To detect if the presented research and especially the process of impression formation and brand appraisal consisting of four components can be hold, twelve authentic Rolex owners were interviewed. The interview method is used as it enables to “understand themes of the lived daily world from the subjects’ own perspective” (Kvale 1998, p.27). The interview also enables to “reach areas of reality that would otherwise remain inaccessible such as people’s subjective experiences and attitudes” (Peräkylä 2005, p.869). Consequently, as in this qualitative research the perceptions and experiences of the participants are of primary concern, the qualitative in-depth interview research is applied. Twelve interviews with authentic brand holders were conducted, and the interviews lasted from 30 to 50 minutes and were audio recorded. All interviews were transcribed to text for analysis. During the interviews visual aids in form of pictures were used. Five pairs of Rolex pictures representing an authentic and a fake product were used to detect if the interviewees could distinguish between the fake and the authentic product. This is of importance as this study claims that people do not distinguish between fake or real in reference to the appearance of the product, but make inferences from the overall image of the bearer to decide if the product is fake or genuine. Therefore, it is important that people are aware of the fact that some products cannot be distinguished only in reference to the appearance of the product and that they might rely on other facts to distinguish between fake and real. Further, five pictures of different people were shown during the interview, and it was claimed that all of these people had a Rolex. The intention was to detect if the interviewees decided in reference to the perceived overall image of the people if the Rolex was authentic or pirated, and if they identified or compared themselves with them. This exploratory study should help to clarify if the suggested process of impression formation and product piracy can be hold and what implications can be derived for the overall brand reputation of pirated brands.

RESULTS

The participants refer to many attributes when they form an impression of an encountered person. The most mentioned ones are clothes, shoes, watches, brands carried, personal appearance or public manner, jewelry or accessories, trimness and speech of the person encountered. Other attributes some interviewees rely on when forming an impression of others are trimness of face, hair or

hairstyle, facial expression, posture, movement, physical appearance, occupation, age and even how spruce the finger nails are. Some interviewees indicate that they first rely on attributes like clothes and shoes or public appearance to form an impression of the encountered person, and that these attributes compose the most important ones and are used more intensively than other attributes, as interviewee#6 remarks: "Clothes make up most for me. The first impression for me is, how somebody is dressed, particularly the shoes. And then the next impression is the talk. Thus, how he acts, how he answers, how the language is. And then a first impression is formed. The first impression is appearance and clothes." This aspect also emerges when encountered people are described in a context. As soon as a context is included to the impression formation process, some attributes are more chosen to describe the impression they have of the person. In the most cases when the pictures are shown, immediately the occupation of the person is mentioned and the resulting implications for the overall impression formed are noted. Almost all participants mention attributes without objection, which indicates that they are aware of the process of attribute seeking in impression formation, and that they do it consciously. Therefore, it can be concluded that the interviewees rely on several attributes like clothes, speech, occupation, accessories, brands carried etc. to form an overall impression of the encountered person.

Further, the interviews evidence that the impression formation process also comprises categorization of the encountered people. The response of interviewee#5 illuminates this aspect: "It is looked at the overall picture. How the occurrence is, and of course it is looked at the clothes, at the movement and then in this context the person is positioned in a group, which is classified by oneself." The categorization results from deduction of several characteristics from the overall impression formed. This means that first an overall image with reference to attributes like clothes, appearance etc. is formed, and that next from this overall image other characteristics are deduced. The mentioned characteristics, which the interviewees derive from the overall impression are financial resources or income, education level, and class membership. In respect to class membership, they distinguish between middle class and upper class or between blue-collar worker and white-collar employee or just wealthy people. Some interviewees notice that their inferences are based on prejudice, but remark that they are aware that they do it and assume that others behave in the same manner. The interviews reveal that the interviewees infer consciously or unconsciously from the overall image formed especially attributes such as financial success, education and class membership.

The next step was to identify if the interviewees classify, based on the overall image formed of others and the inferences they make from this overall image, the bearers of the Rolex as owning a real or a fake product. For the detection if the interviewees refer to other attributes than only the product observed when they distinguish between fake and real, it might be important to elaborate what the brand Rolex meant for these people. As in the theoretical part of this work already exemplified, the detection of misrepresentations might depend on mismatches between brand reputation and the overall impression formed of the person. Therefore, it is intended to detect what Rolex represents for the interviewees in order to be able to determine if their decisions are based on these representations of the brand in their minds. When asked what Rolex represents for them, some interviewees mention both which attributes the person should have who owns it and brand specific attributes. Other interviewees only mention brand specific attributes without considering traits of the people who own it. Among the attributes which the person should have are that the person should be self-confident,

should be stylish, should be well dressed, should have a sense for quality, should be spruce, should be educated, should have a smart occurrence and should have a good income. Further, these people are regarded as not showing off, as people who consciously spend money on luxury and as people who indulge oneself in buying such things. When they refer to the specific attributes of Rolex, they mention the high quality of the product, the durability of the product, the timelessness and the constancy of the product, luxury, the stable value of the product, the product being an asset, status symbol, perfection and as being the crown of the watches, as its brand label indicates it. Next, it was of interest to detect if the interviewees having specific brand representations refer also to other attributes than product appearance when they evaluate the bearers as owning a fake or an authentic Rolex. People who are perceived as having an overall elegant appearance or as being stylish dressed, as having a good job or working at higher levels, as being wealthy or as having higher income and as being well educated are assigned as owning an authentic brand. In the most cases the interviewees use these descriptions in some combination to reason their decisions. In contrast, people who are perceived as working at low qualification jobs, as being not so wealthy or as having less income, as being young and as not being well dressed were assigned as owning a fake brand. Again in the most cases the interviewees use these descriptions in some combination to reason their judgments. Therefore, the interviews highlight the aspect that people do not only differentiate between fake and real in reference to the observed brand or product, but they also refer to the overall impression formed of a person or to the deductions made from this overall impression to distinguish between fake and real bearer. The response of interviewee#11 evidences this argument: "You recognize it immediately from the quality. But it should not be forgotten that really good imitations exist. Thus, it exists A and B, average, normal and one to one very excellent imitations, with which even the expert has difficulties to recognize. But you recognize it from the person who has it. Certainly, you look at that person and ask yourself, can such a person afford for example such a watch or a product like that."

The next step is to assess if the interviewees compared or identified themselves with the people who are identified as fake or real owners and what implications this has on brand reputation. When the pictures of the people, who are judged as owning a real Rolex, are presented to the interviewees and asked if they identify themselves with these people, the responses are manifold. First, some interviewees respond that they identify themselves with the person presented in reference to his or her style; appearance; occurrence; clothes; and with the context in which the person is, like being in a convention. Second, others respond that they identify themselves with the person presented only in some attributes like style, and that they differ in regards to other characteristics like the person is more conservative or classical. Third, some interviewees tell that they could not identify themselves with the person presented, but give positive descriptions of the person like being nobler, more elegant and more career-minded. Although the responses are differing no one mentions any negative associations in reference to these people. When asked what it meant for the brand or for their perception of the brand if such a person owns an authentic Rolex, the responses are predominantly positive. Such positive responses are that they have a good feeling; that Rolex is worn by people, who are esteemed; that it has a positive smack; that it is a good promotion, which strengthens Rolex; that they have a positive attitude towards these people, and therefore as well a positive attitude toward the brand; that it strengthens their relation to the brand; and that they are confirmed in their product choice. As

no negative perceptions are mentioned and with reliance to these references it can be concluded that these people in the main enhance the perception of the brand reputation.

When the pictures of the people, who are judged as owning a fake, are shown and asked if they identify with these people, most of the interviewees respond that they could not identify themselves with these people. Whereas some of the interviewees only reply that they simply cannot identify or compare themselves with these people, some also reason why they do not compare or identify themselves with them. The reasons mentioned are how they dressed; the milieu they are in; the age of the person; these people did not amount to much, if they are satisfied with a fake; the job of the people; and that they are in a different income class. Therefore, it can be concluded that in general the interviewees do not identify themselves with these people. In the next step the interviewees are asked what they think why these people buy a fake Rolex. The most common responses are that these people esteem or admire the brand, as otherwise they would not buy the fake product; that the brand is in demand, but they cannot afford it; that they buy it just for fun; that they want to cheat; that they want to show off; that they want to keep up; and that they want to enhance their prestige. When asked what it meant for the brand or for their perception of the brand when such people own a fake brand. The responses again are predominantly positive, although beforehand as above indicated some negative responses such as they want to cheat or show off were stated, most of the interviewees argue that it proves that the brand is esteemed, admired and wanted, and they add that only valued products are copied. Ten interviewees state these descriptions and always conclude that therefore the owning of fake products by these people should not have negative implications for the brand. The interviews demonstrate that most of the interviewees do not regard the usage of fake products by these people as a problem, but quite the contrary, it is thought to enhance brand reputation.

Finally, the interviewees are asked if they believe that others perceive them as owning a real Rolex and how they deal with this situation. Nine interviewees state that they believe that others perceive them as owning a real Rolex. Three interviewees tell that they pay attention to their appearance, and that others surely regard them as owning a real Rolex because of the overall impression they display. The other six interviewees assert that they surely are regarded as having a real Rolex because of the profession they perform. One interviewee who is an army officer mentions that it depends on if he wears plain clothes or if he is in uniform. If he wears plain clothes, he is sure that people refer to him because of his appearance as owning a real Rolex, but if he is in uniform, he supposes that he is considered as having a fake product, as people think that such people do not earn enough money. But he tells that this does not bother him, as he values the brand in any case. Two other interviewees tell that they are probably not regarded as having a Rolex because of their overall impression displayed. One of them tells that he has a young appearance and due to that people might consider him as having a fake product. The other tells that she performs lots of free time activities like sports and because of her appearance at that time people might refer to her as having a fake product. But again both tell that their relation to the product is very intense, and therefore they do not care what others think of them.

DISCUSSION

This study extends existing theories on impression formation taking the fact of product piracy into consideration. It frames an impression formation and brand appraisal process consisting of four components. The first component comprises the impression formation theory and Veblen's conspicuous consumption (Veblen,

1945 [1899]) and indicates the formation of an overall impression of an encountered person and the inference of attributes such as wealth or social status. The findings of the qualitative research confirm the reliance on several attributes to form an overall impression and the inference of further characteristics, such as class membership, education and income or wealth. The second component demonstrates the detection of misrepresentations. This study confirms Goffman's (1951, 1959) detection of misrepresentations in regards to social status and extends it by including the detection of the authenticity of brands and products. The third component embraces Bourdieu's social space (Bourdieu, 1989a, 1989b) and describes the differentiation aspects from people belonging to other social classes. The interviews reveal that people compare or identify themselves with others who have similar economic and cultural capital and distance themselves from people with different economic and cultural capital endowment. Finally, the fourth component incorporates the implications on overall brand reputation in accordance to the other three components. The results of the interviews indicate that people clearly distinguish between real and fake owners with reference to their formed overall image and the detected misrepresentations (component one and two). As people who own fakes can easily be identified, they do not get the opportunity to cheat and position themselves in a higher position (component three). In reliance to the specification of these three components the authentic users conclude that fake owners in most cases use a fake brand because they admire or esteem it, and not for deceiving others. Further, the admiration of the brand by these people proves according to the authentic owners that the product is really wanted and this again enhances brand reputation. Further, they also indicate that the existence of the fakes is positive for the brand, as only brands are copied which are valued, and that this again confirms their product choice (these arguments comprise component four indicating an overall positive brand reputation). Our findings contribute to the theory of impression formation and add a better understanding of how people wearing fake products are perceived. Due to the found clear distinction of fake and real bearers of products, the results of this study also have major practical implications, suggesting that under certain circumstances product piracy may serve as counter-intuitive marketing instrument which in part contradicts the predominant negative view of product piracy for brands.

However, the presented results comprise first findings. In this research we concentrated on one product category (watches), one brand (Rolex) and one interest group (owners of the authentic brand). Further research could demonstrate if the findings can be generalized or extended to other product categories or interest groups such as potential customers.

The Present Location of Temporal Embeddedness: The Case of Time Linked Consumption Practices in Dual Career Families

Shona Bettany, Bradford University, UK
Caroline Gatrell, Lancaster University, UK

ABSTRACT

This paper examines the time linked consumption practices of professional dual career families, examining the kind of consumption practices these families use to manage their lives. The study found that rather than being slaves to time scarcity, professional dual career parents actively 'speed up' and 'slow down' time through particular consumption practices to take more control of their family lives and times. This paper utilises these empirical accounts to develop theory on time and the family in consumer research which not only enriches understanding of families and familial consumption but also provides a theoretical development of the concept of time within consumer research

INTRODUCTION: PROFESSIONAL DUAL CAREER FAMILIES AND TIME

In previous work on this subject matter (Bettany and Gatrell 2007), we presented an empirical interpretive analysis of time linked consumption practices in professional dual career families. Our argument for this work was that, to date, consumer research on the family, being focused primarily on decision making, life cycle and roles had presented a narrow conceptualisation of 'the family' as a construct (Ekstrom 2005, Price and Epp 2005). Moreover, that this narrow conceptualisation was also highly gendered and gender/role normative around the notion of the "normal" nuclear family with father as breadwinner and mother as carer, housewife and nurturer (Commuri *et al* 2005). Conversely to this picture, as Ekstrom (2005) has argued a plurality of families exists today leading us to the conclusion that the family itself may not be the most appropriate construct with which to theorise what we might call 'kin'. As Price and Epp (2005) have argued examining how families are enacted might be more worthwhile than taking the family as an already self evident construct. Examining these alternative family enacting constructions led us, as well as others (Gentry and McGinnis 2003) to a concern with the most quickly growing family construction (Macran *et al* 1996), the "peer marriage" of professional dual career parents with small children. "Peer marriages" are defined as those marriages where *'partners are social equals, have careers, share equal responsibility for finances and other decision making, and where the husband assumes far greater responsibility for child-rearing'* (Gentry and McGinnis 2003). As a family form, peer couples with children, defined here as "professional dual career families" have risen exponentially. Professional dual-career couples, have *'jobs which require a high degree of commitment and which have a continuous developmental character'* (Rapoport and Rapoport 1969) with a lifestyle career pattern including high levels of career responsibility and personal investment of time and energy (Johnson, Kaplan, and Tusel 1979, Bird and Schnurman-Crook 2005). However, and perhaps not surprisingly, when we examined the concept of the peer marriage within consumer research the primary focus of consumer research on the family is still upon decision making and family roles in these decision making processes. This often reduces these monumental changes in family form, structure and activities to 'families with working wives' becoming a variable in family decision making research (see for example Mangleburg 1999). Traditional decision making research and research on family roles does not, and can not,

begin to understand the complex entanglement of family 'making' processes and consumption activities in contemporary families, especially professional dual career families that have highly complex lives.

'Time' is a central theme in studies of the family in consumer research, particularly those that focus on the "working" mother. The working mother emerges in these studies as the key figure in terms of time pressure, time management and time scarcity (Gross 1987). Thompson's (1996) study of "the juggling lifestyle" of professional working mothers, for example, as well as others (Joag, Gentry, and Ekstrom 1991, Joag 1985, Joag, Gentry, Gentry *et al* 1996, Commuri and Gentry, 2005 among others) predominantly focus on mothers only and by doing so, these studies implicitly position women *only* as functioning and managing in both the work and domestic spheres and thus subtly act to reinscribe the domestic sphere as the feminine domain. The ability of women to balance home and work through time management is studied (or put under question), while the father is not considered. This therefore doesn't consider the specificity of professional dual career families. It has been documented in the consumer behaviour field that there is little evidence in the consumer research literature that husbands have taken on more household roles. However, as Rudd (1987) points out, if the research has asked the woman about shared roles (e.g. Foxman and Burns 1987), this may have skewed the findings somewhat. In other fields it has been documented that fathers undertake an increased level of childcare and other roles (Gatrell 2005, Hochschild 1997) and interdependence of roles is common (Bird and Schnurman-Crook 2005). Research on the dual career family and the division of domestic labour is a contested field and in professional dual career households, management of, and juggling between, the domestic sphere and the work sphere has been reported as highly complex (Sullivan 2000, Windebank 2001). As well as this focus on the mother as primary time manager, many of the studies in marketing emphasise the negativity of working women's lives with a focus on concessions, compromises and guilt. Thompson's paper opens with a quote from a respondent which begins 'sometimes I go through guilt trips...'. The article goes on to assert that *'women... must find ways to cobble together a compromise between the competing cultural ideals of traditional motherhood and career oriented professionalism'* (1996:388-our emphasis). This may be correct, but the message is that families with professional working mothers are highly problematic and that living in these families is likely to be a negative experience.

In trying to develop an understanding of this negativity in the literature and in the public and political commentaries given above we kept returning to the issue of time and how time was being conceptualised. We concluded that this negativity was predominantly linked to the idea of "time scarcity" in these families as the root of their "problem". From our own experience as professional working mothers we could endorse the idea that time was scarce from our own households, but we both felt that the understanding of the phenomenon of time needed a more nuanced analysis and that the idea of "time scarcity" as a central factor may be a little simplistic. Supporting this, Southerton (2003) argues in his study of suburban households that although his respondents all presented narratives of "time harriedness", in depth examination of their

experiences of this phenomenon led him to assess that this did not automatically equate to “time scarcity” and that their consumption, management and experience of time was highly complex.

The combination of a scarcity of research on “alternative” family constructions and the rather outdated and one might say naïve conceptualisations of both ‘the family’ and ‘time’ in consumer research led us to our interpretive study of professional dual career families and time. In the initial paper from this study we presented a rich interpretive study of peer families actively managing and subverting time through complex consumption patterns. In this presentation, we utilise a portion of that empirical evidence to make a further contribution concerning the conceptualisation of time within consumer research.

TIME AND CONSUMER RESEARCH

*Future consumer research should emphasize analyses of the socio-temporal contexts of consumer behavior. This means that consumer behavior should not only be related to clocks and calendars. It should also be temporally related to other activities, and to specific patterns of interaction and location. The social temporality of consumer behavior should be identified by specifying the particular preceding, succeeding or coinciding events, and by examining the consumer's own perceptions and reflections regarding these temporal relations between the consumer behavior and other events...[Consumer researchers need] to develop more insight into how consumers themselves perceive and reflect on this temporal coordination of consumer behavior in relation to other events, including action, actors and arenas, within particular contexts.
(Gronmo 1989:341)*

The quote above was taken from the groundbreaking article by Sigmund Gronmo (1989) where he effectively exploded the myth of a one-dimensional concept of time with which consumer researchers had previously been theorising their research concerning time and the consumer (see also Hirschman 1987). Research on time in consumer research, until then had been dependent upon a concept of time borrowed from economics (Jacoby, Szybillo and Berning 1976). This concept of time, where time is seen as an external, objective fact, as a mechanical, clock based, linear and standardised resource led to consumer research on time that focused on time allocation (Robinson 1975, Wilson 1984), time as a resource to be spent and/or saved (Hendrix 1984), time scarcity (Gross 1987) and time expenditure choices (Chapin 1974, Holman and Wilson 1982). In general, all time conceptualising consumer research concerned the ‘use of time’ as a finite, objective and limited resource (see also Anderson, Karns and Venkatesan, 1988; Arndt and Gronmo, 1977; Golden, Umesh, Weeks and Anderson, 1988; Hawes, 1977; Hendrix, Kinnear and Taylor, 1978). In his article, Gronmo argued that there were at least three different conceptualisations of time, and that this mechanical, economics based view was only one of these. The most important conceptualisation of time for consumer research, he argued, is social time, that is the concept of time as defined through the subjective perception and experience of time as embedded within specific socio-cultural contexts, this he called ‘social temporality’.

Given our concerns as researchers regarding what we considered as the rather simplistic conceptualisation of time within peer families as related to “time scarcity”, and given that “time scarcity” fits within the mechanical economics based concept of time, we looked for research in the consumer behaviour discipline that developed Gronmo’s call for a broader and more multi dimensional

theorisation of time. More specifically we looked for work that developed Gronmo’s call for attention to social temporality. The two major pieces of work that have used the concept of social temporality are Szmigin and Carrigan’s (2001) study of elderly consumers and Thompson’s (1996) study cited above, of the juggling lifestyle of working mothers. Szmigin and Carrigan (2001) argue that very little research indeed has been done in consumer behaviour discipline regarding time as a social concept embedded within particular social and cultural groups, citing only their own and Thompson’s study.

Both the Szmigin and Carrigan (2001) and Thompson (1996) articles utilize Dapkus’ (1985) phenomenological framework of time experiences to organize their analyses. However, both use this framework only as a methodological and analysis organizing tool, neither develop any further time and consumption based theory. Moreover, both articles, as they rely on Dapkus phenomenological approach, cannot extend the theory of time beyond the mechanical model. Phenomenology, because of its focus on pure experience takes linearity (as a key element of participant narratives) for granted. As a result, although the work is “social” in its approach, the concept of time per se, remains as a mechanical, economic, linear and fundamentally objective concept.

Given the lack of theoretical development of this area and order to develop the theoretical contribution of this work, there is a requirement to go outside the discipline of consumer research and examine how time is being conceptualized in sociology and cultural theory, particularly how time is being used to theorize family life and the case of peer families. Although, as posited by Weik (2004) “many authors in the field of sociology and social theory have integrated temporal features into their theories, there is still a lack of theories based on time” and Torres (2007) complains of the “theoretical shortfall” with regard to time in the social sciences, one theory has emerged concerning the highly complex experience of time and the management of work and home by professional couples. This is the theory of “the extended present” (Brennan 2002, 2005). Time as the extended present, is not a linear and measurable construct, but rather a subjective experience. Analysing the extended present means focusing upon the nature and intensity of the time experienced, and how time itself is constructed through activities, practices and experiences. In the extended present, there is a heightened sense of the present, and the past and future are backgrounded and often distorted (Brown 1998). In the extended present the focus is on the here and now, activities are viewed in relation to the present, not the long term future, work/home times and practices become fragmented, entwined, complex and multiple and not easily explained in terms of simple “time scarcity”. “The extended present” has three characteristics, outlined by Brennan and Nilsen (1994) *time simultaneity*, *time compression* and *time autonomy*. *Time simultaneity* is the experience and management of “multiple times”. This might be expressed in terms of the practice of multi-tasking, but is more akin to simultaneously managing different worlds with highly different time bases and expectations. *Time compression* is the feeling that more and more tasks have to be concentrated into a shorter time period, but also that there is a requirement to be ultimately flexible to any unexpected occurrence in the present time. In time compression, people are constantly switched on and available for action demanded from many different (and often incommensurate) sources. *Time autonomy* is the state of being self managing in terms of time, but that this self management extends into a timetabling of every waking moment, there is a sense with time autonomy that one can manage ones own time, but that the tasks are potentially never ending, and there is no “off-time” without awareness of things that need to be done.

The extended present as a theory provided an interesting way to organise our initial analysis, and certainly went beyond the previous analyses of time in consumer research. In terms of the negativity presented in research on peer families it provides an alternative viewpoint. Living in the extended present is not simply dystopian or utopian but shows multiple heterotopias of temporality that peer families have to manage, and live within. However, although this is undoubtedly useful, it still adheres to a basic ontology of time as an objective 'thing' to be managed, and relies heavily on the typical economic metaphors of the mechanical conceptualisation of time. We felt that the behaviour of our respondents required more dimensionality of analysis, respondents were not slaves to time, just 'coping with' time and 'managing' time, they were far more active in their negotiations. Parents were 'enacting' time, engaging in consumption practices to actively slow down and speed up time in the present. This points to not only the different conditions that structure time, but to a different ontology of time. The challenge here, then, is how to theorise time in a way that avoids the traps of the mechanical conceptualisation that positions peer families in this simplistic way.

Beginning with the extended present as a starting point begins to address the ontological traps of prior analyses in that its focus is on "the present" rather than presenting some kind of temporal progress narrative. In studies of time and discourse, Cooren *et al* (2005:265) also begin with this starting point but add the ontological progression of enactment to their analysis arguing that, "the structuration of time occurs through the articulation of different agents *doings*" (emphasis ours). In other words, they analyse time not as something external, to be managed, spent and saved, but as a discursive achievement or enactment within specific social settings. The authors argue that in these discursive analyses of time, the past, present and future are simultaneously embedded within the discursive event of the research situation, and their analytical focus is on the processes of engagement and disengagement that indicates enactment of these different time "zones", not as things in themselves, but as produced in the present. This analytical focus and ontological approach can be applied to this analysis concerning enactment not of past present and future in the present, but as enactment of different concepts of time itself. This analytical focus of the present oriented enactment of different concepts of time within very specific research settings and research moments we have called "a present location of temporal embeddedness".

EMPIRICAL EXAMPLE

From Coping with Time to Enacting Time: A Present Location of Temporal Embeddedness in Peer Families

Speeding up time: consuming surrogates, 'not doing' and the Taylorisation of the home

Theorists have discussed how the management of home and work for dual career parents has led to a 'Taylorisation' (Hochschild 1997, Lyon and Woodward 2004) of the home and there was some evidence for this in our interpretations. Taylorisation (Taylor 1911) is associated with mass production methods in manufacturing and is better known as scientific management. The basic premise is to discover the most efficient way to do particular work tasks to improve productivity. This sort of task-oriented optimization is found in manufacturing (E.g. production lines) and in services (E.g. fast food restaurants). Taylorisation is based upon a highly masculinised conceptualisation of time (Odi 1999), as it is measurable, linear, commodifiable and instrumental, and thus, this Taylorisation of the home has been seen as running counter to traditional feminine time conceptualisations of family life

(Hochschild 1997, Tietze and Musson 2002). There was some evidence to support the idea that some aspects of home life were being 'Taylorised' as a way to speed up time and increase efficiency through specific consumption related practices.

One of the ways that this was being managed was by a compartmentalising of certain 'drudge' tasks that required little thought, as Angela explains

Domestic management, the real boring repetitive stuff, the ironing, the washing etc. is a real bone of contention. I hate the chores, I hate laundry and the endless repetitive trips upstairs, empty the airing cupboard, put stuff away, fill it with new things, put another wash on...and then you look around and the linen basket is full... (Angela Academic)

Parents used various strategies to speed up the time these tasks took. Sharing of tasks was one route that respondents took to increase efficiency. It was clear from the data that although some sharing of some tasks was being used as a way to speed up time, management of this still usually fell to the woman, for example in organising slots of time for the man to contribute and in the case of men's data, discourses of helping the wife were common, which did not go unnoticed...

(my wife) will prompt me by saying the bath hasn't been cleaned for ages which usually means Charles go and clean the bath and ill do it... (Charles Scientist)

I feel like I'm dragging my husband like a donkey, and he has said on occasion "I'll help you out, I'll help you out by cleaning the bath" and I always make a big fuss about it because there is no 'helping me out' to it! We live here its two adults, you and me... (Lianne A Level Teacher)

Some women in the sample resented this bitterly, and it was obviously a cause for contention for both parties. As a result, they had to find other ways of offloading routine chores, and one of the ways they did this was through the consumption of 'domestic surrogates' in the form of paid help, or outsourcing. Consumption of surrogates was an important time linked consumption practice for these parents. Largely, it was the mother that organised these surrogates.

I manage it...its amazes me how much time that takes. So I organise that the washing is done, to leave out in the basket so that (the cleaner) can take it out and iron it, and I tidy up so that it isn't too bad when she is trying to clean (Eleanor, Senior Education Manager)

This phenomenon of doing domestic tasks for the surrogate was very common, especially cleaning before the cleaner arrives. Further to this, the mother often paid for the surrogates out of her own salary.

A further strategy deployed by respondents to speed up time was 'not doing'. Many reported having 'dropped their standards' by simply not engaging in particular activities.

The house gets cleaned only when people are coming, because something has to give. I know that I can't do everything... (Sonia, nurse manager)

It became clear through the analysis of the data that there was evidence to suggest that the home had become 'Taylorised', al-

though it was much more complex than it might first appear. Clearly, the women in the study felt under more pressure than the men to be more efficient in the home and reported that they used skills developed in the workplace to speed time up significantly. Tasks were more shared, but the traditional model of the family seemed to impinge upon the women more strongly. The discourses emerging from the men in the study (and quite a few of the women) of *helping* and responsibility indicated that in the main, however equitable the task allocation was, the implication was that in 2004, a was found in the 1980s by Coltrane (1989), management of the home was still largely the woman's domain.

Slowing down the extended present: slow parenting and the subversion of speed

What became clear in terms of the Taylorisation of the home thesis is that it applied to very specific tasks and activities. In relation to other activities it did not hold. The respondents appeared to have selected certain practices which were subject to a *slowing down* of time linked to heightened and meaningful experiences. The slowing of time has been described as '*conscious negotiation of the different temporalities which make up our everyday lives deriving from a commitment to occupy time more attentively...a deliberate subversion of the dominance of speed*' (Parkins 2004). We felt that this described other practices the parents were doing in contrast to the 'speeding up' of time. This could not be conceptualised as simply 'saving time' to get 'free time' but in terms of spending time differently, slowly and meaningfully. Urry (2000) has argued that choosing slowness over speed equals a heightened sensory or aesthetic experience. In terms of time linked consumption practices, this became another important area for our analysis.

Parents were slowing time using very specific time linked consumption practices that were often described in terms of '*real parenting*'. Often these activities were highly time consuming, for example, Angela, an academic recalled how she made some sugar mice for her daughter's birthday:

She had seen the picture of these mice in a children's magazine about a mouse who is a ballet dancer, and she wanted them for her birthday party. I had never done anything like that and I had no idea how difficult it would be. Fortunately, we had a 'dry run' in advance of the day, because it took me several goes to get it right. The first couple of tries just produced a sticky mess; you certainly couldn't shape a mouse out of it. Anyway I looked through some old cookery books and I found a recipe for peppermint creams which were similar. And it turned out that the magazine had got the quantities wrong, so no wonder it didn't work. So I tried again and this time I got it right and I was able to make these little mice, and I put icing roses for ears, and pink liquorice tails and little silver balls for the eyes. And when the actual birthday came, I knew I could do it and they were perfect, and my daughter was so pleased, and that made it all worthwhile (Angela Academic)

Sometimes these time linked consumption practices were linked to special purchases. However, we must make it clear here that in all cases this did not extend to the consumption of expensive toys or over consumption. Sophie, a solicitor, preferred her son to involve himself in creative play, rather than relying on expensive presents to keep him entertained.

I've never thought that as far as my son is concerned he must have x, y and z just because I didn't have it as a child. It is quite the reverse, I don't want him to be spoilt...(Sophie Solicitor)

Special purchases seemed to be not hugely expensive or extravagant, but imbued with particular meaning and usually this was meaning that could be linked to 'slow' parenting practices.

*I was really busy, away on business and I wanted to buy her these special pyjamas, ones you could get in New York but no where else I had seen them the last time I was away and told her about them...well I hunted all day and finally I found these b**** things I couldn't remember... Anyway it was all worth it when I saw her little face. My job is putting her to bed in the evening and we get the pyjamas and make sure the fairy on them is smiling...we get so much fun out of them in the evening, the fairy reads the book and whispers to me... (Peter Accountant)*

Peter emphasised here that his purchase was not to compensate for him being away, but to enjoy his parenting on his return. His explanation of this was that compensation, for him meant the father perfunctorily buying toys and sending the child away to play with them. For Peter, the pleasure of these consumption activities were in facilitating a special 'slow' parenting time that had a high cost in terms of time he could spend doing other activities..

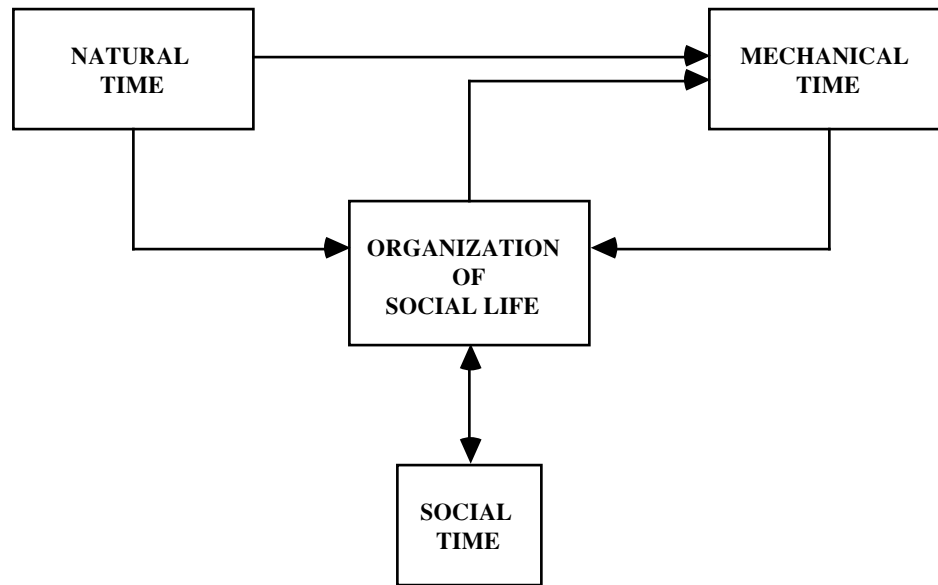

This slowing of time for parenting included aspects of parenting and consumption which were quite surprising given the degree of disposable income that this group often had access to. For example, going to the library seemed to be considered a much more rewarding parenting practice than buying books for many of the parents even though this was much more time consuming for them. This indicated for us an important aspect of these activities which was not that the respondents were slowing time to do less, but slowing time to do *more*, often highly labour intensive practices. An example of this concerned food consumption as part of parenting.

Although most parents used 'convenience' foods there seemed to be a commitment to eat better and to feed children in a more natural way at least some of the time. Organic foods were often mentioned as well as home made baby food and 'proper' family meals. This was an aspect of consumption activity that fathers seemed happier to be involved with and enjoyed the preparation of some meals which became complex time linked consumption practices. This father explains...

What I do enjoy is at the weekend there is a market in the town, often a French market and we go down and choose nice veg and go to the butchers for meat and the deli for nice bits then I cook a lovely meal for the family on Saturday evening. It is a special time now that they are getting a little bit older. They learn about things...what kind of things err well...we were looking at celeriac, it is so ugly why would you want to eat it but it tastes lovely so you have to get them over the ugliness of it...they did eat it (laughter) its important that they understand how...how to eat actually (James Senior Manager)

One of the important aspects of this 'slow parenting' was that the fathers, like James above, actively sought these time linked consumption practices as a way to significantly develop the parent-child relationship. All of the fathers in the study exhibited high levels of commitment to developing this key relationship, often over and above the commitment to the relationship with their wives/partners. Parents might experience conflict over who is responsible for the rationalised, 'Taylorised', mundane tasks, but where these special 'relationship forming' times were concerned both parents wanted to engage in them. Parents were prepared to expend signifi-

FIGURE 1
Gronmo's Model of relationships between time concepts
(From Gronmo 1989)

cant amounts of time and energy, often mediated through specific consumption practices as has been illustrated above.

MODELLING THE PRESENT LOCATION OF TEMPORAL EMBEDDEDNESS: A RETURN TO GRONMO

As Knights (2006) has argued, one of the common problems shared by mechanical models of time, and research which takes an oppositional stance to that conceptualisation of time and instead utilise the theory of social time is that both still adhere to a concept of time that is basically essentialist, external, objective and linear. Neither approach appreciates the social processes through which alternative conceptions of time are enacted. It is certainly the case, as argued above, that the scant literature using the concept of social time in consumer research does not consider these issues. In the analysis above, we have gone beyond the idea of both social time as it is conceptualised in consumer research and the extended present, demonstrating instead how parents are actively enacting different time concepts to create a 'present location of temporal embeddedness' where time is enacted or discursively constituted in particular ways. This conceptualisation does not rest ontologically upon the concept of time as essential, objective and linear but as enacted, subjective, socially and discursively embedded and 'in the present'.

Developing Gronmo's model (Figure 1) we will develop a model of the "present location of temporal embeddedness" in peer families that represents the research above. Gronmo's initial model is a very useful model to begin with, as it already admits the existence of multiple time concepts and that these are interconnected and impact upon one another.

For Gronmo, the organisation of social life is based upon a negotiation between what he calls 'natural time' and 'mechanical time'. Mechanical time has already been defined, natural time is dictated by changes and rhythms in nature, social or familial processes and is cyclical. This negotiation results in social time/social temporality which is the focus of analysis he calls for in consumer research. It is quite easy to make the connections between our analysis of slowing down and speeding up time with these

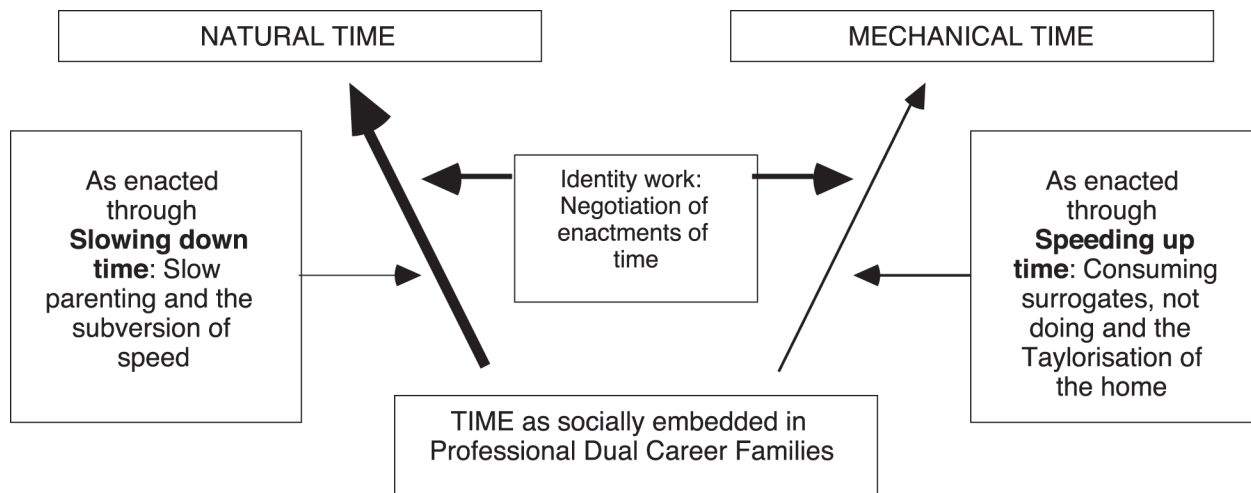

categories. Natural time is most often associated with the home, motherhood and nurturing and mechanical time is most often associated with work. Where we depart from Gronmo is that rather than social time being the outcome of a negotiation between natural and mechanical time, in our model (Figure 2) social time, or rather the social embeddedness of time (in this case within the context of peer marriage) enacts natural and mechanical time concepts in specific ways.

In our research, thinking about our data in terms of the present location of temporal embeddedness allowed us to develop our analysis into the realms of asking what is being achieved in these social settings, what is being enacted, achieved and mobilised through these enactments of time. In the model we show how the embeddedness of enactments of time focus around complex enacted negotiations between natural and mechanical time where natural time is privileged through slowing down and mechanical time is de-emphasised by speeding it up. We concluded that these discursive strategies reflect a social setting in which the actual parameters of parenting itself is being redefined. Parents are actively securing their identity as 'good parents' through their enactment of time and furthermore 'being a good parent' is being achieved in the research setting through these complex time enactments. There is a clear speeding up and de emphasis of tasks not directly connected with active parenting experiences and a slowing down of heightened parenting engagements with children.

Further to this, within this shared discursive achievement of being a good parent there are quite clear battlegrounds associated with the enactment of each time concept. Power and gender roles are quite clearly evident and being played out across the enactment of these times. One of the most important findings of the research concerns the changing roles of fathers within peer families. Our research found that fathers emphasised relationship forming times with their children (as reported above) This was an important finding for this research, fathers as well as mothers wanted to invest a significant amount of time and emotional capital to develop close relationships with their children, and these were often mediated through consumption practices. As well as being a source of pleasure for the fathers, they often discussed this in terms having

FIGURE 2

The present location of temporal embeddedness in professional dual career families

choices removed by developments in the future, for example, redundancy or divorce. Fathers seemed to want significant parenting time at least partly as a response to uncertainty over their roles in the future of their children's lives.

Mothers in our study focused on the other time concept, which as can be seen from the empirical example became a battleground not only over who was doing these mundane everyday tasks, but over the actual conceptualisation of what is 'is to be a mother' in peer families. There are clear battle lines being drawn over tasks such as cleaning the bath, which the father quite proudly admits that he does "to help his wife", and the mother then has to remind him that his language assumes the task is owned by her and she has to strongly resist that. This shows production and reproduction of gender within the peer family. This illustrates the importance of looking at this phenomenon through this particular ontological lens, and demonstrating how whereas experience based research might report that tasks are shared and gender discrimination in peer families is being eroded, discursive analysis instead shows that the task is still discursively constituted as a female one, and presumably then, one that is still ultimately the mother's responsibility!

In conclusion, our model of the present location of temporal embeddedness in professional dual career families shows these families actively using time enactment of different time concepts and actively slowing and speeding up the time/s associated with each concept. Time enactments are used as a discursive resource to cope with a highly complex life situation, as parents try to make their identities 'as parents' coherent but also use these time enactments to help negotiate and renegotiate power charged gender and parenting roles.

The Feeling of Love Toward a Brand: Concept and Measurement

Noel Albert, CERAG and WESFORD, France

Dwight Merunka, University Paul Cezanne Aix-Marseille (IAE-CERGAM) and Euromed Marseille, France

Pierre Valette-Florence, IAE and CERAG, France

Since the 90's, research concerning brands has strongly developed and notably the brand-consumer relationship or consumer connections to brands thematics through constructs such as brand trust, brand commitment or brand loyalty (Chaudhuri and Holbrook, 2001; Fournier, 1998; Fournier and Yao, 1997; Samuelsen and Sandvik, 1998). Among these different constructs, the feeling of love toward a brand appears to be recent and researchers (Ahuvia, Bagozzi and Batra, 2007; Carroll and Ahuvia, 2006; Whang and al., 2004) and practitioners (Roberts, 2006) manifest their interest for this novel construct when applied to objects or brands.

First investigations concerning the brand love construct dealt with the definition and conceptualization of the construct (Shimp and Madden, 1988; Ahuvia, 1993). More recent research aims at measuring the feeling of love a consumer might hold for a brand (Carroll and Ahuvia, 2006). This research current leads to a better understanding of the non-interpersonal love feeling and to more managerial relevance. Uncovering and measuring dimensions of love and consequences of love for a brand may help managers in the definition of their brand strategies.

This research focuses on the measurement of the love construct. It points to conceptual limitations in love scales available in marketing and develops, tests and validates a new scale to apprehend the feeling of love toward a brand. This scale leads to a better understanding of consumer brand relationships. This article is composed of two parts. In the first section, we discuss the state of the art in consumer love literature pertaining to three main domains: (a) conceptualizations of the love construct in a marketing context, (b) limitations in the studies of love in marketing, and (c) measurement issues linked to the two brand love scale currently available in a marketing context. In the second part we present the construction of the proposed new love scale, from exploratory studies to the dimensionality of the brand love scale and the presentation of its reliability and validity assessments.

CONCEPTUALIZATIONS AND MEASUREMENTS OF THE FEELING OF LOVE TOWARDS A BRAND

Main conceptualizations of love in marketing

The first authors introducing the feeling of love in marketing are Shimp and Madden (1988). They adapt in a marketing context the interpersonal love theory of Sternberg (1986) named the Triangular theory of love. The three dimensions of love (passion, intimacy and decision/commitment) are slightly transformed in a consumption context and become: yearning, liking and decision/commitment. The presence, or not, of these components in a brand-consumer context lead to 8 different relationships (Nonliking, Liking, Infatuation, Functionalism, Inhibited Desire, Utilitarianism, Succumbed Desire, Loyalty). Ahuvia (1993, 2005a, 2005b) also thoroughly study the concept of love applied to various object categories (places, ideas, pets, consumption objects, etc.). According to him, the feeling of love toward an object is composed of 12 characteristics (excellence, irreplaceability, sense of meaning, etc.). This early work enables better understanding the meaning of the love feeling toward an object. However, it also contains some conceptual problems and limitations. For example, Ahuvia (1993) considers satisfaction or well-being as dimensions of the love

feeling whereas these constructs are usually considered as outputs or consequences of interpersonal love (see for example Hendrick, Hendrick and Adler (1988) for satisfaction and Kim and Hatfield (2004) for well being).

Ahuvia (1993) proposes a conditional integration theory to explain the feeling of love toward an object. The starting point of Ahuvia's thesis is the Aron and al. (1986) theory who claim that love is the inclusion of others in the self. He distinguishes two kinds of variables linked to the self: the actual level of integration into the self and the desired level of integration into the self. Ahuvia (1993, p. 87) explains that : « *Love then, can be defined as the situation in which both the desired and the actual level of integration are high* ». Later, Ahuvia (2005b) compares interpersonal love and the feeling of love toward an object. Results of this comparison indicate that they have more common points (the lover finds the object attractive, the object provides something the lover wants or needs, a sense of natural fit, love is enduring, etc.) than differences (non-presence of negative emotions in love for objects, self sacrifice). Whang and al. (2004) measure the feeling of love of bikers toward their motorcycles using an interpersonal love scale that they apply without adaptation (that of Hendrick and Hendrick, 1986). Results indicate that bikers love for their machines is made of passion (Eros), possessiveness (Mania) and altruism (Agape). Carroll and Ahuvia (2006, p.5) define brand love as: "*the degree of passionate emotional attachment a satisfied consumer has for a particular trade name*". According to those authors, five characteristics describe brand love: (1) passion for the brand, (2) attachment for the brand, (3) positive evaluation of the brand, (4) positive emotions in response to the brand and (5) declaration of love for the brand. This helps us understand what the feeling of love is in a consumption context. Nevertheless those studies have some important limitations.

Limits of the study of love in a marketing context

We identify three main limitations in the studies of love in marketing: theoretical, methodological and managerial.

Theoretical limitations: two main frameworks are currently used to approach the brand love feeling. Some studies specifically rely on one interpersonal love theory and apply it in the marketing context (Ahuvia, 1993; Shimp and Madden, 1988; Whang and al., 2004). Love is a complex feeling and phenomenon and it seems difficult to claim that an interpersonal theory will capture all of this particular feeling when applied to objects or brands. Moreover, selecting one of the available interpersonal theories and adapting it to marketing also means not taking into account the findings from other studies in the search of the understanding of love. Another approach is characterized by the fact that authors do not refer to any interpersonal theories on love (Fournier, 1998). These studies may be deemed a-theoretical and may lead to some problematic interpretations. For example, why are intimacy, commitment and integration to the brand proposed by Fournier (1998) not linked to the passion/love dimension as it is in interpersonal theories (e.g.: Sternberg, 1986; Aron et al., 1986)?

Methodological limitations: Some authors explicitly use the term "love" during their qualitative interviews and indicate it may help understanding the prototype of love (Ahuvia, 1993, 2005b).

However, the explicit use of the word “love” may well introduce an important bias. The responses of the respondents may well be made with reference to their conceptualization of interpersonal love, since the concept of love in memory is more strongly linked to interpersonal concepts than to brand or object concepts (Fehr and Russel, 1991). Moreover, this method probably falls short of enabling to uncover specific brand love dimensions since the dominant pattern in memory is undoubtedly that of interpersonal love.

Managerial limitations: Many authors have worked on the feeling of love applied to objects (Ahuvia, 1993, 2005b; Shimp and Madden, 1998; Whang et al., 2004). From a brand management standpoint, these studies may be limited since objects can be diverse from pets to homes and places. We believe more interesting to propose a love scale applied to brands with a clear concept of a brand such as defined by many authors (Keller, 2007). New developments in the field of love towards brands should try to circumvent these limitations.

1.2. Brand love measurement scales.

We present the two brand love scales currently available in marketing and point to some limitations.

Caroll and Ahuvia's Brand Love Scale (2006)

Caroll and Ahuvia (2006) propose a brand love scale composed of ten items composing a unique dimension. The items are: (1) this is a wonderful brand; (2) this brand makes me feel good; (3) this brand is totally awesome; (4) I have neutral feelings about this brand (reverse-coded item); (5) this brand makes me very happy; (6) I love this brand; (7) I have no particular feelings about this brand (reverse-coded item); (8) this brand is a pure delight; (9) I am passionate about this brand; (10) I am very attached to this brand. The important question concerning this scale is its claimed unidimensionality. Firstly, in the interpersonal love literature, love is generally presented as a multidimensional construct (Hatfield, 1988; Sternberg, 1986). Secondly, examining the items of the scale questions its possible unidimensionality. Items composing the scale carry different meanings (passion, happiness, attachment, well being, etc.) and probably favor multidimensionality. Also, passion and attachment which here belong to the scale and therefore to the same dimension are considered as two different dimensions or steps in interpersonal love theories (Hatfield, 1988; Sternberg, 1986).

The Thomson, MacInnis and Whan Park Brand Love Scale (2005)

The second scale in marketing which may be used to measure a love feeling towards brands is that of Thomson et al. (2005). This scale is remarkably constructed and tested from a methodological standpoint. However, while the authors label the construct to be measured as ‘*Emotional Attachment*’, we contend that the proposed scale deals more with the love construct than the attachment construct. In particular, the conceptualisation of ‘*attachment*’ integrates here the dimension of ‘*passion*’. Beyond rare exceptions, the attachment component of a love relationship does not include the passion dimension (Hatfield, 1988; Baumeister et al., 1999; Fisher, 2006). With the inclusion in the scale of the ‘*Passion*’ dimension (one dimension out of three, the two others being Affection and Connection), and the use of the item ‘*Loved*’ which belongs to the Affection dimension, we believe that the construct studied and measured is similar to that of Love. Dimensions and measurement items of the Thomson et al. scale are given in Figure 1.

From a conceptual standpoint, the two dimensions, Affection and Connexion are considered as a unique dimension in the interpersonal love literature. Affection is also called intimacy (Hatfield, 1988) or attachment (Fisher, 2006). Connection is generally con-

sidered as an element defining affection or intimacy. For example Sternberg (1997, p.315) defines intimacy as ‘*(...)feelings of closeness, connectedness, and bondedness in loving relationships*’. According to Baumeister and Bratslavsky (1999, p.50): ‘*intimacy refers to the way the two people feel that they are close to the other*’. Also, Hendrick and Hendrick (1983, p.18 cited by Baumeister and al., 1999) explain that: ‘*Intimacy means the degree of closeness two people achieve*’. Recent findings on interpersonal love from neurosciences (Fisher, 2006) and social psychology (Hatfield, 1988) demonstrate that the feeling of love is composed of two dimensions: affection and passion. There is no mention of a connection dimension. Of course, the scale may be different because applied to brands. However these conceptual difference at least call for more research on the theme. Finally, there are important correlations between the three dimensions of the Thomson et al. (2005) scale. In study 4 of the research, the three dimensions have correlations superior to 0.72 (connection–passion : $r=0.79$; connection–affection : $r=0.72$; passion–affection : $r=0.75$) which we believe to be high and may question the dimensionality of the construct.

METHODOLOGY AND RESULTS

The scale construction is first detailed following procedures recommended by Churchill (1979). We then present the structure of the scale and its reliability and validity tests. Finally, we focus on the nomological validity of the love scale and its predictive validity of three common constructs: brand loyalty, brand trust and positive word of mouth.

2.1 Scale construction

We first present the procedures used to generate the items of the love scale. We show how the steps followed here attempt to overcome precedent limitations mentioned. We then present data collection procedures and data collected for the scale development.

Item generation

Two exploratory studies are conducted in order to understand the brand love construct and generate the items for the scale. These two studies (interviews and an internet survey) are designed to overcome limitations uncovered in previous research.

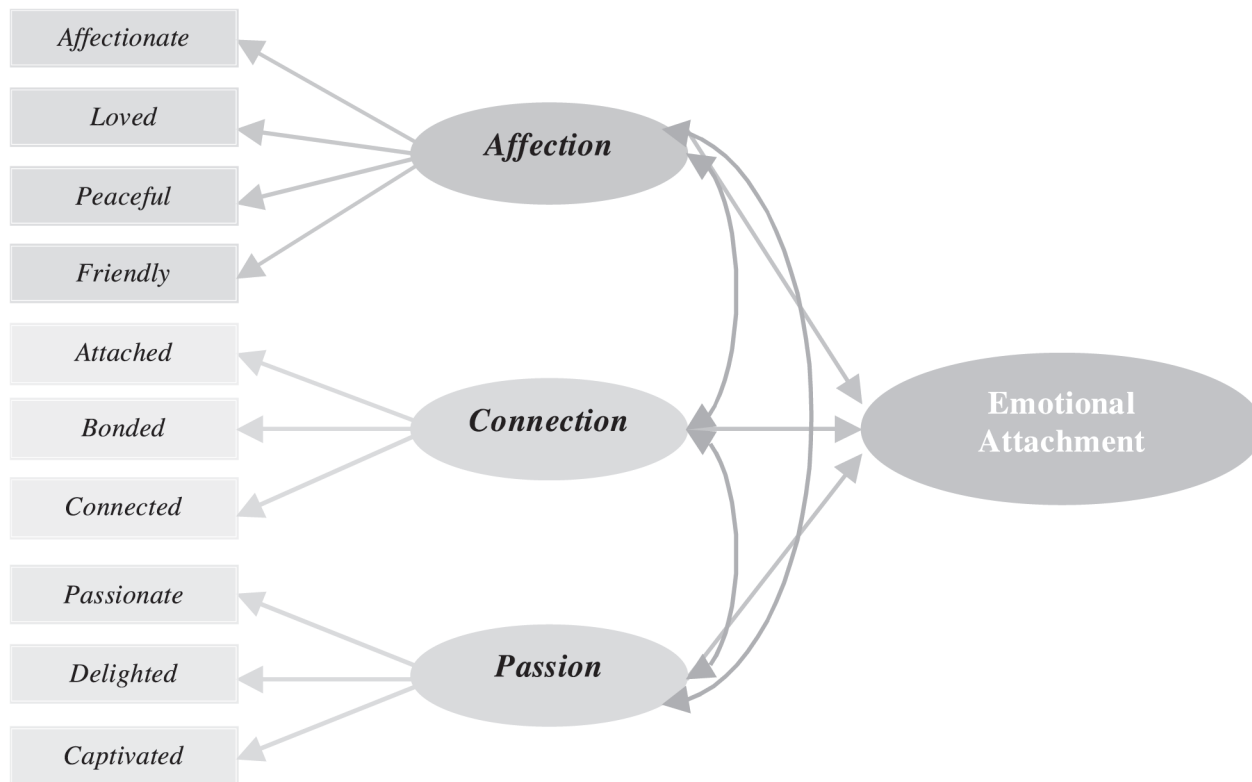

Seventeen structured interviews are conducted with 7 women and 10 men aged 19 to 59. During these interviews the word love is explicitly mentioned in order to help understanding the brand love prototype (Ahuvia, 1993, 2005b). However, this procedure may also impose a pre-established model of interpersonal love on the respondents. Therefore, we conduct an internet survey using projective methods and not mentioning the word “love”. Nineteen pictures are chosen to represent brand consumer relationships and among the 19 images, three symbolize the feeling of love. We use different open-ended questions to understand brand consumer relationships without using the word love (e.g.: “*Why did you choose this image to represent your relationship with the brand?*”, “*Is the brand special for you? If yes, please explain why?*”).

In opposition to previous research (Ahuvia, 1993, 2005b; Whang et al., 2004) which applied one specific interpersonal theory to a marketing context, both studies conducted here are truly exploratory and no underlying theory was referred to. The exploratory dimensions obtained are confronted to the interpersonal literature in order to retain only true dimensions of love and avoid selecting antecedents or consequences. This should enable to avoid conceptual limitations previously mentioned.

Data collection for scale development

For scale construction purposes, we integrate two categories of items : (1) items identified in our two exploratory studies and (2) items used in three interpersonal love scales. We select items from

FIGURE 1
Items and dimensions of brand love feeling (Thomson and al., 2005)

the Passionate Love Scale (Hatfield and Sprecher, 1986), the Triangular Theory Love Scale (Sternberg, 1986), and the Romantic Love Scale (Rubin, 1970) which are largely referred to in the love literature. A total of 248 items are used to construct the instrument. All those items are linked to the love feeling and include its dimensions, its antecedents and its consequences. Among those 248 items, 107 of them measured love dimensions. Respondents used a 10 points Likert scale, ranging from 1 (does not apply at all) to 10 (totally applies), to describe the extent to which the items could apply to the brand they chose for the survey.

The Internet survey offered 4 versions of the questionnaire in which the order of the items was randomized. We also developed a paper and pencil questionnaire. All in all, 825 fully completed questionnaires were used for analysis. The final sample of respondents consists of 35.8% of men (64.2% women) with a majority of younger persons (66.3% less than 30 years of age). 43% are students, 23% executives, 17.8% employees. 65.6% of respondents are single and 25.6% are married. Table 1 presents the product categories and the 10 brands most mentioned by the participants.

