultural Habitats: How Fit with the Environment Influences the Stickiness of Products and the Success of Ideas”

Jonah Berger, University of Pennsylvania, USA

Why do some products and ideas succeed and spread contagiously while others fail? Though researchers have often focused on how aspects of individuals (e.g., how “influential” they are, Katz and Lazarsfeld 1955), or social network structure (e.g., Watts and Dodds 2007) influences whether cultural items spread, much less research has looked at how aspects of these cultural items themselves (e.g., characteristics of products and ideas) influence their success.

We argue that fit with, or frequency of cueing by, the surrounding environment has an important influence on success. Product recall is important to purchase (Nedungadi 1990), but for something to be recalled it must first be cued by the environment, and little work has examined how the *distribution* of cues in the environment might influence success. We suggest that products or ideas have a habitat, or set of environmental triggers that encourage people to recall, transmit, and act on them. Just as certain regions or areas contain the food and conditions particular plants and animals need to survive, products and ideas have triggers that prime people to be more likely to think about and act on them. These triggers can be self-generated, or encountered in the environment, and can be any sort of stimuli (e.g., newspaper articles, conversation topics, or stimuli encountered while walking down the street) that activate or prime the related product or idea (Anderson 1995).

Importantly, cue prevalence varies across different environmental contexts. People encounter the color green more around St. Patrick's Day and more articles about politics in election years. We argue that the success of products and ideas will vary with the

prevalence of such related cues. Specifically, we suggest that products and ideas will be more likely to stick in memory and succeed more broadly if they are cued more frequently by the environment.

Study 1 examined whether people would eat more fruits and vegetables if a slogan reminding them to do so was linked to a prevalent environmental cue. Participants recorded what they ate every day over two weeks. Half-way through the period, as part of an ostensibly unrelated study, they were repeatedly exposed to a slogan about fruit and vegetable consumption. Importantly, students' real-world environments varied: some ate in dining halls that used trays while others did not. Building on this difference, some students received a slogan which linked fruit and vegetable consumption to this cue. Others received a control slogan which was liked more in a pre-test but not cued by the environment. Results indicated that increased cueing by the environment led to greater fruit and vegetable consumption. Compared to the control conditions (same environment, different slogan and different environment, same slogan) participants whose environments cued them to think of the slogan ate 25% more fruits and vegetables.

Study 2 investigated how habitat prevalence influences the success of catchphrases. Participants had dyadic conversations regarding pre-selected topics. They were also given a long list of catchphrases and asked to use some of them in their conversations. Pretesting generated topics that provided more frequent cues for certain catchphrases (e.g., fuzzy math) as opposed to others (e.g., lockbox). Results indicated that particular catchphrases were more likely to be used in conversations which provided more frequent cues.

The next two studies examined whether habitat prevalence would predict success in the broader cultural environment. In the late 1990s, an email circulated suggesting that Microsoft needed people to forward a particular message to test their new email tracing program. If the message reached 1000 people, everyone who forwarded it would get \$1000. We tracked the prevalence of this rumor over time using a searchable newsgroup database (Study 3). To proxy for habitat prevalence, we recorded the number of Top 50 newspaper articles that mentioned Bill Gates over that same period. An OLS regression found that habitat prevalence predicted rumor success; the rumor appeared more frequently in times when there was greater public attention to related cues (i.e., Bill Gates). Study 4 found similar results examining the success of a political factoid (about the school problems of the 1940s vs. the 1980s). The factoid appeared more frequently in times when there were more frequent cues to related issues in the public discourse.

This research demonstrates that the prevalence of related cues influences stickiness and success. While people often focus on making messages read more persuasively, these findings illustrate the importance of linking public health campaigns and other initiatives to prevalent environmental cue. Attending to the structure of the environment can increase success.

“When Bad News Sticks: The Effect of Valence and the Timing of Source Credibility on Attitude Strength”

Matthias Birk, Humboldt-University of Berlin, Germany

Gita Johar, Columbia University, USA

Jaideep Sengupta, Hong Kong University of Science & Technology, China

What makes bad news stick? When will they hurt consumers' brand attitudes and shake their confidence in their evaluations? Consumers are frequently confronted with negative brand information without a clear understanding of how trustworthy the information really is. With the rise of consumer self reports on the Internet, source credibility often remains ambiguous or it becomes clear only

after reading the information. In our context, “stickiness” refers to how the negative information affects the strength of the attitude, so that it can continue to have an impact in the future (e.g., the link to behavioral intentions). We propose that negative information can have either a strengthening or weakening effect on brand attitudes depending on two critical factors: a) the credibility of the source providing the information; and b) whether the recipient is made aware of source credibility before or after processing the negative information.

Prior research has shown that early knowledge that a message source is highly credible lowers message elaboration, as recipients accept the new information without much processing (Priester et al. 1999). Based on Grice's work on conversational maxims (see Grice, 1975) we predict that when relevant (i.e. either credible or non-credible) source information is provided *after* negative brand information, this will alert consumers to feel that they should have paid greater heed to the brand information. This will cause them to carefully re-think the information that they have just processed. In contrast, when irrelevant or ambiguous source information is given *after*, this should not lead to heightened elaboration. When the source is credible, such heightened elaboration should lead to increased attitude ambivalence, thus producing an overall weakening effect (cf. Sengupta and Johar 2002). A different prediction obtains, when the source of information is viewed as non-credible. In this case, once again, being made aware of the source's lack of credibility *after* exposure to the negative brand information should cause consumers to carefully rethink this information—however, the low source credibility should cause the elaboration to primarily take the form of counter-argumentation. Such counterarguing should lead to the strengthening of the original attitude, in line with recent findings in the arena of attitude resistance (see Tormala and Petty 2002). When source information is ambiguous neither a weakening nor a strengthening effect should be obtained.

Experiment 1 tested these hypotheses by first providing participants with initial positive brand information about a DVD-Player, followed by negative brand information under four conditions: negative information from a credible source vs. an ambiguous source and whether the source was known prior to or after processing the negative information. The two critical dependent variables were: a) the extent to which the negative information was elaborated; and b) the accessibility of the final brand attitude. In line with our prediction, given a credible source, elaboration was heightened when the credibility of the source was revealed after exposure to the negative information (vs. before); further, this heightened elaboration led to the hypothesized lowering of attitude accessibility. For the ambiguous source, however, no differences in elaboration or accessibility were obtained for the source-before vs. source-after conditions.

Experiment 2 provided participants with a credible source vs. a non-credible source, varying time of source information as in experiment 1. Additional strength-related dependent variables were included. Results from this study supported both the predicted strengthening and weakening effects. Replicating Experiment 1, results for the credible source conditions revealed a weakening effect: making participants aware of source credibility after (vs. before) exposure to the negative brand information led to increased elaboration, increased attitude ambivalence, lowered accessibility and a lowered correspondence between attitudes and behavior. On the other hand, results for the non-credible source supported a strengthening effect: the source-after (vs. source-before) condition led to heightened elaboration, no difference in ambivalence, higher attitude accessibility and a stronger attitude-intention link.

Our results suggest that consumers re-access and elaborate on information when they are subsequently told that the source of the

information was either extremely credible or extremely non-credible, not however when subsequent source information is ambiguous. As a result, bad news is most sticky when presented by a high-credibility source *after* the information is initially processed, and by a low-credibility source *before* the information is processed. A third experiment, now in progress, tests the elaboration mechanism presumed to underlie the findings by manipulating the ability to process information. The results have interesting implications on how and when bad news should be presented for maximal impact.

SYMPOSIUM SUMMARY

Goals Shared with Others: How to Increase Motivation Toward Social Goals

Minjung Koo, University of Chicago, USA

SESSION OVERVIEW

The majority of goal research has focused on consumers' personal goals, such as losing weights or saving money. However, consumers often strive toward group or social goals, defined as goals that are achieved by a group of individuals working together toward a common cause. For example, consumers in a focus group meeting work together to generate opinions on a product, people make pledges to a charity organization to meet the campaign goal, and family members join forces to complete a common task. Classic research finds that whenever a group of individuals work on a collective rather than individual task, they often exhibit less effort, typically labeled social loafing or free riding (Karau and Williams 1993; Kidwell and Bennett 1993; Ringelmann 1913). Accordingly, the focus of this symposium is on understanding the motivation to contribute to a social goal and how to reduce social loafing. Across several lines of research, we further wish to identify how marketers, managers, and other social agents can motivate people to contribute to their social goals.

Three papers explore the motivation to pursue goals shared with others. The first two papers examine what motivates individuals to contribute to a shared social goal. The third paper explores how people respond to goal conflicts between social goals and their own personal goals.

In the first paper, Koo et al. examine what factors best motivate individuals to work toward group goals. These authors find that individuals who are not highly identified with members of a group are most affected by information on other group members' contribution to date, because this information suggests that a group's goal is valuable. In contrast, individuals who are already highly identified with members of a group are most affected by information on required contributions to complete the goal, because this information emphasizes the need to progress to complete the goal. For example, the information on accumulated donations to date (vs. remaining donations to go) increased participants' contributions, when the victims were presented as out-group ("they"; low identification) versus in-group ("we"; high identification).

In a second paper, Ratner et al. investigate how to motivate individuals toward a social goal in the context of charitable giving. They find that advocates for a cause (e.g., individuals making a fundraising request on behalf of an organization such as American Cancer Society) are more effective if they have a personal connection to a victim of that cause (e.g., they lost a family member to cancer) than if they do not have a personal connection. That is, having a relationship with a victim renders one a more effective advocate for the cause thus increases contributions, because such an advocate exerts powerful social influence on potential donors.

The third paper, by Fitzsimons, addresses the problem of goal conflict. With limited time and energy, people are often faced with a conflict between personal goals (e.g., career pursuit, academics) and social goals (e.g., relationship with family members). This paper investigates how people respond to conflicts between social and personal goals when making choices about their future actions. It finds that perceived goal conflict increases both commitment and ambivalence towards the more chronically important goal. For example, participants who chronically valued relationships more than academics reinforced their commitment to relationship goals in the face of conflict; however, they also showed increased

negative affect and frustration about their relationship goals. The pattern was mirrored for participants who chronically valued academics more than relationships.

Taken together, the three papers provide an overview of how people pursue goals shared with others, which have important theoretical as well as practical implications for goal research. Data collection in all papers is complete and the session includes a total of 9 studies. All participants have agreed to present should the session be accepted. Each presentation will be for 20 minutes, which will allow 15 minutes for discussion by Dilip Soman (the discussion leader) and Q&A at the end of the session.

We expect that this session will be of interest to a broad audience of consumer researchers but of special interest to those researchers interested in issues regarding goals, motivation and social influences. The area of goals is one that has generated considerable interest over the past several years, and we hope that our presentation of recent findings on how people pursue group goals will result in active debate and generate ideas for future research.

EXTENDED ABSTRACTS

"Group Goals and Sources of Motivation: When Others Don't Get the Job Done, I (Might) Pick Up the Slack"

Minjung Koo, University of Chicago, USA

Ayelet Fishbach, University of Chicago, USA

Marlone Henderson, University of Chicago, USA

Many goals that people strive to attain qualify as group goals, which are defined as goals that a collection of individuals works together to achieve (Zander 1980). Examples include goals such as engaging in social movements, pledging to charity, volunteering for community outreach programs, generating ideas in team meetings, and accomplishing chores with housemates. Interestingly, despite the benefits group goals produce, individuals do not always work efficiently or effectively in collective settings. While much inefficiency of groups can be explained by incongruence in values and demographic differences amongst members (Jehn, Chadwick and Thatcher 1997), group productivity or performance also tends to suffer because of motivational deficits that occur when a goal is shared with others (e.g., social loafing, Ringelmann 1913, and free riding, Kerr and Bruun 1983). Acknowledging this general tendency to underperform, the present work addresses the different sources of motivation to contribute to group goal striving.

The theory and research on the dynamics of self-regulation (Fishbach and Dhar 2005; Koo and Fishbach 2008) attest that people ask themselves one out of two questions when deciding to invest in a personal goal: is the goal valuable? Or, is the pace of pursuing the (already valuable) goal adequate? For example, students can decide to study for an exam because they believe it is important to master that topic of knowledge or, alternatively, because they think they have not made enough progress. We propose that the sources of motivation described above not only apply to personal goals but to group goals as well. Group members may wish to assess whether a group goal is valuable, in which case they seek social proof for goal value in others' contributions (Cialdini 1993). Under such circumstances, prior contributions by others would increase one's own contribution through a dynamic of

highlighting other group members' actions. Group members may also wish to assess whether a goal has progressed to a sufficient level, in which case they infer need for progress on the basis of others' inadequate efforts. In such situations, people would compensate for or balance out the actions of others with their own contributions.

What, then, determines people's concern with whether others are pursuing a valuable goal versus pursuing a goal sufficiently? We propose that the level of identification with other group members determines whether one's source of motivation is the perceived value of the goal versus need for progress by group members. Individuals identify highly with others that they categorize as part of themselves, but identify less so with others that they deem as separate from themselves (Tajfel and Turner 1986; Turner 1987). In turn, high group identifiers feel more committed to their group and experience the positive and negative outcomes of their group as their own, whereas low group identifiers wish to evaluate the importance of the group to their identity (Ellemers, Spears and Doosje 1997; McCauley 2001).

We predict low group identifiers are posited to ask whether a group's goal is valuable. Therefore, an emphasis on prior effort expenditures by other group members that signal high goal value should increase their own efforts. High group identifiers, on the other hand, are already committed to their group's goal, and, consequently, are posited to focus on need for progress. Therefore, emphasizing lack of effort by others rather than prior effort expenditures should increase their own efforts more.

Three studies tested these predictions. Study 1 examined the contribution of ideas to a focus group. To assess each individual's contribution, participants work individually but assume their input will be collapsed with other group members (Jackson and Williams 1985). The group goal was to generate ten promotion ideas for a new cellular phone (iPhone). We manipulated identification by describing other team members as affiliated with an out-group (rival universities; low identification) or salient in-group (same university; high identification). We manipulated the framing of progress information (presumably, 50%) by informing participants that other group members had contributed about half of the ideas to date, or that half the ideas were missing to meet the goal. As expected, we found that the focus on to-date (vs. to-go) contributions increased idea generation for low identifiers but decreased idea generation for high identifiers.

Study 2 and 3 extended these findings in the context of a charitable fundraising. We predict that the level of identification with a victimized group influences the source of motivation for people's actions toward the group, particularly their responses to solicitations when information about to-date versus to-go contributions is made salient. Specifically, Study 2 assessed Americans' willingness to help the victims of Southern California wildfires after fall 2007. We manipulated identification with the victimized group by describing them as members of an out-group ("they, the residents of Southern California") or in-group ("we, Americans"). We further provided information on money raised to date or money still required to achieve the campaign goal. As predicted, we found that emphasizing donations to date (vs. to go) increased willingness to donate for out-group members, but decreased willingness to donate for in-group members. Study 3 was a large-scale field experiment (with Compassion International), which assessed actual contributions. Following Kenya riots in December 2007, we created a campaign that established a special crisis fund to support affected children. In the solicitation letter, we manipulated identification with the victims (they vs. we) and the focus on accumulated versus remaining donations. Consistent with

Study 2, we found that group identification determined the relative impact of focus on accumulated versus remaining contributions.

Taken together, the current article provides important lessons with respect to how to increase contributions to a group goal. First, it suggests that situational factors such as background of group members or semantic framing (they vs. we) can push people to increase or decrease their group identification. Second, it suggests that boosting group identification does not necessarily guarantee greater contribution to a group goal but one should employ appropriate strategies that correspond to the sources of motivation (value vs. need for progress) as determined by the group identification. Such strategies will be successful at increasing contributions and can reduce the robust social loafing and free riding.

"How Can You Say "No"? Deference Granted to Advocates Who Are Victims"

Rebecca Ratner, University of Maryland, USA

Min Zhao, University of Toronto, Canada

Dale Miller, Stanford University, USA

What factors impact whether consumers will donate their money and time to others? Organizations like the American Cancer Society rely on individual donations, and understanding the factors that impact individual donation behavior is of interest to a growing number of consumer researchers. Recent findings suggest several factors that impact the degree to which individuals feel sympathetic toward victims of causes and their likelihood to engage in actions to support the cause. For example, an identifiable victim produces greater sympathy and donation compared with an unidentifiable victim (Small and Loewenstein 2003), and friendship with a victim leads to greater sympathy towards other victims of the same misfortune (Small and Simonsohn 2008). Related work indicates that people feel more sympathy toward a single victim than toward many victims who suffer the same fate (Slovic 2007).

In the present research, we explore the role that social influence can play in impacting people's willingness to engage in donation behaviors. Specifically, we test the hypothesis that being a victim gives one psychological standing to have one's requests honored, even when a victim is not more effective at changing people's attitudes toward the cause for which they are advocating. In these studies, we look both at those who were directly impacted by a cause (e.g., the person suffered physical harm) or indirectly via a close relationship to the immediate victim (e.g., the parent of a child who died due to an unsafe product).

Our first study tests people's lay theory and demonstrates that people expect an advocate who is a victim to be more knowledgeable, persuasive and sympathetic than a non-victim. Further, we find that people have a lay belief that victims are more effective spokespersons than non-victims because of the greater persuasion that the former engender about the importance of the cause.

Our subsequent studies investigate whether the social influence produced by the victims comes about because they are more persuasive, or whether they simply elicit more compliance. One study employed a 2 (illness that caused suffering for the advocate: heart attack vs. cancer) X 2 (organization: American Heart Association vs. American Cancer Society) between-subjects design. Results indicated that people find it harder to say no to another person who asks them to attend a meeting when the cause of the meeting is the same as the cause of the advocate's suffering. Respondents felt significantly more disrespectful saying no when the advocate's parent had cancer and the organization was the American Cancer Society than the American Heart Association and significantly more disrespectful saying no when the parent had a heart attack and

the organization was the American Heart Association than the American Cancer Society. Information about the advocate did not change people's perception of the importance of the cause.

Another study provides further evidence that people find it hard to say no to a victim because of perceived standing, rather than because of attitude change. In this study, people find it harder to say "no" to help a victim who provides weak arguments in support of the cause than a non-victim who provides strong arguments in support of the cause.

A final study provides additional evidence that the greater deference provided to appeals made by those who have suffered personally is due to compliance rather than persuasion. This study presented the respondents with a question of how much they will donate (i.e., WTP) to a Cancer Society after learning of a charitable appeal by someone who identified their status as a victim (i.e., that their parent had cancer) versus non-victim of the target disease (i.e., the had a heart attack). Half of the respondents were asked to indicate an amount between \$0 and \$10 whereas the other half of the respondents were asked to indicate a donation amount that is either \$0 or \$10 to the Cancer Society. We found that when respondents could choose any amount between \$0 and \$10, the number of people donating \$10 did not differ significantly as a function of whether the advocate had suffered because of cancer. However, when asked whether they would donate \$0 vs. \$10 to the cause, significantly more participants who read about the appeal from the individual whose parent died of cancer (rather than heart disease) opted to make the \$10 donation. Therefore, when the advocate indicated a connection to the cause as a victim, it increased donors' willingness to give something rather than nothing. People did not want to refuse to help the person who identified their victimhood because they otherwise felt guilty.

Together, these results suggest that being a direct or an indirect victim not only makes a person more sympathetic to a cause (Small & Simonsohn in press) but also makes the person him or herself a more effective advocate for the cause because others find it hard to reject their requests. Although we find that people endorse a lay belief that the effectiveness of a victim is driven by attitude change, our results suggest that the effectiveness is driven by their psychological standing to make requests. An advocate's status as a victim makes it hard to say no to them, as long as the request relates to the issue about which the victim suffered. As a result, a consumer's own willingness and motivation to engage in donation behavior can be strongly influenced by the social context in which the donation request unfolds.

"Effects of Personal vs. Interpersonal Goal Conflicts on Goal Commitment and Goal-based Choice"

Grainne Fitzsimons, University of Waterloo, Canada

With limited time and energy, people are often faced with conflicts between important goals. For many people, a primary goal conflict is between personal goals (goals to improve one's health or to advance one's career) and interpersonal goals (goals to maintain

or improve the quality of relationships with friends, family members, and romantic partners.) For example, an individual may feel torn about whether to work late (advancing career goals) or return home early to spend time with her family (advancing social goals.) In a series of experiments, we investigated how people respond to goal conflicts when making choices about their future actions and preferences, testing the hypothesis that perceived goal conflict would increase commitment to the more chronically important goal, but would also cause increased ambivalence and negativity about the chosen goal.

In the first study, we set out to test the basic hypothesis. Participants completed pre-measures of the importance of their academic achievement and romantic relationship goals. In the experimental session, participants read an article apparently from a popular magazine reviewing research that either (a) showed that relationships and academics were a zero-sum game in that most people struggled to successfully pursue goals in both domains, or (b) showed that relationships and academics were not a zero-sum game in that most people could easily successfully pursue goals in both domains. Participants then evaluated their commitment and affect towards their relationship and academic goals. As predicted, participants who chronically valued relationships more than academics reinforced their commitment to relationship goals in the face of conflict; however, as predicted, they also showed increased negative affect and frustration about their relationship goals. The pattern was mirrored for participants who chronically valued academics more than relationships.

In the second study, we set out to manipulate the importance of the goal, and to examine the consequences of personal-interpersonal goal conflicts for choice. Participants (all undergraduate females) completed pre-measures of the importance of their dieting/fitness goals and their friendship/social life goals. In the experimental session, the importance of the fitness goal was temporarily manipulated via a goal salience manipulation, in which participants were led to feel they were doing well or poorly on this goal. The manipulation was taken from Fishbach & Dhar (2005): Participants are asked to mark the divergence of their ideal from current weight on a scale. In the low goal salience condition, the scale ranged only a small amount, leading participants to perceive a large discrepancy between their current and ideal weights. In the high goal salience condition, the scale ranged a large amount, leading participants to perceive a smaller discrepancy between their current and ideal weights. Participants then read an article modified from a recent popular fitness magazine reviewing research that either (a) suggested that friendships often interfere with achieving dieting goals, or that (b) friendships do not interfere with dieting goals. Participants evaluated their commitment and affect towards their social and dieting goals, evaluated dieting-consistent (e.g., organic energy bars and fruit) and inconsistent products (e.g., candy and chocolate bars) that served as rewards for experimental participation, filled out ballots to enter in a draw for dieting-consistent gift baskets (i.e., filled with healthy foods, gift certificates for local gyms and fitness clothing stores, and subscriptions for fitness magazines) and neutral gift baskets (i.e., filled with gift certificates for local clothing stores and movie theaters, and subscriptions for entertainment magazines), and chose a reward (fruit or candy). As predicted, participants in the high dieting goal salience condition, for whom the dieting goal was temporarily of increased importance, responded to perceived goal conflict by enhancing their commitment to the dieting goal as shown in their self-reported ratings and their choices. They were likelier to fill out ballots to win dieting-consistent gift baskets and to choose a dieting-consistent reward. However, as predicted, the increase in

commitment was again accompanied by an increase in negative affect towards the dieting goal in self-report ratings of the goal and goal-consistent products. Participants in the high dieting goal salience condition responded to perceptions of conflict by choosing goal-consistent products, but by providing more ambivalent ratings of the goal-consistent products.

In these two studies, participants responded to perceptions of goal conflict by increasing commitment to the focal or chronically important goal, as evidenced in their self-reports and their goal-consistent product choices. However, the perceived goal conflict produced an additional cost: Participants also felt more negatively and ambivalently towards the goals and the goal-consistent products. Thus, in everyday life, when people face these common personal vs. interpersonal goal conflicts, there are important consequences for goal commitment and goal-based choice.

SYMPOSIUM SUMMARY

Going Green and Seeing Green: Social Routes to Conservation and Monetary Roadblocks to Consideration

Eugene M. Caruso, University of Chicago, USA

SYMPOSIA OVERVIEW

In consumer contexts, purchase decisions that benefit the individual (e.g., buying a sports car) can often impose costs on others (e.g., damaging pollution of the environment). In this session, four papers explore the factors that facilitate or inhibit consumers' motivation to consider others in their beliefs and behaviors—including behaviors that have a direct impact on the welfare of society as a whole. The first two papers offer novel strategies for promoting environmentally friendly ("green") consumption, and the final two papers pinpoint a pervasive roadblock to such prosocial behavior. By providing both theoretical and practical contributions, this symposium raises new questions about the effects of status, social norms, and money on consumer behavior specifically and social interaction more generally.

In the first paper, Griskevicius, Tybur, and Van den Bergh investigate the role of status-attainment goals in consumption. Drawing on evolutionary theories of altruism and status, this research shows that activating status motives can actually increase the tendency of people to choose green products over superior non-green products. Goldstein, Griskevicius, and Cialdini examine the role that certain reference groups play in motivating hotel guests to conserve environmental resources, showing how such consumers give greater consideration to the normative behaviors of reference groups whose immediate surroundings most closely match their own.

In contrast to such prosocial behavior, the remaining two papers examine how a factor inherent to consumption activities—money—can serve as a barrier to the consideration of others' needs and perspectives. Because money can remind people how they can achieve their own goals without the input or influence of others, it can reduce their dependency on others and their desire for social connectedness. Mead and Baumeister show that individuals who are primed with money are less driven by self-presentation concerns and are less well liked by an interaction partner. Unlike priming status goals, priming money seems to reduce the motivation to make a good impression on others in the service of forging interpersonal bonds. Caruso, Mead, and Vohs examine the underlying mechanism for the asocial effects of money. This research finds that the mere presence of money leads people to behave in a more self-centered (egocentric) manner, which makes them less likely to take the perspective of others and less likely to help a stranger (unless they were financially dependent on that stranger). As such, money may hinder people's ability to understand social norms, anticipate others' reactions to their behavior, or be sensitive to the needs of other people—all of which may prevent them from pursuing behaviors that benefit not only the welfare of others but of society as a whole.

Taken together, the papers in this symposium offer some specific strategies for promoting prosocial behavior and some important barriers that can prevent it. Considering that the bulk of the consumer literature has tended to focus on the factors that incline consumers toward self-focused consumption rather than other-oriented consumption and conservation (Mick 2006), we think that this symposium will be part of the movement to address this imbalance. We feel that a deeper understanding of the goals that are active in various consumer contexts can further our efforts to

increase the motivation and execution of actions that embrace, rather than eschew, the concerns of others.

This symposium should be of interest to researchers in the areas of persuasion, motivation, social influence, prosocial behavior, decision-making, and consumer cognition. Because the papers in this symposium utilize multiple and diverse methodologies, it should also appeal to those who value the combination of field and laboratory experiments. The speakers will integrate the presentations by highlighting their contribution to the consumer behavior literature and their implications for marketing research and practice. Each speaker has agreed to serve if the proposal is accepted, and all papers have data from several experiments and are in advanced stages of completion.

EXTENDED ABSTRACTS

“Conspicuous Conservation: Promoting Green Consumption through Status Competition”

Vladas Griskevicius, University of Minnesota, USA

Joshua M. Tybur, University of New Mexico, USA

Bram Van den Bergh, Catholic University Leuven, Belgium

How can we motivate consumers to go green? Traditional approaches suggest providing people with information (about the plight of the environment) or with incentives (to switch to green products). Although both techniques can certainly spur conservation, such approaches largely ignore the social nature of—and the social motivation behind—conservation.

Consider what a person communicates about himself by going green. By purchasing a hybrid car rather than a gas-guzzler, for example, a person can signal to others that he is a relatively altruistic, rather than a selfish, individual. That is, instead of purchasing an environmentally wasteful product that will benefit only him, he chose a product that will benefit others by helping the environment, even though choosing the green product often means foregoing the luxury of having a more powerful engine and ample trunk space.

Engaging in prosocial behaviors such as green consumption can earn people a prosocial reputation (Semmann, Krambeck, and Milinski 2005). Individuals with such reputations are seen as more trustworthy (Barclay 2004) and more desirable as friends, allies, and leaders (Cottrell, Neuberg, and Li 2007). Considering that prosocial individuals are highly valued, prosocial actions are directly associated with status. Indeed, self-sacrifice for the benefit of the group has been shown to increase a person's status in the group (Hardy and Van Vugt 2006).

An altruistic reputation can be so valuable that individuals across modern and traditional societies (and even across species) are known to compete for status by trying to be seen as more altruistic—an evolutionary theory called *competitive altruism* (Van Vugt et al. 2007). Given the relationship between prosocial behavior and status, the theory of competitive altruism suggests that people should engage in prosocial actions particularly when they are motivated to compete for status. Thus, because green products enable a person to signal that he is cooperative and prosocial, activating a motive for status should lead people to prefer green over non-green products.

The current research examined how activating a status motive influenced product choice. Consider one choice facing a person in a bustling car show room: Should he buy the relatively luxurious, higher-performance, but energy-wasteful car, or the less luxurious, lower-performance, but energy-efficient Hybrid car. If he is motivated to gain status at the time of the decision, a traditional perspective suggests that he should choose the more luxurious option (e.g., Godoy et al. 2007). After all, this car has better performance, comfort, and indulgence. But the theory of competitive altruism suggests that status should lead him to choose the green product because there is an important public cost to choosing the more luxurious non-Hybrid car: Such a choice may signal to others that the owner is selfish and doesn't care about the welfare of others.

The first experiment examined how status motives influenced product choices between three types of green products (e.g., Toyota Camry HYBRID) and a more luxurious non-green counterpart product (e.g., Toyota Camry XL V-6). Findings showed that although the more luxurious products were generally more preferred (in the control condition), activating status motives significantly increased people's tendency to choose the green product.

According to competitive altruism theory, a key factor in how status motives should influence product choices is whether the act of purchasing can publicly signal the buyer's prosocial or selfish nature. The second experiment thus examined how status motives influenced choices when purchases were made in public versus in private (e.g., shopping alone at home on the Internet). Consistent with traditional perspectives, when shopping in private, status motives led people to prefer the more luxurious products. However, in line with competitive altruism, when shopping in public, status motives led people to choose the green (rather than luxurious) products. The third experiment examined how the relative price of the green vs. non-green products influenced their desirability. Results showed that status motives led green products to be particularly desirable when such products cost more than their non-green counterparts.

In summary, although status has been traditionally associated with luxury and "status goods," this research shows that activating status motives can lead people to forego such products. Instead, consistent with the theory of competitive altruism, status motives can lead people to choose non-luxurious and poorer-performing green products because such products can signal a prosocial rather than the selfish nature of the person. This research has both theoretical contributions and practical implications for consumer behavior.

"Limitations of Global Norms on Global Conservation: Using Provincial Norms to Motivate Pro-Environmental Behavior"

Noah J. Goldstein, *University of California, Los Angeles, USA*

Vladas Griskevicius, *University of Minnesota, USA*

Robert B. Cialdini, *Arizona State University, USA*

Recently, many consumer researchers have noted that very little research has been conducted on the factors that influence consumers' prosocial behaviors, and even less on pro-environmental behaviors (Menon and Menon 1997; Mick 2006; Robin and Reidenbach 1987; see also Bendapudi, Singh, and Bendapudi 1996). We sought to better understand such actions in several domains, including the domain of hotel towel reuse. With the adoption of environmental programs by hotels, more and more travelers are finding themselves urged via signs to reuse their towels to help conserve environmental resources by saving energy and reducing the amount of detergent-related pollutants released into

the environment. Guests are almost invariably informed that reusing one's towels will conserve natural resources and help save the environment from further depletion, disruption, and corruption. Notable in its complete absence from these surveyed persuasive appeals was one based on a potentially powerful motivator of prosocial behavior: descriptive social norms.

When consumers learn that seven out of ten people choose one brand of automobile over another or that teeth-whitening toothpaste has become more popular than its less functional counterpart, they are getting information about descriptive social norms, which refer to how most people behave in a given situation. Descriptive norms motivate both private and public action by informing individuals of what is likely to be effective or adaptive behavior in that situation (Cialdini, Kallgren, and Reno 1991).

The complete absence of a descriptive normative approach to hotel conservation programs is especially remarkable considering that studies conducted by the largest manufacturer of hotel towel reuse signs indicate that approximately 75% of guests who have the opportunity to participate in such programs do reuse their towels at least once during their stay. From a practical perspective, then, one purpose of this research was to investigate whether utilizing an appeal that conveys the descriptive norm for participation in such programs would be more effective at encouraging towel reuse than the current industry standard appeal. We tested this hypothesis in Experiment 1 by creating our own towel reuse cards and recording the extent to which each of the two appeals spurred guests to participate in a hotel's conservation program. Consistent with predictions, we found that the sign employing the descriptive norm approach produced significantly greater towel reuse than one employing the standard environmental approach.

A second purpose of the present investigation was to examine how hotel guests' conformity to a descriptive norm varies as a function of the type of reference group tied to that norm. In Experiment 2, we examined whether the norm of hotel guests' immediate surroundings, which we refer to as the *provincial norm*, motivates conformity to the norm to a greater extent than the norm of guests' less immediate surroundings, which we refer to as the *global norm*. Specifically, we investigated whether guests who learn the descriptive norm for their particular room (provincial norm) are more likely to participate in the program than guests who learn the same descriptive norm for the whole hotel (global norm), even though the provincial norm in this context is rationally no better an indicator of correct or proper behavior than the global norm. Consistent with predictions, the sign employing the provincial norm led to the greatest amount of towel reuse, even though individuals considered this group to be comparatively much less meaningful to their personal identities than to other reference groups used for other descriptive normative appeals in Experiment 2.

The more powerful influence of provincial norms was conceptually replicated in Experiment 3. In that experiment, participants went to a large on-campus computer center, where they learned the (pro-environmental) norms for either the entire computer center (global norm) or simply for the people who had previously sat at their particular computer (provincial norm). Consistent with the field data, those who learned the provincial norm were more likely to engage in pro-environmental behavior than were those who learned the global norm. Several other experiments in the computer center setting help reveal potential mechanisms for the effect. Theoretical and pragmatic implications of this work are discussed.

“Money Reduces Self-Presentation and Interpersonal Likability in Novel Social Situations”

Nicole L. Mead, Florida State University, USA

Roy F. Baumeister, Florida State University, USA

Because humans have a fundamental need to belong, they often try to put their best face forward when meeting new people in an attempt to be perceived as likable (Baumeister 1998). In fact, self-presentation is vital for success in life. Many desirable outcomes, such as making friends, success in one’s occupation, and maintaining healthy relationships, are influenced by the ability to manage one’s impression according to situational demands (e.g., Schlenker 1980).

However, people are not always successful at getting their desired impression across to others. Because self-presentation is a conscious and effortful process, people are not always willing or capable of exerting the resources that self-presentation requires (Vohs, Baumeister, and Ciarocco 2005). The current research examined how money influences self-presentation and interpersonal likability. It was expected that, because money reduces people’s desire for social connectedness (Vohs, Mead, and Goode 2006), nonconscious reminders of money would reduce self-presentation strategies and interpersonal likability.

Experiment 1 tested the hypothesis that reminders of money would reduce concern with creating a desirable impression on a new interaction partner. After completing filler questionnaires in front of a money or a fish screensaver, participants were told they would engage in a 5 min conversation with another participant. The experimenter explained that, because it can be difficult for people to have a conversation with a stranger, both participants would record an introductory video that would be viewed by the partner before the interaction. Self-presentation was measured by having a group of independent raters code how hard participants were trying to create a good impression in their video. Consistent with our hypotheses, results indicated that money-primed participants tried less hard than neutral-primed participants to create a good impression on their partner.

In Experiment 2, we tested the hypothesis that money would reduce interpersonal likability by having two previously unacquainted participants engage in a semi-structured conversation for 5 min. In each pair, one participant was assigned to be the target of the interaction (the person who rated for interpersonal likability) and the other the rater. Participants, naïve to experimental condition, were put in separate rooms and completed a jumbled phrase task. Half of the targets descrambled phrases containing money-related words whereas the other half of targets descrambled sentences containing only neutral words. Raters always performed the neutral version of the descramble task. After a 5 min interaction, raters were asked to indicate how likable, competent, and friendly the target was during the interaction. Both the target and the rater were asked to indicate how much they cared about the impression they made on their partner during the interaction. Results indicated that, compared to participants who descrambled neutral-phrases, participants who unscrambled money phrases were rated as less likable. Moreover, money-primed participants were seen as less friendly during the interaction, which mediated the effect of the money-prime on reduced likability. Money-primed participants also cared less than about the impression they made on their partner than neutral-primed participants. Additional analyses indicated that results were not attributable to mood or differences in perceived competency.

Results of two experiments suggest that money reduces the likelihood that people will self-present to a new acquaintance. Although this could have positive implications for the self, such as

ability to stand up for one’s rights, it may have negative implications for others, such as reduced prosocial behavior.

“There’s No “You” in Money: Thinking of Money Increases Egocentrism”

Eugene M. Caruso, University of Chicago, USA

Nicole L. Mead, Florida State University, USA

Kathleen D. Vohs, University of Minnesota, USA

The psychological effects of money long have been suspected, and now are beginning to be revealed in experimental research. Particularly in consumer contexts, money is a potent incentive because it enables consumers to obtain the goods and services necessary to achieve their personal needs (Lea and Webley 2006). Because money tends to engender a self-sufficient state of heightened personal goal pursuit and reduced dependency on others (Vohs, Mead, and Goode 2008), reminders of money may harm interpersonal sensitivity by increasing attention to the self and away from others.

Theoretically, money’s ability to reduce social sensitivity can be understood as resulting from the exchanged-based rules that govern the use of money in consumer contexts—rules that are diametrically opposed to the forces that promote communal behaviors (Fiske 1991). Empirically, participants reminded of money tend to offer less help to others, request less help from others, and put more physical distance between themselves and others relative to those not reminded of money (Vohs, Mead, and Goode 2006). In the current research, we explored whether money has the effect on basic human cognition of increasing egocentrism—the fundamental tendency to interpret the world in terms of the self.

Because money heightens personal goal pursuit (Vohs et al. 2006), and because active goals direct cognitive resources (Bargh et al. 2001), reminders of money may focus the mind on the self. Given finite cognitive resources, increased focus on the self means reduced focus on other aspects of social life, including other people. In addition, egocentric correction is a costly controlled process that is less likely to be activated when people are insufficiently motivated (Epley et al. 2004). Because money stimulates self-sufficient behavior, it may well reduce attempts to understand others’ perspectives. In four studies, we tested the hypothesis that reminders of money may reduce people’s willingness to correct their own egocentric perspective.

In Study 1, we asked participants to draw a symbol on their foreheads (Hass 1984). We manipulated the salience of money by having some participants draw a dollar sign (\$) and others draw the letter *S*. A greater percentage of participants drew the symbol egocentrically (as though the writer would read it herself) when drawing the symbol \$ than when drawing the symbol *S*, suggesting that they were less likely to spontaneously adopt another’s visual perspective.

In Study 2, we activated the concept of money for some participants but not others before they read some social information (facts about another student) and some nonsocial information (a list of nonsense words). On a subsequent surprise memory test, those reminded of money made more errors when recalling information about the other student but not the nonsense words, suggesting that money’s effects on information processing may be specific to social information.

To test whether money reduces the tendency to adjust one’s egocentric beliefs, Study 3 asked participants to rate both how much they personally, and how much other people, agree with various statements about abortion (Ross, Greene, and House 1977). Participants who were subtly reminded of money through a faint back-

ground image on the computer showed greater egocentric projection of their own beliefs and their predictions of another's beliefs.

Finally, Study 4 tested whether a financial incentive for accuracy would overcome the effects of money primes on egocentric behavior. Because a financial incentive provides direct benefits to the self and may allow consumers to fulfill their own goals and needs more effectively, we predicted that money-primed participants would be more inclined to work for a financial incentive than a social one. In a maze task that required participants to give directions to help a blindfolded participant navigate a series of paths, the financial incentive (but not the social one) reduced the number of egocentric errors made by participants primed with money.

Money has become an integral part of consumer societies, as people desire to accumulate the goods, services, and (presumed) happiness that it affords. When a consumer has enough resources to be self-sufficient and meet her own goals, she has little need to interact, trade, or negotiate with other consumers or sellers in a marketplace. Furthermore, moving beyond one's egocentric perspective may be a necessary step in promoting prosocial behavior, such as empathizing with those in need or donating to charitable causes (e.g., Batson 1994). We feel that a deeper understanding of the effects of money on human cognition and behavior in general—and on the egocentric tendencies it appears to engender in particular—should help both consumers and marketers develop strategies that enable the perspective taking necessary to facilitate efficient exchanges and promote choices that benefit both the individual decision makers and the societies to which they belong.

SYMPOSIUM SUMMARY
When Consumer Behavior Meets Islam
Elizabeth Hirschman, Rutgers University, USA

SESSION OVERVIEW

This special session will offer an initial look at consumption behavior in one of the most under-studied cultural domains—the Islamic world. As the process of globalization intensifies, the need for knowledge about the consumption behavior of other cultures has become imperative. However, though the cross-cultural literature generally recognizes the importance of studies in this area, in most cases it focuses on Western and Asian countries. The research on consumer behavior in the Islamic culture in general and, in Islamic countries in particular, is scarce.

Thus, this special session will attempt to provide consumer behavior scholars with the opportunity to acquire a unique insight into various aspects of consumption in the Islamic world. Hopefully, this session will stimulate an exchange of ideas and promote collaboration among researchers revolving around the issue of consumption behavior in different cultures, which ultimately will contribute to the development of the consumer behavior field.

The *likely audience* will include researchers interested in studying cross-cultural aspects of consumer behavior.

The three papers in this special session revolve around the concept of consumers' acculturation, spanning a wide range of issues. The *first paper* explores the meaning of home, space and personal possessions for women and men in Qatar. Using an ethnographic approach, the study finds that, as in Western culture, homes and possessions are expressions of self and family. However, the meaning of home spaces and possessions differs from their interpretation in the West. Middle Eastern cultures generally have a more restricted sense of what is totally private, making a sharper distinction between men's and women's spaces and between public and private spaces. The study also examines favorite possessions within Arab Muslim households in Qatar, seeking those characteristics that are unique and common to Middle Eastern and Western cultures.

The *second paper* examines the meaning of Christmas from the minority point of view of Tunisian Christians. Relying on in-depth interviews, its findings suggest considerable differences between the manner in which Christmas is constructed by Christians living in a Muslim setting vs. those who celebrate it in North America. Expatriates often import holiday food and decorations from their homelands and overstuff their homes with external representations of Christmas in an attempt to create a Christian haven for themselves that resembles the celebration of the holiday in a mythologized childhood in their countries of origin. While they may integrate certain iconic and sensory elements of Islamic traditions into their celebration of Christmas, the holiday creates a cross-cultural bond among Christians that, temporarily at least, distances them from their Muslim friends.

The *third paper* reports on a four-year ethnographic study in Turkey about the discourse between Islam and consumption. Its results contradict the common Western perception that Islam is opposed to capitalism and consumerism. On the contrary, Islam is deeply embedded in a consumerist and capitalist ethos. As in Western culture, Islamic consumers take pleasure in the consumption experience and adopt global brands. Islamist companies compete in the international market and utilize modern tools of marketing. This paper concludes that the logic and ideology of capitalism and consumerism coexist with the logic and ideology of Islam, and

that Islamic consumers exhibit behaviors that are similar to those observed in the Western world.

Each of the following presenters has agreed to serve if the proposal will be accepted: Rana Sobh, Mourad Touzani and Özlem Sandıkcı.

Finally, our discussant will be Prof. Elizabeth Hirschman, a leading, internationally recognized scholar on cultural aspects of consumer behavior.