Model

Exploratory and confirmatory analyses

We first conducted an exploratory Factor Analysis on the 107 items (corresponding to real love dimensions) and for the 825 observations. Items that refer to antecedents or consequences of the love feeling were not taking into account for scale construction. A

bootstrap analysis, based on 300 new samples, was used. Two kinds of items were eliminated at this step of the analysis. First, the items with a small loading or with cross loading on two or more factors. Items that correspond to constructs only related to love (i.e. its antecedents or consequences) were also eliminated from the analysis. The final set of items retained (22 items) reflected a seven-factor solution (see Table 3).

The structure uncovered for the brand love feeling is easy to understand and seems to offer a good description of the concept. In order to check the validity of this solution, a set of CFA using structural equations modeling (SEM) was conducted. Table 2 presents the goodness of fit of the model which is satisfactory.

We now detail the 7 dimensions of the brand scale. The first factor indicates that the consumer considers the brand as unique and/or special (*'Uniqueness'*). The second factor highlights the pleasure given by the brand to the consumer (*'Pleasure'*). Items from interpersonal love compose the third factor which underlines the proximity between the consumer and its brand (*'Intimacy'*). The fourth factor (*'Idealization'*) is also composed of interpersonal items. The long relationship between the consumer and the brand constitutes the fifth factor (*'Duration'*). The sixth factor represents important persons or events for the consumer and symbolized by the brand (*'Memories'*). Finally, the seventh factor translates the fact that the brand is present in the consumer's mind (*'Dream'*). The correlations between the factors are positive and significant. Because of the presence of interpersonal items in the scale ob-

tained, the feeling of love towards a brand is identical or highly similar to an interpersonal love feeling as Whang and al. (2004) have already demonstrated.

Results also indicate the presence of two second order dimensions. The first second order dimension is linked with five first order factors (duration, dream, memories, intimacy and uniqueness). This factor is named '*Affection*'. The second factor is linked with the two last first order dimensions: idealization and pleasure. This second order factor is named '*Passion*'. Affection for the brand highlights a long relationship with the brand and the proximity between the consumer and the brand. The brand is perceived as unique by the consumer and the consumer often thinks about it. Passion for the brand is due to the idealization and pleasure provided to the consumer by the usage or possession of the brand. This second order solution is notably interesting with respect to the interpersonal love literature. Affection and Passion are present in numerous theories on the subject (Hatfield, 1988; Sternberg, 1986; Rubin, 1970). Moreover, neuroscience research (Fischer, 2006) also demonstrate that the love feeling is composed of the same two dimensions, passion and affection. Loadings between the factors of the first and second order are given in Figure 2.

Reliability

Scale's reliability is good as shown through the Joreskog coefficients. Six of the seven factors have a reliability coefficient superior to 0.7 and one factor has a reliability coefficient of 0.672 which can be judged satisfactory.

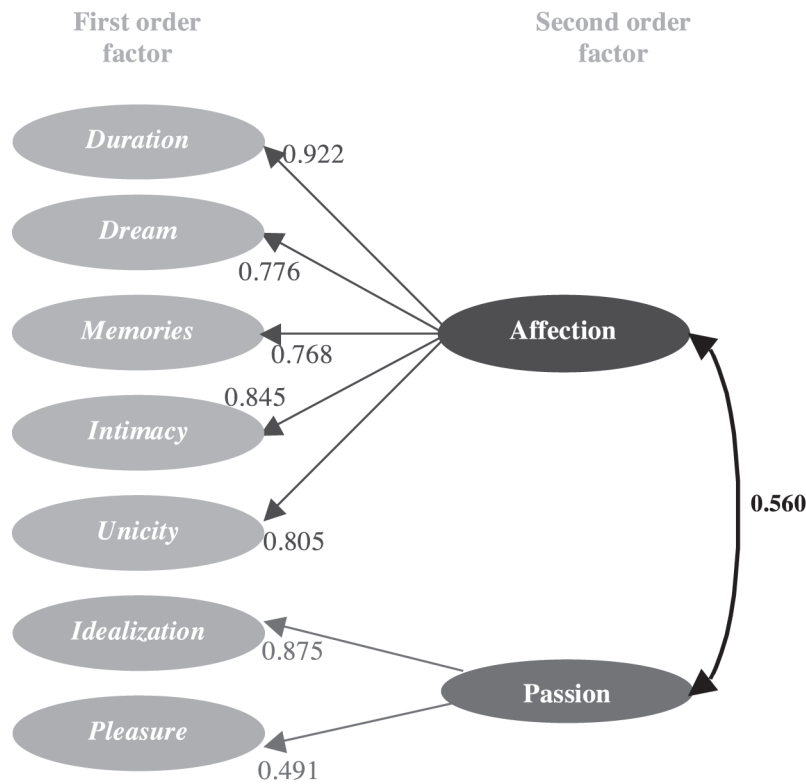

Convergent validity

We followed the The Fornell and Larcker (1981) recommendations for the estimation of convergent validity. Bootstraps analysis are used to compute the variance shared between each factor and its indicators. Results from Table 3 indicate good convergent validity for 5 of the 7 factors. Factors 4 and 5 exhibit a lower convergent validities (respectively 0.447 and 0.446) but it is still satisfactory, mainly due to the fact that the respective loadings are greater or equal to 0.63. All t tests are superior to 2, which confirms the good convergent validity of the scale.

Discriminant validity

The discriminant validity is tested by comparing the chi-square from a constrained model (factors' correlations constrained to one) to the chi-square from a free model (correlations between factors are free) (Bagozzi and Yi, 1991). The chi-square difference between the constrained model and the free model is always

FIGURE 2
Second order conceptualization of the brand love scale

superior to the theoretical chi-square which confirms discriminant validity.

Nomological Validity

The love feeling is linked to a lot of different behaviors, emotions or feeling in the interpersonal relationship literature. In a consumption context, Carroll and Ahuvia (2006) demonstrate a positive direct effect of brand love on both loyalty and word of mouth. Thomson et al.’s (2005) emotional attachment construct is linked to four attachment behaviors (proximity maintenance, emotional security, safe haven, separation distress) and predicts brand loyalty and the willingness to pay a premium price. Our survey contains love items but also items which measure other constructs usually considered as outputs of love. We test the relation between the brand love scale uncovered and the constructs of brand trust, brand loyalty and positive word of mouth. The measurement of these constructs are ad hoc measurements since we did not use scales already tested in the literature but items about brand trust, brand loyalty and word of mouth that were identified in our exploratory studies.

Several characteristics of passion could explain its link with positive word of mouth. According to Sternberg (1986) or Shimp and Madden (1988), the passion component of a romantic relationship leads to infatuation. Passion is also considered as the motivational dimension of love. Moreover, Hatfield (1988) indicates that passion is characterized by excitation. Infatuation, motivation and excitation are supposed to be linked to positive word of mouth about

the brand. In a marketing context, Carroll and Ahuvia (2006) have demonstrated a positive link between brand love and positive word of mouth. Bauer and al. (2007) also demonstrate that brand passion influences word of mouth.

Loyalty has been defined as an element present in the description of affection love (Fehr, 1988) but loyalty is also not the same construct than love. Carroll and Ahuvia (2006) have demonstrated that brand love has a positive effect on brand loyalty. Consumers who feel affection for the brand are expected to be loyal to this brand.

Finally, we think that brand affection could explain brand trust. Trust has been often considered as an antecedent of attachment/affection (Palmentier and al., 2006). However, as Belaid and Bekhi (2008, p.8) explain: “Trust is not necessarily a prerequisite to brand attachment but it plays a main role in enhancing this affective bond. Moreover, brand attachment could reinforce brand trust.”. Love is a complex phenomenon and its relations with other constructs are usually hard to define. Hendrick, Hendrick and Adler (1988, p.981) indicate for the relation between love and satisfaction (one of love’s consequence): “However, process and outcome in a close personal relationship are part of the same feedback loop, with satisfaction in turn affecting the levels of love or investment that initially predicted satisfaction”. The same phenomenon applies to the others antecedents and consequences of love. Consumers who feel affection for the brand are expected to trust the brand.

Results support our hypothesis. Passion is linked to positive word of mouth while affection is linked to brand trust and brand loyalty. In Table 4 are shown the loadings of the items measuring

TABLE 3
Loadings, Reliability and Convergent validity of the brand love scale

Factor	Items	Loadings (<i>t test</i> >2)	Reliability <i>Rho of Jöreskog</i>	Convergent validity (% of shared variance)
Uniqueness	This brand is special	0.703	0.672	0.506
	This brand is unique	0.720		
Pleasure	By buying this brand, I take pleasure	0.845	0.822	0.538
	Discovering new products from this brand is a pure pleasure	0.718		
	I take a real pleasure in using this brand	0.612		
	I am always happy to use this brand	0.741		
Intimacy	I have a warm and comfortable relationship with this brand	0.752	0.771	0.530
	I feel emotionally close to this brand	0.694		
	I value this brand greatly in my life	0.736		
Idealization	There is something almost ‘ magical’ about my relationship with this brand.	0.675	0.707	0.447
	There is nothing more important to me than my relationship with this brand	0.631		
	I idealize this brand	0.697		
Duration	(I feel that) this brand has accompanied me for many years	0.694	0.707	0.446
	I have been using this brand for a long time	0.670		
	I have not changed brand since long	0.638		
Memories	This brand reminds me someone important to me	0.825	0.856	0.666
	This brand reminds me memories, moments of my past (childhood, adolescence, a meeting, ...)	0.723		
	I associate this brand with some important events of my life	0.891		
Dream	This brand corresponds to an ideal for me	0.682	0.812	0.521
	I dream about that brand since long	0.682		
	This brand is a childhood dream	0.721		
	I dream (or have dreamt) to possess this brand	0.796		

each of the three constructs (word of mouth, brand trust and brand loyalty). Relationships between the two second order factors (Passion and Affection) and the three outcome variables are given in Figure 3.

DISCUSSION

Consumers may experiment a real feeling of love toward some brands as demonstrated in numerous research findings. Concerning the measurement of the love construct, two brand love scales have been developed but they are subject to conceptual limitations according the definition of love. The main objective of this research

is to propose a valid scale enabling measurement of the feeling of love towards a brand. The solution obtained is composed of 22 items and 7 first order dimensions: Uniqueness, Pleasure, Intimacy, Idealization, Duration, Dream and Memories. The seven factors offer a second order solution with two factors labelled Passion and Affection, which is consistent with the most recent findings on interpersonal love in social psychology and neuroscience. This validates the proposed scale from a conceptual standpoint. Our findings confirm that love towards a brand is highly similar to interpersonal love. Statistical analysis confirms the reliability, validity and the quality of the structure of the proposed model.

TABLE 4
Results from the CFA of the outcomes of the brand love feeling

Items		Loadings (<i>t test</i> >2)	Reliability <i>Rho de Jöreskog</i>
Trust	This brand does not disappoint	0.411	0.576
	In the event of failure from the brand, I think I will forgive. Everyone can make mistakes	0.636	
	I have never been disappointed by this brand	0.619	
Word of Mouth	I defend this brand at any cost	0.712	0.801
	Sometimes I talk a lot about this brand	0.758	
	I think it is a good brand, I will recommend it to friends and family	0.658	
	I often speak about this brand	0.576	
Loyalty	I am loyal to this brand and I think I will be for a long time	0.740	0.764
	I am very loyal to the brand	0.709	
	I do not intend to switch to another brand	0.548	

FIGURE 3
Test of the nomological validity (path coefficient)

Finally, the brand love scale predicts three positive behaviors, namely Trust, positive word of mouth and loyalty. The use of the brand love scale may now help managers to detect consumers who feel love toward their brand, measure the importance and the dynamics of the phenomenon and help them propose adapted communications, loyalty programs or novel consumer segmentation schemes.

These interesting results must be tempered by some limitations. First, although the brand love scale predicts brand loyalty, brand trust and positive word of mouth, we did not use scales developed and tested in the literature. Although we believe that the

items used do a good job in measuring the constructs, a more formal test is required in further research.

Given current limitations with this research and the very limited number of studies on the subject of brand love, we encourage future research in the area. Both antecedents and consequences of brand love need further exploration. What creates brand love? Are brand image, brand differentiation, brand uniqueness an issue? Is the type of brand both in terms of its category or its positioning an issue? Are some consumers more love prone than others? May the love feeling be linked to history or nostalgia? The nomological validity tests indicate that the dimensions of passion and affection

do not have the same outputs. Could it be the same about brand love antecedents? Are there specific antecedents and consequences for brand affection and brand passion? What mixture of antecedents is then required to generate both passion and affection? Another interesting issue is the level of analysis to which the brand love concept may apply. Can a consumer be in love with a brand independent of the products that carry the brand? Or is the consumer in love with a branded product? Does love transfer with brand extensions? We believe that this concept is in its preliminary phases of development. Cultural variations may also affect the concept and measurement of love towards a brand. Much research is yet needed to better understand, measure and assess the importance of the brand love construct.

Can Brands Make Us Happy? A Research Framework for the Study of Brands and Their Effects on Happiness

Jean-Francois Bettingen, University of Innsbruck, Austria
Marius K. Luedicke, University of Innsbruck, Austria

ABSTRACT

Brands permeate consumer culture. Yet, despite their ubiquitous presence, one of the societally most relevant and fundamental questions of brand existence remains among the most difficult to capture: Can brands make us happy? Academics have identified emotional and cognitive influences of brands on loyalty and studied the broader well-being effects of income and consumption. This paper adds to this discourse by analyzing the roads and barriers of researching correlations between brands and happiness. We first evaluate methods to reliably assess general influences on happiness. Then, we differentiate three levels of the consumer-brand experience and discuss if and how their respective correlations with happiness can meaningfully be measured. As a result, we offer a roadmap for brand-related happiness research that directs and inspires further inquiry.

INTRODUCTION

When Apple's first cellular phone, the "iphone," hit the U.S. Market in June 2007, the most devoted fans went to such lengths as to spend several nights in front of the Apple stores to get a hand on the device. Once acquired, they petted the product, showed it around, cheered the brand, and thus rejuvenated the brand-based market system. Has the owners' happiness been driven by the device itself? Was it the brand? Or was it the entire system of brands that molded the iphone in to being such a powerful identity resource?

Brands have been important since about 1885. Since these early days, brands have become means not only for making better-informed purchasing decisions, but also for advancing individual identity projects (Elliott and Wattanasuwan 1998); as symbols of taste, wealth, and belonging (Levy 1959), as objects of desire (Belk, Ger and Askegaard 2003, Ahuvia 2005), as motives for social community building (McAlexander, Schouten and Koenig 2002), and as relationship partners (Fournier 1998). Whereas these functions have been perceived as implicitly positive for consumer well-being, brands have also long been criticized (Fisk 1967). Over the last decade, a rising number of authors have investigated the darker side of corporate branding, the brand's potential backlash (Handelman 1999; Holt 2002; Klein 1999; Kozinets and Handelman 2004; Lasn 2000). The key point of these studies is that the "branding of cultures" by corporations advances a superficial culture of over-consumption, resulting ultimately in the destruction of human and environmental resources, a reduced quality of human relationships and diminished overall well-being (Csikszentmihalyi 1999).

The above findings evoke the fundamental question of whether brands can make us happy. Existing research has illuminated various influences of consumption on happiness, such as car possession, smoking, or leisure activity levels, and scrutinized demographic influences such as income, employment, or race on happiness, but remains silent on the level(s) at which brands might influence consumers' and society's psychological well-being. This paper offers an important next step towards closing this gap in knowledge by reflecting on the roads and barriers of brand-related happiness research. We first discuss the concept of happiness, its various influences, and its most reliable measures. Then, we de-

scribe three distinct levels of brand experience from which consumers might derive happiness; brand clues, brand systems, and the overall system of brands. Lastly, we combine the suitable happiness measures with these three realms of experience to present a research framework for future brand-related happiness research.

THE LEVELS OF BRAND EXPERIENCE

A brand is a "name, term, sign, symbol, or design, or a combination of them, intended to identify the goods or services of one seller or group of sellers and to differentiate them from those of competitors" (Chernatony and Dall'Olmo Riley 1998, 419). This and various other more cultural and multi-faceted concepts of brands underlie an extensive body of literature that has illuminated the individual-psychological (Aaker, Fournier and Brasel 2004; Tybout and Carpenter 2001), communal-sociological (Arnould and Thompson 2005; Hellmann 2003; McAlexander, Schouten and Koenig 2002), and economic-managerial (Aaker 1995) merits of branding. However, for our purpose, we need a definition of the brand that differentiates the tangible, observable elements of a brand (e.g. a specific thing) from the meanings of them (e.g. its community associations) and again from the meanings of the entirety of brands in society (i.e. attitude towards brands in general). We next describe these three levels of brand experience as brand clues, brand systems and the system of brands.

Brand Clues

A "brand clue" is a set of distinctions that consumers experience with their physical senses-sight, hearing, smell, touch and taste. As manifestations of brands, brand clues include logos, products, price tags, stores, sounds, smells and other clues through which consumers identify the derivation, quality, or function of a particular good or service. For an observer, that is an owner or non-owner, a brand clue in itself is experiential and meaningless. However, brand clues are also links to the brand system.

Brand Systems

Brand systems are systems of communication that organize the meanings of brand clues for an observer (Giesler 2003). Such meanings may include the particular identity connotations of a brand (e.g. the innovative spirit of Apple products), the connotations of group belonging (e.g. the community of Harley Davidson owners), and the (largely imagined) social responses that consumers derive from interpreting brand meanings (e.g. responses to wearing fashion brands).

Brand systems are characterized by three markers (Luedicke 2005). First, brand systems are established through social communication about brand clues. They proliferate with every reference made to the brand, but are as oblivious as human minds. Second, distinctive clues with high social relevance influence the brand systems' communicative "noise." That social noise is independent of whether consumers accept, alter, or oppose the suggested meanings of the brand clues. Third, being intelligent in their social reproduction, brand systems negotiate and perpetuate specific programs and structures that guide, constrain, and inspire communication. Programs and structures allow consumers, marketers and other observers to communicate in accordance with—or against—the

FIGURE 1
Three ontological levels of brand experience

predominant meanings of a brand system and use these meanings for their marketing or identity goals.

The System of Brands

The system of brands is a theoretical concept for studying the entire presence and role of brands for an observer. Brands and their social utilization by organizations and consumers are understood as a functional subsystem of consumer societies, and operate with particular programs and codes. In distinction to the brand system, which embraces communications around a specific brand, the system of brands refers to the general logic of brands that enables consumers to recognize brands as parts of a larger system. The shared knowledge about the system allows consumers to employ brands both as a means for social distinction as well as for better making purchasing decisions.

In concert, these three notions allow us to meaningfully define the notion of brands, and to correlate brand experiences with consumer happiness (see Figure 1). Observers (e.g. consumers, marketers, journalists) perceive brand clues independent of brand knowledge (e.g. a Ferrari is a loud red car). When they learn about the brand's social attributes and how they are perceived in a particular cultural context (e.g. a Ferrari is a high status vehicle, or a "pimp ride"), they experience the brand system. Observers that, for instance, have their first experiences with consumer cultures will get an understanding of the system of brands in this particular context. They will learn that particular brands have an effect on social responses or that some social realms demand the usage of brands whereas others rather despise it. Differentiating these three levels of brand experience enables us to distinguish suitable measures for their assessment.

WHAT IS HAPPINESS?

Ancient Greek philosophy understood happiness as the absence of pain (e.g. Epicure), and was focused largely on the body or the result of intelligent reflection (e.g. Cicero). The hedonist philosophy of Aristippus of Cyrene, however, theorized that happiness was the sum of material pleasures, and the meaning of life was the maximization of delight (Layard 2005, Fromm [1976] 2007). This hedonistic concept of happiness was particularly influential for the Italian metropolitan elite of the Renaissance, and the British and French bourgeoisie of the 18th and 19th centuries. Hedonism continues to be expressed in contemporary consumer culture with the creed of "having more" is "being more" (see Fromm 2007 for a critique). Whether happiness is—or should be—the ultimate goal in life remains an unresolved philosophical question. However, it is evident that American consumers accept the "pursuit of happiness"

since the Declaration of Independence in 1776 as a salient life goal and consumption as a central means for leveraging it.

The definition of happiness is largely author dependant. In the literature, a person's "happiness" is determined in at least four different ways. Psychologists tend to use the construct of "subjective well-being" (Diener et al. 1999). This term reflects the idea of happiness as a non-physical state that cannot be objectively measured (as opposed to body temperature or blood pressure). In this view, subjective well-being is "the degree to which an individual judges the overall quality of his/her own life-as-a-whole favorably" (Veenhoven 2001, p. 4). Economists, in contrast, understand well-being as a function of a person's income and the utility derived from consumption (Sunanyi-Unger 1981). Another stream of literature theorizes happiness as one of many human affects. For these researchers, happiness levels can be derived from the observation- and averaging-of a person's affects over a period of time. Lastly, researchers in the field of neurobiology perceive happiness as an activation state within a particular region of the brain.

What Influences Happiness?

Generic influences on happiness (using measures of satisfaction) were found to include income, personal characteristics, socially-developed characteristics, how respondents spend their time, attitudes and beliefs towards self/others/life, relationships, and the wider economic, social and political environment (Dolan, Peasgood and White 2008, p. 97). Such research has found, for instance, significant differences in the evaluation of subjective well-being depending on people being employed versus unemployed and single versus living with a partner (ibid.). People with high self-esteem, a sense of personal control, optimism, and extraversion were found to be generally happier (Myers and Diener 1995). Research has also tested for happiness correlations with gender, age, education, and ethnicity, but results vary among the various studies (Andrews and Withey 1976; Diener 1984). It seems that money can buy happiness, but only temporarily (Myers and Diener 1995).

The question underpinning all these analyses is whether happiness can be influenced. Some authors argue that about 50% of one's satisfaction is predefined in the human genetic program and that life circumstances only marginally affect human happiness (Lykken and Tellegen 1996). Others believe that a change in behavior, such as an eventual grateful gesture to a friend, can change overall happiness levels (Wallis et al 2005, Seligman 2002). Self-evaluation has been variously used in studies correlating consumption with happiness (see Table 1)(Diener and Suh 1999, Frey and Stutzer 2002, Layard 2005). It has been reported, for

TABLE 1

Correlates of Consumption Measures and Happiness (Source: The World Database of Happiness)

Consumption Measure	Correlation with Happiness
Car Ownership	$r=+.17$
Active involvement in sports	$r=+.19$
Possession of micro-wave and dish-washer	$r=+.15$
Leisure activity level	$r=+.14$
Smoking	$r=-.10$

instance, that among 3,500 Dutch consumers above 18 years of age car ownership correlates moderately positive with happiness ($r=+.17$, $p<.05$ in 1997 and $r=+.12$, $p<.05$ in 1993).

Whereas these above studies provide some evidence of consumption influences on happiness, they tell little about brands and remain vague on both the various levels of brand experiences and on the direction of causality. Consequentially, the ultimate question of whether-and how-brands influence consumer happiness has yet to be answered.

HOW IS HAPPINESS MEASURED?

Approaches to measuring happiness are many fold. As stated above, scholars understand happiness in at least four different ways. However, the economists' reductionism approach of objective well-being does not add to our quest as this stream abstracts from subjective and individual evaluations. In the sections that follow, we describe the key approaches of subjective well-being, hedonic affect, and physiological activation in more detail.

Measuring Happiness as Subjective Well-Being

A broad variety of scales have been used to quantify peoples' quality or satisfaction with life. Among the former, the "Satisfaction with Life Scale" of Pavot and Diener (1993) ranks as the most reputed. It evaluates overall happiness with five questions rated on a scale from 1 (strongly disagree) to 7 (strongly agree). Other examples of multi-item scales include the "Oxford Happiness Inventory" (Argyle et al. 1989) with 29 items and the "Depression-Happiness Scale" (McGreal and Joseph 1993) with 40 items.

For some authors, single-item scales are, on average, as valid as multi-item scales (Burisch 1984). Such scales typically use a question such as "On the whole, are you very satisfied, fairly satisfied, not very satisfied, or not at all satisfied with the life you lead?" (European Commission 2008), or "Taken all together, how would you say things are these days? Would you say that you are...?" Answers on a 7 point Likert type scale range from "completely unhappy" to "completely happy" (Andrews and Whitney 1976). For these single-item scales it was found to make no empirical difference in results if the word "satisfied" or "happy" was used (Hirata 2006). This makes the single-item scale applicable for large-scale surveys.

The subjective well-being approach and its underlying beliefs have two important implications for our study. First, happiness is

not understood as a peak of life evaluation, but being happy means that a person judges his or her life favorably rather than unfavorably at a particular point in time. Typically, such measures are repeated over months and years to measure changes in correlations and to abstract from punctual emotions. Second, happiness is understood as a subjective appreciation of one's life without any objective standard. Hence, if consumers judge themselves to be happy, then, as far as the researcher is concerned, they are happy. Difficulties with studying satisfaction with life arise from whether it is a stable personal trait or an evaluation that depends on life circumstances (Veenhoven 1994), and whether happiness is perceived as absolute or relative (Veenhoven 1991). As it currently stands, most researchers in the satisfaction of life paradigm agree that happiness depends on both personal traits and life circumstances. It is further found to depend on both the respondents' social environments and as absolute in the sense that happiness cannot occur unless basic human needs—such as security, health, and food—are satisfied.

Measuring Happiness as Hedonic Affect

Happiness correlates not only with the subjective evaluation of the degree to which personal expectations have been met (see Bentham 1789, Veenhoven 1984, Myers and Diener 1995), but also with the relative presence of positive and negative affects. These include the pleasantness of emotions (e.g. love), sensory feelings (e.g. taste), and mood (a mixture of affects). The World Database of Happiness lists more than 200 different scales for measuring hedonic affects. Affect scales explicitly ask for affective states, in contrast to subjective well-being scales that avoid words referring to feelings or moods, but ask for achievements, wants, and goals. Furthermore, researchers applying affective measures are not restricted to self-reports, but can also draw on external observations such as those of family members or the researchers themselves (Noelle-Neumann 1977).

Affective experiences can be evaluated simultaneously good and bad, and should therefore be described as bivalent rather than bipolar (Kahneman 1999). The Positive and Negative Affect Schedule (PANAS) measure of affect rates among the most frequently used affect scales (Watson, Clark, and Tellegen 1988). Participants are asked to rate ten positive affects (interested, excited, strong, enthusiastic, proud, alert, inspired, determined, attentive, and active) and ten negative affects (distressed, upset, guilty, scared, hostile, irritable, ashamed, nervous, jittery, and afraid) according to

their emotional strength at various points in time. Answers range from 1="very slightly or not at all," to 5="extremely" (ibid.). As affects change in situ, they must be measured repetitively to inform about a participant's overall happiness. The "Experience Sampling Method" (ESM, Csikszentmihalyi, Lason and Prescott 1977) acknowledges this dynamic by asking respondents several times per day to report the situation they are engaged in at that moment and to evaluate the presence or absence of various feelings. Although this method reveals valuable insights on the intensity of current feelings in a specific situation, it remains difficult to be implemented for larger scale surveys. Therefore, Kahneman et al (2004) developed the "Day Reconstruction Method" (DRM) that combines elements of time diaries and experience sampling. Respondents are asked to reconstruct the previous day by dividing it into various episodes and to indicate the time dedicated to that episode. In a second step, respondents are asked to report the intensity of feelings along nine affect dimensions on a scale ranging from 0 (not at all) to 6 (very much). The assessed net affect of an experience is defined as the average of the 3 positive affect dimensions (happy, warm, enjoying myself) less the average of the 6 negative affect dimensions (frustrated, depressed, hassled, angry, worried, criticized) (Kahneman and Krueger 2006). These dimensions are nevertheless not fixed and the list can vary depending on the research goals.

The measure of happiness via affect is not without its disputes. Kahneman and colleagues, for instance, argue that remembering effects disturb the correct assessment of happiness. Therefore, their approach inquires into the lived experiences of people in situ. They found, for instance, that the five most positive activities for Texas housewives are (in descending order) sex, socializing, relaxing, praying or meditating, and eating, rather than taking care of children (Wallis et al 2005). Seligman (2002) and others argue against this position because they find memories and stories telling more about authentic happiness than the actual experiences. Seligman concludes that engagement and meaning are more influential to happiness than the pursuit of pleasure.

Measuring Happiness via Physiological Responses

Since neurobiologists have found reliable correlations between self-reported happiness and the activation of particular brain regions, happiness is considered to some extent measurable objectively. Methods for deriving results are electrophysiological (EEG, EKG) and imaging (e.g. fMRI, PET) response techniques. Subjects respond to various stimuli, such as haptic experiences or social stimuli (e.g. family pictures or a movie), with changes in their skin conductivity, heart rate, or activation of brain areas. These findings largely abstract from cultural influences on happiness evaluations and from individual interpretation of emotions. However, researchers must define the levels of activation that translate reliably into self-reported happiness. Hence, as they entail the opposite strength and weaknesses of the self-report techniques, these measures are useful as complementary methods. Realistically, however, most researchers will be unable to cover the financial expenses of an fMRI study with a representative sample of consumers.

ROADS AND BARRIERS FOR MEASURING BRAND-RELATED HAPPINESS

Consumption inspires human senses as much as it evokes their thoughts (Holbrook and Hirschman 1982). With their refined qualities, brands are likely to do so in specific ways at the above three experiential levels. Consumer researchers have inquired at various occasions into the short and long term hedonic responses of consumers to brand or product stimuli (cf. Chaudhuri and Holbrook 2001; Ruth 2001; Sundie et al 2006). Some studies have also

considered how the evaluation of these affects or responses may be mediated by the cognitive appraisal of emotions (Edell and Burke 1987), personality (Matzler, Bidmon and Grabner-Kräuter 2006), and experience and background knowledge (Ruth 2001; Washburn, Till and Priluck 2004). Most of these studies, however, focus too narrowly on selected emotions (e.g. Di Monaco et al 2004) or character traits (e.g. Matzler, Bidmon and Grabner-Kräuter 2006) and ignore well-being outcomes. They also use the brand notion rarely distinct from the products or companies they represent, so that the particular effect of brand clues and systems remains unappreciated. In their attentive study of the influence of brand trust and affect on market performance, Chaudhuri and Holbrook (2001, p. 87) come closest to an explicit study of brand-related happiness. They measure correlations of brand affect and loyalty by asking three direct questions: "I feel good when I use this brand", "This brand makes me happy", and "This brand gives me pleasure." While these authors provide insightful information, we find such unconcealed, intrusive questions not only likely to provoke biased answers, but also unsuitable for capturing consumer experiences with brands comprehensively (see Kahneman and Krueger above). Hence, we next evaluate potential methods for understanding the role of brands for happiness based on the above distinct levels of brand experience and the most reliable measures. Figure 2 provides an illustrative overview of the various options and limitations that we discuss next.

Brand Clues and Happiness

A brand clue was defined as a visual, audible, haptic, olfactory, or gustational experience that can be evaluated via physiological response tests and affect measures. The experiencing of brand clues, such as driving a Porsche, will have little (if any) direct influence on cognitive appraisals of well-being, but probably a mediated one. Brand clues can be evaluated by participants that have no previous experience with, or knowledge of the social meaning of the branded good or service. Hence, discrimination of hedonic or physiological responses can be attributed to experiences with goods of different sensual qualities. Researchers may consider various sorts of high and low end branded products for comparison.

From the above methodical and conceptual findings we derive three suitable ways for measuring potential brand clue effects on happiness. First, we suggest conducting laboratory or field experiments at which consumers are confronted with high and low quality, status, price, etc. brand clues. Subjects' physiological responses can be measured via electrophysiological (EEG, EKG) and imaging (e.g. fMRI, PET) techniques and related to subjective well-being measures.

Second, the day reconstruction method appears useful for evaluating emotional responses to brand clues over a period of several days, weeks, or even months. These brand-specific in situ self-evaluations can be flanked with external observations of these consumers' emotional responses to brand clues over this period of time. For such external data, the researcher or the friends and family observe and note facial expressions, posture, voice, and other physical behaviors.

Websites and mobile computer applications allow for more timely evaluations of brand-related affects than previously. The "hedonimeter.net" art project of Christine Wong Yap foreshadows such an empirical approach where respondents record and comment their emotions throughout their day (see e.g. <http://www.hedonimeter.net/results/index.php?op=view&id=2> [03/18/2008]). Results can be averaged and deviations can be calculated to reveal the respondent's amplitude and frequency of positive and negative brand-related feelings. An ascription of "happy" or "unhappy" requires the setting of threshold values.

FIGURE 2
A research roadmap for brand-related happiness research

Happiness Measure Brand Experience Level	Physiological Responses	Emotional Responses / Affects	Subjective Well-being Evaluations
Brand Clues Sensory consumption experiences	Electrophysiological (EEG, EKG) and imaging (e.g. fMRI, PET) comparative experiments with brand clues	Brand-specific in situ self-evaluations (via DRM, ESM) and external evaluations of emotional responses to brand clues	Correlates of self and external SWB evaluations with physiological and emotional responses; potential new measure to correlate brand clue and system influences with satisfaction.
Brand Systems Ideological and social consumption experiences	Electrophysiological (EEG, EKG) and imaging (e.g. fMRI, PET) comparative experiments with social brand perceptions	Brand-specific in situ self-evaluations (via DRM, ESM) and external evaluations of emotional responses to social brand perception	
System of Brands Societal systemic brand experiences	-	-	

Third, for understanding influences of brand clues on satisfaction, we suggest (if applicable) calculating correlates of self and external measures of well-being with the physiological and emotional responses noted above. In addition, we suggest to develop a new scale that allows for measuring indirect brand clue influences on happiness, such as the number of high and low end brands owned, the amount of pleasure derived from consuming the brand in public, the number and type of responses to brand consumption, or the enjoyment with acquiring new products. Such a scale development process would require a qualitative study to evoke relevant brand clue effects. It seems though unlikely that a single temporally limited affect may influence significantly and permanently a consumer’s overall subjective well-being. Causality between a favorable appreciation of a brand clue and a high level of subjective well-being may also be difficult to define.

Brand Systems and Happiness

Brand systems capture the social meanings of a brand that evolve through communication about brand clues (Giesler 2003, Luedicke 2005). Understanding the meaning of these communications within a particular culture requires cognitive processing of brand-related messages, such as corporate advertisements, the brand tales of friends, or the symbolic references that brand clues (e.g. shape, material, or style) make in a popular culture. Ownership of a branded good that is perceived as signaling high status-such as a Rolex watch-might influence owners’ self-evaluations of their well-being because wearing a brand clue with high status recognition-rather than a socially less relevant product-might be perceived as an indicator for success and social achievement. In consumer cultural research, the symbolic value of brands has often been studied but seldom refined for a subsequent study of happiness. Among others, Fournier (1998) and Ahuvia (2005), for instance, report on consumers experiencing brand-related emotions from love to hate and Pichler and Hemetsberger (2007) argue that consumers develop extreme devotional relationships with brands. However, these authors remain ambiguous on specific happiness influences. Further examples of emotional responses to brand systems resides in the consumer resistance literature (e.g. Kozinets and Handelman 2004). This body of literature offers accounts of

strong responses to brands and organizations that, again, unfold their cultural and marketing relevance both on the level of affect and of cognitive evaluation.

Two ways of measuring brand systems’ influences on happiness appear viable on the above methodical and theoretical grounds. As a first approach, we suggest inquiring into the affects that brand-related communications provoke (cf. Ruth 2001 for partial findings). This exercise largely overlaps with evaluating the role of brand clues for happiness. However, while using the same empirical approaches-e.g. ESM or DRM-the researcher focuses on in situ reports of social relationships that a brand inspires and on reports of symbolic use and consumer responses. The measure can be flanked by subjective well-being evaluations for consistency tests.

Alternatively or additionally, researchers may seek to reveal potential correlations between a person’s general brand appreciation, brand ownership, and subjective well-being by means of multi-item scales. This approach operates on the level of a specific brand system (probably around a high profile brand) symbolizing the achievement of life goals. For instance, the possession of a Porsche may serve as mediator for the life goal “successful career.” To understand this relationship, the researcher measures in a first set of items the respondents’ general sensitivity towards brand meanings that is expressed, for instance, in brand knowledge, brand experience levels, brand name recall for product categories and the across-respondents overlap of brand associations. These questions need to be developed and tested carefully and should be less intrusive and obvious than existing ones. The second set of questions captures the effective use and meanings of brands that matter to respondents in particular social ways. The scale would allow for self-evaluations of brands that evoke high to low social responses and for indicating the type of responses that these brands evoke, such as surprise, rejection, or respectful recognition from others. Further it is of interest, what kind of relationships the respondents form with those meaningful brands, including positive and negative, short-lived and traditional relationships (see Fournier 1998). These data would provide an idea of the respondents’ usage frequency and direction of brand meanings and allow for revealing potential correlations among the various appreciations of brand systems and happiness.

We hypothesize that the influence of brands systems on subjective well-being is existent but limited whereas the physiological and attitude measures may evoke more vivid responses. However, most likely, it will be difficult to separate the brand clue from the brand system level responses.

The System of Brands and Happiness

On the system of brands level, we expect brands to influence individuals in their entirety as a social mechanism that not only facilitates purchase choices and (partially) quality evaluations, but also provides a cultural structure for symbolic uses of goods and services. Consumer culture theorists have used notions such as the "world of consumer products" (Fournier 1998) and "the web of brands" (Klein 1999) for describing brands on this systemic level. The major critique against brands also operates on this level of experience. The guiding question on this ontological level is, if the overall existence and influence of brands on consumers' lives has an impact on happiness evaluations, and if so, in which direction(s)? A broad range of answers is possible. Respondents might feel that the symbolic communication that brands reinforce changes their social life to the worse (argued e.g. by Klein 1999), because they have to actively consider what their products are telling others about themselves to avoid trouble. Yet, they might also and even simultaneously be positive towards the system of brands as it allows them to facilitate other aspects of social life, including even symbolic rebellion (Holt 2002). As an example, not having an Apple ipod has almost become a social stigma in some European schools. Parents that pay for their children not to be plagued at school experience this system in a particularly direct way.

Similar abstract constructs have been tested elsewhere for their influence on happiness. Frey, Leuchinger and Stutzer (2004) have, for instance, measured the influence of terrorism on overall happiness using the number of attacks and the number of people killed to define the periods with more or less terrorist activity. Later, they compared these data to longitudinal national happiness surveys. We might consider data such as national advertising expenses, density of billboards in downtown, or the number of brands in a country as comparable indicators, but they abstract from actual perceptions. We suggest conducting an explorative study for developing an appropriate measure of individual brand perceptions. Such a measure of the respondents' appreciation of the system of brand must allow for multi-faceted responses. Respondents must be able to appreciate and disapprove of aspects of the system at the same time, rather than rating the system in its entire social effect. Again, these responses would later be correlated with the same respondents' ranking on a subjective well-being scale. Such correlations are likely to occur for some groups of consumers (e.g. less affluent parents) and less for others (e.g. young urban professionals), depending on life circumstances, social comparison groups and particularly on income levels.

Combining Measures

Depending on scale length and complexity, it appears useful to combine the evaluations of brand clues, brand systems, and the system of brands for testing the measures for further correlations. It seems logical to combine the system of brands evaluation with the affect reports evaluated using the day reconstruction method.

CONCLUSIONS

This study offers an important step towards answering the question of whether brands can make us happy. We have argued that happiness (or frustration) may result from consumers' experiences with sensory brand clues, social brand systems and the overall system of brands in a particular society. We have shown that three

distinct paths can lead to a reliable evaluation of happiness: physiological responses, emotional responses (affect measures), and subjective well-being evaluations. On these conceptual and methodical grounds, we have developed a research framework; a guide to the most viable directions and approaches for further research into brand-related happiness. The limitations of this study coincide with its purpose; to invite fellow researchers to work on measures for hedonic responses to brand clues, on scales for the cognitive appreciation of brand systems, on evaluations of the system of brands, or on refining the directional guide with further options.

This ongoing research contributes to consumer behavior research, marketing theory, and public policy in three important ways. First, we seek to provide empirical evidence of consumers' multifaceted evaluations of brands and how they relate to each other in everyday consumption contexts. Second, we expect to learn more about the sources of happiness in brands for deriving marketing implications. And lastly, we hope to respond to social activists' critiques of the system of brands with reliable empirical data. This lack of empirical research has led to an abundance of populist critiques and affronts against corporations and brands, and cries out for independent scientific scrutiny.

Shopping for Civic Values: Exploring the Emergence of Civic Consumer Culture in Contemporary Western Society

Janine Dermody, University of Gloucestershire, UK
Stuart Hammer-Lloyd, University of Gloucestershire, UK
Richard Scullion, Bournemouth University, UK

ABSTRACT

In this paper we critique how consumerism is considered an antithesis of citizenship, how acting as a consumer and acting in a civic manner are often viewed as detached parts of our lives. We seek to do this by exploring the blurring of consumerism and citizenship, which is culminating in an emerging area of politicised consumption based on citizenly rights, obligations and social inclusion together with competition and autonomous choice. We illustrate this emergence with specific reference to 'green' citizen-consumers to demonstrate the changing face of civic society in the west, where shopping can act as a vector for civic values and hence facilitates the emergence of civic consumer culture in contemporary western society.

INTRODUCTION—A CRISIS IN CIVIC SOCIETY?

With consumerism dominating the ideology and behaviour of western society, the halcyon days of civic engagement, where individuals act as 'good citizens', are purported to be in decline. This concern exists because of the negative consequences associated with consumerism, in particular the charge of self-indulgence with little consideration for others. This has been compounded by the increasingly visible connections between consumerism and climate change, which is resulting in some profound implications for human, social and environmental capital. All western governments are undoubtedly concerned about the degradation of our society and planet, and have been for some time. In this paper, we are advocating that some of the underlying causes that threaten our planet can be linked to a breakdown in western civic society, and that, what might initially seem paradoxical, we believe combining civic and consumerist values may hold the key to reinvigorating the health of our planet and our society.

Concern about the breakdown in the traditions of civic society is echoed in academic work on social capital and active citizenship. For example David Putnam (2000), in *'Bowling Alone'*, portrays the unparalleled collapse, since the 1960s, of social capital in America. The research of Hoskins et al (2006) indicates a mixed pattern of active citizenship in Europe. While David Halpern (2004) concurs that the strength of social capital in some western societies is cause for disquiet, he is much more concerned with the transformation of social capital per se. Halpern argues that what is more important is recognition that traditional types of social capital are in decline globally and are being replaced with more issue-specific and less time-demanding forms, with the most explicit manifestation residing within a universal increase in individualistic social capital. We argue that this mirrors many of the influences of consumerism in individuals' life-worlds and underlines the challenges associated with consumerism and climate change.

The British government is so concerned by this 'shift' in society, they have implemented educational policy to ensure citizenship now features highly on the educational curriculum in British schools, and are currently considering citizenship ceremonies for British school children to convey what it means to be a citizen of Britain—a sense of shared belonging, higher social cohesion, and for children to understand their rights and responsibilities as British citizens (BBC News24 2008). This concern is also

reflected in wider educational networks, for example the CiCe thematic framework (see cice.londonmet.ac.uk).

Are we then facing a crisis in western society while we wait for an enlightened new generation to brandish the torch of citizenship as adults? Of course this depends on what is meant by citizenship and civicness. Professor Bernard Crick, who was asked to advise the British Government on introducing classes in citizenship into schools, makes a distinction between being a good citizen—obeying laws—and being an active citizen—getting involved in prescribed types of activity that are deemed of civic worth (for example voluntary work). However, this offers a somewhat narrow view of what it means to be a modern citizen living in the west, particularly if we accept that being civic and having a sense of community are perceived experiences, (Couldry et al 2007). Hence, it becomes necessary to look beyond the obvious places to better understand the state of 'civicness' in contemporary western society. At the same time it is also necessary to understand consumerism and its implications for civic society. In this paper we seek to do this by exploring the blurring of what has been viewed by traditionalists as two contrasting concepts, namely that of consumerism and citizenship, which is culminating in an emerging area of politicised consumption based on citizenly rights, obligations and social inclusion, together with competition and autonomous choice. We illustrate this emergence with specific reference to 'green' citizen-consumers to demonstrate the changing face of civic society in the west, where shopping can act as a vector for civic values. We begin our exploration by considering the underlying premises of civic culture, citizenship and consumerism.

THE UNDERLYING PREMISES OF CIVIC SOCIETY, CULTURE AND CITIZENSHIP

The attributes of a civic society and culture are considered essential for a healthy public sphere and thus for legitimate democracy to survive and flourish. Civic society is generally considered to be the terrain in our lives between those spaces occupied by the economy and the State. It is within this terrain that citizens reside. Taking its cue from Habermasian theories of the public sphere, civic society has to be situated in accessible spaces where the flow of information and ideas are largely unfettered so that a communicative interaction between citizens is encouraged. Thus, "*norms of equality and symmetry*" prevail (Dahlgren 2006, 277), allowing all an opportunity to participate. Discussion of a civic nature, about issues that affect society generally, is considered vital for democracy to survive. Without such activity the hollow institutions of democracy may remain but without moral authority (Dahlgren 2006). These somewhat abstract notions have to be rooted in the everyday, the personal and the subjective lives of individuals and it is from this assumption that the idea of civic culture becomes crucial.

Dahlgren (2000, 2003) argues that civic culture requires social agents to act as citizens because it is through and by such acts that road markers are set out shaping future patterns of civic thought and behaviour. Traditionally this civic space has been located between that occupied by state and private life spheres, where consumption would have been placed firmly within the private sphere. He

TABLE ONE
Dahlgren's Civic Culture model

Values	Must include positive disposition towards democracy as the best way of organising political life.
Identity	People must see themselves as a political entity, as a citizen among the many identities they hold.
Affinity	Minimal sense of commonality must exist based on recognition of mutual needs.
Knowledge	A degree of understanding about democracy and the literacy skills to participate.
Experience	There must be some recurring practices that concretise democracy from an abstract to an actual occasion/event for people.
Discussion	Forms of civic interaction and discussion must take place in accessible locations.

Source: synopsis of the ideas of Dahlgren (2003), *Reconfiguring Civic Culture in the New Media Milieu*.

outlines six variables making up civic culture-table one. At any given point the specific mix of these variables shapes the civic environment that might then be characterised and positioned on a continuum of empowering–disempowering for those living within such a culture.

Within this civic environment, citizens are afforded a trio of rights: personal freedom, participation in political processes and a sharing of the benefits from societal wealth (Marshall 1964). Marshall's notion of citizenship places it beyond individual self-determination despite being centred on entitlement, because the benefits of citizenship result largely through the collective development of a civil society (Turner 2001). Citizens are concerned with solving public problems (Boyte and Skelton 1998), through possessing a sense of belonging to a wider community (Abala-Bertrand 1996). Citizenship is thus about rights balanced with responsibilities, where agency is manifest through voice, where decision-making involves giving due consideration to justice, equality and the widest possible consequences, a space that ultimately affords superiority to broad societal wishes. Crick (2000) makes it clear that citizenship involves more than passive adherence to law *and* it also entails a willingness to take part in the public domain, which in itself, presupposes a belief in some sense of the 'common good'. Thus citizenship offers a notion of freedom that includes duty, which, in effect, imposes a certain direction and purpose on that freedom. In this way being a citizen involves the checking of some individual rights because the collective rights supersede them. Citizenship is then, to varying degrees, about equity, participation, delayed gratification and some form of representation.

The liberal model of citizenship-premised on individual rights (Isin and Turner 2002)-is well entrenched in many Western societies. Accordingly liberty is promoted through allowing individuals to pursue their own interests, and, because a certain form of rational choice is assumed, the actions of one such individual is thus considered unlikely to limit the liberty of others. This form of citizenship is the political equivalent of a *laissez-faire* market. Alternative theories of citizenship challenge the dominance of this liberal perspective, arguing that communitarianism affords a much greater role for community cohesion, (Etzioni 1993), where the emphasis is on our socio-cultural obligations to one another. This is the political equivalent of social economy models that call for vigorous State intervention. In his polemic, Dahlgren (2006, 269) argues that a republican model of citizenship acknowledges elements of both liberal and communitarian thinking, it is "*citizenship as a mode of social agency within the context of pluralistic interests*". This articulation of citizenship thus offers a vision of society that creates space for us to move between individual and collective

states of liberty. All three views of citizenship offer a view on the appropriate relationship between individual agency and community or social cohesion, between liberty and responsibility, between a freedom to and a freedom from. Parallels are evident in market spaces where the equivalent key relationship might be between consumer sovereignty and producer power. Nonetheless it is evident, from this brief account, how notions of the citizen and civic culture appear distant from a more consumerist-orientated culture.

THE CORE NOTIONS OF CONSUMERISM AND CONSUMERS

Consumerism is typically associated with hedonism, narcissism, nihilism, decadence, instant gratification and social control (Cohen 2003; Desmond 2003; Durning 1991; Ewen 1976; Firat and Dholakia 1998; O'Shaughnessy and O'Shaughnessy 2002; Thompson 1996; Thompson and Tambyah 1999). It is therefore not surprising that, as Kass and Kass (2000) observe, the more people grow to love their freedom and to view it as a distinct element of their lifestyle, the more they will view themselves as having no obligation but to self-indulge. O'Shaughnessy and O'Shaughnessy (2002) argue that it is this sovereignty and liberty of choice that is complicit in the negative reputation of consumerism. Consumerism is thus often perceived as a negative influence on the morals of society—encouraging 'false values', materialism, unrestrained choice and indulgence and the isolation of individuals from their traditional communities as they seek 'never-to-be fulfilled' promises from their consumption choices. This, in turn, feeds consumers anxiety and self-doubt, undermining their sense of subjective wellbeing, and so reducing their levels of happiness with their lives (Chaplin and John 2007; Borgmann 2000; Csikszentmihalyi 1990, 2000).

It is thus interesting to note that for an increasing number of people, the influence of consumption on their lives is growing, and with it, an increase in individualism. Consequently, around the world, mass consumer society has emerged as the major source of economic and social influence (Bauman 1998; Borgmann 2000; Desmond 2003; Schor 1998). As a result, a modernist perspective has emerged from this evolution (civilising) of society that emphasises the modern, self-disciplined, individual self (Elias 1994), where consumers, in accordance with the pursuit of scientific enlightenment and Cartesian control, are perceived as rational, self-maximising economic individuals in control of their emotions. This, at least initially, seems to strengthen a belief in the *distinction* between notions of civic and consumer culture.

However this modernist account of consumerism and its consequences for consumers fails to appreciate more contemporary

understanding of consumers and their expanded consumption choices and meanings they ascribed to them. That is, the varied traditions, dialogue and practices that constitute their ‘cultures of consumption’ (Arnould and Thompson 2005; Belk 1988; Bevir and Trentmann 2007; Holt 2002; McCracken 1986; Mick and Buhl 1992), as advocated by scholars exploring consumer culture theoretics. Within this more culturally-focused perspective, consumerism is regarded as a process of shared, social learning, laden with emotion, symbolic meaning and identity, and consumers less as culture bearers and more as culture-producers (Arnould and Thompson 2005; Belk 1988; Dermody and Scullion 2001; Maffesoli 1996; McCracken 1986, 1990; Mick and Buhl 1992). Consequently the marketplace, where the balance of power has, in some ways, shifted in favour of consumers, provides consumers with an assorted repertoire of mythic and symbolic resources enabling them to create their individual and collective identities—through their (expanded) consumption choices (Arnould and Thompson 2005; Baudrillard 1993; Belk 1988; Belk et al 2003; Elliott 1997, 1999; Holt 2002; Mick and Buhl 1992; Schau and Gilly 2003; Taylor and Saarinen 1994). What then emerges about contemporary consumers and their consumption is that they are interpretative agents who, in creating meaning from their consumption, play, individually and collectively, within a spectrum ranging from acceptance to (pseudo)rejection of the dominant identity and lifestyle images conveyed by advertising and mass media (Holt 2002; Kozinets 2002; Kozinets and Handelman 2004; Murray 2002; Thompson 2004). From this account, we see how consumerism has become a powerful influence on both individual and collective behaviour. Consequently can the empowering dimension of consumerism also be used to nurture additional civic threads within modern British society? We will now move our discussion on to consider the idea of the citizen-consumer.

EVALUATING THE IDEA OF THE CITIZEN-CONSUMER

Critics of consumerism typically perceive citizenship and consumerism to reside at opposite ends of the spectrum, a contrast between outward-looking, public interest versus private, inward-looking self-interest, where citizens are ‘worthy’ and consumers are ‘unworthy’. Certainly the traditional version of civic culture and citizenship has been seen in stark contrast with what being a consumer entails; with, as we have previously discussed, the two positions residing within different cultural values and norms (Lasch 1978). Sharply contrasting world visions have been developed; one based on involvement in society as citizens of a nation, the other with involvement in a corporate world as consumer units (Elliott 1982). Sennett (cited in Bull 2000) argues that our immersion in consumerism leads to apathy about others, for him, being a consumer is instead of being a citizen. A dichotomy is thus exposed between a fundamental principle of the market, namely segmentation, which places emphasis on difference and a first order principle of citizenship—the idea of a common good (Cohen 2003). Consumerism is rooted in self-interest, whilst citizenship takes its inspiration from a regard for others. Citizenship is rooted in trust of others, consumerism in self-reliance (Sennett 1998). The dominance of a consumer culture has thus been articulated as a withdrawing from citizenship, with this void being filled by a small, anti-political group of activists, devoid of claims for legitimacy beyond their own pet projects and pet hates (Bauman 2001). Lash’s (2002) notion of the ‘loss of the common’, related to common good, common experience and common troubles, has negative consequences for civic culture. He argues that this has resulted in an offloading of once public functions into private spaces (Lash 2003). Beck and Beck-Gernsheim (2002, 26) talk of how individualisation has

become culturally embedded, thus public space is now characterised by “*conflictual coexistence*”. Couldry (2006) maintain that our predominant orientation is away from anything considered public, many of us choose to place ‘the other’, the more distant, and the things we are less sure of in a public space. All of these are signs that we use ‘public’ to denote remoteness from our own responsibility and agency. Couldry’s study concludes that any vague sense of a ‘public connectedness’ that their respondents felt did not generate civic deliberation or action. Accordingly they talk of a disarticulation between awareness of public issues and the place such issues are afforded in individuals’ life-worlds. One discourse sees the rise of consumerism at the expense of citizenship contributing to a decline of the public over the private sphere (Marquand 2004). Consumer culture is thus distinctly different from the articulation of civic culture expressed by Dahlgren (2003) in table one. For example, with respect to values, there is more individuality and materialistic values, whilst for identity, choice becomes the arbiter of truth—table two.

Overall, then, for many, the impact of contemporary consumer society on traditional citizenship and civic culture has been regarded as negative because this distinct consumer culture has become so dominant.

Historically, however, these divergent positions are untrue (Cohen 2003). As Cohen observes, citizens and consumers have at times been in conflict and sometimes in harmony as the political and economic landscape changes. For example during 1890-1920, activist citizen consumers used their power in the marketplace, through boycotts and buycotts, to achieve progressive political reform in American society (Cohen 2003). The consumer boom then dominated the British and American political landscape, and in particular, according to Hilton (2001) and Bauman (2008), undermined the majestic collective ideals of citizenship by crushing the critical faculties of individuals as citizens in favour of individuals as shoppers. While this might have been true for rational, self-maximising, economic consumers, as our preceding discussion of contemporary consumers indicates, while consumers are embedded in capitalism, they are not passive, complacent nor non-evaluative in their consumption choices, which they weave into their complex, fluid identity projects—for their individual and collective purposes. Consequently they are “*not the unwitting dupe of legend, who responds rat like to environmental stimuli of Skinnerian caprice. Nor...transfixed, rabbit-like, in the headlights of multinational capital*” (Foxall et al 1998, 244). For some consumers, then, particularly those who are better educated, with high levels of political interest (Scammel 2003), and who have a particular personal values orientation, they are using their analytical talents and their economic power to achieve political reform in twenty-first century consumerist society. Widespread and often localised boycotts are illustrative of this. As a result what emerges is the distinction between materialistic and more citizenly-orientated types of consumers, as motivated by their personal values system rather than a broad distinction between citizens and consumers. Mapping this orientation to the values research of Schwartz (1992), materialistic consumers will reside within the domain of self-enhancement, based on the values of power, achievement and hedonism, while citizen-consumers reside within the domain of self-transcendence based on the values of benevolence and universalism. We see, for example, the growth in concern for the welfare of animals in the supermarkets and a growing interest being taken in the production processes of our favourite brands (Klein 2001). Therefore polarised classifications that see the concepts of citizenship and consumerism as only and always in opposition are under increased scrutiny (Bevir and Trentmann 2008; Chambers and

TABLE TWO
Adaptation of Dahlgren’s Civic Culture model-Consumer Dominant *over* Citizen

Values	Individuality dominates in our constant quest for self-expression, understanding and high self-esteem. Immediacy is privileged over transience. Personal values are promoted at the expense of others and those identified as civic i.e. equality, justice and reciprocity are superseded. (Bauman 1998, 2001; Giddens 1991, 1998).
Identity	As self-enterprising individuals our sense of agency is realised most readily through consumer choice where personal taste and preference becomes the arbiter of truth and where our high self-efficacy is encouraged. (Rose 1996; Campbell 2001).
Affinity	Weak relationships are formed with brands and retailers based on an extended form of exchange e.g. loyalty schemes. Rights are seen to be actualised through individual not common actions-through notions of consumer sovereignty-thus located in the marketplace. (Gabriel and Lang 1995).
Knowledge	Little sociological imagination is required to operate successfully in the consumer sphere where knowing your own desires is considered to be most important. The linguistic capability/dominant discourse of marketing is, if not alien to civic speak, not supportive of it. (Belk et al 2003; Couldry 2004)
Experience	Experiences as a consumer dominate establishing our sense of expertise and everyday routines and practices. These tend to be framed in a way that eschews collective or public considerations. Our memory bank is characterised as fragmented rather than collective and is dominated by our experiences as consumers. (Warde 2005, Scullion 2006).
Discussion	Efforts are made to avoid talking politics with shopping and its associated interests acting as a key deflector. Little direct connection is made between our daily consumer lives and political action. Acceptable forms of public discourse are limited and increasingly personalised and local. Marketing tends to offer a single non critical type of discourse/form of discussion (about best deals not questioning the very ethics of deals). Closed loop so anti-pluralist. (Couldry 2005; Eliasoph 1998).