EXTENDED ABSTRACTS

“Consuming Gendered Space in Islam”

Rana Sobh, University of Qatar, Qatar

Russell Belk, York University, Canada

The idea of personal versus shared spaces within homes is relatively new. Tuan (1982) shows that it is only within the last few hundred years that notions of privacy and separate public and private spaces within the home have emerged. Notions of private space are also encoded architecturally (Sommer 1969). Intimacy within the nuclear family is a concept that has grown as extended families have diminished (Rybczynski 1986). There are also differences in the use and sense of ownership of various spaces within the home by individual family members. Different family members think of areas of the home as being their territories (Altman 1975). Even when a particular area like the bathroom must be shared it is common to temporarily claim private space for hygienic, purifying, and beautification rituals (Kira 1970). When these spaces are encroached upon by others, there is a sense of contagion or violation (Belk 1988). We formally or informally designate boundaries defining personal space, spaces for close kin, and spaces where friends, neighbors, and strangers can meet within the home (Allan 1989). Such concepts have been extensively studied in the West (e.g., Gallagher 2006; Marcus 1995; Munro and Madigan 1999), but little comparable work has been done in non-Western homes.

Compared to the West, Middle Eastern standards of privacy involve a more restricted sense of what is totally private (e.g., Kadivar 2003), due largely to the moral concerns of Islam. This results in a sharper distinction between public and private space, often with high exterior perimeter walls and inward facing courtyards (Waly 1992). Public and private spheres within Muslim cultures also differ from Western Paradigms (Tarvis, 1992). Within the home, women's public sphere for instance includes being in the company of non-mahrems (family members/those permanently ineligible for marriage to her). But outside the home women may paradoxically have a more private sphere restricted to Mahrems (Boulanouar, 2006). Furthermore, there is a sense of private space that a Muslim woman carries with her as she goes from home to marketplace (e.g., Asad 2003), facilitated by various forms of veiling.

Within Arab Muslim homes, there is also a sharper distinction between men's and women's spaces as well as transitional spaces in moving from one to another, as Farah and Klarqvist (2001) found in Sudan. The basis for such spatial gendering are cultural and do not seem to arise from prescriptions within Islam (Farah and Klarqvist, 2001), although there is some disagreement on this point (Nageeb 2004). While some contend that having a space of their own is extremely important to women's identities as well as their

sense of social and economic status (Cooper 2001), others call such a space a “neo-harem” and find that it reduces women’s sense of space and of control over their lives (Nageeb 2004). We discuss these contending perspectives based on our findings regarding gendered areas within and boundaries within Qatari homes.

Favorite possessions within the home are a part of our extended self (Belk 1988) and thus serve a key function in our self-definition and expression of cultural values. These possessions and the meanings ascribed to them vary with culture and gender. For instance, Wallendorf and Arnould (1988) found that Americans’ favorite objects were more likely to be linked to personal memories, while those from Niger were more likely to mention objects linked to social status. They also found gender differences, with men in Niger more likely to cite the Quran and women more likely to cite silver jewelry as well as objects given to them by others. While some research in this vein has been conducted in other, largely non-Islamic parts of the world, we examine favorite possessions within Arab Muslim households in Qatar and attempt to identify local and regional specifics as well as what is unique and common in Middle Eastern and Western cultures relating to homes and meanings of possessions.

“Looking for Christmas in a Muslim Country”

Mourad Touzani, University of Tunis, Tunisia
Elizabeth Hirschman, Rutgers University, USA
Ayalla Ruvio, University of Haifa, Israel

Despite the fact that Christmas is celebrated by Christians around the world (e.g., Liebeson 2001; Wernecke 1979), virtually all the research on Christmas familiar to consumer researchers has been conducted in North America (e.g., Barnett 1954; Caplow 1984; Laroche, Saad, Kim and Browne 2000; Time-Life Books 1998; Schauffler 1907; Guttman 2007). Within this body of inquiry, themes of hedonism (Hirschman and LaBarbera 1989), materialism (Belk 1987), communalism (Caplow 1982), generosity (Pollay 1986), selfishness (Moschetti 1979), joy (Hirschman and LaBarbera 1989), and anxiety/resentment (Hirschman and LaBarbera 1989) have been identified. Further, the familiar secular Christmas iconography of snowy winter sleigh rides, strings of glittering green and red lights, Santa’s reindeer and elves, Christmas trees, mistletoe and holly (despite their Celtic, pagan origins) have been examined from multiple vantage points. As have, of course, the sacred symbols including Mary and Joseph standing near Baby Jesus lying in a manger, while the shepherds, angels and wise men look on (e.g., Belk 1987; Kasser and Sheldon 2004). One reason for the distinctive pattern (and perhaps the narrowness, as well) of these findings is that they emanate from studies set in Christian-dominant cultures. In both the United States and Canada, Muslims, Jews, Hindus, Buddhists and Jains, Sikhs and Wiccans are but small minorities operating within a dominant Christian society.

Our purpose in the present study is to learn what happens when the tables are turned, that is, when Christians must celebrate their primary holiday within a non-Christian culture, especially one which is far removed topographically from the Currier and Ives settings associated with the North American Christmas. What happens when Christmas is re-located to North Africa, where Muslims are the majority religion and snow-covered ponds, horse-drawn sleighs and even chimneys are absent?

Tunisia, the site of our study, is positioned on the Mediterranean coast between Libya, Egypt and Algeria. It is hot, arid and sandy, features more palm, date and olive trees than evergreens, and contains a Christian community comprising less than 2% of the population, most of whom are European expatriates drawn from Italy, France, Spain and North America.

In-depth interviews conducted with these Tunisian Christians revealed a dramatically different meaning structure vis a vis that found in North America. Among the most notable differences are:

The necessity of importing holiday-appropriate foodstuffs and decorations from ethnic Christian homelands in Europe and North America, which are viewed as more authentic and nostalgia-inducing than those purchasable locally.

Casting oneself back to a mythologized childhood or ancestral setting in which Christmas is celebrated openly and widely.

A feeling of Christmas scarcity, sparseness and frugality within the surrounding society, contrary to the desired sense of abundance, grandiosity and frivolity found in Christian-dominant cultures. This external sparseness is compensated for by overstuffing the interior of the home with food, decorations, music and other signifiers of the holiday, creating a Christian/Christmas refuge/haven.

A willingness to embrace iconic and sensory syncretism in which Islamic traditions, foods, songs and décor are blended with the traditional Christmas rituals.

The development of a sense of cross-Christian communality that binds together these minority religious affiliates, despite their disparate national origins in Africa, Arabia, Italy, France and North America. The result is a submerging of the racial, ethnic, and national boundaries that usually separate these Christian celebrants.

Concurrently, there is a tendency to temporarily distance oneself from Muslim friends and associates, in order to maintain a sense of sacred and social boundaries.

"Islam and Consumption: Beyond Essentialism"

Ozlem Sandikci, Bilkent University, Turkey

Guliz Ger, Bilkent University, Turkey

The rise of Islam is generally seen as an opposition to capitalism and Western consumerism (Barber 1996; Bocoock 1993; Ray 1993; Witkowski 1999). For instance, Turner argues that "consumerism offers or promises a range of possible lifestyles which compete with, and in many cases, contradict the uniform lifestyle

demanding by Islamic fundamentalism" (1994, p.90). According to Turner the cultural, aesthetic and stylistic pluralism fostered by postmodernism and the spread of global system of consumption contradict with the fundamentalist commitment to a unified world organized around incontrovertibly true values and beliefs. While "the consumer market threatens to break out into a new stage of fragmented postmodernity in late capitalism," fundamentalism "acts as a brake on the historical development of world capitalism" (Turner 1994, p.80).

We argue that such essentialist readings mystify the relationship between Islam and consumption and willingly or unwillingly contribute to the discourse of the "clash of civilizations". Drawing upon a four-year long ethnographic project we have undertaken in Turkey we argue that Islam, at least in the context of urban Turkey, does not oppose consumption or offer an alternative to consumerism. Rather, Islamism is deeply embedded in a consumerist and capitalist ethos.

We find that the more ascetic and orthodox Islamists may restrict their consumption and refrain from purchasing products or brands that are perceived to be associated with the West: e.g., Coca Cola or McDonalds. However, most of the Islamists do not oppose consumption—they actively engage in consumption albeit in an Islamic way: for example, hanging a picture of Kaba rather than a figurative painting on the wall, or drinking juice rather than beer. The urban Turkish case demonstrates that consumption patterns can be and are appropriated into religiously acceptable styles without undermining consumption itself. This is perhaps even easier in the case of Islam for which hedonism is an accepted way to life and is less of a sin than Christianity. Islam permits the pursuit of desires as long as they are integrated with moral principles such as generosity, sharing, giving to the poor, and fairness, and one is not enslaved by passionate attachment (Belk, Ger and Askegaard 2000). Islam accepts that material things are important in life. However, it requires that acquisitiveness and competition are balanced by fair play and compassion. That is, material goods are to be distributed and wealth is to be shared among all in a just manner. Being honest, fulfilling commitments, seeking virtue, providing for dependents generously, and being socially conscious legitimize consumption.

We also find that Islamism is in alliance with capitalism. Since the 1980s, companies which identify themselves as Islamist businesses have emerged in Turkey. However, far from opposing capitalism, these companies utilize capitalist tools and compete with national and global brands both in Turkey and in foreign markets. The development of the Islamist companies coincided with the economic restructuring of the Turkish economy beginning in the mid 1980s. As the economy was privatized, liberalized, and globalized, both the manufacturing landscape and the consumption landscape changed. In order to boost export revenues, the governments encouraged both the big, established companies as well as the entrepreneurs of conservative smaller towns to develop their businesses and form transnational connections. Backed with government incentives as well as international funding coming mainly from the Islamist organizations in Germany and Saudi Arabia, the small- to mid-size companies grew rapidly, creating an Islamist business sector that came to compete head on with the secular sector in almost every field. A wide variety of products and services positioned as "Islamic," ranging over summer resorts, financial institutions, clothing, food, newspapers, decorative objects, and shopping centers targeted the newly-emerging Islamist middle/upper classes.

In 1990, an association called MUSIAD (the Independent Industrialist and Businessmen Association) was founded to repre-

sent the interests of Islamist companies. MUSIAD supports market capitalism with an accentuated Islamic business ethics. It has close ties to the Islamist parties and strong transnational connections, including a very prominent presence in Germany. MUSIAD emphasizes the compatibility of Islam with capitalism and uses Islam as a basis for cooperation and solidarity among both local and international producers, and advocates a model of development sensitive to the cultural identities (Bugra 1998). Given that the prophet Mohammed himself was a merchant and Islam had always been wedded to commerce, the development of globally-oriented Islamist businesses suggest a “natural” course of economic progress.

We observe greater differences between social classes than between Islamists and Westernized seculars. Religious convictions seem to blend with cultural capital, taste, and related discourses of aesthetics all of which construct different lifestyles and consumption patterns along class lines. Religion provides yet another discourse, one among many others that shape and legitimize consumption practices. Religious or not, so long as consumers invent justifications for their consumption, they consume what they deem desirable and affordable.

Overall, we find that Islamism, as it is experienced in urban Turkey, does not oppose capitalism and the consumerist ethos. Islamist companies adopt and utilize the tools of modern marketing and forge international business connections. Similarly, consumers who identify with Islamism do not generally oppose consumption or global brands. On the contrary, they enjoy the fleeting pleasures of consumption. The logic of capitalist markets and the ideology of consumerism coexist with the logic and ideology of Islam, constructing consumption practices that negotiate daily tensions, just like in any other context.

SYMPOSIUM SUMMARY

Exclude or Include? Consideration Set Strategies and the Choice Process

Joseph K. Goodman, Washington University in St. Louis, USA

SESSION OVERVIEW

Decision making research shows that there are two ways to narrow down a set of options—an include and an exclude strategy—and that they can have systematic consequences on consideration set construction and choice (Heller, Levin, and Goransson 2002). Related research has also used the terms *accept*, *select*, *choose*, or *retain* versus *reject* or *eliminate* to refer to a choice between two (or three) options (e.g., Meloy and Russo 2004; Ordóñez et al. 1999; Shafir 1993). This session will bring these two research streams—which have predominately been investigated separately—together to find common ground and promising avenues for future research. Across the three papers we investigate a) what factors affect the use of include and exclude strategies (paper 2), b) how these strategies affect the weighting of attributes and the composition of consideration sets (papers 1 and 2), and c) how these strategies affect final choice and consumer satisfaction (papers 2 and 3).

The first paper, by Irwin and Naylor, investigates the influence of include and exclude strategies on attribute weighting, demonstrating that forming a consideration set by excluding (vs. including) alternatives results in greater weighting of ethical attributes. Interestingly, they also show that consumers judge others' behavior more negatively if they exclude ethical product alternatives. The second paper, by Goodman and Broniarczyk, proposes that, contrary to the findings of prior research, an exclude strategy may not be the default strategy when forming a consideration set. They provide evidence that consumers are more likely to use an include strategy as the assortment size increases and that this strategy choice can have subsequent effects on consideration set formation. They also provide evidence that the use of an include strategy can increase decision difficulty and regret in the final choice phase. The third paper, by Machin, focuses on including and excluding in the choice phase (termed *selecting* and *rejecting*) and finds that rejection can lead to greater satisfaction than selection. Five studies, using actual and imagined consumption experiences, identify two mediating processes and two moderators, and show that a rejection- (versus selection-) based decision strategy increases negative thoughts about foregone options.

This symposium provided a unique opportunity for researchers to broaden the traditional focus of the include/exclude and reject/select domains. The symposium format allowed researchers to explore alternative ways of understanding differences in decision strategies and how these strategies can affect consumer consideration set construction and choice and to discuss how to blend these two streams of research. In addition, the symposium was especially important because it addressed other current consumer issues: how consumers use and weight ethical attributes in choice, how consumers choose decision strategies, and consumer satisfaction. Researchers interested not only in judgment and decision making, but also in ethical attributes and choice, consideration set satisfaction, and satisfaction, were particularly attracted to this session. The papers presented and the insightful discussion provided by Lisa Bolton went beyond an exploration of the include/exclude phenomenon to create a lively discussion for fruitful avenues of future research.

EXTENDED ABSTRACTS

“Ethical Decisions and Response Mode Compatibility: Weighting of Ethical Attributes in Consideration Sets Formed by Excluding versus Including Product Alternatives”

Julie Irwin, The University of Texas at Austin, USA

Rebecca Naylor, University of South Carolina, USA

One of the most pervasive and puzzling inconsistencies in human behavior is the discrepancy between stated values and actual behavior. Psychologists have studied this attitude-behavior link across many contexts and have paid special attention to instances when people appear to be practicing “moral hypocrisy” (Batson et al. 1999) by not reflecting their supposed moral beliefs in their observed actions. For marketers, this puzzle takes a concrete form; it is surprising that products embodying commonly-held values do not perform better in the marketplace. Why, for instance, does furniture made from rainforest (vs. tree farm) wood continue to sell? Why have market forces not eliminated animal testing in the cosmetics industry? Why are corporations able to continue to mistreat workers, often with no obvious market reaction? Ehrich and Irwin (2005) showed that part of the problem is that consumers will not ask for ethical product information even though they would use it if it were available.

For some product categories, however, ethical attribute information is readily available. In those cases, why might there be a discrepancy between values and behavior? Along with the myriad of other possibilities, such as hypocrisy (Batson et al. 1999), there may be contextual elements of the decision that guide consumers toward (or away from) considering the ethical possibilities. In this set of four studies, we establish that “exclusion” versus “inclusion” (Heller et al. 2002) results in greater weighting of ethical attributes in consideration set formation, even though normatively which task is used should not have any systematic influence.

In our first two studies, we demonstrate that ethical attributes are weighted more in consideration sets formed using exclusion versus inclusion because the exclusion and inclusion tasks are differentially compatible (Fischer et al. 1999; Tversky, Sattath, and Slovic 1988) with ethical attributes. We argue that ethical attributes are weighted more in exclusion than in inclusion because the goal of exclusion tasks is to indicate which alternatives one does not want to further consider. Although, normatively, both modes make a statement about one's values, we argue that the expression of moral values feels more natural in exclusion than in inclusion: ethical issues are compatible with the goal of indicating what you do not want. Explicitly rejecting the “bad” items (the items unattractive on the ethical attribute) allows for an indication of adherence to the ethical principle. This explicit rejection seems to match the reaction people have to values that are protected (or at least strongly held); the typical response to a particularly egregious ethical violation is to reject everything about it (Lichtenstein, Gregory, and Irwin 2007). In our first two studies, we also test another proposition based on our compatibility argument; namely that there should be no difference in weighting for attributes without direct ethical implications. As predicted, we find no differences in the weighting of nonethical attributes such as price and performance across response mode.

Although we theorize that compatibility is driving our expected result, there are two alternate explanations for this finding, which we rule out in our studies. First, attribute framing could induce our results, making them redundant with past research (e.g., Shafir 1993). Ethical attributes often are expressed negatively (i.e., in terms of the number of exploited children, the amount of wasted environmental resources, etc.). To establish that it is the ethicality of these attributes, not their frame, driving our results, in Study 2 we demonstrate that manipulating the framing of the ethical attribute to be positive or negative does not affect the weighting of the ethical attribute across response modes. Second, differential weighting across the two modes might also be influenced by increased emotion in the exclusion mode that leads to avoidance of the ethical attribute. Loss modes, which may include exclusion contexts, induce negative emotion and concomitant coping strategies, such as avoidance (Luce et al. 2000). It is possible that the increased emotion of exclusion and/or adding an ethical attribute to the decision process causes participants to avoid making tradeoffs and to simply not act on the ethically attractive options, resulting in their being left in the consideration set. This possibility would be interesting, but not particularly new given the literature on loss and coping. The explanation we propose is not driven by how emotionally involved participants are with a given ethical issue but rather by differential compatibility between ethical attributes and response modes. To address this possible affect-based explanation, in our first two studies we provide statistical evidence that affect does not drive our effects.

In our third study, we provide direct evidence that consumers use the principle of compatibility when evaluating an ethical decision by demonstrating that consumers judge others' behavior more negatively if they exclude ethical products (as opposed to not including ethical products). Finally, in our fourth study, we demonstrate that ethical attributes are given greater weight in exclusion than in inclusion in a laboratory study involving real (vs. hypothetical) consideration set formation and an actual monetary decision.

Together, the results of these four studies suggest that consumer consideration of ethical products is driven not only by motivational issues such as hypocrisy and guilt, but also by simple cognitive issues such as how context guides the decision in one direction versus another. Our results therefore have important implications for the marketing of ethical products, both specifically (e.g., it is important to encourage exclusion modes) and generally (e.g., the failure to consider ethical products may reflect seemingly minor contextual issues guiding the decision process and not consumer disinterest in ethical issues).

“Screening from Large Assortments: The Use of Include and Exclude Strategies in Consideration Set Construction”

Joseph K. Goodman, Washington University in St. Louis, USA
Susan Broniarczyk, The University of Texas at Austin, USA

Decision making research shows that there are two ways to narrow down a set of options an include and an exclude strategy—and that they can have systematic consequences on consideration set construction and choice. The research has argued that an exclude strategy is the default strategy and is more likely to be used in consideration set construction (Ordóñez et al. 1999; Heller et al. 2002). Consideration set construction strategies, or screening strategies, are particularly important as assortment size and choice difficulty increase because a consideration set is more likely to be formed as the choice set size increases (Lussier and Olshavsky 1979). Thus, an important question is whether assortment size can lead consumers to use a different strategy to narrow down the set of options given that they use a consideration set. Could this influence what attributes and options are considered, and ultimately influence

decision difficulty and regret? If consumers faced with a large assortments are more likely to use an include strategy, then an include strategy may be the more common strategy overall.

Though little attention has been given to how assortment size may affect the decision strategy, there is evidence that strategy choice may affect the consideration set. Prior research shows that compared to an exclude strategy, an include strategy can decrease the size of the consideration set (Heller et al. 2002). There is evidence from the binary choice literature (Meloy and Russo 2004; Shafir 1993) that the use of include strategy will lead consumers to weight positive attributes more and negative attributes less (see also Irwin and Naylor in this symposium). Thus, we propose that consumers faced with larger assortment will be more likely to use an include strategy and that this strategy choice will lead consumers to have more positive thoughts and fewer negative thoughts when constructing consideration sets.

Across three studies we show how assortment affects the use of an include versus exclude strategy in consideration set construction and its consequences on consideration sets and final choice. In the first study we manipulate the size of the assortment by presenting participants with either a small assortment (6) or large assortment (30) of gourmet chocolates. Participants are instructed to either select an include strategy or an exclude strategy and narrow down the set of options to those that they “would actually consider buying” (adapted from Heller et al. 2002). They then respond to questions measuring decision difficulty and anticipated regret. The results show that contrary to previous research, an exclude strategy is not always the “default” strategy, and that participants are more likely to use an include (vs. exclude) consideration set strategy in large (65%) compared to small assortments (31%). The results also indicate that consideration sets are significantly smaller when participants choose an include compared to an exclude strategy, and this is especially true as the assortment size increases. Lastly, the study shows that consumer's experience heightened decision difficulty and anticipated regret when they use an include strategy in large assortments compared to an exclude strategy.

In the second study we test whether the use of an include strategy changes the thought process of consumers during consideration set formation. We collect written protocols during the consideration set formation process and have two independent judges code their thoughts. In addition, we use two product replicates to extend our results to a new category, backpacks, and we investigate an important moderator to strategy selection, maximization. Maximizers tend to seek out the best options in choice whereas satisficers simply seek acceptable options (Schwartz 2004); likewise, maximizers will likely seek the best strategy (i.e., switch to an include strategy) depending on the assortment. The results show that compared to satisficers, maximizers are especially likely to show a difference in strategy in large versus small assortments. In addition, we demonstrate that an include (vs. exclude) strategy leads consumers to focus more (less) on positive (negative) attributes, express more (fewer) positive (negative) thoughts in the consideration set construction process, compose smaller consideration sets, and focus more (less) of their thoughts on options (not) in the consideration set.

Since studies 1 and 2 allow participants to choose which strategy to use when forming their consideration set, it is possible that the results are due to self selection. Study 3 manipulates which strategy consumers use and finds consistent results with the previous studies.

This research suggest that an exclude strategy may be the “default” strategy in small assortments, but when consumers are faced with large assortments they are more likely to use an include strategy to form their consideration set. Marketers and consumers

should be aware that not only will their strategy change as the size of the choice set increases, but that it can systematically influence the composition of final consideration set and final choice.

“Choosing by Selecting or Rejecting: How Decision Strategy Influences Consumer Satisfaction”

Jane Machin, Virginia Polytechnic Institute and State University, USA

Two moviegoers face a choice between caramel and buttered popcorn. One selects an alternative (“Mmm, caramel popcorn”) while the other rejects an alternative (“Yuck, buttered popcorn”). Both eat the same popcorn. But who is more satisfied? Prior research suggests that selection and rejection are not complementary strategies and can have different and non-trivial effects on which options are chosen (e.g. Shafir 1993). There are occasions, however, when there will be no systematic difference in choice between selectors and rejecters — for example, choices among functionally equivalent options (Levin, Jasper, and Forbes 1998) or choices with a clearly superior option (Shafir 1993). This begs the question of whether decision strategy matters when there are no systematic differences in choice. There is currently little understanding of the down-stream, post-choice consequences of decision strategy. The present research addresses this gap focusing specifically on consumption satisfaction. Over four studies I provide evidence for the novel proposition that using a rejection-based decision strategy (“Yuck, buttered popcorn”) can lead to greater consumption satisfaction compared to a selection-based decision strategy (“Mmm caramel popcorn”).

Study 1 demonstrates that rejecters experience greater satisfaction compared to selectors when they have a relatively negative experience, such as eating stale popcorn. Differences in counterfactual thought direction (Roese 1993) mediate the relationship between decision strategy and satisfaction. Compared to selectors I find that rejecters generate more *downward focused* counterfactuals (“things could have been worse”) when the experience is negative. I demonstrate in study 3 that this difference in counterfactual thought direction occurs because of a divergence in information focus during the decision process. A rejection-based decision strategy not only focuses attention on more negative information in general, but focuses attention specifically on negative aspects of the foregone alternative. When a rejecter later reflects upon what might have been, thoughts about how the outcome could have been worse are more easily generated because the initial decision focused on the negative aspects of that alternative outcome. Consistent with the principal of affective contrast (Markman et al. 1993) rejecters then recruit these thoughts to mitigate dissatisfaction with the negative experience. Satisfaction does not differ when the consumption experience is positive, since positive experiences do not prompt counterfactual thinking (Landman and Petty 2000). Evidence for mediated moderation is presented.

Using a multi-alternative (rather than binary) choice set and a new choice context, study 2 provides additional evidence that using a rejection-based decision strategy increases satisfaction after a negative consumption experience. Study 2 also introduces a second moderator: salience of the foregone alternative. In study 1, the foregone alternative was visible to all participants when they consumed the chosen item. Since salience of the foregone alternative is important in the ability to generate any counterfactual thoughts (van Dijk and Zeelenberg 2005), decision strategy should only influence satisfaction if the foregone alternative is salient at the time of consumption. As predicted, study 2 finds that, compared to a selection-based decision strategy, a rejection-based decision strategy generates more downward focused counterfactual thoughts, which mitigate satisfaction, only when participants are reminded of

the foregone alternative and the consumption experience is sufficiently negative.

Study 3 provides more direct evidence of the psychological processes that lead to the difference in counterfactual thought direction. Participants’ thoughts while making their decision were coded for the number of positive, negative, and neutral thoughts about the chosen and foregone alternatives. Analysis reveals that rejecters have more negative thoughts about the foregone alternative compared to selectors (both in absolute terms and when compared to the number of positive thoughts). A multi-step mediated moderation process demonstrates that (1) thoughts during the decision process mediate the relationship between decision strategy and counterfactual direction and that (2) counterfactual direction mediates the relationship between decision thoughts and satisfaction. Combined, decision thoughts and counterfactual thought direction fully mediate the relationship between decision strategy and satisfaction.

Study 4 replicates the basic finding using participants’ self-generated decision strategy, thus providing some real world validity. Participants who spontaneously use a rejection-based decision strategy to make their choice are more satisfied with their consumption experience compared to participants who spontaneously use a selection-based decision strategy, when the consumption experience is negative and the foregone alternative is salient. Counterfactual thought direction again mediates the relationship between decision strategy and satisfaction.

Together, these studies demonstrate that *how* a decision is reached has implications beyond the actual choice. Compared to a selection-based decision strategy, a rejection-based decision strategy leads to greater satisfaction when the consumption experience is negative and the foregone alternatives are salient. Thoughts at the time of the decision and counterfactual direction after the consumption process play mediating roles. The studies find either no difference in expectations and/or supportive results for a relative satisfaction measure that controls for initial expectations helping to rule this out as an alternative explanation. There are also no differences in perceived ease of strategy or perceived amount of choice.

Inasmuch as consumers may not be perfectly satisfied once a product is consumed, my research suggests that marketing managers may wish to encourage consumers to adopt a rejection-based decision strategy. Subsequent reminders of the foregone options would mitigate dissatisfaction and could prevent further downstream consequences, such as brand switching. From the consumer’s perspective, my research suggests it would be better to use a rejection-based decision strategy whenever a negative consumption experience is possible.

Exploring the Concept of Brand Embarrassment: The Experiences of Older Adolescents

Ian Grant, University of Strathclyde, UK

Gianfranco Walsh, University of Koblenz-Landau, Germany

ABSTRACT

Although consumer behavior researchers pay continuing attention to brands and their importance to consumers, not much is known about the negative emotional effects of brands. The authors extend prior research by introducing a new construct called 'brand embarrassment'. Brand embarrassment refers to anxiety and negative emotions evoked by brands in certain consumption contexts. A qualitative study with older adolescents in the United Kingdom finds that embarrassment is experienced in the private and public domains. Brand embarrassment is explained in terms of issues of the *personal-self* and *relationships with brands*. Overwhelmingly, the participants claim that they try to avoid possible brand embarrassment.

INTRODUCTION

Branding research is largely premised on the belief that consumers want brands as they form a shortcut in the minds of consumers when making a purchase decision, make a quality promise, package meaning, and define the consumer's sense of self (e.g., Aaker and Biel 1993; Chan et al. 2003). However, a perspective that is largely absent from the literature is that brands can evoke negative feelings in consumers. The position advanced in this research suggests that in certain consumption contexts, brands can cause embarrassment to consumers. Growing attention has been dedicated in recent years to deepening our understanding of the emotion of embarrassment in consumption contexts. It has been recognized as a "familiar and widely occurring emotion that affects many facets of our social behavior" (Dahl et al. 2001: 473) and hence deserving of scholarly attention. It remains an under-researched subject however in comparison to the dominant moral emotions of shame, anger, empathy and guilt (Haidt 2003: 853). And yet as Miller (1995) highlights, embarrassment is an emotion that all humans experience at some point, as it is unlikely that an individual will never be affected by what others think of him or her.

In a consumption context, a growing body of researchers have focused on identifying incidents of embarrassment through different stages of the consumer purchasing cycle, from initial purchase through usage until disposal (Dahl et al. 2001; Verbeke and Bagozzi 2002; Iacobucci et al. 2003; Grace 2007). Researchers to date have detailed instances of product and service-related embarrassment irrespective of the existence and importance of brand meaning in that experience. This ignores the symbiotic relationship between consumer's emotional feelings, both positive and negative, and the influence of brand associations, image and meaning (Edel and Burke 1987; Aylesworth et al. 1999). The paper will examine links between the negative emotion of embarrassment and theories of branding before detailing a qualitative study exploring the conceptualization of brand embarrassment.

EMBARRASSMENT IN A CONSUMPTION CONTEXT

Embarrassment is an emotion almost all humans feel at some point, given the importance of how individuals are influenced by what others think of them (Miller 1995). It can be defined as a commonly occurring, short-lived, negative emotional response arising from a perceived threat to the presented or public-self, in the presence of real or imagined audiences (Miller and Leary 1992). Unlike other self-conscious emotions such as guilt and shame,

embarrassment involves social interaction. If embarrassment is experienced in private, it is thought to be because individuals are imagining what others might think of them (Sabini et al. 2001). Protecting the public-self from unflattering and unwanted evaluation is a powerful motive that underlies such behavior. In this way, embarrassment can be viewed as an important regulator of social behavior (Goffman 1956).

Miller (1996) reminds us that negative relationships occur between embarrassment and previous events and so researchers have focused on the importance of familiarity as an influence on embarrassing experiences (Dahl et al. 2001). Uncertainty following an unwanted event can produce feelings of embarrassment for either party (Parrott et al. 1988). Baumeister et al. (1995) remind us however of the importance of social context in any evaluation of self-conscious emotions, defined by individual's socialization experiences. This might include issues of social environment and place (Verbeke and Bagozzi 2002), social composition and social status.

LINKING BRAND ASSOCIATIONS TO EMBARRASSMENT

Negative emotions have a significant influence on consumers' purchase and consumption patterns (Kapoor 2008). Mizerski and White (1986) argue that brand-related cues seek to overcome such negative affective reactions. It has long been recognized that branded products are capable of influencing, even shaping consumer emotions and feelings. Dobni and Zinkhan's (1990) definition of brand image specifically highlights the emotional, as well as reasoned perceptions consumers attach to brands. As Levy (1959) argues, products are often purchased (or avoided) not for their functional qualities, but because of how, as symbols, they impact on the user's status and self-esteem. According to Aaker (1997), brands have distinct personalities (defined along the dimensions of sincerity, excitement, competence, sophistication, and ruggedness) and consumers are generally expected to seek brands that are consistent with their personality. The concept of brand image is therefore a shared mental concept, steeped in emotional as well as rational interaction. It therefore suggests a relationship between emotional states (both positive and negative) and consumer brand image. Banister and Hogg (2003: 850) discovered in the UK fashion context that "consumers often decide whether to accept or reject products and brands on the basis of their symbolic (as opposed to functional) attributes".

Researchers have detailed relationships between advertising (the dominant driver of brand image) and such positive and negative feelings (Batra and Ray 1986; Aylesworth et al. 1999). This covers both conscious and more involuntary consumption conditions. Edel and Burke (1987) extended this work to include the impact of emotions toward branded associations but remind us that negative feelings will not always predict advertising and hence brand attitudes. One rare study linking embarrassment with brand advertising (Ray 2001) focused on embarrassment communicated by advertising acknowledging that over time, a process of image transfer occurs with repeated exposure to negative stimuli.

An important link between the emotional state of embarrassment and brands is the involvement of reference or peer groups (Stafford 1966). Sirgy (1982) suggests that consumers attach varying degrees of importance to how they believe others view their

preferred brand. Given the prerequisite for self-conscious evaluation before experiencing embarrassment, it is likely that negative feelings such as embarrassment may emerge if the values and attributes collectively held amongst peers are deemed socially unacceptable. A consumer's need for social approval often leads consumers to evaluate the perceived risks attached when purchasing a specific brand. Certain brands inevitably carry negative consequences, either physical or social. Consumers are therefore more susceptible to group influence and perceived risk when a brand decision involves social interaction. There are also instances of consumer avoidance of social encounters where negative feelings toward brands might occur. Leith and Baumeister (1996) referred to this as the dark side of embarrassing situations. Consumers may disown their favored brands if they foresee the potential for embarrassment as was recently evidenced by the problems for the Burberry brand in the United Kingdom.

In summary therefore, we hypothesize the existence of what we have termed 'brand embarrassment', a form of social anxiety that occurs when a person's public identity in a particular situation is threatened. This form of embarrassability refers to an individual's general susceptibility to feelings of awkwardness and uncomfortableness in connection with a branded encounter. The embarrassment might be experienced by either party in anticipation, during or shortly after the event.

AN EXPERIENTIAL UNDERSTANDING OF BRAND EMBARRASSMENT

In this study, we seek to explore stories of embarrassment as they relate to past, present and anticipated branded experiences. Our focus on the negative emotional experiences of late adolescence (aged from 18 to 22), reflects their transition from highly brand conscious years as adolescents through to a growing sense of maturity in adulthood (see Wooten 2006). In this sense, we hoped to tap into their experiences of brand embarrassment, reflecting adolescents' status as media and marketing literate (Buckingham 2002) yet highly self-conscious consumers. This age group merits special attention because theirs is a time of experimentation and risk-taking (Larson 2001), embroiled in issues of peer-influenced identity formation and the projection the 'self' identity (Moschis and Churchill 1979). According to Chaplin and John (2005: 121) "adolescence brings an even greater appreciation of brand images along with an increased understanding of the role that brands play in defining the self" suggesting a time in which negative branded experiences could be highly influential.

Thompson et al. (1989) argued that an approach based on the principles of existential phenomenology allows for analysis of context-dependent, 'lived-in' experiences; researchers ask participants to articulate their own "personalized understandings of consumption phenomena" (Thompson and Haytko 1997: 19). This implies that any meanings derived from an experience are always situated in their current experiential context. In this study, we treat embarrassment as intrinsically embedded rather than distinct from the phenomenological surrounding (Tangney 1995). Experiences of brand embarrassment were recounted in the context of older adolescents' everyday lives thereby providing thematic descriptions of the consumption phenomena in question.

Research Method

In keeping with phenomenological principles, this study used a series of in-depth discussion sessions, conducted amongst friendship pairs. According to Hunt and Miller (1997 cited in Banister and Hogg 2003: 857), 'friendship pairs' provide a naturalistic, intimate setting encouraging participants to more openly discuss issues of identity and consumption. Six initial sessions comprising of twelve

participants were conducted in the summer of 2007, providing opportunities to explore different lines of questioning and to pilot naturally-forming 'friendship pairs'. A further thirteen sessions were then held from autumn 2007 till early 2008, allowing for the emergence and exploration of core themes. Although there emerged a balance of gender across the study, 'pairs' were as often mixed as single sex, reflecting participants' ease in the company of mixed gender. All respondents were United Kingdom undergraduates, or friends of undergraduates. A £15 incentive linked to a local record store was used as incentive to encourage participation.

Participants were encouraged to provide visual representation of potential embarrassing brands to discuss, including newspaper and online images, and even digital photographs. These were used in a projective manner to help alleviate any issues of inhibitions before recalling embarrassing incidents, and to enrichen discussions surrounding those events. Discussions were unstructured, but covered initial experiences, differences across product categories, the nature of embarrassment and resultant behaviors and linked emotions. Once transcribed, the data was analyzed using phenomenological interpretation (Thompson et al. 1989). Salient themes, recurring ideas and patterns of beliefs linking people and cultural setting together were identified. A second stage then involved relating patterns of commonality between different transcripts and seeking different interpretations of similar phenomena.

FINDINGS

This paper will focus on the range of influences that combine to create and perpetuate brand embarrassment. Influences are artificially separated into those relating to the *personal-self* and then *relationships with brands* although such distinctions are difficult to separate given the interlinked, symbiotic nature when discussing experiences of brand embarrassment.

Influences of the Personal-Self

Issues of social class and status

Given the nature of embarrassment with its signaling of a perceived or actual threat to the presented or public-self, many of the initial and more obvious experiences related to participants' perceived social status with class distinctions apparent. Such examples were most marked when discussing secondary school experiences where issues of class distinction are marked and on view. As Andy explains when discussing his embarrassing memories of drinking branded vodka when seventeen:

It wholly depends on the class thing, when I look at what Glen's (vodka) ... it completely reminds me of people that I knew in school and the phrase "drinking Glen's by Inverness Castle".

In this example, the cheaper brand of vodka serves to remind Andy of unpleasant memories of school amongst fellow classmates he did not want to be associated with. The brand of vodka plays a central associative link, providing a strong emotional tie between the social status of its users, the matching downmarket associations of the brand and his implicit reaction. Experiences of such ties between brand and social status extended across many different product categories, from retail stores visited, to cars driven, to mobile phones owned. Most prolific were stories relating to fashion clothing brands as Iain explains:

I would never go and buy another pair of trainers or a Kappa tracksuit—it's the connotation, you can just hear the screech of 'neds' in the back. That is not something you want to be associated with. ... that's the thing, because Kappa do produce

some really good clothes and it is generally reasonably priced and I am sure I have got a t-shirt that I use for training now and again—I do my best to sort of hide it.

In his case, it was not the product quality of the clothing that was in question but the user-associations that caused the embarrassment. ‘Neds’ is a euphemism for socially undesirable adolescents, often from underprivileged backgrounds who hang around in gangs, clearly distinguishable by prominent branded clothes they display. In certain cases (such as the commonly reported Burberry brand), high quality expensive fashion brands were requisitioned by such groups resulting in a transferal of negative user imagery to the clothing brand. Other examples in this study included Berghaus (outdoor wear), Lacoste and Firetrap. Branded clothing was recognized as a form of tribal uniform causing embarrassment for companies and others who came into close proximity.

In school environments, especially those with restricted uniform policies, adolescents use brands as a means of establishing social standing. As Tracey explains, branded clothing creates social status and inevitably feelings of awkwardness and a very visual sense of social inferiority:

It was always like when you were doing PE in school and stuff you always had brand names and without like, say the two stripes down your trousers instead of three like the adidas ones and it would be “why are you wearing them kind of things?”. It was always like “oh, you don’t have any money?” and we were always paranoid about what kinds of tops you wore... not realizing you were judging people.

Social judgments, through the clothes displayed, extended to more functional items such as the make of white shirt or the choice of black shoe, with the brand recognizable just by the style:

Fraser: At my state school, the only freedom you had was the type of shirt, it has to be white but you could buy an expensive or a cheap white Asda shirt and the shoes, they were the most obvious because they had to be black but the type of shoes ... these were the only two items you really had any freedom of choice over; it became whether you had a Calvin Klein shirt or a George shirt from Asda, or whatever cool shoes were in. If you did not have the best in these, it defined your social standing.

Feelings of embarrassment were not however linked exclusively to concerns over downmarket stigma. There were also a few examples of embarrassment when faced by brands that signified more upmarket associations according to Jamie:

Where I was brought up, and where my dad was brought up, it was a sort of rougher area. I notice it when I go back, my dad has got quite a nice brand of car and you are parking it and heads are turning. It is not an outrageous one, it is an Audi. You are almost embarrassed to have such a good car when you are driving about and stuff—it stands out a mile.

Both however indicate that brands play an important part in creating feelings of discomfort and social stigma and highlight how the brand imagery and related user associations create both personal embarrassment (in defense against the ridicule of the accusers) or projected toward others who might be the focal point for the brand in question.

Transitions in adolescence

For adolescents in particular, the rapidly changing public and private worlds, with its associated issues of experimentation and social risk, provided fertile ground for stories of branded embarrassment. In one particularly vivid episode, Grant tells us how his lack of social knowledge in a new school setting provided the impetus for an acute case of brand embarrassment:

This is really peculiar because I went to a private school for high school but still lived with a lot of friends that I had gone to primary (state) school with so it was obviously two completely different worlds. Especially at that age and it was sort of like my 1st year at high school, first school disco. I turned up with a Helly Hansen jacket which would have been really cool (at my primary school), but it meant different things at the private school. It gets worse because underneath I had a Kappa tracksuit. The tracksuit was really acrylic shiny fabric ... there was a complete scene at the disco. In retrospect, I am really embarrassed about it but at the time, I wasn’t so much because I had this kind of feeling that I was right and they were wrong. But as time progressed and they educated me in the ways of fashion, I was mortified ... meeting lots of new people and trying to create my own identity.

This case demonstrates a temporal aspect to brand embarrassment. Embarrassment can emerge unexpectedly with changing circumstances and although not always overtly obvious to the recipient, the effects in terms of reduced social standing and a feeling of inadequacy are evident. Identification with brands can change very quickly during the formative identification years of adolescence with both the changing cycles of fickle fashion and the constant movement between social circles. It is likely that brand embarrassment may also occur in other situations of transition, such as the move to a new job or a geographical re-location as consumers move between social expectations and social norms. This was however beyond the scope of this research study.

Generational and age distance

There were numerous examples of how brand embarrassment might emerge when faced with an age-related generational gap. Such embarrassment typically emerged between adolescents and their parents, even grandparents. Examples such as highlighted by Jamie below, illustrate how powerful user associations from one generation compare with ignorance or ambivalence from an older one:

My dad used to climb when he was younger but he is quite a savvy shopper, like he usually gets the cheap stuff normally, but decent stuff—he comes into the house one day with a big grin on his face, he has bought the most expensive jacket of his life, and I was like, “...all right, let’s see it”, and he tells me it was £320, puts it on and we just start laughing. It was a Berghaus Europeak jacket—he works down in Parkhead (east Glasgow), that’s where all his patients are, lots of ‘neds’, so he does not wear it there any more!

The experiences of Jamie’s father illustrate the complex mix of generational differences, social status and negative brand associations. Stories of adolescents being embarrassed to be associated with the brands displayed by their parents included dissociation with downmarket supermarket brands purchased by their parents, expensive designer clothes worn by image-conscious mothers and even the brands of cars driven by parents on the school run.

Embarrassment, sometimes never revealed, led to examples of masking the brand, parental avoidance and even lying to their friends. For many, their parents either lacked the same brand-driven values or were ignorant of the depth of meaning implicit.

Socialization: Distance, tribes and environments

Brand embarrassment was also a function of the nature of the socialized relationship between parties growing up in a peer driven culture. For many of those spoken to, brand embarrassment occurred not between the very best of friends but between those they knew less well or not at all. Tracey highlights how a feeling of embarrassment relates to a past friend:

When we were younger, even still now, I would say that say you are in Asda and you buy Smart Price (Asda Own Label) and you go to the check out, and then your pal who you were at school with, is serving you, it is an embarrassing thing. We kind of recognize that it should not be an embarrassing thing because it is, because of the cheap associations.

This type of avoidance behavior is consistent with Goffman's (1956) description of efforts to avoid the gaze of others as visible signs of embarrassment. Indeed, the highly tribalized nature of adolescent lives leads to stories of embarrassment between the brand conscious cliques and social circles. Adolescents are known to join such groups for the purposes of ego enhancement, achievement of status superiority and identity formation (Danesi 1994). In the formative secondary school years, brands were used to define social acceptance and for those not able to, or unwilling to display those brands, a sense of embarrassment was felt as a result of ridicule and social exclusion:

Amanda: In high school, it was always because you were in such tightly packed social environment, where everyone was sort of competing to be popular, so if you did not wear Kickers shoes, you were excluded.