Kymlickc 2002; Dahlgren 2006; Edwards 2004; Soper and Trentmann 2008), particularly with the acknowledgement that consumption is now a key political site (Miller 1997; Michellette et al 2004; Nava 1991; Schudson 2007; Stevenson 2002). Thus, an alternative view to this idea that consumer culture *has replaced* civic culture is one that suggests they coalesce and this has brought about a change in the character of citizenship. Consequently the boundaries between private market and political spheres have broken down. This blurring of public and private, of what it signifies to be a consumer and a citizen, means actions once considered part of civic life are increasingly part of what we do as contemporary consumers. For example, in Britain in the last few years we have witnessed a consumer revolt over ‘excessive’ bank charges, a campaign against the practices of ‘ticket touts’ making huge profit margins on resold concert tickets and collective pressure being exerted on business and government alike over fuel prices. Of course original motives for involvement may have been about self-interest, but all have also resulted in a greater sensitivity to fairness and reasonableness. This is reflected in our second reiteration of Dahlgren’s model of civic culture, where we illustrate how this synthesis reinvents interactions in a fusing of a civic and consumerist society—table three.

Accordingly we argue that this *changes* rather than simply *challenges* the nature of civic culture. Dahlgren (2003, 161) acknowledges that placing any notion of civic culture into a contemporary setting “*we find consumerism as an ideological vector in political discourse.*” And this is particularly apparent within more ethically-orientated consumption, for example increasing consumption of fair-trade brands, and among consumers who ‘force’ commercial organisations to adopt more responsible business practices, for example the pressures placed on the British food industry and retailers, by parents, to make children’s’ food more healthy.

Furthermore, while civic-consumers tend to take a lead on creating a ‘better society’, they are also more likely to revise their own already civic-consumption choices to strengthen their ‘civic cause’, for example cycling rather than using public transport or getting involved in car share schemes to help save fuel and the environment. It is also interesting to observe that, similar to the persona typically portrayed of citizens (Collins and Butler 2003), the citizen-consumer takes an enduring rather than episodic approach to their market engagements; for example willingly entering into relationships with ethical investment organisations who emphasise a long term and more holistic perspective (Zwick et al 2008). We have developed a clearer sense of links between the various life-spheres we occupy, “*the notion of public has been sequestered by ‘electorate’ consequently increasing the areas of life open to general scrutiny*” (Giddens 1991, 152). This has led to a heightened awareness and salience that our personal lives are wrapped up with global perils.

However, Bauman (2008) and Stevenson (2002) make important caveats to this merging of citizen and consumer. Bauman (2008) argues that consumer activism, including politicised consumption, is dangerous because it undermines the traditions of democracy; since it is the unelected select few acting for what *they* perceive as the good of others. While we acknowledge an undemocratic element within politicised consumption, this does not mean that it is inherently bad, particularly when considered within the context of climate change, discussed later in our paper. Furthermore, it must also be recognised that traditional avenues for democratic expression in western society are weakened by declining voter turnout and a low sense of efficacy, caused in part by public cynicism towards the tarnished reputation of politicians and parties (Dermody et al 2010), reinforcing doubt in the traditions of democracy to further causes that augment human, social and

TABLE THREE

Adaptation of Dahlgren's Civic Culture model—The Merging Citizen-Consumer

Values	Personal versions of humanist values are held where self-reliance and self-responsibility are fused with understanding the need for reciprocity and a desire for fairness. (Bauman 1998, Beck and Beck – Gurnsheim 2002).
Identity	This involves an increased reference to global and cosmopolitan identity with community and tribal alliances formed through shared consumer practices (Rose 1996, Warde 2005).
Affinity	Growth of single issue personalised political participation results in episodic collective action often through the marketplace. Through environmental concerns, there is a growing sense, in the west, of sharing responsibility for the fate of worlds future. (Stevenson 2002, Micheletti et al 2006, Zwick et al 2008).
Knowledge	A growing awareness emerges of the links between consumer actions and their impact on the broader world. There is a greater desire for transparency from both commercial and governmental organisations. (Klein 2001, Couldry 2004).
Experience	The ability to influence commercial and political organisations—often through marketplace actions— has increased. The mass media give widespread coverage of consumerist political campaigns. (Stevenson 2002, Scullion 2006).
Discussion	There is almost universal access to marketplace discussions that take on a political quality (for example the origins and fairness of food production). A choice agenda discourse emerges related to increased expectations of both private and public service delivery. (Collins and Butler 2003; Marquand 2004).

environmental capital. Stevenson (2002, 310) warns “*while consumption may raise ‘ethical questions’, it does so only by being connected to more formal citizenship criteria of rights, obligations and social exclusion.*” Thus, not all consumers will act in a civic way—the distinction between the personal values orientations of materialists vs. citizen-consumers discussed above; and in addition, the cognitive capability and sense of personal efficacy to believe that their behaviour can make a difference. As Castells (1997, 359) remarks, the “*sites of this power are people’s minds.*” Hence the notion of a citizen-consumer appears to be reflective of consumers who, as interpretative agents, are immersed within the capitalist cultural production system, but who can choose to become politicised through their consumption, which they use collectively and individually to interact with their lived world, and in so doing aim to enhance civic society. A vital outcome of this blurring of consumer and citizen, as illustrated in table 3, is a greater sense of transparency and reflexivity. Hence we increasingly see and experience the connections—the politics of being a consumer—and so they shape what it means to live in contemporary society. Accordingly, we now illustrate and explore this within the context of sustainable consumption, which offers a pertinent illustration of this blurring of consumer and citizen.

THE GREEN CITIZEN-CONSUMER

Ecological destruction, for example current predictions of climate change and finite resources, means that we are “*currently living in the shadow of our own annihilation*”. (Stevenson 2002, 312). The latest United Nations Intergovernmental Panel on Climate Change states that evidence of global warming is incontrovertible, with catastrophic consequences, (IPCC 2007). Set within this shadow, environmentally responsible-‘green’ citizen-consumers—will be pursuing issues surrounding rights, obligations and social exclusion—as part of their economic power of consumption choices. Typically this will involve boycotts and buycotts (Friedman 1999, 2006; Micheletti et al 2006; Shaw et al 2006); where consumers pursue sustainability issues pertinent to human, social

and environmental capital, for example goods that are fairly traded, organic, cruelty-free, resource-efficient, recyclable, and/or local. As Friedman (1999) observes, boycotts—as expressions of “*economic democracy*” (198) that fuel media interest—are a highly attractive tactic that enable ordinary people to fight for a more sustainable future. Indeed, the involvement of more civic-orientated consumers in the development of more sustainable consumption patterns has been advocated for some time, (see for example Rio, 1992). Accordingly, political consumerism is becoming a core part of civic life as consumption becomes increasingly “*suffused with citizenship characteristics*” (Scammell 2000, 351). Consequently it is reflective of the start of a shift in political power in the UK that allows politicised consumers, albeit still a minority with limited influence (Kennedy 2006), to take immediate action to preserve our planet; and as Follesdal (2006, 8) observes, “*political consumerism can...be a stopgap measure until global structures are in place with sufficient enforcement power.*” Clearly given the latest findings from the IPCC, political consumerism constitutes an important interim and ongoing response to help combat climate change.

Evidence has shown that the intensity of consumers’ commitment towards environmentally responsible -‘green’-consumption can vary (Dermoddy and Hanmer-Lloyd 1999 Kilbourne 1995). In turn this reflects the different roles that political consumerism can have per se. The work of Follesdal (2006) is pertinent here. He proposes five different notions of the role of political consumerism, which are not mutually exclusive. We have located these within the realms of sustainability and added indicators of the status (strength) of each role—table four.

As can be seen the more activist green political consumers adopt a role of ‘reforming business practices’—which includes reforming government policy, while the more passive role is one of ‘mutual respect’ where repugnance is expressed but no action is taken.

It is also important to reflect on these roles in relation to engendering a more green civic society. Hence we will now

TABLE FOUR
Roles of Green Civic-Consumers

Role	Summary	Status
1. Agency	Green civic-consumers use their own agency to distance themselves from ‘evil acts’, for example environmental pollution and corporate exploitation of child labour. Through boycotting these offending brands and companies they avoid complicity in evil behaviour that they believe is damaging to human, social and environmental capital. Thus they are attempting to break the causal chain between their own acts and immoral, non-sustainable outcomes.	Active
2. Expression of Self (Identity)	Green civic-consumers, through their ‘green’ consumption choices are actively expressing their post-materialist values. Their consumption choices fall within the realms of ethical and responsible, for example actively choosing organic fair-trade brands to strengthen human, social and environmental capital.	Active
3. Expression of Mutual Respect (Identity)	Behaviour is based on the belief that certain companies are violating fundamental normative constraints, e.g. a coffee company abusing the rights of coffee growers (human capital). These green civic-consumers, as individuals, will express repulsion at these violations by refusing to buy the offending brands, but they will not attempt to change the behaviour of others. Protecting economic capital will be important.	Moderately active
4. Instruments for Reforming Wrong-doers	Green civic-consumers will pressurise individuals to change their ‘wrong’ behaviour, e.g. driving SUVs in cities, non-recycling, by attempting to re-socialise them using, for example, the principles of punishment (shunning, rejection, etc). There is an orientation towards strengthening social capital– to reform the values of society for communal benefit.	Active
5. Instruments for Reforming Business Practices	Green civic-consumers– mainly through protests and boycotts– will drive/punish companies and governments to change their values and thus their behaviour/policies to secure better human rights and human security and so build human, social and environmental capital.	Very active

elaborate on the merging citizen-consumer we presented in table three, contrasting this with the original ideas of Dahlgren (2003) in table one. Potentially the most distinctive difference occurs within *values*, where Dahlgren maintains that a positive disposition towards democracy must exist as the best way of organising political life. Yet for the citizen-consumer, they possess a sense of self-reliance and self-responsibility, which go beyond the traditional vessels of democracy to include the ‘power’ of the marketplace. Accordingly these individuals will possess the self-belief that they can make a contribution to democracy through their values-orientation of benevolence and universalism that directs their behaviour. This combination will be very potent in achieving the behaviour and policy changes needed to engender a more sustainability-orientated, civic-consumer culture. All of the roles identified by Follesdal (2006) will be influential here, but mutual respect may be the weakest. Consequently a picture begins to emerge of individuals actively pursuing the cause of human, social and environmental capital through the actions they take on behalf of others within the marketplace as ‘agent’ and as ‘reformer’. In so doing, they express the fundamentals of their self-identity as green civic-consumers. Illustrations of these behaviours can be found in table four. Secondly, with respect to *identity*, people seeing themselves as a green citizen-consumer will regard themselves as politicised consumers with a global and cosmopolitan identity who, with reference to their community and tribal alliances, operate politically within the marketplace to further the cause of sustainability as a whole. With reference to Follesdal’s roles, we can envisage strong connections

with ‘self identity’–principally post-materialist values that engender the pursuit of ethical and responsible consumption–namely fairly-traded, organic, local, energy-efficient, etc. There is also likely to be a strong relationship with ‘agency’. Thirdly, with Dahlgren’s notion of *affinity*, where a growing sense of commonality is needed based on recognition of mutual needs, ‘mutual respect’ could be influential here and certainly the pursuit of social and environmental capital would be pertinent in working towards a civic culture that embraces sustainability. Fourthly, regarding *knowledge*, while individuals will need to understand democracy and possess the literacy skills to participate, equally important will be their cognisance of the market and how they can influence corporate, government and consumer behaviour to further the cause of sustainability by enhancing human, social, environmental and economic capital. ‘Agency’ and ‘reform’ will be important in achieving this. Dahlgren maintains in his fifth element of civic culture, namely *experience*, that there must be some recurring practices that concretise democracy from an abstract to an actual occasion and/or event for people. Consequently while elections will be important events, the positive outcomes of environmental and societal boycotts and protests will also concretise a broader sense of civicness through democracy-using the marketplace to further the cause of sustainability. ‘Agency’ and ‘business/government reform’ will be integral here. Finally, with respect to *discussion*, civic interaction and discussion must include integration of marketplace issues, both in terms of a critique of materialism as well as activism through political consumption that enables change to be achieved

and thus furthers the sustainability agenda. The diversity of communication resources this engenders must be accessible to all. 'Agency' and 'business/government reform' will be important in facilitating this. Accordingly some interesting relationships begin to emerge between the persona of the green citizen-consumer and the roles they can play in enhancing the health of civic society. Clearly, though, further research is needed to empirically explore these relationships.

Becoming a 'green' citizen-consumer, however, is not easy since sustainability is, in itself, a complex issue (Giddens 1994; Goodland 2002). The pursuit of sustainability requires us to evolve to a higher plane of consciousness, for our orientation to become one of self-transcendence (Schwartz 1992), as we become more civic in our orientation (Berglund and Matti 2006; Doherty and de Geus 1996), which enables us to make more responsible and equitable choices as we interact within our capitalist system. It requires us to envision the world differently to enable us to re-engage with it. In many ways, it reflects Dahlgren's (2003) vision of civic society embedded with rights, obligations and social inclusion, but coupled with consumer power within the market system. This, in turn, mirrors the words of Kofi Annan, UN Secretary-General, (2000) when he stated: "*We have to choose between a global market driven only by calculations of short-term profit, and one which has a human face....Between a selfish free-for-all in which we ignore the fate of the losers, and a future in which the strong and the successful accept their responsibilities, showing global vision and leadership. Let us choose to unite the powers of the markets with the authority of universal ideals.*"

CONCLUSION: THE EMERGENCE OF CIVIC CONSUMER CULTURE

In conclusion, our preceding discussion demonstrates that consumerism and citizenship can reside together, and in so doing, they can change each other. Hence contemporary citizenship is alive and active through politicised consumption—where shopping acts as a vector for nurturing civic values. Consequently this expression of citizenship operates through a 'cultures of consumption' paradigm—where individuals have a voice through their consumption choices, which they use to pursue social, human and environmental capital, which, in turn reflects a self-transcendence orientation, in accordance with the tenets of civic culture. Consumerism, then, can be empowering, and it has triggered a new expression of personal politics—through shopping—for increasingly powerful, compassionate, reflexive and self-consciously politicised consumer groups. Accordingly we are witnessing the emergence of a civic consumer culture, rooted in consumerism merged with citizenship, which has the potential to enhance the future health of our planet and civic society in the west.

Exploring How Perceived Store Price-Level and Customer Characteristics Influence Price-Related Emotions

Stephan Zielke, University of Göttingen, Germany

ABSTRACT

This paper demonstrates how the perceived price-level of a retail store and individual differences between customers impact on several price-related emotions as parts of a retailer's price image. The findings support the hypothesis that the perceived store price-level influences price-related emotions such as enjoyment, distress, anger, fear, interest, contempt, shame and guilt. Price consciousness and price-quality inferences moderate these relations and they also have direct effects on some of the emotions. The findings extend the limited knowledge regarding price-related emotions and illustrate the importance of customer characteristics in understanding emotional reactions to prices.

INTRODUCTION

Emotions receive attention in marketing research (Bagozzi, Gopinath, and Nyer 1999; Erevelles 1998). However, only a few studies mention the role of emotions in price perception and processing. They discuss smart shopper feelings (Schindler 1989) and price-related emotions theoretically (Raghubir 2006), analyze the role of emotions in explaining price fairness (Campbell 2007) and price acceptance (O'Neill and Lambert 2001), or treat emotions as a part of a retailer's price image (Zielke 2006). The limited number of studies about price and emotion is surprising as many people know from their own experience that cheap or expensive prices cause feelings of enjoyment, distress, anger, fear or interest. In addition, shopping in cheap stores may also trigger emotions like contempt, shame or guilt.

Knowledge of these effects is very important from a practical point of view as emotions may have a substantial behavioral relevance. Several studies prove that emotions mediate the relation between cognitions and response variables, such as attitudes, spending and customer migration (Chebat and Michon 2003; Chebat and Slusarczyk 2005; Holbrook and Batra 1987), and that they improve the prediction of such variables (Agarwal and Malhotra 2005; Allen, Machleit, and Schultz Kleine 1992; Allen et al. 2005). In a retail context, price-related emotions should accordingly have an important impact on attitudinal and behavioral store loyalty. Therefore, retailers have to understand the emotional consequences of their pricing activities, and should be aware of individual differences in the process of emotion formation, which are an important basis for segmentation approaches.

This study contributes to the understanding of price-related emotions by analyzing their antecedents. Building on price-image research (Zielke 2006), the paper focuses on the impact of price-level perception (as a belief) on different price-related emotions that are part of the retailer's price image. Thus, this paper concentrates on associating or anticipatory emotions rather than emotions in concrete shopping situations. The emotions analyzed as dependent variables are enjoyment, distress, anger, fear, interest, contempt, shame and guilt. This selection is based on Izard's (1977) catalogue of emotions and prior research (O'Neill and Lambert 2001).

In addition, this paper analyzes individual differences in the relationship between price-level perception and the different emotions. Previous studies identified the customers' price consciousness and price-quality inferences as antecedents of price acceptance (Lichtenstein, Bloch, and Black 1988; O'Neill and Lambert 2001). Building on the appraisal theory (Bagozzi et al. 1999), these characteristics can influence the relevance of different goals, which

play a role in emotion formation. They should therefore have effects on price-related emotions and moderate the emotional impact of price-level perception.

In summary, the central research questions of this paper are the following:

- What is the impact of price-level perception on different price-related emotions like enjoyment, distress, anger, fear, interest, contempt, shame and guilt?
- What is the impact of price consciousness and price-quality inferences on price-related emotions?
- How do price consciousness and price-quality inferences moderate the emotional impact of price-level perception?

Answering these research questions extends the existing literature on price-image research and exploratory studies on the role of emotions in price perception and processing.

DEFINING PRICE-RELATED EMOTIONS

In the psychological literature, many definitions of emotions emphasize different aspects of this construct (Kleinginna and Kleinginna 1981). Building on cognitive theories of emotion, Bagozzi et al. (1999) define emotion as "a mental state of readiness that arises from cognitive appraisals of events or thoughts". They illustrate further that appraisal is "an evaluative judgment and interpretation thereof" and that "emotions arise in response to appraisals one makes for something of relevance". Thus, in the context of this paper, evaluative judgments (e.g. price-level perceptions) and the relevance of these judgments (that depends e.g. on the customers' price consciousness) can cause different price-related emotions. Hence, price-related emotions are defined as emotions that result from evaluating a firm's pricing activities.

LITERATURE REVIEW ON PRICE-RELATED EMOTIONS

Only a few studies in the literature mention the impact of price perception and processing on price-related emotions. Schindler (1989) argues that cheap prices result in ego-expressive feelings, which he describes as smart-shopper feelings. However, he does not analyze these feelings empirically. Raghubir (2006) also discusses several emotions related to pricing, spending and saving in a theoretical paper. Campbell (2007) found that general affective reactions to price situations have an impact on price fairness judgments. O'Neill and Lambert (2001) investigate the role of emotions on the relationship between price consciousness, price-quality inferences, product involvement, internal reference price and the latitude of price acceptance for a pair of sports shoes. In their study, they measure six of Izard's (1977) basic emotions. However, their model only includes enjoyment of prices and surprise, while the iterative process of model fitting excluded distress, anger, disgust and contempt. Emotions also play a role in price image research. Zielke (2006) argues that remembered emotions are an integral part of a retailers' price image. He empirically identified an emotional image dimension, which correlates strongly with price-level perception. However, the study does not analyze the relationship between price-level perception and specific emotions.

To sum up, the literature analysis indicates that the perceived store price-level is related to emotions and that price consciousness and price-quality inferences may have an impact on this relation.

However, no study in the literature analyzes these relations empirically.

CONCEPTUAL FRAMEWORK

The present paper builds on existing research, analyzing the impact of perceived store price-level, price consciousness and price-quality inferences on different price-related emotions. Perceived store price-level is defined as the perception of a store's prices without taking differences in product quality or services into account. In the literature, many studies interpret price-level perception as the price image of the store (e.g. Büyükkurt 1986; Desai and Talukdar 2003; Nyström 1970; Zeithaml 1984). Therefore, the term price-level image is used in the following. High scores for the price-level image mean that perceived prices are low, while low scores mean that perceived prices are high.

Price consciousness and price-quality inferences are conceptualized according to definitions by Lichtenstein and his colleagues. Price consciousness refers to "the degree to which the consumer focuses exclusively on paying low prices" and the price-quality schema is the "generalized belief across product categories that the level of the price cue is related positively to the quality level of the product" (Lichtenstein, Ridgway, and Netemeyer 1993).

Two approaches are available to conceptualize price-related emotions. The first develops catalogues of basic emotions, which are building blocks for other higher order emotions (Ortony and Turner 1990). Izard (1977) differentiates between ten fundamental emotions, namely interest, enjoyment, anger, disgust, contempt, distress, fear, shame, guilt and surprise. A lot of empirical studies in the marketing field build on these catalogues (e.g. Allen et al. 1992; Oliver 1993; Westbrook 1987; Westbrook and Oliver 1991). The second describes and measures emotional experiences according to the dimensions pleasure, arousal and dominance (Mehrabian and Russell 1974). This approach is mostly applied to the analysis of store atmosphere (Baker, Grewal, and Levy 1992; Donovan and Rossiter 1982; Donovan et al. 1994).

According to Machleit and Eroglu (2000), discrete emotions contain more information and are better predictors of shopping satisfaction than general emotional dimensions. Hence, Izard's catalogue of basic emotions is an appropriate basis to conceptualize price-related emotions. For the present paper, eight out of the ten basic emotions suggested by Izard were selected. Disgust is left out, because of the difficulty to relate this emotion to prices. Surprise is also excluded because the relationship between price-level perception and surprise is probably non-linear and thus requires special treatment in the analysis. Interest is included, although interest might be more of a cognitive state than an emotion (Richins, 1997) or a mode of action readiness (Frijda, Kuipers, and ter Schure 1989). To sum up, eight emotions, namely enjoyment, distress, anger, fear, interest, contempt, shame and guilt, are included in the following analysis.

HYPOTHESES

In the first stage, hypotheses regarding the impact of price-level image on the different price-related emotions were developed. The theoretical basis for the following hypotheses is the appraisal theory, according to which *goal relevance* and *goal congruence* play an important role in emotion formation (Bagozzi et al. 1999; Lazarus 1991; Smith and Lazarus 1993). In the context of price-level perception, different goals are potentially affected:

- Firstly, low prices support the goal of saving money while expensive prices violate this goal.
- Secondly, buying in cheap stores has an impact on the goal of social status (Ashworth, Dark, and Schaller 2005).

- Thirdly, low prices can affect the goal of social responsibility because buying budget-priced groceries may have negative consequences for small local shops, farmers and the environment (Lavorata and Pontier 2005).

Thus, low prices are congruent to the goal of saving money, but at the same time incongruent to other goals.

Furthermore, the specific goals can produce different emotions (Lazarus 1991). The congruence or incongruence to the saving goal should be related to enjoyment, distress, anger, fear and interest. According to appraisal theorists (e.g. Roseman, Spindel, and Jose 1990), these emotions occur in situations, for which the retailer (his pricing policy) or other circumstances (e.g. cost structures) are responsible. Assuming that congruence or incongruence to the saving goal are attributed to the retailer or circumstances, lower prices should lead to increased enjoyment and decreased distress, anger and fear. In addition, lower prices should also decrease interest. Interest should be stronger in expensive stores, where the incongruence to the saving goal makes customers more attentive, focused and alert regarding prices.

Incongruence to the goals of social status and social responsibility might be perceived as more self-induced, as customers can sacrifice these goals in favor of making a good deal. Emotions resulting from the incongruence of self-induced goals are shame and guilt (Roseman et al. 1990). Thus, low prices might lead to the incongruence of social goals, resulting in higher levels of shame and guilt. The same effect should hold for contempt because contempt can be interpreted as a projection of shame. The individual's own blameworthy behavior that induces shame should induce contempt if it is performed by others (Ortony, Clore, and Collins 1988).

In summary, low prices lead to the congruence of the saving goal and thus have a positive impact on enjoyment but a negative one on distress, anger, fear and interest. However, they also lead to the incongruence of social goals, resulting in stronger feelings of contempt, shame and guilt.

- H1:* The lower a customer perceives a retailer's price-level, the stronger the price-related enjoyment, contempt, shame and guilt and the weaker price-related distress, anger, fear and interest is.

The next hypotheses refer to the impact of price consciousness. By definition, price consciousness has a positive impact on the relevance of saving money. An increased relevance of the saving goal has two effects: firstly, respondents might experience enjoyment, distress, anger, fear and interest on a higher level, irrespective of the prices in a store. Secondly, price-conscious customers will react more emotionally to differences in price levels.

- H2:* The stronger the price consciousness, the bigger the enjoyment, distress, anger, fear and interest.

- H3:* For high price-conscious customers, the impact of price-level perception on enjoyment, distress, anger, fear and interest is stronger (compared to customers who are less price-conscious).

Similarly, price-quality inferences also affect the relevance of the saving goal. However, the effect is in the opposite direction. Customers with strong price-quality inferences might evaluate the saving goal as less relevant because it conflicts with quality goals. Consequently, the levels of enjoyment, distress, anger, fear and interest should be smaller, and customers with strong price-quality inferences should react less emotionally to changes or differences

TABLE 1
Item-scale (extract)

Price-level image	The prices are generally very low here.
Price consciousness	I mostly buy very cheap products when shopping for groceries.
Price-quality inferences	If I pay more for groceries, they are generally better quality.
Enjoyment	I am often delighted by the prices in this shop.
Distress	The prices in this shop make me sad.
Anger	I become angry when I think about the prices in this shop.
Fear	I am scared of paying too much in this shop.
Interest	I am very attentive when it comes to prices in this shop.
Contempt	I find that more strange people shop here than elsewhere.
Shame	I feel a bit embarrassed when I have to shop here.
Guilt	I have a bad conscience when I buy groceries here.

in price levels, regarding these emotions. However, for the level of fear and interest, cue utilization and uncertainty can mask this effect. This is explained in more detail in the discussion section.

Price-quality inferences also affect the goals of social status and social responsibility. If low prices signal poor quality, buying in cheap stores may become more embarrassing and thus the incongruence of low prices with the goal of social status increases. As a consequence, customers experience higher levels of contempt and shame, and they react more emotionally to differences in price levels. In addition, price-quality inferences should have an impact on guilt, especially if credence qualities like the environmental compatibility of the production process or animal welfare are affected. Thus, the level of guilt increases and customers react more emotionally with regard to this emotion.

H4: The stronger the price-quality inferences, the smaller the enjoyment, distress, anger, fear and interest and the stronger are contempt, shame and guilt.

H5: For customers with strong price-quality inferences, the impact of price-level perception on enjoyment, distress, anger, fear and interest is weaker while the impact on contempt, shame and guilt is stronger (compared to customers with weak price quality inferences).

MEASURES

Testing the hypotheses empirically requires measures for the different constructs. The price-level image was measured with five items, price consciousness and price-quality inferences with four. The item scales for these constructs were used by the author in various earlier studies (e.g. Zielke 2007). Three to four items measured each price-related emotion. Most items were generated based on the Differential Emotions Scale from Izard (1977). However, the original items were adapted to relate the emotions to prices. Table 1 presents an extract of the item scale (the complete scale is available from the author upon request). Following the recommendation of Bagozzi et al. (1999), unipolar seven-point scales were used. The scales ranged from totally disagree (1) to totally agree (7).

RESEARCH DESIGN AND SAMPLE

The different measures were embedded into a questionnaire. The questionnaire included questions on the respondents' buying behavior, a scale measuring price perception and price-related emotions, scales for price consciousness, price-quality inferences and questions regarding the socio-demographic and socio-economic status of the respondents.

Each respondent rated the price-level image and price-related emotions for two stores, which are different in their price positioning. They selected the two stores from a list of several grocery retailers, including discounters, supermarkets, hypermarkets and small grocery businesses. No particular criteria were given for store selection, except that the stores differ in their price positioning. This procedure should guarantee a sufficient amount of variance in the data. Furthermore, the procedure has the advantage that respondents rate the stores relatively to each other, which should be closer to real world shopping situations.

University students collected the data. They were advised to distribute the questionnaires to respondents of different ages, gender, household size and income. The generated sample comprises 291 respondents or 582 cases (because each respondent evaluated two stores). The mean age of the respondents is 37 years, 64% are female and 74% live in a household with two or more persons. The median income is between 1,500-2,000 Euros. In 39.9% of all cases the respondents rated their preferred store, and in 39.5% they rated stores where their grocery expenditures do not exceed 25 percent. Hence, the results are not biased towards preferred stores.

RESULTS

For all constructs, the alpha coefficients are similar to those reported by Izard (1977), and they exceed the value of .70. The discriminant validity is also sufficient according to Fornell and Larcker's (1981) criterion. One exception is fear, which correlates strongly with the price-level image. Therefore, the results for fear should be interpreted with some caution.

The hypotheses are tested with covariance structure analyses, using the MLR estimator in Mplus (Muthén and Muthén 2007). The

TABLE 2
The emotional impact of price-level image, price consciousness and price-quality inferences

Independent Variables	Dependent variables							
	Enjoyment	Distress	Anger	Fear	Interest	Contempt	Shame	Guilt

* significant effect for $p < .05$

results for H1, H2 and H4 are presented in table 2. All fit-indexes are acceptable, but not outstanding. R-square values are large for fear, but small for contempt, shame and guilt.

H1 stated that the lower a customer perceives a retailer's price-level (indicated by high scores for the price-level image), the stronger the price-related enjoyment, contempt, shame and guilt and the weaker the price-related distress, anger, fear and interest is. This hypothesis is supported by significant positive coefficients for enjoyment (.67), contempt (.10) and shame (.13) and negative coefficients for distress (-.46), anger (-.51), fear (-.86) and interest (-.52). Only the coefficient for guilt is contrary to H1 negative but not significant.

H2 assumed that price consciousness influences the levels of emotions, which are related to the saving goal. Supporting H2, price consciousness significantly increases the level of distress (.26), anger (.25), fear (.22) and interest (.54). The effect on enjoyment is also positive but small and not significant. In addition, price consciousness has a positive impact on the level of guilt (.17). This effect was not hypothesized.

According to H4, price-quality inferences should decrease the level of enjoyment, distress, anger, fear and interest, while they increase the levels of contempt, shame and guilt. The hypothesis is only supported for emotions that are related to social goals. Price-quality inferences have a positive impact on contempt (.21), shame (.35) and guilt (.36). The results do not support the hypothesis for emotions that are related to the saving goal. The coefficients for enjoyment, distress and anger are not significant. The effects for fear (.11) and interest (.25) are significant but contrary to the hypothesis positive.

H3 and H5 assumed that price consciousness and price-quality inferences have an impact on how emotionally customers react to changes or differences in the perceived store price-level. According to H3, the impact of the price-level image on enjoyment, distress, anger, fear and interest should be stronger for high price-conscious customers. Using a scale split, the respondents were separated in two groups with high and low price consciousness. Differences

between both groups were tested with multiple group covariance structure analyses in Mplus. Table 3 presents the results.

Supporting H3, high price-conscious customers react more emotionally to differences in the perceived store price-level for enjoyment, distress and anger. For fear and interest, the coefficient is also larger in the high price-conscious group. However, the multiple group model does not differ significantly from a restricted model, where the effects are identical in both groups. In addition to the hypothesized effects, more differences between both groups were found. The price-level image influences shame only for low price-conscious customers (.25). The results for guilt are most interesting. If customers are not price-conscious, lower prices increase guilt (.18), but for high price-conscious customers, lower prices reduce guilt significantly (-.32).

H5 was also analyzed using a multiple group covariance structure analysis. Table 4 presents the results. According to H5, for customers with high price-quality inferences, the impact of the price-level image on enjoyment, distress, anger, fear and interest is weaker while the impact on contempt, shame and guilt is stronger (compared to customers with weak price-quality inferences). The results support H5 for enjoyment, distress, interest and shame. For anger and contempt, the size of the effects is as hypothesized, however the effects or differences are not significant. Contrary to H5, the coefficients for fear are identical. Again, the effect for guilt is most interesting. If price quality-inferences are strong, lower prices increase guilt (.26). However, if these inferences are weak, lower prices have negative impact on guilt (-.34).

DISCUSSION

After presenting the results, some unexpected findings should be discussed in more detail. Firstly, without considering moderating effects, the price-level image has no impact on guilt. Interestingly, whether low prices increase or reduce guilt depends on customer characteristics. If the price consciousness is small or the price-quality inferences are large, low prices increase guilt. Otherwise, low prices reduce this emotion. However, there is an explana-

TABLE 3

* significant effect for $p < .05$; # effects between both groups differ significantly for $p < .05$ (chi-square difference test according to Satorra and Bentler (2001))

tion for these effects. A violation of the social responsibility goal is not the only thing that might result in guilt; price-conscious customers and those with small price-quality inferences might feel guilty if they buy in expensive stores, resulting in a negative relation between low prices and guilt.

Secondly, price-quality inferences do not have a direct effect on enjoyment, distress and anger. Contrary to the hypotheses, the impact on fear and interest is positive and significant. As indicated in the hypotheses section, it is possible to explain the results for interest and fear. If price-quality inferences are strong, customers might use prices as cues for product quality. Hence, they are more interested in prices. The impact on fear might be positive, because price-quality inferences can cause uncertainty in the price evaluation process, resulting in stronger fear.

Finally, price-consciousness influences the impact of low prices on shame. This impact only exists for low price-conscious respondents. An explanation for this finding might lie in social desirability and consistence effects. High price-conscious customers who usually buy in cheap stores might not admit to or suppress feelings of contempt and shame.

IMPLICATIONS, LIMITATIONS, AND FUTURE RESEARCH

The results have important implications because they widen the understanding of the antecedents of price-related emotions. The perceived store price-level is an important predictor of several emotions. Price-consciousness and price-quality inferences moderate this impact and they have direct effects on some of the emotions. The findings extend the prior research on retail price images (Zielke 2006), individual differences in price perception and processing (Lichtenstein et al. 1988) and exploratory studies on price-related emotions (O'Neill and Lambert 2001).

Besides these theoretical implications, the results are also important from a management perspective as they underline the fact that emotional reactions to prices depend on customer segments with different levels of price-consciousness and price-quality inferences. Therefore, retailers should consider these variables in their segmentation approaches. The results also show that retailers can influence price-related emotions without changing their price levels, for example by influencing price-consciousness or price-quality inferences.

The study also has certain limitations. Firstly, the measurement of emotions is based on Izard's Differential Emotions Scale. Richins (1997) argues that this scale does not capture the full range of consumption-related emotions, and this argument might also hold for price-related emotions. Secondly, the independent variables explain the emotions to a limited extent. Some R-square values are small, especially for contempt, shame and guilt. Furthermore, the fit-indexes of the models are improvable. Thirdly, in the hypotheses section, most arguments are based on goal relevance and goal congruence. However, these constructs were not measured explicitly.

Hence, future studies should analyze additional emotions, for example surprise or pride. They should also introduce more antecedents of price-related emotions, for example value for money, and they should measure goal relevance and goal congruence explicitly. It might be also interesting to investigate the moderating effects of other customer characteristics, for example prestige consciousness or ethics orientation. Future studies might also consider alternative methods, for example experimental approaches. Finally, future research should analyze the consequences of the different price-related emotions. Consequently, this paper is hopefully a starting point for subsequent studies on price-related emotions.

ABSTRACT

Previous research on price changes has focused on the analysis of price increases on the basis of rational processes. This paper focuses on the examination of the moderating role of emotions on the relationship between the magnitude of price increases and perceived price fairness. In addition, we analyze the effect of perceived price fairness and willingness to pay in consideration of the moderating influence of emotions. The empirical results demonstrate that emotions have the potential to compensate for the negative impact of price increases on perceived price fairness and the willingness to pay.

INTRODUCTION

A great many companies today are acting on markets that are suffering from saturation of consumption. Overcapacities lead to price wars. Although most managers are aware of the negative influence of price decreases on financial performance, such price decreases are common practice (see Diller 2008). According to Marn and Rosielle, "Improvements in price typically have three to four times the effect on profitability as proportionate increases in volume" (Marn and Rosielle 1992, 82). Further empirical evidence is provided by Simon and Dolan (1996). Their empirical study demonstrates that a price increase of 20% leads to a quintuple gain in company profit in the chemical industry. To set effective prices, marketers need to predict how consumers are likely to respond to price changes (Campbell 1999).

The acceptance of price increases has been identified as one critical factor of profit gains. Therefore, the knowledge about customers reaction to price increases is indispensable in order to realize effective prices. However, knowledge about customers' reaction to price increases is rarely addressed in marketing literature (Homburg, Hoyer and Koschate 2005). Critical determinants of the evaluation process are presumably the quality (Monroe 1973) and the perceived fairness (Hermann, Wricke and Huber 2000) of an offer. Xia, Monroe, and Cox (2004) state that the consumer will be more sensitive to the price of a product or service if the price leaves a corridor in which the price is perceived as fair and appropriate.

Most articles in behavioral pricing literature focus on cognitive aspects of unfairness perceptions (Homburg and Koschate 2005). While marketing research confirms the role of emotions (Westbrook and Oliver 1991; Bagozzi, Gopinath and Nyer 1999) in information processing and behavior, the influence of emotion¹ on price fairness judgments has been neglected so far (Cohen and Areni 1991). O'Neill and Lambert (2001) and Babin, Hardesty and Suter (2003) suggest that there is likely to be a relationship between price and emotion. We propose that emotion is an important element that accompanies the cognition of perceived price fairness.

¹There are divergent views about the emotion construct and its terminology. For purposes of this study, we focus on emotion as a state of affect. The term "affect" is typically defined as a valenced feeling state. Emotion is one example of this feeling state. While mood is lower in intensity, emotion is higher in intensity and is object-specific (Cohen and Areni 1991).

The neglected integration of emotional factors into the information processing is surprising. Churchill and Surprenant (1982) maintain that in some situations cognitive aspects as moderator variables are of less importance than are emotional aspects. Empirical support is given by Westbrook and Oliver (1987). Their research examined the hypothesis that emotional components may even dominate cognitive components. In this context, an academic discussion of the emotional aspects of the customer within the behavioral pricing literature is valuable.

Therefore, this article enhances the understanding of situations in which consumers evaluate price increases as fair. Thus, in study 1 we assess price increases in the context of positive and negative emotions, and identify conditions in which a price increase may be considered as unfair. The phrasing of our hypotheses is based on equity theory (Adams 1965; Walster, Walster and Berscheid 1978).

In a second study we intend to confirm the positive relationship between perceived price fairness and the willingness to pay, as did an earlier study by Bolton, Warlop, and Alba (1999). However, our study considers interaction effects due to emotions as well.

The article is divided as follows: (1) Hypotheses are derived from the theoretical background of how price increases affect perceived price fairness, and for this we review literature on equity theory and dual entitlement principle. (2) We conduct two experiments to confirm the stated hypotheses. (3) The results of the ANOVA provide implications to realize "successful" price increases and combine price actions with corporate communications.

THEORETICAL BACKGROUND AND HYPOTHESES DEVELOPMENT

Relationship between the magnitude of price increases and perceived price fairness

Price fairness research is based on the idea that consumers evaluate prices as fair or not fair, rather than evaluating prices rationally. Fairness is achieved if there is a balance between the contributions individuals make and the outcomes (rewards) they receive. Relative to those of other persons (Adams 1965), individuals seek distributive equity. Over the last ten years, several authors have focused on price fairness issues (Campbell 1999; Bolton, Warlop and Alba 2003; Xia, Monroe and Cox 2004). Kahnemann, Knetsch and Thaler (1986a) explain that judgments on fairness neither refer to cost-plus considerations nor to ask-and-bid relations. Rather, the profit could be identified as a critical influencing factor of perceived price fairness. Consequently, price fairness is determined by economic and psychosocial components (Maxwell 1995; Campbell 1999).

In marketing literature the explanation of fairness judgments is usually based on equity theory (Huppertz, Arenson and Evans 1978; Dickson and Kalapurakal 1994; Maxwell 1995). According to equity theory, fairness results from the means of decisions and allocations (Adams 1965; Walster, Walster and Berscheid 1978). The basic question, answered by equity theory, addresses what individuals perceive as fair and how they react to unfair relations. Judgments are based on a precise concept of exchange proportion-

ality, the equity function (Adams 1965), which opposes outcomes to inputs of exchange partners. Walster, Berscheid and Walster (1973) extend the theory by explaining that inputs can be allocated by positive inputs (assets) and negative inputs (liabilities). While positive inputs enable the exchange partner to achieve positive outcome, negative input enables to achieve negative outcome (Walster, Berscheid and Walster 1973). If input-outcome-relations do not differ significantly, the individual perceives equity or fairness. The perception of inequity results from an imbalance of the equity function. Adams (1965) claims that outcomes and inputs are subjective perceived values. Therefore, individuals evaluate input and outcome differently.

In the context of reactions to price increases, two equations play a major role: (1) a comparison of input-outcome relations before and (2) a comparison of input-outcome relations after the price increase (Homburg, Hoyer and Koschate 2005).

The higher the increase in price (price as input variable), the stronger the imbalances of the equity equation will be. We assume that the equity equation is balanced before the increase in price. Consequently, the stronger the imbalance of the equations after the increase in price is, the stronger the decrease in perceived price fairness. Extreme price increases result in perceived inequity (Maxwell 1995). On the basis of this discussion we propose the following basic hypothesis:

H1: The higher the magnitude of price increase, the lower the perceived price fairness.

Moderating effects of emotions on the relationship between price increases and perceived price fairness

Marketing literature on price fairness has, to date, concentrated on the cognitive influencing factors (Xia, Monroe and Cox 2004). In their comprehensive study, Bolton, Warlop and Alba (2003) explore a variety of factors that contribute to consumer perception of price fairness.

The authors investigated the role of three reference points—past prices, competitor prices, and costs—on price fairness judgments (Bolton, Warlop and Alba 2003). Using two studies, Campbell (1999) confirms the influence of the inferred motive for a firm's price increase in perceptions of price fairness. The data analysis indicates a positive impact on price fairness (Campbell 1999). However, the role of emotions within the cognitive information processing has been neglected by the literature so far. Also, the study of Kalapurakal, Dickson and Urbany (1991), which identifies a positive relationship between the reputation of a company and the perceived price fairness, did not control for emotions. Considering Izard's (1981) basic emotions, O'Neill and Lambert (2001) explore the influence of emotions on several price perceptions constructs and define the expression "price affect." The authors analyze the relationships between price quality, internal reference prices, price consciousness, and willingness to pay, and integrate the emotions "surprise" and "happiness" in their model.

This neglect of attention to emotion is surprising since, for decades, literature on emotion has confirmed that individuals tend to adapt perceptions according to their needs, wishes, and goals (Izard 1981; Frijda 1988). Izard (1981) has revised the relationship between emotion and cognition. Several authors agree on this interaction, and even more importantly, the interaction's impact on consumers' perceptions (Forgas 2001; Adolphs and Damasio 2001; Harmon-Jones 2001; LeDoux 1998; Zajonc 1980).

Emotions are also associated with equity theory. As a powerful social-psychological theory, equity theory can shed light onto the subjective view of fairness. Equity theory claims that the

comparison processes among buyers lead to the idea that their rewards should be proportional to their investments (Homans 1961). Emotions may lead to the reevaluation of equity. Provided that there are constant outcomes, a price increase leads to cognitive dissonance (Festinger 1962). This is caused by the difference of the input-outcome relations before and after the price increase. Based on the argument of Zajonc (1980) and LeDoux (1998), which states that emotion and cognition are interrelated, it can be concluded that the cognitive inconsistency of inputs and outcomes has to interact with emotions. Emotions may influence the perceptions of the inputs and the outcomes, as well as the proportion of both inputs and outcomes to the other.

Understanding inputs and outcomes as subjective elements (Homburg, Hoyer and Koschate 2005), an acceptance of a price increase may be higher in the context of positive emotions. Emotions will influence perceived price fairness such that individuals confronted with positive emotions will adapt their inequity to a greater degree than individuals confronted with negative emotions. From an equity theory perspective, that means that a price increase leads to a raised input for the consumer, and to a reduced input-outcome relation. In this case positive emotions initiate a reinterpretation of the input- and outcome-variables, which in turn balance the input-outcome equation. In contrast to positive emotions, negative emotions cannot equalize the equity equation.

In summary, research based on the equity theory indicates that people make inferences about emotions, and that whether the emotion is positive or negative influences the perceptions of input-outcome relation before and after the price increase. We extend this research and suggest that the factor of emotion is likely to provide insights as to when a price increase is likely to be perceived as fair or unfair. The perception of the price increase will depend on the magnitude to which the consumer evaluates the new input-outcome relation in the context of emotion. Especially in buying decisions of high-involvement and branded products, Zeitlin and Westwood (1986) demonstrate that emotions, prices, and their individual perception play major roles.

Based on the consideration of emotions as influencing factor of the equity theory, we add to the literature by proposing that positive and negative emotions are another factor that influences perception of price fairness.

H2: Emotions moderate the relationship between the magnitude of a price increase and the perception of price fairness. Positive emotions increase the perception of price fairness more than negative do emotions.

Price fairness and willingness to pay

To quantify willingness to pay Thaler (1985) states that fairness is the "most important factor in determining p" (Thaler 1985, 205). Willingness to pay is defined as the maximum amount of money a customer is willing to pay for a product or a service (Winer 1985). Therefore, the construct provides a good measure of the value in monetary units (Goldman, Leland and Sibley 1984). To theoretically justify the nature of the relationship between price fairness and willingness to pay, we turn to Maxwell (2002), whose study determined that fairness of price practices influences attitude towards both a seller and willingness to pay. In general, it is feasible to maintain that customers who perceive a price increase as fair are more willing to accept a higher price (Maxwell 2002).

An unexpected price increase is likely to lead consumer considerations about why the firm raised the price. Consistent with Kahnemann, Knetsch and Thaler (1986b), price increases will be perceived as fair if the company's profit stays constant. To evaluate

an inferred motive of pricing acts, cost transparency has to be given. Consequently, increasing prices, which function as input variable can be compensated by an increase in outcome. A balanced equity equation means, in turn, perceived price fairness (Walster, Berscheid and Walster 1973). It is fair for a firm to raise prices when faced with increasing costs. Hence, we hypothesize

H3: The higher the perceived fairness of price practice, the higher the willingness to pay.

Moderating effects of emotions on the relationship between perceived price fairness and willingness to pay

Loomes and Sugden (1986) developed the disappointment theory, which integrates the expected utility model with emotions. The disappointment theory states that the perceived product value depends on the difference between the real value and the expected value. Loomes and Sugden (1986) refer to the specific emotion function $D(u(x)-u(\bar{x}))$, with $u(x)$ as the perceived value and $u(\bar{x})$ as the expected value, based on experience. Consistent with the expected value theory, we assume that consumers intend to maximize their utility. Because the intensity of emotions increases the higher the intercept, the authors conclude that the function is convex for positive values of $u(x)-u(\bar{x})$ and concave for negative values of $u(x)-u(\bar{x})$. Consequently, the intensity of emotions rises for extreme differences between the expected value and the per-

ceived value (Loomes and Sugden 1986). Referring to the emotion function of Loomes and Sugden (1986), positive emotions may increase the willingness to pay, while negative emotions disproportionately decrease the willingness to pay.

H4: Emotions moderate the relationship between the perception of price fairness and the willingness to pay. Positive emotions increase the willingness to pay, whereas negative emotions decrease the willingness to pay.

METHODOLOGY

Sample design and experimental procedure

Two studies were conducted to test these hypotheses. The sample was comprised of 210 students from a German university. The average age of the participants was 26.7 years, and the sample included 134 men and 76 women. The stimuli consisted of written scenarios describing a sports shoe retailer that realized to increase prices. Laurent and Kapferer (1985) and Zaichkowsky (1985) identified athletic shoes as a high-involvement product and tested them within several experimental designs (Laurent and Kapferer 1985; Zaichkowsky 1985). The basic scenario described a situation of buying athletic shoes.

We did not pay incentives to participants. While it is common practice in experimental economics to employ financial incentives to increase performance, we doubt that such a practice is worth the

effort in our context (Hertwig and Ortmann 2001). Decision within our experiments cannot be evaluated in terms of right or wrong and thus, give no basis for performance-oriented payments.

In all studies we used a 3x2 between subjects designs (Hair et al. 2007). In order to control confounding variables, we assigned subjects to the experimental groups in a randomized way (Homburg, Hoyer and Koschate 2005).

STUDY 1

Study 1 uses a 3x2 between subject design, crossing the magnitude of a price increase and emotions (positive, negative). The dependent measure was the perceived price fairness.

The pricing literature offers little guidance when it comes to manipulating price levels. The price increase was changed at three levels. Thus, to pretest the level of price increases we conducted a Vickrey auction (Vickrey 1961). Based on a starting price of 80€, the three proper levels of price increase were 5 € (6.25%), 15 € (18.75%) and 20 € (25%).

The experimental factors of emotion were manipulated before describing the scenarios and collecting the data. There are several methods to manipulate emotions (Gerrards-Hesse, Spies and Hesse 1994; Lang, Bradley and Cuthbert 1997). We used the International Affective Picture System (IAPS) by Lang et al. (1988). The success of IAPS was confirmed in several studies (Bradley and Lang 1994; Lang, Bradley and Cuthbert 1997). Positive and negative emotions were manipulated by 12 pictures each. The pictures used are presented in Table 1.

Participants completed manipulation checks. To measure emotions, we used the PAD (Pleasure-arousal-dominance) scale developed by Mehrabian and Russel (1974), which has been used by marketing scholars to assess emotional response to interpersonal aspects of shopping (Izard 1981; Plutchik 1989; Mehrabian and Russel 1984). The scale contains 18 semantic differential items, six each of pleasure, arousal, and dominance.

The manipulation in experimental groups perceiving positive and negative emotions was confirmed by the PAD-scale. Subjects confronted with positive pictures reported more positive emotions ($Mean_{pos. Emotion}=4.35$) than did subjects to whom we presented negative pictures ($Mean_{neg. Emotion}=3.69$). A pairwise t test on the locus of emotion measure between the two scenarios was large in the intended direction ($t=8.23$; $p<.001$). The pretest to measure the level of price increases served as a manipulation check. The use of a pretest study is adopted when it is difficult to obtain a manipulation check within the main study (Perdue and Summer 1986).

After reading through one scenario, subjects provided fairness evaluations. Consistent with Kahneman, Knetsch, and Thaler (1986) and Maxwell (1995), we measured price fairness by using a four-item scale from 1 ("fully agree") to 7 ("fully disagree"). The midpoint of the scales are described as neither. Scales were: "The price is fair," "The price increase of the shoe is appropriate." "All consumers were treated fairly," and "Price calculation of the athletic shoe is understandable." The scale had an acceptable Cronbach reliability (Cronbach's Alpha=.84). Also, exploratory factor analysis of the scale returned a single factor solution.

It was hypothesized that participants will perceive price increases as more fair in a scenario with positive emotions. Results strongly support this hypothesis. In order to test the significance of the differences a 3x2 ANOVA using the fairness as dependent measure revealed the desired main effect of the price increase ($F=91.64$; $p<.001$). Also, the interaction effect, which means that emotions moderate the main effect, can be confirmed ($F=7.137$; $p<.012$). Results indicate that the higher the price increase; the less important are emotions as influencing factors.

As well, the second main effect is tested significantly ($F=18.993$; $p<.000$). This means that subjects find the price increase in the positive emotion scenario to be more fair than in the negative emotion scenario. However, in the context of low price increases, emotions are even more relevant. This effect is presented in Figure 1. Surprisingly, results indicate that positive emotions have a greater impact in price fairness than do negative emotions.

STUDY 2

Study 2 examined different levels of price fairness as the independent variable. Experiment 2 assessed the impact on the willingness to pay (Hypothesis H3). Additionally, we test hypothesis H4, which maintains that emotions mediate the relationships between the magnitude of price fairness and the willingness to pay (Hypothesis H4). Study 2 involved a 3x2-between subject design. Before measuring the willingness to pay, subjects were confronted with a similar scenario in the shoe store, as used in study 1. The experimental groups with different emotions ($Mean_{positive Emotion} > Mean_{negative Emotion}$) were manipulated in terms of three different levels of price fairness.

The levels of price fairness are positive inequity, negative inequity, and perceived equity. Thus, the scenarios read as follows: "To buy a athletic shoe, you visit a store shop. A friend has recommended a certain shoe. But the price of the shoe has increased. The salesperson, who is a friend of yours, explains that the company raised the prices of their shoes due to increased R&D and production costs"(equity). Because the marketing literature does not provide an appropriate manipulation procedure, we manipulated the scenario using Campbell's (1999) inferred motive for price increases for a firm's price increase. When participants inferred that the company had a negative motive for the price increase, the increase was perceived as less fair than the same increase when consumers inferred that the company has a positive motive (e.g., rising production costs) (Campbell 1999). Therefore, the reason for the price increase varied between three different groups: In one group the price increase was justified by rising production costs. Consequently, participants should perceive the price increase as fair (equity). When the price stays the same despite rising production costs, we expected the perception of fair prices (positive inequity). When the salesperson does not explain the price increase, the price increase shifts the input-outcome relation of the equity function to the disadvantage of the producer. Negative inequity would be the consequence (Campbell 1999). We used the same measurement of price fairness as in the first experiment. Positive and negative emotions were manipulated using IAPS-pictures. Subjects were confronted with the same type of emotions as in the first experiment. These pictures guaranteed a well-founded manipulation. The results of the PAD-Measurement of Mehrabian and Russel (1984) supported this approach.

Willingness to pay was measured using the card method (Hoevennagel 1996). The subjects were given a certain number of cards with prices printed on them. Subjects are instructed to choose the card of the highest price they were willing to pay (Mitchell/Carson 1989). Even if the presentation of cards restricts the choices, the procedure eliminates anchoring-effects (Hoevennagel 1996). At the same time, the presentation of prices is easily implemented. Participants can chose between different cards on a scale from 25 € to 150 €. Results of the measurements indicated that prices range from 45 € to 145 €. Ignoring the manipulations, the mean price of the athletic shoe was about 87 € ($Mean_{WTP}=86.59$).

The same items used in the first interviews were used to measure the price fairness (Cronbach's Alpha=.93). The item-to-total correlation gives no reason to skip an item. The measurement

FIGURE 1
Means of price fairness by experimental condition

of emotions reveals a high difference between positive and negative emotions ($t=7.63$; $p<.001$).

The manipulation checks do not justify the differentiation in equity, positive inequity, and negative inequity. Positive inequity and equity do not provide a significantly different mean value ($t_{\text{Positive InequityEquity}}=1.53$). Therefore, we use a 2x2-between subject design and limit the experiment to negative inequity and positive inequity. Subjects of the "negative inequity" scenario ($\text{Mean}_{\text{Negative Inequity}}=3.753$) perceive the price increase as more unfair than do the subjects of the "positive inequity"-scenario ($\text{Mean}_{\text{Positive Equity}}=5.18$).

Hypotheses H3 and H4 were tested by means of a 2x2-ANOVA with willingness to pay as dependent variable. Both main effects were significant. In terms of the results for willingness to pay, there was a main effect for emotion ($F=7.387$; $p<.007$). Participants in the positive emotion condition were willing to pay a higher price than participants in a negative emotion condition. The positive relationship between price fairness and willingness to pay was also tested significantly, meaning that participants who perceive price increases as fair are willing to pay more ($F=12,264$; $p<.001$). However, the interaction effect cannot be confirmed.

IMPLICATIONS AND FUTURE RESEARCH

This is an exploratory study. Thus, there are few strong conclusions, and many limitations. Our study extends previous research in the area of price fairness research by investigating how emotions moderate the relationship between perceived price fairness and consumer's willingness to pay. The implementation of price increases is easier if price increases are perceived as fair. Our paper indicates the impact of emotions on the relationship between the magnitude of price increases and the perception of price fairness. We add emotion as an important element of price fairness perceptions that accompany the cognition considerations of equity theory. It is logical, therefore, to speculate about the nature of the relationship between emotions and price fairness. However, our study focused on positive and negative emotions. Further research should extend the spectrum of emotions and investigate whether positive and negative emotions compensate each other or negative

emotions dominate positive emotions, as stated by Izard (1981). In addition, we did not measure the negative emotions caused by the price increase itself.

As with any methodology, there are limitations associated with experimental research. The results refer to a limited data set. Additionally, the use of the athletic shoe scenarios is not complex enough to generalize the findings. Consequently, future research should explore the relationship between emotion and price for other consumer groups and buying situations.

Our results provide explanations for irrational behavior of consumers. Cognitive behavioral theories have to consider emotional aspects. This article supports the rising attention of marketing literature towards emotions because cognitive theories are revealed to be limited in explaining consumer behavior. Price judgments are complex and intrapersonal procedures. Emotions and emotion-induced actions cannot, therefore, be neglected. The integration of emotions revalues the prognosis of pricing actions and consumer behavior.

With regard to the moderating effect of emotions in the impact of price increases on the consumer's willingness to pay, our study indicates that a 20% increase in price can be absorbed by positive emotions. The impact of positive emotions declines for higher price increases. Hence, firms should consider emotional and cognitive aspects within their price measures. Advertising needs to pay more attention to the role of emotions in all aspects of marketing (O'Neill and Lambert 2001). Advertising currently relies on repetitions, while strong emotions are avoided. Feelings of delight, joy, sympathy, and happiness should be reflected in the store appearance. Especially pictures have an impact in this concern.

Cannibal or Commodity Fetish: Body as Material Interaction

Ai-Ling Lai, University of Gloucestershire, UK
Janine Dermody, University of Gloucestershire, UK

ABSTRACT

This paper seeks to address the call to bridge the dichotomous divide between subject and object within consumer research. Adopting an embodied perspective and drawing on our empirical research, we highlight the paradoxical meanings surrounding the fetishization of the body as a commoditized object as well as a kernel of personal history. We explore the extent to which participants are willing to overcome the depersonalizing transformation to their embodied self, as they negotiate the meanings surrounding the progressive objectification of the body, inherent in the practice of organ transplantation. Our analysis suggests the difficulty in delineating where the embodied subject ends (donor as self) and the commoditized object (donor as cadaver) begins. As such, the boundaries that mark the agentic capability of the embodied donor as commodity/intentional subject are mutable, indeterminate and intersubjectively emergent. We therefore seek to create a dialogue among consumer scholars to reconsider the body as the 'material interaction' between consuming subjects and material objects. Only in so doing, can we begin to advance the discipline beyond its essentialist roots.

"Transplanted organs become one of many examples of objects rendered culturally significant by new medical technology. Their cultural value lies in their economic and their social worth; they are rare commodities in part because they are personalized objects"

- Sharp, 1995: pp. 378

INTRODUCTION

This paper seeks to address the need to transcend the subject-object dualistic legacy of Cartesianism within consumer research. Increasingly, consumer researchers are called to reflexively elucidate the relationships between subjects (consumers) and objects (commodities) and how the ensuing cultural meanings are mediated within marketplace cultures (Borgerson, 2005; Arnould and Thompson, 2005; Elliot and Wattanasuwan, 1998; Wallendoff and Arnould, 1988). Accordingly we are responding to recent calls for consumer researchers to bridge the dichotomous divide between the consuming subject and commodity object, by reflecting on:

"...the radical indeterminacy of both 'subject' and 'object' ...which begin from the assumption of an emergent ontology with bodies, objects and meaning entangled, co-constituted, fragile and often ambivalent." (Bettany, 2007: 45)

This call is reflective of a shift in consumer research, away from the 'essential characteristics of consumption objects' (Bettany, 2007: 42) towards the agentic primacy of the consuming subject, as exemplified recently by CCT (Arnould and Thompson, 2005). By privileging either the subject or the object, consumer researchers have yet to appreciate the purposive (intentional) communion between the consumer and the material world (Merleau-Ponty, 1945/2002; Dant, 2006; Joy and Venkatesh, 1994; Heidegger, 1927/1962; Borgerson, 2005; Miller, 1987; Latour, 1987), and have therefore reinforced the legacy of Cartesian philosophy (Thompson *et. al.* 1989; Arnold and Fischer, 1994). In other words, by endorsing the binary opposition between subject/object, consumer researchers have overlooked the concept of *intentionality*¹—which is

considered to be at the root of agency (Borgerson, 2005). This paper will therefore adopt an embodied perspective, drawing from the phenomenology of Merleau-Ponty (1945/2002) and Heidegger (1927/1962) to address the intentional comportment (Merleau-Ponty, 1945/2002), which connects consumers to material culture. As Dant (2006) suggests, it is through embodiment that the embedded material capital of objects emerges. In the light of this, Dant (2006) defines 'material interaction' as:

"...the meeting of the materiality of peoples' bodies, including the mind and imagination that are part of those bodies, with the materiality of objects, including the qualities and capacities that has been designed and built in by the combined and collective actions of a series of other people." (Dant, 2006: 300)

This is important because it helps us to realize the dialectical connection between subject and object (Merleau-Ponty, 1945/2002; Borgerson, 2005)—which is mutable and indeterminate (Bettany, 2007). As such, we can begin to appreciate that *agency* is necessarily co-determined through the intersubjective network of embodied beings. We propose to situate our analysis within the context of cadaveric organ donation, by establishing the body (cadaver) as the point of 'material interaction' (Dant, 2006) between different stakeholders within the transplant community,² who contest what the body is, the extent to which the body can be considered a constituent of selfhood and how its boundaries should be defined (Seale *et. al.*, 2006). The decision to become an organ donor is therefore embedded within a nexus of competing narratives, through which the body is thematized as a battleground where the battle concerning its agentic capability (*i.e. are bodies intentional or inert*) is fought. The body therefore occupies an ambiguous position within the discourse of organ transplantation, as it is at once a commoditized object and a biographical marker of the self (Sharp, 2005). Through empirical research, this paper presents accounts of the negotiated meanings of potential donors, as they attempt to relate their embodied experience to the progressive objectification of the body, inherent in the medical practice of organ transplantation. We begin our analysis by considering pertinent themes within the literature, namely: (1) the body as enfleshment of the world, (2) the body in plenum and (3) the objectification of the body.

THEMES FROM THE LITERATURE

The Body as Enfleshment of the World: Towards the Dissolution of the Subject-Object Dualism

Within consumer research, the body has often been conceptualized as an inert object. Its status as a kernel of existence and locus of knowledge is subordinated to the superiority of the mind (Burkitt, 1999; Joy and Venkatesh, 1994). The body has therefore assumed

¹Intentionality is a concept first introduced by Franz Brentano (1837-1917) to explicate the relationship between the subject and the object. To say that the subject is intentional is to say that it is always directed towards or refers to some objects.

²The intersubjective connection between donors, recipients, donor/recipient families, medical professionals and marketers

a liminal presence in the discipline, where it has long been eclipsed by the hegemonic legacy of Cartesianism (Joy and Venkatesh, 1994; Thompson *et. al.*, 1989) and rendered docile under the panoptic gaze of the 'inscriptive perspective' (e.g. Thompson and Hirschman, 1995; Grosz, 1994). More recently, consumer researchers have begun to acknowledge the 'lived experience' of consumers as essentially 'incarnated' (Patterson and Elliot, 2002; Lai *et. al.*, 2008; Joy and Sherry, 2003). In order to fully embrace the consumers as 'incarnated beings', researchers are called to re-instate the body as the conduit of intentionality by 're-establishing the roots of the mind in its body, and its world' (Merleau-Ponty, 1963:3 in Grosz, 1994). As Merleau-Ponty (1945/2002) suggests, human beings cannot simply be reduced to 'purely mind' (subject) or merely bodies (object) for our mind is always incarnated and vice versa (Grosz, 1994; Howson and Inglis, 2001). By introducing the notion of 'body-subject', Merleau-Ponty demonstrated that the body is not merely a *possession* of the subject (having a body); rather it reveals the primordial intertwining of our subjectivity and corporeality (being a body), which is purposefully orientated towards the world it inhabits. Consequently we both *have* and *are* bodies (Turner, 1996). From a Merleau-Pontyan perspective, objects (materiality) are constructed (designed) as the enmeshment of consumer culture, which are then embodied by the consuming subjects who, in so doing, consecutively shape the process of material civilization (Merleau-Ponty, 1968; Lai *et. al.*, 2008; Dant, 2006). We will now move on to consider the body as the conduit of intentionality, with reference to Merleau-Ponty's and Heidegger's ideas on embodiment.

The Body in Plenum: The Existential Conceptualization of the Body as a Conduit of Intentionality

While Heidegger has very little to say about the body, on closer reading it becomes apparent that his hermeneutic account of *Dasein* is essentially embodied (Heidegger, 1927/1962). In the German language *Dasein* literally means Being-*there* (Macquarrie, 1972). As the body is our anchorage of being-in-the-world, Being-*there* necessarily implies that *Dasein* is an embodied being (Macquarrie, 1968). In *Being and Time*, Heidegger (1927/1962) criticized the prevailing Western thinking that tends to regard Being in terms of thinghood (Macquarrie, 1972). The Cartesian dualistic substance of Mind/Body is one such example. Similarly, Merleau-Ponty (1945/2002) is vehemently opposed to the reduction of the embodied subject to a passive *res extensa* (1945/2002: 381), in which it is rendered as a thing-in-itself (Sartre, 1943/1956). To regard embodied beings as passive objects is to engage in an 'act of depersonalization' (Heidegger, 1927/1962: 73) that withdraws from the person, his right to dignity, mystery and humanity (Marcel, 1949 in Macquarrie, 1972: 176). For Heidegger, *Dasein* is embodied through and through—where man comports himself towards his *Being* as a 'holistic fusion of body, soul and spirit' (1927/1962: 73). By taking up the issue of *Being*, *Dasein* is responsible for who he is and what he may become. Here, the parallels between Heidegger's concept of *Dasein* and Merleau-Ponty's 'body-subject' begin to emerge.

As a body-subject, *Dasein* projects into future possibilities *ahead-of-itself* (Heidegger, 1927/1962: 279). Such projection into future trajectory is what Heidegger called *transcendence* (Dreyfus and Rubin, 1999: 300). Thus, as a transcendental being, *Dasein-as-embodied* has an *intentional* comportment towards the world (space) and his project (time), through which he plays an active part in the meaning-making process. Accordingly, through our embodied experience, we creatively infuse our life-narratives with meanings, drawing from the *possibilities* open to us in our purposeful communion with the world.

Our embodied existence is therefore a dynamic process, which suggests 'being in a plenum' (Merleau-Ponty, 1945/2002: 525)—i.e. to exist is to always be in action. The precursor to existence, then, is our embodied transcendence. To exist is to 'perform' life-*I do therefore I am*. It is in 'doing' that we attain concreteness and fullness of existence (Macquarrie, 1972). Inverting the *cogito*, it is because 'I can that I am' (Merleau-Ponty, 1945/2002: 446), and thus 'I am therefore I think' (Macquarrie, 1972; Craib, 1998). Merleau-Ponty and Heidegger have therefore reversed Descartes' claim to the certainty of existence by relocating it's locus from the dispassionate 'I think' to the embodied 'I can'.

Death therefore represents the transformation from 'I can' into 'I no longer can' (Leder, 1990). The silent sphinx of the cadaver heralds the annulment of intentionality (Bauman, 1992). Thus, the omnipresence of death reveals to *Dasein* his underlying nullity, where he can no longer 'perform' life (I can't therefore I'm not). For Heidegger (1927/1962) then, nonbeing is in the fibre of our very being. As Merleau-Ponty argues, we as intentional beings are betrothed to the world through which we are held *responsible* for our 'commitment' to exist.

"I can no longer pretend to be a nihilation (néant), and choose myself continually out of nothing at all. If it is through subjectivity that nothingness appears in the world, it can equally be said that it is through the world that nothingness comes into being. ... We are always in a plenum, in being, just as a face, even in repose, even in death, is always doomed to express something." (Merleau-Ponty, 1945/2002: 525)

In short, our dialogical engagement with the world means that we, as embodied beings are not simply inert entities lying around, indifferent to our surrounding. In Heideggerian terms, we are never simply *present-at-hand* (1927/1962: 67). A synthesis between the ideas of Merleau-Ponty and Heidegger thus portray *Dasein* as *chiasmatically* conjoint to his world as *one flesh*—i.e. the *flesh of the body* is also the *flesh of the world* (Merleau-Ponty, 1968; Lai *et. al.*, 2008; Dant, 2006)—thereby rendering the traditional subject-object dualism obsolete. If the body-as-subject defies objectification, to what extent can body parts be commoditized as social gifts within the discourse of cadaveric organ donation? To what extent does the tension between the subject-object status of the body (cadaver) mediate the material interactions between different members of the transplant community?

The Objectification of the Body within the Discourse of Cadaveric Organ Donation

As organ transplantation becomes increasingly routinized, concerns have been raised with regards to the slippery slope of body commodification (Scheper-Hughes, 2001; Hogle, 1995; Lock, 2002; Belk, 1990). This is not surprising as organ donation inevitably entails the fragmentation of the embodied self. As the body is isolated into interchangeable components, it can then be commoditized as a form of merchandise (Helman, 1988; Seale *et. al.*, 2006). Thus, by objectifying the body, organ donation becomes conceivable as it is stripped of its emotive and social value, i.e. an object devoid of personhood. This reflects the Cartesian conception of the mind/body dualism, which reinforces the inert quality of the body.

Within the medical context, the body is further reified through the clinical gaze (Foucault, 1973) and various medical rites (e.g. pathological examination). Medical professionals are required to engage in what William Hunter called 'necessary inhumanity' or clinical detachment (Armstrong, 1987; Lock, 2002; Richardson,

1987; Lynch, 1990) in order to achieve medical objectivity. This clinical gaze transforms the cadaveric donor into a 'thing-in-itself'—an assemblage of body parts (Lynch, 1990; Helman, 1988). Thus organ transplant procedures have been described as a form of late modern cannibalism (Scheper-Hughes, 2001), where organs are 'extracted', 'salvaged' and 'replaced' (Robbins, 1996), mirroring the taking of functioning parts from a machine (e.g. cannibalizing car parts) to repair another that is broken (Youngner, 1996; Richardson, 1996; Fox and Swazey, 1992). As Heidegger (1927/1962) feared, such medical construction has reduced the body into an undignified object of biology—a corporeal thing. As the integrity of the embodied self is violated, the status of body parts as the locus of the self becomes a matter of social dispute (Seale *et. al.*, 2006). In breaching bodily boundaries, transplantation has given birth to hybrids that threaten to undermine the western conception of the coherent self (Helman, 1988; Hallam *et. al.*, 1999). In other words, the leaky bodies of organ transplantation violate the 'taken-for-granted' modernist western assumptions about the 'bounded body', where '*being whole*' is defined in terms of corporeal solidity, immutability and impermeability by otherness (Hallam *et. al.*, 1999; Douglas, 1902/1966). Furthermore, upon receiving an organ, transplant recipients often undergo transformative experience that alter their sense of self (Sharp, 1995)—which they *fetishize* with lingering animism (Lock, 2002; de Brosses, 1760/1970). Such anthropomorphism of the body thus reflects broader societal concerns over the reconfiguration of body boundaries (Douglas, 1902/1966; Hallam *et. al.*, 1999).

Belk (1990) contends that body parts and organs can retain their sacredness by being given and received as gifts (see also Titmuss, 1972). Hogle (1995) and Lock (2002), however, are perturbed by the gift exchange of organs, arguing that such ritualistic practice of gift-giving merely conceals the progressive objectification of the body and obscure the darker side of organ transplantation (Youngner, 1996; Richardson, 1996). By normalizing the 'gift-of-life' discourse, potential donors are promised a *ressurrectiv* appeal to become technologically "immortalized". Thus, donors can "live on" literally in the body of organ recipients (Sharp, 1995) and symbolically in the collective memory of society (Lock, 2002); while remaining oblivious of the cultural production that transforms donor cadavers into routine cyborgs (Hogle, 1995). Marx (1867/1976) called this the *fetishization* of commodity, where consumers are removed from the production process through the medium of commodity. Hence, through the promotional rhetoric of the 'gift-of-life', the body becomes commoditized as social object (Helman, 1988; Seale *et. al.*, 2006; Kopytoff, 1986). Such objectification of the body violates the integrity of the embodied self, '*causing tension between the status of body parts as 'self' (subject) or not self (object)*' (Seale *et. al.*, 2006: 26).

For the potential donors, the body continues to carry a personalized imprint of the self (Sharp, 1995). Biographical narratives are told *through* and *with* the bodies. As such, the '*biographical body*' is also a historical body-engraved with the epiphany of life, where personal triumphs and tragedy are chronicled. It is through their 'historical body' that potential donors are able to experience a sense of continuity, which unites the past, the present and the future (Thompson, 1997; Giddens, 1991; Mick and Buhl, 1992) as their ongoing existential project (Thompson and Hirschman, 1998; Merleau-Ponty, 1945/2002). Hence, the body is a conduit of intentionality that perpetually comports towards its *potentiality-for-being* (Heidegger, 1927/1962) and cannot be easily depersonalized.

Having reviewed the premises and paradoxical meanings underlying the *fetishization* of the body as a commoditized *object-in-itself* as well as an animistic site of lingering subjectivity, we now present the methodology of this empirical study.

METHODOLOGY

In recognition of the need to transcend the Cartesian legacy of subject-object dualism, we have adopted the philosophical perspective of hermeneutic-phenomenology (Arnold and Fischer, 1994; Thompson *et. al.*, 1994) to inform our interpretive inquiry of cadaveric organ donation. Hermeneutic philosophy emphasizes the ontological status of Being (Heidegger, 1927/1962), in which the interpreter (researcher as subject) enters into a dialogical relationship with the interpreting-object (participants as co-author) to arrive at a mutual understanding of new possibilities of what it means to be human (embodied subjects). Hence both the researcher and the participants are embodied beings, who are intersubjectively comported towards each other (Merleau-Ponty, 1945/2002) in a '*continuous state of coming into understanding*' (Arnold and Fischer, 1994: 59). Through the collaborative approach of active interviewing (Holstein and Gubrium, 1995), the researcher (first author) engaged the participants in a shared narratological dialogue (Thompson, 1997). Multiple active interviews, of approximately 4 hours each, were conducted with 14 British female potential organ donors, aged 21-30, who harbour ambivalent perceptions towards organ donation—generating extremely 'rich' and complex data.

Hermeneutic-phenomenology also insists that researchers must first understand the pre-objective 'lived experience' of the participants (*emic perspective*) prior to the construction of knowledge (Merleau-Ponty, 1945/2002; Thompson *et. al.*, 1994). Hence the construction of knowledge necessarily emerges as a *fusion of horizon* (Gadamer, 1989) between the participants and the researcher (Holstein and Gubrium, 1995; Thompson, 1997). Thus, in this study, this *fusion of horizon* occurred when the participants' perspectives slipped into the perspectives of the researcher (first author) and vice versa (Merleau-Ponty, 1945/2002; Langer, 1989), mutually enriching and expanding horizons of understanding of all involved. The interpretation of data presented in this paper is therefore the concretized form of understanding (Gadamer, 1989) derived from this *fusion*. In this way, the subject-object dichotomy is bridged (Arnold and Fischer, 1994)

THEMATIC ANALYSIS AND DISCUSSION

Our findings reveal that participants have predominantly depicted organ donation as involving the disintegration of the body. The 'fragmented' and 'leaky' body emerge as overriding representations in participants' narratives, which collide with their embodied experience for '*being whole*' (Lock, 2002). The 'fragmented body' also implies the transgression of body boundaries, where participants fear the '*cannibalistic*' repercussions of merging with the bodies of anonymous others (Kopytoff, 1986; Sharp, 1995; Dant, 2006). In our thematic analysis, we explore various perspectival standpoints from which participants negotiate the situated meanings surrounding the mortal body. In doing so, we can begin to illustrate how they attempt to make sense of the depersonalizing transformation of their embodied self and thus, reconcile the competing narratives surrounding the transgression of corporeal boundaries that underlie the practice of cadaveric organ transplantation.

Being Whole/Being Fragmented: Negotiating the Progressive Objectification of the Disintegrated Body

In their pre-objective description (*emic perspective*), participants have predominantly depicted cadaveric organ donation as involving the fragmentation of the body. For example, the body is portrayed as being '*scattered about*', '*cut up in little pieces*', '*hacked up*', '*butchered*', and '*chopped up*'. It is therefore not surprising that transplant surgeons and/or doctors are often depicted as '*psychotic*', '*crude*', '*monstrous*' and '*horrendous*'. Mean-

while, organ transplantation, as a practice, is deemed 'barbaric', 'crude', 'gruesome' and 'intrusive'. Estelle's description below is an archetypal portrayal of organ donation:

"I see it in a crude sense. I am just like 'oh they just take an organ out of someone and plonked it in someone else's.' It is just in a horrible, disrespectful way that is just pictured in my head. And they just make it sound like really nice but unpersonal type thing.... Like if someone's had their like organs donated they'll be all hacked up.... it'll be taken out of them and that's just horrible because they'll be cut up for no reason. They don't have...like time to pass away peacefully or time for the family to say goodbye. It is more like, they are just the donor. They are not a person that's kindly giving you something. It is just like, "right, another one." Seems quite horrible....it's not a person any more, we'll just get out the organs because we need them and they (the donors) don't matter." (Estelle, Age 21, Interview 1)

Like all the participants, Estelle sketched a somewhat 'crude' representation of organ transplantation, which she perceives to be a *de-humanizing* procedure that routinizes body mutilation. Here, the transplant professionals are demonized through the 'othering process', as the 'they'—who 'just take organs' from an anonymous pool of donors and 'plonked' them into the collective bodies of transplant recipients (*someone else*). Donor-cadavers are 'hacked up' or 'cut up for no reason' in order to fulfill 'greater' social needs. Therefore, emphasis is placed on the utilitarian concern of organ shortages, while the potential donor as a person pales into insignificance. As a result, donor-cadavers are transformed into routine cyborgs (Hogle, 1995), that can be replaced like interchangeable spare-parts that are merely present-at-hand (*they are not a person that's kindly giving you something. It is just like, "right, another one"*). No longer able to project into the *potentiality-of-being*, the cadaver donors thus lose their intentionality as embodied beings (*they are just donors*). Drawing from her embodied standpoint, Estelle argues that the practice of transplantation has crudely neglected the social significance of the donor, whose body continues to express an orientation to the 'Being who has just lost his life' (Heidegger, 1927/1962: 282). For her, the body continues to be the locus of personhood, whose 'subjectivity' is co-defined through the interpersonal network in which it is located. As a point of intersubjective interaction, the body must therefore be left in peace to allow the bereaved to say their final goodbye. While the appeal for organ donation has been 'gift-wrapped' to make it 'sounds nice', such an intuitive appeal stands in contradiction to Estelle's pre-objective understanding of organ transplantation, which she considers to be 'disrespectful' and 'horrible'. Similarly, in her narrative below, Kierra provides a macabre depiction of cadaveric organ donation as involving the practice of clinical detachment, which she deems as the ultimate sign of disrespect to the donors and their families.

"I know one of my friends is studying to be a doctor. And he just tells me about cadavers, is that the right word?...Anyway, he tells me about the story about cutting people up and....they don't seem to....it is not really a personal thing to them. It's like the body is a piece of meat and they fix it and sew it up, you know. It is like, the body is on the cutting board you know, (they) open you up gradually, sew it up and fix it and change it and do what you need to do. And that's how I think of it. But for me, I think of body in terms of people and I think life is very important. Well, the medical students see them as...although they know they are people...the doctors would have to detach

themselves, haven't they, I think... "there are some people here who donated themselves for our benefit and aren't we lucky and we must respect these people and appreciate it". I don't think I can walk into a room with a dead person and laugh and take pictures and drink coffee really. And I think of that and I think of people laughing around cadavers and not thinking about them as people. It is kind of....it is a natural....it is somebody....they may be dead but still you know....very significant....that person is dead." (Kierra, Age 24, Interview 1)

Kierra is cognizant of the term *cadaver* being a discursive construction specific to medicine (Youngner, 1996). For her, the medical concept of the disembodied *cadaver* clashes with her *pre-objective understanding* of the deceased person in her lifeworld. As a medical construction, the *cadaver* is a pathological specimen of objective science (Foucault, 1973; Williams and Calnan, 1996). Sequestered to the private realm of the operating theatre (Walter, 1996), the *cadaver* undergoes the rite of *dehumanization*, where it lies submissively on the 'cutting board' (operating table) like a 'piece of meat', ready to be 'sewn', 'fixed', 'opened up' and 'changed' by the clinically detached professional. As Heidegger (1927/1962) has forewarned, such acts of depersonalization (*it is not really a personal thing to them*) have denied embodied subjects their last shreds of dignity (Lynch, 1990). Despite acknowledging that such 'necessary inhumanity' (William Hunter circa 1780 in Richardson, 1987) is essential to achieve medical objectivity, (*doctors would have to detach themselves*), Kierra insists that the body continues to be a significant embodiment of the deceased donor whose life is 'very important'. As such, the fragmentation of the body into medical objects is unthinkable for the majority of the participants. Not only does it disrupt the intersubjective bond between the deceased and the bereaved, it also signifies the disintegration of the embodied self, as Carmen explains below:

"Because of just how important I am to me and my body. The body is to me how I was made up here, so it's almost like you are shattered (laugh) when you are scattered about. Erm...so that's why....cause you can't keep a hold of it. You can't keep track of everything." (Carmen, Age 23, Interview 2)

For Carmen, the integrity of the body represents 'how she is made up'. Transplantation involves the breakup of the intact body, as it is 'shattered' to pieces before being dispersed (*scattered about*) into the bodies of anonymous others. As such, she fears the 'loss of control' over the management of her body. For Carmen, this powerlessness to exercise control over the 'scattered body' will 'shatter' the concreteness of her Being, and thus herald the collapse of her identity project. Carmen then reflects on what it means for her to 'be whole':

"You want to be whole; everything is working in conjunction to each other. You as a person, you know, you have got nothing missing, you have got nothing wanting.... You know I want to feel at home where I am...and whole where I am. My own perceptions of being whole in everything, being yours in its right place even if it is not working, you know, you are not needing it....because without it (the body) we wouldn't be here." (Carmen, Age 23, Interview 2, our emphasis)

In this narrative, Carmen suggests that *being whole* affords her a permanent sense of corporeal familiarity (*everything is in its right place*)—which she can then weave around her as a protective cocoon (Giddens, 1991) to help her 'feel at home' in the world (Heidegger,

1927/1962). Such a refuge furnishes her *ontological security* (Giddens, 1991) and facilitates her ongoing project of the self. It is therefore important for Carmen to maintain the integrity of the body despite the cessation of its biological life. In existential terms, it is through the body that she is able to ‘be-in-the-world’ (Heidegger, 1927/1962). As Carmen insists, “without the body, we wouldn’t be here”. This implies that ‘being-a-body’ is to be ‘somewhere in the world’ (Heidegger, 1927/1962; Macquarrie, 1972)—that is to be in the continuity in terms of time and space. As such, a *disembodied* existence is inconceivable for participants; as the body represents the concreteness that anchors their lived experience and thereby supports the fullness of their existence (Macquarrie, 1972; Bauman, 1992). As a kernel of existence, the body is in perpetual transcendence and must continue to “emerge or stand out from nothing” (Macquarrie, 1972: 62). This is expressed below by Willa:

“Nothingness is frightening, you know, it’s a void. It’s...erm...it’s out of...it’s beyond my perception and therefore because I...because it’s beyond my imagination I suppose that makes me afraid of it. Like some general sort of existence I suppose. Some general being part of time and space....erm...because we are...we’re sort of Earth-bound aren’t we? We are physically rooted to the ground in a sense...erm...Sort of constrained (by the) body. Gravity keeps us...keeps us down on the Earth and...erm...we’re as rooted really as... almost as a tree is rooted into the earth. I mean we’re rooted on Earth because of...erm...because of gravity and so on. I’m...I’m...I’m scared of (cosmic) space...that’s... beyond my imagination...Because...because to me the idea of being unearthed, sort of ungrounded...it takes me out of life as I...as I know it, and it moves too far towards concepts I don’t understand..... so the thought of...the thought of being in a spaceship or some rocket thing and looking down on Earth, I think my sanity would go immediately” (Willa, Age 31, Interview 2, our emphasis).

For Willa, to exist is to be part of the space-time continuum, anchored by her body. Drawing from her embodied experience of ‘being earth-bound’, Willa describes her incarnated *existence* as analogous to a tree taking roots in the soil of the earth. In contrast, Willa equates *nothingness* to being in the void of cosmic *space*, which she claims to be ‘beyond her imagination’. As perception is intentional (i.e. the perceiving subject is comported towards an object in the world), nothingness is imperceptible to her as her (and our) imagination cannot stretch beyond what she has no experience of (Merleau-Ponty, 1945/2002; Bauman, 1992). Being adrift in the abyss of the cosmos creates in her an empty vacuousness, akin to Sartre’s ‘Nausea’ (1938). Her perception cannot entertain the ‘*idea of being ungrounded*’, as it defies the familiarity of her embodied senses that ‘takes her out of life as she knows it’. For Willa, nothingness is therefore a boundless void that offers no refuge to her perceptual need for groundedness (Bauman, 1992). As she loses the concreteness for being-in-the-world (Macquarrie, 1972), she also loses the ‘wholeness’ for Being (*my sanity would go immediately*) and thus the ‘liquidation’ of her (and our) self (Heidegger, 1927/1962). For the participants then, ‘Being-in-the-world’ entails *having* and *being* a ‘bounded’ body, through which they are able to project *ahead-of-themselves* towards the *possibilities-for-Being* (Heidegger, 1927/1962). The body is therefore permeated with intentionality as it is always in a plenum, incessantly ‘performing’ the act of living (Merleau-Ponty, 1945/2002). From an embodied standpoint, then, we can begin to appreciate our female participants’ apprehension concerning the objectification of the body through cadaveric organ donation, as this implies being in a *stasis*

where they are no longer capable of meaningful transcendence. We will now move on to consider this.

Cannibalistic/Transcendental Potential of Organ Donation: On Merging With Anonymous Other

As participants contemplate the intercorporeal exchange of organs, their narratives take on a sinister undertone as they problematize the ‘ressurrective’ promise to ‘live on’ in the body of anonymous transplant recipients. The merging and breaching of body boundaries evokes considerable anxiety among the participants as it violates the ‘taken-for-granted’ assumptions about the ‘bounded body’. In other words, organ transplantation thematizes the ‘leaky body’-a marginal construct, permeated with dangerous intent, as Carmen describes below:

“I think that’s WRONG. It’s eerie and not right... “No, I don’t want to do that.”...erm...You know, I don’t actually want to live on forever more and erm...I want me to be me, special as I am. erm...And it...just it sounds like almost like something out of a horror film if you feel that parts of you is going to live on in other people. I think that’s a bad way to go. It doesn’t sit easy with me. Cause it’s adulterated. It is like you are not pure anymore because it would be somebody else as well. So I think you are truly you when you are you, not bits of you and bits of somebody else”. (Carmen, Age 22, Interview 2).

For Carmen, the idea of being technologically immortalized is met with a strong sense of repulsion. By situating her interpretive position within the genre of horror films, Carmen implies that the ‘ressurrective’ potential of organ transplantation is verging on the realms of the ‘supernatural’. Her narrative can therefore be read as a cautionary tale (Thompson, 2004) that forewarns of the ‘menacing’ ramifications ingrained in the promise of technological transcendence. For Carmen, the breaching of bodily boundaries is ‘adulterating’ (Douglas, 1902/1966), as it threatens to defile the ‘purity’ of the embodied self. The practice of transplantation has therefore created a new class of hybrids, whose ambiguous coupling throws us into ‘radical doubt’ as to what the body is (Shilling, 1993; Hogle, 1995; Ohnuki-Tierney, 1994) and what constitutes our selfhood (Shilling, 1993, Seale *et. al*, 2006). To consolidate her sense of individuality (*I want me to be me, special as I am*), Carmen expresses a strong resistance to such hybridity, arguing that ‘*you are truly you when you are you, not bits of you and bits of somebody else*’. Such violations to the ‘bounded body’ have therefore provoked a sense of unease among our participants, insinuating that organ donation is saturated with cannibalistic potential (Scheper-Hughes, 2001).

For the participants, transplanted organs are *fetishized* objects, enlivened with animistic qualities (Sharp, 1995; Lock, 2002). This has created room for participants to ‘give voice’ to the ‘knowing body’ (Merleau-Ponty, 1945/2002), thereby substantiating it as an agentic field of resistance. Such anthropomorphism of the body is pervasive among the participants, best captured in the narrative constructed by Chloe below:

“I don’t know...probably something just like a mental image more than anything else. With everything the doctors seem to be able to do now, you would be able to survive rejection. But there’s...the organ itself would always be...you can...almost see the heart itself going, “No, I don’t belong in here”, and sort of...erm...you having to take drugs to stop rejection, it’s almost like the organ going, ‘No, I don’t belong in here. Let me out’. erm...which is why they, you know, they sort of give drugs to sort of...I don’t know, calm the organ, to pacify it, to

make it sleepy, so it isn't permanently sort of going "Let me out! Let me out! I don't belong in here!" Probably like a joke, saying, you know, that ...in obviously donating an organ, you know, you'll know that you're helping somebody else walk around with your heart. This is in my imagination just ...you just know it was that person down there has got what was once yours. There's probably a selfish element like me, you know, it's like, "That's mine! You shouldn't have it. Put it back, it's only borrowed". Despite the facts that you don't...you're not going to need it again." (Chloe, Age 24, Interview 2)

In her narrative, Chloe forewarns of the peril that may befall the transplant recipient when the barricade of the bounded body is breached (Sharp, 1995; Hallam *et. al*, 1999). Specifically, she portrays the heart as bewildered and rebellious, seemingly taking on a life of its own, as it struggles to liberate itself from the fleshy casing of a foreign body. Like Chloe, most participants in this study depict the heart as the strongest site of defiance, as it is culturally considered to be the seat of personhood and emotion (Manning-Steven, 1997; Haddow, 2000; Belk, 1988). The 'imagined biography' (Kopytoff, 1986) constructed around the heart is therefore richly elaborated (Sharp, 1995).

By constructing a social biography of the transplanted heart, Chloe envisages the alienation of the self, which is manifested through the biological (natural) rejection of foreign body parts (in this case the heart). In order to avoid being discounted as 'irrational', Chloe draws on the scientific discourse of immunosuppressive rejection to 'legitimize' her embodied standpoint. As Chloe observes, it is on the corporeal frontiers that the battle of power and control commence between biomedicine (a cultural invention) and the biological body. Immunosuppressant drugs such as cyclosporine are weapons wielded by medical professionals to pacify the wilful organs to subordinate them to the power of science. And in so doing, fulfilling the modernist project that upholds the superiority of culture (science) to overcome the limitations of the 'natural' body (Bauman, 1992; Hirschman, 1990; Shilling, 1993). Chloe indicates that such medical infringement of the body has also blurred the boundaries that have culturally marked the ownership of our body (Sharp, 1995). Disputes therefore arise as to who (i.e. donor or recipient) should be accorded the rightful control over the transplanted organs. In her narrative, Chloe vehemently maintains that selfhood is an incarnated phenomenon, emphasising the body's 'natural' defences to protect its borders from the invasion of alien objects. In other words, the 'knowing body' has 'declared' its 'natural' allegiance to its owner (donor), who should therefore retain their rightful dominion over their organs. Not surprisingly then, organ donation is imbued with vampirish tendencies where the transfer of personalized organs is tantamount to the transference of the donor's agentic life-force. Further illustrating this, Cyd states:

"I've heard stories about people that say they have flashbacks that aren't their memories or that they feel things or that they like certain foods now because they have someone else's body parts and things, and it just doesn't seem right that we should take on somebody's else's that's not ours. It's...yeah...(laugh) Yeah, I don't know really... I don't know, because I've seen things on telly before where people have never met and they don't know anything about the other person's life but yet they've got a memory of their wife or something...I don't know, I think perhaps your body and your body parts take on more than we really think and so then to transfer it, maybe you

do take a little piece of that soul with you...If that really is true, then for that person that might not be a great experience either to have like parts of you in...because they might not always be good bits, maybe there would be bad bits too... Yeah. They could pass on your demons or something. (laugh)" (Cyd, Age 22, Interview 2)

Cyd suggests that the body is saturated with the donor's personal history, which becomes embodied as 'memories'. Such 'embodied memories' are sedimented within their corporeal schema (Merleau-Ponty, 1945/2002). Thus, by donating their organs, they may also transfer their 'embodied memories' onto recipients', and hence modify their corporeal schema. This transference of 'embodied memories' is euphemized as '*passing on her demons*'. As Cyd implies, her 'embodied demons' may transform the recipients' experience of being-in-the-world (*say they have flashbacks that aren't their memories or that they feel things or that they like certain foods*) and thus alter their personal history. For Cyd, the transplanted organs are more than just inert biological objects. Rather, they are intentional objects that have the potential to inhibit the social agency of the organ recipient.

In their narratives, participants often make intertextual reference to the genre of thriller and horror films. Posed as a counter-narrative, these films provide cultural commentaries, warning the dangers of violating body boundaries. Participants tend to sensationalize various urban myths represented in these films, such as the horror of identity swap (*Face/Off, All About My Mother*), seeing ghosts (*The Eye*), the tyranny of gifts (Fox and Swazey, 1992), where the donor family stalks transplant recipients to seek reciprocity to their grief (*21 Grams*). This is exemplified below by Estelle:

"Carrie (friend) told me this film she watched (The Eye) and I am just picturing that. It is really scary. She had a... I think it is a retina transplant And she looked into the mirror, and she sees the donor's ghost reflected in the mirror. Like she sees her eyes...that other person's reflection. That's why it was freaking me out there. It's just the whole idea of...someone else's identity mixed up with yours because...Oh! Have you seen Face/Off the film? It's like really unrealistic, because it's just like the different actors playing the different characters but...this guy has...erm...got this criminal arrested, but he has been given or he's been knocked out and his face has been stolen, so the criminal lives the life of him and he the cop. And...that'd be awful. Just...just the idea that you're assumed to be someone else." (Estelle, Age 21, Interview 1)

CONCLUSION

In their narratives, participants imply that the decision to become an organ donor relies on individuals being willing to overcome the depersonalized transformation of the body to embrace the redemptive spirit of the 'gift'. Hence, participants are actively engaged in a reflexive negotiation, to establish the parameters to which their embodied self can be objectified, fragmented and reincorporated as medicalized objects (Hogle, 1995; Youngner, 1996). Thus, while the idea of breaking up the body seems abhorrent to our participants, this does not mean they reject cadaveric organ donation outright. Instead, as it thematizes competing narratives surrounding the mortal body, it feeds their confusion, and thus their ambivalence surrounding becoming an organ donor.

Specifically, our participants perceive body parts as permeated with 'imagined social agency' (Miller, 2002 in Borgerson, 2005), which have the potential to (1) hinder the agency of the organ

recipient whose embodied self becomes cannibalized, and/or (2) annul the embodied intentionality of the donors whose embodied self becomes 'literally' devoured by the recipient. The 'ressurrective' appeal of the 'gift-of-life' is therefore rife with ideological contradictions (Sharp, 1995); as participants are presented with the *transcendental promise* to 'extend their biographies' while simultaneously being confronted with its *cannibalistic potential*. As Lock (2002) argues, the fetishism of the body is doubly at work. On the one hand, the promotional discourse of organ donation has concealed the progressive objectification of the body through the fetishization of the 'gift' (Richardson, 1996; Youngner, 1996). For the potential donors, however, the body is infused with animistic quality that mystifies it as a fetishized object akin to religious relics (Sharp, 1995, Lock, 2002; de Brosses, 1760/1970).

Embedded within this nexus of competing narratives, the body therefore occupies an ambiguous position within the discourse of organ transplantation, as it is at once a commoditized cadaver and the vessel of personal history (Sharp, 1995). It is therefore difficult to establish where the embodied subject ends and the commoditized object begins. Consequently, the boundary that distinguishes the embodied/disembodied constituent of selfhood is indeterminate, mutable and emergent (Dant, 2006; Bettany, 2007), as its locality is co-defined through the intersubjective network that makes up the transplant community. As such, the 'agentic capability' attributed to the body is negotiated through the 'material interaction' between members of the transplant community. In summary, organ donation has thrown into confusion what the body is, how it should be treated and to what extent the body can be considered as the kernel of existence. The corpse, though lifeless, continues to express an orientation to life and is imbued with social and personal significance.

Accordingly this paper therefore seeks to create a dialogue among consumer scholars to reconsider the relationships between consuming subjects and material objects. Only in so doing, can we begin to advance the discipline beyond its essentialist roots. We propose mortal embodiment as a promising area of study that enables us to recognize that material civilization is cultivated through the bodily utilization of cultural objects-molded in the enmeshment of consumers' experience of being-in-the-world. We leave you with the thoughts of Merleau-Ponty -

"The body is our general medium for having a world. Sometimes, it is restricted to the action necessary for the conservation of life, and accordingly posits around us a biological world... Sometimes, finally, the meaning aimed at cannot be achieved by the body's natural means; it must then build itself an instrument, and it projects thereby around itself a cultural world" (Merleau-Ponty, 1945/2002: 169).

Living with the Obesity Stigma: Perceptions of Being Obese from Three Cultures

Ekant Veer, University of Bath, UK

ABSTRACT

One defining antecedent of marginalized consumer groups is their status as being stigmatized. Although much research has investigated the perceptions of onlookers of a stigmatized person or group, little research has been conducted regarding the stigmatized person themselves and what impact the stigma has on his or her behavior. Using qualitative methods, this paper investigates the way in which an understanding of the obesity stigma develops within the individual, the impact that the obesity stigma has on consumers' perceptions of themselves and finally, their ability to internalize and act upon social marketing interventions.

INTRODUCTION

The increasing interest in marginalized consumer research has led to a recent increase in exploratory work in the area. One defining antecedent of a marginal consumer is his or her status as being stigmatized or separated from society in some way (Burden 1998). Many studies have elucidated the range of effects expressed by onlookers of stigmatized consumers; however, little research has focussed on the effect a stigma can have on afflicted consumers themselves. This paper uses the visible stigma of obesity as the context for understanding how consumer perceptions and actions may change as the stigma attachment is internalized in the obese individual's life. As such, the questions are asked: how does the sense of stigmatization develop in an obese person, and secondly, how do obese people cope with this feeling of stigmatization? Qualitative research methods were employed to understand how informants' lives have been affected by their stigmatized status as being obese, and subsequently offer avenues of investigation for social marketers in order to more effectively target marginalized groups with their campaigns.

After exploring the extant literature surrounding stigmas and prejudices a brief discussion of the methodology is presented. This is followed by a summary of findings, a discussion of main themes from the research and some implications for social marketers, public policy makers and academicians.

WHAT IS A STIGMA?

A stigma, in its simplest form, is any distinguishing mark or characteristic that distinguishes a consumer as being different (Allport 1954). Although stigmas do not necessarily need to be negatively valenced, stigmas are often reported as being negative marks or characterisations. For example, Link and Phelan (2001) note that stigmatisation is the combination of distinguishing a person or group based on known differences; associating these differences with negative attributions; separating these individuals or groups based on these negative differences and assigning a loss of status to this stigmatized individual or group. This definition, based on the earlier research of Goffman (1963), outlines both the distinguishing quality of stigmas but also the dynamic, processual nature of stigmas.

In the case of obesity, known differences between an obese person and a non-obese person can result in the obese person being stigmatized and therefore, thought of as being lesser by the non-obese person. For example, obese persons are excluded from certain social groups (Crocker and Luhtanen 1990), thought of as having lowered self control (Brown, et al. 2003) and academically less superior than non-obese persons (Tiggeman and Anesbury 2000).

One of the precursors to modern stigma research stems from Gordon W. Allport's work in the 1950's and Henri Tajfel and John Turner's work on Social Identity Theory (SIT), beginning in the mid 1970's. SIT is grounded in the premise that consumers, as social beings, categorize themselves into separate groups and protect their 'in-group' from the distinct 'out-groups' (Tajfel 1979, Turner 1991). In-groups are characterized as being groups that one currently belongs to or wishes to belong to, while an out-group is any group that one does not belong or does not wish to belong to. Stigmas form the basis for forming in-groups and out-groups. For example, a male consumer may walk into a women's clothing store with his partner. Generally speaking, the male consumer in outside of his normal domain and surrounded by persons he represents as being part of his out-group. In an attempt to feel some form of belonging and comfort in his surroundings he may instinctively approach another male in the store who appears equally uncomfortable. Even though the two persons may never associated with one another in a 'normal' setting, when surrounded by a distinct out-group a male in-group is formed. The two consumers may never have met however, if the stigma of discomfort was not perceived by both members. That is, the discomfort of the two men drew them together to form an in-group. If one of the consumers expressed extreme ease and comfort with the situation the other male may not have been able to associate himself with the comfortable consumer and no contact would have been made.

A prejudice, in its mildest form, can be thought of as the relative preference of one's in-group over the out-group, expressed in evaluation, liking, or allocation of resources (Struch and Schwartz 1989). The strength and explicitness of an individual's prejudicial tendencies was dichotomized by Allport (1954) from the bigoted individual to the compunctious individual. The actual strength of prejudice seems to vary from individual to individual from a mild annoyance to a true hatred of a stigmatized group. Although a compunctious individual may feel a sense of guilt once his or her prejudicial behavior has been brought to light, the fact remains that subconscious favoritism towards one's in-group and the relative discrimination of an out-group is endemic of natural human behavior.

The two-factor Justification-Suppression Model (JSM) of prejudice by Crandall and Eshleman (2003) operationalizes prejudicial expression as a function of both suppressive factors (the internally or externally motivated attempt to control or reduce the expression or awareness of prejudice) and justifying factors (the internal or external process that can serve to express genuine prejudice without the threat of sanctions). The JSM model determines that an individual's prejudicial behavior and thoughts are expressed in such a way based on their ability to control or justify innate prejudicial desires (genuine prejudice).

Although genuine, an innate prejudice may exist within an individual but it may or may not be expressed overtly based on his or her ability to justify or suppress the prejudice respectively. Allport's (1954) notion of the bigot would have relatively high justification factors in play compared with his or her suppression factors; whilst a compunctious individual would have the reverse. That is, the prejudice exists innately within the compunctious individual, but is repressed rather than expressed.

Renfrew's (1997) study into the causes of aggression showed that certain 'noxious stimuli' can elicit escape, avoid or punishment strategies. In a similar way, stigmas can elicit prejudicial or aggres-

sive tendencies toward a stigmatized individual or group. A stigma can be seen as an activator or initiator for prejudicial expression; that is, the stigma is used as the distinguishing mark that leads to favoritism towards unstigmatized persons or groups and aggression, avoidance or animosity towards stigmatized persons.

Explicit stigmas include sex, age, ethnicity or weight and are easily identified by onlookers. A person may have an innate or genuine prejudice towards persons of Asian descent but this would only be expressed either when in the physical presence of an Asian person or the subject of Asian ancestry is highly salient in the minds of the racist, such as when persons of Asian descent are discussed amongst others. As the name suggests, latent stigmas are more concealed than the above examples, which may result in prejudicial behavior not being expressed until the stigma is unveiled. For example, an environmentalist may have a strong attachment with a commercial whaler until realising their ideologies clash (latent stigma), at which point it is likely that varying levels of prejudicial expression would surface depending on the strength of the participant's use of available justification and suppression factors. Obesity falls into the first of the two stigma categories. Obesity is often easily identifiable, allowing those with prejudicial beliefs about the obese to make quick assumptions (Ferraro and Holland 2002). Some overt consequences of prejudicial behavior often include, but is not restricted to, physical detachment; social segregation, fear, reduced family cohesion, secrecy and lowered social status (Phelan, et al. 1997).

Hebl and Mannix (2003) extend the stigma literature to show that it is not only the stigmatized individual that is subject to prejudicial expression, but also persons that associate with the stigmatized individual. In their study, Hebl and Mannix (2003) found that an unstigmatized person standing with their obese partner was seen as less favorable than an unstigmatized person standing with their nonobese partner.

WHY OBESITY?

The clinical definition of obesity is an excess of fatty tissue to the point that the person is in significant medical risk (Aronne and Segal 2002). However, it is not the presence of fatty tissue that is of concern in the present study, but rather the perceptions that are associated with the excess fat that an individual carries. One may be slightly overweight and feel far more stigmatized than one who is extremely overweight.

Obesity not only defines a person as being different, but is still considered by many to be a point of negative differentiation (Crandall 1994, Ferraro and Holland 2002). Weiner, Perry, and Magnusson (1988) empirically showed that the stigma associated with obesity is one of the most damaging of the 10 they studied. Obese persons were seen as being highly responsible and to blame for their current size, one of the least liked groups in society and worthy of little pity or financial assistance. Respondents identified obesity as one of the least likely stigmas to deserve social welfare. Other than drug abusers and child abusers, obese persons are ranked as being the stigmatized group most undeserving of affection.

Aside from the extreme effects obese consumers may experience by being stigmatized are the increasing rates of obesity across much of the Asia Pacific region. The New Zealand Ministry of Health rated research designed to curb the rise of obesity rates as being its most important goal in the near future (Minister of Health 2003, New Zealand Ministry of Health 2001). The Australian Department of Health and Ageing has ranked Australia as being one of the fattest developed nations in the world and has instigated a number of initiatives to control the onset of obesity in Australian society (Australian Department of Health and Ageing 2004). Further research into all aspects associated with obesity has been called for

from a number of academic sources, including the Journal of Consumer Research (Mick 2003).

The greater understanding there is surrounding obese consumers' perceptions towards themselves and the obesity stigma, the greater likelihood that more effective social marketing campaigns can be developed that meet their needs as well as promote healthy weight goals. Qualitative research methods were employed so as to provide richness of data regarding the obesity stigma. The following section discusses the methodology drawn on and the respondents that participated in the investigation.

METHODOLOGY

Qualitative methods were employed in order to gain a greater understanding of the perceptions, motivations and feelings behind the informants' actions. As with much interpretivist work the research was undertaken with the aim to inform and develop theory, rather than to generalize or predict actions and behavior to populations (Walsham 1995). Two main qualitative methods were undertaken. Firstly, focus groups were used to help individuals open up and discuss the topic of obesity amongst peers who were in a similar situation. It was reasoned that a group forum would allow greater flow of conversation and interaction with the sensitive topic of obesity stigma (Onkvisit and Shaw 1987). Following the focus groups depth interviews were conducted to gain further insight based on individual cases. Depth interviews provided a more private setting where an informant was able to express themselves without the fear of social judgement (Thornton and Moore 1993). With obesity becoming increasingly prevalent in the South Pacific region the countries of Fiji and New Zealand were used as a source of data for the current research.

Four focus groups were conducted in three distinct populations. Two focus groups were conducted in an indigenous Fijian community based outside of Suva, Fiji. One group was made up entirely of male informants, and the other comprised solely of female informants. One focus group was conducted with Indo-Fijian women living outside of Suva, Fiji. The final group was taken from high school students studying in the south Auckland suburb of Mangere, which is recognized as having a high proportion of Pacific Island and Maori students. All respondents felt they were overweight or obese. Actual weights and body fat measures were not completed so as to not further emphasize the obesity stigma in the minds of the respondents.

Although each group may be distinct from one another in many ways all groups were well represented by high levels of obesity, generally low levels of education and income in their communities and very little understanding regarding the consequences of obesity and its related illnesses. For the Fijian and Indo-Fijian groups a local interviewer was used to conduct the focus group and translate the transcripts into English for analysis. Local interviewers were chosen so that informants can communicate in their native language, providing greater expression and more effective communication. Each interviewer was provided with a standard set of questions, but also encouraged to ask questions along a line they felt may be useful. Interviewers were hired from a local medical college and were both experienced in qualitative interviewing techniques as well as obesity related issues.

During each focus group a second researcher was present to take fieldnotes of general observations made during the focus groups. Even though the second researcher may not understand the language being spoken, the observations made provided valuable insight into the setting in which the focus was conducted as well as the overall tone and atmosphere of the focus group; qualities that the moderator may not have had time to note. Table 1 outlines the make up of each focus group.

TABLE 1
DESCRIPTION OF FOCUS GROUP INFORMANTS

Group	Number of Informants	Language Spoken	Length	Researchers present
Fijian males	7– ranging in ages from 25 to 50 years old.	Fijian	90 minutes	1 Fijian speaking moderator, 2 non Fijian speaking observers. All male.
Fijian females	9– ranging in ages from 30 to 52 years old.	Fijian	65 minutes	2 Fijian speaking moderators, 1 non Fijian speaking observer. All female.
Indo-Fijian females	7– ranging in ages from 18 to 55 years old.	Fijian Hindi	80 minutes	1 Hindi speaking moderator (female), 2 non Hindi speaking observers (male).
Mangere High School students	8– ranging in ages from 15 to 18 years old.	English (all informants fluent in English as a first language)	55 minutes	1 English speaking interviewer (male), 1 English speaking observer (Female).

One on one depth interviews were then conducted with selected focus group participants. Snowballing data sampling was used to acquire further informants. Depth interviews were conducted in order to obtain greater clarification about issues the researcher felt were important to discuss but not appropriate for a group forum. That is, issues that may be deemed shameful to the social group, such as binge eating, depressive feelings or suicide, could be more readily discussed with an interviewer in a private setting. Eight depth interviews were completed in total. Table 2 provides a brief description of informants who participated in depth interviews.

Each transcript was analysed by two researchers, one using the native language and one using the English translation. Open ended and Axial coding methods were used in order to obtain a number of coherent emergent themes within each transcript and then across all transcripts (Spiggle 1994).

Final inter-coder reliability was ascertained by comparing themes and major quotes from transcripts pertaining to each theme. Conflicts were discussed between the coders and resolutions made. When no resolution was possible a third coder, independent from the research collection process, was called to examine the discrepancies and offer a final opinion. Final agreed upon themes were then independently scrutinized by two judges in order to determine their value in aiding the understanding of stigmatized consumer groups.

FINDINGS

Three major themes emerged as being both salient and valuable in informing extant theory. These themes have been labelled *Hopelessness*, *Blindness*, and *Variable Saliency*. Each theme will be discussed in greater detail with relevant implications for theory.

Hopelessness

Although the notion that the obese can suffer from depressive disorders is not novel, the consistent theme of hopelessness indicated a strong sense of a deeper, more enduring feeling of despair.

Interestingly it was not exacted at other aspects of the individual's life. Divya recounts her previous experiences with dieting and her weight as being a never ending cycle.

“It’s not...It’s not as if my life, my size is not a problem. I know it is...I know the pain I suffer from the diabetes and the puffing [breathlessness]...but it [weight loss] can’t be done...I have done it before and I...I just can’t do it...it’s too hard and too difficult...if it was easy and I could do it, it would still be too hard I think...I just have no more power or fight left...” Divya, 55 year old Indo-Fijian female

Lei narrates how his father and mother continue to talk to him about his size and what it means to them.

“I don’t understand it sometimes...I know I can do it but my Mum keeps saying “it’s too late...it’s too late for me to, to be healthy-but you, you have [a] chance...” I guess they’ve given up and accepted it...” Lei, 18 year old Asian male.

The sense of hopelessness in the older informants and the desire for the younger ones not to lose hope or stop trying is also evident in the way the parents purchase and cook foods for themselves and for their children.

“it’s not right I know...but the children need to run and the children need to play and they need to have good food...we give them a little bread and some butter and some milk and they play...while we buy for ourselves the bad [fatty] foods and the drink...I don’t want my son to be me this way...I want him to be big and strong...but not big...like me...” Joeli, 38 year old Fijian male.

There is also a sense of fear espoused by the older informants. However, rather than dispossess the feared self as suggested by self

TABLE 2
DESCRIPTION OF DEPTH INTERVIEW INFORMANTS

Name ¹	Relationship to other groups	Language Spoken	Length	Age	Researchers present
Sitiveni	Male, part of Fijian community	Fijian	70 minutes	26	1 Fijian speaking interviewer (male)
Joeli	Male, part of Fijian community	Fijian	65 minutes	38	1 Fijian speaking interviewer (male)
Adi	Female, part of Fijian community	Fijian	45 minutes	45	1 Fijian speaking interviewer (female)
Rangi	Male, high school student in Mangere	English	45 minutes	16	1 English speaking interviewer (male)
Lei	Male, high school student in Mangere	English	65 minutes	18	1 English speaking interviewer (male)
Hine	Female, high school student in Mangere	English	45 minutes	17	1 English speaking interviewer (male)
Asha	Female, part of Indo-Fijian community. Daughter of Divya	Indo-Fijian	60 minutes	18	1 Hindi speaking interviewer (female)
Divya	Female, part of Indo-Fijian community. Mother of Asha	Indo-Fijian	80 minutes	55	1 Hindi speaking interviewer (female)

¹Note that names have been replaced with synonyms to retain the anonymity of informants.

regulation theory (Carver and Scheier 1981) Joeli has chosen to accept his status but attempts to protect his dependents from the consequences of his actions.