Fraser: When I was back in school, it was just my mates, and I had a pair of shoes and I just wore them with jeans one day and just got a ripping because of the pressure to wear branded trainers like, sort of more skate brands like Vans or Ethies, and all that sort of thing, and I was wearing, I think they were from Clarks or somewhere, just black normal shoes.

Such stories bear a close resemblance to Leary's (1995) understanding of embarrassment as an aversive stimulus that encourages circumspection of public image and importantly, discourages behaviors that might threaten that desired peer-driven image. Furthermore, such cases of embarrassment were often shared amongst observers around, in which teasing and social degradation was a shared social norm (Miller 1987). Wooten (2006) argues that embarrassment in such circumstances is a consequence of the peer ridicule that has arisen and such individuals will become conditioned over time to recognize and takes steps to avoid grounds for potential embarrassment.

Participants also emphasized the importance of social context and place. Environments such as the sports changing room in which the wrong choice of brand of deodorant or make-up displayed could lead to feelings of embarrassment through teasing, ridicule or even fears of bullying. In such circles, the need to establish and maintain social approval became dominant. Haidt (2003) locates this within individuals' powerful desire to 'belong' in group situations. This need to belong extends toward the consumption of branded products and the desire to keep up with group fashions. In fast moving markets such as mobile phones, brand embarrassment was per-

ceived to occur when individuals in the group were left behind by the latest technological fashion as Colin comments on:

In 2nd year, the first phone I got was really top of the range at the time, a Nokia 3310 which is now a brick, but at the time, it was fantastic but within a couple of months, all my mates had them and I was "ok, you had a perfectly good phone anyway", and they do the same thing, but maybe they felt they needed to get them because they felt embarrassed about their against mine.

Feelings of brand embarrassment were also contingent upon the occasion as much as the brand in question. Alcoholic drinks were perceived to be potent territory for brand embarrassment given the image-conscious nature of drinks marketing and changing brand loyalties between differing social groups and drinking occasions. In the example below, Martin talks about an experience in which embarrassment was caused as much by a change in social environment, from one which was acceptable to one that was clearly not:

About three months ago, I was with this person who was the only person I knew. All his friends were drinking Bacardi Breezers and I was like "this is not the way we do it in my group of friends", we always bought a few pints .. I think in that sort of environment, you're a bit embarrassed and everyone else is drinking this so...you feel pressured because you don't want to stand out ... whereas if I was with my mates, I would feel embarrassed to drink that.

Issues of self perception and identity

Finally, participants believed that embarrassment with brands was also a function of issues of self-perception, a lack of self-confidence and individuals' personality and character. Negative images and associations linked to brands worn or consumed produced feelings of undesirability, similar to what Banister and Hogg (2001: 244) described as the "undesired self". This was often based on experiences resulting in teasing, ridicule and isolated cases of bullying. In one such example, a fifteen-year-old boy was so embarrassed to be wearing the wrong choice of school bag that he still remembers the hurtful taunts that followed. Some six years on, he feels that this and several other branded incidents led to a draining of confidence and arguably a deep rooted negative self-portrayal.

Relationships with Brands

In her study, Fournier (1998), drawing on interpersonal relationship theory, suggests that consumers form different types of relationships with their brands. A deeper understanding the phenomenon of brand embarrassment relates not just to issues of the self and socialized environment but also the types of branded relationships consumers establish, maintain or disown.

Brand familiarity and knowledge

Consistent with theories of embarrassment which recognize that a lack of familiarity can encourage the formation of embarrassment (Miller 1992) and also studies of product and purchase embarrassment (Dahl et al. 2001), participants in this study such as Scott below recounted examples in which a lack of knowledge about either a brand's attributes or a lack of confidence in the brand image might result in possible future embarrassment:

It would be different if you did have a really good brand, say you bought a big Sony, I am not saying you would be like "check out my Sony television" but you would maybe slide it

in there. At the other end, I would be embarrassed if I had a television like say a Matsui

In the same vein, stories of embarrassment, either actual or anticipated, occurred in situations in which the participant risked perceptual ridicule if they revealed their lack of branded knowledge in keeping with Gilovich et al.'s (2000) concept of the 'spotlight effect'. In one such example, the choice of a brand of malt whisky to present to a twenty-one year's father as a gift was fraught because he was concerned that the brand of whisky he chose, Glenfiddich, might reveal his lack of knowledge about the sophistication in choice of Scottish malt whisky brands.

The scrutiny of brand attributes and brand knowledge also worked in reverse with examples of feelings of embarrassment because of a lack of knowledge amongst others consuming the brand in question. As Kai explains, he anticipates embarrassment as he does not want to be associated with a brand of wrist bands because of the ignorance of its users:

The Make Poverty History (wrist bands)—I found really difficult—everybody just jumped on the bandwagon and obviously became a fashion statement around that summer ... never mind the whole politics behind the whole actual event, I just thought it would be really embarrassing to be walking round because I would be seen to be like somebody who just like, you know, they may not even know the ins and outs of the campaign and stuff. They just wanted a wrist band to prove a fashion point.

Therefore, the lack of brand knowledge can create both experienced embarrassment and projected embarrassment, amongst known individuals and in the case of Kai, unknown passer-bys.

Associations and meaning

As Levy (1959) argues, the symbolism of brands plays an important part in the creation of meaning influencing positive and negative associations with brands. In this research, there were different forms of symbolism creating feelings of embarrassment toward the brand in question. Perhaps the most frequently cited example was the Burberry 'check' design, the most visible emblem of the 'ned' culture so prevalent in the United Kingdom from the late nineties onwards. But other examples included the design patches on jeans pockets, the archway 'M' for McDonalds and even the crocodile label for Lacoste. In Judith's case, it relates to Diesel jeans:

Some folk were going out to spend more money on buying, say, a £150 pair of Diesel jeans or something. And I think folk did, well I certainly did, feel kind of pressured as such, but you would buy say like jeans that had like the brand name plastered across the back pocket so that you would be seen to be wearing them.

In such examples, the brand through its most visible association becomes synonymous with those who visit, purchase and consume it. The embarrassment becomes more vivid with a single symbolic focal point for negative feelings. In a similar vein, embarrassment was also evident toward those who sought to identify with a faked or imitation brand. In such situations, the embarrassment was more akin to sympathy, even antipathy toward the recipient. One participant described occasions in which she would always look down to check whether a passer-by was indeed wearing original 'ugg' boots, identified by their minimal label on the back heel. When noticing individuals wearing the fake version without the original label, she felt embarrassed that such individu-

als should be seeking a shared identity with genuine 'ugg' owners. The concept of a shared mental image (Dobni and Zinkhan 1990) was therefore compromised and negative emotions are fostered.

Participants described how brand names and logos were sometimes covered over to avoid potential embarrassment including the removal of labels from bottles of own-label water, the covering up of laptop logos, the scratching of a brand name off a skateboard with childish associations and the customization of a fashion brand label to disguise its true provenance. In the example below, the increased importance of ethical credentials for branded foods is evident in the actions of a mother seeking to avoid embarrassment when serving coffee. The mere sight of the wrong label was sufficient to provoke a negative reaction as Judith tells us:

Take my mother—she would be embarrassed to buy a brand that was not ethical. She would be embarrassed to say to her friends that it was not ethical so she would be embarrassed to buy Nestle. I remember when we were growing up and my brother Stephen really wanted something from Nestle and she would buy it and hide it in the cupboard or put it in a different package so that when her friends came round, they would not see she had bought Nestle.

In common with theories of symbolic consumption and image transfer, there were many examples of anticipated embarrassment because of the negative associations these might infer:

Mediums of branded embarrassment

Studies have shown that advertising socially sensitive products can cause embarrassment through the awkward nature of how the product is promoted, classically through its advertising, causing feelings of awkwardness and discomfort (Ray 2001). This research suggests that embarrassment can also be caused through the branded communication, creating a sense of embarrassment in a product category not normally associated with embarrassment. Examples centered around either the style of the advertising or the characteristics of the source celebrity used to communicate the branded message. Carlenes explain why she would be embarrassed to be associated with a perfume promoted by an infamous UK celebrity:

I would really have to push myself before I would buy it. Because I just think that it is the tackiest concept in the world and that I would just feel really embarrassed if someone said "oh what are you wearing" and I would have to say "oh, it's Jade perfume"—I would just feel that would be really embarrassing.

In other commonly cited examples, several participants claimed to no longer shop at a well known frozen foods retailer because of a recent association with a fallen pop celebrity, Kerry Katona. Once an ideal role model for families with young children, the celebrity suffered a downward slide in popularity with several high profile incidents eroding her family-friendly image. For Gary, who took pride in the quality of his cooking, the negative brand associations caused by the fallen celebrity were enough to cause acute embarrassment avoidance.

Beyond the negative associations of celebrity promotion, sometimes the style and tone of the advertising was sufficient to cause mild forms of embarrassment causing the viewer to 'cringe' and feel negatively disposed toward the advertiser. Although such examples were often 'enjoyed' for their awfulness, any thoughts of association with the advertiser would undoubtedly have led to personal ridicule and social stigma. Examples discussed included past advertising for Ferrero Rocher, current campaigns for Esure online insurance and finally a well known DIY chain.

DISCUSSION AND CONCLUSIONS

A review of the literature highlights how previous studies focusing on the consuming aspects of embarrassment take little or no account of anticipated or experienced embarrassment centered on the 'branded encounter'. Our findings confirm that this is rich territory to explore; the embedded nature of brand associations, image and meanings in adolescents' everyday lives making experiences of embarrassment almost inevitable. Brand embarrassment was found to be influenced by the symbiotic relationships between the *personal-self* and individuals' *branded relationships*. The findings enhance our understanding of the processes of advanced socialization, identifying how issues of status and class, age and generational differences, interaction within and between groups, social transitions and finally the development of self-identity contribute toward feelings of embarrassment when faced by negative branded encounters. Given the brand-saturated society through which adolescents now navigate, such feelings are widespread. This research gave rise to a range of behavioral consequences, from playful teasing and awkwardness through to possible long-term harm from social stigma and even bullying.

The research also provides a bridge between our understanding of embarrassment and the symbolic consumption of branded products and services. It recognizes the symbolic importance of consumption during adolescent years (Belk et al. 1992) but refines our understanding of how branded associations, images and meaning contribute toward negative as well as positive emotional feelings amongst adolescents (Chaplin and John 2005) through the conceptual lens of embarrassment.

We recognize that this is a small scale study with an emphasis at this stage on exploration but believe it provides fertile ground for continued extensive research which seeks to examine the conceptual links between causes, nature and consequences of brand embarrassment.

Extending the Research in Relation to Materialism and Life Satisfaction

Eda Gurel Atay, University of Oregon, USA

M. Joseph Sirgy, Virginia Polytechnic Institute and State University, USA

Muris Cicic, University of Sarajevo, Bosnia and Herzegovina

Melika Husic, University of Sarajevo, Bosnia and Herzegovina

ABSTRACT

This paper builds on Sirgy's (1998) theory of materialism by integrating exposure to materialistic advertising and social influence into a more comprehensive model. The data collected in Bosnia/Herzegovina showed that exposure to materialistic advertising and social influence contribute to materialism. Materialism, in turn, leads to the use of all types of standard of comparisons (affective- and cognitive-based expectations) to make judgments about standard of living. As the use of these standards of comparisons increases, people start to evaluate their standard of living more negatively, and this negative evaluations of standard of living leads to dissatisfaction with life.

INTRODUCTION

Materialism, defined as "the importance ascribed to the ownership and acquisition of material goods in achieving major life goals or desired states" (Richins 2004, pg. 210), has been studied extensively in the past 20 years. Several studies demonstrated that the more materialistic people are less satisfied with their lives than their less materialistic counterparts because the more materialistic people believe that any given level of possessions is inadequate to meet their living standards. (La Barbera and Gurhan 1997). For instance, Belk (1984) found that aspects of materialism (i.e. possessiveness, nongenerosity, and envy) were negatively related to happiness and life satisfaction. Similarly, Richins and Dawson (1992) found a negative correlation between life satisfaction and three subdimensions of materialism (centrality, success, and happiness). Sirgy, Lee, Larsen, and Wright (1998) also were able to demonstrate that materialistic people are less satisfied with their material possessions and less satisfied with life than non-materialistic people. However, these findings did not explain the negative relationship between materialism and life satisfaction. To address this issue, Sirgy (1998) advanced an explanation to account for this negative relationship. The gist of the explanation is that materialistic people have inflated expectations of their standard of living, whereas non-materialistic people have realistic expectations. These inflated expectations cause materialistic people to evaluate their standard of living negatively. This negative affect spills over to judgments of life overall, making materialistic people feel dissatisfied with life. Thus, one goal of this paper is to test this explanation in a formal way.

Our second goal is to further develop the research tying TV viewership to materialism (e.g., Goldberg and Gorn 1978; Greenberg and Brand 1993; Rahtz, Sirgy, and Meadow, 1989). For instance, Sirgy et al. (1998) were able to empirically demonstrate that TV viewership contributes to materialism, which in turn plays an important role in negative evaluations of standard of living and life dissatisfaction. How? We designed our study to help answer this question. Specifically, we believe that TV viewership affects materialism through exposure to materialistic advertising. That is, exposure to ads that links consumer goods and services with status and prestige is hypothesized to be a key factor influencing the development of materialism (cf. Moschis and Moore 1982; Buijzen and Valkenburg 2003; Pine and Nash 2002).

HOW DOES MATERIALISM LEAD TO LIFE DISSATISFACTION?

Sirgy (1998) developed a theory explaining how materialism leads to life dissatisfaction. He reasoned that in evaluating standard of living, materialistic people tend to employ affective-based expectations (e.g., ideal, deserved, and need-based expectations) rather than cognitive-based expectations (e.g., past, predictive, and ability-based expectations). Affective-based expectations are value-laden and they lead to experiencing intense emotions. These emotions can be positive feelings of elation, joy, and pride as well as negative feelings of anger, envy, and possessiveness. In contrast, cognitive-based expectations generate cognitive elaboration in evaluations of one's standard of living.

There are at least three types of affective-based expectations. The first type is *ideal expectations*. Ideal expectations are standards of comparisons based on remote referents rather than situational ones. For example, an ideal expectation of becoming "filthy rich" is remote in the sense that is cultivated by adopting standards and goals of people that are imaginary, distant, and based on vicarious experiences not grounded by the reality of one's situation. Materialistic people are more likely to compare their own standard of living with people who are "filthy rich" making them feel dissatisfied with their own standard of living. That ideal image of being "filthy rich" may be an image cultivated from watching too much television and seeing the lives of the rich and famous—remote referents. The second type of affective-based expectations is *deserved expectations*. This type of expectations reflects the tendency to make equity-based comparisons involving income and work. Materialistic people, compared to their non-materialistic counterparts, tend to think that they work harder than others but earn less. These equity-based comparisons generate feelings of injustice, anger, or envy. Lastly, *minimum-need expectations* of a standard of living reflect spending money to meet minimum (basic) needs. Materialistic people believe that they need more money to make ends meet. That is, their basic needs tend to be much more inflated than non-materialistic people.

In contrast to materialistic people, people who are not materialistic are more likely to use cognitive-based expectations in evaluating their standard of living. For instance, they may compare their standard of living with their *past* (their past material possessions). That is, nonmaterialistic people evaluate their income by assessing how far they have come along—compared to last year, a couple of years ago, or further back in time. Alternatively, non-materialistic people tend to evaluate their standard of living using *predictive expectations* (expected future wealth). Another type of cognitive-based expectations reflects the perceptions of *ability* to achieve in life a certain standard of living. That is, non-materialistic people use their perception of their ability to achieve a certain amount of wealth based on their education and occupational skills in evaluating their standard of living.

Overall, affective-based expectations can be viewed as unrealistic and inflated goals that result in dissatisfaction with standard of living, whereas cognitive-based expectations are more realistic and non-inflated goals. Evaluations of standard of living based on

cognitive-based expectations are not likely to lead to feelings of dissatisfaction with one's standard of living.

Based on the preceding discussion, our study will test the following hypotheses with respect to the relationships between materialism and the use of specific types of expectations in evaluating one's standard of living:

- H1a: Materialistic people are more likely to use ideal expectations in evaluating their standard of living than non-materialistic people.*
- H1b: Materialistic people are more likely to use deserved expectations in evaluating their standard of living than non-materialistic people.*
- H1c: Materialistic people are more likely to use minimum need expectations in evaluating their standard of living than non-materialistic people.*
- H1d: Non-materialistic people are more likely to use past expectations in evaluating their standard of living than materialistic people.*
- H1e: Non-materialistic people are more likely to use predictive expectations in evaluating their standard of living than materialistic people.*
- H1f: Non-materialistic people are more likely to use ability expectations in evaluating their standard of living than materialistic people.*

Furthermore, our study will test the following hypotheses with respect to the relationships between the frequency of using certain types of expectations of standard of living and satisfaction with standard of living:

- H2a: The greater the frequency of evaluation of standard of living based on ideal expectations, the lower the satisfaction with standard of living.*
- H2b: The greater the frequency of evaluation of standard of living based on deserved expectations, the lower the satisfaction with standard of living.*
- H2c: The greater the frequency of evaluation of standard of living based on minimum-need expectations, the lower the satisfaction with standard of living.*
- H2d: The greater the frequency of evaluation of standard of living based on past expectations, the higher the satisfaction with standard of living.*
- H2e: The greater the frequency of evaluation of standard of living based on predictive expectations, the higher the satisfaction with standard of living.*
- H2f: The greater the frequency of evaluation of standard of living based on ability expectations, the higher the satisfaction with standard of living.*

Feelings of satisfaction or dissatisfaction with standard of living plays an important role in the evaluation of life overall. There is a huge literature and much empirical evidence in the quality-of-life literature that suggests that life satisfaction is a judgment made by evaluating a variety of life domains such as leisure life, social life, work life, family life, spiritual life, and material life. The latter (material life) reflects one's overall feelings related to one's standard of living. Thus, life satisfaction is determined mostly by evaluations of important life domains, including material life (see Diener 1984, and Diener et al 1999 for a review of that literature). Based on the preceding discussion, our study will test the following hypothesis:

- H3: The higher the satisfaction with standard of living the higher the satisfaction with life.*

HOW DOES TV VIEWERSHIP AFFECT MATERIALISM?

One of the most examined antecedents of materialism is *TV viewership* (e.g., Goldberg and Gorn 1978; Greenberg and Brand 1993; Rahtz, Sirgy, and Meadow, 1989). For instance, Sirgy et al. (1998) were able to empirically demonstrate that TV viewership contributes to materialism, which in turn plays an important role in negative evaluations of standard of living and life dissatisfaction. However, *exposure to materialistic advertising* might mediate the relationship between TV viewership and materialism. In other words, TV viewing might lead to exposure to materialistic advertising, which in turn, augments materialism. Therefore, exposure to ads that links consumer goods and services with status and prestige is hypothesized to be a key factor influencing materialism (Moschis and Moore 1982; Buijzen and Valkenburg 2003; Pine and Nash 2002). Therefore, our study will test the following hypothesis:

- H4a: The higher the exposure to materialistic advertising the greater the materialism.*
- H4b: The greater the TV viewership the higher the exposure to materialistic advertising.*

Social influence has also been found as an antecedent of materialism (e.g., Churchill and Moschis 1979; Clark, Martin, and Bush 2001). Social influence, in this context, can be defined as the impact of family and peers on consumer behavior. Moschis and Moore (1979), for instance, found that family communication structures influences adolescents' materialism levels. Similarly, Churchill and Moschis (1979) found that materialism levels of children tended to increase as the frequency of communication with peers increased. Therefore, based on previous studies, it can be said that there is a positive relationship between materialism and social influence. Formally stated:

- H5: The greater the social influence the higher the materialism.*

THE OVERALL HYPOTHESIZED MODEL

Our overall hypothesized model builds on Sirgy's (1998) theory of materialism by integrating TV viewership, exposure to materialistic advertising, and social influence into a more comprehensive model. Specifically, it is hypothesized that TV viewership contributes significantly to exposure to materialistic advertising. Exposure to materialistic advertising, in addition to social influence in buying behavior, contributes significantly to materialism. Materialism, in turn, contributes to setting affective-based (inflated and unrealistic) expectations of standard of living. Materialism and inflated, unrealistic expectations are negatively related to the satisfaction with standard of living (SOL). Satisfaction with SOL, on the other hand, contributes to life satisfaction. The conceptual model depicting these hypothesized relationships is shown in Figure 1.

METHOD

To test the conceptual model depicted in Figure 1, a consumer survey was conducted in a major city in Bosnia and Herzegovina. First, consistent with the Anderson and Gerbing's (1988) 2-step method, the measurement model was estimated in the first step. Then, in the second step, the structural model was estimated and

FIGURE 1
The Conceptual Model Linking TV Viewership with Life Satisfaction

modified. LISREL 8.80 (Joreskog and Sorbom 2006) was used to analyze the covariance matrices in all analyses.

Sample

The data were collected from 301 adults in Bosnia and Herzegovina in 2007. Cluster sampling technique was used to collect the data. Specifically, the city was divided into neighborhoods and these neighborhoods were categorized as high, medium, and low income. After selecting two sample neighborhoods from each category, the researcher used the systematic random sampling to collect survey data. Once a potential respondent agreed to complete the questionnaire, the researcher made arrangements to pick up the questionnaires 4-7 days later. One hundred and one, 100, and 100 questionnaires were collected from low, medium, and high-income neighborhoods, respectively. Of 301 respondents, 120 (39.9%) were men, 180 (59.8%) were women, and gender was missing for one participant. The age of respondents ranged from 18 to 84 with a mean of 36.36. The percentage of missing data was less than 5% for each variable and those missing data were randomly distributed. Therefore, they were handled by using maximum likelihood estimation.

Measures

TV viewership. To measure TV viewership, three questions were adapted from Churchill and Moschis (1979). Two questions assessed how many hours they spent watching television in a day during the weekdays and weekend. The response sets included 17 responses ranged from 0 to 16+ hours. The third question assessed how many hours they watched television in total per week and the response set included seven categories.

Exposure to materialistic advertising. Participants were instructed to think about their image of most of the ads they had noticed about consumer goods and services in the last few weeks. Then, they were asked to describe their images of these ads along the following attributes on 7-point scale: high status/low status; affluent/non-affluent; high prestige/low prestige; high class/low

class; extraordinary/ordinary; glamorous/non-glamorous; luxurious/non-luxurious; expensive/not-expensive; for the rich/for the poor; and snobbish/non-snobbish. The first five of these attributes reflect lifestyles while the second half reflects the monetary values of goods/services. Therefore, this construct was considered a two-factor correlated construct. Indeed, an exploratory factor analysis and a confirmatory factor analysis verified this 2-factor structure (Satorra-Bentler scaled χ^2 (34, N=301)=67.17, $p<.001$; CFI=.99; SRMR=.044; and RMSEA=.057).

Social influence. Social influence was conceptualized as the impacts of friends and family on buying behaviors. It was measured by three questions adapted from Churchill and Moschis (1979) on five-point scales (1=all of the time, 5=never). These items assessed whether participants talked with their friends and family about buying things and whether they learned from them what to look for in buying things.

Materialism. Materialism was measured by using nine items (Gurel-Atay and Sirgy 2007) with 5-point scales (1=strongly agree, 5=strongly disagree). Materialism was conceptualized as a 3-factor construct: happiness (the belief that material possessions bring happiness to life; e.g., "Having luxury items is important to a happy life."), success (the belief that possessions symbolize achievement and success; e.g., "I feel good when I buy expensive things. People think of me as a success."), and distinctiveness (the belief that possessions make people feel distinctive from others; e.g., "I usually buy expensive things that make me look distinctive").

Standards of comparison (affective and cognitive-based expectations of standard of living). We developed the measure of standards of comparison for this study. Respondents were provided with the following prompt: "Most people have strong feelings about their standard of living because they compare their family's current financial situation with different types of standards of comparisons. The questions below are designed to capture the *standard of comparison* you use in evaluating your family's standard of living." Single items were used to measure each of the six standards of comparison in evaluating standard of living on ten-point scales

where 1 means “no, my feelings about my standard of living are not based on this standard of comparison” and 10 means “yes, my feelings about my standard of living are based on this standard of comparison.”

Satisfaction with standard of living (SOL). Two sets of questions were developed to measure satisfaction with SOL. The first set included two Likert-type questions. One of the questions asked respondents to describe their current financial situation of their immediate family (1=very poor; 5=very healthy), while the other question probed the feelings of respondents about their family’s current financial situation (1=very bad; 5=very good). The second set included five semantic differential items (Ogden and Venkat 2001). Specifically, participants were asked to report their feelings about the things their family owns, their family’s standard of living, and their family’s financial situation overall on a seven-point scale (happy/angry; good/bad; elated/tense; contented/frustrated; fulfilled/disappointed; and pleased/displeased).

Life satisfaction. To measure life satisfaction, short version of Campbell, Converse, and Rodgers (1976) scale was used. Participants were asked to rate their life on the following seven items by using seven-point scales: boring/interesting; enjoyable/miserable; useless/worthwhile; full/empty; discouraging/helpful; and disappointing/rewarding; and brings the best in me/doesn’t give me much chance.

Item Parceling: Before conducting the analyses, parceling was used on four sets of measures: exposure to materialistic advertising, materialism, satisfaction with SOL, and life satisfaction. Based on Bagozzi and Heatherton’s (1994) advice, at least two parcels were created for each construct to account for measurement error. Because exposure to materialistic advertising is considered as a two-factor construct, the indicators of each factor were summed to develop two parcels. Similarly, each dimension of materialism constituted a parcel. That is, materialism was represented by three parcels. Satisfaction with SOL, on the other hand, was represented by two parcels. One parcel included the Likert-type items while the other parcel included six semantic differential items. To develop the item parcels for life satisfaction, this measure was subjected to one-factor model. Then, the items were rank ordered based on their loadings on this factor and assigned one of two groups to provide the item-to-construct balance (Little, Cunningham, Shahar, and Widaman 2002; Russell, Kahn, Spoth, and Altmaier 1998). That is, the average loadings of each item parcel on the factor were approximately equal. These item parcels were used in subsequent analyses.

RESULTS

Measurement Model Results

Prior to conducting the CFA, normality of the observed variables was inspected. Some of the variables had high skewness and kurtosis values. Even though maximum likelihood (ML) estimation method is considered to be very robust even with highly skewed/kurtosis data, West, Finch, and Curran (1995) argue that ML produces too high chi-square statistic and leads rejecting too many true models when the variables are highly nonnormal. To deal with this problem, Satorra-Bentler correction was reported in all analyses.

To estimate the measurement model, the constructs were modeled as freely correlated first-order factors with their respective indicators. The Anderson and Gerbing (1988) convention was followed to fix the loadings and measurement errors of item parcels. First, composite reliabilities for each item parcel were computed. Then, the highest composite reliability for a given construct was chosen. For instance, materialism had three parcels (i.e. happiness, success, and distinctiveness) and composite reliabilities for each of

these parcels were .899, .924, and .929, respectively. Because distinctiveness had the highest value, the loading of distinctiveness on materialism was set equal to the square root of its composite reliability. Lastly, the measurement error of distinctiveness was set to one minus its composite reliability. The same procedure was followed for exposure to materialistic advertising, satisfaction with SOL, and life satisfaction. For the constructs with single indicators (i.e. standard of comparison constructs), the loadings were set to unity and measurement errors were set to .25, which was the smallest measurement error value found for the other, estimated error variances (Anderson and Gerbing, 1988).

Satorra-Bentler scaled chi-square value was 306.83 with 163 degrees of freedom and it was significant at .001. Even though chi-square statistic was significant, other goodness of fit statistics suggested a close fit to the data with the root mean square error of approximation (RMSEA; Steiger and Lind 1980; Browne and Cudeck, 1993)=.054 (confidence interval=.045-.063, PCLOSE=.22), Bentler’s (1990) comparative fit index (CFI)=.96, and standardized root mean square residual (SRMR; Bentler 1995)=.051. Therefore, it was decided that fit was adequate.

The summary of tests related to the convergent validity (internal consistency) of the constructs and item parcels is included in Table 1. According to Fornell and Larcker (1981), average variance extracted (AVE) by each construct should be greater than .50 and the composite reliability of a factor should be equal to or greater than .60 to verify convergent validity. As Table 1 shows, the only construct that had AVE less than .50 was social influence and its AVE was .49. All other AVE values ranged from .55 to .87. Composite reliabilities were greater than .60 with a range of .74 to .94. Similarly, coefficient alphas were high and ranged from .73 to .93 with a mean of .83. Furthermore, all factor loadings were significant at .05 level. All these results imply that convergent validity (internal consistency) was satisfactory for the constructs.

To test for discriminant validity, the squares of correlations between any two constructs were compared with the AVE estimates of those two constructs (Fornell and Larcker 1981). Because the AVE for each construct was greater than its squared correlation with any other construct, discriminant validity was supported.

Structural Model Results

Table 2 presents the results for the original model as shown in Figure 1. As can be seen from the table, the fit of the model to the data was not adequate. The Satorra-Bentler scaled chi-square value was significant and other fit indices were not in acceptable ranges. The results showed that the path from TV viewership to exposure to materialistic advertising was nonsignificant. Indeed, only 1% of the variance in exposure to materialistic advertising was explained. Therefore, this path was dropped from the analysis by removing the TV viewership construct from the model. As stated in the methods section, standards of comparison constructs were represented by single indicators. Inspection of modification indices revealed that these indicators were interrelated. Moreover, the standardized residuals between these single indicators were large (greater than 2.58), meaning that those residuals were correlated. Further, modification indices for the *psi* matrix (the matrix that includes structural residuals) showed that the residuals of the standard of comparison constructs are correlated. All these findings implied that these constructs have something in common. Indeed, they are all types, or standards, of comparison people can use to evaluate their standard of living. Theoretically, one can propose that materialistic people use all kinds of comparisons more often than nonmaterialistic people do. Actually, the signs of the path coefficients from materialism to each of these standards of comparison were positive. Therefore, it was decided to include a single construct called

TABLE 1
INTERNAL CONSISTENCY RESULTS (N=301)

	Coefficient Alpha	Composite Reliability	AVE
TV Viewership	0.792	0.839	0.643
Social Influence	0.732	0.737	0.490
Materialistic Ad Exposure		0.843	0.735
Parcel 1: Lifestyles	0.888	0.902	0.650
Parcel 2: Monetary Values	0.868	0.874	0.580
Materialism		0.863	0.683
Parcel 1: Happiness	0.866	0.899	0.750
Parcel 2: Success	0.891	0.924	0.803
Parcel 3: Distinctiveness	0.892	0.929	0.813
Satisfaction with SOL		0.827	0.715
Parcel 1: Likert type questions	.642*	0.900	0.810
Parcel 2: Semantic differential	0.932	0.940	0.730
Life Satisfaction		0.898	0.815
Parcel 1	0.745	0.794	0.563
Parcel 2	0.800	0.826	0.545

Notes. AVE=Average variance explained.

Composite reliability and AVE values for parcels were calculated from separately conducted confirmatory factor analyses; composite reliability and AVE values for latent constructs were calculated from the final confirmatory factor analysis that included all constructs.

* Pearson correlation for two items

TABLE 2
STRUCTURAL MODEL RESULTS

Model Tested	χ^2	df	p	CFI	SRMR	RMSEA (C.I.)
Original Model	867.56	183	.001	.820	.110	.112 (.110-.112)
Modified Model	355.02	134	.001	.920	.097	.074 (.065-.084)

Notes. χ^2 = Satorra-Bentler Scaled Chi-Square; CFI=Comparative Fit Index; SRMR=Standardized Root Mean Square Residual; RMSEA (C.I.)=Root Mean Square Error of Approximation (Confidence Interval); N=301

standard of comparison in the model and use six types of comparison as indicators of this construct. This model is shown in Figure 2.

The modified model fit the data better with Satorra-Bentler scaled χ^2 (134, N=301)=355.02. Even though the chi-square was significant, it can be expected given the relatively large sample size. Other goodness of fit statistics were in acceptable ranges: CFI=.92, SRMR=.097, and RMSEA=.074.

Table 3 shows unstandardized parameters with standard deviations, the standardized parameters, critical ratios that were calculated by dividing unstandardized parameters by the estimates of corresponding standard errors, and the level of significance (*p* values) for parameters. As expected, materialism was affected significantly by both exposure to materialistic advertising and social influence. Approximately, 11% of the variance in materialism was explained by these two variables. Materialism, in turn, explained 10% of the variance in standard of comparison. The positive path coefficient between these two constructs suggests that

as materialism increases, the use of standards of comparison increases. Standard of comparison, on the other hand, influenced satisfaction with SOL negatively. That is, as people use standards of comparison to evaluate their SOL more often, they become more dissatisfied with their SOL. Eleven percent of the variance in satisfaction with SOL was explained by standard of comparison. As predicted, satisfaction with SOL contributed to life satisfaction positively. Twenty six percent of the variance in life satisfaction was explained by satisfaction with SOL. Overall, general support was found for the modified model.

DISCUSSION

Two goals guided the current study. The first goal was to test the theoretical explanation of the negative relationship between materialism and life satisfaction as provided by Sirgy (1998). After modifying the original model, the results provided a moderately good fit to the data. As expected, all relationships between variables

FIGURE 2
The Modified Model

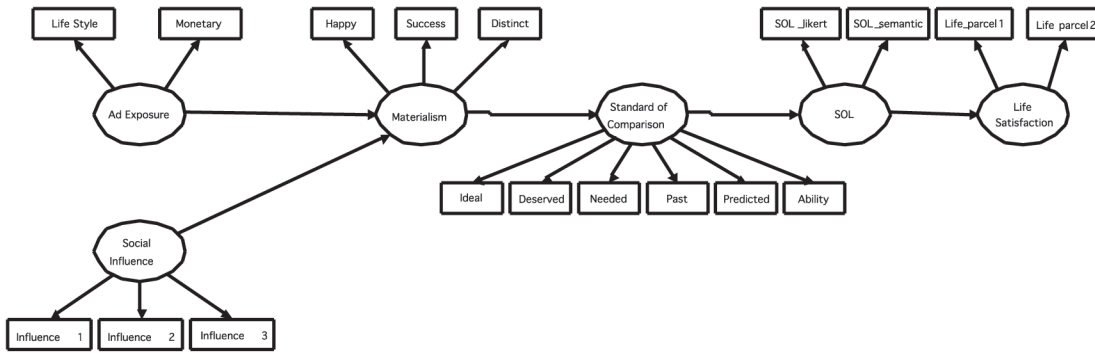

TABLE 3
PARAMETER ESTIMATES

Path	ML Estimates (Std. Dev.)	Std. ML Estimates	C. R.	p values
Materialistic Ad Exposure → Materialism	0.06 (0.02)	.15	3.00	0.003
Social Influence → Materialism	1.23 (0.29)	.30	4.24	0.001
Materialism → Standard of Comparison	0.26 (0.06)	.31	4.33	0.001
Standard of Comparison → Satisfaction with SOL	-0.53 (0.24)	-.16	-2.21	0.027
Satisfaction with SOL → Life Satisfaction	0.34 (0.05)	.51	6.80	0.001

Notes. ML=Maximum likelihood; Std. Dev.=standard deviation; C.R.=critical ratio

were significant. The study findings did not support Sirgy’s explanation but the same findings shed new light on a possible different explanation: the more materialistic people are, the more they seem to use all types of standard of comparisons (affective- and cognitive-based expectations) to make judgments about their standard of living. And the more they use these standards of comparison (irrespective of whether these expectations are affective or cognitive) the more they judge their standard of living negatively. The more negative their evaluations of their standard of living the more they feel dissatisfied with their lives. Of course we expected that the more-materialistic people use affective-based standards of comparison (ideal-, deserved-, and minimum-need expectations) the more likely they are to evaluate their standard of living negatively. But we didn’t expect the fact that the more they use cognitive-based expectations the more likely they are to make negative evaluations about their standard of living. We expected the opposite. Perhaps the reality is that the more people are materialistic the more they preoccupy themselves with all kinds of thoughts related to standard of living. These thoughts are likely to conjure up all kinds of expectations, cognitive and affective-based expectations. And the more they think about their standard of living, the more their expectations become inflated and unrealistic. This may be one

explanation for our study findings. Another explanation may be that our standard-of-comparison measures were not sensitive enough to force respondents to make distinctions among cognitive versus affective-based expectations. Yet another methodological explanation may be a response bias effect. Respondents were biased by the way these measures captured their expectations and responded in the same manner across all six items designed to capture these expectations. Future research should explore this issue further and conduct studies with more sensitive expectation measures. The expectation measures should be captured with multiple indicators and the placement of these measures should be varied in the survey questionnaire to minimize response bias.

The second goal of this study was to test the explanation that materialism is not directly affected by TV viewership but through exposure to materialistic advertising (controlling for the effects of social influence). The study findings showed that materialism can indeed be predicted significantly by exposure to materialistic advertising and social influence. However, the same data failed to show that TV viewership has any predictive effects on exposure to materialistic advertising. Why did our study fail to replicate previous studies linking TV viewership with materialism? Is it possible that this finding is idiosyncratic (i.e., an outlier)? That is, could it be

that television advertising in Bosnia/Herzegovina is significantly different from advertising in other countries (e.g., USA) that the frequency of television watching may not influence consumers' recall of recent advertising as being status-oriented? Future research should explore this issue by collecting data across different countries (including Bosnia/Herzegovina) and conduct cross-cultural analysis.

There are additional study limitations that should be aired. First, all variables were measured concurrently. Therefore, the statistical relationships among the constructs may not reflect causation. Future research should conduct longitudinal studies and perhaps experimental studies too. Another limitation may be related to the sample. The percentage of females participated in this study was higher than that of males. The study should be replicated with equal percentages of males and females. In addition, all analyses were conducted on a single sample. The findings should be replicated with a new sample. Lastly, the data were collected in Bosnia/Herzegovina, a collectivist country. Cross-validation of results is needed across different cultures, to include both individualistic and collectivistic cultures.

At Face Value: Visual Antecedents of Impression Formation in Servicescapes

Joost W. M. Verhoeven, University of Twente, The Netherlands

Ad Pruyn, University of Twente, The Netherlands

ABSTRACT

Consumers may base employee impressions on physical appearance and displayed personal objects. In a scenario experiment, using photos of a physician and a 360-degree panorama of his consultation room, we examined the effects of appearance and tangibles on impression formation. Study 1 shows that observers employ various strategies of combining information from different sources when forming an impression of the employee's friendliness and competence. Whereas previous research has shown that impression formation based on personal appearances proceeds in an automatic fashion, the findings of study 2 indicate that impression formation grounded in the perception of tangibles requires more elaborate processing.

INTRODUCTION

In the MTV Dating Show "Room Raiders", a young woman examines the bedrooms of three men to decide who she would like to go out with. Through a careful investigation of the rooms she tries to find out as much as possible about the tastes, hobbies, and personalities of the three candidates. For instance, upon finding a comic book, she may draw the conclusion that the guy is immature, a snowboard may signal that he is adventurous and sporty, while a messy room may suggest that he is too lazy to clean up. Without meeting even one of them, she has formed a detailed impression of the three men and she has made her decision. When she is to announce the winner, she meets the three candidates for the very first time. Even before any interaction has taken place, she is confronted with a new wealth of information: she sees what the three guys look like. However, it's too late to change her mind.

This example illustrates how people find out more about others by studying their personal living environments. By altering and customizing personal working- and living environments people express and confirm their (desired) identities (Belk 1988; Schlenker 1985). Consequently, the environments that people live in are rich with information about the personality, values and lifestyle of the occupant (Gosling *et al.* 2002). Observers, in turn, use those elements of the tangible environment as a 'lens' through which they view underlying constructs such as the personality, preferences, and lifestyle of the occupant (Brunswick 1956). In addition, personality impressions are affected by personal appearance. For instance, people use others' facial features to infer the personality (Berry and Wero 1993). In all, the example shows how people use different sources of information to assemble personality impressions.

The role of visual cues in social perception is not only interesting from the viewpoint of interpersonal communication; it is particularly prevalent in customer judgments of services. Since in services the 'product' consists of actions or performances rather than goods, the impressions consumers hold of service employees are central in the quality perception and satisfaction (Zeithaml, Bitner and Gremler 2006). As customers largely lack the information and skills to reliably assess the service providers' capacities, they search for alternative indicators (Hoffman and Bateson 2006; Zeithaml 1988). Visual cues may be used as such alternative indicators. In the present studies we will focus on the ways in which a consumer bases an impression of a service provider on the tangible service environment and personal appearance.

PERSONAL APPEARANCE AND IMPRESSION FORMATION

Personal appearance may be the most direct source of information about other people (Shevlin *et al.* 2003). Zero-acquaintance studies have found that personality ratings of strangers that are solely based on personal appearance are significantly correlated with self-ratings (Borkenau and Liebler 1992) and personality ratings of acquaintances (Berry 1990; Borkenau and Liebler 1993). This does not only imply that others use personal appearance as a source of information in impression formation, but that this information, at least with respect to some personality traits, is often fairly accurate (Shevlin *et al.* 2003).

In many services, competence appears to be among the most important traits that consumers use when they evaluate employees (Czepiel, Solomon and Surprenant 1985; Gronroos 2000). Even though service encounters usually comprise rather short interactions with service employees who are usually unknown to the customer, customers are generally quite capable of forming a first impression based on brief exposures to employee appearance (Czepiel *et al.* 1985; Grandey *et al.* 2005). In the political domain, Todorov (2005) illustrated the far-reaching consequences of competence judgments at zero acquaintance: Competence judgments based solely on minimal exposure to photographs of politicians significantly predicted the outcomes of elections for the U.S. Congress. Impressions following from zero-acquaintance seem to be primarily based on faces (Berry and Wero 1993). However, besides faces, a number of other appearance attributes cues may be at play, such as clothing (Mangum *et al.* 1997), posture, and locomotion. In this article, we will argue that personal attributes may also be incorporated into impressions of service employees.

TANGIBLE ENVIRONMENTS AND IMPRESSION FORMATION

Individuals design and alter their environments in such a way that they reinforce and express their personal identities (Belk 1988). Observers are confronted with this information, which they process and use in impression formation processes (Gosling *et al.* 2002). Several studies have examined the effects of tangibles on perceived traits of occupants (e.g., Burroughs, Drews and Hallman 1991; Gosling *et al.* 2002; Tedeschi and Melburg 1984). Occupants of high-status offices, for instance, are judged as more neat, critical, sincere, intelligent and less noisy than occupants of low-status offices (Cherulnik and Sounders 1984). Likewise, friendliness perceptions may be based on furniture arrangement: In an 'open' office setup (desk against the wall), occupants are perceived as more friendly than in a closed setup (Morrow and McElroy 1981). In a physician's consultation room, an impressive set of medical handbooks and a diploma on the wall signal competence, whereas personal objects reinforce the image of a friendly and involved person (Verhoeven, van Rompay and Pruyn 2007). These studies all illustrate how, in the eyes of observers, certain characteristics of the environment 'transfer' to the occupant.

Gosling and colleagues (2002) proposed two mechanisms through which these inferences may be made. First, inferences may be the result of stereotype activation. Some object or symbol in the environment may trigger a stereotype (Kay *et al.* 2004), which is

typically associated with a set of traits. Observers, in turn, may more or less automatically infer that these stereotypical traits apply to the occupant of the place. For instance, a poster with a peace symbol may activate the hippie stereotype, which may lead observers to believe that the occupant is laid back and is sympathetic towards certain social and political movements. Second, inferences may be the result of a two-step inference mechanism. Because behaviors that take place in an environment naturally leave residuals, observers may infer the behaviors that have taken place in an environment from the residues. Subsequently, observers infer the dispositions that underlie these behaviors (Buss and Craik 1983). Upon finding a full ashtray, one may infer that the occupant has been smoking, which may lead the observer to believe that the occupant has certain dispositions that are typical for smokers. In conclusion, tangible possessions on display may affect a wide variety of inferences about the 'displayer'.

HOLISTIC IMPRESSIONS

Personal appearances and tangible environments are seldom perceived in isolation, but observers are usually confronted with these sources of information simultaneously. Their combined effects give rise to a holistic image that shapes consumers experiences (Grove and Fisk 1989). Apart from the importance of congruence among various elements in the servicescape (Mattila and Wirtz 2001), different elements may also complement each other in terms of the meanings that are portrayed. For instance, in a healthcare setting, consumers' needs are typically twofold (Arneill and Devlin 2002; Laine *et al.* 1996). First, one needs to be assured that the care providers have the technical competence needed for successful outcomes (Czepiel *et al.* 1985). Second, patients have a desire for a service provider that shows empathy. In line with Driver and Johnston (2001), we expect that physicians will make the best impression when they express both professional and empathic qualities, through either their appearance or personal environment. In other words, we expect that information from different cues will complement each other. This prediction was tested in study 1. We used a healthcare setting to explore the role of personal appearance and tangibles in impression formation.

STUDY 1

Pretest

To make an informed decision regarding the selection of stimulus material, a pretest was conducted among 41 student (13 men, 28 women; mean age = 20.0, SD = 1.40). They were instructed to carefully watch 10 photos of physicians. The physicians were photographed in white coats, from the waist up without any environmental features visible. They varied in age and appearance. Patients rated the physician's friendliness (6 items, $\alpha = .74$) and competence (13 items, $\alpha = .93$). For study 1, we used photos of the physician (physician 1) that was rated friendly ($M = 7.33$, $SD = .67$), but relatively incompetent ($M = 5.86$, $SD = 1.18$) and the physician (physician 2) that was rated as competent ($M = 7.28$, $SD = .84$), but relatively unfriendly ($M = 6.11$, $SD = .88$). The physicians differed significantly in terms of friendliness as well as anticipated competence: $t(19) = 5.36$, $p < .001$ and $t(19) = -5.21$, $p < .001$ respectively.

Method

In the main study 77 students participated (32 men, 45 women; mean age = 21.0, $SD = 2.37$). Participants were randomly assigned to one of the four cells in a 2 (friendly vs. competent appearance) x 2 (professional vs. personal objects) between-subjects experimental design. They were asked to imagine having an appointment with a lung specialist in a general hospital because of respiration com-

plaints. The patient was asked to take a seat in the consultation room and to wait for the specialist to get ready. Next, participants used a 360 degree panorama photo to look around in the room. Using the mouse, they were able to control the speed and angle of the presentation of the room. This room contained either professional objects (such as a diploma, medical handbooks and scale models of organs) or personal objects (such as decorative sculptures, a miniature sailboat and a shawl of a sports team). After 60 seconds, participants were told the physician came in and his photo appeared on the screen. This was the physician that was rated in the pretest as either friendly but relatively incompetent, or as competent but relatively unfriendly. After exposure to the scenario, the 360 degree panorama, and the photo of the physician, participants were asked to indicate to what extent they thought the physician was competent (13 items, $\alpha = .95$), friendly (6 items, $\alpha = .84$) and to what extent they would be satisfied with this physician (2 items, $r = .70$). All items were scored on 7-point scales.

Results

In an analysis of variance, we found replication of the pretest results: participants rated physician 1 as more friendly ($M = 6.98$, $SD = .75$) than physician 2 ($M = 6.50$, $SD = 1.12$, $F(1,73) = 4.71$, $p = .03$). The environmental manipulation did not exert an effect on perceived friendliness and neither did the interaction between both factors ($F > 1$).

Analysis of variance showed no significant main effects of our manipulations on perceived competence ($F < 1.4$). However, the interaction between both factors was significant: $F(1, 73) = 4.19$, $p = .04$. Analysis of the simple main effects showed that the physician with a friendly appearance was perceived as more competent when he displayed professional ($M = 6.21$, $SD = 1.00$) rather than personal objects ($M = 5.41$, $SD = 1.68$): $F(1,37) = 3.31$, $p = .08$. The physician that looks competent, on the other hand, is judged as competent regardless of the objects he is surrounded with (professional objects: $M = 5.95$, $SD = 1.32$, personal objects: $M = 6.35$, $SD = 1.07$, $F < 1.1$).

Furthermore, results showed a 2 x 2 interaction on anticipated satisfaction (see Figure 1). Examination of the simple effects shows that patients are more satisfied with a physician that looks friendly in a professional consultation room than they are with the same physician in a room with personal possessions: $F(1,37) = 6.05$, $p = .02$. For a physician that looks competent, this effect reverses: $F(1,37) = 3.26$, $p = .08$. The main-effects of both factors are non-significant: $F < 1$.

Discussion

In line with studies in patient satisfaction (Arneill and Devlin 2002; Laine *et al.* 1996), study 1 shows that patients are only satisfied with physicians when they express both their technical and their empathetic qualities. However, the way patients infer competence seems to differ from the way they infer friendliness. Friendliness judgments in our study are based on personal appearance, but not on our manipulation of displayed possessions. On the other hand, when assessing the physician's level of technical competence, patients seem to combine information from different sources (appearance and the tangible environment). Patients infer that a physician is competent when either his appearance or his consultation room signals competence (or both).

The present study is an investigation into the cues that patients use to assess the physician. Many factors may be involved in impression formation. It is very likely that patients use all their senses and cues may include visual, auditory, and even olfactory stimuli (Grove and Fisk 1989). Although our study only examines two visual factors, it does provide us with insights as to how

FIGURE 1
Effects of appearance and tangible objects on anticipated satisfaction.

observers combine information from various sources into one meaningful impression.

First, the effects of our manipulations on perceived friendliness indicate that one cue in the environment may be so dominant that the influences of other sources become negligible. Observers will try to attend to those cues that they believe are most accurate for a specific trait, while ignoring inaccurate cues (Brunswick 1956). For instance, observers may believe that faces are most accurate in conveying information about personalities (Cloonan 2005), whereas physical spaces may be believed to hold cues as to characteristics such as a person's tidiness, values and recreational pursuits (Gosling *et al.* 2002). Hence, when judging information derived from various sources, personal appearance may be thought of as a far more direct and reliable indicator of friendliness than the tangible environment is.

Second, and more interestingly, observers may find ways to combine information from various sources in interesting ways (Grove and Fisk 1989). When inferring the level of competence from indirect cues, the default assumption may be that a physician is competent. This default belief may be so strong that a single (visual) source of information is insufficient to overrule this standard belief. Yet when a number of factors simultaneously reinforce an image that deviates from the default, an observer may discard this default belief.

Finally, when it comes to patient satisfaction, the cues seem to complement each other: patients are only satisfied when personal appearance and possessions have signaled both technical and empathetic qualities (Czepiel *et al.* 1985). It should be noted that patient satisfaction may not only be based on cues that are informative about the primary care provider (in this case the lung specialist), but also on cues that are telling about other care providers (nurses, administrative personnel etc.). Such information was not included in the study.

When consumers are confronted with an employee, they will direct their attention toward the cues they believe most accurately describe this person. As study 1 illustrates, an impression may very well result from a synthesis of different sources of information. However, not all information is processed simultaneously. As an observer's processing capacity is limited, there is a restricted amount of information that can be processed in the immediate stages after perception (Ambady and Rosenthal 1992; Peracchio and Luna 2006). In their two-stage model, Raghbir and Krishna

(1996) suggest that consumer judgments are formed and framed in an initial automatic stage, which is followed by conscious deliberate processing.

Previous research indicates that upon perceiving a target person, people usually incorporate information abstracted from his or her appearance in this initial snap-shot processing stage (Todorov *et al.* 2005). However, it remains unclear in what stage of processing environmental information is attended to. The tangible environment seems to be a rather indirect indicator, requiring more interpretation and hence more elaborate, thoughtful processing. Therefore, we predict that information derived from tangible environments is typically attended to in later stages of information processing. This prediction was tested in study two.

STUDY 2

Method

A total of 126 undergraduate students participated in a single-factor between subjects design. They were invited into the research lab and guided to separate rooms with a computer. Instructions were provided on-screen. Participants were confronted with two photos of physicians in their working environments (at the left and right side of the screen). Next, they were instructed to click on the photo of the physician that they thought was the more competent of the two. The two physicians were selected from the pretest of study one. Their appearance was rated as approximately equally competent ($M = 6.83$, $SD = 1.11$ vs. $M = 6.49$, $SD = .95$; $t(20) = 1.08$, $p > .10$). In every set, one of the physicians was displayed in a room with competence cues (medical handbooks and mock-ups), the other one was displayed with personal objects (decorative sculptures and a set of luxurious toy cars). The position on the screen (left and right) and the appearance of the physician were counterbalanced, so that we can be sure that these factors did not affect the results in any way. Half of the participants were instructed to choose between the photos as fast as possible. The other half of the sample looked at the photos for at least 30 seconds and was subsequently asked to make their decision. This procedure was adopted from Todorov and colleagues (Todorov *et al.* 2005) to measure participants' impressions in the early stages of information processing. We omitted 11 participants from the rapid response condition whose response time was above 3 seconds.

TABLE 1
Choices between rooms as a function of length of exposure

	Consultation room without competence cues	Consultation room with competence cues	Total
t<3 sec	28	25	53
t>30 sec	10	52	62
Total	38	77	115

Results

In line with the pretest, we found that both physicians were chosen as the more competent equally in both the rapid response- and the long exposure condition: $\chi^2(1, 115) = .002$; $p > .10$.

Competence cues in the environment did not exert an effect on the chosen photo when participants responded within 3 seconds, while the vast majority of participants in the long-exposure condition did choose the physician with competence cues over the one without them (see table 1): $\chi^2(1, 115) = 17.40$; $p < .001$. These results confirm the prediction that impression formation based on tangibles requires more elaborate processing: only when participants are given the time for elaborate processing do tangible cues affect their choices.

GENERAL DISCUSSION

“During a consultation there are two people at work. While the doctor is searching for a diagnosis, the patient is quietly summing up the doctor. And it is often the patient who reaches his conclusion first” (Short 1993).

In a healthcare setting, patients may feel like their faith is in the hands of strangers. In such a situation, one naturally feels the need to assess the service provider’s competence level (Czepiel *et al.* 1985). As the results of our studies show, empathic qualities are also required. Customers may turn to both personal appearances and tangible elements in the service environment to assess these characteristics but, in this study, only those cues related to personal appearance are processed in a quick, rapid fashion. Whereas rapid judgments are made without deliberate effort on the part of the consumer, conscious processes, on the other hand, are intentional, controllable and consume cognitive resources (Dijksterhuis *et al.* 2005). The findings reported suggest that this deliberate effort is needed for tangibles to affect impressions. The results from the present studies seem to suggest that in impression formation, tangibles can only be effective when they are consciously being processed. This does not mean that individuals cannot be affected by tangibles at an unconscious level. A considerable and growing body of literature stresses otherwise (Meyers-Levy and Zhu 2007). For instance, Kay *et al.* (2004) showed that, at a subconscious level, objects can prime certain constructs and steer behaviors. However, our results suggest that, when competing, more direct cues are available (such as personal appearance), consumers appear to attend to those cues first. Only later, they direct their attention to tangible cues.

Models of social cognition and decision making are of special interest to our findings. These models posit a distinction between unreflective effortless “system 1” processes and slow, deliberate effortful “system 2” processes (Chaiken and Trope 1999; Kahneman 2003). Many inferences about other people, such as those based on facial expressions, can be characterized as effortless system 1

processes (Todorov and Uleman 2003). Interestingly, person impressions that are formed on-line in the very first encounter can affect subsequent information processing. Arguably, immediate system 1 judgments based on personal appearance can steer the subsequent encoding of environmental cues that are subject to multiple interpretations. This means that tangible competence symbols are likely to be interpreted as sincere and authentic when they are displayed by a person that looks competent, but may be regarded phony when displayed by someone who does not have a competent appearance. Likewise, system 1 processing of facial personality cues can affect the encoding of verbally expressed information.

Apart from the availability of cognitive resources, the extent and elaboration of processing of environmental cues is also likely to vary with customer involvement. Arguably, high-involved customers are more likely to engage in deliberate processing of various sources of information embedded in the servicescape, incorporating effects of tangible elements, whereas low involved customers are less likely to attend to these more ‘subtle’ or indirect sources of information. In addition, elaboration of processing may vary as a function of dispositional differences such as need for cognition (Cacioppo and Petty 1982).

In addition, future research should explore whether other types of environmental factors, such as atmospherics (e.g., scent, color or music) and layout, also affect impression formation processes in the same or different ways as the visual stimuli that were under investigation in the present studies. Arguably, such influences are more pervasive and therefore may be more likely to receive attention in an earlier stage of the impression formation process than the tangible objects discussed in this paper. Furthermore, in future research, ecological validity of scenario methods should be increased by studying consumer responses to (transcripts of) actual interactions that are open to multiple interpretations. This would provide additional proof for the relevance of the findings in actual service encounters. In the meantime, the findings reported confirm the importance of the tangible servicescape in consumer decision-making and hint at the importance of exploring and establishing the ways in which environmental cues are processed.

Disentangling the Effect of Culture and Language on Imagery Generation

Beichen Liang, East Tennessee State University, USA

ABSTRACT

This study attempts to isolate the effect of culture and language on imagery generation. By asking subjects from China, Singapore, and the U.S. to read Chinese and English messages, my findings show that it is not language, but culture, that drives the higher imagery generation capability of the Chinese people. The Chinese generate more mental images than do both Singapore Chinese and Americans, even when all groups are tested in English because Chinese have a predominantly concrete way of thinking. Singapore Chinese generate the same number of images when exposed to both languages because they have a balanced mental representation.

Past research has maintained that certain words have higher imagery value and were more likely to facilitate imagery generation than other words (Paivio and Foth 1970; Paivio 1971; Paivio and Csapo 1973; Paivio, Yuille, and Madigan 1968; Richardson 1980). For example, concrete words, such as apple, watch, or table, are more likely to create an image in one's mind than abstract words, such as love, freedom, or justice.

However, recent studies have shown that these finding on imagery generation may not hold for more distinctive cultures. When exposed to low imagery words, Chinese subjects tend to generate more images than do their American counterparts. However these studies do not differentiate the effect of culture from the effect of language. The high imagery generation capability of the Chinese may be due to a higher imagery value of ideographic language or the Chinese concrete way of thinking. This paper tries to disentangle the effect of culture versus language on imagery generation and examines in more detail which influence, language or culture, will contribute more to the high imagery generation capability of Chinese people.

LANGUAGE AND IMAGERY GENERATION

Language plays an essential role in an individual's cognitive development (Vygotsky 1962) from childhood onwards. First developed as a way of communication, language later becomes an important tool in shaping the cognitive process (Ji, Zhang, and Nisbett 2004). Recent studies in marketing have shown that linguistic differences between the Chinese and English-speaking people can influence their way of thinking (Logan 1986; Nisbett et al. 2001), categorization (Ji, Zhang, and Nisbett 2004), a consumer's verbal information memory (Schmitt, Pan, and Tavassoli 1994), judgment and choice (Schmitt and Zhang 1998), and even verbal processing (Tavassoli, 1999). It is well known that Chinese is an ideographic language while English is an alphabetic language. Such language differences may influence consumers' ability to generate imagery.

The earliest Chinese characters were formed by drawing pictographs. These characters were originally pictures of people, animals, or other objects. For example, the sun was written as , the moon as , water as , and so on. Second, Chinese created indicatives by adding a kind of sign to a character to indicate a certain meaning. For example, by adding a point to “刀” (knife), a new word “刃” (blade) is formed. Third, in order to express abstract ideas or concepts, the ancient Chinese created “associated compounds” by combining two or more elements or characters. For example, pictographs of the sun and moon were written together to

form a new character, , to express the meaning of “bright or brightness”. Over the centuries, Chinese characters have evolved from irregular drawings to stylized forms, from picture-based hieroglyphics to ideographic “square characters,” but they do continue to have a similar structure and grammar. So, the inference is that the processing of Chinese is more likely to generate pictures in people's minds than other language will.

Moreover, the structure of Chinese characters has nothing to do with their pronunciation. The pronunciation is based on “rote associative learning” (Tavassoli 1999, p.171). So, the learning, reading, and memory of Chinese characters rely heavily on visuospatial information or on how to discern subtle structural differences between characters.

The Chinese language widely uses classifiers to categorize words into different groups (Schmitt and Zhang 1998). Words are classified based on their physical properties, such as shape, size, thickness, and length, and also their conceptual properties, such as bendable, elastic, and graspable. For example, “zhang” is used as a classifier for objects (such as tables, desks, photos, and paper) that have properties of flatness and extendedness. The processing of such classifiers also relies heavily on visual code. On the other hand, English, French, German, and Spanish never use such classifiers.

In contrast, the entire English alphabet consists of 26 meaningless letters whose orthography represents the pronunciation of words (Tavassoli 1999). English speakers subvocalize (phonologically recode) written words (McCusker, Hillinger, and Bias 1981) and rehearse words in a phonological loop of short-term (Baddeley 1986). Moreover, English speakers tend to phonologically recode visual information as well (McCusker, Hillinger, and Bias 1981). So, the process of English is dominated by phonological representation (Schmitt, Pan, and Tavassoli 1994; Tavassoli 1999) and thus the ability to generate imagery may be inhibited by allocating mental resources to such subvocalizing of words.

In summary, the processing of Chinese words may rely heavily on visual code and ignore, at least partly, phonemic recoding (Rozin, Poritsky, and Sotsky 1971; Sasanuma 1975; Schmitt, Pan, and Tavassoli 1994; Tavassoli 1999). In contrast, the processing of English words may rely mainly on phonological code. So, the unique structures of Chinese characters may facilitate the imagery generation of Chinese subjects while English letters have no such effect.

CULTURE AND IMAGERY GENERATION

Scholars have found that the Chinese have an interdependent view of self. They view the self as part of a surrounding social context and believe one's behaviors are primarily organized, controlled, or contingent upon the thoughts, feelings, and actions of others (Markus and Kitayama 1991). Thus they attach more importance to others and emphasize their relationship and harmony with others.

The appreciation of the relationship between self and others makes Chinese people, including self and others, an integral part of the context in which they are imbedded (Markus and Kitayama 1991). The behavior of a person is strongly based on the nature of context, especially when others are present (Markus and Kitayama 1991). One learns about the self in reference to others in a particular situation; conversely, one learns about others in reference to the self

in a specific context. As a result, persons are only parts of the context and cannot be fully understood when separated from the surrounding social context (Phillips 1976; Shweder 1984). So, for Chinese, specific social contexts are more likely to serve as the unit of representation than one's unique internal attributes (Markus and Kitayama 1991). Therefore, Chinese develop a concrete way of thinking (Cousins 1989; Kühnen, Hannover, and Schubert 2001) and tend to direct their attention to a specific daily context (Cousins 1989; Nisbett et al. 2001). This way of thinking is defined as "a boundedness to perceptual stimuli, a tendency to perceive things as part of the real-life settings from which they normally take their meaning, rather than to mentally isolate objects or their attributes and generalize across contexts on the basis of conceptual similarity" (Cousins 1989, p. 124).

In contrast, Westerners view the self as a bounded, unitary, and stable entity that is separated from social context. They emphasize attending to self, the appreciation of one's uniqueness from others, and the importance of asserting the self. Therefore, their attitudes, feelings, and behaviors should be determined by themselves without being controlled by any external factors (Markus, Mullally, and Kitayama 1997). They learn about the self without considering others and the context (Nisbett et al. 2001). They organize knowledge about self into a hierarchical structure, with the person's distinctive internal attributes as the superordinate nodes, resulting in a greater cognitive elaboration of attributes of the self across contexts (Markus and Kitayama 1991). So, for Westerners, the specific internal attributes will serve as the unit of representation. They develop an abstract way of thinking whose definition is to "mentally isolate objects or their attributes and generalize across contexts on the basis of conceptual similarity" (Cousins 1989, 124).

In sum, even when facing abstract words, Chinese tend to think concretely because abstract stimuli are unnatural for them and must be supplemented with contexts (Cousins 1989). So, Chinese are more likely to generate imagery when exposed to abstract words because they tend to retrieve scenes from specific daily life to fill in the missing context (Markus and Kitayama 1991), whereas Americans are less likely to do so because they tend to think in an abstract manner.

OVERVIEW OF EXPERIMENT 1

According to the above discussion, both language and concrete thinking may result in the high imagery generation ability of Chinese. But it is not easy to separate these two factors because culture influences people's thinking through language (Whorf 1956). Based on drawings, the Chinese writing system reflects the concrete way of thinking of Chinese (Logan 1986). Therefore, language is a medium that the Chinese use to transmit and internalize their culture (Ji, Zhang, and Nisbett 2004). As a result, culture and language are embedded in each other. However, these two factors can be separated by using bilinguals as research subjects (Ervin and Osgood 1954; Ji, Zhang, and Nisbett 2004).

Ervin and Osgood (1954) indicate that there are two types of bilinguals: Compound and coordinate. Compound bilinguals are individuals who learned two languages as a child, whereas coordinate bilinguals learned a second language later or even in adulthood. In other words, compound bilinguals generally learn native and second languages simultaneously, whereas coordinate bilinguals generally learn two languages consecutively (Ji, Zhang, and Nisbett 2004). An individual's age and the context of learning a second language are often closely related (Ji, Zhang, and Nisbett 2004). For example, learning a second language at a very early age often take places in the same family context, whereas learning the second language later often involves a school context that is quite different from a family context. Therefore, compound bilinguals who learned

two languages during childhood are more likely to have a single cognitive representation. In comparison, coordinate bilinguals may have two distinctive representations, one for each language (Ervin and Osgood 1954), because learning different languages in different contexts results in more functional separation between the bilinguals' two codes (Lambert, Havelka, and Crosby 1958). Compared with compound bilinguals who have a higher degree of interdependence in the organization of a word and its translation equivalent, coordinate bilinguals have two relatively independent association networks for translation equivalents and tend to make more semantic distinctions between these two codes (Lambert, Havelka, and Crosby 1958).

Moreover, since coordinate bilinguals learned a second language later, they should be more proficient in their native language, and their ways of thinking would tend to be dominated by native culture because their cognition had been shaped significantly by their native culture before they learned the second language. Even in the process of learning the second language, their ways of thinking were also enhanced by their native culture because they were exposed to their native culture significantly more than they were exposed to the foreign culture. As a result, bilingualism for coordinate bilinguals is not balanced (Ji, Zhang, and Nisbett 2004).

The findings of Ji, Zhang, and Nisbett's (2004) study provide evidence for these arguments. In their study, which examined the effect of language or culture on categorization, Ji, Zhang, and Nisbett (2004) found that language had no effect on categorization preference of Hong Kong and Singapore Chinese (compound bilinguals). Their finding shows that compound bilinguals tend to have a single representation, while mainland Chinese tend to have an unbalanced one.

The distinction between compound and coordinate bilinguals is also supported by evidence from neurology. Kim et al. (1997) examined the spatial relationship between native and second languages in the cortex by using functional magnetic resonance imaging (fMRI). They found that for coordinate bilinguals who learned their second language in adulthood, the second language was spatially separated from the native language. In contrast, the native and second language of compound bilinguals who learned their second language at an early age are represented in common frontal cortical areas. Chee et al. (1999) found a similar result after using fMRI to examine Singapore Chinese bilinguals. They found that Singapore Chinese bilinguals use the same neuroanatomical regions during the conceptual and syntactic processing of a written sentence, regardless of testing the language, because they were exposed to Chinese and English in early childhood.

In this experiment, I examine whether culture and language have relatively independent effects on imagery generation by testing bilingual subjects in two languages (Chinese vs. English). Although it is very hard, if not impossible, to completely separate culture from language, testing bilinguals allows me to examine the effect of one, while controlling the effect of another one.

If culture is the primary driving factor behind imagery generation, then bilinguals, especially coordinate bilinguals, should generate a similar number of images when exposed to different languages. Since coordinate bilinguals have an unbalanced representation (the native language dominates the second one), and compound bilinguals have a shared representation (equal representation from both languages), I expect that coordinate bilinguals will generate more images than compound bilinguals, regardless of languages used in the test, if culture is the key driver of imagery generation. However, if language plays a key role in imagery generation, I should observe a language effect among bilinguals, especially among compound bilinguals. In other words, bilinguals should generate more images when exposed to Chinese than when

TABLE 1
ABSTRACT MESSAGES

Abstract Messages
A Classa digital camcorder has ultra compact size and weighs less than one pound.
A Classa digital camcorder performs very well under low light conditions. With its new filters and lenses, a light as dim as a candle is enough.
The Classa allows you to capture a scene clearly from a long distance with its 12X optical and 480X digital zoom. Because of the high zoom, you can get clear pictures even from a mile away.
The Classa can help you in several sports, too. It records all your movements with great accuracy. You play them back in the minutest detail, using slow motion and freeze-frame to analyze and correct your mistakes

exposed to English. Moreover, there will not be a significant difference among coordinate bilinguals, compound bilinguals, and Americans when tested in English if languages matter.

EXPERIMENT 1

The purpose of this experiment is to examine the effect of culture when controlling the effect of language and the effect of language when controlling the effect of culture.

Method

Participants. Fifty-two Chinese students from a southwestern university in mainland China, 48 Singapore Chinese students from a university in Singapore, and 26 American students from a southeastern university in the U.S. were selected. All Mainland Chinese subjects were majors in English to ensure that their English skills were strong enough. Both mainland and Singapore Chinese read stimuli in Chinese and English. Americans only read English stimuli.

Singapore Chinese were selected because Singapore has been a British colony for more than 100 years and is more westernized than Mainland China. Second, since English is one of the official languages in Singapore it is learned from kindergarten and used frequently in daily communication. Third, both Singapore and mainland China use simplified Chinese, so the effect of language is comparable. In contrast, for the majority of mainland Chinese, English is generally learned after elementary school and is rarely used in daily communication outside English classes. Hong Kong Chinese will not be used, because Hong Kong uses traditional Chinese, which differs significantly from simplified Chinese in terms of structural variations. So the effect of language is not comparable.

Stimuli. Stimuli were adapted from those used by Unnava and Burnkrant (1991) to ensure that there was no significant difference on such dimensions as believability, understandability, meaningfulness, distinctiveness, self-referencing, informativeness, or the perceived strength of arguments. A digital camcorder was used as the target product because the product category was of enough interest for the participants to be able to process the ads meaningfully. I chose a digital camcorder because participants were probably quite familiar with it even if they did not have one. So, the ability to generate images may not be inhibited here as might occur in situations where little or no schematic knowledge exists (Wright and Rip 1980). A completely fictitious name (Classa) was used to

eliminate the effect of prior experience with established brands. The ad described four attributes of the digital camcorder (size, low-light performance, zoom, and the ability to capture sports action).

Message. Only abstract word messages were adapted from those used by Unnava and Burnkrant (1991) because both literature and studies suggest that culture difference occurs only when people are exposed to abstract words. The messages are shown in Table 1.

Procedure. Participants were first asked to read a cover story and advertisement messages. Participants were also told they were taking part in an important survey and were in a small group of students whose opinions would be valued greatly, which is a typical mechanism to increase involvement. After reading the ad, the participants were asked to do a two-minute math quiz to clear their short-term memory. Then the participants were asked to write down the imagery generated in their minds when they read the ad. Next, participants completed a series of ancillary measures and a "Ten Statement Test" (TST) in which they were asked to respond ten times to the question, "Who am I?" Finally, the participants were thanked and dismissed.

Cousins (1989) used a Twenty Statement Test. However, I used a Ten Statement Test (TST) because in a pretest students found it very difficult to complete twenty statements. The coding schema used by Cousins (1989) was adapted to code the statements into two categories, concrete or abstract thought. Physical (e.g., I am 23 years old), social (e.g., I am a marketing major student), concrete preference (e.g., I like swimming; I like cats), concrete wish (e.g., I hope to be an accountant), activity (I am doing a project for my marketing class), and qualified attribute (I am nice to my friends) were coded as concrete statements. Global preference (e.g., I like music/sports/animals), global wish (e.g., I wish the world to be better), pure attribute (e.g., I am friendly), or other global statements were coded as abstract statements.

Result

Manipulation Check. Two bilingual judges who were blind to the purpose of the study coded the responses to TST into two groups: concrete or abstract thought. The reliability was 92%. A 3 (country) x 2 (language) ANOVA with the number of concrete thoughts as the dependent variable was conducted. A main effect of country emerged ($M_{\text{China}}=5.61$, $M_{\text{Singapore}}=4.58$, $M_{\text{U.S.}}=3.19$; $F(2, 120)=11.957$, $p<.01$). The Tukey Test showed that mainland Chinese generated more concrete thoughts than both Singapore Chinese and Americans ($ps<.01$). Singapore Chinese also generated

TABLE 2
STUDY 1 RESULTS: MEANS AND STANDARD DEVIATIONS

Country	Language	Image	SD	n
China	Chinese	2.44	1.67	27
	English	2.00	1.10	24
Singapore	Chinese	1.64	1.11	25
	English	1.65	1.30	23
U.S.	English	0.92	0.84	26

FIGURE 1
IMAGES GENERATED BY SUBJECTS FROM CHINA, SINGAPORE, AND U.S.

more concrete thoughts than Americans ($p < .01$). When exposed to English, the Tukey Test showed that there was no significant difference between mainland and Singapore Chinese ($M_{\text{China}} = 5.13$, $M_{\text{Singapore}} = 4.48$; $p > .1$). But both mainland and Singapore Chinese generated more concrete thoughts than Americans ($M_{\text{China}} = 5.13$, $M_{\text{U.S.}} = 3.19$, $p < .01$; $M_{\text{Singapore}} = 4.48$, $M_{\text{U.S.}} = 3.19$, $p < .05$) when exposed to English. When exposed to Chinese stimuli, mainland Chinese generated more concrete thoughts than Singapore Chinese ($M_{\text{China}} = 6.04$, $M_{\text{Singapore}} = 4.68$; $F(1, 50) = 8.393$, $p < .01$).

Generated Images. A 3 (country: China, Singapore, and U.S.) \times 2 (language: Chinese vs. English) ANOVA with a number of images as a dependent variable was conducted (please see Table 2 for means and standard deviations). Only a main effect of culture emerged ($M_{\text{U.S.}} = 0.92$, $M_{\text{China}} = 2.24$, $M_{\text{Singapore}} = 1.65$; $F(2, 120) = 7.126$, $p < .01$; see Figure 1). Mainland Chinese generated more images than Singapore Chinese ($p < .08$); both mainland and Singapore Chinese generated more images than Americans (China vs. U.S., $p < .01$; Singapore vs. U.S., $p < .05$).

When exposed to English, the Games-Howell Test (Levene's Test, $p < .1$) showed that both mainland and Singapore Chinese generated more images than Americans ($M_{\text{China}} = 2.00$, vs. $M_{\text{American}} = 0.92$, $p < .01$; $M_{\text{Singapore}} = 1.65$, $M_{\text{American}} = 0.92$, $p < .07$). However, there was no significant difference between mainland and Singapore Chinese subjects ($p > .1$), although mainland Chinese subjects generated a few more images. When exposed to Chinese stimuli, Chinese participants generated more images than Singapore

Chinese ($M_{\text{China}} = 2.44$, $M_{\text{Singapore}} = 1.64$; $F(1, 50) = 4.101$, $p < .05$). For mainland Chinese subjects, there was no significant difference between Chinese and English stimuli ($M_{\text{Chinese}} = 2.44$, $M_{\text{English}} = 2.00$; $F(1, 49) = 1.222$, $p > .1$). Singapore Chinese subjects generated almost the same number of images when exposed to Chinese and English stimuli ($M_{\text{Chinese}} = 1.64$, $M_{\text{English}} = 1.65$; $F(1, 46) = 0.001$, $p < .01$).

Discussion. My findings show that it is not language but culture that drives the higher imagery generation capability of Chinese. Imagery generation capability ranks high for mainland Chinese subjects, medium for Singapore Chinese, and low for Americans because mainland Chinese are on the concrete side and Americans are on the abstract side, while Singapore Chinese are in the middle. Singapore Chinese subjects have a balanced cognitive representation, so they generated almost the same number of images when exposed to both Chinese and English stimuli. Since mainland Chinese have a predominantly concrete mode of thinking, they generated more images than both Singapore Chinese and American subjects, even when tested in English.

GENERAL DISCUSSION

This paper attempts to differentiate the effect of culture from that of language on imagery generation. My findings show that culture is the main factor driving imagery generation. Mainland Chinese have higher imagery generation capability than both Singapore Chinese and Americans because they are more likely to

think concretely. Singapore Chinese generate the same number of images when exposed to both Chinese and English stimuli because they have a balanced mental representation. Moreover, since their representation is a mix of Eastern and Western cultures, Singapore Chinese are in the middle in terms of imagery generation. Although my study did not find that language affected imagery generation significantly, its effect should not be ignored because mainland Chinese generated fewer images when exposed to English stimuli than when exposed to Chinese stimuli. Moreover, culture shapes individuals' cognition through language.

This study did not examine the possible effect of location on imagery generation. Studies have shown that the cognitive process could be modified after living in another culture for even a short period of time (Brewer and Gardner 1996; Ji, Zhang, and Nisbett 2004). Future studies should examine whether mainland Chinese have a lower imagery generation capability after living in Western cultures for some time.

Successful Brand Alliance and Its Negative Spillover Effect on a Host Brand: Test of Cognitive Responses

Ji-Yeon Suh, Korea Advanced Institute of Science and Technology, Korea
Se-Bum Park, Korea Advanced Institute of Science and Technology, Korea

ABSTRACT

The current research demonstrates that a high-favorability host brand can benefit from co-branding with a moderate-favorability partner brand due to greater (fewer) positive (negative) cognitive responses. By contrast, a moderate-favorability host brand can enhance the evaluation of its co-branded product by partnering a high-favorability partner because the partner brand can facilitate more positive cognitive responses while blocking cognitive responses. We also found that a high-favorability partner brand may do more harm than good to a moderate-favorability host brand's new product because the partner brand does not block the activation of counter-arguments after co-branding is terminated.

INTRODUCTION

Brand alliance, defined as the situation in which two or more brands are joined together in some fashion (Rao, Qu, and Ruckert 1999; Rao and Ruckert 1994; Simonin and Ruth 1998), provides means to examine the effects of brand equity on consumer reaction to brand combinations. Several empirical studies on brand alliance have documented mostly positive effects of brand alliance on consumer brand evaluations. Rao and Ruckert (1994), for example, have claimed that brand alliance allows consumers to assume that high-quality products will only partner with other high-quality products. Brand alliance triggers the transfer of positive affect from the high-quality brands to the low-quality brands (Levin, Davis, and Levin 1996), improves the image of one or the other partners and signals greater product quality (Park, Jun, and Shocker 1996), and conveys information about the quality of a product even when its quality has not or cannot be observed (Rao et al. 1999). Relatedly, Simonin and Ruth (1998) demonstrate that an attitude toward a co-branded product influences subsequent impressions of each partner's brand such that positive spillover effects emerge.

The current research, however, maintains that partnering with high-quality brands may do more harm than good to host brands. Sternthal, Phillips, and Dholakia (1978), for example, have demonstrated that individuals who are favorably predisposed to message appeal are more persuaded by a moderate-credibility than a high-credibility message source because individuals are not highly motivated to retrieve thoughts that are presumably positive or the high-credibility source may engender a feeling that the position is adequately represented and thus no more support argumentation is necessary when the high-credibility message source advocates a view that individuals initially favor. In contrast, individuals freely generate and rehearse their own repertoire of thoughts as well as those included in the message when a moderate-credibility source endorses the message. However, a high-credibility message source exerts a greater persuasive impact on attitudes of message recipients with a negative initial opinion toward an advocated issue because the high credibility blocks the retrieval and rehearsal of counterarguments (Sternthal, Dholakia, and Leavitt 1978; Sternthal et al. 1978). For example, Voss and Tansuhaj (1999) find that consumer evaluation of an unknown brand from another country becomes more positive when it partners with a well-known domestic brand. Drawing on the cognitive response theory, we thus hypothesize that consumer evaluation of a co-branded product will be moderated by the degree of a partner brand's favorability in the brand alliance context.

Regarding the spillover effect of brand alliance, Keller and Aaker (1992) maintain that a prior, successful extension increases consumer evaluation of not only a proposed brand extension but also of a core brand itself. By contrast, a poor brand extension dilutes consumer evaluation of a core brand (Loken and Roedder John 1993; Sullivan 1990). Considering a brand alliance between a moderate-favorability host brand and a high-favorability partner brand, one would expect a positive spillover of the brand alliance on a host brand to emerge because consumer evaluation of a co-branded product between these two brands becomes positive based on the cognitive response account. We hypothesize, however, that negative cognitive responses will be activated once the host-brand does not carry the high-favorability partner brand any more, resulting in a contrast effect, a negative spillover effect of the brand alliance. To test these hypotheses, we conduct an experiment in which the favorability of a host and that of a partner brand are varied to examine their impact on consumer evaluation of the brand alliance and its spillover effect on the host brand's new product.

BURBERRY AND LOUIS VUITTON STUDY

Overview of the Study

The objectives of the current research were twofold. First, we intended to investigate how a host brand's favorability and a partner brand's favorability would influence the evaluation of their co-branded product. Second, we aimed to examine whether or not the favorability of the co-brand evaluation would help or hurt the evaluation of the host brand's new product launched after their brand alliance is terminated. Toshiba and Sony were chosen as representing a moderate- and a high-favorability host brand respectively, and Burberry and Louis Vuitton were selected as representing a moderate- and a high-favorability partner brand respectively.

Method

Participants and Design. Two-hundred and ten adults participated in this experiment for a cyber-money gift certificate. Of 210 participants, females were 102 (51.9%), and their mean age was 32.3 years old. Their occupation were undergraduates (27.6%), graduates (6.2%), businessmen (58.6%), and self-employed and housewives (7.6%).

The current research employed a 2 (host brand's favorability: Toshiba or Sony) x 2 (partner brand's favorability: Burberry or Louis Vuitton) between-subjects design in which Toshiba (Sony) represents a moderate (high) favorability host brand, and Burberry (Louis Vuitton) represents moderate (high) favorability partner brand.

Procedure and Measures. At the beginning of the experiment, participants were asked to read a product description about either a Toshiba's or a Sony's new laptop partnered with either Burberry or Louis Vuitton. As shown in the appendix, participants were shown the color pictures of the co-branded laptop including one standard interior cut and one exterior cut embroidered with the partner brand's prototypical patterns and colors. In addition, identical hardware specifications such as CPU, memory, hard disk, and LCD size were provided across all treatment conditions. Next, participants were asked to evaluate the co-branded laptop on the following

FIGURE 1
CO-BRANDED LAPTOP: TOSHIBA VERSUS SONY

six seven-point bi-polar items: dissatisfied-satisfied, unfavorable-favorable, dislike-like, unreliable-reliable, unappealing-appealing, and unattractive-attractive. These six items were loaded on a single factor and were averaged to form a reliable co-brand's evaluation index ($\alpha=.92$). Right after the evaluation of the co-branded laptop, participants were asked to list their thoughts about the co-branded laptop, which were coded and categorized into positive, neutral, and negative thoughts by three independent judges.

Next, participants were told that either Toshiba or Sony would launch this new laptop of its own, and were shown its pictures that did not vary across the treatment conditions except for brand logos. Participants were then asked to evaluate the host brand's new laptop on the identical bi-polar items to the co-branded laptop. Again, the six evaluative items were averaged to form a reliable host brand evaluation index ($\alpha=.92$). After participants evaluated the host brand's new laptop, they were asked to list their thoughts about the laptop. Participants were then asked to evaluate the partner brand on the following eight seven-point scale items (1=not at all, 7=very much): interested, attention-getting, familiar, preferred, aspiring, luxurious, unique, and valuable. These eight evaluative items were also averaged to form a reliable evaluation index for the partner brand ($\alpha=.95$). Last, participants' prior attitude toward the host brand was evaluated on the same bi-polar items used for the co-branded and the host brand laptop. Again, these six evaluative items were averaged to form a reliable prior attitude index toward the host brand ($\alpha=.93$). Participants were then debriefed and thanked.

Results and Discussion

Manipulation Checks. A 2 (host brand's favorability) x 2 (partner brand's favorability) ANOVA was conducted to check participants' prior attitude toward the host brand and their evaluation of the partner brand. Our analysis first yielded a significant main effect of the host brand on the prior attitude toward the host brand, indicating that participants preferred Sony ($M=5.0$) to Toshiba ($M=4.5$, $F(1, 185)=10.02$, $p<.01$). Our analysis also found that participants evaluated Louis Vuitton ($M=4.7$) more favorably than Burberry ($M=3.4$, $F(1, 183)=62.95$, $p<.001$).

Co-Brand and Host Brand Evaluation Indices. First, the analysis conducted a 2 (host brand's favorability) x 2 (partner brand's favorability) ANOVA on the evaluation index for the co-brand. As shown in figure 1, the analysis only yielded a significant host-partner brand interaction ($F(1, 206)=18.05$, $p<.001$), suggesting that participants evaluated the Toshiba-Louis Vuitton laptop ($M=5.1$) more favorably than the Toshiba-Burberry laptop ($M=4.6$, $t(104)=2.67$, $p<.01$). By contrast, participants preferred the Sony-Burberry laptop ($M=5.4$) to the Sony-Louis Vuitton laptop ($M=4.7$, $t(102)=3.33$, $p<.01$).

Second, a 2 (host brand's favorability) x 2 (partner brand's favorability) ANOVA on the evaluation index for the host brand's new laptop was conducted. As figure 2 indicates, the analysis yielded a significant main effect of the host brand, suggesting that participants liked the Sony's laptop ($M=4.9$) more than the Toshiba's ($M=4.6$, $F(1, 206)=5.1$, $p<.05$). The analysis also revealed a significant host-partner brand interaction ($F(1, 206)=6.2$, $p<.05$), demonstrating that participants evaluated the Sony's new laptop more favorably after exposure to the Sony-Burberry's laptop ($M=5.2$) than the Sony-Louis Vuitton's laptop ($M=4.8$, $t(102)=2.65$, $p<.01$), whereas no significant difference was found for the Toshiba's own laptops.

Spillover Effect of Co-Branding on the Host Brand Evaluation. Consistent with Simonin and Ruth (1998), the analysis offered strong support for the spillover effects of co-branding on the host-brand evaluation except for the Toshiba-Louis Vuitton condition. As shown in figures 1 and 2, participants' evaluations of the Toshiba's and the Sony's new laptops were assimilated to their prior evaluations of the Toshiba-Burberry, the Sony-Burberry, and the Sony-Louis Vuitton co-branded laptops. However, the analysis found a contrast between the Toshiba's own laptop ($M=4.7$) and the Toshiba-Louis Vuitton's laptop ($M=5.1$, $t(52)=2.45$, $p<.05$). To further examine the underlying cognitive mechanism of the spillover effects, we analyzed participants' cognitive responses next.