Blindness

The theme name was chosen as it highlights the lack of understanding, especially amongst the younger informants, about the risks of obesity and the reality of being stigmatized until they were confronted with a situation in which prejudice was expressed.

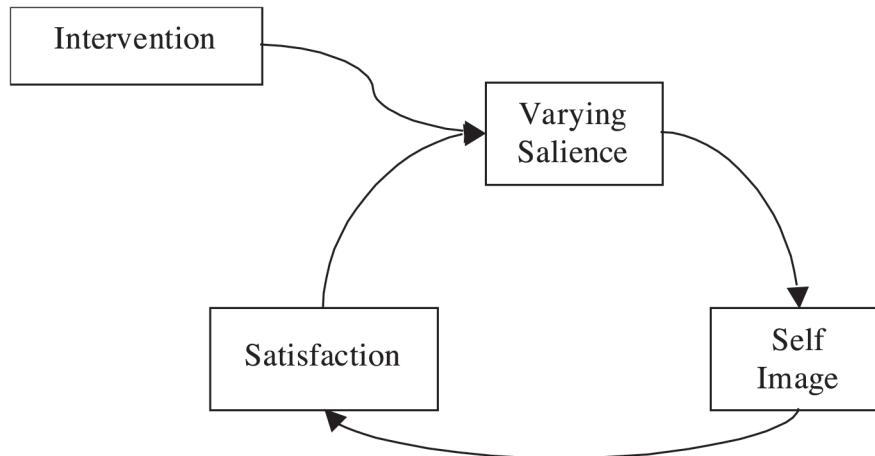

“I really didn’t understand it aye...you know, they are all the same...well...they are all us...but it was like they didn’t want to have anything to do with me and wanted to look at me as the fat guy that people like to laugh at you know...I was like only 12 then and I didn’t think about it until then...it’s like I just [expletive deleted] woke up for the first time...I had to look at myself for a while...you know...think about it and wonder what happened to me...” Rangi, 16 year old Maori male.

Lei continues with his narrative of his parent’s history with obesity

“My dad tells me that he gets looked at you know...by the family and the other people at work...I didn’t even think of it that way...he’s just my dad...it’s like some people look at him...at his weight...and then others look at *him* (emphasis present) at himself...not what he looks like, but who he is...I only thought of it afterwards when some people look at me differently...like at the dairy [local shop] there’s always bad food there and people watch me as I buy it...it’s not like I noticed before...but now I do...” Lei 18 year old Asian male

Not only is there a sense of distress, as with those informants who expressed hopelessness, but also a ‘loss of innocence’ regarding their perceived self. There is a turning point where suddenly the stigma becomes apparent to the obese informant, and it is from this awareness that his or her perceptions and actions change. Lei’s father seems to have been subject to ongoing situations that significantly impact his life, which in his mind, continue to reinforce the stigma attachment. These situations or *negative interventions* are now being seen by Lei himself, which also heightens his awareness about his size and the stigma associated with it.

FIGURE 1
PROCESS OF STIGMA REINFORCEMENT

Variable Salience

The final theme discussed here is that of variable salience regarding the obesity stigma. It was seen from the data that at various times the felt importance of informant's obese stigma was more or less pronounced. That is, situations arose where informants would think more about their physical size in a negative sense. As with Rangi's account these interventions could lead to a time of personal reflection and introspection. That is, after an intervention is a time of reflection about the prior occurrence and a time of self examination. Sitiveni recounts occasions such as this in his time at school.

"yeah...there were times when I knew I was bigger...I mean...we'd play rugby against people...small people and everyone would laugh at me as I would be bigger than two people and they said we just need four Sitiveni's and we'd win...I mean...It was good that I am thought of as strong...but not then...but at other times...like with my family...I don't think of my size...I like fit in with the group and I'm just normal...but then I remember where I have just been and I think again about myself...it's different for us you know..." Sitiveni, 26 year old Fijian male.

Reed (2004) discusses how varying levels of heightened awareness about a personal characteristic may lead to altered perceptions and behavior; however, with the nature of a prejudicial stigma being a negatively valenced characteristic the effects are far more pronounced.

"I hate it when I feel ugly...when it's my bigness that makes me ugly...it's when the younger girls I know are laughing...but with my husband I know I am not ugly...it's a way of think[ing] I know...it's my way of thinking more and more about what my belly is doing...and more and more about my looks...it's not right..." Adi, 45 year old Fijian female.

This quote by Adi reinforces the sentiment that there are occasions or interventions when the negative connotations associated with her obese size can lead to feelings of negative self worth and

subsequent levels of dissatisfaction about her size. However, the relatively short lifespan of such feelings is also evident. That is, as quickly as negative feelings may appear in her life they also disappear when she is with her husband. The cumulative effect on her overall body satisfaction may be of no consequence; however, with ongoing interventions that continue to make her feel negatively about her self it is anticipated that a more enduring feeling of being stigmatized and 'ugly' could occur.

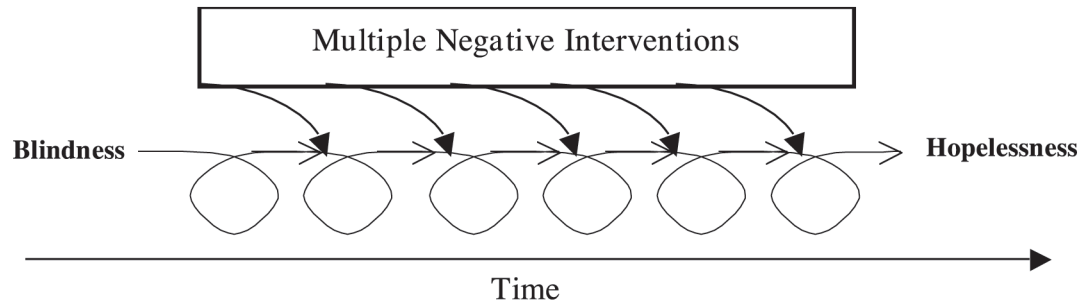

DISCUSSION

The findings indicate a definite change from a state of blindness about the obesity stigma and its effects on obese individuals to a state of hopelessness about ever changing state. Understandably there are a multitude of intermediary stages, for example acceptance, apathy, motivation or narcissism. However, it is at the extreme poles of the scale that the most explicit findings can be discussed. The relationship between salience and self image is key to understanding exactly how the iterative process operates. As shown in Figure 1, it is theorized that an intervention at some point has led to an increased sense of salience about the obesity stigma. This starts a period of personal self reflection and personal dissatisfaction, as Rangi discussed, which then comes back to a sense of varied salience. Depending on the valence and the frequency of the interventions the process continues to reinforce the stigma attachment in the mind of the victim to the point, over many years possibly, whereby the individual feels a sense of hopelessness about his or her situation.

The process of moving from a state of blindness to that of hopelessness does appear to be an iterative one, developed over time over a number of intervening situations. For example, Lei's account of his father being stared at by colleagues or family members can lead to increased salience about his size, and depending on the messages being internalized the outcome could be a positive or negative self image. Figure 2 shows how the process of stigma reinforcement can continue in a vicious cycle from a point of blindness to a state of hopelessness.

Figure 2 represents a deterioration in self efficacy regarding an individual's perceived ability to lose weight (Wilson, Wallston and King 1990). This is in contrast to a notion of external locus of

FIGURE 2
ITERATIVE PROCESS FROM BLINDNESS TO HOPELESSNESS

control whereby the blame may be directed elsewhere (Weiner, Perry and Magnusson 1988). Here we see that these informants know that they had control, however, have since lost the ability to enact any significant change in themselves.

Hopelessness is theorized here as being a state of zero self efficacy that is a result of longitudinal deterioration. The methods needed to alter an individual who exhibits signs of no personal self worth or no perceived ability to change would need to be both rigorous and ongoing. Early positive interventions are critical.

CONCLUSION

The role of the intervention as a method for social change has been discussed in length by many leading social marketing academicians (Andreasen 1995, Donovan and Henley 2003, Kotler and Roberto 1989). However, understanding how the everyday interventions, such as family meetings and social interactions may lead to a feeling of negative self worth has not been investigated. From this study there exists a gap in the extant literature regarding the importance of stigma salience as a driving force for understanding how consumers can go from total unawareness about the need to lose weight to a state of hopelessness regarding their ability to lose weight.

The premise therefore exists that one off ad hoc campaigns are unlikely to provide any significant impact on the consumer's sense of personal efficacy. That is, when ongoing negative interventions surround the consumer there needs to be adequate positive interventions to ensure that the consumer does not continue to spiral into a deeper feeling of hopelessness. This is not to say that obese consumers are praised for their size, rather that they are encouraged and motivated by their in-group to maximize their feelings of personal self efficacy. Ideally any intervention would be targeted early on when the consumer has been fraught with only a few negative interventions and he or she still feels the ability to make significant changes to his or her weight. The evidence presented here directs greater attention towards the need for more social marketing interventions to be targeted at younger populations before hopelessness takes hold and self efficacy deteriorates. Further research is needed to identify specific motivating antecedents that may increase self efficacy, motivation to lose weight and locus of control so that more effective social marketing campaigns can be developed and implemented.

Commodify Thyself: Neither MySpace® nor Your Space but a Space for Mass-Objectification of Subjects

Soonkwan Hong, The University of Texas-Pan American, USA

ABSTRACT

The blogosphere that promotes objectified and commodified identities is contested by individual bloggers and the blogger body as a whole. In the blogosphere, the discourse of power haunts not only between a blogger and the blogger body, but also between the blogger and the blogosphere as a market system providing identity project services. Netnographical data reveal a triadic power relationship in the online market system that facilitates the traffic of identity resources. Notwithstanding the ever more complex power structure, the market still serves its function as expected. The unparalleled magnetism of the viral marketing tranquilizes the observed tension among the three parties and lubricates the market system.

INTRODUCTION

Online self-portrayal has drawn much attention from consumer research because its theoretical importance as to identity projects of consumers today and the ubiquitous interests in personal websites represented mostly by blogs (e.g., Arnould and Thompson 2005; Schau and Gilly 2003). A number of websites in U.S., such as *MySpace*, *Facebook*, and *Blogger* successfully attract more subscribers. Blogging in China has also been widespread and reported as disseminators of consumer culture, including but not limited to fashion, food, and travel (Zhao and Belk 2007). A particular Korean blog (*Cyworld*®) has accomplished a tremendous success as more than 20 million people, out of 48 million total population, have subscribed to the blog (e.g., Jung, Youn, and McClung 2007). European countries are no exception. This exponential growth of the blogosphere can be attributed to the identity-laden nature of contemporary consumer culture (e.g., Giddens 1991) and the commodification-facilitating nature of online consumption activities. A blogger may act as an iconic celebrity as s/he “sells” the identity through his/her blog, or spontaneously become popular when many others wish to appropriate his/her identity and the relevant images.

The blogosphere, as such, invites a substantial portion of consumers and provides commodified and commodifying self-expressive contrivances. It should be, nevertheless, noted that the identity projects of consumers executed on the blogosphere are distinct from those conducted in off-line contexts in that consumers choose to become objects as they disclose their identities online. The subject/object dichotomy (see Firat and Venkatesh 1995) is overtly defied as consumers objectify themselves in their blogs and make their identities transparent. Despite this theoretical significance of blog as a new agent for identity projects, studies on online consumer self-presentation are centered only on the consumptions of signs, symbols, cultures, experiences, and materials (e.g., Peñaloza 2000, 2001). Those consumption activities and experiences as elements of one’s identity become widely available, as they are posted online, and exchangeable for the same kinds of consumptions with different cultural substances created and distributed by other online consumers. The blogosphere has become another type of market in which embodied, audio-visualized, and embellished cultural materials-different types of consumptive actions-are put up for sale. Commodification of the cultural materials is evident

because consumers seek more and varied materials in the market at the expense of their own materials available for other consumers (c.f., Benjamin 1973).

The commodification of the objects that belong to a subject will, however, erode the subjectivity. Celebrities are neither subjects nor objects. They become objects on the day they make their debut on TV. Correspondingly, the demarcation between subjects and objects blurs in online settings. Subjectivity can be maintained intact only until the blogger posts his/her identity-relevant cultural products and/or artifacts. The blogosphere is not only a completely commodified, commercialized, and marketized agent for identity projects, but also a commodifying and objectifying agent.

Given the theoretically intricate yet particularly significant online consumer culture, a few questions need to be addressed. What theoretical lenses can be utilized to explicate the selective commodification of identity? Do all bloggers want to commodify their identity? If not, why and how do they protect their identities from an over or unnecessary commodification? Hence, this study first seeks to provide theories that address voluntary commodification of identity and potential withdrawal of the commodified identity. Second, the present study identifies the preventive measures that bloggers employ to shield their identities from excessive or reprehensible commodifications. Third, the study also provides a discussion on the opposition of bloggers to the mass-culture on the blogosphere necessitating the commodification of subjectivity.

The second and third objectives are especially important because they evince that the discourse of power must be embedded in online consumption activities. Insightfully, the discourse of power (see Foucault 1977, 1980) in an online context envisages a novel structure of power. Dissimilar to the dyadic discourse of power as to identity projects in the conventional market system (e.g., Thompson 2004; Thompson and Tian 2008), the power may possibly circulate in a triadic relationship among the market, a blogger, and other bloggers. The nature of the relationship is seen neither as a conflict between blogging consumers and the market, nor a friction between “me” and “others.” The relationship rather appears to compel each blogger to manage his or her appropriate power level in order to culturally benefit from each other, and the market may also be required to control the level of its influence and intervene between two or more bloggers.

The complex mechanism of identity protection in the blogosphere is a peculiar phenomenon of interest for two reasons. First, it seems a self-contradiction of bloggers because they are in opposition to the objectification of subjectivity even though they have chosen to objectify themselves online as they subscribe to the websites. Second, bloggers have to wrestle with two different entities: the market (blogosphere as a mainstream cultural arena that obliges identity disclosure) and other bloggers (they require a constant and unlimited identity disclosure). In order to unearth the tangled power relationship in the blogosphere, a particular blogging website called *Cyworld* in Korea is selected as the site for the theorization. A literature review as to “commodified identity” will be followed by a netnography-aided grounded theory (Glaser and Strauss 1967; Kozinets 2002) that should stimulate a more profound discussion on the triadic power relationship in the blogosphere.

THEORETICAL BACKGROUND OF COMMODIFIED IDENTITY

Reciprocity of Identity Disclosure in the Blogosphere

“Give and take” must be emphasized and necessitated in the blogosphere. The reciprocity seems the most prominent catalyst of commodified identity. The function of reciprocity of intimate disclosure of self is described as “[d]isclosure seems to beget disclosure, such that people who receive intimate disclosure feel obligated to respond with a personal disclosure of equal intimacy” (Moon 2000, p. 324). Whether or not identity is seen as a purely private or public concept, the description applies to the blogosphere quite fitly. If a blogger deems identity more public than private, disclosure does not require but assumes reciprocity. On the contrary, reciprocity will be imposed strictly on the blogging activity as an identity project when identity is conceived totally private. The quintessence of identity is, however, neither private nor public; rather, it is always balanced (e.g., Brewer 2003; Grubb and Grathwohl 1967). Therefore, reciprocity of identity-disclosure confuses bloggers with respect to the selection between “exhibition and concealment” of identity.

Bloggers have to determine the appropriate level of identity-disclosure as they understand both requirements for identity. Nevertheless, there are two forces that bloggers should confront when they determine the level. First, the disclosure of identity will only be heightened and deepened. Simply, everything and anything about a blogger’s identity is asked to be revealed as the disclosure interacts with other identities disclosed (Derlega, Metts, Petronio, and Marguilis 1993). Second, the online context does promote face-to-face human-interaction-like social activities (e.g., Moon and Nass 1996). Bloggers might be unconsciously involved too much with identity-disclosure albeit the potential pitfall of identity-replication by other bloggers. The unconscious or unrealized involvement with “online identity showcase” is either due to the numbing nature of online environment (e.g., Hoffman and Novak 1996) or because of the bloggers’ daydream of a perfect reciprocity in the blogosphere.

Disclosure generally means a chance to be commodified and objectified just as we have seen in many cases of artistic products. The two aforementioned reasons for disclosure-required by others and stimulated by the market (blogging websites)-also concretize the newly proposed notion of the triadic relationship of power in the blogosphere. A management of only one relationship with either entity will not ameliorate the convolution of the extended discourse of power.

Appropriated Identity

Commodification of identity in the blogosphere operates as a process that enables bloggers to assimilate to other bloggers’ identity projects as constituents of the mass-culture of blogging. Bloggers, however, “deassimilate” themselves from the others so as to maintain unique identities in the blogosphere as an ultimate reservoir of identity. Baudriallard (1998) marks a noteworthy characteristic of commodification that idealizes a double-barreled praxis of commodified identity projects in blogs. Simultaneous homogenization and the differentiation of bloggers’ identity-presentation, which is possibly analogous to each other’s, beget a self-contradictory tension among bloggers. Echoing this notion of dual-meaning commodification, Rindfleisch (2005) postulates, “once a self-identity is formed it is immediately appropriated, eventually consumed, and a different form of self-identity must be reconstructed” (358). Identity reconstruction has long been inculcated since postmodern thinkers and researchers defied identity

as a consistent and uncontested concept (e.g., Featherstone 1995; Gergen 1991; Schouten 1991). Technology-enhanced identity projects accelerate the dissemination of popular identities, and thus the necessity to revise bloggers’ identities is intensified and detected earlier than before. Consequently, bloggers-intimidated by the speed and scale of identity simulation and emulation in the blogosphere-are required to protect their own identities and further culturally rebel against the “identity-theft” promoted by the market.

METHODOLOGY

A pool of narratives, excerpts, and notes is developed through a netnographical field study (see Kozinets 1998, 2002). The data collection method employed is to justify the interpretation procedure in a naturalistic setting. The textual discourses automatically transcribed online are culturally enriched “thick descriptions” (Clifford 1990). The descriptions are also expected to be identity-laden as the bloggers narrate their deep-hearted emotions, ideologies, and internal struggles. The data collection ceases when there seem no more insightful categories of interest and importance found. The methodology can be judged as a grounded-theory (see Glaser and Strauss 1967) because an induction will derive a theory explaining the individual bloggers’ power management strategies.

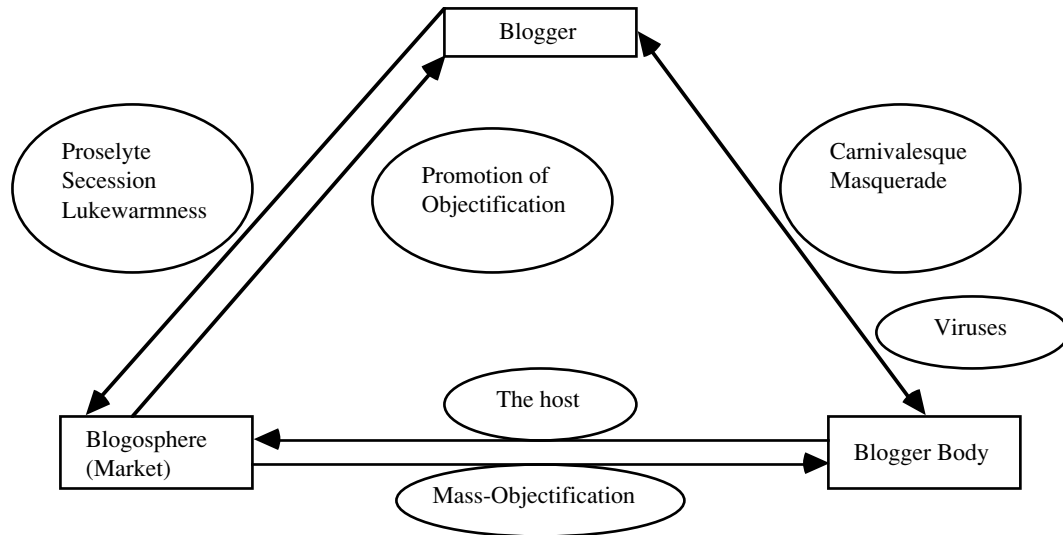

A keyword searching method is used due to the immense (over 20 million bloggers) resources of data in *Cyworld*, a blogging website in Korea. The choice of the research site is rationalized through three reasons. First, liberatory expressions of self in online settings are more prevalent in Korea across different age groups because the country has not fully adapted to modernism. A place where modernity did not prevail or at least sufficiently permeate tends to be more open to postmodern ideas (e.g., Firat and Dholakia 1998). Second, ironically, the fast acceptance of postmodern lifestyles and cultures in those places also appears to be contested more easily and earlier than elsewhere because of the “root-absent” nature of the culture. Lastly, the collectivistic cultural orientation of Korea may evidently entail the power relationship with other bloggers, which may not be manifest elsewhere yet.

The narratives and excerpts, translated from Korean to English, as well as the researcher’s observational fieldnotes compose the data set to be interpreted (Note that the names for direct quotes that appear in later sections are all initials). Disjunct and less meaningful textual data are sorted and bundled together for a codified schema of identity protection from external power sources (e.g., Arnold and Wallendorf 1994). Following Thompson (1997) and Spiggle (1994), a creative, playful, subjective, and yet substantially translative hermeneutics is expected to yield a meaningfully concentrated and culturally fertile model of the triadic power relationship in the blogosphere.

FINDINGS: A TRIADIC POWER RELATIONSHIP

Postings on the personal online diary (or repository) type of blogs in *Cyworld*, field observations, and the researcher’s personal (also familial) direct interactions with other blogger friends reveal the immanent and yet conspicuous management of the tensions with the market and other participants in the market (blogosphere). The ideological commotions of bloggers as consumers of identity project service in the blogosphere emanate the fever from the cycle of acceptance, commensalism, and repudiation. The relations of bloggers with two different power sources, wielding isomorphic influences over individual blogging service consumers, entail unique management strategies respective to each influence. Moreover, there accrues a schema of the triangulate power relationship in the blogosphere (see Figure 1), in which each entity operates to contribute to the sustainability and transformation of the marketplace.

FIGURE 1
Triadic Power Relationship in the Blogosphere

Carnavalesque in the Blogosphere

Bloggers obtain various entertainments from the blogosphere that frees bloggers to enunciate conventionally unexposed aspects of their identities. The blogosphere seems an extremely enjoyable milieu (c.f., Kozinets et al. 2004) because of the widely accessible repertoires for identity projects, and owing to the learning experience as to different craftsmanship of identity projects by the blogger body. A blogger KY notes:

I know I have to present my own color in my blog, but it is very hard to find one that fits me. Too much fun, too much to learn... For the time being, I'd rather get so much fun around without thinking anything serious. Having a fun identity in my blog is just great because I have been thinking that it should always be something serious. I think blogging will make me able to have some kind of orgy and an identity at the same time.

Enjoyment, craze, fetishization, and bizarreness in the blogosphere attract more users to the identity project service, and the degree to which the users reflexively indulge in the fiesta intensifies. This escalation of reflexivity, however, only produces bloggers' anxiety for over-exposure and misuse of their identities, and the anxiety appears to exceed the perceived benefit and fun from blogging (c.f., Hong 2008). In association with the contradictory apprehension of bloggers, HS concedes:

I hate somebody taking my postings and using them as if they are his own creations. I think it should be banned somehow, but I can blame only myself because I love to put my stuff up online. Once we started doing so, we can never stop but just confuse other bloggers with too much going on in our blogs. Then, they get bombarded or intimidated by the extreme presentations of our identities. You know what? I had a visitor to my blog that left a message, saying "you're really something disgusting, pervert, and never acceptable." That's exactly what I wanted, so I got happy because they wouldn't want to fake my stuff but just let them go. No worries anymore. ☺

Difficult to replicate but extremely ludic expressions of one's identity are repeatedly witnessed guards from the overuse and exploitation of identity expression. Bloggers strive to be superordinate to others with regard to their identities' cultural meaningfulness and profoundness while accentuating playfulness. The carnivalesque in the blogosphere increases the difficulty level to appropriate the identities available in blogs but constantly require better quality creativeness from the defensive bloggers. The "overly enriched" cultural manifestations, however, still serve as an apparatus for a blogger to retain a superior power over the other identity (re)creators.

Masquerade in the Blogosphere

Another way to handle the ever complex task of identity show-off and the subsequent shrink of the presenter to maintain a preferable power level in the blogosphere is to bewilder other presenters with a multitude of camouflages. It seems impossible to pinpoint the salient identity of a blogger because s/he introduces as many personas as possible; therefore, the mission of protection of the blogger's focal identity among multiple identities is more likely to be accomplished (see Laverie, Kleine, and Kleine 2002 for identity salience). HM posts:

I know who I am, but nobody seems to. Maybe, I have too many characters to show, but it doesn't matter as long as I do not lose, nor am confused, with myself. I hope everybody feels the same...

Bloggers do not appear to want to explore a new and/or inimitable type of identity and declare a preoccupation of the newly created identity; rather, they provide unnecessarily central identity artifacts. Perhaps, bloggers conceive that this is the only plausible way to commodify and exchange identity and the relevant resources with others. Accordingly, the maintenance of power level is continuously achieved, provided a blogger's central identity is not "degraded" for others' identities. The harder to figure one's real façade, the less worry about unwanted objectification of identity.

FIGURE 2
A Bizarre Presentation of Identity in Cyworld ®

The blogger narrated that she failed to communicate with the heater shown in the picture. Interestingly, the subtitle of the photo section is “managing boredom.”

The wishfully authentic identity, which the blogger distances from the objectification and the following commodification is still misinterpreted and misapplied in the worst case because of the other “cluttering” identities. In her monologue, SM confesses her identity presentations have unconsciously and unintentionally become a multiple-personality type of self-disclosure:

Today, my friends told me I must be crazy or something and said I had to stop this thing. They said I was not supposed to claim myself to be a Christian if I’m regularly drinking and trashed in clubs so often. But I don’t care whatever they say because, as everyone knows, people have so many different phases of life that may or may not represent them. If others think all the things are my identities, that’s their choice. I just want to keep updating things about me whether or not they make me look really crazy. I want to let you judge...

The masked or possibly distorted identities offered in the blogosphere are different from the carnivalesque of identities in that the former intoxicate and obfuscate other bloggers with irresistible but unrealistic amusement, and that the latter reduces the odds of losing the pivotal identity, not to be copied, by showing ostensibly unrelated and disjointed identities. An individual blogger and the blogger body as a whole enforce and defend the identity-commodification as they concurrently exchange their identity supplies and try to “demarketize” their identities. As a result, the power flow between the two entities is always egocentric, which thus can never be contributing to the market system unless the market commercially intermediates (e.g., viral marketing) between the two.

Proselyte

Bloggers’ management of power in relation to the market (blogosphere) is surprisingly simple and prompt. They simply explore and connect their identities to a new form of marketplace,

such as the UCC (user created contents) in *YouTube®* that enables more in-depth and culture-rich expression of identity. DR feels a compulsion when he posts in his blog:

I started it (blogging) as a hobby, but now it’s become a burden in my life. So sometimes I stretch myself all the way, but it doesn’t work at all. To convey myself only through writings and some pictures certainly has a limitation. I feel I am going to collapse pretty soon, which oppresses me harder.

The converts explain that they need a better “distribution system” of identities. The market (blogosphere) only promotes and implicitly obliges bloggers to supply the merchandises (identity and the relevant creativeness) without intermediaries for a better system. Consequently, they seek a more effective system that prevents the identities from being “sublimated” due to systematic incompleteness. These bloggers do not resist the idea of commodified identity but seem to contest the market system, which promotes the traffic of abstracted commodification of identities. The market may never suggest the sublimation of one’s identity presentation. Intriguingly, the proselytes, however, do not always move to a more liberal place. SE utters:

There is much emotion, culture, information, and other things to learn and help me better express myself in traditional media, like papers, news, and books. Newspapers are 50 cents a day and ten dollars per month. My blog doesn’t deliver anything but some funny things about me so it is supposed to be about one cent. It should just be a hobby because it doesn’t help me nor others either.

Bloggers may choose traditional media through which they find the necessary “raw materials” for identity (re)construction and discontinue blogging because of the less meaningful contents found in the blogosphere. The bloggers admit the fact that they may not

meet the quality standard of the identity presentation in the market because of the “tacky” nature of the postings and that they also find fun but possibly low-class identities drifting in the blogosphere. This resistance to the commodification of identity denotes a self-critical withdrawal of self from the market. In sum, bloggers retire from the market if they detect the system to be inefficient for their fully descriptive expression of identity, and when they become self-reflective due to the inability to aid others in collecting quality resources for identity. In either case, bloggers abandon the commodifying proposal by the market as a counterproposal for the market system.

Secession

The other type of bloggers who vie with the market hegemony, requiring commodification of identity, abscond or leave the market temporarily or permanently. The temporary escape of bloggers from the market corroborates Kozinets’s (2002) account that indoctrinates the unfeasibility of complete aloofness from the market. They “submerge and surface (a direct translation of a Korean slang)” as they perceive the commodification of identity differently in terms of the level of exploitation, distortedness, sublimation, and showiness of the commodified identities in the blogosphere. The bloggers who leave the market temporarily are lukewarm identity creators and suppliers; they return to the system as they find it necessary. They may once again need some ingredients for their identity renovation, or want to be a popular identity supplier. TK writes:

I’m going to submerge for the time being or maybe forever. Please don’t ask me why because I know you feel like doing the same thing sometimes for some reasons. Doing this thing is just sick and tired and exhausts me. People talk whatever way they want... talk too much about my stuff, and the problem is that I keep doing this even though I hate them. Actually, I don’t hate the people, but I hate this thing existing for us. For us??? Well, for somebody else, not me...

Whether the submergence is an escape or just an impermanent lukewarmness depends on whether the blogger opts to come back to the commodifying space or vanishes from the market for identity projects service. Bloggers, however, tend to make a second or further launch of their identity showcases after an optimal length of cessation of work. A back-to-work blogger JW advertises in his blog:

Folks, I’m back here. I hope you haven’t missed me too much. I will post so enthusiastically from now on. I think I have found more things to amuse you guys. Well, I think I was wrong to think this is a totally crappy thing to do. I am happy to realize that I need this thing because it makes me alive. Unexposed existences are all dead.

Bloggers who actually disappear from the blogosphere are also observed. Nevertheless, it is also detected that many of them still opportunistically peep into the market as they visit blogs. They are still consumers of commodified identities but not producers of them. Their effort to manage the relationship in the blogosphere is partially successful, which, in turn, signifies that consumers may imperfectly escape the market by discarding one of the roles (consuming and producing) in the market. The discourse of power in the marketplace becomes nihilistic if both roles are disposed.

Viruses

Although the discussion of viral marketing may not be thorough in this study, the significance of the phenomenal marketing activity is exceptional because of its potential to be a new promotional device for voluntary commodification of identity. The market sustains its efficiency and dominion over consumers in the blogosphere through the incorporation of more explicit marketization of identity symbols. Branding itself and the following instillation of brand images and meanings can be more effective and widespread as intended (c.f., Leskovec, Adamic, and Huberman 2007). The blogger body serves as a host of the viruses, even though they oppose the mass-objectification of subjectivity, inasmuch as the market provides novel, acceptable, and utilizable identity materials: brands and the brand spirit. Figure 3 illustrates the use of a brand by the market in order to coordinate the power flow in the blogosphere. Moreover, the paradoxical tension between a blogger and the blogger body is diminished as they agree to transmit and share mutually beneficial brand images and cultures as identity resources. Consequently, the market always functions as an unavoidable power source that nullifies the superfluous struggle for power and encourages sustainable symbiosis (e.g., Schouten and McAlexander 1995) in the online identity project service market.

DISCUSSION

The marketplace conflict stabilized and digested through the transmittance of viral branding strategies reorganizes the market system (e.g., Giesler 2008). Therefore, the commensal relationship between the market and consumers is again substantiated. The historically and theoretically irrefutable concept of co-optation in a close relation to the discourse of power is also to appear in the online marketplace (see Thompson and Coskuner-Balli 2007 for co-optation). That is, the theoretical twist found in this study is that the triadic power relationship possibly renders a new type of co-optation. In the power structure, the market appears to co-opt the ability of consumers to efficiently and immediately distribute the brands and the relevant ideas, instead of appropriating the consumers’ cultural competency that may well be marketized. This co-optation may generate less negative repercussions in the marketplace than the co-optation in the traditional viewpoint does because the consumers in search of identity resources can collaborate in obtaining and delivering brands as identity resources.

The viral brands can, nonetheless, regress to the historical model of branding that Holt (2002) presents. The pursuit of sovereignty of consumers again contradicts the viruses (brands) that may be transmitted too fast and too widely. After a certain point, the brands do not serve as the identity project service due to the possibility that consumers’ identities can no longer be individuated but manufactured. The marketplace turmoil may be just around the corner once again.

In response to this dialectical discussion on the evolutionary market, consumer culture research should embark upon two agendas. First, the discourse of power in the triadic power structure found in the study must be followed by a closer investigation of the “modest” power management of the market. The nature of the power management realized by the concept of viral marketing should differentiate it from the historical market hegemony, which may be more explicit, coercive, and homogenizing. It is certainly of interest and significance because the bloggers voluntarily participate in the “totalizing logic” (c.f., Firat and Venkatesh 1995). Second, the concept of co-optation also needs to be theoretically dissected due to the newly explored type of co-optation in the study. Consumers’ cultural creativeness and the capability of disseminating brand cultures may not be the all to be co-opted.

FIGURE 3
Viral Brand in the Blogosphere

EXR is an apparel brand in Korea that cooperates with Cyworld to promote their brand and infuse their brand culture into the blogger body. A large number of bloggers visit the blog to obtain resources for their identity.

The Effect of Gender and Product Categories on Consumer Online Information Search

Jooyoung Park, Korea Advanced Institute of Science and Technology, Korea
Yeosun Yoon, Korea Advanced Institute of Science and Technology, Korea
Byungtae Lee, Korea Advanced Institute of Science and Technology, Korea

ABSTRACT

This article analyzes clickstream data collected from a popular online retailer to observe actual consumers' information search behavior in terms of both gender and product categories. The results show that, compared to males, females tend to be comprehensive processors, searching for more product information including customer reviews and using an assistant agent more while shopping online. Also, unlike males, females use both customer reviews and the assistant agent significantly more when shopping for experience goods than when shopping for search goods. These results will help academics and practitioners to have a deeper understanding in consumer behavior in the online context.

INTRODUCTION AND BACKGROUND

With the advance of Internet accessibility and the reduction in service delivery costs, online shopping has continued to grow over the past years. In 2005, the volume of consumption through online retailing in the United States rose by more than 20% compared to 2004 (Mulpuru, Johnson, and Tesch 2006), and reached \$100 billion in 2006, indicating that the Internet has emerged as a significant marketplace today (Cassis 2007).

As more and more consumers visit the Internet to shop, researchers have explored various characteristics of the Internet to observe their influences on consumer behavior in the online shopping environment. Many studies have addressed that the most commonly cited reason that consumers purchase online is the widespread availability of information on the Internet (Wolfenbarger and Gilly 2001). In addition to the voluminous information, online retailers also enable consumers to have interactive experience by providing shopping aids, such as customer reviews or assistant agents. The abundant information and the interactive experience seem to enable the Internet to realize the expectation that it would become an important retailing channel.

Even though the growth of the online marketplaces appears to be evident, both academics and marketing managers argue that consumers are still reluctant to shop on the Internet. Researchers said that, contrary to the traditional shopping environment, consumers perceive greater risks toward online shopping due to limited physical contact with products or services (Korgaonkar and Wolin 2006). According to Korgaonkar et al. (2006), consumers are especially less willing to purchase experiential products online, because they are unable to determine the product quality prior to the actual purchase (Nelson 1974). In addition, several researchers suggest that the perceived risks are significantly affected by personal factors such as gender (Kehoe, Pitkow, and Morton 1997). Kehoe et al. (1997) said that since females have higher levels of computer anxiety and are more emotionally vulnerable to lack of interaction with other people, they tend to perceive greater risks toward online shopping than men and become reluctant to shop and purchase online.

Past studies imply that both product characteristics and gender are important factors that influence online shopping and purchasing. However, there has been little research into the influence of gender and product characteristics on consumer behavior in the online shopping context. As a result, despite prior research efforts, less is known about how males and females differ in their informa-

tion search behavior in the online shopping process. Since understanding consumers' information search behavior is critical to provide consumers with better shopping experience, the primary objective of this research is to examine gender differences in information search behavior in the online channel and to show how gender differences are manifested in shopping for different types of product categories.

LITERATURE REVIEW AND HYPOTHESES

Gender Differences in the Variety of Information Search

A commonly cited theory related to gender differences, the selectivity model (Meyers-Levy 1989; Meyers-Levy and Maheswaran 1991; Meyers-Levy and Sternthal 1991) describes gender differences in the information process. According to this model, males are regarded as 'selective processors', while females are considered 'comprehensive processors' in terms of information processing. That is, males acquire information in a heuristic fashion, therefore missing subtle cues, whereas females tend to engage in an effortful, comprehensive and itemized analysis of all possible information.

Several studies have observed gender differences in the consumer shopping context as well. Campbell (2000) proposed the principal ideological differences between males and females in the context of shopping. He said that males generally view shopping as something that is 'needs-driven', so they tend to form negative attitudes toward it. Additionally, they see it as a work to be accomplished with minimum input of time and effort. On the other hand, females consider it enjoyable and associate it with a leisure frame and form highly positive attitudes. Corresponding to previous research on the information search process, several studies centered on the shopping context found that, unlike females, males simplify the shopping process by attending to a smaller number of information sources, with the intention of obtaining the actual goods with the least "fuss" (Laroche, Saad, Cleveland, and Browne 2000). Following the previous research on gender differences in the information search process, we expect that females would search for more information by visiting a greater number of product pages than males would in the online shopping process. Therefore, the first hypothesis follows:

H1: Compared to males, females are likely to search for more information by visiting more product pages in the online shopping process.

Gender Differences in Social Interaction

According to Carlson (1971), males are more likely to be guided by agentic goals, whereas females may be guided by communal goals. Specifically, studies on gender differences in motivational orientation found that males are motivated by achievement needs and directed towards individualistic tasks (Venkatesh and Morris 2000). Males are also more likely to be independent or assertive (Venkatesh et al. 2000), while females are more sympathetic and prefer harmony (Briton and Hall 1995). Also, Meyers-Levy (1989) further suggested that these gender differences in the goal orientation have a significant effect on information processing.

Especially, females are generally more willing to share personal information and change their behaviors through interactions with others compared to males (Brannon 1999).

Unlike the direct face-to-face relationships between sellers and buyers in the traditional shopping context, the relationship in the online context is between buyers and the mediated environment, resulting in lack of social interaction. Instead of physical contact with products and face-to-face interactions with a salesperson in the brick-and-mortar retailers, online retailers try to offer similar experiences through interactive decision aids such as customer reviews and an assistant agent. Customer reviews are defined as a type of product information created by users based on their own experiences, working as sales assistants to help consumers identify the products that best match their expected usage conditions (Chen and Xie 2004). Acknowledging the interactive characteristics of customer reviews, Chen et al. (2004) stated that customer reviews are a new element of marketing communications.

Abundant research has stated that salespersons play an important role in the market place. Specifically, Meyer (1990) suggested two distinct benefits of consumers' interaction with salespersons. Firstly, the functional benefit is defined as a consumer's desire to get help from a salesperson to fulfill his or her needs. Also, researchers argue that the social aspects of a customer-salesperson relationship are critical as much as the functional benefit (Czepiel 1990) since customer's emotional reactions to a personal interaction with a salesperson may influence the customer's overall satisfaction with the purchase experience (Westbrook 1981) and future purchase intentions (Babin 1995). In the online context, a salesperson is not physically present, even though a help from salespersons is indeed necessary. In order to resolve consumers' frustrating experience caused by the lack of salesperson's assistance, online retailers provide an assistant agent to enhance consumers' shopping experience by responding consumers' inquiries and requests. Importantly, this agent also provides online consumers with a kind of social interaction with salespersons, allowing the consumers to ask for information about their orders, products or services on the website.

Given that distinct goal orientations generate the gender differences in the information processing, we assume that females will be more likely to interact with other consumers through customer reviews and an assistant agent.

H2a: Compared to males, females are likely to read customer reviews on products or services more in the online shopping process.

H2b: Compared to males, females are likely to use an assistant agent more in the online shopping process.

Gender Differences in the Perceived Risks

One stream of research on gender differences has addressed that specifically females perceive greater risks in a wide variety of domains (Garbarino and Strahilevitz 2004). In the online context, researchers have also found that females tend to perceive greater risks toward online purchasing (Garbarino, et al. 2004). As consumers are less willing to purchase when they perceive more risks (Shimp and Bearden 1982), results from previous studies indicate that women are less willing to purchase online and spend less money than men (Allen 2001), while men perceive the characteristics of online shopping more favorably than women (Slyke, Comunale, and Belanger 2002).

With the purpose of exploring the influence of the characteristics of products or services on the consumer information search process, researchers have categorized products in terms of whether the quality of goods or services can be verified prior to purchase.

Most commonly cited, Nelson's (1974) theory suggests two product categories: search goods and experience goods. Search goods refer to products or services for which the most critical attributes can be evaluated before purchase. On the other hand, experience goods are products or services for which the cost to evaluate the most essential attributes is so high that direct experience is often the evaluation method with the lowest costs in terms of time, money, cognitive effort, or other resources (Nelson 1974).

Although the Internet enables consumers to search for enormous information, the Internet interrupts consumers' experiences involving the sense of touch or feel (Burke 1997). According to Korgaonkar, Silverblatt, and Girard (2006), the perceived risks are greater for experience goods than for search goods because of this limited experience like directly touching or feeling products in the online environment.

Since female customers tend to perceive greater risks than males, and the risks are even enhanced when shopping for experience goods than when shopping for search goods, we believe that females would read more customer reviews and use an assistant agent more frequently when shopping for experience goods than when shopping for search goods. We propose the following:

H3a: Compared to males, females are likely to read customer reviews more when shopping for experience goods than when shopping for search goods in the online shopping process.

H3b: Compared to males, females are likely to use an assistant agent more when shopping for experience goods than when shopping for search goods in the online shopping process.

METHOD

Data Collection

When a consumer visits several pages of an online retailer, the separate records of those pages construct a "path", sometimes called "clickstream" in the form of a log file. This clickstream data includes information about each customer's ID, requested pages, visited time, software connected through, and personal information such as the email address and name. Based on the information involved in the clickstream data, we can directly observe what kinds of pages consumers visit while shopping online. For this reason, researchers commonly analyze the clickstream data to examine consumer behavior on the Internet (Bucklin, Bell, and Sismeiro 2000).

Online retailers collect records of visits by all customers on visits in their database. The information provided by this data is quite realistic, companies are often reluctant to provide data due to customer privacy. Fortunately, however, seeing the significance of our research, the online retailer that we contacted provided us with their data, given the condition that consumer privacy is protected. The online retailer providing the data opened the online website in August 2001, and became one of the biggest online retailers in Korea, earning more than \$108 million in 2006. Similar to one of most popular online retailers in the US, Amazon.com, the online retailer places various products and services ranging from electronics to groceries.

We asked for all records of pages that customers have viewed during a month from July 1 through July 31 in 2006. In order to make the data usable for our research, we went through several steps of dividing the data into analyzable forms. Since we focus on the information search behavior during each visit to the online retailer, we divided the whole data into individual visits by each consumer, which are called "sessions." Practitioners often define a session

when a consumer is inactive for a certain amount of time. The online retailer that provided the data also defined each session by 60 minutes of inactivity. In this basis, we first separated the data into a set of sessions of each visitor, and then kept only one visit for each consumer to make the data more representative. We also deleted data containing less than five pages, because it is meaningless to examine those data including little information. Finally, after preprocessing the data, we matched them with the customer demographic file to identify consumer information.

Measurement

Independent Variables

Gender. To compare the information search behavior in the online shopping context between males and females, we included gender information in the preprocessed data, denoting gender by 0 or 1 (0=female, 1=male).

Product Category. In order to observe the effect of product characteristics in the online retailers, we chose two product categories: clothing and electronic appliances including personal computers. These two product categories are most frequently purchased in the online retailer. Also, Girard, Silverblatt, and Korgaonkar (2002) categorized personal computers as search products and clothing as experience goods. Consistent with this categorization, we selected clothing for experience goods and electronic appliances including personal computers for search goods. We denoted the electronic appliances category by 1 and the clothing category by 2.

Dependent Variables

Pageviews. Studies that analyzed clickstream data commonly measure pageviews, the number of pages viewed, to observe consumer information search behavior. Similarly, we measured the number of product pages that the consumers visited to measure the variety of information search.

Customer Reviews. To identify how males and females rely differently on customer reviews, we counted the number of customer reviews that a consumer read during a session. Therefore, a greater number of customer reviews implies a higher tendency to rely on customer reviews.

Assistant Agent. For the purpose of observing gender differences in the use of an assistant agent, we counted the number of clicks on an assistant agent to request information about the products or services. The result implies that the greater the number of clicks on an assistant agent is, the more consumers request for assistants.

RESULTS

Sample Description

Over a period of a month, 377,797 visits were recorded in the database of the online retailer, but only 890 data items, consisting of 618 females and 272 males who visited clothing and electronic appliances categories, satisfied our criteria and were included in the data analysis. According to the statistics of total visitors to the retailer, 59.4% of the visitors were females and the average age of the visitors was 39. Because females are generally more interested in the clothing category (Zhou, Dai, and Zhang 2007), the final data includes a higher percentage of females than the average of total visitors. Specifically, 151 females and 155 males were examined in the electronic appliances category, whereas 467 females and 117 males were considered for clothing category.

Hypothesis Testing

To investigate gender differences in the variety of searching for information in the online context, we first compared the numbers of product pages visited between males and females. As

expected, the number of product pages visited by females differed significantly from that of males ($M_{\text{males}}=5.73$, $M_{\text{females}}=8.36$). An ANOVA showed that the mean of the number of products that viewed for females was greater than that of males ($F(1, 888)=9.707$, $p<.003$).

Secondly, we observed gender differences in the use of decision aids. Hypothesis 2a suggests gender differences in the utilization of customer reviews in the online shopping process: females will read more customer reviews than males. The result shows that females actually used customer reviews significantly more than males ($M_{\text{males}}=.91$, $M_{\text{females}}=3.83$, $F(1, 888)=26.247$, $p<.001$). Additionally, females were also more likely to read customer reviews than males. While 21.7% of males read customer reviews, 46.3% of females did so ($\chi^2=48.100$, $p<.001$). Hypothesis 2b addresses gender differences in the use of an assistant agent in the online shopping process. The results show that females asked for help more often than males do ($M_{\text{males}}=0.67$, $M_{\text{females}}=1.17$, $F(1, 888)=7.174$, $p<.009$). Furthermore, females were more likely to use an assistant agent than males ($M_{\text{males}}=19\%$, $M_{\text{females}}=29\%$, $\chi^2=9.244$, $p<.004$). As we have hypothesized, females used customer reviews as well as an assistant agent more frequently than males.

Finally, we observed the interaction effect of gender and product categories on consumer information search behavior. According to the results of an ANOVA analysis, females read more customer reviews when shopping for experience goods than when shopping for search goods ($M_{\text{experience}}=4.42$, $M_{\text{search}}=2.01$). On the other hand, there was no difference in the use of customer reviews for males across product categories ($M_{\text{experience}}=.91$, $M_{\text{search}}=.91$). This interaction effect ($F(3, 886)=12.488$, $p<.001$) implies that only females were sensitive to product categories when shopping online (figure 1). By comparing the percentage of online shoppers' use of customer reviews across two product categories, we also found that females were more likely to read customer reviews when shopping for experience goods than when shopping for search goods ($M_{\text{experience}}=49.9\%$, $M_{\text{search}}=35.1\%$, $\chi^2=10.044$, $p<.003$). Again, unlike females, males did not show significant difference in the willingness to rely on customer reviews across product categories ($M_{\text{experience}}=24.8\%$, $M_{\text{search}}=19.4\%$; $\chi^2=1.158$, $p>.301$). Lastly, we observed gender differences in the use of an assistant agent when shopping for different product categories. An ANOVA reveals that only females showed significant differences in the use of an assistant agent depending on product categories ($F(3, 886)=3.917$, $p<.01$) (figure 2). Females used an assistant agent to a greater degree when shopping for experience goods than when shopping for search goods ($M_{\text{experience}}=1.29$, $M_{\text{search}}=0.81$). The additional analysis demonstrates that females were more willing to use an assistant agent when shopping for experience goods than when shopping for search goods ($M_{\text{experience}}=32\%$, $M_{\text{search}}=19\%$, $\chi^2=8.975$, $p<.004$). Again, males did not show any significant differences in the use of an assistant agent across two product categories ($M_{\text{experience}}=21\%$, $M_{\text{search}}=17\%$, $\chi^2=.672$, $p>.439$).

DISCUSSION

The purpose of this research is to understand how gender and product categories influence the consumer information search behavior in the online context. Our results show that, compared to males, females tend to search for various information including both product and customer reviews and to use an assistant agent more frequently in the online shopping process. Consistent with the selectivity model (Meyers-Levy 1989; Meyers-Levy et al. 1991; Meyers-Levy et al. 1991), the results imply that females are more likely to be comprehensive processors than males in the online

FIGURE 1

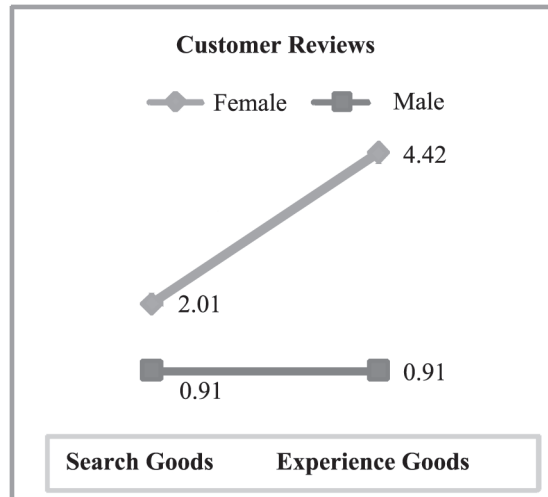

FIGURE 2

environment. According to previous studies on perceived risks in the online context, we suggest the interaction effect of gender and product categories on the consumer information search behavior with the online retailers where the physical contact with products or services is limited. Specifically, females consulted customer reviews and used an assistant agent more often when shopping for experience goods than when shopping for search goods. On the other hands, males showed no significant differences in information search across product categories. This implies that the influence of product characteristics on consumers' information search differs between males and females.

The findings of the present study have significant theoretical implications. Foremost, unlike most behavioral studies that examined perception or attitudes of consumers, this article observed actual behaviors by analyzing data derived from a popular online retailer. Therefore, by keeping track of the actual consumer behaviors in the shopping process, the present research would contribute to making more accurate predictions on the consumer behaviors in the online context. The present research also expands theorists' current understanding of online consumers in terms of both personal factors and product characteristics.

Our findings from the real world data could help practitioners apply the results directly to their online retailers. Considering the evidence that females perceive greater risks toward online shopping, managers should try to decrease the perceived risks felt by females by providing various information sources, such as customer reviews. Our research also suggests that degrees of consumers' desire for interactive experiences differ depending on gender and product categories in the online context. We recommend online retailers to furnish various interactive website features, such as real-time interaction with salespersons, to make the online shopping experience more comparable to the traditional shopping experience especially for females who are shopping for experience goods.

LIMITATIONS AND FUTURE RESEARCH

Despite several contributions, this research should have some limitations. First of all, the data included in this research is collected from one single online shopping retailer. Therefore, further data collection from globally dominant online retailers will help to generalize the results.

Second, the present research involves only two types of product categories, clothing and electronic appliances. However,

researchers have categorized products or services in various ways. For instance, Copeland (1923) classified goods according to the degree of effort consumers are likely to expend and the degree of preference formation at the beginning of the shopping process: convenience, shopping, and specialty goods. Therefore, future research can examine the influence of product characteristics on consumer information search behaviors based on different classifications of product types.

Previous studies have suggested that computer experience (Slyke et al. 2002), the amount of computer training (Liao and Cheung 2001), and the knowledge of online shopping are positively related to consumers' adoption of online shopping. Since consumers' knowledge and experience of shopping increase as their use of the Internet grows, consumer information search behavior will also change accordingly. Therefore, further research is needed to observe how consumer online shopping behavior, especially information search behavior, evolves over time with more experience.

The Body and Technology: Discourses Shaping Consumer Experience and Marketing Communications of Technological Products and Services

Margo Buchanan-Oliver, The University of Auckland, New Zealand
Angela Cruz, The University of Auckland, New Zealand

ABSTRACT

Frontiers of thought in other disciplines, popular culture, and marketing communications are continually 're-visioning' technology and influencing how consumers think about and experience technology-based products and services. Providing a glimpse into these frontiers, this paper re-introduces the body into theorisations of consumer-technology interaction and reviews interdisciplinary discourses shaping views of the body and technology. The key theoretical discourses of body-machine liminality, control and freedom, embodied interaction, and identity are discussed. These discourses expand conceptualisations of technology beyond a limiting focus on functional benefits, offering new frames and foundations for investigating consumer experience and marketing communications of technology-based offerings.

INTRODUCTION

How do consumers understand and experience technology? How do marketers and advertisers communicate these experiences in a compelling way? In addressing these issues, present theorisations of consumer-technology interaction in marketing literature offer a narrow perspective, with a lack of attention to the body restricting the focus of marketing theory to the functional benefits of technology.

Underlying this pervasive disembodiment of the consumer is an assumed Cartesian dualism which not only separates the mind from the body but also privileges the former over the latter. Such dualism is evident, for instance, in the assumption of a simple dichotomy between the online self and the physical self in explaining consumers' construction of online identities (Schau and Gilly 2003). However, this Cartesian dualism underlying dominant conceptions of the self in consumer research is profoundly unsettled by consumers' interaction with increasingly ubiquitous technologies. Today, there is a proliferation of mechanical, digital, and biomedical technologies which not only allow consumers to transform and communicate their bodies across time and space (e.g. avatars in immersive virtual environments such as *Second Life*), transport themselves beyond their immediate physical location (e.g. cell phones), but also increasingly merge with and enter consumers' bodies in a more literal sense (e.g. pacemakers). Thus, such interactions are destabilising the traditional mapping of the individual self onto a single biological body.

In addition, rather than a natural, pre-determined, and discretely-bounded entity, the body is increasingly revealed as a malleable and porous construction. Not only does the body function as a site for multiple, shifting layers of cultural meaning (Schroeder and Dobers 2006), but its actual materiality is similarly elastic. Featherstone (2000), for instance, sees body modification ranging from simple prosthetic devices to enhance body motor and sensory functions (e.g. spectacles), to the building of technological environments around the body, to the incorporation of technology into the body. These interactions reveal a complex negotiation occurring in the boundary between the body and technology than is initially apparent through a Cartesian-framed first glance. In essence, the ubiquity of machines and the diversity of consumers' interactions with them are dramatically dissolving the boundaries between the body and technology and raising fundamental questions about what it means to be and to have a body, and what it means to be human, in an environment saturated with technology.

Conversations around these issues have circulated in other academic disciplines, popular imagination, and in marketing communications viz. Apple's classic '1984' advertisement (Scott 1991). Ericsson's 'Designer Technology' print campaign (Schroeder and Dobers 2006), Sony's print campaign for the Memory Stick™ (Venkatesh, Karababa, and Ger 2002), and Nike Lab's 'Les Jumelles' and 'Eye(D)' (Campbell, O'Driscoll, and Saren 2006) television commercials (TVC) have recently been analysed as exemplifying the merger of the body with technology.

These explorations have emerged from a visual cultural approach in marketing communications research. Schroeder and Dobers (2006), for instance, illustrate how visual rhetoric is used in a range of print advertisements to represent information technologies in increasingly corporeal ways, using the body as a means of anthropomorphising abstract technologies and rendering them familiar and accessible. Campbell et al. (2006) have presented a brief typology of visual tropes used to represent the posthuman technologised body, as exemplified in Nike's TVC 'Les Jumelles'.

However, understanding visual rhetoric per se, while insightful, requires contextualisation within existing discourses which inform the construction and interpretation of specific tropes. As Arnould and Thompson (2005, p. 869) note, these "manifestations of consumer culture are constituted, sustained, transformed, and shaped by broader historical forces (such as cultural narratives, myths, and ideologies)." These discourses therefore provide a discursive context to ideologies articulated in consumer narratives around technology (Kozinets 2008). Conversely, as these discourses are largely implicated in the social construction of shared cultural meanings, understanding these discourses also enhances understanding of the wider psychological and socio-cultural implications of such representations in marketing communications. These can be linked to emerging works (Venkatesh et al. 2002; Giesler 2004; Giesler and Venkatesh 2005) exploring the notion of 'posthuman consumer culture' as a theoretical lens for consumer research. Thus, an awareness and understanding of these conversations about the body and technology frames not only visual rhetoric in marketing communications involving the body and technology, but also consumers' phenomenological experience of technology. Clearly, these are fundamental discourses which marketing theory cannot afford to ignore.