Test of the Cognitive Response Hypothesis. First, our analysis demonstrated significant host-partner brand interactions for positive thoughts ($F(1, 204)=23.64$, $p<.001$) and negative thoughts ($F(1,$

TABLE 1
COGNITIVE RESPONSES: MEANS (AND STANDARD DEVIATIONS)

Host brand	Partner brand			
	Louis Vuitton		Burberry	
	Co-brand's	Host brand's	Co-brand's	Host brand's
Toshiba				
Positive	1.47 (.14)	1.00 (.12)	.89 (.11)	1.06 (.11)
Neutral	.16 (.06)	.13 (.05)	.09 (.04)	.13 (.05)
Negative	.18 (.05)	.46 (.11)	.74 (.16)	.31 (.07)
Sony				
Positive	.91 (.12)	.96 (.11)	1.60 (.16)	1.24 (.12)
Neutral	.19 (.07)	.30 (.08)	.12 (.06)	.18 (.05)
Negative	.67 (.11)	.54 (.10)	.14 (.05)	.24 (.07)

204)=27.48, $p < .001$) for the co-brand evaluation. As table 1 shows, the findings suggested that participants generated more positive ($M_{\text{POSITIVE}}=1.47$) and fewer negative thoughts ($M_{\text{NEGATIVE}}=.18$) for the Toshiba-Louis Vuitton laptop than for the Toshiba-Burberry laptop ($M_{\text{POSITIVE}}=.89$, $t(102)=3.28$, $p < .01$; $M_{\text{NEGATIVE}}=.74$, $t(102)=-3.36$, $p < .01$, respectively). By contrast, participants generated more positive ($M_{\text{POSITIVE}}=1.60$) and fewer negative thoughts ($M_{\text{NEGATIVE}}=.14$) for the Sony-Burberry laptop than for the Sony-Louis Vuitton laptop ($M_{\text{POSITIVE}}=.91$, $t(102)=3.59$, $p < .01$; $M_{\text{NEGATIVE}}=.67$, $t(102)=-4.28$, $p < .01$, respectively).

On the other hand, only a significant main effect of the partner brand on negative thoughts emerged for the evaluation of the host brand's new laptop ($F(1, 204)=5.77$, $p < .05$), suggesting that participants generated more negative thoughts when two host brands, Toshiba and Sony, did not carry the Louis Vuitton ($M=.50$) name than when they did not carry the Burberry brand name ($M=.28$). These findings were considered providing empirical support for the cognitive response hypothesis such that a moderate-favorability partner brand (Burberry) prompted greater elaboration of positive thoughts when partnered with a high-favorability host

brand (Sony), whereas a high-credibility partner brand (Louis Vuitton) generated greater positive thoughts and blocked the activation of negative thoughts when partnered with a moderate-favorability host brand (Toshiba). Of particular, when a moderate-favorability host brand (Toshiba) introduced its own brand after the co-branded product with a high-credibility partner brand (Louis Vuitton), the deactivated negative thoughts were released, resulting in a negative spillover, the contrast effect.

SUMMARY AND CONCLUSION

The current research has successfully tested and supported the cognitive response hypothesis that the high-favorability host brand can benefit from co-branding with the moderate-favorability partner brand because greater (fewer) positive (negative) cognitive responses are generated. By contrast, the moderate-favorability host brand can enhance the evaluation of its co-branded product by partnering with the high-favorability partner brand because its partner brand can facilitate more positive cognitive responses while blocking the activation of negative cognitive responses. The current research has also shown that the evaluation of the high-favorability host brand may backfire when co-branding a high-favorability partner brand because individuals generate more counter-arguments than supporting arguments. From the managerial standpoint, these findings suggest that marketers for moderate-favorability host brands should keep in mind that high-credibility partner brands both help and hurt their brand. In addition, marketers for high-favorability host brands should be reminded that teaming-up with equally high-favorability partner brands may do more harm than good in certain conditions. From the theoretical standpoint, the current research contributes to brand alliance research in that the underlying cognitive mechanisms of consumer evaluation of co-branding and its spillover effects are identified. Also, the current research has provided further empirical support for the cognitive response such that the favorability of a partner brand either enhance or undermine consumer evaluation of brand alliances. However, the current research is limited in that the role of cognitive resources is not taken into consideration. Individuals with lack of cognitive resources, for example, low-involvement individuals may prefer a high-favorability host and partner's co-branded product because their thought generations are restricted and thus use a brand-name heuristic.

“...Do I need it, do I, do I really need this?”: Exploring the Role of Rationalization in Impulse Buying Episodes

Andreas Chatzidakis, Royal Holloway University of London, UK
Andrew P. Smith, Nottingham University, UK
Sally Hibbert, Nottingham University, UK¹

ABSTRACT

The paper complements existing research regarding the interplay between impulsive and deliberative processes in consumer decision making, by examining how cognition (in the form of rationalizations or motivated judgements) enables people to proceed with (rather than control) their impulses. It applies the concept of neutralization (Sykes and Matza, 1957), in the manner of a theory of motivated cognition and as a taxonomy of pre- and post-behavioral rationalizations; and presents findings from a preliminary study which suggests that neutralization theory can be applied to accounts of impulse buying episodes.

INTRODUCTION

The negative externalities of consumption are often rehearsed (e.g. environmental impact); whereas the personal negative consequences of consumption are often neglected in the policy domain (with the possible exception of debt). Likewise impulse buying is often represented as a benign activity in many forums. However, it can have negative consequences for the participant, particularly if the consumer succumbs to impulses on a regular basis or has limited financial means. Consumer debt in developed economies is excessive (e.g. Brown et al. 2005) and causes concern for policy makers, debt related charities and consumer interest groups. Household bankruptcy rates are increasing, and this appears to be attributable to excessive spending on consumer durables and services rather than more run of the mill household expenses. Indeed, there is an established empirical link between indebtedness, bankruptcy and the propensity to succumb to *Akratic* repeated ‘excessive’ impulse purchase (Wood 1998). Research has also shown that impulse purchases can have negative psychological consequences for the participants (Wood 1998; Green and Smith 2002) as well as lead to domestic conflict and other negative social consequences (Green and Smith 2002). Repeat impulse purchase can be a problematic form of buying behavior whatever the financial resources of the consumer. Even those who can afford it may experience the negative familial and psychological consequences (the research reported here does not explore impulse buying which is attributable to an impulse disorder-Lejoyeux et al. 1996).

Research into impulse buying has provided many insights, which are explored below, however there is still some ambiguity about a) the exact role of cognition on impulse restraint and enactment and b) how consumers deal with impulses that carry negative consequences both in post-behavioral (i.e. as a result of an impulsive purchase) and pre-behavioral stages (i.e. at the time of purchase) of the impulse formation and enactment process (Dholakia 2000). Indeed, the consumers’ cognitive ability to cope with any doubts or internal conflicts should be a key facilitatory factor of repeated impulsive behavior. In an attempt to redress this issue, the current paper advances the concept of neutralization (Sykes and Matza 1957) and explores its applicability in twenty consumer accounts of impulse buying episodes.

CONCEPTUAL CONTEXT

Impulsiveness in any context is a difficult construct, and one that can be defined in many ways (Coscina 1997, Webster and Jackson 1997a, 1997b), nonetheless the basic elements of these generic psychological definitions are evident in most existing definitions of impulse buying, such as that offered by Rook and Hoch (1985): 1. Sudden and spontaneous desire to act; 2. Temporary loss of control; 3. Psychological conflict and struggle; 4. Reduction of cognitive evaluation; 5. Disregard for consequences. This perspective is reflected in Rook’s (1987) definition of impulse purchasing as “a sudden, often powerful and persistent urge to buy something immediately” (Rook 1987, 191). Vohns and Faber (2007) note that recent research continues to reflect this viewpoint, by for example, distinguishing between people that are impulsive and those that are not. They caution, however, that this distinction overlooks the fact that nearly everyone occasionally engages in impulse purchases and even the most impulsive people sometimes do manage to control their impulses.

Impulse buying has been consistently linked with mood states (e.g. Hill and Ward 1989, Rook and Gardner 1993). Interestingly Rook and Gardner (1993) found that positive mood states are more favorable to impulse buying than negative ones, but also suggested that consumers may use impulse purchasing to extend or alter mood states, for example people might buy on impulse in negative moods, that is, as a “therapeutic mood alteration tactic” (Rook and Gardner 1993, 19). Luomala (1998) provides support for this in a study of self-gift behavior, arguing that the self-regulation of negative moods through consumption related activities was a “common and integral part of consumers’ lives” (Luomala 1998, 109). Other studies of self-gift behavior and compensatory consumption have also shown that consumption can be used as a device for mood repair (Mick, DeMoss and Faber 1992, Woodruffe 1997a, Woodruffe-Burton 1998a). The link between these forms of consumption and impulse buying remains largely unexplored however. Moreover as Rook and Gardner (1993) postulate it is a not only negative mood that may encourage impulse buying. Youn and Faber (2000) investigated cues that might trigger impulse buying and found that both negative and positive moods or feeling states might prompt impulse buying. It should also be remembered that mood is both an ‘input’ and an ‘output’ to impulse buying.

Several studies have emphasized the influence of external situational and environmental factors on impulse buying; including atmospherics, exciting shopping environments, in-store promotions, point of purchase stimuli, physical proximity, layout and space allocation of products within the store (Bellenger and Korgaonkar 1980; Desmet and Renaudin 1998; Faber and Vohs 2004; Hoch and Loewenstein 1991; Kollat and Willett 1967; Peck and Childers, 2006). However their exact effect on the process of impulse buying is still under-investigated. There is also a dearth of research into the effect of companion shoppers and other social effects (for exceptions see Green and Smith 2002; Luo 2005).

Studies into impulse buying have been criticized for focusing mostly on the emotional and situational elements of the phenomenon, as opposed to adequately considering the potential of the cognitive perspective (Burroughs 1996; Piron 1991). Burroughs

¹The authors would like to acknowledge Sarah Green for collecting the data.

(1996) argued that the cognitive processes of impulse buying were particularly important when one considers how consumers map the symbolic meaning of objects onto conceptions of the self. Moreover, Rook and Hoch (1985) suggest that even at the height of impulse buying episodes, customers often engage in 'inner dialogue'. Additionally some studies have examined how consumers may reject the impulse to buy something and exert self-control when negative normative evaluations reach some critical level (Rook and Fisher 1995). Other consumers may actively employ strategies to prevent impulse buying. For example, people may attempt to regulate their own behavior through willpower, not going shopping or leaving credit cards at home (Hoch and Loewenstein 1991, Lehtonen 2000).

Related to the above, the perceived and actual consequences of impulse buying and their exact role on impulse restriction or enactment remain a neglected area of study. Although many definitions of impulse buying suggest that it occurs with a disregard for consequences (Rook 1985), impulse is typically perceived as having negative psychological consequences that trigger internal conflict (Emmons et al. 1993). For example, impulsive persons often exhibit a sense of guilt (Wishnie 1977) and regret (Spears 2006). Research on compulsive buying and addictive consumption has explored negative consequences of consumer behavior that might be relevant to impulse buying. For example addictive consumption is viewed as having long-term and serious negative consequences, not least guilt, self-loathing and debt (Elliot, Eccles and Gournay 1996; Friese 1999; Green and Smith 2002; O'Guinn and Faber 1989).

Recent research into impulse buying (and consumer behavior more broadly) has re-emphasized the interplay of impulsive (affective) and cognitive (deliberative) processes (Shiv and Fedorikhin 1999; Strack, Werth, and Deutsch 2006). In the context of consuming candies, Hofmann, Rauch, and Gawronski (2007) found that under conditions of high cognitive capacity, dietary restraint standards were more influential on behavior than implicit attitudes, however, this trend was reversed under conditions of low cognitive capacity. Similarly, in a series of experiments Vohs and Faber (2007) showed that depletion of self-regulatory (primarily cognitive) resources in preceding tasks leads to increased willingness to behave impulsively in subsequent tasks. From this perspective, consumer decisions can be viewed as ongoing conflicts between desires, triggered for example by mood states and environmental stimuli, and willpower; or more reflective, cognitive attempts to exercise control over these impulses (Hoch and Loewenstein 1991). Nonetheless, desires can affect cognitive processes in more perplexing ways (e.g. Eagly and Chaiken, 1993). For example, under a "motivated reasoning" perspective, (Baumeister 1996; Ditto et al. 1998; Kunda 1990), urges, desires and similar motivational states "may affect reasoning through reliance on a biased set of cognitive processes: strategies for accessing, constructing and evaluating beliefs" (Kunda 1990, 480). Cognition, in the form of biased judgments or rationalizations, may therefore facilitate rather than inhibit impulse enactment. In this respect, the exact role of "inner dialogue" (Rook and Hoch, 1985) on impulse buying episodes remains unexplored.

THE ROLE OF NEUTRALIZATION

In an attempt to understand the Consumption Impulse Formation and Enactment process (CIFE) holistically, Dholakia (2000) distinguishes between consonant (harmonious) and dissonant (conflicting) impulses. Consistent with the above, he notes that while cases of consonant impulses (no perceived constraints from impulse formation to enactment) are theoretically possible, most often, consumers experience psychological conflict or dissonance,

arising from incongruence between their emotional (desires) and cognitive preferences (Emmons et al. 1993; Rook 1987). Importantly, this results in a more thought-based evaluation of the consequences of impulse enactment. If they are evaluated negatively, the consumer's cognitive system is activated, to employ a variety of resistance strategies, such as self-control, selective attention to information and control of emotions (Dholakia 2000). Cognition, however, in the form of rationalizations or motivated judgments may also play a facilitatory role on impulse enactment. Whereas the impulse buying literature have so far considered only the post-behavioral role of rationalizations (Rook 1987; Sparks 2006), they represent generic mechanisms of adding consonant cognitions, (versus changing existing cognitions or behavior; Beauvois and Joule 1996), that should be equally applicable when the purpose is to alleviate feelings of anticipated (pre-behavioral) as opposed to post-behavioral dissonance (Baumeister and Newman 1994; Tsang 2002) Indeed, the importance of rationalization has been highlighted in recent social psychological research concluding that most claims of irresistible impulses are a matter of rationalization rather than of genuinely being helpless against strong desires (Baumeister 2002; Baumeister et al. 1994). Nonetheless, even the broader cognitive dissonance/social psychological literature has largely focused on the post-behavioral role of rationalizations (see e.g. Beauvois and Joule 1993, 1996). Inevitably, this stream of research has lacked a comprehensive theory of pre- and post-behavioral rationalizing strategies: "although many different examples of self-justification have been documented in the psychological literature, this has not produced a comprehensive taxonomy of self-justification strategies" (Holland et al. 2002, 1714). Originally applied in the context of norm-violating behaviors, neutralization is both a theory of motivated cognition and a taxonomy of pre- and post-behavioral rationalizations that has been widely applied as a way to advance understanding of these processes (Bersoff 1999; Fritsche 2005; Hazani 1991).

In 1957, Sykes and Matza published their seminal article on juvenile delinquency criticising the predominant theoretical viewpoint that delinquency is a form of behavior based on the values and norms of a deviant sub-culture in the same way as law-abiding behavior is based on the norms and values of the larger society. These authors suggested that rather than learning moral imperatives, values or attitudes standing in a complete opposition to those of his/her society, the delinquent learns a set of justifications or rationalizations, that is the techniques of neutralization, which can insulate him/her from self-blame and the blame of others. Furthermore, while these patterns of thought can be viewed as following delinquent behavior, ultimately they can precede it, and make dissonant behavior possible. That is, once successfully internalized, they can truly become neutralizing devices as opposed to post behavioral rationalizations (Grove et al. 1989). Existing longitudinal (Agnew 1994; Minor 1981, 1993; Shields and Whitehall 1994) and experimental studies (Bersoff 1999; Bohner et al. 1998; Fritsche, 2003) have generally found support for this etiological assumption.

Sykes and Matza (1957) originally identified five major categories-labelled 'neutralization techniques'-that describe the rationalizations that people apply to their problematic behaviors. Later applications have identified additional ones which are arguably more applicable in specific contexts (Fritsche 2005; Maruna and Copes 2005). The original five techniques, are listed below (as adapted in a consumer context by Strutton et al. 2004, 254) along with illustrative examples in the context of impulse purchasing:

- 1) Denial of responsibility: A circumstance in which one argues that one is not personally accountable for the behavior because factors beyond one's control are operating; e.g. "Was such a one-off bargain and my friends insisted that I buy it".

- 2) Denial of Injury: A circumstance in which one contends that the consequences of the behavior are not really serious e.g. "What's the big deal, it was such a small purchase anyway".
- 3) Denial of Victim: A circumstance in which one counters the blame for personal actions by arguing that somebody else is the victimizer; e.g. "It's the retailer's fault; the way they promote these things, it's like you buy them before you realize it".
- 4) Condemning the condemners: A circumstance in which one deflects fault by pointing out that those who would condemn engage in similar activities; e.g. "Nowadays, everybody indulges him/herself by buying something absolutely unnecessary once in a while".
- 5) Appeal to higher loyalties: A circumstance in which one argues that behavior is the result of an attempt to actualize some higher order ideal or value; e.g. 'I was so tired and frustrated, and I really needed something to lift my mood so I just had to do it'.

Since its formulation by Sykes and Matza, neutralization theory has been one of the most widely known and frequently cited theories in the sociology of deviance and beyond (for recent reviews see Fritsche 2005; Manura and Copes 2005). Furthermore, neutralization theory has been the subject of more intuitive applications, both within and beyond the boundaries of what is typically labelled as deviant behavior. Examples include bingo playing (King 1990), organizational rule enforcing (Fershing 2003), religious dissonance (Dunford and Kunz, 1973), mothers entering preteen daughters into beauty contests (Heltsley and Calhoun 2003) and eating unhealthily during pregnancy (Copelton 2007).

Neutralization theory has been successfully applied in consumer contexts but research in this domain remains limited (Chatzidakis et al. 2004, 2006; Mitchell and Chan 2002; Rosenbaum and Kuntze 2003; Strutton et al. 1994, 1997). It has not been applied to impulse purchasing, although the importance of social norms underlying this context has often been highlighted in the literature (e.g. Cobb and Hoyer 1986; Bayley and Nancarrow 1998; Peck and Childers 2006; Rook and Fisher 1995). For example, Rook and Fisher (1995) mention how impulsive behavior has traditionally been associated with immaturity, weakness or lack of intelligence and therefore classified as "bad". Accordingly, impulse purchasing is often cited as an example of the so-called "dark side of consumer behavior" (Hirschman 1991). Consumers who violate these norms may need to neutralize in order to alleviate any feelings of guilt or dissonance they could otherwise experience when acting on their impulses.

Nonetheless, it is not only the existence of social norms against impulse purchasing that suggests applicability of the concept of neutralization in this domain. As mentioned earlier, within the consumer impulse formation and enactment process, dissonance might arise after the consideration of various negative consequences, which may relate to societal but also more personal concerns (e.g. monetary waste, weight gain, domestic conflict, anticipatory emotions of guilt and regret; Dholakia 2000; Green and Smith 2002). Within a cognitive dissonance framework, once a specific behavior is perceived as problematic, neutralization, as a generic strategy of adding consonant cognitions, should be more widely applicable to impulsive episodes. Lastly, it is important to note that neutralizing processes neither assume nor require extensive cognitive processing prior to impulse enactment. On the contrary, the techniques represent readily available patterns of thought or "cognitive heuristics" (Chatzidakis et al. 2006) that are compatible with both reflective and impulsive modes of decision-making (Strack et al. 2006); such as peripheral versus central (Petty

and Cacioppo 1986) or heuristic as opposed to systematic (Chaiken, Liberman and Eagly 1989) modes of processing. Accordingly, the aim of the preliminary study reported below, was to identify the types of neutralizations that may be employed in impulse buying contexts and to gain an indication of their cognitive accessibility both at pre- and post-behavioral stages of impulse formation and enactment.

METHODOLOGY

A qualitative method of data capture was deemed appropriate in order to gain preliminary insights on the applicability of neutralization to the impulse buying domain. The study was in the main deductive because the codes were predetermined, that is the 'neutralization techniques'. Nonetheless, additional techniques, sub-themes and issues relating to the process of neutralization emerged in the interviews. The twenty participants were female, aged 18-51, and had varied backgrounds. They were recruited through targeted publicity at community resource centres. All had got into debt at some point directly as a result of their impulse purchasing. The study focussed specifically on women, as previous research has shown that overall women buy proportionately more on impulse than men (Dittmar, Beattie and Friese 1995). Clothes were the primary focus of the study, because women often impulsively buy goods that are symbolic and express their self-image (Dittmar et al. 1995; Rook and Hoch 1985; Criak 1994). Nonetheless, some participants moved on to mention additional impulse buying experiences.

The interviews were humanistic in nature (see Chamaz 1997), and were designed to give respondents the opportunity to tell their own story and fully discuss their own feelings and behaviors (Elliott, Eccles and Gournay 1996; O'Guinn and Faber 1989). A general structure and interview schedule was established before the interviews but the guide was designed to be flexible (Kvale 1983; O'Guinn and Faber 1989; Willis 1990). This inductive element of the study helped illuminate the accessibility of neutralization-type of arguments in the consumers' minds (and therefore their compatibility with both reflective and impulsive modes of processing), and is a key characteristic for successful neutralization (Fritsche 2003). Accordingly, the interplay of deductive and inductive principles has been widely adopted for exploratory inquiries into other applications of neutralization theory (e.g. Byers et al. 1999; Chatzidakis et al. 2004; Ferraro and Johnson 1983; Gauthier 2000; Hazani 1991). The interviews began by asking respondents to describe their most recent impulse buying episode, similar to the strategies adopted by Gardner and Rook (1988) and O'Guinn and Faber (1989). Further questions and the direction of the conversation were based on respondents' comments, in order to explore their experiences (Ritson, Elliott and Eccles 1996). All respondents were fully de-briefed and offered counselling services and the annotated transcripts were cross-referenced.

"Theoretical thematic analysis" was used in order to systematically code and analyse the data with the aim of identifying common patterns, salient themes and sub-themes, which were then contrasted with the pre-existing theoretical framework (Braun and Clarke 2006; Fereday and Muir-Cohrane 2006). Initially, data were coded separately by each of the authors of this paper and then findings were compared to ensure inter-coder agreement and validity (Braun and Clarke 2006). During the coding process it was evident that different neutralization techniques were often used in combination to justify impulsive behavior, which reflects what researchers have remarked in other contexts (e.g. Forsyth and Evans 1998; Hazani 1991). In such instances, data were allocated multiple category codes to indicate the interrelationships between themes. Coding also highlighted that the semantic borders between

single techniques were on few occasions fuzzier (Fritsche 2002). In these cases, the broader context and framing of the statement was an important determinant of how the data were coded. The findings reported below include verbatim extracts and some commentary to give a flavor of the overall nature and recurrent themes from the interviews.

FINDINGS

There was ample evidence to suggest that respondents were readily employing neutralizing techniques to alleviate feelings of dissonant impulses. Indeed, none of the participants was challenged to rationalize their impulses, but all of them did so at various stages in the interviews. In many instances, respondents moved on to explicitly acknowledge the importance of rationalization on the impulse formation and enactment process:

*"You've always got to justify yourself and think well yeah I really needed that cardie, and I really needed that pair of pants even though I've got ten others, and I will use them, and I will wear it and if I'm going wear it and they feel comfortable, that's all that matters, it was a bargain so think how much I've saved."*s

However, in line with previous consumer applications (Grove *et al.* 1989) not all five techniques were equally represented in the impulse buying context. The most popular techniques proved to be denial of responsibility, denial of injury and appealing to higher loyalties whilst there was only tenuous reference to denial of victim and condemnation of the condemners. Furthermore, two additional techniques were identified, and seemed to resemble what has been identified in previous research as "metaphor of the ledger" (Klockars 1974) and "defence of necessity" (Minor 1981).

Denial of responsibility centers on notions of control or the extent to which the consumers view themselves as "acted upon" rather than "acting" (Sykes and Matza 1957). This theme of attribution was evident in several consumer accounts and was perhaps not surprising given the documented evidence on the importance of "self-control" in the impulse formation and enactment process (Dholakia 2000; Vohns and Faber 2007). For example, some participants suggested that it was their friends or partners who were in effect responsible for their impulsive behavior:

"We went into, erm, a shop once to buy a fridge freezer and I came out with a television and a video as well (laughs) but that's really...that's more my husband than me...he's quite bad at things like that, he's like just get it, he sort of encourages me, I try and...not to, he is sort of quite a big influence on me, makes me do things like that, spend extra, six hundred quid on something when it was only going to be three or something."

Other participants denied responsibility on the grounds that they were influenced by atmospherics or other environmental and situational characteristics, somewhat implying their function at levels beyond their conscious control:

"Well if, its nice discreet lighting, subtle and the mirror makes you look good, yes it will certainly encourage you..."
"Alright, because sometimes when you're on holiday you buy things and because you're in a hot country, it's all flowery or whatever, brighter colours, because you're in, I don't know what the heat does to you..."

Denial of injury was primarily based on financial considerations, especially for products that were considered to be within a very affordable range and hence unproblematic purchases:

"I thought, they're cheap, I'll buy them."

A different version was based not on the absolute monetary value of the product, but relative to longer term considerations, such as frequency and occasions of usage:

"...this was fifty quid, and I was with my friend when I bought it and I went but I really like it, and she went yeah but you know its fifty pounds, and I said I know but I could wear it to work and I would wear it outside of work and she went oh well if you're going to wear it for both then perhaps you will get your moneys worth out of it."

Interestingly, few participants felt the need to justify potential injuries to their household as opposed to personal finances (e.g. the fact that the family might have to forgo other consumption events such as vacations because of any spending was hardly ever alluded to). Likewise, broader negative consequences for the environment (e.g. waste of resources) or society (e.g. fair trade clothing), were rarely mentioned, but this could be because ethical clothes shopping is still a trend in its infancy (Shaw *et al.* 2006).

Appeal to higher loyalties can be perceived as the technique which comes closer to a situation of a behavioral dilemma, whereby the "negative (unintended) consequences of one action are logically implied in positive (intended) consequences of the other action and vice versa" (Villenave-Cremer and Eckensberger 1986 in Marks and Mayo 1991, 720). In line with the existing impulse buying literature, the higher loyalties served by the (impulsive) behavior mostly related to personal desires and self-gratification:

"...erm I just thought it'll really cheer me up if I get something new for the weekend, you know if I go out at the weekend I've got something new to wear and er, I just kind of felt a bit better about myself."

"...well, sometimes I try things on but sometimes I'm just so happy that I've found something I like I just take them to the till there and then and buy it."

Other frequently mentioned higher-ordered values, related to notions of deservedness or the existence of an opportunity:

"Erm, cos you think well, I've worked for this money, I've worked to buy this..."

"Sometimes you think oh well I'll get it before somebody else gets it, yet everybody else is seen in it, or you think well maybe if I come back and its really popular, there'll be none left, you know what I mean, like your size and none'll be left and they won't be able to order you another one, and its frustrating then. (AtHL)"

Additional Techniques: Some additional themes were also identified in the interviews, which seemed to relate to techniques that have been previously identified in neutralization research as "metaphor of the ledger" (Klockars 1974) and "defence of necessity" (Minor 1981). The metaphor of the ledger refers to circumstances in which individuals justify their behavior in question based on other activities which have led to credits they can somewhat "cash in" (Hollinger 1991; Minor 1981). In the context of impulse buying this was often translated into excuses for self-giving, such

as having accomplished certain ends or having done more than what is required for one's friends or family:

"...the children have far more clothes than I do really, they get far more presents and I think as they get older you realize that you can't spend your whole life spending all your pay on them, you've got to have a life yourself, so maybe as they get older it gets far easier to spend money on me (laughs)".

Lastly, defences of necessity were based on reasons such as special occasions and circumstances, urgency of satisfying specific emotional or functional needs and which somewhat rendered the impulsive purchase prudent, if not necessary:

"...we'd got all the kids presents which were quite a lot, and then this computer came up at a good price, so I bought it. And I justified it by saying that my daughter, being in the new school now needed a computer, would help her and also her brother with their schoolwork."
 "Yeah, I usually try and justify them as a necessity. Cos I don't usually, if it's Christmas or birthdays and things I don't tend to ask for clothes cos, they're a necessity."

DISCUSSION AND CONCLUSIONS

Given that most consumers engage in inner dialogue even at the peak of impulse buying episodes (Rook and Hoch 1985), it is imperative that theories of impulse buying evolve to explain the multiplicity of roles that cognition may play on the impulse formation and enactment process (Dholakia 2000). Accordingly, this paper advances the concept of neutralization in an attempt to illustrate how (motivated) cognition, in the form of pre- and post-behavioral rationalizations may also facilitate rather than inhibit impulse enactment; and ultimately sustain repeated impulsive behavior. An exploratory study probed the applicability of the concept and identified the types of neutralizing arguments that consumers may use in relation to impulsive purchases.

The findings from the present study are mostly illustrative however, because the sample was restricted in terms of size, demographic and psychographic profile and, of course, it could not demonstrate causation and therefore confirm that the arguments are used as neutralizing devices. However, the study did shed some light on the chronological ordering question because the need to justify even at the point of purchase was very commonly cited by almost all the respondents (as was the experience of guilt in the post-purchase phase). Furthermore, it provided strong indication that consumers have a sufficient range of accessible neutralization techniques to alleviate feelings of dissonant impulses. This is particularly important in the context of impulse formation and enactment, as it implies that neutralizing processes should not necessarily require extensive cognitive effort. As such, they are also compatible with impulsive modes of processing (Strack et al. 2006). Future research could benefit from studies that probe the applicability of the concept in more diverse contexts of impulse buying, with different sample profiles and methods that may help better understand contemporaneous cognitive processes such as "shopping with consumers" (Lowrey et al. 2005; Otnes et al. 2005). At a second stage of research, experimental approaches would be needed, in order to directly address the causal ordering issue as well as specify conditions and moderating variables that affect the influence of neutralization on enactment and persistence of consumer impulses. For example, intervening variables could relate to anticipated or post-purchase guilt, mood state and adjustment, and deprivation of a need (see e.g. Strack et al. 2006).

Such a research endeavor could have important implications for marketing communications and public policy initiatives against impulsive behaviors that carry negative personal, broader societal and environmental consequences. For example, marketing campaigns could challenge specific neutralizing arguments by pointing to their logical fallacy or dangerously prevailing nature. Furthermore, creative attempts to counter the employment of neutralization techniques can even be found in cognitive-behavioral treatments and therapeutic communities such as narcotic and alcoholic anonymous (Maruna and Copes 2005). This is of increasing relevance given the emergence of specialist anti-impulse buying programmes.²

The Involved Ostrich: Mothers' Perceptions of Fathers' Participation in the Transition to Parenthood

The VOICE Group¹

VOicing International Consumption Experiences

ABSTRACT

This study focuses on mothers' perceptions of fathers' attitudes toward consumption decisions related to the introduction of the first child in the family. Two interviews were conducted with each respondent, pre- and post-natal, using the long interview method; in this paper we focus on pre-natal data. Data revealed that men, according to their partner's perceptions, used consumption as a virtual umbilical cord, although levels of consumption involvement varied from co-involvement for most purchases, to limited involvement, and/or involvement for 'large' items, particularly travel systems and technical items. This research also revealed that men partook in highly masculinized forms of "nesting," and in general shunned pregnancy book reading; although some did engage in "research" activities such as searching the internet for product safety information. We conclude from this study that the transition into parenthood can be difficult for men due to their lack of a physical connection to the pregnancy, a perception that the baby industry is not designed for them, the continuance of male stereotypes in the media, and also the time available to men to become involved in consumption activities immediately prior to a baby's birth.

INTRODUCTION

Parenting is one of the most studied and discussed facets of the human experience. There are thousands of popular press books on the subject as well as journals, dissertations, and monographs with topics ranging from sleep strategies, disciplining models, educational excellence, and sibling rivalry.

Within consumer behavior, the topic of the family took center stage as traditional marketers found the household a useful unit of analysis for promoting goods and services (Commuri and Gentry 2000). The family quickly emerged in the marketing literature as a "unit of analysis" that made decisions as a group. Beyond this cursory analysis, the complexities of family life have remained largely unstudied. While recently new mothers have begun to garner attention from consumer researchers (e.g. Prothero 2002; Hogg, Curasi, and Maclaran 2004), there continues to be a dearth of research on fathers, fatherhood, and fathering styles within the field of consumer behavior (see Harrison and Gentry 2007 (a) and (b) for notable exceptions). Although fathers were classified as a 'consumer group' as early as 1990 (Barbour 1990), we know very little about the extent to which fathers participate in consumption decisions, especially when related to children.

This study serves to shed some initial light on the processes that men use in the transition into parenthood. And while the light is being shed through the perspectives of their female partners, it is an important place to begin as it allows researchers to formulate some initial ideas that can be then supported or refuted once studies with men commence. Using pre-natal interviews of twenty women from four countries, this study looks at the perceptions of their partners' participation in the consumption decisions related to

getting ready for a new baby. While previous research has focused on the role of others on mothers' preparations for the baby and the impact of the marketplace on new mothers' confidence in their new role (Davies et al 2007), no work in the consumer behavior field has been conducted to consider how mothers perceive fathers' level of interest, amount of effort, or perceived role in this transitional stage to parenthood.

MOTHERHOOD, FATHERHOOD, AND CO-PARENTING

Who is the modern day father? This is perhaps a more complicated question than appears on the surface. Each decade seems to capture through television or movies the stereotypical father of the times, for example *Father Knows Best* in the 1950s and the *Cosby Show* of the 1980s. Media today paints a fragmented picture of fathers; oftentimes, either showing (disproportionately) the single dad struggling to raise children on his own (*Two and a Half Men*) or the well-balanced co-parent who willingly contributes equally to all activities domestic (Medium). In advertising, fathers are often shown as inept buffoons or disinterested and useless appendages (Harrison and Gentry 2007a).

In certain circles, fathers are attempting to take a more active role than in previous generations. There appears to be a shift in how fathers are participating in family activities, including childrearing, housework, household maintenance, and kinship work. This shift is less voluntary and more of a requirement when the family is headed by a single father (Harrison and Gentry 2007a). The father must learn to manage a household, including grocery shopping, school clothes shopping, and homework preparation, in the absence of the mother who previously took care of those things. The current generation of fathers is the first to truly embody the fourth and ultimate level of parenting as outlined by Pleck and Pleck (1997). The movement away from the "genial dad and breadwinner" to "equal co-parent" has emerged without explicit expectations and guidelines, without scripts or role models. This more egalitarian approach has left many heterosexual couples grappling with issues of femininity and masculinity and a need to improve upon the parenting styles of their own parents. Both mothers and fathers in a co-parenting household seem to be following a "making it up as we go" mentality that transcends social class, racial, and ethnic boundaries (Summers et al 1999).

Recently, Harrison and Gentry (2007) studied the effects of single fatherhood on family consumption decisions. This groundbreaking work further strengthened the pre-existing belief that women are the primary arbiters of the marketplace when it comes to family purchases such as school clothes and groceries and that, in their absence through either divorce or death, when men enter the marketplace they are often strangers in a strange land (de Certeau 1984), lacking the skills or knowledge of what or how to buy. Imagine a single father having to help his daughter choose tampons, for example.

Researchers also point out that advertising often depicts fathers as helpless, inept, or ignorant when it comes to household processes and purchases. Research in the 1970s and 1980s portrayed both men and women in highly stereotypical roles (Harrison and Gentry 2007). Images began to shift in the 1990s with women being shown more favorably (Coltrane and Allan 1994). Yet, men continue to be portrayed in stereotypical ways. The image of the

¹This paper is the result of collective, collaborative research undertaken by members of The VOICE Group. The members of this group, in alphabetical order, are Andrea Davies, Susan Dobscha, Susi Geiger, Stephanie O'Donohoe, Lisa O'Malley, Andrea Prothero, Elin Brandi Sørensen, and Thyra Uth Thomsen.

family man is still extremely rare in ad campaigns. Kaufman (1999) stated that ads are socializing agents for all parents but particularly fathers because they have chosen not to use their own fathers for this purpose.

Recent ad images are showing fathers in a different light. In some cases the father exerts superhuman powers to complete a task (for instance washing the dishes) that the mother was unable to accomplish using her merely human powers. Also, images of fathers holding or otherwise engaging young children have begun to emerge in parenting magazines and on certain TV ads but they are still the exception rather than the norm (Harrison and Gentry 2008).

While consumer research has ignored this facet of family consumption decision making, the parenting research is abounding with models of positive father involvement and the measurement of mothers' perceptions of fathers' participation in parenting.

RESEARCH FROM THE FAMILY AND PARENTING LITERATURE

The role of the father has been well studied in the family and parenting research. The seminal article by Lamb, Pleck, Charnov, and Levine (1987) created three constructs that measure fathers' involvement: "accessibility, engagement, and responsibility" (p. 259). Summers et al (1999) use this same model to measure mothers' perceptions of fathers' engagement by measuring "interaction or direct engagement between father and child; accessibility or availability to the child, and taking responsibility for the child (p. 293)." Summers et al (1999) go on to say that "this framework appears to be emerging as a generally accepted view of the critical dimensions of positive fathering (p. 293)."

Also, much of the family literature on fathering has used as a central measurement mothers' perceptions (Fagan and Barnett 2003; Futris and Schoppe-Sullivan 2007; Krishnakumar and Black 2003). This use of mothers' perceptions stems from the fact that while co-parenting appears to be the aspirational parenting model of the moment, mothers "continue to assume the primary role in child rearing (Simmernan, Blacher, and Baker 2001; p. 325)." At the same time, while men are playing a greater role in the family and especially inside the home, one study showed that they were largely unable to report on specific details of their children's lives, such as teachers' names and outside activities (Lareau 2000). The mothers' level of knowledge of the children's day to day activities was much higher and much more specific than the fathers'. Douglas and Michaels (2004) point this out as well: "after all, a dad who knows the name of his kid's pediatrician and reads them stories at night is still regarded as a saint; a mother who doesn't is a sinner (p. 8)." Therefore, while it is extremely important that fathers' voices be recorded and studied, this study focuses on mothers' perceptions of fathers' participation in the period prior to the arrival of their first child in order to learn more about fathers' role in this period of transition. It also gives the opportunity to test McMahon's findings that "men and women may both be parents, I was told, but they act, think, and feel differently as parents (1995, p. 234)."

METHOD

The data for this paper was collected as part of a larger project on the role consumption plays in the management of a woman's transition into first time motherhood. The project includes two interviews each with twenty mothers across four countries (Denmark, Ireland, the UK, and the USA). The interviews were conducted prior to and after the birth of the first child by one of eight researchers who comprise the research group. Other forms of data were also collected, including consumption diaries and photographs of certain goods that were either purchased or received in

other means, such as gifts or on loan. The interviews were driven by the long interview method (McCracken 1988), the photographs were reviewed using autoelicitation techniques (Heisley and Levy 1991) and a snowballing technique was used to garner the participants (Miles and Huberman 1994).

For this paper we are focusing on the pre-birth interviews with mothers, conducted between 32-39 weeks gestation, and are looking specifically at the women's perceptions of the involvement of their male partners in the buying of items needed for the imminent arrival of their baby. It should be stressed at this point that all of our participants were heterosexual, and from middle-class backgrounds.

FINDINGS

The path to parenthood is lined with fear, excitement, intrepidation, and preparation. And while women have many guideposts along this path, men have relatively few. During pregnancy, women are privy to hundreds of book options, constant updating from doctors, and a willingness to dip into their social network's shared wealth of knowledge. Men, on the other hand, are less targeted by the pregnancy book market, are sometimes absent from doctor's visits, and are not used to discussing such intimate issues with their social networks. So, how does a father manage this transition? Murphy (2004) states that "it takes a very long time to negotiate the shift from partners to parents" and that the mother and father's paths will never be "parallel," especially during the initial postpartum phase.

Between 1970 and 2000 Douglas and Michaels (2004) pointed out that over eight hundred books were published on the topic of motherhood, while in recent years only a small number of 'how to' manuals have been published for fathers (Parsons 1997; Smith 2004; Berkman 2005; Brott 2005). While the literature suggests that many women feel the need to read books and research products men do not necessarily feel the same need. So how then are men transitioning from fathers-to-be to fathers? Does consumption play a role during this period of liminality? There were a number of different areas in which the consumption related activities of fathers were highlighted and below we discuss three prominent areas—namely the use of consumption as a virtual umbilical cord; the 'nesting' activities of fathers; and the ways in which father's both desire and seek out information in relation to pregnancy and fatherhood.

Consumption as a virtual umbilical cord

Because men are unable to physiologically perform the act of pregnancy, a number of our participants talked of how their partners felt disconnected from the pregnancy or that the pregnancy did not 'seem real' to them:

Sarah: He's only really realizing it's happening now. He can see the bump getting bigger now, but he kind of feels outside it...So in certain kinds of respects he's really prepared and geared towards it, but in others then he's still a bit of an ostrich on it as well, I think.

Int: And why do you think that is?

Sarah: I think it's just because it's not quite real yet.We've talked about this kind of bonding thing before; like I can feel it moving around, trashing around, but he'll talk to it like, he's really into it that way, but at the same time he can walk away from that where for me there's no walking away now (laughs). (Ireland)

"But also—of course it's different for a man, because he cannot feel the baby and all of these things the same way that I can. He doesn't feel it with his own body. (Heidi, Denmark,)

256 / *The Involved Ostrich: Mothers' Perceptions of Fathers' Participation in the Transition to Parenthood*

One of our Danish participants also talked of how she felt marketing activities were also geared towards women, because men were somehow 'on the sideline':

It's like it's always directed at women. And I know what they say about hormones and all that; and that we are easier to manipulate into buying all kinds of things. But my husband cares about this at least just as much as I do. But he is not the kind who is falling for the pink clothes. But I believe it has a lot to do with women and their pregnancy and the husband is out here on the sideline. And that's not how I experience it. (Nina, Denmark)

Thus, in the same way that the mothers saw consumption as a way of helping them to 'prepare' for the arrival of their baby, our participants also suggested that fathers used consumption to remain connected and engaged, but the amount of involvement varied both within and across cultures. A number of our mothers-to-be talked of how their partners were very involved for most of the purchases made and indeed became emotional at times:

Lise: He is probably just as excited as I am, and he has participated in everything. Right from the beginning he has been with me at the doctor and the scannings and the midwife and he is very involved. It is not just my project. It is the two of us all the way through. He would be very unhappy if bought anything and he was not part of the decision. He likes to be part of the decisions—down to almost the smallest details. It is a big thing for him too. (Denmark)

Int: What was it like to go shopping for a pram—how did you go about doing that?

Karen: I was touched, but in fact it was only because Kasper is so sensitive. When he tried to push the pram he started crying. His sister accompanied us. It was in [a town in Jutland]. And when he was to push it, he started crying, and then I just got so touched, and it really was an extremely nice experience, (Denmark)

Similarly some participants talked about the fun they had shopping for baby items. Here Megan talks about her husband's involvement, even though he normally dislikes shopping:

Even Terry, poor guy, doesn't have a choice of what he wears, he hates shopping; so I just literally go in and go boom, boom, boom and come home and go there you are love, and he's delighted, usually [laughs], most of the time anyway. But, I must say I've liked some of the things we've gone shopping for together. In the States now when we were shopping Terry is a real Irish guy and there were two real beautiful looking girls inside the baby shop we were in buying and Terry was telling them about the U2 concert that we went to the night before and that we were from Ireland, and it was our first baby. I was over looking at the shelves of clothes while he was up at the counter chatting the two women up [laughs], and I could hardly get a word in edge ways as to what colours etc, but he's that type of person. He's very outgoing, he's very chatty, and he loved the shopping with an element of doing his own thing in the middle of it [laughs]. But we've had a good laugh actually through the whole lot of it. (Megan, Ireland)

In contrast to those fathers who were very much co-partners in consumption preparations, some of our participants talked about their partners finding "large purchases" to be important in terms of

shopping time and effort, yet, had very little interest in, and left the smaller purchases to the women:

Int: So Duncan's come along on a couple of trips but...