METHODOLOGY

To uncover and clarify these discourses, key conceptual and philosophical texts were selected based on their salience for lensing consumers' embodied experience of technology. These were sourced through keyword searches in online ACR proceedings and the ABI/Inform database, and informed by the authors' backgrounds in semiotics, literary theory, postmodern theory, and film, television, and media studies, with further scans conducted through reference lists and Google Scholar. These key works encompassed a range of disciplines including cybernetics, cognitive neuropsychology, media studies, cultural studies and critical theory.

A theoretical discourse analysis methodology guided the induction of discursive categories and related sub-themes from these sources. From each text, main concepts and key themes were identified, which were then categorised into broader themes based on perceived commonalities and linkages. A process of iteration

between the emerging discursive categories and the source texts permitted the development of provisional categories, constructs, and conceptual connections for subsequent exploration, thereby aiding the induction of broader, underlying themes from these sources (Spiggle 1994). Triangulation was further ensured through regular discussions of emerging interpretations between the authors.

DISCOURSES OF THE BODY AND TECHNOLOGY

The key discourses which emerged from this analysis were: body-machine liminality, a dialectic between control and freedom, consumers' embodied interaction with technology, and the body as a site for the (re)production of identity.

Body-Machine Liminality

Liminality refers to "a state of transition between two or more boundaries" (Campbell et al. 2006, p. 3). In the context of consumers' interactions with technology, being liminal describes a condition of hybridity, that is, being simultaneously human and machine, and neither human nor machine. Here the boundaries between the human and machine are confounded and revealed as porous and permeable. As Hayles (1999, p. 2-3) writes, "In the posthuman, there are no essential differences or absolute demarcations between bodily existence and computer simulation, cybernetic mechanism and biological organism, robot teleology and human goals."

This discourse of body-machine liminality is fleshed out in various conceptions of posthumanism and cyborgs. Some writings on posthumanism envisage a dramatic discontinuity between the 'human' and 'posthuman'. For instance, when body performance artist Orlan (1996, p. 91) declares that "the body is obsolete," she makes a distinction between the 'natural' body as defined by evolution and the body that is defined by technology. Such conceptions privilege the idea of a 'natural' body which has only been recently surpassed through technology.

This dichotomy between the pre-technological and post-technological body is challenged by Zylinska (2002) who perceives human identity as "inherently prosthetic" (2002, p.3) and by Clark (2003) who conceives of humans as 'natural-born cyborgs' who utilise technology in such a way that it becomes transparent in use and inseparable from our bodies to "extend our sense of presence and our potential for action" (Clark 2003, p. 125). As Clark notes, the plasticity of the brain permits human subjectivity to range over an interactive network of biological and non-biological components, unconstrained by the "biological skin-bag" (Clark 2003, p. 27).

This posthuman dissolution of boundaries is embodied conceptually, figuratively, and metaphorically in the figure of the cyborg which speaks to the inseparability of the body and machine and as a visual representation of this contradictory union (Haraway 1991). The cyborg not only exemplifies the posthuman era (Clarke 2002, Orlan 1996), it is also a manifest representation that technology is an integral aspect of human identity (Clark 2003; Zylinska 2002a).

Specific aspects of body-machine liminality are outlined below.

Liminality of Substance. There is an increasing difficulty in distinguishing as separate entities the human body from the machines with which it interacts, such that the emergent entities are always human-machine symbionts (Clark 2003). Furthermore, in the more literal sense of cyborgism, non-biological material is already embedded within the body (e.g. pacemakers, hearing aids, contact lenses).

Liminality of Form. Liminality of form occurs when the body and the machine are perceived to resemble one another through repeated metaphorical associations in visual rhetoric (Schroeder and Dobers 2006) and in behavioural repertoires. Developments in

cybernetics and artificial life also illustrate the increasing divestment of human agency onto machines.

Liminality of form is also referenced in the increased plasticity of a biological body in its interaction with technologies such as cosmetic surgery.

Liminality of Location. Human-machine interactions are characterised by an indeterminate mapping of the subject with respect to the corporeal body such as occurs in the immersive virtual environment of *Second Life* where users create real-time three-dimensional online bodies which interact with others. In such spaces location of the self proves problematic. Is the self located in the physical body or the online body, in both, or in neither? Steuer's (1992) concept of 'telepresence', in which the consumer simultaneously perceives both their immediate physical environment and the hypermedia computer-mediated environment (Hoffman and Novak 1996), is apposite here.

Control and Freedom

The body can be seen as both master of and slave to technology. This dialectical master-slave relationship is linked to the indeterminate location of agency within individual and communal bodies.

Agency. In its interaction with technology, the body is no longer privileged as the true site of agency, as the self and its associated capacities for independent action extend beyond the boundaries of the skin and are invested in non-biological artefacts. The notion that humans are not the only ones that have an ability to act is explored in Actor-Network Theory (Latour 1993), in which the distinction between human and non-human agents is seen to be an artificial construction of modernity. What emerges in this discourse is a conception of agency which is not unique to the biological body, but rather distributed over a network of hybrid actors.

Enabled and Dependent Body. While new technologies have the ability to extend or enhance human capability and introduce new functionality in human life, this is accompanied by an increased dependency on these same technologies. Shilling (2005), suggests that prosthetic technologies can be perceived as dependent 'corporeal replacement' (e.g. crutches), or 'cyborgian enhancement', enabling new functionality (e.g. running shoes).

Emancipated and Disciplined Body. Technology can be deployed as an apparatus for the production and control of 'docile bodies' (Foucault 1977) by institutional processes, including marketing (Venkatesh, Meamber, and Firat 1997). Since the industrial era, a drive towards increased control and efficiency have led to the body being seen as an appendage to machines inasmuch as machines are seen to extend the body.

Conversely, interactions with technology may not be reduced to the totalising effects of powerful institutions (de Certeau 1984), as new technologies and cyberspace can promise an emancipatory potential where these computer-mediated environments create an idealised 'public sphere' removed from institutional interest (Habermas 1989; Poster 1997, cited in Lister, Dovey, Giddings, Grant, and Kelly 2003). Clark's (2003) promotion of a 'global informational free lunch' in cyberspace, and Rheingold's (1993) conceptualisation of the virtual community as an 'electronic agora' free from the constraints of the 'electronic panopticon' provide such promise.

Creative and Emulative Body. The question of agency encompasses not only interaction between individual consumers and technology, but also communal interaction between consumers where the social 'linking value' of technology products and services takes precedence over their 'use value' (Cova and Cova

2002), and enables intercorporeality, a sense of being connected to and in communication with other embodied beings.

A similar dialectic to that of emancipation and discipline is theorised with regards to communal bodies, with bodies either mirroring or emulating the meanings available in the surrounding consumer culture (Frank 1990) or creatively subverting these meanings and creating alternatives to mainstream consumer culture (Firat and Venkatesh 1995; Giesler and Venkatesh 2005).

Embodied Interaction

Another central informing discourse concerns embodied interaction at the interface, within which the following themes are articulated.

Sensory Body. Consumers' interface with technology involves the senses and engenders embodied experiences of pleasure or pain. The pleasure of interacting with technology has been explored in concepts such as 'flow' and 'telepresence' in computer-mediated environments (Hoffman and Novak 1996), as instantiated by experiences of 'vicarious kinaesthesia' in the immersive video game experience (Darley 2000). In relation to this, Mirzoeff (1999, p. 92) conceptualises virtuality as the transformation of space away from three-dimensional reality to the "polydimensional interior world of the self," asserting that this is not unique to digital technology. In addition, using the example of putting one's avatar on display in public online platforms, Mirzoeff (1999) describes the pleasure of a highly visualised and sensual experience of being both consumer and commodity.

Conversely, the notion of pain at the interface with the machine is highlighted by considering the violence entailed in body modification and prostheticism. As Zylinska (2002b, p. 214) writes, "Physical violence is a manifestation [...] of power exerted on weak but unsubmitive bodies which are then prosththesized (extended, adjusted, bent, etc.) in an attempt to deprive them of their integrity and inviolability." Consider, for instance, the pain experienced in cosmetic surgery, or the strain of sitting at a computer terminal for extended periods.

Erotic Body. Technology facilitates the reproduction of sexual desire, constructing a body which is either/both desired and desiring. Visual culture is particularly implicated in the production of erotic bodies, with relations of desire constructed between gazing subjects (usually male) and gazed objects (usually female), in which the gazing subject is placed in a position of power and domination over the gazed object. Such relations are evident in the use of pornographic codes, particularly the fetish, in the marketing of digital cameras (Schroeder and McDonagh 2006) to signify liminal zones of danger and excitement. In relation to this, Campbell et al. (2006) explore the liminal characteristics of the 'technological gaze' deployed in Nike's 'Les Jumelles', producing a paradoxically sexualised yet empowered female body.

Identity

Identity is another central informing discourse of the body and technology. In this discourse, the body is viewed as a site of difference between subjects, with technology as an apparatus for the (re)production of such difference. Such 'investments of difference' (Grosz 1994) are crucial to the constitution of identity—a sense of who one is as distinct from some other. From a critical perspective, such investments of difference are also seen to produce differential power relations in society, with hierarchical structures of class, gender, and race persisting in new media in different forms, contrary to utopian notions (Mirzoeff 1999). Discourses of identity centre on the following 'modern' categories of difference.

Gendered Body. Bodies are differentiated in terms of gender and sexuality, producing a binary opposition between male and

female bodies, as well as between 'straight' (heterosexual) and 'queer' (non-heterosexual) bodies. Implicated in the construction of gendered identities are particular technologies and modes of visual representation such as 'faceism' (Schroeder and Borgerson 2007) which reinforce these dichotomies. With respect to the body and technology, the figure of the cyborg is contradictory in that it can be seen to offer both liberatory identifications for women while simultaneously confirming gendered stereotypes (Gonzalez 1999).

Ethnic Body. Bodies are also differentiated in terms of race and ethnicity, producing a binary opposition between Western bodies and 'Oriental' (non-Western) bodies, as framed by a Eurocentric view which privileges the former over the latter (Said 1978). In this view, bodies are conceptualised as semiotically charged carriers of meaning, such that the potential for action in racialised bodies is delimited by their history of meaning (Klesse 2000). In this vein, Gordon (1995, cited in Schroeder 2003) posits the concept of an 'epidermal schema' which suggests a variance in cultural associations attached to different skin colours. Moreover, with regards to the technological reproduction of ethnicity, Hammonds (1999) shows how visual technologies have always been, and still are, implicated in the attempts to establish categories of race.

Political Body. In addition, bodies are differentiated in terms of access to technological resources, producing a hierarchical relation in which the privileged upper class comes to dominate the excluded lower class. An increasing inequality between the technological 'haves' and 'have-nots' led Castells (1996) to coin the term 'digital divide', describing a situation in which access to advanced technology and the ability to realise its full potential is concentrated in the developed world. Inequitable class relations are sustained through this concentration of economic and educational capital in the hands of a privileged few (Bourdieu 1984).

Mutable Body. Bodies are also differentiated in terms of age, with discourses of the cyborg implicitly privileging youth over old age. On one hand, authors such as Farquhar (1999) champion the liberatory potential of the cyborg concept, citing the example of reproductive technologies which enable previously excluded women to become mothers. On the other hand, Woodward (1999) writes of normalising discourses in which 'bad' or monstrous mothers are constructed in relation to 'good' or 'natural' mothers, effectively preventing older women from accessing reproductive technologies. This underlines the differential access to technology for people of different ages, as well as the differential meanings ascribed to different kinds of cyborgs. As Woodward (1994) writes, "most of us fear the future prospect of frailty as a cyborg, "hooked up" [...] to a machine."

IMPLICATIONS AND FURTHER RESEARCH

Communicating Technology

These discourses, which pervade consumer culture predominantly through popular texts and marketing communications, reflect an expanding, if not shifting, cultural zeitgeist with regards to how technology is viewed: technology is not merely all around us; it is (inside) us. Marketing communications needs to reflect these concerns in order to pierce the heart of what technology means to consumers.

With regards to visual rhetoric in marketing communications, therefore, one might ask what discourses predominate and what discourses are missing in the communication of technology, how these might differ across product categories and brands, and how these might relate to advertising resonance. Such an inquiry will not only enable a description of dominant practices in marketing communications, but also highlight under-utilised opportunities for creating more compelling appeals and increasing the cut-through of

marketing messages. It is notable, for instance, that the print advertisements analysed in Schroeder and Dobers (2006) predominantly deploy discourses of functionality or enablement. However, it is conceivable that a message based on the sensory aspects of interaction, or on the 'negative' aspects of interaction such as dependency or addiction, can be equally, if not more, compelling (e.g. video game advertisements).

Thus, for brand managers, marketing communications managers, and advertisers, these discourses provide a compass for navigating the turbulent and mysterious waters of socio-cultural meaning. For a marketer of technology-based products and services in a cluttered communications environment, such a compass is essential for illuminating creative blind spots and finding ways to break out of existing formulations. The ability to create unique and resonant messages, based on knowledge of these discourses and the ways in which these are being deployed in one's industry, would certainly endow one's communications with a competitive edge.

Discourses in Consumer Culture

Moreover, this analysis raises questions around the wider socio-cultural repercussions of deploying these discourses in advertising. With regards to gender identity, for instance, one might consider how the visual trope of representing technology using the female body might reflect and perpetuate differential power relations between men and women. On this note, Clarke (2002, p. 35) observes that "Liminal beings are [...] perceived as polluting [...] and are more often than not characterized as monstrous, diseased, queer, marginal, black, insane or female." In a similar vein, advertisements which deploy 'Oriental' (i.e. non-European) bodies as a more potent symbol of liminality may be seen to reinforce binary narratives of ethnicity.

However, it is interesting to consider not only the ways in which traditional dichotomies are articulated, iterated, and reinforced, but also the ways in which these are disrupted. While technology can be seen as an apparatus for the reproduction of such dichotomies, the multiplicity of ways in which consumers interact with machines underlines the artificial and constructed nature of these oppositions and allows for the emergence of ambiguous 'thirdspaces of knowledge' which unsettle traditional binary categories (Campbell et al. 2006). As Campbell et al. (2006, p. 7) write, "Posthuman images produce paradoxical social meaning," in that they blur "the lines that separate the masculine from the feminine, the mechanical and the visceral, and even the divide between nature and culture." Fundamental questions can therefore be raised about the ontological implications of body-machine liminality, and how this might raise questions about what it means to be human or posthuman (Giesler 2004; Giesler and Venkatesh 2005).

Understanding Consumer Experience

Since images of posthumanism already proliferate in the realm of marketing communications (Schroeder and Dobers 2006; Venkatesh et al. 2002), we need to explore how such images might impact consumer experiences with technology. Consumer ambivalence towards technology as examined by Mick and Fournier (1998) might be impacted by the destabilising effect of posthumanism on 'essential' human nature. It might also be shaped by the socio-culturally contested figure of the cyborg (Clarke 2002).

CONCLUSION

In summary, this paper presented and discussed key discourses shaping consumers' views of the body and technology. Through a

discourse analysis methodology, theoretical perspectives on the body and technology from key works across a range of disciplines were summarised. The central discourses found were: body-machine liminality, a dialectic between control and freedom, consumer experience at the interface, and the (re)production of identity.

These discourses of the body and technology represent the frontier in theorisations of technology and provide a promising platform for further research. In order to create compelling communications resonant with consumers' experiences of technology, a deep understanding of the meanings surrounding the body-technology interface and how these are being read by consumers is required. This can provide an insight not only into the ways in which these representations influence how consumers think about and interact with technology, but also how consumers think about themselves and construct their own identities, thereby opening up and framing much-needed discussion around the wider phenomenological, ideological, and ethical implications of marketing communications practice.

Getting Lost “Into the Wild”: Understanding Consumers’ Movie Enjoyment Through a Narrative Transportation Approach

Wided Batat, University of Poitiers, France
Markus Wohlfeil, University College Cork, Ireland

ABSTRACT

As consumers enjoy watching movies for many reasons, this paper takes an existential-phenomenological perspective to discuss movie consumption as holistic private lived experiences. By using interactive introspection, the two researchers examined their own individual private consumption experiences with the recently released movie *Into the Wild* (US 2007) as a complex tapestry of interrelated factors. The introspective data indicates that a consumer’s personal engagement with the movie narrative, its characters and underlying philosophy is of particular importance for one’s enjoyment of the movie. This allows for and even enhances the consumer’s temporary feeling of complete immersion into the movie’s imaginary world.

INTRODUCTION

For more than a century, consumers all over the world have enjoyed watching movies for many reasons that can range from mere short-term entertainment to the personal experience of complete immersion into the movie narrative (Green, Brock and Kaufman 2004) and identification with its characters (Cohen 2001). Yet, a closer review of the literature on movie consumption indicates that we still lack a full understanding of how an ordinary consumer experiences the consumption of movies and what subjective contribution it makes to one’s quality of life. This scant attention may have resulted from marketing’s primary interest in the economic dimensions of movie consumption, where the focus is often limited to box office performances or the sales and rentals of DVDs in specified markets (De Vany and Walls 2002; Hennig-Thurau, Walsh and Bode 2004; Ravid 1999). In doing so, movie consumption is usually reduced to the mere purchase of individual tangible media formats (Basil 2001; Krugman and Gopal 1991) rather than investigated as the actual consumption of movies as intangible brands in themselves (Wohlfeil and Whelan 2008). In film studies, on the other hand, researchers seek to explain the effects of movies on their audiences by means of audience-response theory (Mulvey 1975; Phillips 2003). This involves trained expert viewers discussing in theory how an imaginary, idealised viewer would respond to movie texts and the cinematic experience by assuming probable motives, expectations and prior knowledge (Hirschman 1999). However, a synthesis of ideas from psychoanalysis, linguistics, semiotics, Marxism and feminism has hereby created the image of a passive viewer, who is vulnerable to the manipulative qualities of the cinematic experience (Phillips 2003). Moreover, expert viewers have often discussed suspected audience responses as a means to advance their own political-ideological agenda (see Mulvey (1975) as an excellent example).

A very different approach was recently taken by Wohlfeil and Whelan (2008), in which one of the authors observed introspectively his own experiential consumption of the movie *Pride & Prejudice* (UK 2005). While they identified a complex tapestry of interconnected factors contributing to a consumer’s movie enjoyment, they found a consumer’s personal engagement with the film narrative and its characters to be of particular importance and provided thereby evidence for the applicability of narrative transportation theory (Gerrig 1993; Green and Brock 2000) to movie consumption. Though primarily applied to reading, this theory suggests that enjoyment can benefit from the experience of being

immersed in a narrative world through cognitive, emotional and imaginary involvement as well as from the consequences of that immersion, which include emotional connections with characters and self-transformations (Green et al. 2004: 311). Transportation is hereby seen as a process by which the consumer actively seeks to be taken away from one’s everyday life into different narrative worlds, where one could experience a different self and engage empathetically with media characters like real friends (Gerrig 1993). This private engagement is further enhanced through out-of-text intertextuality by which the consumer connects the movie to one’s own personal life experiences (Hirschman 2000a; Wohlfeil and Whelan 2008). In a recent study, Argo, Zhui and Dahl (2008) found that consumers’ immersion into melodramatic narratives may be dependent on the level of fictionality, whereby females tend to empathise more readily with narratives that feature factual contents, while males prefer to loose themselves in narratives with highly fictional contents.

But similar to previous studies (i.e. Green and Brock 2000; Rapp and Gerrig 2006), their hypotheses were only tested within laboratory experiments, where the staged and artificial setup had little resemblance to consumers’ real-life experiences. The findings also contradict Wohlfeil and Whelan’s (2008) introspective data, which provide clear evidence that the male researcher empathised and even identified strongly with the rather factual narrative and characters in *Pride & Prejudice* (UK 2005). Hence, the question remains whether there is any evidence that those findings on transportation theory would reflect consumers’ real-lived movie consumption experiences. Taking an existential-phenomenological perspective (Thompson 1997; Thompson, Locander and Pollio 1989), this study therefore aims to provide alternative insights into consumers’ holistic movie consumption experiences. As both authors happen to be of different gender, come from different cultural backgrounds and live in different countries, we will compare, examine and discuss our own individual private lived consumption experiences with the recently released movie *Into the Wild* (Dir.: Sean Penn, US 2007) and how we connected the movie to our personal life experiences by using interactive introspection (Ellis 1991; Wallendorf and Brucks 1993).

METHODOLOGY

In order to truly understand movie consumption as a holistic phenomenological experience from an insider perspective, the focus has to be on the consumer experience in the way it presents itself to consciousness (Merleau-Ponty 1962; Thompson et al. 1989). Subsequently, we used a research method known as subjective personal introspection (SPI), which is an experiential, private self-reflection on joys and sorrows related to consumption and found in one’s own everyday participation in the human condition (Holbrook 1995: 201). This method has an advantage of allowing the researcher for an easy, unlimited 24-hour access to an insider’s lived experiences with the investigated phenomenon without having to wrestle with ethical concerns regarding the informants’ privacy (Brown 1998; Gould 2006). However, this also means that we now have to disappoint all those readers who were expecting to find hard, scientific data obtained through hypothetical-deductive methods. Instead, we followed for this study an approach that could be broadly described as interactive introspection and involves

gaining illuminative subjective insights through comparing, contrasting and interpreting introspective essays (Ellis 1991; Patterson et al. 1998; Wallendorf and Brucks 1993).

As it happens, both authors are of different gender and live in different countries. The first author is female, in her 20s, Algerian, lives in Southern France and is for the purpose of this paper referred to as the female viewer (FV). The second author is male, in his 30s, German, lives in the South of Ireland and is now referred to as the male viewer (MV). Both researchers wrote independently from each other an extensive introspective essay on their personal experiential consumption of the movie *Into the Wild* (Dir.: Sean Penn, US 2007), which, by coincidence, they have both watched recently. Based on Jon Krakauer's bestselling book, the movie retells the true story of Christopher McCandless, a young college graduate who decided to abandon his worldly possessions and leave his perfectly planned out life behind in order to escape the trappings of a society he despised by experiencing natural life in all its immediacy in the Alaskan wilderness. While his journey and view on life touched a number of people along the way, his romantic idealism ultimately leads to his doom at the unforgiving hands of Mother Nature. We then exchanged the two essays and each researcher compared and analysed them for both common emic themes and individual differences (Thompson 1997). Finally, we compared our two personal interpretations of the introspective essays for similarities and/or differences and summarised them accordingly (Gould 2006; Patterson et al. 1998).

MAJOR FINDINGS AND DISCUSSION OF THE DATA

The thorough analysis of the introspective data obtained from our personal holistic lived experiences of consuming *Into the Wild* (US 2007) has revealed some very interesting findings. For both viewers, the essence of our private movie enjoyment was the arousal, pleasure and emotional stimulation obtained from the cinematic consumption experience (Holbrook and Hirschman 1982) rather than from maximising some ominous economic benefits (Basil 2001; Eliashberg and Shugan 1997). However, while a tapestry of interrelated factors contributed to the overall movie consumption experience, both viewers experienced the strong personal emotional engagement with the movie narrative and our subsequent ability to lose ourselves mentally *Into the Wild* (US 2007) as essential to our enjoyment of the movie. This confirmed Wohlfeil and Whelan's (2008) earlier findings, as evidenced in the following extracts:

In terms of the lead character Chris, my relationship with him changed several times over the film. At the beginning, I disliked him because he appears to be another spoiled, rebellious and stupid rich kid that feels himself to be totally misunderstood. Then, when the family history was revealed I started to understand his motivations and even empathised with him in his search for a better, more harmonic life based on love and mutual respect. I even understood when he failed to grab his first opportunity. After all, I have failed to notice a few times as well that everything I was looking for was directly in front of my eyes and I just had to take it, but I was too scared or too stupid to see it. However, after he obviously knew that he has found what he was looking for in the flesh right in front of his eyes and feet and still left to fulfil a naïve, romanticised fantasy, then I thought again "what an idiot!" (MV)

"*Into the Wild*" left me sobbing like a baby; I would go as far as to say uncontrollably—Thank God, I saw this alone and in the

darkness. Regarding the character, one scene that stands out in particular is McCandless killing a moose. It both vividly illustrates an intimate aspect of living in the wild and provides an almost existential moment-to-moment take on the newly discovered aspects of the character. (FV)

The story itself is an incredibly important one. Ever had that feeling of wanting to abandon your existing life and living one step closer to nature? I can't deny being touched by the relationships that Alexander (Emile Hirsch) makes on his travels and I was haunted by images of Alexander desperately trying to get food in the Alaskan wilds, in particular his efforts with a moose. This was storytelling so good it could bring you to tears. I was convinced as to touching the nature of Christopher/Alexander. (FV)

It was a captivating movie experience and I believe that it is one of those movies that you can watch over and over again and each time you will discover something new and different. It's also kind of going on a journey of self-discovery yourself each time you watch the film. My relation to the characters differed. I didn't really identify with anyone of them, but empathised strongly with the hippie couple (Catherine Keener and Brian Dierker), Ron Franz (Hal Holbrook) and even Carine—but the latter could be influenced by my admiration for Jena Malone as the actress who portrayed her. (MV)

Both viewers also experienced an equally intensive level of immersion and empathy with the factual movie narrative. Thus, the introspective data would contradict Argo et al.'s (2008) prediction that a consumer's ability to empathise with melodramatic narratives—whether factual or fictional—would be determined by one's gender. In fact, the data would contradict the suggestion that a consumer's ability to immerse in and empathise with a melodramatic movie narrative would be determined by any of the common socio-demographic variables such as age, ethnicity, nationality or cultural background. But while its intensity may appear to be similar, we discovered nonetheless some interesting differences in each viewer's account of our private lived movie consumption experiences, which influenced the nature of the personal transportation experience and, hence, warrant a closer examination. Although both viewers agreed that each of our private *Into the Wild* (US 2007) consumer experiences started with a search for relevant information across similar media (i.e. magazines, IMDb, websites, TV or YouTube) long before actually watching the movie in the cinema, the type of information we sought and our underlying motivations to do so differed significantly:

Once a couple of years, there comes a movie that is both unapologetically soulful and offers a gentle philosophical take on one of the timeless myths and human tendencies. ... The first time I heard about the film was in January 2008 in a French TV talk show. I decided to learn more about the movie by looking for information on the Internet. ... I ensured myself of the quality of the movie by gathering much information on the story, the character, the moviemaker Sean Penn, magazine criticisms; comments comparison between French and English websites. In addition, I checked for the box office of the English media on Yahoo UK. (FV)

My interest and experiential consumption of this movie actually started already as early as October 2006, when I read in an interview with Jena Malone in *Mean* magazine that it was just

being filmed...As it so happened, in this article she talked not only about her then recent film release "*The Go-Getter*" and her increasing interest in expressing herself in self-produced music and short films, but also that she would soon starting to film "*Into the Wild*" with Sean Penn. Jena Malone then vividly recalls how she had accidentally hung up on Sean Penn when he phoned her at home near Lake Tahoe to cast her, because due to a defective connection she couldn't hear him and thought it was an obscene call. I really loved the way she told the story during the interview...In September 2007, the movie trailer of "*Into the Wild*" appeared on YouTube. Without hesitation I used YouTube Catcher to download the trailer. Not that the trailer was giving much away, but it definitely stimulated an appetite for more in me...Jena Malone being in the movie was enough reason for me to must see it anyway!!! (MV)

As it turned out, the male viewer is the self-confessed fan of a movie actress and much of his interest in the movie, subsequently, stems from her involvement in the movie production. In fact, he became only aware of the movie as a result of reading an interesting interview with her. Furthermore, much of his information search was directly associated with the actress, such as catching glimpses of her in the movie trailer, downloading video clips of her interviews or photos of her at the movie premiere. The female viewer, on the other hand, had no fan-related interests and learnt only by chance about the film in a TV show. Her search for information about the movie was driven by her awakened interest in its mythological narrative (Hirschman 2000b), the true background story and the lead character's philosophical ideals, which have touched her emotionally. The movie, nevertheless, has also awakened in her an admiration for the leading actor Emile Hirsch—though her perception of him blurred increasingly by merging his off-screen persona with his on-screen character.

Emile Hirsch gave the best performance of his career and he literally carried the whole movie on his shoulders...I shared the same values as Emile Hirsch who goes on to display a person, who is selfless and whose goal is simply to go somewhere where he can live peacefully... Throughout, it was Emile's smiles and caring advice that seem to be constant reminders to me to have hope, to believe that there's more out there than the rat race we're so wrapped up in. (FV)

As a result of those different individual motivations for watching this movie, both viewers also differed in our personal engagement with the movie's melodramatic narrative and the characters as well as in the way we actually lost ourselves in the movie experience. As is already evident in the earlier extracts and confirming Wohlfeil and Whelan's (2008) earlier findings, the male viewer engaged very closely and emotionally with the individual characters in the movie—a response that most previous literature only ascribed to female audiences. Oatley (1999) and Cohen (2001) argued that personal engagement with literary characters and their stories in novels can take with increasing level of immersion broadly three different forms. On the weakest level, a consumer merely sympathises with the characters (= feels with them) as a side-participant who likes them. On the next level, the consumer feels empathy for the character (= shares the character's emotions) because of perceived similarities to one's own private experiences. Finally, the consumer identifies with the character (= feels the character's emotions as one's own) for the moment similar to an actor playing a role.

While sympathising with the parents in their desperate, but fruitless search for their son, the male viewer empathised during his movie consumption experience strongly with the hippie couple, Ron Franz and Chris's sister Carine. However, much of his empathy for her may result from his admiration for the actress Jena Malone, who portrayed her. On the other hand, though he didn't directly admit to it, there is also evidence that his ambivalent emotional engagement with the lead character Christopher McCandless is more than positive and negative empathy, but in fact a form of identification (Cohen 2001). Indeed, the use of out-of-text intertextuality (Wohlfeil and Whelan 2008), by which the male viewer connected Christopher's experiences on screen with his personal life experiences, suggests that the character's naivety, idealism, motives and even foolishness served as a mirror through which the male viewer relived his own experiences.

While Chris moves on and meets a kind couple of hippies (Catherine Keener and Brian Dierker) with their own sad background story of a lost son, we can see in flashbacks behind the façade of the McCandless family life. His father is a career-minded individual for whom his family is more or less a necessary status symbol... Chris and Carine are consistently caught up in the middle of [their parents regular] fights or even recipients to the fighting. More and more I was beginning to understand the motivation behind Chris's actions. His journey wasn't really the expressed statement of an over-ideological kid, but a desperate attempt of escaping from the white suburban middle-class society that his family represented. (MV)

And I could fully empathise with him now, as I also sought myself to escape desperately from a (lower working-class) living environment I was growing up in and deeply despised... Most of the time, I was told what I couldn't do and any dream, creativity or ambition for experiencing and doing something different, something that matters, was cruelly slaughtered [by parents, teachers, career counsellors] right from the start... Instead, I ended up working in retailing for years. In all those years, movies provided me with the only source of escape and the only source of inspiration—like Jack London novels did for Chris McCandless. I needed to get out... (MV)

Interestingly, the female viewer did not really sympathise, empathise or even identify with any of the characters as such. In taking a macro-perspective, her transportation experiences were instead based on her personal engagement with the lead character's (and, thus, the story's) philosophical view on looking for the human condition and the meaning of life in modern Western societies rather than with his person. Thus, the female viewer seemed to empathise or even identify herself essentially with the presented ideals by connecting them through out-of-text intertextuality with her own personal ideals and philosophical views—an aspect that the literature on narrative transportation theory has overlooked so far, but would warrant further, more detailed investigation at a different occasion.

The mission of Christopher seemed to be showing that at some point a long time ago, we got so far from what it's really all supposed to be about. He lived by example in showing that the best way to try to figure out, where we went wrong, would be to go back to when man lived in the wild, surviving only on his wits and his instincts. At the end, he made the ultimate sacrifice trying to figure out the answer for us—and he did—that

we are social beings, who need companionship and society to be really happy. (FV)

I think that *Into the Wild* is a gentle mediation on the poetry of the road and the extent to which personal philosophy is coloured by our own bruised sensibilities (some people don't feel they deserve to be loved, says McCandless to the ageing hippie at one point) and drive to be free, primarily free of emotional attachment to people. It explores the thin line between idealism and escapism, freedom from and responsibility to others, and the degree to which our tendency to sleepwalk through our choices can sneak up on the ideal of living in the wild far from the modern society. (FV)

However, despite our different motivations for watching the movie and, subsequently, the different nature of our personal transportation experiences with *Into the Wild*, for both viewers watching a film is like being in a dream where we can enjoy the peaceful moment of losing ourselves into the melodramatic narrative for awhile. Hence, both reviewers engaged in a certain routine of additional consumer behaviour to enhance their movie consumption experiences in advance. The female viewer, for example, discovered that the film was not shown in her local cinema, so that she had to carefully plan for a 1 hour train journey to the nearby city on the weekend, where the movie was actually screened. In order to make the trip worthwhile, she decided to meet up with friends and to go shopping, which she arranged around her main event—the cinematic movie experience.

I learnt that "*Into the Wild*" had only been released in Poitiers, which is an hour journey away from the town I live in. I decided to go there on the next weekend to watch the movie and to spend some time with my friends there. Before booking my train tickets, I first phoned the cinema to enquire about their time schedules for showing *Into the Wild*... The next weekend, I arrived on the morning to have lunch with my friends and do some shopping in the area before going to the cinema. But I did not ask them to go with me to the cinema, because I preferred to be on my own and not to share the movie experience with them for the simple reason that I didn't want to listen to other people's troubles, but to lose myself in the movie's story. (FV)

The male viewer also faced the difficulty that the film wasn't screened in a cinema nearby and had to consider a 50 minutes bus trip towards to a multiplex further away or to wait for the DVD release. Fortunately for him, the local arthouse cinema was showing *Into the Wild* (US 2007) four weeks later and he chose this option at the end. But this also turned out to be an advantage, as he prefers the more personal and intellectual atmosphere of arthouse cinemas in comparison to that of modern multiplexes, which he perceives to be noisy, commoditised and disrespectful to film as an art form with their blockbuster & popcorn diet. Interestingly, both viewers had in common that we prefer to watch movies on our own and not to share the experience with others. While this doesn't necessarily mean that we won't sometimes (but not always) discuss the movie with friends afterwards (!), both of us simply feel that the presence of friends during actually watching the film may only invite continuous comments or chats about private matters that disrupt or even prevent us from enjoying our transportation experiences. In fact, we experience all disruptive influences on our movie enjoyment, which also include late-comers, talking audience members, chatty teenagers and noisy families with kids running wild around, simply as quite annoying and frustrating.

I know only too well that many people decide to go to the cinema on a rather short notice and then often choose the respective movie on the spot—a regrettable habit that has probably emerged from the rise (and partial monopolisation) of the multiplexes and their brainless blockbuster & popcorn diet—but I'm not one of them. ... The good thing about Kino [an arthouse cinema] is that it is visited by an older and more intellectual clientele, which means that the chance of being surrounded by consistently chatting teenagers, running kids and permanently interrupting insensible families, which has become such a common and annoying feature experience with the multiplexes, is close to zero. The diet of independent movies is anyway beyond their interest and intellectual horizon. Thus, the chance to genuinely and truly lose myself in the movie was quite good. (MV)

However, the movie consumption experience didn't stop for both viewers with watching the movie in the cinema. Instead, both of us engaged in efforts to transform our temporary, intangible movie experiences into tangible objects to prolong our enjoyment of the movie, its melodramatic narrative and its atmospheric audiovisual impression on our minds. Therefore, each of us enhanced our movie consumption experience by purchasing movie-related items and merchandising such as a CD of the soundtrack, an original cast-signed movie poster, movie stills and, maybe most important of them all, the movie itself on DVD. The overall aim of this kind of consumer behaviour enabled both viewers to experience the movie enjoyment either once again and/or to provide clues for remembering one's feelings from watching the movie for the first time.

The film went around in my head for days. I purchased on eBay this autographed movie poster, which was personally signed by the entire cast, to decorate the wall of my office directly over my desk. It still hangs there. In the meantime, I also bought on eBay the official press booklet for \$2.99. And I placed already a pre-order on Amazon.com for the region 1 double-disc DVD pack of the film, which will be released on 4th March 2008. The region 2 DVD will be released in the UK one week later and I hope it will also be available in Ireland, because I intend to buy it for my collection as well. (MV)

I was interested in the awesome movie soundtrack of "*Into the Wild*" as well, which was so beautiful and so touching. Eddie Vedder of Pearl Jam was simply brilliant and deserves an Oscar for this effort. All the songs are just so powerful and bring back the deep emotion from the movie. It's simply amazing how Eddie Vedder wrote songs that fit perfectly with Christopher McCandless's story. However, I did not know the singer, but I knew how to deal with this problem. Indeed, I've gone through the same research process in relation to "*Blood Diamond*" in order to identify the singer's name on the Internet. Of course, my primary interest was to check for a free video on YouTube and, then, to buy the soundtrack on CD, because it reminds me of the movie—even if it was a little bit expensive. (FV)

As can be seen from the last extract, the soundtrack of the movie served to enhance the nature of the female viewer's experienced immersion into the movie melodramatic narrative based on her identification with the presented underlying philosophy on the human condition. Yet, not only had the musical soundtrack provided her with this kind of stimulation, but also the impressive and captivating cinematography of the Alaskan wilderness, which fascinated and drew her literally into the narrative. Urry (1990)

proposed that, as an individual chooses to gaze upon a specific place, anticipation is sustained through a variety of distant non-tourist practices, such as films that construct and reinforce the gaze. In recent years, the *Lord of the Rings*-Trilogy and *Whale Rider* are known to have increased public awareness and demand among international tourists for travelling to New Zealand. Hence, by watching *Into the Wild* (US 2007), the female viewer experienced in her the growing desire to visit the shown landscape of Alaska in its natural beauty and purity herself as a tourist one day soon, which also stimulated an interested search on information about Alaska.

After watching *Into the Wild*, my interest in visiting Alaska has intensified. I was inspired to visit some of the locales and landscapes featured in the film. I learned about Alaska through the movie and I was positively influenced by the beautiful areas in the US displayed in "*Into the Wild*". (FV)

CONCLUSIONS

The study's findings clearly prove that movie enjoyment should be understood as a private lived consumption experience that depends on a holistic tapestry of interrelated factors and, subsequently, should be studied in its entire complexity. Subjective personal introspection offers hereby the potential for gaining interesting insights into the private domain of movie consumption that is less accessible to the traditional methods, which focus mainly on the collective domain. In line with previous studies, we found that an individual's personal emotional engagement with the narrative, its characters and underlying philosophy, which allow for the temporary immersion into the movie's world, is of particular importance for one's movie enjoyment. The level and nature of a consumer's experienced immersion into the movie narrative is determined less by age or gender, but by one's very private motives and interests.

The managerial implication of these findings is for film producers to stop heeding the calls of consultants (i.e. De Vany and Walls 2002; Eliashberg and Shugan 1997) for mass-produced, family-friendly, made-by-standard-formula movie packages that serve the smallest common denominator. As consumers want to enjoy the feeling of loosing themselves in the movie consumption experience for diverse personal and intimate motives, the narrative has to be challenging and stimulate personal engagement from a variety of different angles. This would require each movie to be created again as an artistic product rather than as an interchangeable commodity. The point seems to be supported in particular by the recent global success and the growing popularity of both independent films and world cinema movies that tend to provide audiences with unique, interesting, involving, challenging and much more demanding narratives than Hollywood's current standardised and family-friendly blockbuster-diet. Moreover, after loosing their former elitist image, arthouse cinemas and film-clubs in Europe are becoming increasingly popular alternatives to the multiplex cinema chains, which are often the vertically-integrated exhibition division of the major Hollywood studios (Kerrigan and Özbilgin 2002, 2004). Maybe, rather following the advice of accountants and consultants, it is time for film producers to listen again to real consumers as to how and why they enjoy watching movies in order to understand what movie consumption is really all about...

Adults' Consumption of Videogames as Imaginative Escape From Routine

Mike Molesworth, Bournemouth University, UK

ABSTRACT

This paper considers the adult consumption of videogames as a form of escape from routine and often unsatisfactory aspects of consumers' everyday lives. Drawing from a phenomenological study of 24 adult players, I illustrate aspects of escapism through play, specifically: nostalgia; 'everyday' daydreams; media-derived fantasies, and; virtual tourism. I consider these themes in light of the sociology of consumption and of play to highlight adult videogame consumption as a significant trajectory of experiential economies where the market provides commodities that allow for the actualisation of the imagination.

A GROWN-UP VIDEOGAME MARKET

According to Mintel (2006a) UK videogame sales were £2,626m in 2006 and growing at 17%, significantly more than other leisure activities such as pre-recorded music, cinema, live entertainment, or visiting museums and galleries. Globally a similar picture is presented. Kolodny (2006) cites PricewaterhouseCoopers data that predicts that the 2010 global market for videogames may be worth \$46.5 billion. The message from this data and its reporting is that we should 'take videogames seriously' on the basis of their considerable economic contribution.

This market expansion also defies the popular view of videogames as the preoccupation of male teenagers, obsessively playing alone (see Poole, 2001). For example, the Entertainment Software Association's (2007) claims that the average age of players is now 33 and that less than a third are under 18. In the UK over half of adults between 20 and 55 play videogames at least occasionally (Mintel, 2006a) and 17% of adults (over 18) play video games in any one week (Mintel (2006b)). To reinforce the 'importance' of adult digital play, Mintel's (2006b) analysis of UK leisure highlights the very limited amount of time adults have for such activities. Leisure time is precious and more adults than in the past are choosing videogames to fill it. In this paper I therefore provide one account of what adults do with videogames. In doing so I note consumers' use of the imagination-aided by the consumption of technology-to 'escape' the limitations of everyday life.

THE CONSUMPTION OF THE IMAGINATION

It is easy to dismiss escapism as idle daydreaming. Yet there is an established body of work in consumer culture that places the imaginary at the heart of our consumer society. First let's consider imaginative play. The imagination is implicit in the most significant play theories of the 20th century. For example, it is seen in the non-materiality of the 'magic circle' articulated by Huizinga (1938) who goes on to argue for play as a foundation of culture, and in Caillois's (1958) *paidia*, the chaotic, 'free-play' that is the opposite of rule-bound *ludus*. Other theorists such as Turner (1982) and Schechner (1984) are more explicit about the role of imaginative play as an outlet for fantasies that cannot be actualised in everyday social life. Here, aesthetic endeavours are a way to 'deal with' societal issues in a way that is separate from everyday life.

This recognition of the significance of play of the imagination, according to Sutton-Smith (1997), has its roots in the Romantic period as a reaction against the growth of industrialisation and urban lifestyles. As thought and behaviour was increasingly ordered through work practices, a movement grew to free individuals from these constraints. And such a need to escape routine is a central focus of Cohen and Taylor's *Escape Attempts*, (1992). Their

account of resistance to everyday life suggests that as individuals become aware of limitations in the apparently scripted life-plans that society gives them to follow, they seek various strategies to escape them.

What consumer researchers add to this is the detail of how the market now provides both the source material for this imagination, and activities that aid emancipation from routine. The call to consider the fantasy in consumption was first made 25 years ago by Holbrook and Hirschman (1982) and there is now a significant 'playful turn' in consumer research. For example, McCracken (1988) argues that goods may act as bridges to desired, but 'displaced' meanings. Individuals create idealised states of being in their imagination—a golden past, a utopian future, or a promised other land—that are then deliberately removed from the everyday context to avoid possibly that they are revealed as less than what is imagined. Commodities are then used to access these desirable daydreams. This suggests a speculative, 'wishing' mind, disconnected with everyday arrangements, and seeking to actualise fantasy through consumption. The implication is that 'daydreaming' about commodities is more than simple distraction, but rather an activity for meaning making and personal transformation.

Campbell's (1987) sociology of consumption is also consistent with this discourse. He describes a 'modern hedonism' that has developed from a Protestant ethic that suppressed overt desires, and that flourished as indulgent imagination as a result of a Romantic influence. Consumers have therefore become dream-artists who: "*employ their creative, imaginative powers to construct mental images, which they consume for the intrinsic pleasure they provide*" (1987:77). This resonates with characteristics of play, especially Sutton-Smith's (1997) 'play of the imagination' that is based on the same Romantic foundations. For Campbell pleasure is derived from emotional experiences created by the imagination rather than physical ones, but 'modern hedonism' is not, as Boden & Williams (2002) suggest, only a disembodied-mentalist experience, but one where daydreaming *may* result in actualisation in the form of consumption. Consumer goods allow for daydreams to come true and therefore anchor abstract thoughts to the material world. In other words, daydreams are bolted onto material objects or experiences.

Although fantasy *may* feed from an unlimited use of the imagination—i.e. may have no grounding in material existence—such extremes are a problematic way of escaping mundane reality because they cannot transform that reality. As Belk Ger & Askegaard (2003) explain, desire requires there to be hope that the object of desire can be obtained. They also argue that desire is not attached to an object because of its intrinsic qualities, "*but on the consumers' own hopes for an altered state of being*" (Belk et al, 2003:348). Cohen and Taylor express it like this: "*Our sense of the specialness of our inner life, coupled with our fears about allowing it to 'run away with us' may lead us to attempt transformations of reality by bringing our fantasies into the real world. In other words, instead of allowing fantasies to be mere adjuncts to existing scripts, we actually set out to script our fantasies, to give some concrete expression to our imaginings.*" (1992:109)

For example I may happily desire a new car (and subsequent transformed life), but to desire to be a wizard or Jedi would 'normally' be 'futile'. Society therefore has established imagination 'norms', especially related to commodities. Yet Campbell also recognises the potential for novels, films and TV to provide

individuals with the raw material for daydreams. We might now want to add videogames to Campbell's list of media and note that through these technologies, even the desire to do magic may be actualised. This is relatively new. The result, as has been previously argued (Molesworth & Denegri-Knott, 2007), is that there may be a continuum of imaginative labour from daydream to fantasy with varying degrees of potential for actualisation through both material and digital virtual consumption.

So play is at the heart of culture and now of our consumer society and videogames represent a trajectory towards the consumption of fantasy, aided by technology.

RESEARCH METHODS

To understand the lived experience of adult videogame consumption I draw on part of a larger phenomenological study of adult videogame consumption.

There has been growth in the acceptance of interpretive research methods in consumer behaviour over the last 20 years (Arnould & Thompson, 2005; Goulding 1999) with Thompson in particular becoming associated with phenomenology (Thompson, Locander & Pollio, 1989; Thompson 1990; Thompson, Pollio & Locander, 1994; Thompson, 1997) and other consumer researchers also drawing from the lived experiences of consumers. For example Belk and Costas' (1998) investigation of mountain man retreats; Kozinets's (2001) study of Star Trek culture; Kozinets's (2002) study of the Burning Man Festival; Holt's (2002) investigations into consumer resistance to brands; Belk, et al's (2003) investigation into consumer desire; Martin's (2004) study of *Magic the Gathering*, and; Stevens and Maclaren's (2005) study of the use of women's magazines to evoke the imagination. Such studies also provide example of the market's ability to either aid the 'escape', or re-imposes itself after a temporary, 'carnavalesque' period. The result is recognition in consumer research of a desire for escape from societal norms, and a range of interpretive approaches that might be used in such studies. I have drawn on such methods here.

Thompson et al (1989) explain that phenomenological interviews focus on actual experiences of the phenomena under investigation. A phenomenology then seeks to reveal patterns of experience or 'global themes' that are supported by direct references the reported experiences, and as a result the analysis remains closely tied to the specific data generated, and in the 'emic' world of the participant (Thompson et al, 1989). Hence the idea is to generate nuanced narratives of consumers' experiences rather than generalisable theory. The value of such accounts lies in the insight they provide into consumer experiences rather than predictive models.

For a phenomenology sampling is based on participants' ability to relate in detail their experiences of the phenomena under investigation. A small number of participants may be sufficient to arrive at global themes. For example, Thompson (1990) considers the lives of working women with reference to just four interviews; Woodruffe-Burton (1998) considers male shopping using case studies of three men, and; and Holt (2002) considers consumer resistance to brands using 12 participants. Ideally a researcher simply continues to talk with different participants until no new experiences are revealed so that 'exhausting' the range of experience is more important than large samples. For this study I interviewed a total of 24 adult videogame players from a range of social backgrounds, professions, and domestic arrangements in order to understand experiences of consuming videogames. Fieldwork took place in the South of England, over a 5 month period in 2006. Here I draw on the experiences of six participants as illustrative of the themes specifically relating to 'escapism'.

VIDEOGAME CONSUMPTION AND THE IMAGINATION

Four themes emerged from discussions with adult players in the context of escapism: a form of nostalgia; the enactment of 'daydreams' (aspects of people's lives that they would like to be true, or that they once desired, but now cannot hope to achieve in the material world); the exploration of fantasies that are beyond what they might ever experience in the material world, (but which may have been stimulated by books or films), and; the experience of novelty, through 'visiting another world'. I will now illustrate each.

Nostalgia (being as you were)

Most of players I spoke to re-played old games from time to time. For example Matthew is a 26 year-old Soldier who lives with his fiancé in a small house a few miles from the army base where he works. He has recently been posted in Bosnia and in the Middle East and has now decided to get married and leave the army. He explains that most of his friends live either some distance away, or on the base and therefore he seldom socialises with them. Throughout the interviews Matthew recalls playing videogames as a child and teenager. He also explains that he still plays some of these childhood games.

"I asked for the Amiga because what I wanted it for was the Football Manager game you see. And to this day I'm still a massive football manager fan.... And I actually got it for my laptop. I got Championship Manager 94, 95, you know. And it's not so much, it's not a great management game, well it was then, but you know compared to what you've got now, but it's just more the retro thing about going back and doing it. I sit and play; it's good fun. It kind of takes you back to be honest, to whenever you were that age, kind of thing."

Later Matthew tells me more about playing retro games:

"Nothing was better than Championship Manager you know. And that was me, my cousin and my mate, used to sit up for days on end.... And that's why it's on my computer. I guess it's trying to go back to that, but it doesn't feel the same. It's good and it's fun and it's enjoyable, but you know, it's more of a novelty. Whereas before it was.... Because you're not 17 any more. And because the games have progressed I would say. I mean, you're going back, I'm going back, say to Doom, after playing Halo, which is not necessarily the same game but is a game later on and they've evolved so much you know. But when you go back to it, it's not as good as now, At the time that was the best game on the market and it was the best game in the genre that you had and for me there was nothing that could compare at the time, but now there's an absolute host of games that are better, you know, but what they don't have is my cousin and my mate sat there, you know, at whatever age and drinking coke and eating sweets, and eating crisps, playing it, you know.... For me, I had an enjoyable childhood, you know, and even in my teenage years it was enjoyable you see, And I enjoyed it and I enjoyed doing that stuff, you know and ten years, twelve years on and it's responsibility."

Matthew explains a dissatisfaction with the re-experience of playing old games. He is drawn to play them to recapture an experience he remembers as pleasurable, but the experience doesn't live up to the memory that it allows him to access. This is a recurring theme amongst those players that re-played old games. Players have fond memories of games that may have taken up a significant

amount of their younger years. They seek these out, often using emulators, but sometimes re-buying old consoles and games. But the reported experience of re-playing such games is ultimately of disappointment. The warm feeling of nostalgia that accompanies familiar graphics and controls soon fades. The 'problem' with nostalgic play is that players soon realise that 'things have moved on'. At the time players had never seen or experienced anything like it, but in subsequent years technology has developed and the things that make the game originally special, are now 'routine'. Perhaps more significantly, those that they played with are absent. Recognition of this prompts reflection on their own life that has continued along a plan they cannot now change.

Actualising daydreams (being a better you)

Players may look to games for experiences based on things they feel they should have done, but never actually achieved. So Matthew also tells me about playing military combat videogames, explaining why he enjoys such games, and comparing them to actual combat that he has not experienced despite his recent tours of duty.

"You never get to go what you do in the game. Apart from the select few that have been to war and actually done it, you never get to shoot back and this, that and the other, and be involved in real sort of dangerous situations. And I always sort of tell people when they ask, 'would you want to go to war, or would you want to, you know' and soldiers say 'yes'. And why would you want to do that, you say well you know 'would you want to train as a bricklayer and never build a wall', you know, it's what you've been trained for all this time. And you want to see what you are made of when it comes down to it."

Janice is a 39 year-old forklift and delivery driver who lives with her partner in the suburbs of a large city, a long and slow commute from her work. She explains her enduring interest in motor sport. Again she plays games, for example *Grand Turismo*, based on these activities as a substitute for driving in the material world, even though she seems clear that the games are in many ways an inferior experience:

"I enjoy driving and I've done single-seater racing car driving and I enjoy motorcycling, I enjoy going at speed. But you can't do that out on the highways and byways. But you can-it's escapism isn't it-like all of the games and stuff? It doesn't compare to the real thing really, because it's not you know, it's not the real thing is it, but it's as near as damn it and it's probably more than you are ever going to do. You are never going to be able to get into a top class car and drive round the streets of Paris or London or whatever, but it's just escapism isn't it and it's a matter of going at some speed..."

Later in the interview Janice returns to this idea:

"You can't do on the roads, or in my job, what I can do in the game. I can't get into a top class sports car and go hurtling down the road in a race and winning the pot of four grand. I can't do that at work. I take a box of black things over to someone so they can fill them and then bring them back again. At work I behave myself because I don't want to loose my licence and I don't want to loose my job."

Here Janice actualises her interest in racing through a videogame, recognising and overcoming what she perceives as

impossibilities in her work and financial limitations of a low paid job. She cannot afford the exotic cars that she enjoys driving in games, or afford to risk losing her driving licence. Luke, a 29 year-old single web designer provides another account. Here at least part of his actions in videogames are about consumer daydreams that he may still hope to materially actualise. He talks a lot about sports and hobbies, and in particular about his interest in customising cars. He uses games to explore these interests:

"Need for Speed, I would say, has taught me a lot about cars. It's taught me what bits do what to some extent, what you can do to a car to change its performance, that kind of thing. It gives you an incentive to learn things in a way. You are virtually experiencing doing that thing. If they have got it anyway near right, then you will learn. You are not going to learn the handling obviously because there is no feel, but you do learn stuff about travelling on the road.... It's one of the reasons I buy them. It's what I'm interested in. It's a way to learn about things I'm interested in, so it's different to buying books on the subject [laughs] or actually doing them. I've got a Honda CRX, but I haven't done anything to it. I was going to change the air filter on it, maybe the exhaust, and take it from there.... But I would do it in Need for Speed, but I probably wouldn't go out and waste my money in reality [laughs]. That was the reason I bought it, was because I wanted a racing game.... And just this whole modifying thing.... It's crossed my mind to go out and modify the car, but I'm too sensible now, I've had a lot of debts in my time and I hate them so I won't put anything huge on my credit card even though I'd like to.... Because it's easier and cheaper in the game than trying to do it properly [laughs].... To some extent if you want to be at the top of the NBA, or whatever you can do it in a game, probably in a weekend, whereas in life all you are going to hit is rejection and well you might succeed, but the chances are small. So in the game you can achieve it, you know it's achievable, it's not just a pipe dream, sort of thing."

Everyday life seems to produce desires to do things that are not possible because of physical, legal, financial or time constraints. Some of these may be fleeting (a sudden urge to drive fast as a result of a frustrating traffic jam, tempered by threat of speed camera); some may be more enduring such as the desire to be good at sports. These may accumulate over years, yet never be acted on, leaving individuals with a sense of something that might have been and that may be re-visited through game-play. With other daydreams there may still be a hope of some achievement (when finances allow, for example). In various ways games seem to be a way for players to access these daydreams and in doing so keep them alive and/or compensate in some way for their inability to made them happen. This is a role for games that allows specific and managed access to the imagination.

Actualising fantasy (being someone else)

Although the interest of some gamers remains in the order of daydreams, for others games are pleasurable because they address more fantastic imaginings. For example Elaine is an 18 year-old student who lives in a cramped apartment with her divorced mother who often works long hours. They are under considerable financial hardship. Elaine explains that she has few friends and little money to go out socialising. She provides an account of playing *The Sims* that suggests that an individual may use the same game for both daydreaming about their future and to engage with a fiction-derived fantasy. She starts by explains how she creates the 'perfect' life:

"In The Sims I make my own life and it's like me but it's perfect. It's just the way you want your whole life to go, you can just make it happen. Ok, this is where I use the cheat codes, because you can give them lots of money [laughs].... A good house, they don't have to have a job, so they can spend all their time at home [laughs]...., the cheats I use mean that they don't have to cook meals, they don't have to sleep. And I spend the whole time I guess making friends with all of the ones already in the game, so it's just you can see what it would be like if your life was perfect."

Elaine then goes on to tell me about her other 'neighbourhoods' in *The Sims*:

"Well I've got two, I've got one called the Wizarding World, which has all Harry Potter characters in, as well as myself. And then I've got one called Sphera, out of Final Fantasy V. And I've got all of the characters from that in there.... I downloaded all sorts of things, so I can make them fly on broomsticks and things, which you couldn't normally do in the game. And I guess it's just unique and it's kind of like creating your own game. Or your own film. And you can have things go just the way you want them with characters from other things. I mean I've written—sorry about the Harry Potter fixation—fan fiction which is like 400 pages long at the moment, but I can just put that into The Sims and just make that happen. It just feels really good when you see it all done."

Max provides a similar story. He is a 31 year-old overseas PhD student who lives in student accommodation, isolated from friends and family. He explains an enduring interest in the *Star Wars* films and how games have allowed him to inhabit this 'universe'. Like Elaine, Max explains that he has his own version of the films 'in his head'. He has built and maintained his own fantasy space from the raw materials of Lucas's films. Max tells me in detail about many of the *Star Wars* games that he plays but there is a recurring theme:

Jedi Outcast is a game that I play. I've been playing it since it came out. I haven't finished it yet because it has some frustrating bits and then I just put the game away for months and don't touch it.... And Rebel Strike is just a game that I play for the quick fix, you know, flying around, shooting, destroying stuff. I don't like the tactical element in it. I think it's just that I can finally sit in an X-Wing or in a TIE-fighter and shoot stuff, because that's always been one of my dreams."

People gain access to other worlds and experiences through films and books. They come to know of these places and people (or creatures), but only in third person. However games may give them more direct access to these fantasies. They allow players to become the heroes of fictions, or to experience these worlds 'firsthand'. This seems to be a slightly different strategy for dealing with the mundane familiarity of everyday life. Rather than change aspects of that life and live out those changes in a game, players opt to negate the material world altogether in favour of some other type of 'ideal' existence, first imagined, then actualised through a videogame.

Virtual tourism (being somewhere different)

The final way in which these players articulated escapism was in terms of simply wanting to 'be somewhere else' or 'experience something new, beautiful, or exciting'. For example Carl is 40 year-old IT manager. He is married (for the second time) and has 3 children (2 from his first marriage). Carl explains that for him

games are a space away from demanding work and from his complicated family arrangements:

"If I am just having a stroll about in the game then I will play something like Breed where I can go anywhere and I'll just avoid the bad guys, I know where they are so I'll just avoid them and I might have a pop with my snipers rifle occasionally, but really while I'm in there I'm just seeing what is over the next hill. It's quite a clever game Breed is...., it's a bit more free form, which allows you then to take a stroll."

Later Carl returns to explaining the pleasure from simply taking in the beauty of a game.

"I mean sometimes the effects are just so beautifully done and so detailed in the way that they have been produced; how the sprites on the screen are actually detailed and there is a whole area of that that actually draws you into playing the game, you know. Yeh, the aesthetics of it is also something that's important. I suppose that's part of the 'what if'. I mean if I wander about in Breed it is partly the aesthetics, you know, the way that they have designed the building and some of the complexes, it's fascinating, you know. It's actually quite a beautiful game, in quite a raw way.... There is almost a beauty to it, you know the drop ship is like the drop ship out of Aliens with quite a square body and there is a practical feel to it that actually appeals to me and I think that's actually quite real you know."

Towards the end of one interview Carl explains a specific time in his life when he had a need to escape into another world; to 'get away!'

"I think for me personally it was about leaving the world behind. You can do that.... when I went through the divorce I would be at work at seven o'clock sometimes, doing legitimate stuff, but that was also one of my strategies for losing myself. But when I was at home then, especially when the children had gone to bed, I would play games, because I could turn the lights off and my whole world then would be what's on that screen and I could get very, very involved and it didn't involve the pain I was going through. I'm very sure there wasn't transference there. I didn't want to play violent games, so it wasn't me transferring my anger at my ex-wife into a game. I just wanted to get away from it. I wanted to be somewhere else. And in a non-physical way, that was a way of doing that."

Players report taking pleasure in exploring game worlds. Rather than acting out a daydream or fantasy, here the pleasure is in the unknown; the excitement of not knowing what comes next and of having no clear script to act out. So rather than actualising the imagination players are asking for their imagination to be stimulated. Again this may be taken as an attempt to somehow 'deal with' every day life. The same furnishings in the same house, the same desk in the same office, or same shop floor, the same routine tasks re-experienced every day may feed a desire to escape. And in Carl's case, the routine 'pain' of a failing marriage creates an especially strong desire to 'be somewhere else' and videogames facilitate this.

PLAY, THE IMAGINATION AND 'ESCAPE' FROM ROUTINE

I now want to consider the implications for such imagination-based consumption. I start by reviewing the consistency of these

observations with existing 'Romantic' consumption theories and more broadly with theories of play. Here I argue that there is a need for more theoretical consideration of the interactive between consumption, the imagination *and technology*. I also want to consider possible critiques of such consumption activity, noting the tension between the libratory discourse of 'escape' and the market structuring of the imagination.

Players imagine times past, 'lost' and ideal futures, and fantastic worlds, both familiar and novel. In doing so they may temporally and spatially extend their existence in a series of digital virtual activities that seem to confirm McCracken's (1988) strategies for displaced meaning. We might also see such behaviour as contemporary examples of the 'escape attempts' articulated by Cohen and Taylor (1992). As they put it: "*At any moment it is as though we can throw a switch inside our heads and effect some bizarre adjustment to the concrete world which faces us—make horses fly, strip the women, assassinate the boss—or else conjure up an alternative reality...*" (1992:90). Only now the switch is on the console and not just in our head. Videogames provide various ways for the player to remove themselves from their everyday lives. As an ideal commodity form of our time (see Kline Dyer-Witheyford & De Peuter, 2003) games therefore represent a significant point in consumer culture; not just a move from Fordism to experiential consumption, but perhaps to consumption as the actualisation of the imagination, aided by technology. In consuming videogames we are literally buying into our fantasies and this seems a solution to economic and material limitations in markets and in consumers themselves. There is almost no limit to what may be produced and consumed in the digital virtual spaces of videogames. This is also an expanded view of the consumer imagination that doesn't just desire novelty, or desire itself, but also craves the past, fantasy, or just to 'get away' from material reality. Videogames are therefore not trivial, but for these users are significant resources for the management of everyday life.

In terms of Caillois's (1958) broader sociology derived from play videogames and the experiences they create are a reflection of society's rules and freedoms. This idea is also articulated in iterative relationship between the aesthetic and the social that Turner (1982) and Schechner (1984) articulate. The popularity of videogames tells us something about the society we live in. We see adults dealing with a life-world that promises so much more than they might ever materially achieve. This is perhaps less a Romantic society (see Campbell, 1987) than one where consumers' imaginations are over-stimulated, (there is so much to want) in contrast to the reality of a rather mundane adult existence. They then look to marketised technology to bridge this gap.

For example Players find and re-play old games as a conscious way to access memories of pleasurable times in their lives that are now lost to them. However this is seldom a satisfactory approach as such memories provoke a realisation that the past may never be re-created; that they are stuck in their adult world. This is also McCracken's (1998) complaint against nostalgia as a suitable location for displaced meaning.

Other locations may be more suitable for successful actualisation. Games allow for the maintenance of a long-held interest in sport, driving or other 'possible' activity, allowing a player to maintain an interest, but at a distance. Players hold an ideal scenario in which, for example, they are a professional basketball player, or a skilled race driver. Games become a way to access many such desires. When they play, players may experience a temporary and partial actualisation of their daydreams without risk of 'breaking them' by subjecting them the harsh reality of material attempts at such activity with their legal, physical, or financial implications.

For others the media (books and films in particular) form the basis of an imaginary world that exists in their mind in some detail and which may then be enacted in a game. For this group of adults existing media narratives were articulated clearly (*Star Wars* and *Harry Potter*). These 'public' fantasies are sufficiently detailed to allow them to be evoked in the imagination. Players may spend considerable time playing these games, diverting their attention from the circumstances of their daily lives. This is also like the form of distancing described by Cohen and Taylor. By being able to tell themselves that their everyday life isn't 'all they are', players may better manage the scripts of daily routine. And material commodities no longer limit such imaginative acts, as Campbell (1987) and others suggest in theories of imagination-based consumption. Now fantasy becomes that which may be consumed and the limit is the imaginations of writers and filmmakers who may produce fantastic adventures for us to fill our minds with, and then the skills of videogame producers who may create these worlds in a form that we may inhabit. The player is therefore involved in the sort of mental management of scripts that Cohen and Taylor (1992) articulate, balancing a 'mundane' and/or unsatisfactory existence with fantastic escapes.

Cohen and Taylor also see the holiday—that other favourite of the experiential economy—as a potential source of escape from routine and here videogames provide the opportunity for 'virtual tourism', (although perhaps tripism, the term Lehtonen and Maenpaa (1997) give to short recreation shopping excursions, is a better description). Players may take these trips for just an hour or so in the evening. The desire is to simply lose oneself in the spectacle of a previously unseen landscape. As Featherstone (1991) suggests of other contemporary consumer practice, it is controlled decontrolling; a measured and managed sense of other-worldliness, now enabled by technology. We might question the nature of authenticity in such activity. For example both Urry (1990) and Cohen and Taylor (1992) highlight that tourism for many has become the futile search for an authentic experience against the recognition of a manufactured lifestyle. But in games, authenticity is abandoned in favour of endless, novel manufactured worlds. The result is a space where players are free to enjoy an aesthetic experience, and to forget their paramount reality for a while (especially where this reality is depressing or unsatisfactory).

This may all sound liberating, but a critical analysis of such 'escapes' might present videogames as complex leisure 'pacifiers' like those described by Huxley in *Brave New World* (1932). Videogames combine aspects of *Soma*, *Centrifugal Bumble-puppy* and the *Feelies*; they may calm those frustrated with life, involve them in complex and expensive leisure consumption, and/or distract with interactive spectacle. They are a technological cure for the consumer ennui Shankar, Whittaker & Fitchett (2006) describe, leaving players to carry on with the rest of their life-script as planned. Yet we might note that much of their angst for a better life results from market and media derived desire. As consumer culture, games may therefore serve a conservative role, channeling resistance into activities that deflect criticism away from broader market ideology. Like other studies about emancipation from the routines of our *consumer society*, the conclusion is that such escape is ultimately 'futile'.

Yet when Cohen and Taylor re-evaluated their first edition of *Escape Attempts* they noted that they should have: "*shown rather more appreciation of the comic/heroic diversity of people's search for something outside paramount reality... more sensitivity to the idea that the very activity of 'attempting' to escape is an imaginative way to understand more about the limitations of our world.*" (1992:28). Perhaps the same might be true of these players. In

negotiating a mapped-out life with largely predictable scripts these players find ways of using videogames to 'cope' with the frustrations of life and their occasional recognition of its futility, to feed, experience and to actualize their imagination. To reduce players to a predictable 'alienated consumer' script would be a denial of their complex and nuanced life-worlds. Emancipation from the market may be an impossibility for these consumers, as might the material actualization of an 'ideal' life, but their skill and success in 'making the best of it' might still be acknowledged.

Baby-blue “Bullet-proof” Satin Bras: The Excursion Into The Soviet Consumer Realities

Natasha Tolstikova, University of Gloucestershire, UK

INTRODUCTION

Researchers debate if consumer culture in the Soviet Union was a valid phenomenon. Traditional Western view on consumption in the Soviet Union is captured in the statement by Karpova et al (2007). The authors argue that in the Soviet planned economy neither marketplace nor consumers existed in the Western understanding of the terms, mainly because the freedom of choice did not exist (106). However, several researchers demonstrated that Soviet consumer culture, albeit different from that of the Western one, was valid and existed throughout, citing a number of manifestations and elements (e.g. Reid (2002); Kelly and Volkov (1998); Cox (2003)). At the start, it was characterized by shortages and later by the black market; consumer culture has manifested itself through such powerful consumer drives and desires that in post-Soviet times it resulted in the explosion of the market economy. To satisfy purists, we shall call this phenomenon “para-consumer culture,” where the state encouraged the population “to consume in *particular* ways” (Reid 2002, 216) and consumers were skillful in obtaining and interacting with the goods.

To study particulars of Soviet consumer realities has an additional allure because it becomes an arena of the struggle between an ordinary citizen and the state, thus destroying the myth of totality in the totalitarian state. “It was . . . in the everyday that the grand master narrative of the Soviet Union moved in a Bakhtinian sense from the monologic to the polylogic as Soviet citizens proceeded to reformulate or subvert it—not with the intent of bringing down the system, but simply to buy a decent pair of shoes” (Baker 1999, 22). Some researchers argue that it was shortages of goods and faulty distribution that eroded Socialist economies and led to the collapse of the whole system (i.e. Reid 2002).

For the most part of the Soviet history everyday mundane objects such as underwear and undergarments have been ignored or neglected by the economy. The state also instilled certain policies toward underwear not only through its limited production but also through non-action: by ignoring the issue. Yet, the people’s attitudes toward underwear demonstrate a complex web of ingenuity, creativity, and desires. Understandably, there was no need to advertise for the item produced in limited quantities. However, a few images were uncovered. This paper analyses the history, representation, and meaning of Soviet women’s underwear as a manifestation of consumer attitudes and resistance.

This article claims that the gradual strengthening of the Soviet consumer culture was evident in changing social beliefs and attitudes evident in advertising. These changes were reflected in the visual and verbal gestalt of the advertisements. The paper analyzes four advertising posters corresponding to the leadership periods of Lenin, Stalin, Khrushchev, and Brezhnev. Using historical analysis and textual reading, it provides a contextual background to the images that act as “bearers of meaning, reflecting broad societal, cultural and ideological codes” (Schroeder 2006, 9). My method rests upon the iconographic approach envisioned by Panofsky and interpreted by Leeuwen (2001).

Unlike most semiotic analyses that are concerned with signs and their relationships, iconography additionally is preoccupied with the context and “how and why cultural meanings of their visual expressions come about historically” (92). There are three levels of pictorial meaning: representational (similar to “decoding” or description of the images), iconographical symbolism (or relation between objects and signs that concentrates on the concepts at-

tached to images), and iconological symbolism (that identifies ideological meaning of the image) (ibid, 100-101). My analysis will be employed along these three dimensions.

BRIEF HISTORY OF WESTERN WOMEN’S UNDERWEAR

There are two prevalent positions explaining the reason for undergarments to come about: symbolic and practical. Saint-Laurent argued that “the birth of [under]clothing must be placed between that of religion and art, it cannot be compared with weapons, hunting implements or agricultural tools” (1974, 7). As such, social classes signified their status through different wears; different sexes who sported same type of outer clothing (such as togas in Ancient Greece) wore underclothes that were strictly feminine and masculine (36). The other theory holds that early underwear appeared for the reason of protecting the bodies from scratchy and stiff fabric of outerwear and also of protecting expensive costumes “from the dirt of the bodies they adorned” (Wilson 2003, 102). The early underwear did not even resemble contemporary lingerie; in ancient times women wore slips that progressed to Victorian bifurcated undergarments (not, however, connected at the crotch) (Entwistle 2000). Women’s panties in a contemporary form appeared only in the 20th century (Wilson 2003, 102). Whatever the start was, fairly quickly it gained one more function: women’s underwear became a tool of seduction, turning into the kind of clothing that is “more naked than nudity” (Carter 1982, 97). Already in the late Victorian era the appearance and meaning of women’s underwear changed, making it “more elaborate and sexually codified” (Entwistle 2000, 203). Its mere proximity to the skin and its intricate construction with lace, frills, and see-through fabrics made it erotically charged. Particularly, stockings has been a common sex fetish (ibid, 204).

Historically, underwear has been a personal item, visible only to the wearer and to intimate partners. The wide universe of lingerie: panties and brasseries, stockings and garter belts, corsets and girdles long have been mechanisms of transforming the woman’s body into a fashionable shape. With its enhancements, such as pads and whale bones, undergarments have been deceptive by nature; “their function is to make artificial shape seem real” (Saint-Laurent 1974, 68). Jantsen et al. argued that undergarments have been instruments of containment and control of women’s bodies that made them fit the “aesthetic ideals and political concerns of a male-dominated society” (2007: 178). At the same time, their article demonstrates that lingerie empowers women even when she is not in public (ibid).

Curiously, lingerie becomes a meeting point for the public and the private, where outerwear signifies the public and underwear stands for the private. Historically, the first undergarments were originally outer garments (Saint-Laurent 1974, 12). While the underwear grew in numbers and complexity, it was intermittently worn either under the clothes or over the clothes (i.e., according to Renaissance fashion, the bustier was worn over the dress). The distinction is fluid. In the Western culture of the 20th century the deliberate visibility of underwear parallels “ambiguity surrounding privacy, intimacy and sexuality” (Wilson 2003, 107).

Generally, advertising is designed to stir emotions and desires in its target. At first, advertising for underwear was rather modest, praising functionality of the product. At the end of the 19th century, American advertising for corsets emphasized their ability to en-

hance one's figure as well as the comfort and ease of wear (Reichert 2003, 56-60). But soon the practicality was replaced by sensuality and seductive abilities of underwear. By the 1900s, advertisements for stockings commonly displayed women lifting their hems to show off the product (ibid, 83). With the increase in variety of underwear brands, their promotion became more explicit and suggestive, relying on sexual images that activate biological instincts. In his study of sexual images in advertising, Reichert suggested that women in undergarments have been often used as an allure for selling everything—including products that have nothing to do with neither women, nor underwear (ibid).

SOVIET UNDERWEAR

The Bolsheviks had an aspiration to build a new society where the personal would be eliminated and equal citizens would enjoy collective property. Reportedly in the early Soviet communes people shared not only pots and pans but personal clothing, including underwear (see Tolstikova 2001). The ideology of eradicating distinctions between sexes was reflected in the style of the New Soviet body and the style of clothing. The cult of muscular bodies and asceticism was manifested in mass sports parades and unisex clothing, particularly underwear. There were two main unisex items of Soviet underwear, knitted cotton undershirts and boxers which meant to signify comfort, ease of movement, simplicity, and hygiene. Practical Soviet women underwear was designed to better serve the new roles of women's physical activities in the factory and the kitchen (Abrahams, 2006). In the process of creating a New Soviet person, Soviet sexes were merging; a woman meant to be attractive not because of her sexual attributes (highlighted by sexualized underwear), but through her class dignity (Bulgakova 2002).

A woman could easily become an ideological suspect for wearing a dress adorned with frills or silk stockings (Starshinina 2007). In the 1930s, when the country began to militarize, the garment industries worked overtime, producing military uniforms in massive quantities with men's underwear as a part of it. Although, women's underwear was produced as well, the outputs were very limited and it was difficult to buy. As in pre-Industrialization period, women continued to sew their undergarments themselves or to seek services of private seamstresses (ibid). In the planned economy, standards for women underwear were limited. In the 1940, it assumed a single prototype of a brasserie with three sizes (Sevriukova 2006). In the West, since 1920s artificial silk became the fabric of choice for producing intricate underwear and stockings, making them affordable for the masses (Ewing 1974, 88). Similar Soviet items were made of natural fibers such as cotton and wool making them practical but unappealing and even uncomfortable.

In the 1950s, Stalin wanted to project an image of imminent abundance in the desolated war-torn country. Artificial fibers began to be used by consumer industries introducing a Soviet equivalent of nylon—kapron (Fillipov 2007). For the first time, Soviet women could experience an affordable luxury, see-through, sleek, leg-shaping kapron stockings. Nevertheless, women exposed to foreign lingerie in the Second World War became weary of the unseemliness of their underwear. In public perception, undergarments were almost obscene; semantics reflected this attitude—people referred to the specific types by their folk nicknames, such as “the anthracite” for the men's cotton black boxers or “the bullet-proof” for reinforced blue satin bras (Anon 2004-2005). According to the Soviet oral mythology, in the late 1950s, a French movie actor, either Yves Montand or Gérard Philipe or Alain Delon (the mythological details vary depending on the speaker) was so shocked by Soviet underwear that he bought it in large quantities and created a

sensation by displaying his private collection in Paris (Sevriukova 2006).

Soviet attitude towards underclothing was ambiguous. Women were ashamed of its plainness, and while wearing it they exercised rules of modesty. Nevertheless, bras and panties, sometimes, very unsightly, worn and mended, without a shame were hanged outdoors or in communal hallways to dry up after the wash. There was a paradox of chastity bordering on sanctimony when people ignored or even pretended not to notice each other underpants openly displayed in the communal spaces. Because specialized clothing such as swimming or sports suits was difficult to come by, both women and men often wore underwear as outerwear when working on their garden plots, swam or sunbathed (Starshinina 2007), creating ambiguity between private and public.

Living in the system where apparel industries produced uniform-style clothing, and perhaps, because they were forced to have public existence, Soviet women wanted to make their underwear different and distinct. There were few choices available to express their individuality through the underwear. Those, lucky to have a slender built preferred to shop in children's departments: made from multi colored fabrics, the panties for girls was more appealing than adult underwear. In home economics classes, schoolgirls learned how to sew panties; they often made them from colorful calico and adorned with ribbons and lace (Denisova 2002). When a Soviet person was going abroad, usually on business, his female relatives supplied him with a list of everybody's measurements of waists, chests, and the lower bodies so women were able to establish their uniqueness and if not to express their identity, at least to differentiate themselves from others (Culloudon 2004).

The Soviet state tried to control all aspects of human existence, including the underwear. The system supplied the utilitarian bare necessities, depriving women of the symbolic and the sensual. However, after Stalin's death Khrushchev came to power and lifted the symbolic Iron Curtain, exposing the country to foreign fashions, images, and culture. As a by-product, during the 1960s period nicknamed A Thaw, the culture of romanticism with its symbolism and anti-materialism took hold (see Tolstikova 2001). However Brezhnev's times brought individualism, erasing the altruistic revolutionary spirit. The long neglect of consumer desires made some authors to suggest that underwear was never advertised (Culloudon 2004). Using recently published collections of Soviet advertising posters, I was able to uncover a few examples. Soviet underwear advertising reflected the trend shift from the functional to the symbolic. Advertising examples from different eras will provide the visual proof of this transformation.

ANALYSIS

The first example is an agitation poster from 1934 by A. Kokorekin (Snopkov et al. 2004, 158) (Figure 1). The country was in the midst of industrialization with large population migrating to urban centers (Filtzer, 1999). Women had important roles as able-bodied workers and procreators of future generations. The poster propagates physical culture among women. On a representational level, there is a woman in her black underwear in a household setting doing an exercise routine. There is a window behind her and a Vienna back chair with a kitchen towel hanging from it. What looks like a domestic striped rug lies underneath her white sports slippers. The vertical panel on the right shows different exercises for the routine with the words underneath “Daily physical exercise routine—necessary for passing the physical state norms.” The slogan underneath the image states “Be ready for labor and defense!”

Iconographic symbolism that reflects relations between objects signifies the importance of the woman; her stocky and muscular figure with spread arms occupies the center of the poster.

FIGURE 1

FIGURE 2

Traditional fascination with pale refined beauties gave way to respect for the red cheek healthy ideals. The strength of the woman’s body symbolizes the changed roles of women in a proletarian state and the importance of being physically fit and ready to lend her hand to the cause of building the new world order. She, nevertheless, exhibits traditional female traits: she retained long hair gathered in the back of her head, her home is tidy and clean, the kitchen towel is pristine white. The picture is also connected with the future: a traditional peasant physique of a woman is exposed to urban industrial landscapes in her background.

Because it is an example of political agitation, iconological symbolism or ideological meaning of the image, reflects in straightforward verbal propaganda of the text. With particular interest to our central concern, the underwear, there is an affirmation of the naturalness of the women’s body minus its carnal attributes. The woman is primary a worker and a mother, an equal social participant approaching a man in physicality. She wears black underwear that

in Western societies is synonymous with naughtiness (Carter 1974, 96) but was used as sports wear in Soviet Russia on the 1930s. The woman is comfortable in her body and wants to improve it for physical labor. The underwear here is a functional utilitarian item.

The second image is the advertising poster from 1952 by V. Pimenov (Snopkov et al. 2007, 224) (Figure 2). Stalin was still in power, the country was recovering from devastations of the war. Propagating “the myth of abundance,” Stalin forged an ideological consensus with the party elite by improving their everyday life with consumer goods (Fitzler 1999). Developments in chemistry secured new consumer products; one example was women’s stockings. At the first, representational level of the image, we see an upper body of a woman in a frontal position wearing a short-sleeved dress and showing a sheer stocking to the viewer. She occupies the center of the poster, done in a lavender-pink palette. She looks directly at the viewer; her lips are slightly parted into a tentative smile. The headline states, “Kapron stockings. Beautiful, durable, hygienic.” The word “kapron” is in large red cursive serif whereas

FIGURE 3

the rest is in white blocky sans serif on a pink background. The text on top identifies the distributor, “The Ministry of the Light Industry of U.S.S.R. Moscow Distributor of Sewing Goods.” Typical of Soviet merchandize world, there is no brand name or trade mark; we cannot even be sure that the stockings were Soviet made.

Iconographic symbolism of colors tied stockings to delight and calmness; curved lines and the delicacy with which the woman’s hands hold the stocking probably elicited association with femininity and exquisiteness of the product. The oversized lettering of the product name and a half-smile of the model hinted at the reserved excitement about the product. Her style of dress suggests casual environment thus she is probably not a sales clerk but a perspective user. However, rather than showing the product in use, the poster demonstrates a mere existence of the product somewhere in the Soviet universe.

The artistic style and colors inform ideological symbolism. Through the realistic style the woman depicted in this advertisement communicates qualities of an exemplary Soviet woman; she is modest, her dress is not revealing or seductive yet she is fit; she does not wear any cosmetics or jewelry yet her eyebrows suggest that they have been tweezed; her casual interaction with the stocking demonstrates her sedated joy. Her eyes look directly communicating equality with the viewer thus expressing the principals of collectivity. Even in Soviet fashion one is expected to be modest and simple: the ideology of collectivism prohibited anybody to stand out from the masses (Vainshtein 1996, 71). This woman is rather a display prop for the Soviet stockings. The heart palpitations are non-detectable in this image of a woman who came into a physical contact with the product that is known to have magical transformation capabilities for the female consumer. The stocking can be replaced by any other Soviet product without compromising its general message, “Life is becoming ever better and more joyous!” (the often cited Stalin 1936 quote). This advertising poster possesses “grandeur of purpose” and “somber dignity.”

The third image is an advertising poster from 1966 by S. Lapaev (Snopkov et al. 2007, 238) (Figure 3). Technically, Khrushchev was already ousted but the initiatives that he had started had long lasting effects. Khrushchev wanted to restore the Communist ideals through changing ideological discourse and by

spreading state authority into consumption, taste and fashion, areas of life considered private in other societies (Reid 2002: 216). Youth’s cultural values of romanticism and enthusiasm manifested in developing new virgin territories but also were signified by the “softer” artistic styles (see Tolstikova 2001). On a representational level the advertising image is a drawing of female legs below the knee from the back angle. The rest of the woman is invisible to the viewer. She wears white heels and a sheer skirt/dress/slip. The white background has an abstract spot in grey with a thistle “catching” a stocking which the woman tries to untangle with her hand. The headline reads, “Seamless kapron stockings fashionable and inexpensive.” The advertiser, “The Russian Clothing Distributor of the Ministry of the Trade or R.S.F.S.R.,” is identified with a barely readable text in a vertical side line in the lower right corner. There are five different typefaces used in this advertisement: two of them are serifs and three are sans serifs.

Body cropping/symbolic dismemberment has been a persistent topic in the analysis of Western advertising images (e.g. Kilbourne 1999). The theory holds that when a woman is represented by just a body part, this symbolically signifies that her body is separated from her mind and she ceased to be a whole person and therefore she loses her individuality (Cortese 2005, 38). The iconographic symbolism of this image rests on the assumption that S. Lapaev had chosen to concentrate on female legs for the purpose of calling attention to the product in use—it calls to the viewer to witness how beautiful it makes women’s legs, but also how delicate the product is (but inexpensive too, even if it is damaged by a thistle there will be no trouble to replace it!). Traditionally in art, “the special sexual emphasis was given to women’s legs” (Berger 1972, 138). However, in this case rather than evoking sexual feelings, the visual details celebrate sensuality and romanticism—the angle, the sheerness of the hem, and even the thistle.

The iconological symbolism of this image is a mix of contradictory signs. On the one hand it speaks of modernity (typography, abstractedness of the thistle), elegance and femininity (elongated limbs, dainty gesture of releasing the stocking), sensuality (forces a viewer to concentrate on female legs), and dynamism (the movement rather than stationary position of the 1952 woman). In short the image signifies a new reality by challenging the suffocating

FIGURE 4

artistic Socialist Realist canons. On the other hand, rather than being abstractedly indifferent as in the 1952 advertisement, the depiction is more realistic through a narrative (a thistle).

The final image is a 1965 advertising poster by E. Filimonov (Snopkov et al. 2007, 239) (Figure 4). Brezhnev was already in power and the image reflects the values propagated. Already by the 1960s the state had realized the impossibility of the speedy achievement of Communism; both ideologically and economically the country was in stagnation. The acquisitiveness of material goods intensified. For the first time in the history of the Soviet ideology, material possessions lost its negative connotations. Collectivist socialist ideas had gradually been replaced by individualism (Millar 1985: 703). The poster depicts a female silhouette wearing a fitted pink see-through flowing camisole on a black background. The heading underneath the image states, “Rayon lingerie, elegant and practical.” The producer is identified as The Ministry of the Trade of the Russian Federation. The “female” curves to the back in a coquettish pose, her eyes are turned downward; her arms are stretched to the front and rolled toward her body. She has a full figure with small waist. There are no legs depicted below the hem. The “female” has long hair that falls below the shoulders. Her underwear is visible through the transparent rayon of the camisole.

On the iconographic level, there is a stark contrast between the pink of camisole and the black of background which makes the product to stand out. The pose of the figure is artificial, allowing for demonstration of the details of the camisole, such as its transparency, lace details of the bodice and hem. The “female” is depicted alone in her intimate moment. Unlike women in the 1952 advertisement, she is not only the user of the product but she is emotionally involved with the product, apparently enjoying herself. E. Filimonov chose to represent this user in a “dream-like” image, allowing the imagination of the viewer to do additional work. This depiction of a curvaceous female figure in her undergarments is an open advertising text suggesting sensuality, sex appeal, and fantasy on the part of the viewer, thus opening the dialogic space.

The iconological symbolism of the image suggests the “softening” of the official ideology toward women by recognizing their

feminine appeal and even the right to being sex objects. The contrasting colors attest to the courage to deal with the issue. Factors such as the soft curves of the “female,” manner of representation, chosen point of view (suggesting to the viewer this intimate image as if by accident)—all speak of increasing importance of femininity and recognition of privacy in the society. The clear enjoyment of the product by the subject of the advertisement signifies the growing significance of consumer goods and more favorable attitude toward personal possessions.

IDEOLOGICAL ROLE OF ADVERTISING IN THE SOVIET SYSTEM

In the immediate post-revolutionary years, advertising techniques were used to create ideological agitation and propaganda. For only a few years in the 1920s, the private trade enjoyed a temporary comeback with explosion of street advertisements. After much debates about the role of the advertising under Soviet conditions, whether this capitalist tool should be adopted for different realities (e.g. Tolstikova 2007), the purposes of the socialist advertising were officially defined in 1957 by a Conference of Advertising Workers of Socialist Countries; they were to inform the rational norms of consumption, to assist trade, and, lastly, to educate consumers’ taste (Crowley and Reid 2000, 10-11). Everything that was published in the Soviet Union, be it an article, a book or an advertisement, was authorized by the state—the state was the advertiser and the advertising agency. There were no disagreements between the client and the executor, since they were the same.

Rather than create excitement and desire for the product, the post-war Soviet advertising transmitted the rationality of a material world of Soviet goods. It was important for Soviet advertising to communicate the idea that there were enough material goods for every Soviet consumer. Under these conditions, material goods symbolized the stability of a peaceful Soviet existence. It was often enough to show that the product was simply available (Sal’nikova 2001, 174-175).

Not surprisingly, food was the top priority for the long deprived population. In 1948 Food Advertising Organization, started

to dress “the shop window of socialism” perpetuating the “myth of abundance” (Shkliaruk 2007, 6). Print advertisements depicted oversized tins of crabs and champagne floating in the air and sometimes smiling citizens next to the products. The depiction of an idealized product was intended to create delight and admiration in the customer used to asceticism of the war period.

Khrushchev’s increased output of consumer industries which often resulted in surpluses urged the improvement of product distribution. He considered advertising to be an important tool of the newly developing Soviet marketing that helped to move the goods (c.f. Goldman 1963). Advertising of the 1960s operated under a slogan “Soviet means excellent!” and carried a symbolic meaning of priorities of socialism over capitalism.

The Soviet character prohibited a person from demonstrating extreme desires for material goods therefore Soviet advertising exhibited restraint. The purpose of socialist advertising was not to generate consumer desires but to promote “rational consumption” (Reid 2002, 218). In Stalin’s time, advertising did not surprise or entertain but attracted the consumer’s attention to mostly food items, such as vitamins, fish oil, or toothpaste that would be nutritious for restoring or maintaining health. Advertising photographs were rare; illustrations drawn in the style of Socialist Realism were more likely to promote the idea of abundance. Khrushchev’s regime had a goal of modernizing the country not only through industrialization but through daily life. The realistic representational style of the earlier advertising became inappropriate for the Khrushchev’s Communism project. It required artistic laconism and allowed empty spaces (Shkliaruk 2007, 7).

The advertisements analyzed are advertising posters. Posters were large, colorful and were displayed near the point of purchase, inside the shops. Unlike in the West where in-store advertising would serve as a reminder and an encouragement for a purchase, Soviet advertisements often served as a visual replacement for the physical merchandise (Shkliaruk 2007, 6). Advertising posters were consumed in the public space of a store; depending on its specific location customers either glanced at it briefly or looked at it intently if they happened to have it in their view when they stood in line. During Stalin’s era they demonstrated the promised abundance, during Khrushchev’s they were the window into Communism where citizens were to have everything and during Brezhnev’s they were empty signs or meaningless decorations.

DISCUSSION

Comparison of the four advertisements demonstrates the changes that, on one level, can be explained with the internal historical trends, namely with changing Soviet values and attitudes. Ideological perception of women’s social roles evolved from an equal partner to the proletarian man to the traditional view where a woman was perceived as a vessel for a new life to modern patriarchal where external values such as good looks and fashion started to be important. The analysis also reveals the changes in Soviet advertising from ideological propaganda to a neutral store window to a communication vehicle for symbolism. But, on another level, the changes can also be attributed to macro historical developments. Martens and Casey (2007) argue that after the World War II, the winning countries encountered affluence which was more pronounced in the West where consumption shifted away from the practical/functional to luxury/symbolic (220). Apparently, similar processes manifested itself in the Soviet Union. The attitudes toward individual consumption were changing; contemporary Soviet advertising reflected the changes and confirmed the trend.

Effects of Nostalgic Advertising through Emotions and the Intensity of the Evoked Mental Images

Silke Bambauer-Sachse, University of Fribourg, Switzerland
Heribert Gierl, University of Augsburg, Germany

ABSTRACT

In this paper we analyze effects of nostalgic versus non-nostalgic advertising through elicited emotions and the intensity of evoked mental images on consumers' attitudes and purchase intentions. In addition, we examine if imagery instructions are helpful in the context of nostalgic advertising. We conducted two empirical studies to examine these processes. Our results show that nostalgic advertisements evoke more positive emotions and more intensive mental images than non-nostalgic advertisements which in turn affect consumers' attitudes toward the ad and toward the product and their purchase intentions.

INTRODUCTION

People are often not only influenced by immediate circumstances, but also by their pasts and their anticipated futures (Belk 1990). Consumers cannot return to the past, but they can try to preserve it through nostalgic consumption activities (Rindfleisch and Sprott 2000; Sierra and McQuitty 2007; Stern 1992). Nostalgia is a part of people's consumption experience and, therefore, a part of preference or choice (Goulding 2001). Furthermore, nostalgia is an important marketing topic (Gabriel 1993; Havlena and Holak 1991; Reisenwitz, Iyer, and Cutler 2004) that influences trends in designing, decorating, entertaining, collecting, retailing, media, arts, and advertising (Holbrook 1994). Nostalgic advertising is used in different product categories such as food, beverages (Muehling and Sprott 2004; Rindfleisch, Freeman, and Burroughs 2000), music, movies (Holak and Havlena 1992; Baker and Kennedy 1994; Sierra and McQuitty 2007), toy, clothing, candy, chocolate, furniture, vehicle, outdoor equipment, perfume (Belk 1990; Reisenwitz, Iyer, and Cutler 2004; Rindfleisch and Sprott 2000), financial planning (Rindfleisch and Sprott 2000), coffee, watches, cigarettes, medicine (Reisenwitz, Iyer, and Cutler 2004). Marketing practitioners increasingly use nostalgic cues such as themes, images, jingles, and old slogans in advertising and nostalgic products (Havlena and Holak 1991; Baker and Kennedy 1994) to offer consumption experiences which are characterized by a taste of youth (Stern 1992), to evoke memories of consumers' past personal experiences (Sujan, Bettman, and Baumgartner 1993), and to elicit emotions (Braun, Ellis, and Loftus 2002). Nostalgic cues are used with regard to different aspects of life such as buildings, organizational leaders, colleagues (Gabriel 1993), family members, special events (Holak and Havlena 1992; Muehling and Sprott 2004), entertainment (Havlena and Holak 1991), literature, artwork, technology, home (Sierra and McQuitty 2007), odors (Hirsch 1992), vacations, weddings (Baker and Kennedy 1994), restaurants (Reisenwitz, Iyer, and Cutler 2004), and religion (Holak and Havlena 1992).

The effectiveness of nostalgia in an advertising context with regard to effects such as increasing the level of brand awareness and brand attitude has not been broadly analyzed in the literature (Muehling and Sprott 2004; Reisenwitz, Iyer, and Cutler 2004). Moreover, many former studies on nostalgia are rather exploratory than driven by a theory that could explain and predict consumer behavior in nostalgic contexts (Braun, Ellis, and Loftus 2002; Rindfleisch and Sprott 2000; Sierra and McQuitty 2007).

There are only a few studies that deal with emotions in the context of nostalgic advertising. Early studies in this field of

research rather exploratively examine emotional components of nostalgia on the basis of descriptions of nostalgic experiences (Holak and Havlena 1992, 1998). A more recent study focused on effects of nostalgic advertisements through evoked emotions on advertisement and brand attitudes and on purchase intentions, and provided the finding that nostalgic advertising evokes positive emotions which have direct positive effects on the attitude toward the ad and rather indirect effects on the attitude toward the brand and on purchase intention (Pascal, Muehling, and Sprott 2002). However, the authors of this study only tested nostalgic advertisements and did not consider control advertisements which are helpful as a reference. Thus, it is necessary to examine effects of nostalgic advertising versus non-nostalgic advertising through emotions on attitudes toward the ad and the product and on purchase intentions in a new empirical study.

Studies on mental images that are evoked in the context of nostalgic advertising are scarce as well. For example, Holak and Havlena (1996) examined nostalgia imagery exploratively by asking consumers to create collages. In a more recent study, Muehling and Sprott (2004) found that nostalgic advertisements generate nostalgia-related thoughts in consumers which are not always positively valenced. This finding provides a first insight in mental processes that can be triggered by nostalgic advertising. However, measuring mental images seems to capture the mental processes evoked by nostalgic advertising more comprehensively than just recording thoughts.

Consequently, the purpose of this paper is to analyze effects of nostalgic versus non-nostalgic advertising through elicited emotions and mental images on consumers' attitudes toward the ad and toward the advertised product as well as on their purchase intention. The focus here is on shedding light on possible processes that are triggered by nostalgic advertising in consumers.

This paper contributes to the existing body of research by providing a new theoretical approach to predict effects of nostalgic advertising and by presenting the results of two empirical studies which aim at analyzing effects of nostalgic advertising through emotions and mental imagery on consumers' attitudes toward the ad and toward the product, and on their purchase intention. The findings of the studies presented here enable marketers to understand the processes triggered by nostalgic advertising in consumers in more detail and to consequently use nostalgic cues more target-oriented.

THEORETICAL AND EMPIRICAL BACKGROUND

The Concept of Nostalgia

Nostalgia is not a theory in itself. It is rather a concept that can provide an explanation of a given situation (Goulding 2001). Nostalgia is a feeling or a mood that causes a preference for things that tend to evoke nostalgic responses (Holak and Havlena 1998). In addition, nostalgia is distinct from autobiographical memory (Muehling and Sprott 2004). Nostalgia is often described as a longing for past times. Thus, people try to recreate aspects of the past in their present life by reproducing past activities and focusing on possessions that remind them of the past (Davis 1979; Holbrook 1993; Holbrook and Schindler 1991; Nawas and Platt 1965; Sierra

and McQuitty 2007; Stern 1992). Furthermore, nostalgia is described as a coping mechanism (Best and Nelson 1985; Davis 1979; Goulding 2001) which is characterized by a mythologization or symbolization of the past (Brown and Humphreys 2002; Rindfleisch, Freeman, and Burroughs 2000) as well as by an imaginary character (Belk 1990) and which helps people to come to terms with their present life circumstances (Gabriel 1993) or with concerns over the future (Nawas and Platt 1965). Belk (1990) and Holak and Havlena (1992) see nostalgia as an emotion consisting of both pleasant and unpleasant components. On the one hand, people reminiscing in memories of the past are happy, but on the other hand, people are sad because they would like to relive the past times and because they realize that this is impossible at the same time (Baker and Kennedy 1994).

Effects of Nostalgic Advertising through Emotions on the Attitude toward the Ad

Evoking nostalgic feelings through advertising generates predominantly positive emotions (Baumgartner, Sujan, and Bettman 1992; Holak and Havlena 1998; Pascal, Sprött, and Muehling 2002) because, due to a positivity bias of the memory, people tend to remember rather positive episodes from their lives and because advertisements often aim at retrieving pleasant rather than unpleasant memories (Sujan, Bettman, and Baumgartner 1993). This argument leads to our first hypothesis:

H1: *Ceteris paribus*, nostalgic advertising evokes more positive emotions than non-nostalgic, modern advertising.

Consistent with affect transfer models of persuasion (MacKenzie, Lutz, and Belch 1986; Zajonc 1980), experiencing nostalgic feelings due to nostalgic appeals in advertisements can influence consumers' judgment processes (Sujan, Bettman, and Baumgartner 1993) and lead to the formation of positive attitudes (Muehling and Sprött 2004). Consequently, emotional responses to nostalgic advertisements are believed to have positive effects on consumers' attitudes toward the ad (Batra and Ray 1986; Baumgartner, Sujan, and Bettman 1992; Machleit and Wilson 1988; Muehling and Sprött 2004; Reisenwitz, Iyer, and Cutler 2004). These considerations lead to:

H2: The more positive the emotions that are evoked by a nostalgic versus a non-nostalgic, modern ad, the more positive is consumers' attitude toward the ad.

Effects of Nostalgic Advertising through Mental Images on the Attitude toward the Advertised Product

Nostalgic advertising messages arouse attention and are entertaining (Reisenwitz, Iyer, and Cutler 2004). Furthermore, they can evoke nostalgic reflections in consumers (Muehling and Sprött 2004) and stimulate an imaginative recreation of a past which can be associated with the advertised product (Stern 1992). Consequently, imagery theory can serve as an explanation for effects of nostalgic advertising on consumers' attitude toward the advertised product. Imagery is a sensory representation of a memory that enables people to relive past experiences (Lutz and Lutz 1978) that they ascribe a special meaning (Baker and Kennedy 1994). A mental image is an imagination of a certain event (Sherman et al. 1985). Imagery processing can either consist in retrieving information from memory or in having fantasies (Hoyer and MacInnis 2004; MacInnis and Price 1987; Sherman et al. 1985) that are elicited by pictures, concrete verbal stimuli, or imagery instructions. Imagery instructions are statements that direct the recipients to form a mental picture of a certain concept (Lutz and Lutz 1978).

According to Burns, Biswas, and Babin (1993) mental images work as a mediator in the relation between predictor variables such as cues or instructions to imagine and the target variable attitude.

Transferred to the context of nostalgic advertising, consumers are believed to have mental images of former consumption situations and experiences (Baumgartner, Sujan, and Bettman 1992). Imagery processing can be evoked by nostalgic advertisements or advertisements with a nostalgia-related imagery instruction. Thus, the contact with a nostalgic advertisement for a certain product or a nostalgia-related imagery instruction evokes nostalgic mental images in consumers that are related to the advertised product. These mental images can contain autobiographical memories and are predominantly positive (Sujan, Bettman, and Baumgartner 1993). These considerations lead to:

H3: *Ceteris paribus*, nostalgic advertising evokes a more intensive mental image associated with the advertised product than non-nostalgic, modern advertising.

As comparatively concrete cues evoke more comprehensive and clearer mental images than comparatively abstract cues (Unnava, Agarwal, and Haugtvedt 1996), we assume that a nostalgic advertisement with a concrete imagery instruction elicits a more intensive nostalgic image than a nostalgic advertisement without such a concrete cue. Thus:

H4: A nostalgic advertisement with an imagery instruction evokes an even more intensive mental image than a nostalgic advertisement without such an instruction.

Having nostalgic thoughts evokes a higher identification with the communicated information (Braun, Ellis, and Loftus 2002). Consequently, the information processed in this way is comparatively persuasive (Baumgartner, Sujan, and Bettman 1992). Thus, a mental image evoked by nostalgic advertising is believed to have predominantly positive effects on consumers' attitude toward the product (Babin and Burns 1997; Bone and Ellen 1992; MacInnis and Price 1987; Sujan, Bettman, and Baumgartner 1993) because the advertisement recipients tend to not consider negative aspects of the advertised product when processing the evoked mental images (MacInnis and Price 1987).

H5: The higher the intensity of the evoked mental image the more positive is consumers' attitude toward the advertised product.

Effects of Nostalgic Advertising through the Attitude toward the Ad on Product Evaluation and Purchase Behavior

Consumers who are exposed to a nostalgic advertisement, are supposed to transfer evoked memories of former times to products (Hirsch 1992). Thus, having nostalgic feelings as well as having mental images of former times in mind may positively influence consumers' judgment processes (Sierra and McQuitty 2007; Sujan, Bettman, and Baumgartner 1993), which results in more favorable product evaluations (Braun, Ellis, and Loftus 2002; Pascal, Sprött, and Muehling 2002; Reisenwitz, Iyer, and Cutler 2004; Sujan, Bettman, and Baumgartner 1993). Furthermore, nostalgic feelings and thoughts drive the behavior of people (Hirsch 1992). When experiencing nostalgia in a consumption context, consumers are supposed to show higher purchase likelihood with regard to the advertised products (Reisenwitz, Iyer, and Cutler 2004) and to purchase especially nostalgia-related products (Goulding 2001; Sierra and McQuitty 2007).

FIGURE 1
RESEARCH MODEL

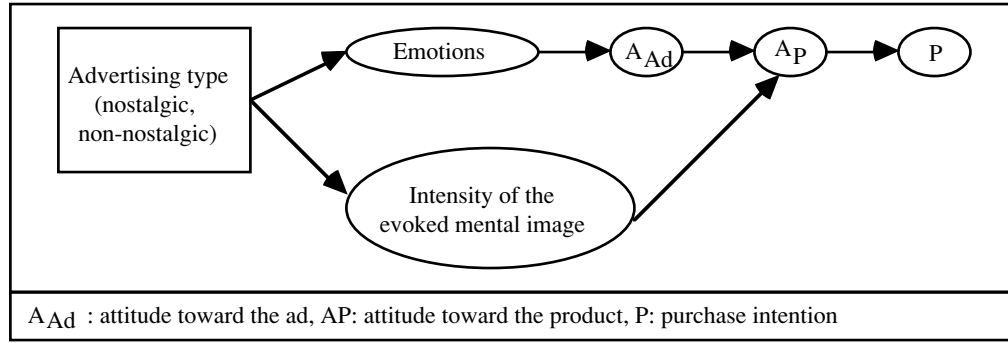

TABLE 1
OVERVIEW OF THE TWO EMPIRICAL STUDIES

Aspect	1	2
Analyzed Variables	attitude toward the ad attitude toward the product purchase intention emotions	attitude toward the ad attitude toward the product purchase intention intensity of the evoked mental images
Sample size	480 participants	465 participants
Respondents	students, employees, retirees	students
Mean age	45.12 years	24.26 years
Gender distribution	242 women, 238 men	231 women, 234 men
Tested products	detergent, pudding, band-aids, cookies	chocolate, soft drinks, fast food, facial cream

Research Model

The theoretical considerations presented above are summarized in the research model shown in figure 1. This research model is tested in an empirical study, which is presented in the next section.

EMPIRICAL STUDIES ON NOSTALGIA EFFECTS IN ADVERTISING

Overview of the Empirical Studies

In order to examine the processes triggered by nostalgic advertising in consumers as comprehensive as possible, we conducted two empirical studies to be able to clearly separate the assumed effects. The two studies differ in one variable: in the first study we measured the emotions, in the second study we measured the intensity of the mental images evoked by nostalgic advertisements. With regard to all other variables the studies are comparable so that the existence of the relations between these variables can be validated by comparing the results of the two empirical studies. Table 1 gives an overview of the two studies.

The study descriptions show that both studies are largely comparable. As nostalgic cues such as nostalgic pictures are believed to be comparatively effective in low involvement advertising situations (Reisenwitz, Iyer, and Cutler 2004), we chose every day low involvement products as examples. We used different product examples in each study to cover a wide range of product categories. We chose brands that had already existed during the childhood of the respondents because early childhood brand relationships are the emotional basis for later adult brand relationships (Braun, Ellis, and Loftus 2002).

Moreover, we intentionally used a sample consisting of people of different age groups in one study and a student sample in the other study to prove that the results hold across age groups.

Nostalgia Manipulation and Measures

In both studies nostalgia was manipulated in the respective advertisements by including nostalgic pictures from former advertisements. The nostalgic advertisements were tested against non-nostalgic modern advertisements from current advertising campaigns for the respective products. In addition to testing nostalgic

TABLE 2
MEASURES APPLIED IN THE TWO EMPIRICAL STUDIES

Model variable	Statement	Factor loadings		Alpha/ correlation
		Study 1	Study 2	
Attitude toward the ad (AAd)	The ad is appealing.	.89 (t=26.50)	.95 (t=43.06)	.86 .92
	I like this ad.	.87 (t=30.05)	.92 (t=25.05)	
	This ad is interesting.	.88 (t=32.55)	.91 (t=29.14)	
Attitude toward the product (AP)	This product is attractive.	.85 (t=21.26)	.92 (t=42.52)	.71 .87
	This product is interesting.	.86 (t=23.92)	.90 (t=46.06)	
	This product is appealing.	.76 (t=7.92)	.86 (t=21.23)	
Emotions (E)	I am fine	.90 (t=31.74)	-	.60
	I feel happy.	.90 (t=32.73)		
Purchase intention (I)	I would like to buy this product.	1.00	1.00	-

Scale: 1 = totally disagree, ..., 7 = totally agree

versus non-nostalgic advertisements in both studies, we had nostalgic advertisements with imagery instructions in the second study. As this study aimed at analyzing the intensity of evoked mental images we intended to additionally examine whether including imagery instructions in advertisements positively influences this intensity. The imagery instruction consisted in the question: "Do you remember the good old days?"

The measures used in the empirical studies are summarized in table 2. Emotions had been operationalized by measuring subjective feelings because those represent the conscious awareness of the emotional state a person is experiencing (Desmet 2004). As the study was conducted in Germany, the items had been translated into German. Each model variable that was used in both studies is ascribed two alpha values (one value for each study). Table 2 additionally contains the factor loadings of the respective items. The significantly positive factor loadings as well as the high alpha values and correlations show that the applied items are appropriate for measuring the respective model variables.

In addition to the variables listed in table 2 we needed to measure the intensity of the nostalgic mental images elicited by the contact with the advertisements in the second study. As the quantity and the vividness of evoked images are the most important dimensions of the intensity of mental images (Ellen and Bone 1991) we measured these two aspects as follows. The respondents were asked to document the mental images that had come to their mind as follows: "Please describe the images that came to your mind when regarding the ad." Instead of asking the respondents to indicate the vividness of these mental images, we coded the images reported by the respondents according to the detailedness with which the respondents described the images (1=low, 2=moderate, and 3=high vividness). The two dimensions of the intensity of the mental images were combined by weighting the number of mental images by the respective vividness.

Procedure

In both studies, each participant saw only one print advertisement for a brand of one of the chosen product categories (either a nostalgic or a non-nostalgic, modern advertisement) because we wanted to avoid that the respondents would be primed for the relevant measures (emotions, intensity of evoked mental images) when evaluating further advertisements. The procedure, which was

the same for both studies, was as follows. The participants saw one advertisement and were subsequently asked to fill in a questionnaire with measures for their emotions/for the intensity of the evoked mental images, and with statements concerning their attitudes toward the ad and toward the brand, and their purchase intention. Finally the respondents had to answer demographic questions which were used to prove that the different experimental groups were structurally equal with regard to age and gender.

Effects of Nostalgic versus Non-Nostalgic Advertisements

For all of the data analyses presented below, we pooled the data across products. In a first step we basically analyze possible effects of nostalgic versus non-nostalgic advertisements on emotions and the intensity of mental images. The results of a *t* test and an ANOVA show that the advertising type (nostalgic versus non-nostalgic, modern advertising) has significantly positive effects on emotions ($E_{Ad_nos}=3.10$, $E_{Ad_mod}=2.85$, $t=2.71$, $p<.01$) and on the intensity of the evoked mental images ($MI_{Ad_nosII}=1.10$, $MI_{Ad_nos}=1.09$, $MI_{Ad_mod}=.65$, $F=4.79$, $p<.01$). Thus nostalgic advertisements elicit significantly more positive emotions and significantly more intensive mental images than non-nostalgic, modern advertisements. However, the data show that the difference between a nostalgic advertisement with and a nostalgic advertisement without an imagery instruction is not significant. Thus, H4 is not supported. Based on these findings, a more detailed analysis of the effects of nostalgic versus non-nostalgic advertising through emotions and the intensity of the evoked mental images on the response variables attitude toward the ad, attitude toward the product and purchase intention is presented in the following section of the paper.

Methods of Data Analysis and Model Fit in Both Studies

In order to test our research model, we applied two structural equation models. The most common procedures to estimate structural equation models are LISREL and PLS. As our independent variable is nominal (nostalgic versus non-nostalgic advertisement) we had to choose the most appropriate procedure. A review of research in high reputation journals has shown that PLS models are preferred over LISREL models if categorical data are used as exogenous variables because PLS models do not require metric input data (e.g., Fichman and Kemerer 1997; Kahai, Avolio, and

TABLE 3
MODEL FIT, RELIABILITY, AND VALIDITY MEASURES IN BOTH STUDIES

****: p<.001, ***: p<.01, **: p<.05, *: p<.10, n.s.: not significant

Sosik 1998). Therefore, we used two PLS models to test the effects assumed in our hypotheses. Both PLS models differ with regard to one variable: the first model contains emotions whereas the second model contains the intensity of the evoked mental images. Emotions are included in the first PLS model as a metric variable measured by reflective indicators. The intensity of the evoked mental images is included as a metric variable with one formative indicator in the second PLS model. Besides this difference, both models contain the same variables. Consumers' purchase intention is the target variable. The attitude toward the product and the attitude toward the ad are integrated as mediator variables. Thus, both models have three endogenous variables in common that are measured by reflective indicators. In the first model the exogenous model variable (advertising type: nostalgic ad versus non-nostalgic, modern ad) is included through one formative indicator which is a common procedure for binary exogenous variables (e.g., Crilley and Sharp 2006; Kahai, Sosik, and Avolio 2004; Li et al. 2006). In the second model the advertising type (nostalgic ad, nostalgic ad with imagery instruction, and non-nostalgic, modern ad) is included through two formative binary indicators (reference:

non-nostalgic, modern ad). The model fit, reliability and validity measures for both models are shown in table 3.

The R² values of the partial models are acceptable. Furthermore, the composite reliability values are sufficiently high (Bagozzi and Yi 1991). Moreover, the average variance extracted values exceed the squared correlations between the model variables proving discriminant validity (Fornell and Larcker 1981).

Results of Study 1: Effects of Nostalgic Advertising through Emotions

The purpose of the first study is to analyze the effects of nostalgic versus non-nostalgic advertising through emotions that are triggered by nostalgic appeals on consumers' attitudes toward the ad and toward the product, and on their purchase intention. The estimated path coefficients of the first PLS model are summarized in table 4.

The results show that the advertising type (nostalgic versus non-nostalgic advertising) has a significantly positive effect on the extent to which consumers experience emotions. Thus, H1 is supported and the data indicate that nostalgic advertisements arouse

TABLE 5
PATH COEFFICIENTS OF THE PLS MODEL IN STUDY 2

Effect of... on	MI	A _{Ad}	A _P	I
Nostalgic versus non-nostalgic ad	.24 (t=2.37**)	n.s.	n.s.	n.s.