Caroline: Yeah, but not, I think the final decision is still mine, as in because it's knowing a bit more and reading a little bit more about things, and then he was quite happy to go along with it. The bigger things, probably like the cot and the pushchair, and that, the more practical things, yeah, he did have more on an input, but like cotton wool and lotion and all that sort of thing, it goes over his head, oh, do we need that, yeah, oh, we do, yes, we do. (UK)

Indeed, sometimes the mother's did not want the father's to be involved in buying some of the smaller items:

Nina: Well, mostly they were joint decisions—buying a car seat or buying a sleeping bag. Also the bigger things, really. We talked about those and agreed on what it should be. I think I was the one pushing it but then my husband also said that we should go ahead and then we did. And now we go get it done in order to be able to leave it alone.

I: And so you did that together?

Nina: But then, these last clothes, I was definitely the one. I didn't let him in on that. (Denmark)

When asked about the level of joint decision making, Claire underscored her leadership role: "he's been very good" taking her places, he defers to her, yet she sees things as "joint decisions, with me leading!" (UK)

Some participants, again in contrast, talked of their partners feeling very happy to leave most, if not all, consumption decisions up to them:

Int: And does Tony feel it will be nice for the baby to sleep in it?

Sarah: I think he does yeah; in some respects he's like 'oh you decide, it's your kind of area' if you like. (Ireland)

There were also cases where some of our participants talked about how their partners would like to be more involved in all sorts of activities, related to the baby, including buying things, but circumstances did not allow this. Ella, for instance talks of how her husband Fintan was not as involved because he was working incredibly hard within his own small business:

I really feel having talked to you that Fintan has really been kind of left out. But to be fair it's probably more circumstances than anything that he hasn't been as involved in stuff. Even from the point of view of reading and everything; if he actually had two minutes he'd probably read some of the books with me. And he did particularly in the beginning when we had that book with all the pictures, every week. He was thrilled with that, it was so amazing to read that, you know after so many weeks this organ was developed. I suppose I feel a bit sorry for him because he hasn't been able to be as involved, but he's a very hands-on kind of person, and he will be. And he's come to the hospital with me a lot. I really feel like I'm defending him, it's not that, I just feel it's a bit unfair that he hasn't been able to be as involved. (Ireland)

There has been much talk in the literature of the involvement of men in the bringing up of their children, and also recently discussions as to how difficult this can sometimes be, due to limited

paternity leave, for instance. Warner (2005) points out that at the turn of the century American men were working on average more than fifty hours per week. Such long hours coupled with both limited paternity and maternity leave created an environment where some fathers were not as involved as they would like to have been. This is also true in our study where the men were all working full-time in the weeks prior to their babies' arrival, and as such would have had limited time to become involved with purchasing, particularly when their partners had began their own maternity leave from work.

Even those partners who had very little involvement in purchasing most items did play a role in the purchasing of bigger and/or technical items for the baby. Indeed, one area where most of our participants talked of their partner's involvement, either in purchasing, or in afterwards assembling, was the buying of the baby 'travel system'. As Megan laughingly told us:

Basically it was very light-weight, very easy to manoeuvre, and my husband thought it was the best thing since his brand new car that he bought a couple of years ago [laughs]. So that's why we bought that. (Ireland)

Ella, also from Ireland, who had highlighted how her husband Fintan had little involvement in most purchases talked of how he was 'adamant' that they purchase a particular type of travel system. Abigail, from the USA, also talks of her husband's enthusiasm over technical items:

Int: Oh, okay. So, has he, how involved has he been?
 Abigail: He's been surprisingly involved. More, much more than I expected him. He's an engineer and like he loves all the, like when we went to register, he's looking at all the stuff, you know, yeah looking at gadgets to see how things go together and you know, we had a shower and I came home and he had every box opened already and I'm like, wait, we might need to return it. I want to see, this is cool. Did you see the car seat? I'm like this time it won't work. Show me what to do. (USA)

Thus in the same way that the mothers in our study used consumption to help them prepare for their babies arrival, fathers, who often felt that the pregnancy was 'not real' to them also used consumption to help them prepare. The level and types of involvement however, varied both within and between countries and ranged from co-decision making for most purchases, to limited and little involvement in other instances. The only area in which there appeared to be consistency was in the purchase of a travel system for a baby, where all fathers had some involvement in the decision making and/or assembly of the product purchased.

Father's Nesting

Many of our participants talked of their partners engaging in a highly masculine form of "nesting," an activity typically attributed to pregnant women. Nesting has been described as a hormonally triggered desire to make the home as clean, orderly, and ready as possible prior to the baby's arrival and tends to 'kick-in' around the fifth/sixth month of pregnancy (Johnston 2004). While there has been limited research about the physiological and behavioral changes of expectant fathers (Storey et al 2000) the authors note hormonal changes in men just before and after their babies' birth have been identified. At the same time, other studies have shown, that men also suffer from post-partum depression (Ballard and Davies 1996; Leathers, Kelley, and Richman 1997), although other research suggests these levels are much higher for women (Douglas and Michaels 2004). Consequently if men's hormones and physiology

also change during this time period do such changes also lead to a male form of 'nesting'? From our interviews, we found many examples of men undertaking 'projects' that could be considered nesting. Activities took the form of large home improvement projects and also putting together complicated baby equipment. Even the men who had been less involved in purchasing items were very involved in various 'projects', with examples including, converting an attic; converting a spare bedroom into a nursery for the baby; and putting together 'complicated' items such as cribs, travel cots, etc. Here, Sarah talks of how her husband has been involved very little in the purchase of things and is also unsure about what will happen when the baby actually arrives, yet is still involved in 'big' projects and is also planning to work less hours following their babies birth:

Int: Does he want to switch off and wait until the baby arrives for everything?
 Sarah: No, he's funny, he's quite prepared, in like the attic is underway, you know what I mean, and he's doing all of that like, and from a furniture point of view, what chair will we use, what will we use as a changing table, and he's got involved with the Moses basket. He got a bit of a shock yesterday when I said "we might leave the Moses basket here" [in the bedroom], and he was like, "is it going to sleep here", and I was like "yes". I just assumed he knew (laughs) so there might be a bit of a debate about that one, but I mean even for the first few weeks it will have to be in with us you know. (Ireland)

Karen explains how her partner, Kasper, builds a new chest for the baby: "I am sort of picky. So we ended up making one ourselves. That was fine. It was Kasper who decided, that he would like to do that. And I don't have to interfere. It is his project. That's nice (Denmark, pre-interview)." Karen also remarks that Kasper restored another piece of furniture:

Yes, the cupboard. I think that is because there is such a funny story behind my purchase of it, and then Kasper restored it. He really has done a lot, I reckon. It was a total ramshackle. He really has restored it from scratch. And that has also been a project for him. [...] It means a lot. He also told me, that I do not have to paint it. He wants to do it all himself. That's his project. It has really been great. He has also sewn a curtain for the nursery station. He has made the nursery station and the cupboard. All himself. Sewn and measured and everything. Yes. (Denmark)

There is much said about a woman's nesting instinct kicking in toward the end of the pregnancy but nothing appears to be mentioned about a man's desire to "get his house in order" for the baby. From our data, it appears that for some men, the desire to construct new things or put together complicated baby apparatus may be a way of making the impending changes seem more real or provide a physical connection in lieu of the physical changes happening to their pregnant partners. Thus, while some father's such as Fintan and Tony had little involvement in buying items for the baby they had engaged in very significant 'projects' in their houses, even though their partners had stressed how busy they were with their jobs and thus unable to engage with other preparations, such as buying products. 'Nesting' for fathers therefore can be an important way of managing role uncertainty and the 'projects' they engaged with can be seen as a way of staging the self (Goffman 1959) and also helping fathers cope with the role disruption they are facing (Solomon 1983).

Fathers Desiring and Seeking Out of Information

The amount and type of information sought out in relation to the pregnancy varied between partners. While a few of our mothers-to-be read very little, most were highly engaged and saw reading about their pregnancy and birth as playing a big role in helping them prepare for their babies' arrivals. The women talked of how their partners did very little or no reading, or who read in a different way:

The only other one (books consulted) was one that I think Duncan's friend bought him, but it was to do with a chap, you're pregnant, too, mate. I did flick through it, but it's written for a guy. It's not something that I would say go and read, because it's written like they're down the pub and they're chatting, and you know the way lads will have a few pints. They're ... and they're fantastic, because it explained everything that would happen or that was happening in boy talk, I think. That's the only way to describe it. I think there must be quite a few of those types of books for chaps. It was completely different to what I would have. I was surprised, initially, that he enjoyed it. You know lads laugh at you, I'm thinking, and then I look at the bit he's just read and think, OK. It's not the most polite about us girls, but, yeah. (Caroline, UK)

So, while women's pregnancy books and publications are often quite graphic, technical, and medically thorough, this particular publication geared toward a man was tongue-in-cheek and almost poking fun of the entire pregnancy process. Indeed, the front cover of one of the few books for men on pregnancy *The Bloke's Guide to Pregnancy* (Smith 2004) has a picture of a football on the front cover, in stark contrast to the often idyllic mother and baby photographs sporting the front cover of most mothering manuals.

The next example is particularly compelling because Karen repeatedly describes Kasper as heavily involved with all aspects of her pregnancy:

Karen: It has been much like 'Kasper, I would really like you to read some of all those books'—but he doesn't bother.

Int: No, he prefers the Internet?

Karen: Yes, he does that too. But he is more like looking things up. He is more like, well, he says 'It is not necessary to read this book from one end to another—you don't get any wiser of that.' You know, that is one thing I have been a bit disappointed about him not participating. (Denmark)

Kasper goes so far as to make Karen question the degree to which she is studying up on pregnancy and parenting:

But Kasper thinks I am exaggerating, he tells me to use them as reference books, not read them as such. I do have a tendency to read them and to find out that oh we have to remember. (Karen, Denmark)

Sarah's partner is so disgusted by the pictures in the pregnancy books and he refuses to look at them:

Int: And what about any of the books, has he looked at any of them?

Sarah: He won't even look at any of the pictures.

Int: Why?

Sarah: What I do is, the book will be on the bed or something, and he'll find it and it will fall open on what he would call really horrendous pictures and he'll go 'agh'. (Ireland)

Sadie's partner also did not look at the pregnancy books but for different reasons:

Int: Did Ed look at it (book on pregnancy) as well?

Sadie: Never, well he doesn't, he's not into reading anyway, and he certainly wouldn't be reading that. He's kind of an old fashioned, macho guy. 'That's women's stuff.' (Ireland)

There were exceptions; here Abigail talks of her husband's involvement at pre-natal doctor's visit as a result of being 'up to speed' from reading baby manuals:

Abigail: We were lucky because he was in school too and it was flexible. Then he's, you know, all freaked out because the last two appointments or whatever, now he starts work and he's like, I can't come, your mom's going to have to go. He's so bummed out that he can't but he's been (inaudible) and he'll ask more questions than I do. I kind of, whatever the doctor tells me, that's fine. And he's like, what about and like, I heard. You know 'cause we have the *What to Expect When You're Expecting* book and yet in this chapter it's and he's all up to speed. (USA)

A clear picture of how fathers prepare for the role of fatherhood does not emerge from these findings. The mothers' perceptions of their partners' involvement shows both similarities and differences; involvement in buying items for instance varies from co-involvement and joint-decision making, for most, if not all purchases, to limited involvement at the other end of the spectrum. Further research to assess what mediates these relationships is therefore warranted. For example, existing research in the parenting literature suggests these differences are not related to class, ethnicity or race. Our study serves to confirm this viewpoint as well as there were difference and similarities both within and across cultures.

DISCUSSION

This study serves to uncover men's consumption activities in the biologically female and culturally feminine experience of pregnancy and childbirth. As the zeitgeist of parenting has shifted to the notion of co-contribution, the implementation of this philosophy has proved problematic during this particular transitional period. During pregnancy especially and to a certain extent after a child is born, nature necessarily forces a different experience on men and women and it is only now that researchers and parents alike are beginning to figure out what equal parenting really means. Murphy (2004) states "whatever you do, keep in mind that it takes a very long time to negotiate the shift from partners to parents... The overwhelming majority of moms I spoke to found that the birth of their baby transformed even the most egalitarian marriage into a kind of Leave it to Beaver time warp... (p. 53)." And while women want their partner to be an equal contributor, as one participant (Claire) said, the reality may be that they want joint decision making with the woman in the lead. In her extremely successful book *The Girlfriend's Guide to Pregnancy*, Vicky Iovine described it this way: "perhaps we new mums are secretly terrified that Daddy is going to be at least as skillful at childcare as we are. Where does that leave us?... So many of us secretly suspect that we are really amateurish at this mothering business and if a man... can do the job proficiently, then our self-esteem and identity lie in shattered little pieces on the bedroom floor (p. 52)."

The complex set of emotions and physiological changes that both men and women experience when transitioning into parenthood is sometimes softened by consumption experiences, such as when Danish consumers buy their first prams, a product laden with

social and cultural capital (Thomsen and Sørensen 2006). Yet, it also appears from related research that the baby marketplace actually exacerbates the fears and concerns of new parents, creating feelings of inadequacy and resistance. How women perceive their partners to be coping with the transition appears to be an important piece in the larger study of how becoming a parent is informed by identity, gender roles and norms, socialization, marketplace ideologies, and sociocultural beliefs. This paper has focused on women's perceptions of their partner's involvement in consumption prior to the birth of their baby; future research is therefore warranted, for perceptions following the birth of the baby on the one-hand, with a need for also investigating the perceptions and opinions of fathers themselves. As stated in the literature review, mother's perceptions of fathers have been utilized as a central measurement in the parenting and family literatures and this study also follows this practice; in the future it is also important to consider father's opinions on their roles and also father's perceptions of mother's involvement, to broaden our understanding and help build on the new ideas, from the differing countries, brought together and highlighted in this paper.

The Appeal of Our New Stuff: How Newness Creates Value

Aimee Dinnin, The University of Western Ontario, Canada

ABSTRACT

This conceptual paper accounts for the thrill associated with a brand new possession. I propose that the perception of newness is an important part of the consumption experience because it creates short-term value. Three factors create the perception of newness: situational product involvement, a sense that the product is pristine, and physical possession. Value is then derived from the hedonic experience of ownership and the motivational force of attraction to be the first user of a pristine, virgin product. The sense of newness fades over time, through product usage, and as the consumer hedonically adapts to possession.

INTRODUCTION

Consider the following hypothetical example of two individuals at a local police station. Both have had their bicycles stolen, and are distressed about their losses. The first person, who has owned his bike about six months, reports that his bike has been stolen. The second person reports "my *brand new* bike has been stolen". Presumably, the second person uses the term brand new to imply that the loss was greater than the first person's. She uses the term to indicate that her bike was, somehow, more valuable and more special because it was brand new.

Next, consider a consumer who has purchased a new car. Initially, he takes great pride in his brand new car; he diligently washes and waxes it, does his best to protect it from scratches, and prohibits his friends from eating inside it. Eventually, despite his best efforts to keep the car in its brand new state, the odometer creeps upward and a coffee is spilled on the front seat. After a finite amount of time and regular use, it is no longer his *brand new* car.

A brand new product is more appealing, and, at some point, the newness fades from new purchases. But why is a brand new bike more appealing than a somewhat new bike? What is different about the brand new bike? In this paper, I offer a description of the factors necessary to create a sense of brand new, and I suggest that the appeal of new possessions creates additional short-term value for the consumer, beyond mere ownership and endowment effects. I also offer an answer to the question: Why and how does my *new* car turn into my car? I argue that our perceptions of the product, and the product itself, change, and I will explain why the newness, and its attendant value, fades.

I believe that newness can be considered a perceived aspect of a product. Sensing that a possession has newness creates value for the consumer by fostering a positive hedonic experience and sense of attraction toward the new possession. Perceiving that a product has newness generates a thrill for the consumer, and this thrill lasts until the person perceives that new newness has faded. Coupland alludes to this, noting that attention to the product fades as newness fades (2005). This suggests that newness creates some sort of value or special appeal for the consumer.

To my knowledge, the concept of newness—as I introduced it—has received limited attention in consumer research. Richins and Bloch discuss newness in their account of why the "new wears off" of new possessions (1986, 280), but they account for the fading sense of newness by linking it to situational product involvement. Product involvement comprises interest and arousal, but it does not explain the pleasure or enjoyment that seem to accompany a perception of newness. Accordingly, I would argue that involvement does not adequately account for newness. Further investigation of how the authors consider newness reveals that they may be

describing a form of novelty, which is conceptually different from newness; any stimulus is considered novel when it is first introduced, but not every new stimulus has a sense of *newness* about it. For example, there may be nothing novel about the tenth pair of Nike running shoes a runner/consumer purchases, but the new pair may seem *brand new* for a short time. Other researchers have discussed the idea of newness in a similar manner, considering new as new-to-market (Wasson 1960), different (Oropesa 1995), or innovative (Hirschman 1980). I suggest that newness is a bona fide concept, distinct from novelty, and worthy of theoretical attention.

This paper will consider the special appeal and value associated with brand new products, with the understanding that the product has not had a previous owner. Additionally, I will only consider newness in the context of a purchase in a product category from which the consumer has previously purchased, and I will not consider novel products in the sense of consumer innovation and early adoption of new product categories. The model does not specifically account for newness in relation to products received as gifts, although there is opportunity for gift literature to inform future model development. Further, because I contend that physical perfection is an essential determinant for newness, this phenomenon will not be considered in relation to services or intangible products.

The purpose of this paper is to explain why and how new possessions create short-term value for consumers. In the first section of this paper, I argue that newness is developed in response to three determining factors: situational product involvement, perception of the product's pristine physical qualities, and possession of the product. In the second section of the paper, I define and discuss the notion of newness, and how it is defined by increased short-term value and loss aversion. In the third section of the paper, I suggest that newness declines as a result of time passage, product usage, and hedonic adaptation. The final section of the paper discusses the propositions put forth in the preceding sections, and identifies some research questions inspired by the model. First, to the question: what makes a product seem new?

DETERMINANTS OF NEWNESS

Situational Product Involvement

Involvement with a new product is necessary but not sufficient to foster a sense of newness. Product involvement can be defined as the consumer's level of interest, arousal, enthusiasm, or excitement toward a product, although it is important to note that involvement is determined by the consumer's interpretation of the product, not the product itself (Antil 1984). Consumer research has demonstrated that this psychological state can be understood as either enduring involvement or situational involvement, and that the principal distinction between them is temporal duration (Richins and Bloch 1986).

Consumers temporarily exhibit situational product involvement when their interest, arousal, and excitement toward a product peak. This peak generally occurs when a purchase decision is made (Richins and Bloch 1986). Situational involvement is experienced during pre-purchase search activities, during the purchase itself, and while the consumer still feels the excitement of having a new product. By definition, it declines over time (Antil 1984).

Situational involvement motivates pre-purchase search activities independently of the level of enduring involvement, which is

the consumer's ongoing or baseline level of interest in a particular product (Richins, Bloch, and McQuarrie 1992). For example, a consumer who has minimal enduring involvement with a car will experience temporary situational involvement when she is in the process of choosing and buying a new car. Consumers can be involved in the purchase but not in the product; as purchase needs are identified and options are analyzed, the consumer becomes involved in the purchase in order to make a satisfactory decision but she does not require a high level of interest in the product in order to become engaged in the purchase (Bloch, Sherrell, and Ridgway 1986). This suggests that only situational product involvement is required to create a sense of newness, because a consumer can sense newness for a product with which she has either a great deal or very little enduring involvement.

Pristine Product

The second necessary determinant of newness is that the consumer must believe that the product is pristine in order to sense that the product is truly new. *Pristine* is a subjective notion, and for the purposes of this paper, it will refer to a product that the consumer perceives to be in its perfect, unblemished, ideal form.

The consumer's evaluation of a product's physical appearance is the first form of connection with the product (Bloch, Brunel, and Arnold 2003), and consumers desire to purchase products that are as physically perfect as possible. When people purchase an apple, for example, they are drawn to choose apples with brilliant color, symmetrical shape, and clean, shiny skin. Blemishes, dirt, and physical damage deter us, just as they do for manufactured consumer products; we are likely to infer that quality and product performance will be compromised when we perceive the product as physically imperfect (Kotler and Mantrala 1985). However, we are also deterred by imperfections that do not explicitly indicate damage to the product or inferior quality. Although consumers differ in their individual levels of focus on product appearance (Bloch et al. 2003), product appearance is considered a universal signal of product quality (Dawar and Parker 1994).

Packaging plays an important role in maintaining a sense of pristine because consumers are less likely to question quality or performance when the original packaging is still intact. Underhill uses, as an example to demonstrate that consumers are deterred by damaged packaging, the following dialogue about shopping for bed linens:

How does it feel? The problem is that most sheets are sold in plastic bags, which allow you to look but not touch. So you tear open the bag with your nail and furtively rub the fabric. Now if you decide to buy, you'll choose another package, because who wants one that's been damaged (even if you did the damaging)? (Underhill 1999, 170)

A product can be considered imperfect if it is physically damaged or otherwise altered from its intended or ideal form. However, a product can also be considered imperfect if the consumer perceives it to be contaminated in some respect. Argo, Dahl and Morales (2006) found that consumers can consider a product to be contaminated if they believe that another consumer has simply touched the product. That is, a consumer can develop a sense of contamination in spite of an unblemished physical appearance. Argo et al. found that that perceived contamination of a product resulted in lower product evaluations, which were driven by the consumers' feelings of disgust. This is interesting because disgust is one of the strongest human emotions (Zaltman 2003), and consumer perceptions of a product can significantly worsen if other consumers are perceived as contaminating a product through touch

(Argo et al. 2006). This reveals that perceiving a product as pristine is more complex than an objective evaluation of its undamaged appearance.

Possession

I propose that physical possession is the third necessary determinant to the experience of newness. In order to sense that the product is brand new, the consumer must actually possess the product and be able to call it mine. Economic theory says the rational consumer takes possession of a particular product to derive utility from its functional benefits. We know, however, that consumers behave in ways that are both consistent and inconsistent with economic theories of choice (Okada 2001). Consumers can be simultaneously rational and emotional, reflective and impulsive, when they choose to take possession of a new product (Strack and Werth 2006). Indeed, "...much, if not all, consumption has been quite wrongfully characterized as involving distanced processes of need fulfillment, utility maximization, and reasoned choice." (Belk, Ger, and Askegaard 2003, 326).

Recently, researchers have espoused a middle ground position, positing that consumers engage in consumption activities to gain utilitarian benefits, which are derived from the functional benefits of the product, and to gain hedonic benefits, which are derived from the sensations of experiencing the product (Voss, Spangenberg, and Grohmann 2003). Thus, actual possession of a product gives the consumer access to the product's usefulness, and allows the consumer to sense the pleasure associated with the possession experience. Additionally, possession entitles the consumer to be the first to use the new product, which is an important stage in the consumption experience.

VALUE FROM NEWNESS

When the consumer senses that a new possession is truly brand new, there is a distinct level of additional value associated with the product. The consumer's sense of newness is generated by his situational involvement in the product, a sense of the product's pristine physical qualities, and possession of the product. These three factors work together to create the additional value associated with newness and the heightened loss aversion associated with the value assessment.

The concept of value is psychologically complex, and involves more than the monetary amount that one ascribes to something. Value can be derived from hedonic experience and from a force of attraction (Higgins 2006). That is, the value of newness can be considered both as the pleasurable experience of owning a pristine, new product, and the strong motivational force to be the first to use the product. Higgins notes that "although the hedonic experience and the motivational force experience often are experienced holistically, conceptually they are distinct from each other" (2006, 441).

I believe that value of newness is partially derived from the pleasure associated with ownership of a new possession. Situational involvement creates a short-term state of arousal for the consumer in relation to his very recent acquisition of a new possession. If the product is physically pristine and "untouched", the consumer should derive a distinct sense of pleasure in relation to his new possession immediately following its acquisition. In fact, many consumers are able to derive some value from the pleasure experienced by merely seeing a physically appealing product (Creusen and Schoormans 2005). It is this source of value that generates the "thrill" associated with a brand new possession, and most consumers should be able to acknowledge and describe the pleasurable excitement that comes from a new product.

I propose that the value from newness is also gained from being the first user of the product. This value is derived from the motivational force experience associated with the consumer's desire to be the first to use a pristine, previously "untouched" product. Higgins describes this source of value as "the experience of the motivational force to make something happen (experienced as a force of attraction)" (2006, 441). Instinctively, most consumers likely have a sense of the product owner's entitlement to be the first user of a pristine, virgin product. The privilege of being the first to wear, drive or operate a product whose newness is salient should be familiar to most of us. In some cases the consumer may be able to derive this value over a long period of time (e.g., a new car) because the product itself seems to hold its newness over several usage experiences. In other cases, however, the value associated with first use may be derived from simply opening the packaging (e.g., a new calculator). Few of us would consider driving a friend's brand new car before she had driven it, because we recognize that the product's owner is entitled to the privilege of first use. Conversely, there can be a distinct sense of disappointment associated with someone else being the first to use your own new possession.

LOSS AVERSION

When a person possesses something, he is motivated to avoid losing it. This motivation to avoid loss is termed loss aversion, which is a general preference to avoid a loss over experiencing a gain (Kahneman and Tversky 1984). In other words, the pain associated with a loss is more pronounced than the pleasure associated with an acquisition (Zhang and Fishbach 2005). Loss aversion reveals itself in a price discrepancy between an individual's willingness to pay to obtain a product, and his willingness to accept to part with the same product (Kahneman, Knetsch, and Thaler 1990). This discrepancy is known as the endowment effect (Thaler 1980), and it explains why owners demand higher prices than potential buyers. The endowment effect occurs immediately: willingness to accept increases substantially as soon as the individual acquires the item. Thus, an object's value increases as soon as the individual takes possession of it (Kahneman et al. 1990).

I propose that newness will create an amplified endowment effect. As previous research has demonstrated, a product's value will increase after the consumer takes possession of it. However, part of this increase in value should be attributed to the value derived from newness; the product's value and the associated loss aversion will decrease as the newness fades.

Owners of hedonic possessions attributed more value to their possessions and were more sensitive to possession loss than owners of utilitarian possessions (Dhar and Wertenbroch 2000). This suggests that possessions that evoke a strong hedonic reaction, such as products for which the newness is highly salient, are valued more highly and instill a higher degree of loss aversion in their owners. The endowment effect can therefore account for the increased hedonic impact of a potential loss (Nayakankuppam and Mishra 2005). In support of this, Belk (1988) reported that people are more likely to invest emotional energy in their possessions when the possessions are newer.

WHY NEWNESS FADES

I propose that the sense of newness fades as the additional value associated with newness dissipates; the appeal of the new product wanes as the hedonic experience and motivational force experience cease to provide value. Richins and Bloch allude to this, noting that "once the purchase has been made, consumer arousal and time spent thinking about the product decline as purchase needs and product novelty subside" (1986, 280). The temporal boundary of newness can be defined as the point at which *my new car* has

become *my car*. Until this point, the value of newness declines over time, through product usage, and as the consumer hedonically adapts to possession.

Product usage and the passage of time since purchase affect newness in three ways. First, situational involvement naturally fades over time, resulting in diminishing value and a declining sense of newness. Second, product usage usually results in the product losing its original pristine characteristics, which will also have a negative impact on newness. Third, the value associated with being the first to use a possession is fully derived through direct experience with the possession.

Hedonic Adaptation

As the consumer becomes familiar with his new possession, he becomes psychologically accustomed to level of stimulation it provides and to the nature of his affect associated with the possession (Strahilevitz and Loewenstein 1998). As time passes, the intensity of his affect decreases, and this process is known as hedonic adaptation (Frederick and Loewenstein 1999). In their investigation of new car buyers, Richins and Bloch (1986) found evidence of hedonic adaptation: as the owners became accustomed to their new cars, their levels of product involvement diminished to pre-purchase levels. Thus, hedonic adaptation takes places as newness fades. The consequences of this adaptation are two-fold: the consumer experiences a reduced hedonic response to his new state of being, and he experiences an exaggerated sensitivity to reverting back to his original state of being (Strahilevitz and Loewenstein 1998). Additionally, hedonic adaptation can explain why a consumer does not experience increased happiness from acquiring more material goods; as the consumer acquires more his aspirations and actual gains are raised equally (Easterlin 2003).

DISCUSSION

The endowment effect explains the consumer's tendency to increase product valuation after taking it into possession; valuation increases when possession occurs. However, the literature on hedonic adaptation suggests that value declines over time, if value is considered in terms of hedonic experience and force of attraction. Thus, it appears that possession valuation may involve a pattern different from—but not contradictory to—the endowment effect; valuation may be amplified for the period of time immediately following endowment. Figure 1 depicts valuation over time according to this model. The solid line demonstrates valuation according to the endowment effect, where value increases after possession occurs and, presumably, stays constant. The dotted line depicts the pattern in valuation according to my theory; valuation increases after possession occurs, but declines over time. Strahilevitz and Loewenstein (1998) allude to this pattern, noting that although the endowment effect occurs immediately after possession occurs, more time is needed for the consumer to completely adapt to ownership. This suggests the possibility that the consumer may value her new possession somewhat less after she hedonically adapts to ownership than she did when first endowed with it.

Conceptualizing newness in this way inspires some research questions that may permit empirical tests of the theory or allow for the future development of the model. A simple experiment could determine if monetary valuation peaks immediately after possession endowment and subsequently declines after time or usage. Further manipulations could identify the extent to which a peak in valuation is dependent on temporary enthusiasm toward the product, the perception of the product as being pristine, or belief that the product has not been previously used. It would also be necessary to assess how usage of a new possession influences valuation.

FIGURE 1
Possession Valuation Over Time

Determining the boundary conditions of the model will be useful in improving our understanding of possession newness. Subsequent testing might address the ways in which product categories influence newness. Do different product categories prompt the consumer to have a heightened sense of newness? What are the characteristics of these categories, and do they involve higher levels of enduring involvement? Is newness enhanced by monetary outlay for purchase, rarity of the product, or the amount of time and emotional energy invested in the pre-purchase search? The influences of individual consumer characteristics should also be addressed. Is newness influenced by personality characteristics, such that some consumers sense newness more strongly than others? Are more materialistic individuals more inclined to sense newness because they place more value on the acquisition of material objects than other people (Burroughs and Rindfleisch 2002)? Does consumer optimism influence newness because people who are more optimistic about the future experience more pleasure in buying new things (Oropesa 1995)? Further, since possessions not only become part of the self, but also help to construct identity (Belk 1988), are consumers more likely to be stimulated by possessions in which they have invested emotional energy? Is newness more salient for possessions that contribute more to identity or sense of self?

Experimental design could also incorporate differences in the nature of the endowment situation. Although this model does not consider products given as gifts, newness may be affected by perceptions of a gifted possession. For example, how is newness influenced by pleasure associated with receiving the perfect gift, by disappointment associated with receiving a bad gift, or by suspicion that the giver has “re-gifted” the item? Further, can newness be perceived in relation to a previously owned product, such as a used car or an antique item?

In addition to empirical testing, it will be important to understand how newness is actually experienced by consumers. This could involve a phenomenological approach, focusing on individual consumer experiences with new possessions. From this perspective, we might gain insights into the emotions and behaviors involved in perceiving newness. If consumers know that the newness will eventually fade, are they sometimes motivated to maximize the intensity and duration of newness because they enjoy the associated hedonic experience? How do consumers try to maximize or maintain a sense of newness? Addressing these questions may help us to understand why consumers are not willing to pay the same price for a physically flawed product, even if the flaw will not affect product performance. Further, it will be important to understand how newness is “used up”. What are the behaviors associated with consumption of newness? Are consumers less willing to share possessions for which the newness is still salient? Are consumers conscious of a privilege associated with the first use of a possession or with using up the newness? Attention to these research questions will allow for a better appreciation of how consumers experience value from their new possessions.

CONCLUSION

In this paper, I described the factors necessary to create a sense of possession newness: situational product involvement, perception of the product’s pristine physical state, and actual possession of the product. When these factors are present, the consumer is able to derive short-term value from the new possession in the form of a distinct, pleasurable response to the product and the privilege of being the first to use the product. The value of newness fades over time, with use of the product, and as the consumer hedonically adapts to ownership.

Considering the concept of newness within this framework can allow for an understanding of how and why consumers perceive some new possessions to hold special appeal. The notion that newness creates a distinct form of short-term hedonic value and a compulsion to be a new product's first user can help to explain behavior toward these possessions and the pattern of valuation. Further, this concept of value from newness integrates literature concerning the endowment effect and hedonic adaptation, thereby deepening our understanding of possession valuation.

Consuming the Black Gospel Culture: An Interpretive Study of Symbolic Exchanges

Yuko Minowa, Long Island University–Brooklyn Campus, USA

David S. Glover, Long Island University–Brooklyn Campus, USA

ABSTRACT

This paper investigates the meanings of Black gospel music and symbolic exchanges of gospel culture within and across gospel and non-gospel communities. Based on an ethnographic account, we analyze our informants' lived experiences with consuming gospel music and culture. Based on the consumption orientation and based on the nature of experience, we find that gospel music consumption is characterized as indulgent, contemplative, communicative, and transcendent. We discuss how gospel music mediates to define and redefine the meanings of the culture within and across gospel communities and Others. While being commodified as a cultural product, gospel music spawns new consumer identities.

INTRODUCTION

Music evolves, metamorphoses, and its meanings and consumer experiences are intricately interwoven, begetting a mandala of symbols while letting the consumer immerse in the vast sea of emotional undulation. Black gospel music is a genre par excellence. Originating in the Negro spirituals, one definition of gospel music may be "a religious music of African Americans that emerged in urban centers during the early decades of twentieth century" (Burnim and Maultsby 2006, 51). It is an expression of the aesthetics, values, and experiences of their community (Jackson 1995). Today, however, gospel music is consumed by both descendants of Africa and those who do not share at all the African American heritage and tradition. It is appreciated through an MP3 player by a lonesome jogger as well as in church as part of liturgical ceremony. The music is sung by religious African Americans in a choir as well as by groups of Japanese Buddhists or Australian atheists. Gospel music is not only sung, but the choir is an object of spectation by tourists. Then, what does it mean to different individuals to consume such supposedly religious and ethnocentric gospel music? How do people consume their experience with the music and culture? The multivocal character of gospel music seems to expand unbounded and continues to augment its multiplicity.

On a Wednesday morning, for instance, a deluge of foreign tourists fills up the sightseeing bus at Times Square and cruises New York City. They head toward Harlem to explore and experience what they believe to be authentic African American urban culture including gospel music. In one of the churches, a few locals walk down the aisle with Chinese takeout in a plastic bag and start rocking their bodies as they approach an open pew, while a group of young Japanese female tourists indifferently listens to the tour guide's explanation about where the donation would go. All of a sudden, a pencil-thin woman staggers up to the stage and speaks to the audience about her personal problems. Then, a man in a red and yellow robe recites the bible while the gospel choir, made up of members of the local addiction rehabilitation center, sings frantically, and some locals, in trance, sing together and shout intermittently "thank you," "hallelujah," and "amen." Chaos and madness permeate this newly renovated church; the site is an apt simulacrum of an "authentic" Black church in Harlem appropriated for a commercial purpose in the global age.

Another way to apprehend gospel music and culture is to critically examine its meanings in relation to consumer culture theory (Arnould and Thompson 2005). Gospel music is a subject of study in various disciplines. Its history and the history of performance are topics in music history as well as cultural studies (Darden

2004; Smith Pollard 2008). As the music of a subculture, in ethnomusicology, its musical tradition in its cultural context is examined (Burnim 1985; Jackson 1995). In sociology, the function of gospel music in symbolic interaction and its power in social influence are explored (Semmes 1974). In anthropology, the hybridization of indigenous and gospel music by locals in the age of globalization has been explored (Magowan 2007).

On the other hand, in consumer research, experiential consumption of music is profoundly related to the subculture represented by age group (Holbrook and Schindler 1989; Blair and Hatala 1992), ethnicity (Schroeder and Borgerson 1999), and religion (Davis and Yip 2004), or any combination of these variables (Gooch 1996). Previous studies on religion or spirituality in conjunction with consumption (O'Guinn and Belk 1989; Kozinets 2001) did not integrate the role of music in cultivating and enhancing religiosity or consumption. On the other hand, there seems to be little research efforts made to investigate consumer behavior of African Americans with few exceptions (Edson Escalas 1994; Stamps and Arnould 1998; Hirschman and Hill 1999). While the postmodern social phenomenon unveils "cocooning" lifestyle and fragmented social identities in urban landscape (Thompson and Holt 1996), previous inquiries about minority communities (Üstüner and Holt 2007) neglected the significance and role of aesthetic consumption in the sustenance of consumer identity. In this regard, gospel music is an integral part of consumer identity, and it is driven by outer-directed forces.

Therefore, the present study investigates the experiential consumption of gospel music by incorporating multidisciplinary perspectives. In particular, the objectives of the current study are: 1) to examine the meanings and structure of the experiential consumption of gospel music, and 2) to explore symbolic exchanges of the gospel culture within and across the communities defined by gospel music consumption. There is a dearth of research on consumer behavior related to African Americans and their cultures in general. There is no prior study on the experiential consumption of Black gospel music in consumer research. While the shortage alone does not rationalize our motivation for the study, we justify the significance of our study because of the tacit impact of the music making and symbolic exchanges on consumer well-being and welfare aside from its contribution to consumer culture theory.

METHODS

We conducted an interpretive study to empirically explore how consumers of Black gospel music inside and outside the gospel communities consume the musical experience and the entire gospel culture. Following methodological approaches stemming from contemporary social sciences that have been applied to consumer research (Arnould and Wallendorf 1994; Charmaz 2000), we employed participant observation and a variety of interviewing techniques, such as ethnographic interviewing, focus group interviews, and in-depth personal interviews. Ethnographic interviewing is a particularly valuable method to apprehend consumer experiences because the interview setting *in situ* evokes the consumption experiences in the past and the present (Holt 1997). Specifically, interviews took place in the lounge of churches, the dining room of the local addiction rehabilitation center, in the living room of the informant's home, and inside the sightseeing bus. People were more likely to talk about their experiences with gospel music and

culture in these sites than in the conference room that was also used for formal interviews.

The study was conducted in several sections of New York City between April 2007 and March 2008. The selection of interview sites was crucial because gospel culture was objectified, consumed, and marketed in divergent ways depending on the geographical location within the city. Harlem, predominantly the home of the African American community, in particular, is considered a focal point for our study since it is socio-historically the center of the development of gospel culture in the North East along with Philadelphia. Also, Harlem is the strategic site for the gospel industry as it became the tourism destination for Others to view and appreciate supposedly authentic black community and gospel culture.

In sum, 27 people were interviewed, which consisted of 12 males and 15 females. All of them but three were descendents of Africans and, to a varying extent, part of gospel communities. When they were asked to identify their cultural background, most of them preferred to call themselves simply New Yorkers. Seven people identified themselves as something else, such as Caribbean or Southerner. Three people from non-gospel communities consisted of two tourists from Japan and one Jewish female from New York. The ages of informants ranged from 14 to 83, with the median age of 40 years. These people were selected on the basis of their self-claimed, highly involved consumption experience with gospel music and culture. The duration of the interviews ranged between 20 and 60 minutes. The informants included students, administrative staff, office clerks, the music director of gospel choirs, the executive director of an addiction rehabilitation center, recovering addicts, and retired school teachers. In other words, the sample included both white- and blue-collar, lower to middle class, and urban gospel consumers. We began interviews with less structured questions and modified them as we felt needed, adjusting to emergent research questions and to informants' responses. All the interviews were either video or audio recorded, and they were subsequently transcribed for analysis and interpretation.

Along with the interviews, we conducted participant observations. We studied participants of concerts, special events during Black history month at the local historical society, which was targeted to a general audience, and at the large concert hall which was targeted to descendants of Africa, supposedly heavy gospel music consumers. We joined an organized commercial sightseeing tour and traveled to Harlem with tourists by chartered bus and saw a gospel concert performed by members of the local addiction rehabilitation center. We took notes manually where digital recording was not allowed. We talked informally with participants of concerts and sightseeing tours about their experience with consuming gospel music and culture.

In analyzing the data, we tried letting the data speak first rather than approaching them with a theoretical frame postulated *ex ante*. Before coding the data, we explicated, explained, and explored the narratives in the transcription following the hermeneutic triad (Czarniawska 2004). Then, we examined data instances, compared conceptual similarities and differences, and sorted emergent themes. During the core analysis when we discussed emerging concepts, we went back to the narratives and examined data iteratively. We repeated the cycles of inquiry until it had reached saturation. All the names that appear in this paper are pseudonyms, followed by the informant's age in parentheses.

SYMBOLIC CONSUMPTION OF GOSPEL MUSIC

Black gospel music is symbolic of the Christian, African American subculture. Various meanings are embedded in the consumer's experiential consumption of the music within the fuzzy

perimeter of subculture. For some, the subculture is well defined with the reinforcement of a strong religious boundary. For example, Tamara (31), whose father was a pastor, says "the whole being raised in church is a part of it. So, it in a way is a culture because the people in church, you know, we all have our own way." Inspirational, encouraging, uplifting, and strengthening are the words most frequently used by our informants to characterize the meanings of the gospel music.

Lyrics of gospel music are the good news, the Devine message. For Daria (58), it is her extended self, symbolic at different levels simultaneously, as it connects her with her ancestry, faith, and culture and music. Spreading activation, shifting the meaning back and forth, she states: "To have the Gospel come from the Book and the Book is old and it was my mother's, it was my father's and now it's mine, so my children, it's just old stuff hereditary. It carries the message in music." The message reminds the faithful that they should continue to stand up and not to give up. Ronald (31) claims that it not only evokes emotion but also invokes a motion; gospel music helps him to take the extra step.

Gospel music is perceived to possess remedial and analgesic properties. Jim (83) says it is a remedy for both physical and psychological pains, and quoted Mahalia Jackson out of his memory: "Blues tells the world your troubles, but, Gospel tells the world your troubles *and* what the solution is." Troubles may be specifically related to consumer behavior: dilemmas and frustrations caused by acquisitions and possessions. Brenda (40) claims: "gospel music allows me to look beyond the material things and see what the real quality, the substance of life is." Gospel music in the religious context helps people tolerate personal difficulties in quotidian circumstances as Imogene (61) says:

I take Him into the doctor's office, my Lord and Savior Jesus Christ and anyone else who would go with me—that's John, Paul, Peter—they all go into the waiting area to get it together cause most times our best bet is to take notes before going into the doctor's office that includes prayer and anything else you got going on.

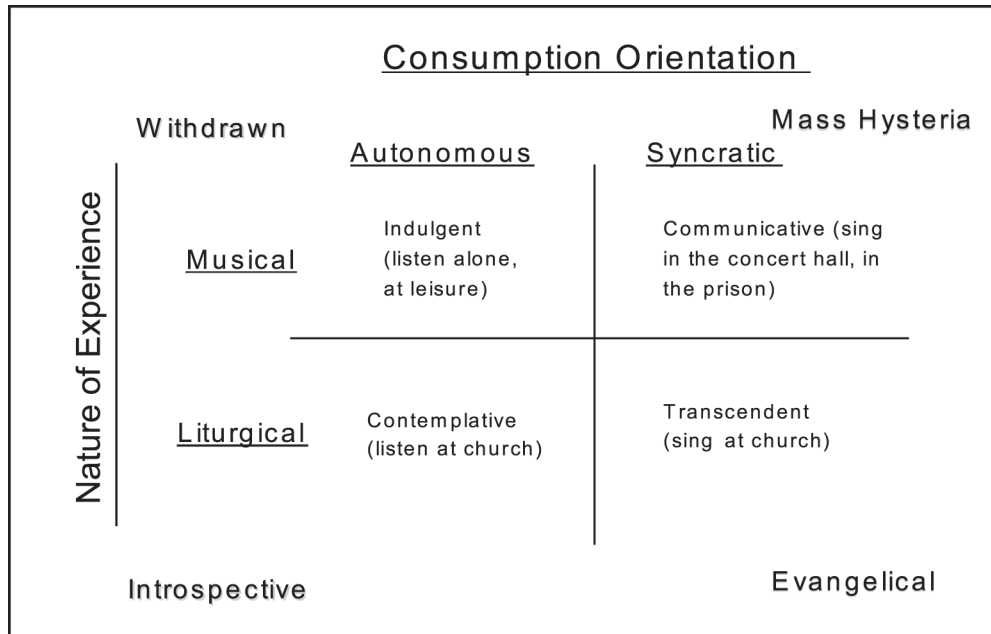

Clinical and therapeutic uses of music have been studied, and their effectiveness in medical, psychoanalytic, and behavioral fields has been attested to (Bunt 1997). However, gospel music can be beyond therapeutic; it comes to the mind of the faithful as a form of prayer, which is invocatory, and aids consumer decision making as discussed by Imogene above.

Nature of Experience versus Consumption Orientation

Analyzing the narratives of the informants, we found the texts can be categorized in terms of the nature of experience and the orientation of consumption. The nature may be either purely musical with a void of religious context or liturgical within ceremonial context. On the other hand, the consumption orientation may be autonomous or syncretic. The music alone can be consumed by individuals, while gospel music, as part of cultural experience, can be shared with other members of the community, or Others who do not share the heritage yet desire to have the cultural experience.

Some of our informants said that gospel music is both a form of worship and a kind of entertainment. As a means of entertainment, Johnson (2005, 59) points out that "we live out the contradictions of our lives, and an aversion to religion does not exclude persons from making personally meaningful connections to gospel music..." But such purely musical experience may be regarded as sacrilegious by the faithful. For example, when listening to gospel music in a concert hall, both the choir and the audience get "lost"

FIGURE 1
Symbolic Consumption of Gospel Music

while entertaining each other in antiphonal reverberations. Tamara (31), an informant from the gospel culture, says: “it’s a lack of sincerity.”

The Symbolic Consumption of Gospel Music

Based on the nature of experience and the consumption orientation, we consider that music as a conduit for indulgence, a means to induce personal reflection, a device for communication with others, and a channel for transcendent experience. These are diagrammatically summarized in Figure 1. The following narratives of informants provide us with insights.

Music as Indulgence. Excessive consumption of gospel music may signal the individual’s proclivity towards withdrawal. The moderate state may be considered as indulgent behavior. Some informants discussed the relaxing efficacy of indulging in gospel music. Linda (52), for instance, is likely to spend her Sunday morning with a cup of coffee listening to gospel music. It enlightens her day. She is Catholic but does not go to church regularly. Nevertheless, starting a day with gospel music is the right course of behavior.

Gospel music, like popular music, can evoke a nostalgic past while indulging with it. For example, Linda (52) recalls her difficult youth and how she dealt with problems by listening to *What a Friend I Have in Jesus*. Similarly, Jim (83) recalls how his aunts on the farm used to always sing as they worked: “They picked cotton, and they chopped cotton . . . and when the season was over, they would sing songs like: ‘So glad, I done got over, I’m so glad.’”

With its hypnotic quality, some gospel music help induce the consumer to withdraw from the outside world temporarily to recollect things from the past, to relieve from present pains, and to avoid confronting future difficulties. For instance, it induces Jim (83) to recollect his hard days:

I was addicted to heroin for many, many years . . . And during one of my drying out periods, I heard this guy singing and playing the guitar, ah, a gospel song, and his voice was so beautiful and clear that it got me back into gospel . . . And it’s always had a deep spiritual meaning and something so spiritual. It was so different from other music that you can hardly explain it.

When the music is felt sublime, it brings the consumer a spiritual cleansing. More recently, Jim’s indulgence with the music led him to acquire an iPod so that he can play gospel songs and sing along with them while he is cooking in the kitchen. The technology has aided enhancing consumer’s indulgent behavior while it united sublime and mundane, or sacred and secular, in consumers’ daily lives.

Music as Personal Reflection. Storr (1993, 95), in criticizing Freud, discusses true sources of religious sentiments, which originated from “a sensation of eternity, a feeling as of something limitless, unbounded—as it were, ‘oceanic.’” Such sentiments may be provoked by introspection, keenly conscious observation of the self. Linda (52) says that gospel music helps her feel closer to her spiritual “ultimate” relationship with God. For Tamara (31), it is a way to put her beliefs to music, a form of expression for her, as she could identify herself with the messages.

Not only personal nostalgia, but gospel music also evokes collective historical experience. Malcom (35) associates it with slavery and the repugnant ordeals that African Americans underwent. Roy (29) links the historical experience and personal sentiments through gospel music. He explains:

I like the earthliness of the Negro spirituals that remind me of the Black experience. In Orangeburg, South Carolina, where

I went to high school, ... they used to do a lot of breeding of slaves. And they sold them in the slave market in Charleston... so when you hear those Negro spirituals ... it speaks to an experience that I'm basically a product of the breeding.

Roy is a southerner who was born after Jim Crow. Although he did not experience segregation, he learned about the hardships of black people at church while growing up. As an indigenous South Carolinian, he believes that he is a descendant of slaves. Thus the collective history is felt immediate as his personal history. Gospel music is not only juxtaposed to his memory of the history, but also it has served to condition him to reflect on his identity.

Music as Communication. When the music is sung in a group, the shared music-making experience is a powerful source of communication. Gospel music is important to Malcom (35) because "it's [his] connection to the community." When Leticia moved from New York to Cleveland, the first thing she did was to look for the right church to join. She had three evaluative criteria: the preacher, church members, and the gospel choir. Our other informants similarly narrate the significance of gospel music as a galvanizing and solidifying force in the community.

The music, however, does not have to be communicated in a large group. The musician and an individual audience can have deep philosophical communication. For Krista (28), listening to the Yolanda Adams song *Open My Heart* gave an answer to her personal problem, because of the perceived similarity between her circumstances and those of the singer: "you know, [the singer] is in a room and she's talking to God and ... she's questioning I guess the situation and she just has to make her decision..." Religion, spirituality, and consumer decision making are united through Krista's subjective feeling and thoughts in communicating with the Divine, which is mediated by her musical experience.

Furthermore, the communication is aimed to salvage the doomed. Steve (52) who traveled with the gospel choir to a prison in Louisiana describes his recollection from "the Underground Railroad Tour":

We were at a prison in Louisiana called the Louisiana State Penitentiary. We were on death row singing for young men, 16 and 17 years old, and no one had ever done a concert on death row before at this Angola State Penitentiary. And I recall ... these were young men who were maybe never going to see outside or maybe they were going to die there. And, I can remember singing for these young men and just hoping that they can get some kind of idea of freedom, even inside of death row....

Having grown up in a dysfunctional family, Steve became a problem child, and then, a drug addict. Then he was taken to a gospel choir, and the music-making experience changed his life. In penitentiaries he visited, he and the choir members were self-designated missionaries. While communicating the good news with inmates, Steve thought he could have been there if he had not been exposed to gospel music. Thus the communication through music can also function to reflect the self and enhance the self respect.

Music as Transcendent Experience. Daniel (49), the director of the gospel choir at one of the African Episcopal Methodist churches, differentiates gospel music from other types of Western music by pointing out that it is an oral tradition rather than being written down. As such, he believes, "it's kind of in a different way and it comes more, you know, initially from within and it just keeps

coming from within." Malcom (35), a musician, plays both gospel and jazz. When he plays jazz, he caters to the crowd's mood. On the contrary, when he plays gospel music, he concentrates on the spirituality and his feelings for appreciating Creator for life, health, strength. He says: "the connection [with the Creator] is so important. I shy away from what the audience vibes or what the congregation would get me to do. But, I communicate with the Creator first."

For Catherine (60), a singer and a devotee in the choir, the performance is a dedication to the Divine:

When I first sang in the choir, you said to me, 'good job my sister.' And I said, 'to God be the glory.' It's not about me, it's about Him. It's not a performance to us, it's a ministry. We don't sing these songs because we want the congregation to say, 'Good job Catherine,' 'Good job Imogene.' No. We want God to get the glory. We want those persons who hear us to feel God is within us when we project these songs.

Her zealous and affirmative pronouncement in a heroic tone suggests that she experiences a kind of psychic syncope while feeling a divine purpose in music. Similarly, during music making, singers and audience in call-and-response often appear not to be fully in conscious control of their behavior; they are out of quotidian time and space, or experiencing "cerebral eclipse" (Becker 2004). These trancers experience positive musical emotions, often accompanied by physiological arousal. The "forestructure of understandings" about musical experience is, however, conditioned by the community (Gergen 1991 cited in Becker 2004, 69) as musical emotion is culturally constructed (Geertz 1983). Transcendent and evangelical experiences can be elicited strategically by the religious community (Becker 2004, 98).

SYMBOLIC EXCHANGES OF GOSPEL COMMUNITIES AND OTHERS

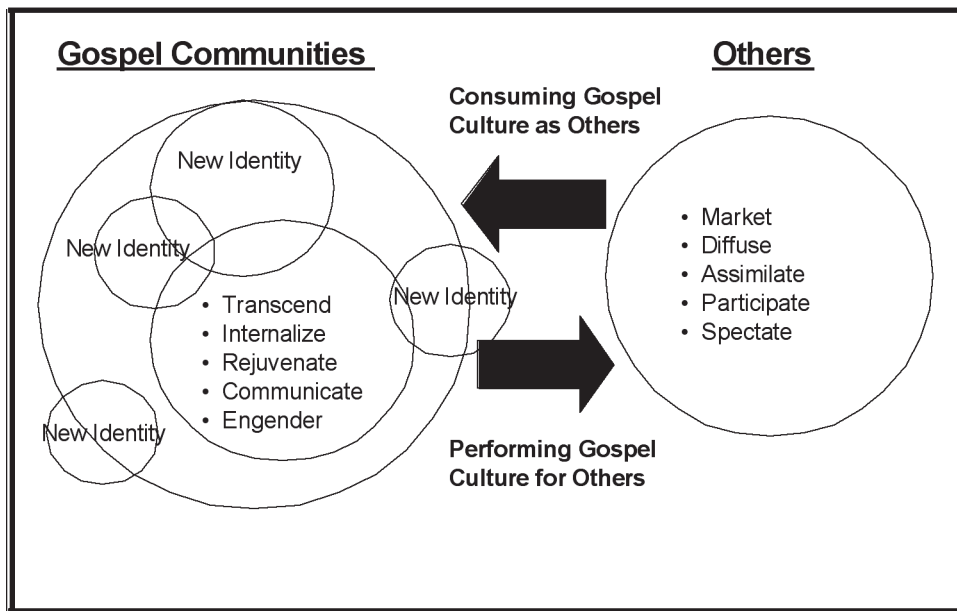

Gospel music functions more than a source of entertainment or a liturgical accompaniment. As a social and cultural agent, it intermediates symbolic exchanges of gospel communities and other communities. In that process, authenticity of blackness was appropriated and re-appropriated reflecting the efforts to adjust to the perceived authenticity of each other. As Johnson argues (2005, 80) "blackness' may exist as a floating signifier in various cultures, but the consequences of its signification vary" and manifest in various ways, such as music, depending on the cultural environment. The opinions toward the consequences vary: the expropriation of black culture; the co-optation of the cultural products by Others. Such amalgamation is viewed as the problem of cultural hegemony (Semmes 1994). In Figure 2, we illustrate the exchange process among and between gospel and non-gospel communities.

Consuming the Gospel Culture as Others

Consumers from non-gospel communities market, diffuse, assimilate, participate, and spectate the gospel culture. Some consumers approach gospel music with intrinsic motives to experience humanistic-oriented spirituality (Emmons and Paloutzian 2005) which is characterized as a universal human phenomenon, and its manifestation phenomenological. Grapsie (65), a Jewish New Yorker, occasionally goes to church in her neighborhood, to listen to gospel music. Her experience exemplifies such spirituality induced by experiential consumption of gospel music:

At joint Passover and Easter celebration, the rabbi and the pastor talk about the similarity. About two years ago, at the end

FIGURE 2
Symbolic Exchanges of Gospel Culture

of the service, everybody got up and sang *We Shall Overcome* together holding hands. And, that made me cry because it brought me back to the 60s, the whole Civil Rights Movement, and all the things that had not happened. So, it was a very emotional experience. I started teaching in 1964, and that was the height of the Movement, and I was teaching in the Black communities in Brooklyn... It was a difficult time because those of us were idealistic.

The propinquity of Jews and Christians she heard and experienced in her personal history and the collective history of her cohorts created a collage of memories, which were synthesized by her musical experience. By participating in the liturgical service as Others, the consumer seems to experience the music as an agent to personal reflection and nostalgic feelings.

Performing the Gospel Culture for Others

Gospel music is a creative agent of the Black community. It expresses and disperses their cultural ethos and aspirations (Semmes 1994). On the other hand, music, in general, influences the behavior of society. Summarizing the prior studies, Crozier (1995) contends that multiple factors—*affect, arousal, emotion, and mood*—induced by music contribute to social influence. Comparing the influence of rock and rap music and that of gospel music on young people, Jim (83) observes: “their behavioral patterns followed the pattern of the music.”

On the other hand, Jim (83) is a cathartic agent as the director of a choir and addict rehabilitation center: “I probably would not be so strong in the Lord if it wasn’t for gospel; but, it gives me a chance to express, really, to get people’s attention.” He does not do it as a show, though. Once Jim met a young man from Japan, a sound technician, who blatantly stated, “I don’t believe in God.” But when the recording project was completed, the young Japanese said, “You know, I’m going to try that Bible you were talking about,” and for Jim, it was the ultimate gratification of singing; introducing to

somebody who does not believe in God, so that he may say “Hey look, maybe there’s something to it, the God thing.”

Performing and consuming music is a form of social identity. It provides the security of identification, assuring its own group identity while distinguishing the self from the others (Larson 1995). Our informants’ narratives further suggest that singing gospel music and performing gospel culture for Others function to engender new identities for those in the gospel communities. For example, at one church, singers are dressed in Africanized costumes at the concert. These costumes are not authentic but help the singers enhance their perceived African heritage. Each singer has two flags in their hands to wave at the audience. These flags, seemingly real, are only props to enhance their image of being descendents of Africa.

When performing and consuming the culture of Other, the music, as a creative agent, plays an intermediary role. In the process, music and other cultural products are accommodated to spawn and shape a new identity and new culture. Daniel (49) says, “Gospel will always be contemporary... [and] influenced by things that are happening outside of the church.” Leticia (33) who worked with Jay Moss, a prominent gospel singer, for a Black Heritage Celebration in Cleveland, Ohio, by inviting the Latino community, had this experience:

... I’ve never been in a particularly Latino church. But, they rocked it. You know, when they performed, they rocked it. A lot of people were into it. And it was something different. Now I was amazed. I was just like wow, okay. I need to visit your church too. Maybe I’ll learn some Spanish, but, I need to visit your church, too, you know.... I think contemporary music, gospel music has helped that grow... at a very fast pace.

The new identity engendered as a result of the heterogeneity of the audience has necessitated a new music to grow to address the differences. Gospel music with the tint of rap has spawned the new

gospel culture (Gooch 1996; Smith Pollard 2008). Referring to the controversial holy hip-hop, Daria (58) tells us, "I think if it reaches the people, it's all good, 'cause you need a variety to reach different people. So it's all good as long as the message is being put out there." As part of the new generation of the gospel culture, Kelly (14) is insightful: "Young kids that don't believe in God do not listen to gospel unless it's hip-hop." She says nobody should be offended, however, "because God is giving them that gift."

CONCLUSIONS

In this paper, we investigated the meanings of gospel music and symbolic exchanges of gospel culture within and across gospel and non-gospel communities. Based on an ethnographic account, we analyzed the narratives of the informants and interpreted their lived experiences with consuming gospel music and culture. Based on the consumption orientation (i.e., whether the consumption is autonomous or syncretic) and based on the nature of experience (i.e., whether the gospel consumption is musical or liturgical), we found that gospel consumption was characterized as indulgent, reflexive, communicative, and transcendent. We discussed how gospel music mediates to define and redefine the meanings of gospel culture within and across gospel communities and Others.

Consumer culture theory is inclusive of "blurred genres," reflecting the nature of social sciences (Geertz 1983). It does not seem, however, to raise a question whether experiential consumption of music gives us a good life or a happy one. The current study shows Black gospel music does not necessarily lead to either end. Poverty and the resultant social problems continue to exist despite the personal and cultural significance and the edifying properties of gospel music. Then why do we continue consuming the musical experience? Kivy (1993, 31) contends, "the best that we can hope from music ... is that it help to *humanize*." Neither does the humanizing influence of gospel music alone contribute to improving consumer welfare. "The mind strives to imagine only those things which posit its power of acting" (Spinoza 1677 quoted in Curley 1994, 182). The results of the present study are best hoped to bring about more inquiry in to transformative consumer research.

ABSTRACT

This paper examines the impact of gift-recipients' self and identity changes on the meanings of the important gifts that they received a long time ago; and the strategies they employ when dealing with these changes in the context of their "existing on-going" and "disconnected" relationships. This paper addresses the research gap in our understanding of how changes in interpersonal relationships with the gift-givers are incorporated into the changing meanings associated with the gifts over time. Our findings expand upon the existing gift-giving research by examining how old gifts signify different aspects of changes to the self in life transitions within consumers' identity projects.

INTRODUCTION

This paper examines the impact of changes in gift-recipients' self and identity on the meanings associated with their important gifts that were often received a long time ago; and the strategies they employ when dealing with these changes in the context of their "existing on-going" and "disconnected" relationships. We aim to address the research gap in our understanding of the impact which changes in self and interpersonal relationships with the gift-givers has on the meanings associated with the original gifts over time.

How people interpret, and often give new meanings to, their gifts as their possessions gain in importance over time has not been explored in earlier consumer research. Most gift-giving research focuses on the actual gift-giving process from the perspectives of the givers, recipients, or even of a third person in the decision making process of buying a gift. Earlier research has concentrated on the process of searching for a gift, purchasing a gift, choosing the right place or the right time to give a gift, the reaction of recipients when receiving a gift; and how a third person often influences the decision of a giver in purchasing a gift (Joy, 2001, Curasi, 1999, Belk and Coon, 1993, Otnes, Lowrey and Kim, 1993, Sherry, McGrath and Levy, 1992, Lowrey, Otnes and Ruth, 2004, Sherry 1983).

However, Josselson, Lieblich and McAdam (2007) commented that "relationships are central, from the very beginning of and throughout life, to the constitution and expression of the self" (p. 3). Through their narratives about the important gifts that they have received, informants reveal how their selves are maintained, modified or changed in two contrasting relationships, i.e. the "existing on-going" and "disconnected" relationships, with the gift-givers. Four informants' narratives about their important gifts are used to explore how the sense of self, and the associated interpretation and meanings of important gifts, change and co-evolve over time.

Earlier research used six relational meanings of gifts to examine the creation and maintenance of relationships from the perspective of gift-recipients (Ruth, Otnes and Brunel 1999). However, how gift-recipients' identities, and the meanings of their important gifts, change over time has not been explored. Building upon Ruth et al.'s (1999) study of "how relational meanings are created through gifts" (p. 385), this paper focuses firstly, on the interpersonal relationships between gift-givers and gift-recipients; and secondly on the gifts that recipients received a long time ago and whose meanings have evolved over time. The emotionally and symbolically-laden meanings of gifts may change over the life course (Belk,

1988, Solomon, 1983) so that gift recipients reinterpret the meanings of these gifts. These gifts often become special possessions for recipients, bearing witness to their different relationship life stages such as dating, getting married, divorced, or losing their loved ones. Each relationship transition offers an opportunity for recipients to redefine and renegotiate their identities (McAlexander, 1991). Throughout these trajectories of different transitions, some recipients maintained and strengthened their relationships with the gift-givers, whereas some recipients struggled or even ended their relationships with the gift-givers due to relationship breakdowns, personal disputes or death. These relationship changes lead to self-modification and self-change.

In this exploratory study of self-change and self-continuity, we collected and analysed consumers' narratives so that we could access discourses around the self in different settings. Selves and identities are embedded in discourse in the format and construction of stories (Georgakopoulou, 2002). We begin by reviewing the literature on gift-giving, possessions and the use of narratives; before outlining the research design and the method of narrative analysis; then we present the stories from four informants about how they modified their self and identity, and re-interpreted their relationships with their important gifts. We conclude by discussing the different strategies informants employ when dealing with these changes.

GIFT-GIVING

Gift-giving has been studied for decades in anthropology (i.e. the economic reciprocity exchange), sociology (i.e. the social exchange) and psychology (i.e. the motivation of reciprocity exchange) (Mauss 1954, Homans 1961, Schwartz 1967). In marketing, Sherry (1983) proposed a three-stage framework of the gift-giving process involving the gestation stage (i.e. searching for, choosing and buying a gift), then the presentation stage (i.e. the time and place of the actual exchange) to the final stage of reformulation (i.e. realignment and reformulation of the relationships between the gift-giver and gift-recipient). Building upon the economic and social reciprocity exchange of gift-giving, Belk and Coon (1993) identified gift-giving among dating couples as agapic love gift-giving and suggested that the reciprocal exchange is not a requisite feature of gift-giving between lovers. Similar findings were found in studies of romantic couples in Minowa and Gould (1999) and Joy (2001).

Most gift-giving research focuses on the actual gift-giving process and activities (1) from the perspectives of the gift-givers (Joy, 2001, Minowa and Gould, 1999, Curasi, 1999, Belk and Coon, 1993, Otnes et al., 1993) in terms of the decision making process involved in buying a gift (i.e. searching for a gift, purchasing a gift, choosing the right place or a right time to give the gift); (2) from the perspectives of the gift-recipients (Minowa and Gould, 1999, Ruth et al., 1999, Fischer and Arnold, 1990, McGrath, 1989) (i.e. the reaction of recipients when receiving a gift and how they evaluate their relationships after the gift-receiving experiences); (3) the disposition of the gift (Sherry et al., 1992); or (4) how a third person influences people's Christmas gift purchasing (Lowrey et al., 2004). Furthermore, gifts carry many emotional and symbolic meanings including love (Belk and Coon 1993, Fischer and Arnould 1990) and sadness (Mick and Demoss, 1990).

Consistent with the nature of possessions, meanings of gifts will change and evolve according to the recipients' life experiences and social contexts. Andersen (1993) suggested that a relationship trajectory exists between the giver and recipient and consists of the interpretation of the relationship in the past, the current state of the relationship, and the possible relationship in the future. For our study, we are interested in how the relationship trajectory is reflected in and embodied by the different meanings which are invested in the gifts that have become important possessions, over time.

POSSESSIONS AND THE SELF

Belk (1988) argued that people extend the concept of self through their possessions, i.e. products, places, other people and pets. "Our possessions are a major contributor to and reflection of our identities" (p. 139). There are five stages of role-identity development throughout the identity project life cycle, i.e. pre-socialization, discovery, construction, maintenance and disposition (Kleine and Kleine, 2000). People reveal different aspects of their self and identity by retelling stories of possessions. Although aspects of the self are viewed and emphasized in various ways in different cultures, "the fact that these conceptions of self are expressed to some degree through objects seems to be universal" (Wallendorf and Arnould, 1988: 532). Furthermore, Csikszentmihalyi and Rochberg-Halton (1981) commented that "things tell us who we are, not in words but by embodying our intentions. In our everyday traffic of existence, we can also learn about ourselves from objects, almost as much as from people" (p. 91).

In terms of temporality and possessions, items that people acquired in the past carry meanings in the present time and may anticipate meanings in the future (Kleine and Baker, 2004). The temporal features of attachments are consistent with narratives. In narratives, people retell and reorganise their past events and provide evaluations and add new meanings to them in the present time and sometimes also predict possible futures. Therefore, people's selves are revealed through stories about their attachments. As Kleine et al. stated (1995: 327), "a special possession could facilitate self-continuity by connecting a person with a desirable past self (e.g. memories), a present self (me now), or a future self (who I am becoming)".

NARRATIVES

"People live storied lives" (Creswell, 2005: 87). People are natural storytellers who share their stories with friends or colleagues, on a daily basis. "Relationships require narrative to evoke the empathy and multilayered attention necessary for one person to have some sense of the nature of someone else's relational experience" (Josselson et al., 2007: 4). One of the advantages of narratives is that "they organise life, i.e. social relations, interpretations of the past, present and future" (Daiute and Lightfoot, 2004: xi). From their past experience, narrators learn and make who they are at present and who they might want to be in the future. It is clear that narratives provide a sense of self as continuous through time. Furthermore, possessions and narratives are closely linked together. Possessions have a function in helping people to narrate their stories as Kleine et al. (1995) emphasize "possessions to which there is attachment help narrate a person's life story; they reflect "my life" (p. 327).

RESEARCH METHOD: NARRATIVE RESEARCH DESIGN

In the present study, informants were asked to share stories about their gifts as possessions that were special, meaningful and

important to them. Their selves and identities are embedded in their stories as Georgakopoulou (2002) says that "if selves and identities are constituted in discourse, they are necessarily constructed in stories" (p. 428). The snowball technique¹ was used to identify twenty informants (ten males, ten females).

The informants were young professionals aged between 29 and 37; either single or married. Semi-structured narrative interviews were conducted in Hong Kong and lasted on average one hour. Some guided questions were used in order to stimulate a discussion. However, interviews were not strictly constructed and this was in line with Wagner and Wodak's (2006) method of narrative interview. Rather, the flow of topics varied depending on their stories. All the interviews were digitally recorded and transcribed.

The transcripts were read a number of times in order to achieve familiarity with the material. Then, a three-dimensional narrative structural analysis (Clandinin and Connelly, 2000) was applied in order to examine how narrators told their stories under the dimension of interaction (i.e. their belief and values on the personal level and interactions with other people on the social level), the dimension of temporality (i.e. how the past event or experience leads to the present self and will possibly influence informants' future decisions), and the dimension of situations (i.e. time and context). Finally, the story fragments from each narrator were linked up in order to compose a coherent "story line" for each person (Fournier and Mick, 1999, Tagg, 1985).

In this study of gift-recipients' interpretation of the meanings of their important gifts, informants narrated stories about the gifts that had become important possessions. They described gifts that they had owned between 5 and 25 years. We analysed and examined how these narrators told their stories about different aspects of their selves in terms of their relationships with their gift-givers. We chose four informants' narratives for this paper which illustrate the central emergent themes of the "existing on-going" and "disconnected" relationships.

FINDINGS

Data analysis yielded a number of themes that revealed gift-recipients' interpretation of their selves and interpersonal relationships with the gift-givers, and changes in the meanings of their important gifts. Themes will be examined under two dimensions, i.e. "the disconnected relationships" and "the on-going relationships" between the gift-givers and the gift-recipients. Strategies of how informants maintain, modify or negotiate their self and the relationships with their gift-givers will be covered in the discussion section.

DIMENSION: DISCONNECTED RELATIONSHIPS

Ada: Her disconnected relationships with her ex-husband and her deceased father

Ada told five stories about gifts which represented important possessions for her. Four stories related to her ex-husband and one story was about her father who had died 6 years before. Ada is a 39-year old fashion boutique owner who has always wanted to improve her quality of life by challenging herself at different stages of her life. She first narrated her love story in a temporal sequence starting from how Ada and John, her ex-husband, had met in high school and how she had received her first gift from him when dating.

¹The purpose of the snowballing technique is to identify and accumulate informants as each located informant recommends other people to researchers (Babbie 1996, Creswell 1998).

Ada: "We were dating at that time... It (the watch) was so popular at that time to have vintage style watches. He noticed that I like one of the watches there. He secretly bought it and gave it to me at Christmas. He was very fond of me at that time."

After they completed their GCSEs (a high school public exam), John, her ex-husband, was sent to study at university in the US. That was the first time they were apart. Before he left Hong Kong, he bought a Titus watch from their special love series and had it engraved with the words "Everlasting Love" on the back of the watch for Ada as a reassurance of his love for her. Ada narrated how they were apart and how happy and sweet she felt when she received it. However, all of the sudden, she came back to the reality from her narrative and realized that the relationship was over. "Forget it. It's over. It was the past!"

Ada: "The second watch is from him. When he studied aboard, he bought me a Titus. It was the first time we were separated. I didn't wanna let him go. Therefore, he bought me that watch. It was that special love series with the slogan of "It doesn't matter whether we cannot be together forever, the important thing is we have each other at this moment...(pause) Forget it. It's over. It was the past!"

Ignoring her family's objections, Ada went to the U.S. in order to be with John. They had a happy time together in the US. Both of them were students and enjoyed their lives without their parents. John always wanted to surprise Ada by buying or getting something special for her. He secretly asked his friend to buy a "Big Mouth Boy" Japanese cartoon watch, i.e. Ada's favourite cartoon character, for her. The watch was not available in Hong Kong. Therefore, John asked his friend to buy it from Japan.

Ada: "'Little Big Mouth' watch. We were in the US at that moment. He knew that I loved that cartoon character. He asked somebody who was on the way to Hong Kong... bought it... via Japan... came back to the US."

They got married in Canada and then John returned to Hong Kong where he worked as an architect. Ada stayed in San Francisco and tried to complete her studies. Separation was not easy. Ada decided to quit her studies and went back to Hong Kong. Once again, John wanted to show his affection by using his first salary to buy her an expensive watch, i.e. Rolex.

Ada: "We were separated for four months (after the wedding). He saved it for four months. When we met again at the airport, he gave it to me. It was a surprise again. This is my first luxury watch and still the only luxury watch. I think the current price of that model is about HKD 30,000 something."

Sadly the marriage ended after 8 years. It was John who made the decision to end the relationship. Ada was in shock and could not believe that John was going to leave her. Looking back, Ada realized that she had not shown enough appreciation and had taken John for granted. She had not cherished the times that she had had with him. When looking at all the gifts she received from him, she is more touched than before.

Ada: "Currently, I am more touched. I didn't cherish them at that time. When I looked back, I realized nobody would treat me that nice. Not any more... Forget it. Don't talk about it. (Note: She started to cry)"

Ada is still struggling to redefine her sense of self and identity after her divorce. She could not correct the mistakes she had made in the past and that had destroyed her marriage. However, she wanted to move on from this disconnected relationship. During her narration Ada, from time to time, re-emphasized how the interviewer and herself should address John as "her EX-HUSBAND". She consciously kept trying to remind herself of her current status of being "divorced".

The other important possession that she described was a gift from her father who had died 6 years before. She received a watch from her father when she was 15 years old. It was a ritual in her family that all the children received a watch from their father when they reached 15 years old. When Ada received the watch, she felt like she had reached the stage of adulthood. While narrating the story about the watch that she received from her father, she came to a realization that she shared some similarity with her father, being an authoritative figure in her own marriage. She believed that was the reason why her marriage had broken down.

Ada: "I got this watch from my dad when I was 15 years old. The brand was popular at that time... even advertising on TV. It was the first watch I wore at school. Dad gave us a watch when we reached 15. It's like when you are an adult, you got a watch coz at that time watches were quite precious. ...We had some good times and bad times. He was very authoritative and my mum is always gentle and listens to him. I guess I picked my dad's role and became "my dad" in my own marriage. I destroyed my own marriage. Anyway, the feeling not having my dad around is now different. I could console myself that it's gone. But when it comes to details, say see some elderly... that reminds me of my dad. Then I realized I still miss him."

Ada received those gifts more than 20 years ago. The original feelings of receiving those gifts were sweet, touching, full of surprises and feeling like a grown-up. As time went by, Ada faced different life transitions, from dating, getting married, experiencing a divorce and the death of her father. The attachments represented by those gifts intensified and increased as Ada offered new interpretations and meanings for her important gifts.

Ping: his disconnected relationship with his mother, the lost loved one

Ping's mother was his role model. Mrs Wong was hard working and full of love and care. In Ping's eyes, his mother was "invincible". Mrs Wong could cook delicious Chinese food, knit and mend old clothes in order to save money as well as taking care of the church where she worked as a janitor at the same time. Although his mother had died 9 years ago, he still missed her a lot. He wanted to hold on to the gifts that she had given to him so that he could feel her presence. As time has gone by, he has gradually tried to let go of some of the gifts as a sign of learning how to live without his mother's presence.

Ping's mother was good at knitting. She had knitted a lot of sweaters for him when he was young. He did not cherish them at that time. Once his mother passed away, he realized how important it was to keep these sweaters in order to feel her presence. He only has one sweater left now, and it is so precious that he does not dare to wear it as he said "you will never have a second one".

Ping: "A sweater that my mother knitted for me. I have only one left. I cherish it so much that I do not dare to wear it. I used to have quite many sweaters knitted by her. I didn't cherish

them at that time. I have one left and I don't want to wear it... I might take it out and have a look... coz no more... you will never have a second one. I quite cherish it."

His family was not that well-off. His mother always tried to mend clothes and blankets instead of buying new ones for him in order to save money. Ping viewed these as part of the gifts that he had received from his mother. It is a good image of her virtue that he always remembered. In his opinion, Mrs Wong sacrificed herself for the family, especially for her children. He used to have a blanket that Mrs Wong had mended, darned the edges in order to repair it. Ping kept it for several years. As time went by, he started to find the courage to look at some of the gifts that reminded him of his mother. It has been 9 years and he is still learning how to let go of some of the emotion by disposing of some of his precious items.

Ping: "I think I can let go. For example, I just threw a worn out blanket away today. The reason I kept it for a while is that my mum mended the edges of the blanket. I didn't want to throw it away. But I realized I have to let go something."

DIMENSION: EXISTING ON-GOING RELATIONSHIPS

Stephanie: Her on-going relationships with her sister and husband

Stephanie narrated 6 stories about her important possessions, half of which she had received as gifts from her sister and her husband. Stephanie is very close to her sister, Jenny. The age gap between them is so small that they played, cried and fought for toys or clothes when they were young. Jenny sometimes can be quite competitive. For example, Stephanie wanted to be a flight attendant. Immediately, Jenny applied for the same position in a different airline company. Stephanie received a watch from her sister as a birthday gift almost 10 years ago. It was the first time that Jenny had left Hong Kong and lived in another place for a long time. When she was not around, Stephanie missed her greatly. Jenny sent a funny watch to Stephanie as her birthday present during the time she was in the US. Stephanie appreciated the watch because of her relationship with her sister. She has worn the watch for almost ten years.

"Another one (watch)... my sister sent it to me from the US. She and I are very close... sometimes quite competitive... like I decided to become a flight attendant and she immediately did the same. Anyway, I missed her when she was not around. My sister was there with her husband for more than a year. She sent the watch to me as my birthday present. I like it VERY much and have been wearing it for many years... almost ten years."

Stephanie and Alex got engaged in 2001. Alex proposed in a traditional way with a bunch of flowers, a diamond ring and a surprise dinner. Stephanie personally does not particularly like diamond rings. She had bought one for herself in the past. But she emphasized that the ring from Alex is different from any other ring. It is her engagement ring with a heart-shape diamond on it. It is a sign of Alex's promise and love for her. Although the diamond is not that big, it has a significant meaning for her that makes her happy. She cherishes it so much that she does not wear it every day. She only wears it when attending "somebody's wedding" to signify her marital status.

"I am not a big fan of diamond rings. The size of the diamond is not important to me coz I don't like it too big. The big

diamonds don't suit my image. The way I dress... don't match. I like the one I got from Alex... small and a heart shape... because it is meaningful and I like the heart shape diamond. I bought a diamond ring for myself before. But when I go out, I wear Alex's diamond ring not mine. I like that one. But I don't wear it every day. Only when I attend to somebody's weddings... I like it (the ring). It makes me happy. It is meaningful and beautiful."

Stephanie also received a diamond pendant cross from Alex on her baptism before they were married. It has a symbolic meaning because now she is a Christian with a cross around her neck. In addition to the symbolic meaning of the necklace, there were additional lived experiences associated with the pendant because she accidentally dropped the pendant down the sink. The experience taught her that it is always better to solve problems together rather than alone and she appreciated Alex's support and help. The pendant cross carries not only the original meaning of celebrating her baptism, but also an additional experientially-derived meaning that they will always share.

"Alex gave it to me on my baptism... the day to celebrate that I became Christian. I dropped in the sink and took me the whole night to fetch it... Now when I think about it, it is still quite sad coz it took me the whole night and I felt really down... I did not want to wake up Alex. I thought he could not help me. I thought men are careless. How wrong and silly I was?! At the end, we had to solve the problem together and got the pendant out of the tube of drain of the sink. Alex did it with some "Blue tap"... I wouldn't get it out by myself. It was him who did it for me. That was an experience that we learned... to try to solve problems together"

Peter: His existing on-going relationships with his father and wife

Peter was born into a complex family. His father had two wives, or rather an official wife and an unofficial wife (a mistress), more typical of pre-war China. His father owned factories in Hong Kong and China which exported electronic parts to the US. His family was very well-off. Peter is the mistress' son, meaning that he was not recognised by the family. Although Peter has a complicated background, he had a happy childhood with his mother and sister. His father came to visit them as often as he could in order to provide a fatherly figure to him. Peter and his sister went to live with his father's family, consisting of an elder half brother and half sister, when he was about 12 years old.

Peter has a close relationship with his father although his father did not live with him when he was child. He respects his father as an entrepreneur setting up factories on his own. Peter believes his father had a reason to do what he did in the past and does not feel any resentment towards him. Peter received a watch from his father as a sign of reaching adulthood. The watch is important and memorable for Peter because his father gave it to him.

Peter: "Another one I got is from my dad... can't remember the brand... it got a vintage feel of it. My dad likes watches as well... He just gave it to me to wear. He thought I had grown up as an adult and it was time to give me one. Therefore, he passed the watch to me. For me, this is a memorable item. My dad gave it to me."

His father used to own a lot of cars when the businesses were doing very well. However all the companies were closed down, following a financial crisis. Peter's father sold almost everything he

owned in order to pay off his debt. The only thing his father kept for himself, and later passed it on to Peter, was the licence plate BD 2822. His father bought this licence plate when he started his business. The number “2822” has a meaning in Chinese that “2” sounds like the word “easy” in Chinese and “8” sounds like “rich” in Chinese. The licence plate has two symbolic meanings for Peter. First of all, it is a precious item marking his father’s success in the past. His father passed this precious item onto him. Peter wants to continue the spirit of the family legacy to the next generation. The second symbolic meaning of the licence plate is a special link between Peter and his father. Peter admires his father who is a very traditional Chinese father who does not show much of his emotion through words but through objects that he passed on to his son. His father did not give the licence plate to any of his other children, not even to Peter’s older half-brother who is traditionally the heir in the family. The recognition and love from his father meant a great deal to Peter.

Peter: An item...hmm...a licence no. of BD 2822. Dad passed it on to me. He used to have this licence no. to his car. The number is very special. For me, first the Chinese pronunciation of 2822. Also, he gave it to me. If I could pass it on to the next generation, that would be great. This gives me... a family... it doesn't worth any money... but it is like a family legacy you pass it on to the next generation. It is not the jewel of the family. But it has a special link between me and my dad... keeping it. I hope I could pass it on to the next generation some day.

Bonnie, his then-girlfriend and now-wife, bought a lover watch set of Agnes B for Peter during the time they were dating because she wanted to have some proper watches for both of them to wear when attending formal occasions, e.g. Chinese banquets. Peter likes the watch because it is different from the watch he wears at work as a PE teacher. As he said, “it is a proper watch”. Also, it is a lover set of watches that they can use to show their commitment to each other as a couple by wearing them together.

Peter: “Bonnie bought me a watch, Agnes B lover watches. No...no... no... it was a lover set. It was the first love set watches we had but were stolen last year. We always have sporty watches because of our work (PE teachers)... like that kind of digital... Casio... Bonnie wanted to buy watches that we can wear them together in different formal occasions like Chinese banquets. I like it... she had the same watch and I had the same... quite nice... as a couple.”

From dating to getting married, Bonnie and Peter have built up their dreams together through different transitions. Their love has grown strong so that the this gift has acquired additional meanings. Peter had a calling/ vision that he wanted to study theology and to dedicate himself to his church. After serious discussions with Bonnie and attending different retreat camps, he made up his mind to give up his job as a PE teacher and to enrol himself in the Christian ministry and study theology for three years. Although the financial burden fell on Bonnie’s shoulders, she did not complain about helping Peter fulfil his dream. In fact, she was very proud of her husband’s decision. As Peter said, “I really have to thank Bonnie for her unconditional support and patience. The family... that is the most important thing.”

DISCUSSION

Our findings expand upon the existing gift-giving research to illustrate how old and established gifts can signify the evolution of

interpersonal relationships over time, and these meanings co-evolve with self-change and self-continuity. Different strategies are adopted in order to manage the changes within the “disconnected” and “existing on-going” relationships.

In the disconnected relationships our story-tellers often found themselves facing a dialectic tension in their narratives. They were often caught between the stages of identity disposition, identity discovery and identity construction within role identity development (Kleine and Kleine, 2000). The negotiation process of letting go of some things whilst keeping hold of other things amongst their meaningful possessions often helped them cope with loss and to adjust to change in this liminal phase of life transitions. “Possessions bring past meanings into the present and maintain present meanings. Possessions also help them project themselves in to the future, even beyond death” (Kleine and Baker, 2004: p. 9). Due to the fact that they will not or cannot have any further contact with the gift givers, they are in the process of self-reconstruction, moving from disposing of their past identity (e.g. Ada as a married person) to acquiring a new identity (e.g. Ada becoming a divorcee), giving new emotional and symbolic meanings to their gifts that they had received from their gift-givers. In Ada’s case, she did not want a divorce. In general, people who did not take the initiative in the divorce proceedings tend to hold on to possessions or gifts that are related to their partners as if they are still holding on to the relationships (McAlexander, 1991). The strategy of holding on to her gifts implies that she is still in the liminal phase; that she is in “a limbo between the past state (i.e. a married woman) to the current one (i.e. a divorcee)” (Schouten, 1991: 421). Ada is in the process of identity reconstruction, and her narrative captures the dialectic tension experienced as a divorcee within her identity role project. “Attachment itself, and the meanings of attachment possessions, tend to be dynamic in order to manage the relentless conflict between desiring self-continuity and needing self-change” (Kleine and Baker, 2004: p. 5).

In the disconnected relationships with the gift-giver caused by death, Ada and Ping used a strategy of “re-membering”² their lost loved ones on a different level (Myerhoff, 1982). “The parent may be dead, but the relationship did not die” (Silverman and Nickman, 1993: 315). Over time, people accept the reality of the loss and learn how to find a way to include the lost loved ones in their life (Nasim, 2007). Ada had both good and bad times with her father in the past. But she focused on the good times, e.g. a gift that she received from him as a sign of reaching adulthood embodied the best image of their relationship and meant that “I could console myself that it’s gone.” Similar to Ada, Ping tried to find a strategy to balance the dialectic tension in his narrative between “holding on” and “letting go”. The sacredness that Ping invests in his sweater reflects the importance of his mother’s status in his heart (Belk et al., 1989). His disposition of the blanket is a step that he takes in order to try and redefine his relationship with his mother. Both Ada and Ping have kept their relationships with their deceased parent alive at another level in order to help their own self-change within their life transitions (Nasim, 2007).

The strategy for Stephanie and Peter in their “existing on-going” relationships with the gift-givers was to maintain and cultivate a promising future together. In the case of existing on-going relationships with the gift-givers, the symbolic and emotional meanings and values of the possessions were enhanced through interactions (i.e. wearing or using the important gifts on different occasions) (Richins, 1994). In contrast to the role-identity develop-

²Myerhoff (1982) suggested the term re-membering to describe how people redefine their relationships with the deceased and include them in their lives.

ment in the “disconnected” relationships, informants in the “existing on-going” relationships sought identity maintenance in their role-identity development (Kleine et al 2005). Stephanie and Peter focus not only on the past and the present but also look forward to strengthening and cultivating a promising future together.

Peter was a mistress’ son and was not recognised in the family when he was a child. Having moved in to live with his father’s family when he was a teenager, he was eager to be accepted as part of the family. Receiving a watch from his father when he reached adulthood, and a family licence plate as a sign of carrying on the “family legacy”, signified his recognition by his father and the family. These gifts represented the family’s inalienable wealth and carried significant symbolic meanings for Peter (Curasi et al., 2004). Stephanie, in her turn, had been wearing the watch that her sister had given her, for more than 10 years. The watch “evokes richly textured webs of her personal memories” and her relationship with her sister (Belk 1991).

In an interpersonal romantic relationship, a person’s self tends to overlap with his/her partners (Aron et al., 1992). Peter received a watch from Bonnie when they were dating. The watches are symbols of their love. They wear them in public as a signal to other people that they are united, illustrating continuity, affiliation and love. Similar to Peter, Stephanie wore her engagement ring to indicate that she had been engaged in the past and was now married, and working on building a solid foundation for her relationship with her husband (Kleine and Baker, 2004). In terms of her story about her pendant diamond cross, the pendant carries not only the original meaning of celebrating her baptism, but also an additional layer of new meaning that was created by the shared memories of Stephanie and Alex of losing and then regaining the cross.

Collecting and analyzing consumer narratives allowed a deeper understanding in terms of how informants view themselves and their relationships with their loved ones through their important gifts, i.e. the possession value of objects. This captures temporal notions of the self-change/continuity as possessions provide “symbolic benefits delivering self-change/continuity value” (Kleine and Baker, 2004: 25). These informants shared their inner most feelings about their possessions and revealed who they were, how they became who they are, and sometimes also who they want to be in the future, which meant that different views of the self started to emerge around the axes of continuity and change, and different views of the strategies used to manage ongoing relationships with gift-givers also emerged, whether the giftgivers were living or dead.

Buy Genuine Luxury Fashion Products or Counterfeits?

Boonghee Yoo, Hofstra University, USA
Seung-Hee Lee, Kent State University, USA¹

ABSTRACT

The research examined the effect of three groups of variables on purchase intention of luxury fashion designer brands and their corresponding counterfeits: past behavior (past purchases of counterfeits and originals), attitudes toward buying counterfeits (by economic and hedonic benefits), and individual characteristics (materialism, perception of future social status, and self-image). Data of 324 Korean female students confirmed that the variables were determinants of purchase intention of counterfeits and originals and that purchase intention of counterfeits was positively related to purchase intention of originals whereas purchase intention of originals was negatively related to purchase intention of counterfeits.

INTRODUCTION

Counterfeiting prevails throughout the world, accounting for about ten percent of the world trade or worth of about 500 billion dollars, and the U.S. loses a quarter of a trillion dollars due to global piracy and counterfeiting (Heffes 2008). The most popular counterfeit market is clothing, followed by shoes, watches, leather goods, and jewelry. Louis Vuitton, Gucci, Burberry, Tiffany, Prada, Hermes, Chanel, Dior, Yves St Laurent, and Cartier are frequently pirated. Knockoffs of fashion brands are usually manufactured in China, South Korea, Taiwan, and South America (Ritson 2007). While most studies have focused on how to control the supply side of counterfeits, few studies have investigated the demand side, in particular, what factors explain purchase decision-making between counterfeits and originals (see Penz and Stöttinger 2005). The last statement is very true for luxury fashion designer products, whose counterfeits are popular among individual consumers across countries, poor or wealthy. Therefore, the purpose of this research was to examine the impact of three groups of antecedents on intent to buy luxury fashion designer brands versus their corresponding counterfeits. The three groups of interest refer to past behavior (represented by past purchases of counterfeits and originals), attitudes toward buying counterfeits (by economic and hedonic benefits), and individual characteristics (materialism, perception of future social status, and self-image). Figure 1 summarizes the research framework of the study.

RESEARCH HYPOTHESES

Past Behavior

Past behavior is found to be a more significant predictor of later behavior than the effects of intentions and perceptions of behavioral control (Bagozzi 1981; Ouellette and Wood 1998). As long as circumstances remain stable, past behavior forms a habit with repeated performance and later behavior relies more on past behavior than cognitive consideration (Bamberg, Ajzen, and Schmidt 2003). Therefore, past purchases of counterfeits are supposed to result in purchase intention of counterfeits whereas past purchases of originals are supposed to result in purchase intention of originals. In particular, the strong brand equity of luxury fashion brands that has been established over years provides stable image and prestige, which would consequently make consumers rely heavily on their

habit of purchasing luxury fashion brands. Therefore, we hypothesize:

- H1: Past purchases of counterfeits positively affect purchase intention of counterfeits.
- H2: Past purchases of originals positively affect purchase intention of originals.

Attitudes toward Buying Counterfeits

As the theory of planned behavior predicts, attitudes toward an act positively affect behavioral intentions (Ajzen 1991; Ajzen and Fishbein 1980). Attitudes refer to the degree to which a person has a favorable appraisal of the behavior in question and are an immediate indicator by which her/his intention of conducting the specific behavior can be predicted. Therefore, positive attitudes toward buying counterfeits are expected to affect purchase intention of counterfeits positively whereas they are expected to affect the opposite act (purchase intention of originals) negatively.

We recognize economic benefits and hedonic benefits of counterfeits as two major reasons that make consumers develop positive attitudes toward buying counterfeits. First, because counterfeits' prices are a mere fraction of genuine items' prices, consumers enjoy economic benefits and feel values (Albers-Miller 1999). A counterfeit is a lower-quality, lower-price choice whereas a genuine item is a higher-quality, higher-price choice (Gentry et al. 2006; Prendergast et al. 2002). However, counterfeit consumers do not mind low quality and poor materials because they do not see counterfeits as inferior choices when they experience budget constraints and appreciate economic benefits of counterfeits (Dodge et al. 1996; Nia and Zaichkowsky 2000). They perceive purchase of counterfeits to be worthier and enhance societal welfare (Ang et al. 2001; Van Kempen 2003). On the other hand, as consumers are likely to buy originals when they can afford, economic benefits of counterfeits would not necessarily affect their intention to buy originals.

Second, consumers view that the brand name, the label, and identifying design characteristics such as logo, color, pattern, and accessories are themselves valuable. Such hedonic benefits value a product for its own sake (Babin, Darden, and Griffin 1994). When consumers pursue hedonic rather than utilitarian needs, they will easily accept counterfeits. Furthermore, they are not much concerned about low quality. Even in case others notice they consume counterfeits, consumers who do so for a pure hedonic reason will not feel embarrassed. They do not consider a consumer image built on fake products an issue of fragility. Therefore, hedonic benefits of counterfeits are expected to be linked positively to purchase intention of counterfeits and negatively to purchase intention of originals. Therefore, we hypothesize:

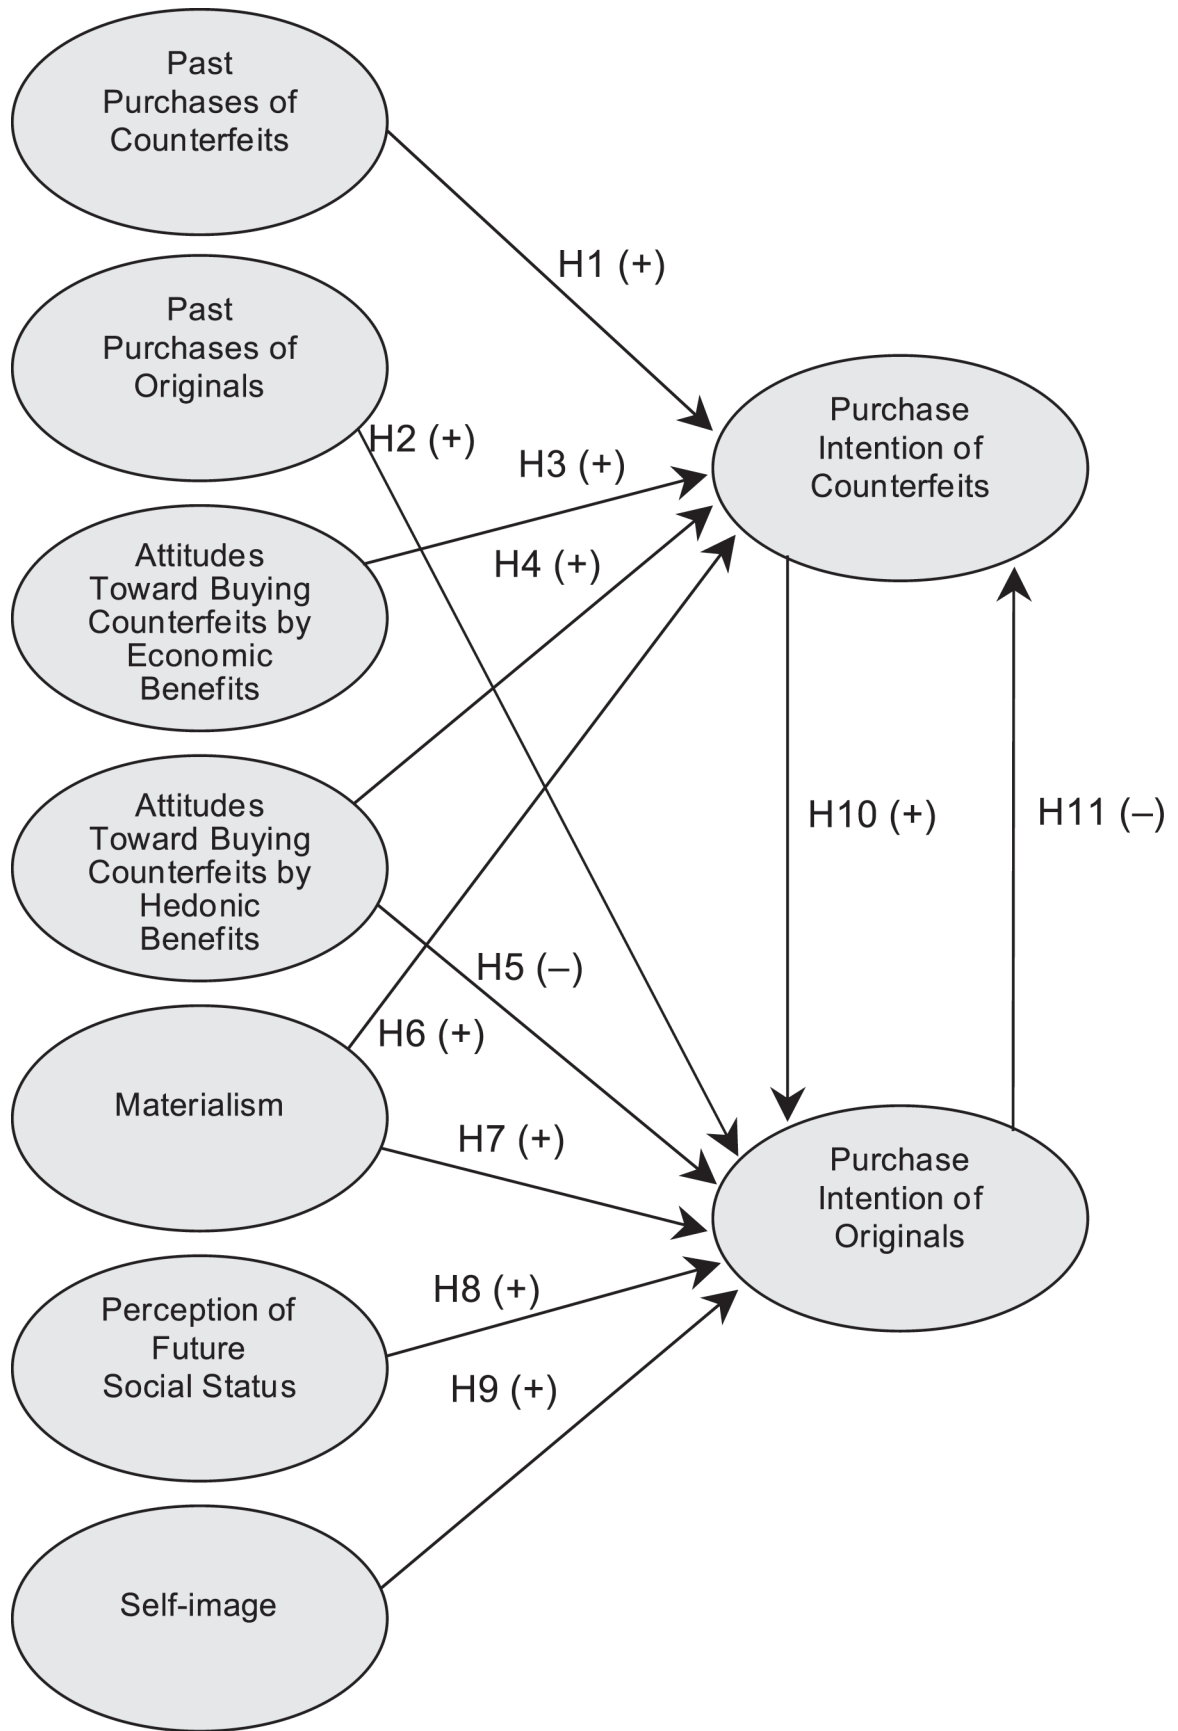

- H3: Attitudes toward buying counterfeits by economic benefits positively affect purchase intention of counterfeits.
- H4: Attitudes toward buying counterfeits by hedonic benefits positively affect purchase intention of counterfeits.
- H5: Attitudes toward buying counterfeits by hedonic benefits negatively affect purchase intention of originals.

Individual Characteristics

Among many other individual characteristics, we examined the impact of materialism, perception of future social status, and

¹The authors acknowledge that this research was supported by a summer research grant from the Frank G. Zarb School of Business, Hofstra University.

FIGURE 1
Antecedents of Purchase Intention of Counterfeits versus Genuine Luxury Fashion Brands

self-image on purchase intention of counterfeits and originals. Materialists place “possessions and their acquisition at the center of their lives” and view them “as essential to their satisfaction and well-being in life.” (Richins and Dawson 1992, p. 304). Their primary goal of material possessions is to impress others rather than themselves. From that perspective, both counterfeits and originals fit the purpose of consumers’ external physical vanity because they provide the image of prestige through the display effect despite significant quality differences. External physical vanity refers to “an excessive concern for, and/or a positive (and perhaps inflated) view of, one’s physical appearance” (Netemeyer, Burton, and Lichtenstein 1995, p. 612). Consumers will have the identical appearance whether they wear a counterfeit or an original. The only difference is that consumers for originals purchase originals for what luxury brands mean, whereas consumers for counterfeits, who need only verisimilitude, purchase just the prestige of the originals without paying for it (Penz and Stöttinger 2005). Nevertheless, both products provide identical appearances, satisfying the materialistic mind.

One major element of social status is personal economic power (Sorokin 1959). When a consumer evaluates her or his future social status to be high, she or he will become less price-sensitive and select genuine fashion products whose prices are, for instance, ten times more expensive than those of corresponding counterfeits. That way, perceived future social status is positively linked to intention of buying the genuine products.

Consumers purchase products whose image matches their self-image to impress others. Self-image concerns itself with issues like “how I am seen by others” (Sirgy and Danes 1982). Therefore, status consciousness and high self-image positively affect purchase intention of originals because genuine products convey the image of affluence, wealth, and social class that match high self-image (Wee, Tan, and Cheok 1995). Therefore, we hypothesize:

- H6: Materialism positively affects purchase intention of counterfeits.
- H7: Materialism positively affects purchase intention of originals.
- H8: Perception of future social class positively affects purchase intention of originals.
- H9: Self-image positively affects purchase intention of originals.

Reciprocal Causation between Purchase Intentions of Counterfeits and Originals

In this section, we examine the reciprocal relationship or feedback-loop between the two types of intention: the intent to buy the counterfeits and the intent to buy the originals. First, counterfeit experiences are expected to cause consumers to develop more preference of genuine luxury fashion products through perceived risks involved with counterfeits. For instance, consumers would realize a high social risk as a result of the discomfort that they would feel if others might notice their use of counterfeits. That risk is derived from the poor physical quality, materials, and delicate design differences of counterfeits. According to Nia and Zaichkowsky (2000), the dominant majority of consumers disagrees that the value, satisfaction, and status of originals are devalued by the counterfeits available in the market. Counterfeits do not decrease the sense of ownership of originals because consumers strongly believe in the inferiority of counterfeits, and, therefore, counterfeits do not affect the demand for originals, which provide the exclusivity, durability, better quality, after-sales service, status, ethicality, and legality (Cheung and Prendergast 2006). Contradictory to the

concerns of luxury brand name manufacturers, consumers are well aware of key attributes and quality of genuine luxury brand names. This is even more true when consumers purchase counterfeits as a trial before committing to the originals (Gentry, Putrevu, and Shultz 2006). Therefore, consumers desire genuine luxury even when buying counterfeits. In a report, a third of consumers for counterfeits wanted to buy the original in the future as a result of negative counterfeit experiences (Ritson 2007). Consumers believe that being counterfeited attests to the fact that the counterfeited brands are well recognized, valued, and desired (Bian and Veloutsou 2007).

Second, consumers who buy originals do not desire counterfeits. Nia and Zaichkowsky (2000) found that owners of originals, perceiving counterfeits as inferior, believe the ownership of genuine luxury brands bring them admiration, recognition, and acceptance by others; thus these consumers demand counterfeits less. Once consumers earn an income high enough to afford genuine luxury fashion items, they are less likely to purchase counterfeits (Wee, Tan, and Cheok 1995). When consumers are highly involved with the product category, care about brands, and are brand-loyal, they are also less likely to purchase counterfeits (d’Astous and Gargouri 2001). Consumers who prefer legitimate originals do not desire counterfeits because they are more satisfied with the originals than the counterfeits in every aspect, except price (Tom et al. 1998). Experiences of originals provide more satisfaction through better physical quality and interpersonal approvals of the products, and, accordingly, make consumers lose interest in counterfeits. Originals serve social and psychological motives better in improving social standing and prestige. Therefore, we hypothesize:

- H10: Purchase intention of counterfeits positively affects purchase intention of originals.
- H11: Purchase intention of originals negatively affects purchase intention of counterfeits.

METHODS

Sample

Female college students in South Korea voluntarily participated. We selected South Korea because it is a major fashion counterfeit manufacturing and consuming country and female college students because they are active buyers and consumers of both counterfeits and originals of luxury fashion brands. We obtained 324 eligible responses.

Measures

Table 1 shows the measure items. All measures, except those for past purchases and future social class, were measured in a seven-point scale format. We developed a six-item scale of positive attitudes toward buying counterfeits by economic benefits and a five-item scale of positive attitudes toward buying counterfeits by hedonic benefits. These two scales measured how positively the consumer considers buying the counterfeits thanks to economic and hedonic benefits, respectively. Reliability of the scales was 0.84 and 0.71. As for materialism, we used Richins and Dawson’s (1992) 18-item scale of materialism. Reliability of the scale was 0.81. We used Ahn et al.’s (2001) 19-item scale of self-image to measure a consumer’s self-image. Reliability of the scale was 0.84.

We examined five different luxury fashion products: handbags, designer shoes, apparel, sunglasses, and jewelry. The purchase intention of counterfeits was measured by the mean score of the participant’s responses to the questions worded, “How much would you like to purchase x counterfeits in the future?” in which x represented the most popularly counterfeited brands from each of

TABLE 1
Constructs Measured

Purchase Intention of Counterfeits (Reliability=0.88)

How much would you like to purchase x counterfeits in the future? (Five-item scale)

Where x=a group of selected brands for each of handbags, designer shoes, apparel, sunglasses, and jewelry.

Purchase Intention of Originals (Reliability=0.91)

How much would you like to purchase x originals in the future? (Five-item scale)

Where x=a group of selected brands for each of handbags, designer shoes, apparel, sunglasses, and jewelry.

Positive Attitudes toward Buying Counterfeits by Economic Benefits (Reliability=0.84)

1. I buy counterfeit products if I think genuine designer products are too expensive.
 2. I buy counterfeit products if I cannot afford to buy designer products.
 3. I buy counterfeit products without hesitation if I have a chance to buy the counterfeits.
 4. I buy counterfeit products, instead of the designer products, if I prefer specific brands.
 5. I boast about counterfeit products as if they are the genuine brand products.
 6. I usually purchase counterfeits when it is difficult to distinguish between the counterfeits and the genuine products.
-

Positive Attitudes toward Buying Counterfeits by Hedonic Benefits (Reliability=0.71)

1. I like counterfeit goods because they demonstrate imitative abilities and ingenuity on the part of the counterfeiters.
 2. I buy counterfeit products because counterfeiters are "little guys" who fight big business.
 3. Buying counterfeit products demonstrates that I am a wise shopper.
 4. I like buying counterfeit products because it is like playing a practical joke on the manufacturer of the non-counterfeit products.
 5. I would buy counterfeit products even if I could easily afford to buy non-counterfeit products.
-

Materialism (Reliability=0.81)

1. I admire people who own expensive homes, cars, and clothes.
 2. Some of the most important achievements in life include acquiring material possessions.
 3. I do not place much emphasis on the amount of material objects people own as a sign of success.*
 4. The things I own say a lot about how well I am doing in life.
 5. I like to own things that impress people.
 6. I do not pay much attention to the material objects other people own.*
 7. I usually buy only the things I need.*
 8. I try to keep my life simple, as far as possessions are concerned.*
 9. The things I own are not all that important to me.*
 10. I enjoy spending money on things that are not practical.
 11. Buying things gives me a lot of pleasure.
 12. I like a lot of luxury in my life.
 13. I put less emphasis on material thing than most people I know.*
 14. I have all the things I really need to enjoy life.*
 15. My life would be better if I owned certain things I do not have.
 16. I would not be any happier if I owned nicer things.*
 17. I would be happier if I could afford to buy more things.
 18. It sometimes bothers me quite a bit that I cannot afford to buy all the things I would like.
-

Perception of Future Social Class (9-point single-item measure)

How would you rank your future socio-economic class? Upper-Upper (= 9), Upper-Middle, Upper-Low, Middle-Upper, Middle-Middle, Middle-Low, Low-Upper, Low-Middle, Low-Low (= 1)

Self-Image (Reliability=0.84)

p<.01 for correlation of 0.14 or greater.

the five luxury fashion product categories. Likewise, the purchase intention of originals was measured by the mean score of the responses to the five purchase-intention questions worded for originals. Reliability of the purchase-intention scale was 0.88 for counterfeits and 0.91 for originals. Perceived future social status was measured by a nine-point single item: one (low-low status) to nine (high-high status). Participants were also asked to answer yes or no as to whether they had ever purchased counterfeits or originals of the selected brands for each of the five product categories. The count of yes answers, ranging from zero to five, was the measure of past purchases of counterfeits and originals. Participants' counterfeit and genuine item purchase experiences were 54% and 20% for the selected handbag brands respectively; 17% and 13% for the designer shoes brands; 25% and 50% for the apparel brands; 7% and 26% for the sunglasses brands; and 34% and 38% for the jewelry brands. Table 2 shows the intercorrelations of the scales and summary information.

RESULTS

We ran a path analysis to test the research hypotheses simultaneously. A completely standardized solution, produced by the maximum likelihood method of LISREL 8.8 (Jöreskog and Sörbom 1993), showed adequate overall goodness-of-fit statistics of the path model. Specifically, chi-square was 6.01 (d.f.=13, p=0.95). AGFI was 0.99. CFI and NFI were 1.00 and 0.99, respectively. Both of RMSEA and SRMR were 0.01. Table 3 summarizes the results of hypothesis testing, which find all hypotheses supported at the significance level of lower than 0.05.

The results showed that purchase intention of luxury fashion counterfeits was positively predicted by past purchase experiences of counterfeits (H1: Estimate=0.49, p<0.0001), positive attitudes toward buying counterfeits by economic benefits (H3: Estimate=0.10, p<0.05), positive attitudes toward buying

counterfeits by hedonic benefits (H4: Estimate=0.21, p<0.0001), and materialism (H6: Estimate=0.17, p<0.01). Purchase intention of genuine luxury fashion products was positively predicted by past purchase experiences of originals (H2: Estimate=0.26, p<0.0001), materialism (H7: Estimate=0.27, p<0.0001), perceived future social status (H8: 0.17, p<0.001), and self-image (H9: Estimate=0.10, p<0.05) and negatively predicted by positive attitudes toward buying counterfeits (H5: Estimate=-0.2, p<0.0001). In addition, the reciprocal paths were supported as hypothesized: purchase intention of counterfeits was positively related to purchase intention of originals (H10: Estimate=0.30, p<0.0001), whereas purchase intention of originals was negatively related to purchase intention of counterfeits (H11: Estimate=-0.21, p<0.01).

GENERAL DISCUSSION

This study provides insights into what factors make consumers purchase luxury fashion product counterfeits (versus originals) and how successfully managers can handle the counterfeiting troubles and market the genuine brands more successfully. First, past purchase behavior is the strongest antecedent of purchase intention of counterfeits. Manufacturers have focused on developing technologies making counterfeiting difficult and policing counterfeit manufacturers, distributors, and sellers, but these measures are relevant mainly to businesses but irrelevant to individual consumers. A new, effective measure should focus on consumers and discourage them to buy counterfeits and consequently form a habit of buying counterfeits. In other words, luxury brand-name manufacturers need to promote buying or consuming of counterfeits as something similar to a crime. Note that the same logic has been applied to consumption of illegal drugs, weapons, and music downloading. Counterfeit buying behavior is indeed anti-social, illegal, and unethical in a sense. For instance, terrorist organizations and regimes are often involved with counterfeiting as a means of

fundraising. Counterfeiters also damage tax revenues by not reporting their production and transactions. The new legal measures targeting buyers and consumers would certainly create strong negative social norms toward buying counterfeits once a society develops a consensus on the seriousness of the social damage due to counterfeits. Manufacturers should pursue this measure to create fear among consumers for a possible legal penalty. This measure, when implemented, will also help consumers to develop negative attitudes toward buying counterfeits.

Second, luxury fashion product manufacturers should investigate the possibility that they might benefit from counterfeits. As H10 and H11 were supported, purchase intention of luxury fashion counterfeits positively affects purchase intention of originals while purchase intention of originals negatively affects purchase intention of counterfeits. This finding clearly implies that counterfeit consumers are very likely to become ultimate consumers for originals over time and do not return to counterfeits, a likelihood that is consistently found in pirated software or illegal music file downloading research, where counterfeits aid a full and fast market penetration of the originals (Haruvy, Mahajan, and Prasad 2004). Likewise, fashion counterfeits might function as a risk-free trial version, generate interest among consumers, and make them spread positive word-of-mouth to other consumers. This could be an immature conclusion, but it is one that is worth investigating.

Third, for luxury fashion brands, social status and self-image must be better promotional themes than materialism because social status and self-image are linked to purchase intention of originals whereas materialism is linked to purchase intention of both originals and counterfeits. This strategy would make consumers buy originals over counterfeits because originals better serve and match their social status and self-image. However, when fashionability or physical appearance is emphasized as the promotional theme,

consumers will choose either counterfeits or originals depending, for instance, on their income, shopping convenience, and hedonic purposes because both provide a good look despite a significant difference in product and service quality.

Limitations and Future Research

Some limitations to this study should be noted, and efforts to resolve them would serve as avenues for future counterfeiting research. First, the findings of the study may have limited generalizability. The sample, which seemed appropriate for a fashion brand counterfeit study, was South Korean female college students. However, it would be more meaningful if the same findings hold consistent in different types of consumers (professional females, high-income females, or older females), in different regions (far more or far less developed countries than South Korea), in different cultures (East versus West; collectivist versus individualist societies), and in functional product categories (cameras, golf clubs, or cell phones). Second, the factors investigated were limited to behaviors and characteristics of individual consumers. Future research needs to examine other factors to explain counterfeit behaviors. Examples include marketing activities (advertising, pricing, store image, warranty, and after-purchase services), brand characteristics (brand quality, brand image, and market leadership), and environmental factors (regulations related to counterfeiting activity, market availability of counterfeits, and national-level animosity against the manufacturing country of the luxury brand). Third, the study used cross-sectional survey data to test the hypotheses whose nature was causal. However, survey data provide correlational, not causal, data at best. Therefore, to overcome this limitation, future research needs to adopt experiments to test the hypotheses properly. Such an approach would bring confident answers to luxury-brand manufacturers and researchers. For instance,

it is yet to be examined whether luxury fashion counterfeit experiences indeed increase the sales of the originals. Not survey data, but experimentation, would answer the question without raising unnecessary controversy or doubt.

CONCLUSION

Responding to the call for investigation of consumer-side explanations of buying behavior of fashion counterfeits, this study found that past purchase experiences, attitudes toward buying counterfeits by economic and hedonic benefits, and individual characteristics (that is, materialism, perception of future social status, and self-image) are major determinants of the purchase intention of counterfeits and originals. In addition, the study confirmed that purchase intention of originals decreases purchase intention of counterfeits, whereas purchase intention of counterfeits increases purchase intention of originals.

Impression Formation in a World Full of Fake Products

Sezayi Tunca, University of Innsbruck, Austria
Johann Fueller, University of Innsbruck, Austria

ABSTRACT

This study extends existing theories on impression formation taking the fact of product piracy into consideration. The conducted qualitative study on Rolex watches confirms the suggested process of impression formation and brand appraisal consisting of four components. Our findings contribute to the theory of impression formation and lead to a better understanding of how people wearing fake products are perceived. The results of this study also have major practical implications, suggesting that under certain circumstances product piracy may entail an overall positive brand reputation which in part contradicts the predominant negative view of brand piracy.

INTRODUCTION

“Counterfeit and pirated goods are a big problem for global business, costing hundreds of billions of dollars, according to manufacturers and trade groups” (The Wall Street Journal 2007, p.B1). Trade in counterfeited and pirated products has been spreading at alarming rates and has reached incredible high proportions. According to McDonald and Roberts (1994) “piracy has developed a momentum all of its own” (p.56). They argue that counterfeiting and product piracy have spread from areas such as music and video recording, garments, watches, leather goods, cosmetics and software to products such as aircraft and automobile parts, prescription drugs, baby pacifiers, mannequins, alcoholic drinks, foodstuffs, contraceptives et cetera. Therefore, it can be argued that nearly no product categories are left unscathed. OECD (2007) suggests based on analysis of international trade data that up to USD 200 billion of internationally traded products could have been counterfeit or pirated in 2005. Additionally, OECD (2007) points out that “the figure does not, however, include counterfeit and pirated products that are produced and consumed domestically, nor does it include non-tangible pirated digital products being distributed via the Internet. If these items were added, the total magnitude of counterfeiting and piracy worldwide could well be several hundred billion dollars more” (p.6).

As counterfeiting and product piracy have evolved into a global problem, research on counterfeiting and piracy has been extensive, and many marketing researchers have addressed different aspects of counterfeiting and piracy. Although, these researchers have not delivered a unanimous definition of counterfeiting and piracy, the most common definitions of these terms indicate, that counterfeit brands refer to a 100 per cent copy of the authentic brand, with the objective of deceiving the consumer into believing that it is the genuine brand (cf. McDonald and Roberts, 1994; Prendergast et al., 2002; Papadopoulos, 2004). In contrast to counterfeit brands the term pirated brand also involves the unauthorised reproduction of patented brands, but without the intention of deceiving the consumer that it is the authentic brand (cf. McDonald and Roberts, 1994; Prendergast et al., 2002; Papadopoulos, 2004). Brand piracy is a supply and a demand side phenomenon as consumers consciously buy the fake brands.

As already indicated counterfeiting and brand piracy have been investigated from supply and demand side, and due to the global impact of counterfeiting or product piracy researchers have given some implications of how this phenomenon could be battled (e.g. Jacobs et al., 2001; Tom et al., 1998; Wee et al., 1995). Therefore, it is well accepted among researchers that this phenomenon might lead to direct sales losses for the brand holder and

consequently it also might result in job losses, and further entails tax revenue losses for the economy of a country. Further, it is also agreed on that product piracy leads to a deterioration of the brand image (c.f. Jacobs et al., 2001; McDonald and Roberts, 1994; Wee et al., 1995; Prendergast et al., 2002; Nia and Zaichkowsky, 2000; Tom et al., 1998).

This study tries to demonstrate that product piracy needs not always be negative. Bamossy and Scammon (1985) hint that if imitation is indeed the highest form of flattery, then companies whose brands are faked have much to be flattered about. In other words, a brand that is not copied is neither desirable nor valued. This study especially argues that the brand reputation of genuine products needs not necessarily be effected negatively by the fakes if looked at the matter in a differentiated way. Therefore, in this study a further interesting approach to this phenomenon, which has been neglected so far, might be to investigate, how people buying pirated products are perceived by others, and based on this perception the argument is that the reputation of pirated products might be evaluated differently. Consequently, this work is based on the assumption that depending on the overall impression formed of a person, a brand is perceived as a fake or a genuine product, and therefore it is argued that product piracy might have positive implications for the overall brand reputation under certain conditions. Thus, it is all about differentiating easily between authentic and fake owners in reference to their overall impression and also deducing positive implications for the overall brand reputation from the usage of fake products by people who can easily be recognized as owning a fake.

THEORY

“Clothes make the man” or “Fine feathers make fine birds”

Those sayings were formed in times when product piracy or counterfeits did not exist, at least to this extent. Also, when scholars introduced their theories how clothes and other material possessions contribute to the formation of an impression about a person, they did not consider that one has to check if the person’s belongings are real or fake products when forming an overall impression about the person. This study extends existing theories on impression formation taking the fact of product piracy into consideration.

This section delivers a sound overview of existing theories contributing to an understanding of impression formation, role of fake and real products, distinction of it and consequences on the perception of fake bearers. Based on the theoretical foundations, it introduces an impression formation and brand appraisal process consisting of four components. The first component comprises the first impression theories and Veblen’s conspicuous consumption (Veblen, 1945 [1899]) and demonstrates the formation of an overall impression of a person and the inferences made from this overall impression. The second component contains Goffman’s dramaturgic perspective (Goffman, 1951, 1959) and illustrates the detection of misrepresentations and the resulting judgement of possessions as fake or authentic. The third component embraces Bourdieu’s social space (Bourdieu, 1989a, 1989b) and describes the differentiation aspects from people belonging to other social classes. Finally, the fourth component incorporates the implications on overall brand reputation in accordance to the other three components.

Impression Formation: We meet a variety of people in every day life and tend to form first impression of others even in short time

encounters. According to Bierhoff (1989) “first impressions do not emerge slowly over a long period of time but are formed almost immediately during the first encounter with the target person” (p.2). He further concludes that “impression formation is best considered as a process by which an organized overall impression emerges in which single traits receive specific meanings” (p.2). Jones (1990) argues that the importance of appearance cues cannot be overestimated in a first impression formation situation, and notes that such appearance cues include the attributions of commonly recognized physical attraction, clothes and grooming, facial expression, and posture. Further, research has shown that in a society where brief social contacts are numerous, clothing has become an important aspect in impression formation (cf. Douthy, 1963; Holman, 1980; Judd et al., 1975; Lennon, 1986; Rosencranz, 1962). These studies further indicate that clothes worn are a major element in appearance, and therefore play a significant role in impression formation and in accrediting socioeconomic class. Research has also placed emphasis on the importance of material possessions in impression formation (cf. Hunt et al., 1996; Belk, 1978; Belk, 1980; Belk, 1981; Belk et al., 1982a; Belk et al., 1982b;). These studies imply that people first use possessions when they present themselves to others and second, also resort to similar possessions when they gather information about others. In other words, people use products to encode information about themselves, and as they develop a knowledge which products can be used to provide certain information, they also refer to these experiences when they decode information about others. Therefore, it can be argued that all these attributes are used to make inferences about others. Consistent with the presented research, this study argues that people refer to attributes like physical attractiveness, posture, facial expressions, material possessions, speech patterns etc. to make inferences about others. Further, it is argued that these single attributes receive specific meanings, and that an overall impression of others emerges according to these assigned single attributes.

Veblen's Conspicuous Consumption: Veblen (1945 [1899]) introduced in his treatise “The Theory of the Leisure Class” the widespread term conspicuous consumption. He states that with growing industrial development the distinction between classes shifted more towards the acquisition of property. He points, “it is even more to the point that property now becomes the most easily recognized evidence of reputable degree of success as distinguished from heroic or signal achievement. It therefore becomes the conventional basis of esteem. Its possession in some amount becomes necessary in order to any reputable standing in the community. It becomes indispensable to accumulate, to acquire property, in order to retain one's good name” (pp.28-29). Therefore, people are exerted to differentiate themselves from others and try to achieve this in acquiring goods, which are out of reach for people in lower social classes. Accordingly, Schulz (2006) outlines that in Veblen's theory a simple and direct relationship between the owners' status and their possessions of expensive goods exists. He implies that Veblen's elite distinguishes herself from the others in consuming goods, which are out of reach for others, and this enables the holders of elite status to enhance their privileged status. Bagwell and Bernheim (1996) suggest that the signaling of wealth is best achieved with “expensive durable goods, including one's automobiles, jewelry, and clothing”, which “are all observed regularly by numerous other individuals during the normal course of social interaction, and provide durable emblems of substantial resource dissipation” (p.367). So far with first impression formation and Veblen's theory of conspicuous consumption we have a theoretical foundation for the first component of the suggested impression formation and brand appraisal process. As soon as people meet each

other, they are inclined to form an overall first impression of each other in reference to their clothing, possessions (especially luxury products), facial hair, posture et cetera, and they are also inclined to make inferences regarding socioeconomic status and characteristic of the encountered person.

Goffman's Dramaturgic Perspective: Goffman (1959) suggests that “when an individual enters the presence of others, they commonly seek to acquire information about him or to bring into play information about him already possessed”, and that “they will be interested in his general socio-economic status, his conception of self, his attitude toward them, his competence, his trustworthiness, etc. If unacquainted with the individual, observers can glean clues from his conduct and appearance which allow them to apply their previous experience with individuals roughly to the one before them or, more important, to apply untested stereotypes to him” (p.1). He argues that the individual plays a role and requests his observers to take seriously the impression fostered. He further indicates that the role is presented in a front (a setting), and this setting involves furniture, décor, physical layout, and other background items. Further, as part of personal front he includes insignia of office or rank; clothing, sex, age, and racial characteristics; size and looks; posture; speech patterns; facial expressions; bodily gestures; and the like. He suggests that once the proper sign-equipment has been obtained and familiarity gained in the usage of it, this equipment can be used for the performance of a favourable social style. Further he claims that “perhaps the most important piece of sign-equipment associated with social class consists of status symbols through which material wealth is expressed” (p.32). But Goffman (1951) also alerts that it is possible “that symbols may come to be employed in a “fraudulent” way, i.e. to signify a status which the claimant does not in fact possess” (p.296). Consequently, Goffman (1959) indicates that it is natural for the audience to judge if the impression the performer seeks to foster may be true or false. As he constitutes: “So common is this doubt that, as suggested, we often give special attention to features of the performance that can not be readily manipulated, thus enabling ourselves to judge the reliability of the more misrepresentable cues in the performance. And if we grudgingly allow certain symbols of status to establish a performer's right to a given treatment, we are always ready to pounce on chinks in his symbolic armour in order to discredit his pretensions” (p.51). The presented research demonstrates that as soon as people encounter others, they are apprehensive to detect if the fostered image of others is reliable or if a misrepresentation is current. They fulfil this task by applying to restrictive devices of misrepresentation. For example, in connection with pirated brands the overall impression of the owner may contradict the personalities conveyed by the brand. Hence, the person observed may be perceived as owning a fake product. This comprises the second component of the impression formation and brand appraisal process, in which it is decided if a product is fake or genuine.

Bourdieu's Social Space: Vogt (2000) argues that Bourdieu has changed the traditional Marxist approach of the economic capital concept in adding cultural, social and symbolic capital to the concept.¹ Bourdieu (1989b) states that people position themselves according to their distributions of these resources in the social space. In *Distinction* Bourdieu (1989a) describes how these various capitals, in particular economic and cultural capital, work in the social field of consumption. Income, financial- and material assets compose economic capital. Thus, economic capital can be equated with wealth (cf. Vogt 2000, Holt 1998, Veenstra 2005). Cultural and factual knowledge, attitudes, preferences, behaviours, educa-

¹For detailed elaboration see Bourdieu 1983, 1989a, 1995

tional attainment, skills, experiences, worldviews, vocabulary, modes of speech etc. compose cultural capital (cf. Lamont and Lareau, 1998; Allen and Anderson, 1994). Further, Bourdieu (1989a) predicates in *Distinction* that cultural capital is an indicator of class position, and that cultural capital is accumulated by family upbringing and social background; formal education and personal educational experiences; and occupational culture (see also Holt, 1998; Veenstra, 2005). Accordingly, for people who hold both types of capital in high and low quantities different lifestyles can be classified. For example, people such as lawyers and doctors not only have high amounts of money to consume luxuries goods, but they also have the necessary cultural capital to position themselves in higher social classes. Further, Bourdieu (1989b) argues that “the representations of agents vary with their position (and with the interest associated with it) and with their habitus, as a system of schemes of perception and appreciation of practices, cognitive and evaluative structures which are acquired through the lasting experience of a social position. Habitus is both a system of schemes of production of practices and a system of perception and appreciation of practices” (p.19). Correspondingly, he concludes that habitus leads to the classification of oneself by choosing clothes, sports, friends etc. that suit ones position, and it also makes one “capable of perceiving the relation between practices or representations and positions in social space (as when we guess a person’s social position from her accent)” (p.19). Consequently, the habitus enables people to distance or differentiate themselves of people who vary in some kind of resource endowment. This can be exemplified in regards to new money people or people who own small businesses. These people may as well possess financial assets to position themselves in a high social status class, but this may be inhibited because they lack the cultural knowledge, which is accumulated via socialization during the family and social upbringing. This displays the third component of the impression formation and brand appraisal process, in which the habitus, which is predominantly shaped by cultural capital, enables to sense one’s and others place in the social space.

The perception of a person as owning a fake or a genuine product might have negative or positive effects on the overall brand reputation depending on the context of the situation. As above explained the bearers of genuine products form an overall impression of others (first component) and judge the same products on others based on their first impressions and distinguish between owners of fake or genuine products (second component). As the users of the authentic products might be prone to think that everybody can easily distinguish between fake and legal product due to first impression formation, they might regard the users of the pirated brands as not intruding in their social status sphere (third component). Quite the contrary, they might regard the users of the pirated brands as individuals who admire their social status and affluence and therefore, regard their social self as affirmed, and this might help them to enhance their self-esteem and might lead to an overall positive brand evaluation (fourth component). To determine if the suggested theory of an impression formation and brand appraisal process consisting of four components can be hold, a qualitative research is conducted.

RESEARCH FIELD

Of concern in this study are luxury brand products. Nia and Zaichkowsky (2000) point out the special characteristics of luxury brands being prestige and rarity, and assume that “the counterfeits may negatively affect the image of the original and hence the desire to own the original” (p.486). “What we have here are uninvited guests to the market party and, like any other party, there are those who will object to the gatecrashers” (McDonald and Roberts,

1994). This implies that the loss of rarity leads to a decline of the prestige aspect, and further the existence of pirated brands produces an area of conflict, which can have a negative effect on the overall perception of the authentic brands, as brand image incongruity might be the consequence of this market practice. A further reason, why luxury brands are chosen is that appearance and visibility are critical for these brands but not salient for functional products such as music CDs and software programs (cf. Tom et al., 1998). Following these arguments, the brand Rolex is used for the qualitative research section. Rolex enjoys a high reputation among all interest groups of the brand, whether they can afford the brand or not. A brand such as Rolex with an excellent reputation is consequently committed to product piracy. This follows the argumentation that a brand that is neither desirable nor valued will not be copied (cf. Bamossy and Scammon, 1985). Further, the argumentations offered in this section are also effective for the brand Rolex, as the loss of rarity might lead to a decline in prestige, and appearance and visibility seem to be critical for this brand as well.

METHODOLOGY