MI	-	n.s.	.34 (t=3.45****)	n.s.
A _{Ad}	-	-	.27 (t=2.68****)	n.s.
A _P	-	-	-	.75 (t=15.17****)

MI: intensity of the evoked mental images, A_{Ad}: attitude toward the ad, A_P: attitude toward the product
I: purchase intention; ****: p<.001, ***: p<.01, **: p<.05, *: p<.10, n.s.: not significant

more positive emotions in the ad recipients than non-nostalgic, modern advertisements. The results also mirror the fact that the advertising type does not have any direct effects on the attitude toward the ad, the attitude toward product, or on purchase intention.

Moreover, the data show that the emotions aroused by the respective advertisement have a significantly positive effect on consumers' attitude toward the ad supporting H2. Thus, the more positive the emotions that are triggered by an advertisement, the more positive is the recipients' evaluation of the ad. The additional effect of emotions on the attitude toward the product is only significant at the 10 percent level. Furthermore, emotions do not influence consumers' purchase intention. Thus, the results show that emotions evoked by an advertisement predominantly influence consumers' formation of an attitude toward the ad. In addition, the results indicate that the attitude toward the ad has a significantly positive effect on the attitude toward the product which in turn has a significantly positive influence on purchase intention. The findings of our first study are in line with previous findings of Pascal, Sprott, and Muehling (2002).

Results of Study 2: Effects of Nostalgic Advertising through the Intensity of Evoked Mental Images

The purposes of the second study were to gain additional insights in effects of nostalgic versus non-nostalgic advertising through the intensity of mental images that are activated in consumers on their attitudes toward the ad and toward the product as well as to validate the findings of the first study. The estimated path coefficients of the second PLS model are shown in table 5.

The results indicate that nostalgic advertising evokes a significantly more intensive mental image than non-nostalgic advertising. Thus, H3 is supported. Again, the advertising type does not have any direct effects on consumers' attitudes toward the ad and toward the product and on their purchase intention. Moreover, the results show that the intensity of the evoked mental images neither has effects on consumers' attitude toward the product nor on their purchase intention, but it does have a significantly positive effect on the attitude toward the product. Thus, H5 is supported. Analogous to the results of study 1, the path coefficients of the second PLS model show that consumers' attitude toward the ad has a significantly positive effect on their attitude toward the product, but no effect on consumers' purchase intention. Finally, the attitude to-

ward the product has a significantly positive effect on purchase intention.

CONCLUSION

The purpose of this paper has been to analyze effects of nostalgic versus non-nostalgic advertising through emotions and the intensity of evoked mental images on consumers' attitudes toward the ad and toward the product, and on their purchase intention. The results of two empirical studies show that, *ceteris paribus*, nostalgic advertisements evoke more positive emotions and more intensive mental images than non-nostalgic, modern advertisements. Furthermore, the results indicate that the evoked emotions are rather ad-related, whereas the elicited mental images are rather product-related.

Positive emotions evoked by nostalgic advertisements positively influence consumers' attitude toward the ad and have positive indirect effects through the attitude toward the ad on the attitude toward the product and on purchase intention. Consequently, marketers can profit from using nostalgic advertisements best when advertising emotional products that are advertised by emotional advertisements because nostalgic instead of modern advertisements evoke additional positive emotions and thus enhance the effect of other positive emotions in this context.

Nostalgic instead of non-nostalgic modern advertisements additionally evoke a more intensive mental image which has direct positive effects on consumers' attitude toward the product. Thus, nostalgic advertising is especially appropriate when advertising products that are likely to be subject to mental images. Moreover, as the effect of nostalgic advertising on the intensity of the evoked mental images can only be slightly enhanced by using an additional imagery instruction, marketers can omit such an instruction when it would cause an information overload in an advertisement.

Moreover, the fact that the positive effects of nostalgic versus non-nostalgic, modern advertising have been shown for a student sample as well as for a sample consisting of younger and older people shows that positive effects of nostalgic advertising do not necessarily depend on the age of the advertising recipients.

In further research, it might be interesting to analyze emotion and mental imagery paths in a comprehensive study because there might be interesting interaction effects. Moreover, further research might focus on controlling for personality variables such as nostal-

gia proneness, visual-verbal style of processing, and need for cognition.

The Effects of Humor on the Processing of Word-of-Mouth

Dave Bussiere, University of Windsor, Canada

ABSTRACT

Exploratory qualitative analysis of 127 actual on-line conversations revealed the presence of humor in word-of-mouth (WOM). This use of humor seemed to weaken the impact of the WOM advice. While there is a rich history of research on the impact of humor on advertising, there is no equivalent research in the WOM literature. Using a 2x2 experimental design, the impact of humorous WOM on behavioral intentions, WOM intentions, evaluations of source credibility and evaluations of message persuasiveness are analyzed. Humor was found to decrease the impact of positive and negative WOM messages.

"At its most basic level humor is an intended or unintended message interpreted as funny. Yet curiously, the communication field has only skimmed the surface of the world of humor." (Lynch 2002, p. 423)

For almost 35 years, marketing research has acknowledged the impact of humor on message processing. This research has focused primarily on the role of humor in advertising and its impact on message persuasiveness, source credibility and behavioral intentions. In contrast, research on word-of-mouth (WOM) has focused on neutral, positive or negative WOM comments. This paper will provide a literature base for future humor research in WOM.

Humor in Advertising

Since Sternthal and Craig's pivotal article (1973), there have been numerous articles that have analyzed various implications of humor in advertising. As Duncan (1979) notes, learning theory suggests that humor should positively impact advertising results through increased distraction, higher arousal, positive conditions and increased source credibility:

"Advocates of humor in advertising argue that light-hearted copy secures audience attention, increases advertisement memorability, overcomes sales resistance, and enhances message persuasiveness." (Duncan 1979, p. 286).

While some studies have found a positive relationship between the use of humor and ad results (c.f. Madden & Weinberger 1984), there are mixed results overall. In fact, the impact of a humorous message seems to be contingent on who receives the message:

"If humor is used in a persuasive communication, its function may also vary depending on how humor is processed by the message recipient." (Zhang & Zinkhan 2006, p. 114).

Message Persuasiveness

While there has been a substantial amount of research on the impact of humor on message persuasiveness, the understood direction of the effect is mixed (Weinberger and Gulas 1992). Duncan and Nelson (1985), for example, found that humor in radio ads had positive impact on lower-order processes like attention, but weakened persuasion. Other studies found that humor increased message persuasion because it reduced resistance to the message (Lammer et al 1983, Zhang 1996).

More common, however, were studies that support Sternthal and Craig's (1973) proposition that humor may, in theory, increase

persuasiveness, but that it does not appear to influence actual persuasion when compared to serious appeals because of the moderating impact of other variables (Booker 1981, Madden and Weinberger 1984). In fact, much of the past research has found indirect effects that moderated the impact of humor such as the need for humor (Cline, Altsech and Kellaris 2003), liking of the ad (Gelb and Pickett 1983), the need for cognition (Zhang 1996) and the attitude towards the ad (Zhang and Zinkhan 2006).

Source Credibility

The impact of humor on source credibility is far less studied and yet the same mix of results exists (Weinberger and Gulas 1992). While Sternthal and Craig (1973) found that "Humor tends to enhance source credibility," (p.17), the only other study found that advertising executives, both researchers and creative directors generally did not agree (Madden and Weinberger 1984).

Behavioral Intentions

There is also mixed support for using humor to increase the likelihood of message recipients intending to follow the advice in the message. One study found that humor did, in fact, increase intentions to purchase the product (Perry et al 1997). In contrast, Gelb and Pickett (1983) and Duncan and Nelson (1985) found an opposite effect. Madden and Weinberger (1984) found mixed support for the impact of humor on purchase intention amongst advertising executives. In a study of humor in promotion for events, Scott, Klein and Bryant (1990) found that humor increased attendance at social events, but had no impact on business event attendance.

Word-of-Mouth Intentions

Only one study analyzed the impact of humor in advertising on word-of-mouth intentions. Perry et al (1997) found that humor increased the likelihood that the message recipient would pass on the message to other consumers.

As the preceding highlights, despite 35 years of research, the impact of humor in advertising remains unsettled. As Weinberger and Gulas (1992) note:

"Though the broad question of humor's effectiveness in advertising is unanswerable, we can compile the accounts of humor research in the proper constraints to gain insights about its effects." (Weinberger and Gulas 1992, p. 35)

Following this line of reasoning, this article will acknowledge imperfect understanding of humor, and expand research to humor in word-of-mouth messages.

Word-of-Mouth

For over 50 years, WOM has been actively researched (Brooks 1957) and yet there is general agreement that the research is incomplete (c.f. Bowman & Narayandas 2001, Wangenheim 2005).

In general, WOM has been found to provide an easy, credible source of information and more effective than ads (c.f. Goldenberg, Libai & Muller 2001). Research has also found that individuals turn to strong-tie, rather than weaker social connections (Brown & Reingen 1987, Gilly, Graham, Wolfenbarger & Yale 1998, Goldenberg, Libai & Muller 2001, Yale & Gilly 1995).

Research indicates that there are many reasons for consumers to participate in WOM discussions. Some participate post-consumption, and want to discuss their experience. Others participate pre-purchase and want to better their purchase decision.

Post Consumption Word-Of-Mouth

Post consumption research has focused on within the consumer complaint literature. This research has examined how service failure increases the likelihood of complaining to the service provider and to other consumers. One of the prime drivers of WOM is the desire to complain about a service failure (Bone 1995, Halstead 2002, Maxham & Netemeyer 2003, Maxham & Netemeyer 2002, Maxham 2001, Nyer & Gopinath 2005, Richins 1983).

The desire to participate in negative word-of-mouth/complaining behavior is lessened by a company's reaction to complaints. Company reaction to complaints influences the degree to which people participate in negative WOM (Brown, Barry, Dacin & Gunst 2005, Halstead 2002, Maxham 2001, Nyer & Gopinath 2005, Richins 1983, Wangenheim 2003, Voorhees, Brady & Horowitz 2006).

Pre-Consumption Word-Of-Mouth

Consumers cannot know everything and so must turn to others for advice and information. In general, this research has found that positive and negative WOM messages have different impacts on consumers—with negative being more effective (DeCarlo et al 2007, Wangenheim 2005).

This negative WOM has been shown to negatively influence consumers' brand perceptions (Bone 1995, Gruen, Osmonbekov & Czaplewski 2006), intentions to buy (Bone 1995, Gruen, Osmonbekov & Czaplewski 2006, Keiningham, Money 2004, Lee, Lee and Feick 2006, Maxham 2001, Mayzlin 2006, Perkins-Munn & Evans 2003, Woodside & Delozier 1976,) and intentions to pass of further WOM (Brown, Barry, Dacin & Gunst 2005, Maxham 2001).

Interestingly, negative WOM has been found to result in stronger perceptions of source credibility (Godes & Mayzlin 2004).

Humor in Word-of Mouth

It is not surprising that humor would exist within WOM messages. As Lynch (2002) notes: "Jokes and humor, in general, play an important part in determining who we are and how we think of ourselves, and as a result how we interact with others." (Lynch 2002, p. 425)

EXPLORATORY RESEARCH

Given the importance of humor within the communication process, it can be expected that it will impact the message exchange within WOM conversations. As such, exploratory qualitative research was undertaken to understand the role of emotions and humor in WOM.

Internet based WOM has become increasingly used in consumer research (Chevalier & Mayzlin 2006, Dellarocas 2003, Godes & Mayzlin 2004, Goldenberg, Libai & Muller 2001, Gruen, Osmonbekov & Czaplewski 2006, Mayzlin 2006, Phelps et al 2004.). In keeping with this line of research, electronic WOM was used in the exploratory research. Prior qualitative research indicated that online home improvement forums contained ample electronic WOM conversations (Bussiere 2000), so 127 naturally-occurring online conversations from the internet newsgroup *alt.home.repair* were analyzed. The conversations varied in length from two comments to over 40 comments. Some conversations included over 20 individuals. All conversations dealt with home improvement issues.

The conversations were analyzed for evidence of any emotion or mood that moved the word-of-mouth message away from a neutral statement. The impact on the flow of conversation was then analyzed. The primary focus of the analysis was the tone of the WOM advice rather than the advice seeker. Samples of the complete text were also coded by two additional researchers to assess reliability.

Findings

Approximately a quarter of messages included elements of humor. This not only altered the tone of the conversation, but also resulted in further use of humor or, at times, angry responses to the humor. In the following conversation, the humorous comment seems to be intentional and seems to seek to make the other participants smile or comment.

After a 264 word question about his furnace, Edge concludes (Conversation 3):

Have I got a faulty thermostat or is there something wrong down at the furnace?

Thanks a million-Edge

The conversation maintains a focus on the question, and yet the humor also becomes an integral part of the conversation. Participants even began using emoticons (e.g. :-)) the sideways smile) to make sure that the comment was being understood as humor.

ANSWER 1: You should have 24 volts ac. (measure again with the meter in the ac mode). If the voltage is still low, check the wiring for a bad connection. this can cause an intermittent problem)

> Thanks a million -

No problem, just send a half a million, please!!! :-)(want the address to send it??)Better yet, I'll pick it up personally. :-)(wouldn't want it to get lost in the mail) :-)

RESPONSE TO ANSWER: Thanks for the tip! It was a loose wire, where the thermostat connects to the gas valve. Hmmm. Half a million? Maybe I can talk you down?

COMMENT FROM OBSERVER: Do what everyone else does—just don't pay.

Christopher

Similarly, a request for help in hanging wallpaper resulted in the following comment (Conversation 29):

Use longer nails?

Alternatively, the humor is essentially tangential to the conversation. The participants likely see it, but it does not actually influence the flow of conversation. Consider, for example, the following conversation. At the end of a conversation that actually addresses the issue, a new participant enters the conversation and takes advantage of the wording of the question to add some adult humor. The question asks about mounting a toilet flange. The final answer is less than useful (Conversation 123).

for good sex i alwayze mount it.

This tangential humor, however, can actually influence the flow of conversation. Consider, for example, the following conversation. The questioner, Stormin Mormon, begins with mild humor in describing his vehicle. More importantly, Stormin Mormon signs his question with additional references to his religion. Because

some participants have multiple postings, it is worthwhile noting the commentor's name (Conversation 76).

QUESTION: Stormin Mormon

My land tank is a 87 Dodge, with the 8 engine, and has about 150K miles. Running about 8 or 9 MPG. Recently had the tune up parts. Cap, rotor, sparks, air filter, fuel filter. What else might help improve mileage?

Christopher

Learn more about Jesus www.lds.org www.mormons.org

ANSWER 1: Tony

Hi, You mean V8? Advancing timing as much as you can will help. Changing

advance curve by trying different springs in the distributor can help changing the thermostat with hotter one (if that old engine can take it without leaking coolant) can help Trying to get lower idle RPM can help. Tranny shift kit may help. Changing the jet in the carb, etc., etc. No new ignition wires?

ANSWER 2: Randd01

Jack it up and put a GMC under it!

ANSWER 3: Loose Cannon

Don't think putting a GMC under it would help get better mileage. I have an

older GMC 'Gaucho' van with a 350. What a pig on gas! Don't know which Chrysler V8 the Stormin Mormon has in his Dodge van, but if it is the 318, the gas mileage should be better than he is getting. Had a few big old Chrysler cars with the 318 engine and got pretty good mileage out of them. Seldom, if ever had any engine problems either.

ANSWER 4: Randd01

My new GMC with 5.3 V8 averages 20 mpg got up to 23 on highway with automatic overdrive tranny. Way better than my 1995 GMC with 350 got.

ANSWER 5: Swampy

get a few of your wives to push it

RESPONSE TO ANSWER 5: Stormin Mormon

Oddly enough, I'm a bachelor. But thanks for the idea.

Note that the humor moved the conversation into a GM versus Chrysler debate. In addition, Stormin Mormon's Mormon status elicited the multiple wife joke. In each case, the actual issue became a side issue.

Yet, at times, humor is used to add strength to the message. The cutting aspect of the humor actually speaks to the seriousness of the issue. In the following conversation, the questioner asks about soldering a natural gas control valve. The response is humorous and serious (Conversation 118):

Increase your life insurance twofold. Have your next of kin two counties away with copies of all important papers when you do this.

This exploratory research indicates that the presence of humor in WOM messages can alter the flow of a conversation. Specifically, the presence of humor seems to weaken the impact of the WOM message on behavioral intentions—the likelihood that an individual who receives the WOM message will be more likely to follow the advice in a purchase decision—and on the likelihood of passing on the advice to others through future WOM.

RESEARCH QUESTIONS

Based on the literature review and the exploratory research, the following behavioral intention, WOM intention, source credibility and message persuasiveness hypotheses were developed.

Behavioral Intentions

- H1a: Positive humorous WOM messages will evoke weaker behavioral intentions than positive neutrally-toned WOM messages
- H1b: Negative humorous WOM messages will evoke weaker behavioral intentions than negative neutrally-toned WOM messages

Word-of-Mouth Intentions

- H2a: Positive humorous WOM messages will evoke weaker WOM intentions than positive neutrally-toned WOM messages.
- H2b: Negative humorous WOM messages will evoke weaker WOM intentions than negative neutrally-toned WOM messages.

Source Credibility

- H3a: Positive humorous WOM messages will evoke weaker perceptions of source credibility than positive neutrally-toned WOM messages.
- H3b: Negative humorous WOM messages will evoke weaker perceptions of source credibility than negative neutrally-toned WOM messages.

Message Persuasiveness

- H4a: Positive humorous WOM messages will evoke weaker perceptions of message persuasiveness than positive neutrally-toned WOM messages.
- H4b: Negative humorous WOM messages will evoke weaker perceptions of message persuasiveness than negative neutrally-toned WOM messages.

METHOD

Participants and Design

Participants were 492 American adults who participated in the survey as part of a paid survey panel. The design was a two (positive/negative WOM message) by two (neutral and humorous WOM) experimental design. Each participant was presented with two WOM scenarios.

Stimuli and Procedure

Four WOM messages were created for the experiment (a positive and negative version of the neutral and humorous messages). All stimuli were based closely on actual messages found in the 127 conversations from the exploratory research. All WOM messages were changed to a fictional brand name (Granger). In keeping with the home improvement focus of the exploratory research, all WOM messages dealt with garage door openers. Five business professors and three adult non-academics rated a total of 16 potential scenarios to ensure internal validity. Additional WOM descriptors were provided to avoid leading the responses (e.g. impatient, confused, shy, curious, etc.). The four scenarios that were used had agreement from all raters.

Participants completed the experiment online. After viewing each WOM message, participants were asked to evaluate the credibility of the source, persuasiveness of the message, behavioral intention and WOM intentions. Using existing scales ensured high reliability of the scales as is demonstrated in Table 1.

Source credibility measured the trustworthiness of the WOM message provider using a 5 item scale that focused on trustworthiness. Persuasiveness of the Message uses a 4 item scale to measure the strength of the WOM message. Behavioral Intentions measures the inclination of the message recipient to follow the advice given

TABLE 1
SCALE RELIABILITY

Scale	Source	
Source Credibility	Mackenzie and Lutz 1989	0.90
Persuasiveness of the Message	Gurhan-Canli and Maheswari 2000	0.89
Behavioral Intention	Mackenzie, Lutz and Belch 1986	0.92
WOM Intention	Price and Arnould 1999	0.93

in the WOM message using a 3 item scale. The WOM Intention scale measured the willingness to recommend the brand discussed in the WOM message using a 3 item scale.

RESULTS

Behavioral Intentions

The behavioral intentions scale was used to determine the inclination of the respondent to purchase the Granger garage door opener if they needed a garage door opener based on the WOM message that they read.

There was strong support for H1a. Behavioral intentions for positive neutral WOM messages ($M=0.80$) were reduced for positive humorous comments ($M=0.26$; $T(261)=15.25$, $p<0.01$). Similarly, H1b was supported—behavioral intentions for negative neutral WOM messages ($M=0.70$) were reduced for negative humorous messages ($M=0.21$; $T(231)=12.48$, $p<0.01$).

Overall, there was strong support for the hypotheses that neutral WOM messages have a larger impact on behavioral intentions than do humorous WOM messages.

Word-of-Mouth Intentions

The WOM intentions scale was used to determine the inclination of the respondent to pass on the WOM comment about Granger garage door openers to others through future WOM conversations.

There was strong support for H2a. WOM intentions for positive neutral WOM messages ($M=0.76$) were reduced for positive humorous comments ($M=-0.92$; $T(261)=12.55$, $p<0.01$). Similarly, WOM intentions for negative neutral WOM messages ($M=0.35$) were reduced for negative impatience messages ($M=-1.11$; $T(231)=11.28$, $p<0.01$), thereby supporting H2b.

Overall, there was general support for the hypotheses that neutral WOM messages have a larger impact on WOM intentions than do humorous WOM messages.

Dissecting The Results

In order to understand why behavioral intentions and WOM intentions decreased with the presence of humor, the role of positive versus negative messages was analyzed.

Positive versus Negative Messages

While the flow of the WOM conversations altered when humor was present, there was some indication that negative and positive comments impacted the flow differently. It was, however, difficult to forecast a directional effect for each of the message types.

Behavioral Intentions

Positive and negative messages influenced behavioral intentions differently, based on the message tone. Neutrally-toned com-

ments that were positive (i.e. supported the Granger brand), exhibited slightly stronger behavioral intentions ($M=0.80$) than negative messages ($M=0.70$; $T(261)=2.82$, $p<0.01$). This was consistent with previous research.

Humorous WOM demonstrated no significant difference on behavioral intentions between positive and negative comments.

Word-of-Mouth Intentions

In general, positive comments had a weaker impact on WOM intentions than negative comments. WOM intentions for positive neutral comments ($M=0.76$) were greater than WOM intentions for neutral negative messages ($M=0.35$; $T(261)=3.22$, $p<0.01$). This was not consistent with previous research.

Humorous WOM demonstrated no significant difference on WOM intentions between positive and negative comments.

Source Credibility and Message Persuasiveness

In addition to answering questions about behavioral and WOM intentions following each WOM, participants also asked to evaluate the credibility of the message giver and the persuasiveness of the message.

Hypothesis 3a was supported. Positive neutral WOM resulted in higher ratings of source credibility ($M=0.84$) than humorous WOM ($M=0.50$; $T(261)=10.33$, $p<0.01$).

Similarly, hypothesis 3b was supported. Negative neutral WOM resulted in higher ratings of source credibility ($M=0.77$) than humorous WOM ($M=0.47$; $T(231)=8.47$, $p<0.01$). This is consistent with Godes & Mayzlin (2004).

In judging message persuasiveness, hypotheses 4a and 4b were both supported. Positive neutral WOM also resulted in higher ratings of message persuasiveness ($M=0.67$) than humorous WOM ($M=0.28$; $T(261)=10.40$, $p<0.01$). Negative neutral WOM resulted in higher ratings of message persuasiveness ($M=0.63$) than humorous WOM ($M=0.23$; $T(231)=10.77$, $p<0.01$).

DISCUSSION

The complete analysis of hypotheses found significant differences between neutrally-toned and humorous WOM comments. These differences are partially explained by the degree of positivity or negativity in the messages. The WOM message tone and degree of negativity have significant influences on perceived source credibility and persuasiveness of the message.

These findings have important implications for our understanding of WOM dynamics and consumer behavior. First, the findings in general indicate that word-of-mouth is a more complicated construct than previously believed. Second, it indicates that the tone of the message may be as important as the actual message. Humor generally detracts from the impact of the message.

Managers will benefit from understanding that WOM is more complicated than previously understood. This means that compa-

nies may want to spark neutral WOM comments rather than using humorous appeals to spark WOM. This is increasingly important given recent interest in viral marketing campaigns.

Future research could evaluate the ways in which these changes interact. Specifically, research that attempts to model the interactions between message positivity/negativity and message tone would provide important insight into consumer analysis of WOM messages.

Given Zhang and Zinkhan's (2006) finding that the impact of a humorous message seems to be contingent on who receives the message, research that further investigates the recipients of humorous messages would be beneficial. As such, demographic analysis may also provide insight into the differing views of males versus females, experienced consumers versus inexperienced, and individuals with varying personal traits. Similarly, an analysis of how market mavens—those most likely to pass on marketplace advice—react to humorous WOM would be beneficial.

This research is limited by its data collection method. Online word-of-mouth messages may not be representative of off-line WOM behavior. Also, the fact that message givers were unknown to the participants may impact results. Again, this may speak to the differences between electronic WOM and traditional WOM. Also, any research based on humor is subject to differing views of the humor. While statistical differences were found, studies that replicate the findings would be useful.

Emotional Network in Control of Cognitive Processes in Advertisement

Andrzej Falkowski, Warsaw School of Social Psychology, Poland

Alicja Grochowska, Warsaw School of Social Psychology, Poland

ABSTRACT

The theoretical background for the presented research are network models of memory and emotion, and the prospect theory. The research examines cause-effect relationships between emotions elicited by the advertisement and the processes of evaluation and memory for ads appealing to positive or negative emotions. Structural equation modeling has been applied as a method of statistical analysis. The two studies show the significance of emotions and the specificity of autobiographical ads and PSA's (non-commercial advertisements), with reference to a consumer's personal gains and losses in the light of the prospect theory.

INTRODUCTION

One of the crucial factors determining the way consumers process information of advertisement are emotional reactions elicited by ads. Ad-triggered emotions, transferred to the ad, can influence the evaluation and memory of both an ad and the advertised brand (Burke, Edell, 1989; Holbrook, Batra, 1987; Morris et al., 2002; Escalas et al., 2004). Recent studies suggest that positive and negative emotions have an asymmetrical effect on reactions to ads (Moore, Hutchinson, 1983; Brown et al., 1998). However, different roles of positive and negative emotions in evaluation and memory of ads have not been explained yet (Cotte, Ritchie, 2005; Faseur, Geuens, 2006; Tanner, 2006). This problem can be solved in the light of network models in which relationships between emotion and cognition are considered. The role of positive and negative emotions in evaluation and memory of advertisement can be modified by the context of ad perception and by instrumental or prosocial motivational factors. Friestad and Thomson (1993) showed that memory of ads was dependent on the context in which they were perceived (ad-directed processing vs. brand-directed processing). Emotional advertisements were better remembered when perceived in the ad-directed context. Furthermore, Sujan, Bettman and Baumgartner (1993) and Baumgartner, Sujan and Bettman (1992) found that consumers' autobiographical memories involving products and product usage experiences were affectively charged and retrieval of autobiographical memories influenced evaluation and memory of advertisement. The stronger the emotions (net-affect) elicited by the ad were, the better the ad and brand were evaluated. The better the brand evaluations, the better memory for brand claims was, but only in strong argument conditions. Relationships between positive vs. negative emotions and evaluation and memory of ads can be analyzed in the light of gains and losses which the consumer incurs by purchasing or not purchasing the product. Such an approach to research matches the prospect theory by Kahneman and Tversky (1979).

The goal of our research is to investigate cause-effect relationships between emotions elicited by the advertisement and the processes of evaluation and memory for ads appealing to positive or negative emotions. Our purpose also is to show the significance of emotions and the specificity of autobiographical ads and PSA's (non-commercial advertisements), with reference to a consumer's personal gains and losses in the light of the prospect theory.

THEORETICAL BACKGROUND

Network organization of emotions

Relationships between emotion and cognition can be well explained by network models of the mind. In the PDP model,

McClelland (1995) explains information processing of objects and events, but not emotions. Parallel and cooperative processing of emotional information were emphasized by Suarez Araujo and colleagues (2005). Bower (1992) took emotions into consideration as well as events and objects in his network model of memory. A constructivist and contextual approach to emotion and memory was presented by Parrot and Spackman (2000). Panksepp's (2000) studies indicated the cooperation of emotional and cognitive processes. The emotional system can be considered as a network structure as well as in other perspectives. There are neurobiological, psychophysiological and psychological arguments that systems responsible for processing positive and negative emotions are independent (Cacioppo, Berntson, 1994; Cacioppo, Gardner, 1999). Research into influences of positive and negative emotions on cognitive processes showed that positive affect improved creative problem solving: it led to cognitive elaboration and flexibility, giving rise to more thoughts, more nontypical thoughts, and innovative solutions to problems. Therefore, it can be claimed that positive affect activates a wide area of a cognitive network. On the other hand, research on negative affect showed that the negative affect is not simply the opposite of positive affect in either its behavioral or cognitive effects. Negative affect increases vigilance more than positive affect, while activating a narrower area of the cognitive network (Ashby, Isen, Turken, 1999).

Positive and negative ads and gains and losses

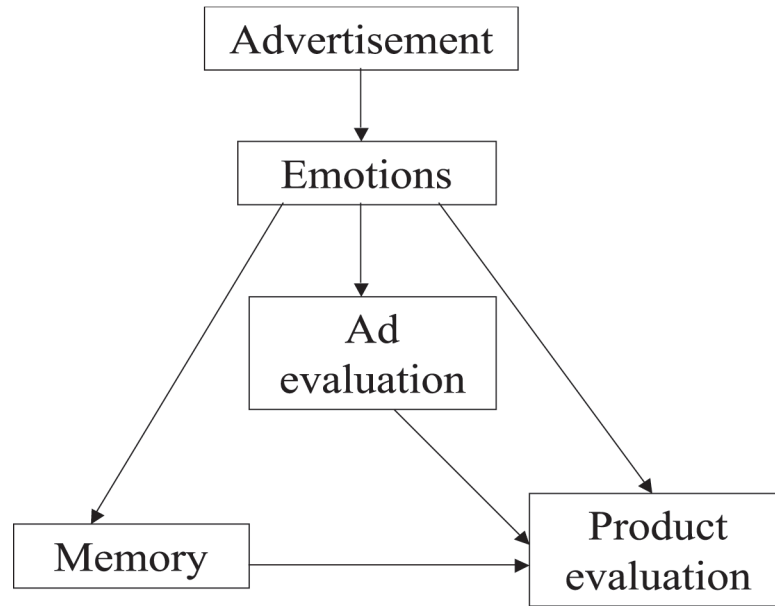

According to the prospect theory by Kahneman and Tversky (1979), 'losses loom larger than gains'. Kahneman and Tversky's research has been concerned mainly with monetary outcomes. However, the authors suggest that the theory is applicable to choices involving other attributes. Positive and negative emotions in advertisement can be significant not only in evaluation and memory of ads but also in experiencing satisfaction of purchase (gains) or dissatisfaction with not having purchased the product (losses). Therefore, one can expect that ads can elicit strong negative emotions and high sensitivity by suggesting what consumers can lose by not purchasing the product, whereas ads implying gains by purchasing the product elicit moderate positive emotions and low sensitivity to the ad. The effect of gains and losses in advertisement can be modified by different motivational factors elicited by both commercial and non-commercial ads. The effect is stronger if gains and losses concern the consumer directly, which is related to instrumental motivation.

Theoretical model

On the basis of the assumptions presented above we propose a theoretical model for print advertisement (Figure 1). Our model is based on Burke and Edell's (1989) research which examined relationships between emotions elicited by advertisement and evaluation of the ad and brand. In Burke and Edell's analyses the fit of structural models to the empirical data was excellent.

In our model, advertisement, as an emotional stimulus, activates nodes in the emotional network. Emotions elicited by the advertisement influence ad and product evaluation, and memory. Furthermore, according to the effect of familiarity, familiar stimuli are more attractive (Zajonc, 1980). Therefore, one can expect that the more familiar the advertisement, the more positive the evaluation of the product. Since we tested memory for brand claims, we did not expect the effect of ad evaluation on memory: Even in

FIGURE 1
Theoretical model: emotions in evaluation and memory of advertisement

positively evaluated ads, brand claims can be processed peripherally. Our model can be interpreted as the emotional-cognitive network, sensitive to the context and emotions elicited by the ad.

STUDY 1

Emotions in evaluation and memory of the autobiographical ad

Personal experiences stored in autobiographical memory have specific properties which are important for research into autobiographical advertisement. First, autobiographical knowledge can be considered a constructive process. Therefore, autobiographical memories are sensitive to the context in which they are retrieved. Second, accessing autobiographical memories is likely to enhance the involvement in communicated information. In autobiographical advertisement emotions are elicited by autobiographical text, referring to personal experiences. Krugman (1965, 1967) emphasized the importance of accounting for the personal experiences that individuals accessed during exposure to an advertisement and assumed that autobiographical memories have an important influence on the process of product evaluation. According to Baumgartner, Sujan and Bettman (1992), encouraging autobiographical memories with an advertisement influences evaluation and memory of the ad. Personal involvement encouraged by the advertisement can also be significant for perceiving gains or avoidance of losses while in possession of the product. This perception depends on whether the advertisement refers to positive or negative autobiographical memories.

In Study 1 we examine cause-effect relationships between emotions elicited by the advertisement and the processes of evaluation and memory for ads appealing to positive or negative emotions. We also investigate the significance of the context in which the ad was perceived (ad-directed processing vs. brand-directed processing) and the significance of positive vs. negative emotions elicited by the ad in its evaluation and recall. Finally, we analyze the results obtained with reference to the consumer's personal gains and losses in the light of prospect theory.

Participants, Materials, and Procedure

One hundred and eighty-eight undergraduate students, age 19–25, took part in Study 1. Participants were volunteers, from universities and colleges in Warsaw.

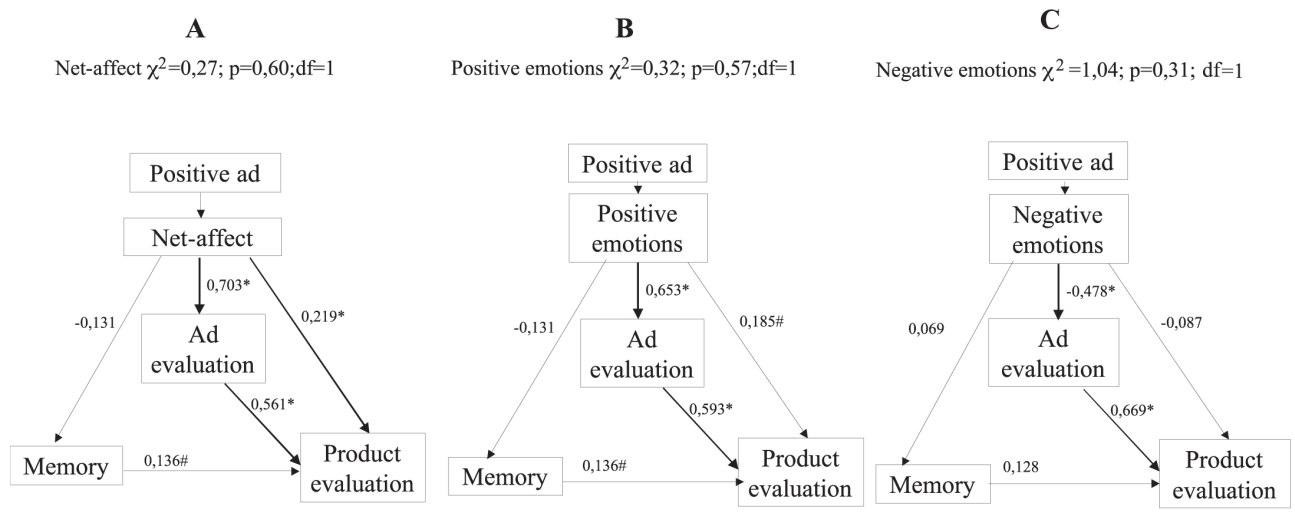

Two *print advertisements* were designed for the purpose of the experiment. Both ads presented a DVD case. Brand claims of fictitious brand General Master were located at the bottom of each ad. The two ads included different autobiographical texts, one referring to positive and the other to negative autobiographical memories.

The *Emotional Network Scale* was used to measure emotions elicited by the advertisement. The construction of our scale was inspired by Burke and Edell's (1989) *The Feelings Scale* and Sujan, Bettman and Baumgartner's (1993) *Net Affect Scale*. The categorical and network structure of emotions constituted the theoretical background for the Emotional Network Scale. Multidimensional scaling methods were applied to establish the network structure of emotions. Psychometric properties of the 21-item scale were described by Grochowska and Falkowski (in print). Three indices of emotions were analyzed: positive emotions, negative emotions and the difference between positive and negative emotions (net-affect). There were 13 and 8 items for positive and negative emotions, respectively. Participants marked their answers on the 7-point Likert scale.

The *Ad Evaluation Scale* was used to measure the subjects' assessment of the ads. In constructing the scale a principal components analysis yielded two factors: positive and negative evaluation. In preliminary studies three ads (positive, negative, and neutral) were investigated and adjectives loaded more than .60, shared by the three ads, were selected. Thus, the scale consisted of 32 adjectives, 16 for positive and 16 for negative evaluation. The index of ad evaluation was the difference between sums of positive and negative items, according to the methodology described by Burke and Edell (1989).

Product evaluation was assessed on four 100-millimeter-long scales, in which 0 was low and 100 was high: satisfaction with, and

FIGURE 2
Structural equation models for the ad referring to positive autobiographical memories

quality, durability, and utility of the product advertised. The four measures were totaled to form an overall measure of product evaluation. Cronbach-alpha was .94.

Brand claim recall. Subjects were asked to list all the brand claims that they could recall from the ad. The number of brand claims correctly recalled was counted. The recall score could vary between 0 and 10.

Procedure and methods of statistical analysis

The study was conducted individually, in laboratory conditions. Subjects were asked to either evaluate the merits of the advertised brand (brand-directed processing) or to judge the merits of the actual advertisement for the brand (ad-directed processing). At first, a buffer ad was implemented. Then, forty seconds were given to view an experimental advertisement. Two groups viewed the ad referring to positive autobiographical memories and the other two viewed the ad referring to negative. Then the subjects were asked to list all the brand claims they could recall from the advertisement, in the order that first came to mind. They were then asked to fill The Emotional Network Scale, The Ad Evaluation Scale and product evaluation scales. Assumptions on the network structure of cause-effect relationships between analyzed variables allowed the testing of the theoretical model applying structural equation modeling as a method of statistical analysis.

Results

Emotions in memory and evaluation of autobiographical ads

The proposed model of effects of emotion on evaluation of ads and products and on memory for brand claims, similar to Burke and Edell's (1989) models, was tested in structural equations modeling. The system was tested by translating the variables presented in Figure 1 into a system of structural equations expanded to include the positive and negative emotions as well as the difference between them (net-affect) elicited by the ad, for the two ads referring to positive or negative autobiographical memories. In this way, the six empirical models were tested. Structural equation models for the ad referring to positive autobiographical memories are presented in Figure 2.

As we can see in Figure 2A, net-affect elicited by the ad referring to positive autobiographical memories had a direct effect on the ad and product evaluation. Although emotions elicited by the ad had no direct influence on the memory of brand claims, the fit of the model to empirical data was worse after removing the path between emotions and the memory of brand claims.¹ This means that cause-effect relationships presented in the model are significant for the entire model. Furthermore, there was an effect of brand claims on product evaluation (at the level of statistical tendency, $p=0,08$). Familiar stimuli were evaluated more positively. Thus, there were three determinants in product evaluations in the analyzed model: memory of brand claims, ad evaluation and emotions elicited by the ad. Similar regularity could be observed in the ad referring to positive autobiographical memories, in the case of eliciting positive emotions (Figure 2B). But this effect did not occur in the case of eliciting negative emotions (Figure 2C) nor in the ad referring to negative autobiographical memories (Figure 3). Thus, positive emotions activated a wide area of the cognitive network. On the other hand, negative affect was not simply the opposite of positive affect in its cognitive effects.

Negative emotions elicited by the ad (Figure 2C and 3C) had a direct effect on one variable only: evaluation of the ad. Negative emotions had an effect on the negative ad evaluations but not on the evaluations of the product itself. In product evaluation subjects relied upon ad evaluation. Relationships between negative emotions and the memory of brand claims and the evaluations of the product were not significant in this model. However, after remov-

¹Akaike's Information Criterion (AIC), (Akaike 1987), has been used for selecting the best model among a number of candidate models. We compared AICs for six models respecting the path between emotions and the memory (-1.729; -1.9; -1.68; -1.62; -0.96; -1.991) to AICs for six models after removing this path (-2.369; -3.739; 39.75; 54.05; 17.23; 34.01, respectively). The model that yields the smallest value of AIC is considered the best. Models respecting the path between emotions and the memory had lower AICs than the models after removing this path.

FIGURE 3

Structural equation models for the ad referring to negative autobiographical memories

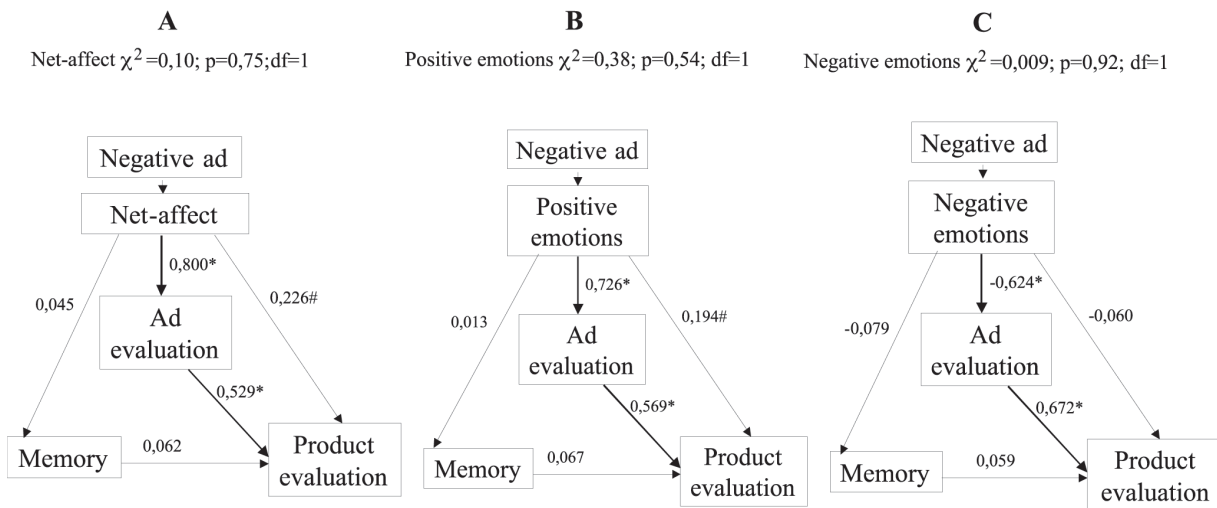

FIGURE 4

Values of fits (χ^2) for models of advertisements referring to positive vs. negative autobiographical memories, in two contexts of ad perception

ing the path between negative emotions and the memory of brand claims, the fit of the model to empirical data was worse. This means that relationships between emotions elicited by the ad and brand claims recall were significant for the entire model, as in models for net-affect or for positive emotions. Furthermore, it can be observed that negative emotions activated a narrow part of the cognitive network compared to positive emotions.

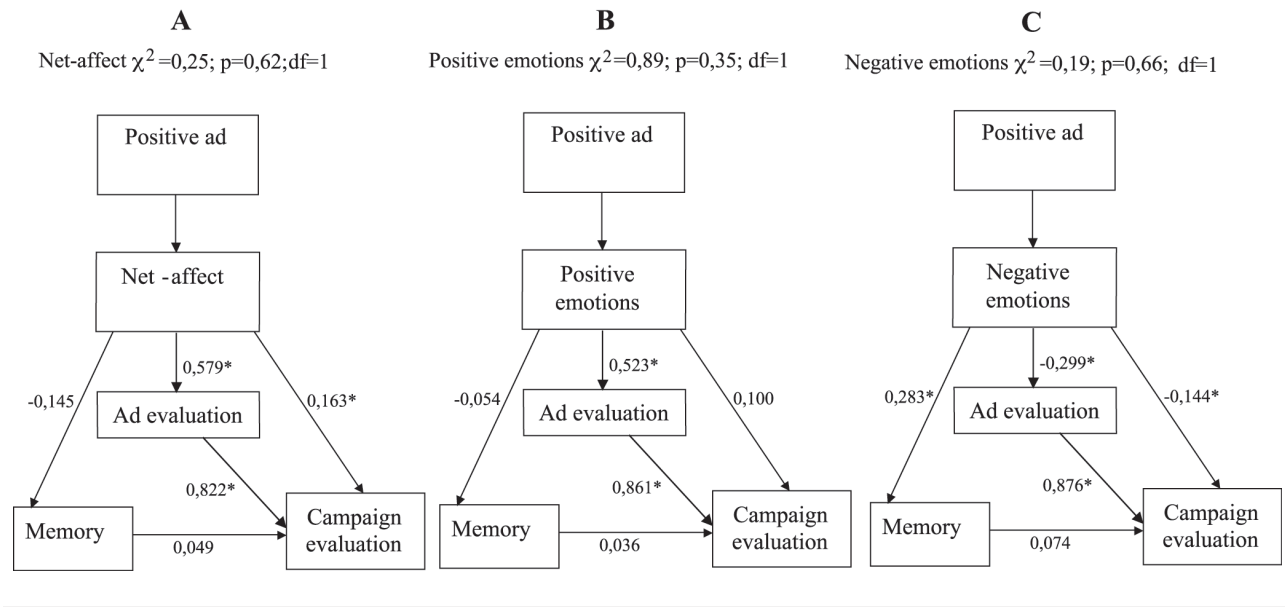

Emotions in evaluation and memory of autobiographical ads, in the two contexts of ad perception

It was expected that the structure of relationships between emotions elicited by the ad, evaluations of the ad and brand, and brand claims recall were modified by the context of ad perception.

In the following analyses the theoretical model was tested for the data obtained in two contexts of ad perception: ad-directed and brand-directed processing. In subsequent analyses, emotions elicited by the ad (positive emotions, negative emotions and net-affect), in two contexts of ad perception, for ads referring to positive vs. negative autobiographical memories, were taken into consideration. Thus, the χ^2 tests were used to estimate the fit of empirical data to twelve theoretical models (Figure 4).

An interesting regularity may be seen in Figure 4: in models for ads referring to positive autobiographical memories the fit of the model to empirical data was much worse than in models for ads referring to negative autobiographical memories. This means that

FIGURE 5
Structural equation models for the PSA referring to positive emotions

subjects were more sensitive to losses (negative, threat message) than to gains (positive message). This result is in accordance with prospect theory by Kahneman and Tversky (1979)—‘losses loom larger than gains’. The same product presented in the perspective of gains vs. losses was remembered and evaluated differently. Moreover, in ads referring to positive autobiographical memories, there was an effect of brand claims memory on product evaluation in the ad-directed context, while in the brand-directed context this relationship was not significant. This means that relationships between memory of brand claims and product evaluation in the ad-directed context had an emotional nature-familiar stimuli were more attractive. In the perspective of marketing application one can say that through positive emotions the ad is better remembered, whereas negative emotions cause deeper, more thorough information processing.

STUDY 2

Emotions in evaluation and memory of PSA, ‘s (non-commercial ads)

The particular feature of Public Service Advertisements is that they usually elicit negative emotions. PSA messages often refer to anxiety or compassion. Appeals to anxiety encouraging the viewer to take action for his own good (for example, to give up smoking) are often used in PSA’s. Appeals to compassion are efficient in PSA’s encouraging viewers to help others (e.g. to support starving children). According to Bagozzi and Moore (1994) negative emotions elicited by the PSA lead to empathic reactions and facilitate making decisions to help others.

The aim of Study 2 was to investigate cause-effect relationships between emotions elicited by the PSA and the processes of evaluation and memory for such ads. The significance of positive and negative emotions in evaluation and memory of PSA’s was also examined. Unlike Study 1, the persuasive message did not refer to personal gains or losses.

Participants, Materials, and Procedure

Ninety-eight undergraduates and postgraduates participated in Study 2. Participants were volunteers, from Warsaw and Lodz universities.

Two *print public service advertisements* were designed for the purpose of experiment. Both ads presented the logo of the fictitious foundation “Loving Bears”, its slogan and information about the campaign. The two ads presented different photographs: one referring to positive emotions (showing a healthy and cheerful child) and the other to negative emotions (showing a sad and scruffy child).

Emotions elicited by the ads were measured with *The Emotional Network Scale*.

Advertisement and the campaign (advertised idea) evaluations were measured on five 7-point adjective scales adapted for PSA’s.

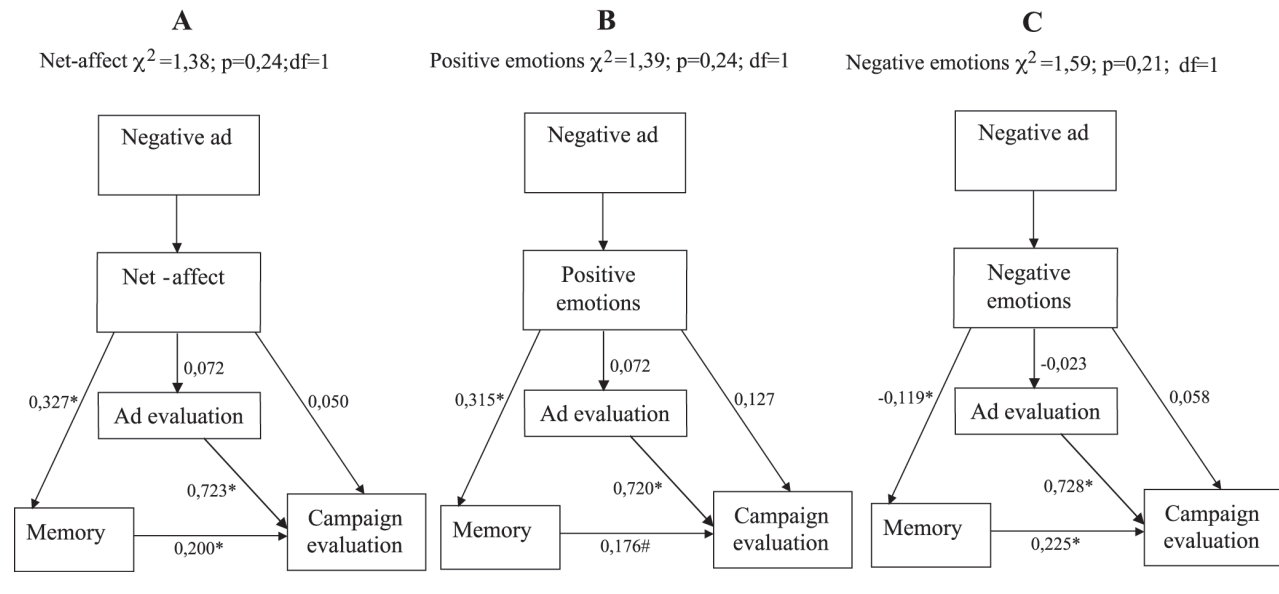

An index of *memory for the ad and the campaign* was a sum of scores on questions on the feeling of familiarity of the ad and campaign.

Procedure and methods of statistical analysis. The study was conducted individually. Each participant was presented one advertisement. One group viewed the ad referring to positive emotions and the other to negative emotions. Then the subjects were asked to fill The Emotional Network Scale, scales for ad and campaign evaluation, and answer the questions on familiarity of the ad and campaign. Structural equation modeling was used as a method of statistical analysis.

Results

The theoretical model was tested by translating the variables presented in Figure 1 into a system of structural equations expanded to include the positive and negative emotions as well as the difference between them (net-affect) elicited by the ad, for the two PSA’s referring to positive or negative emotions. That way, all six empirical models were tested. Structural equation models for the ad referring to positive emotions are presented in Figure 5, and to negative emotions, in Figure 6.

FIGURE 6
Structural equation models for the PSA referring to negative emotions

As we can see in Figures 5 and 6, there was only an effect of emotions on the evaluation of the ad and the campaign when the ad referred to positive emotions, but not to negative. Whereas in the case of the ad referring to negative emotions, an effect of emotions was observed on the feeling of familiarity with the ad and the campaign. The more positive the emotions elicited by the ad presenting a sad and scruffy child, the more familiar the ad and the campaign were reported to be. However, the foundation was fictitious and the ad was constructed for the purpose of the experiment. In the case of the ad presenting a healthy and cheerful child, the evaluations of the ad and the campaign were based on emotions. Whereas in the ad presenting a sad and scruffy child evaluations of the ad and the campaign were based on cognition—i.e. the feeling of familiarity of the ad and the campaign.

Figure 7 presents the fits of the model to empirical data (χ^2) for PSA's referring to positive and negative emotions.

When the ad was not coherent with the problem advertised (presenting a healthy and cheerful child), the fit of the theoretical model to the empirical data was better than in the case of the ad coherent to the problem advertised (i.e. presenting sad and scruffy child). This means that people are more sensitive to dissonant stimuli. The ad presenting a cheerful child could elicit a dissonance, and cause astonishment and more careful attention to the ad.

FINAL REMARKS

The research showed that positive emotions activated a wide area of the cognitive network. Therefore, one could expect that more cues of ad recall are available. On the other hand, negative emotions activated a smaller area of the cognitive network and elicited high sensitivity to the perceived ad, so messages in the advertisement are processed more thoroughly. Therefore, one can say that *cooperation* of positive and negative emotions enables better memory of the ad. It is worth noting that only positive emotions are transferred to product evaluation; negative emotions are not significant here.

Public service advertisements which elicited dissonance and high sensitivity, caused astonishment and more careful attention to the ad. This way the persuasive message in the ad could be remembered better.

Commercial ad referring to losses was processed more sensitively than the ad referring to gains. This result is congruent with prospect theory by Kahneman and Tversky (1979). This effect appeared only in the case of persuasive messages referring to personal gains and losses. The results of our research suggest that advertisers can control the form of persuasive messages to influence the perceived satisfaction of purchase (gains) or dissatisfaction with not having purchased the product advertised (losses).

Pushing the Envelope of Brand and Personality: Antecedents and Moderators of Anthropomorphized Brands

Marina Puzakova, Drexel University, USA
Hyokjin Kwak, Drexel University, USA
Joseph F. Rocereto, Monmouth University, USA

ABSTRACT

The tendency for consumers to perceive brands as actual human beings has significant implications in the area of branding. However, there is a large gap in the marketing literature regarding the process and conditions that may influence the degree to which consumers perceive brands as complete human beings. The present research introduces the concept of anthropomorphized brands and discusses the psychological mechanisms that underlie the process of brand anthropomorphization. Our study builds on the three-factor theory of anthropomorphism to explain how self-concept/brand image congruity may influence the inference process of brand anthropomorphization. Furthermore, we suggest that sociality and effectance motivation variables may moderate the relationship between self-concept/brand image congruity and anthropomorphized brands. Theoretical and managerial implications are also discussed.

INTRODUCTION

The concept of Anthropomorphization has been explored in various academic disciplines: a religious context (Gilmore 1919), application to pets (Cheney and Seyfarth 1990), and even to gadgets (Epley et al. 2008). Among philosophers, the concept of anthropomorphism has been discoursed for more than two thousand years. Anthropomorphization theory has also significant implications in marketing research. For example, Fournier (1998) claims that individuals experience little difficulty in assigning personality features to brands; Levy (1985) and Plummer (1985) provide evidence that consumers easily view brands as possessing human characteristics. It is a widely accepted notion that consumers form different types of relationships with brands (Fournier 1998). However, for a brand to become an actual partner in the relationship, it must be perceived as a complete, literal human.

As marketing practitioners direct their promotional campaigns to attempt to persuade consumers to view brands as fully human, no reasonable explanation has been provided in regards to potential key variables that may impact consumers' ability and motivation to perceive brands as humans. Furthermore, a considerable number of psychological theories have been employed in order to better understand consumer-brand relationships (e.g., theories of love (Shimp and Madden 1988) or trust (Hess 1995)) without exploring the phenomenon of brand anthropomorphization, its antecedents, and underlying psychological mechanisms.

The anthropomorphization phenomenon has been extensively noted in varying streams of literature, but it has not received meaningful psychological account within the consumer behavior literature. Moreover, researchers in various fields of social science have been considering anthropomorphization as an invariant psychological process. Following this tradition, marketing researchers who have utilized the notion of somehow personalized or humanized brands have considered the process of consumers prescribing human characteristics to nonhuman objects as a chronically occurring consumer judgment. However, the three-factor anthropomorphization theory introduced by Epley et al. (2007) posits that different people are more or less likely to anthropomorphize objects, and that the anthropomorphization process is greatly determined by the accessibility of human knowledge, by the pres-

ence of specific situational cues, and by individuals' motivation at the time of judgment.

In summary, the purpose of the present study is threefold: 1) to advance the theory of anthropomorphization by introducing the notion of anthropomorphized brands in marketing research and explaining how anthropomorphized brands are different from other existing marketing brand concepts (e.g., brand personality); 2) to examine the antecedents of anthropomorphized brands; 3) to investigate the moderating roles of sociality motivation and effectance motivation on the relationship between self-concept/brand image congruity and anthropomorphized brands. The overall conceptual model is presented in Figure 1.

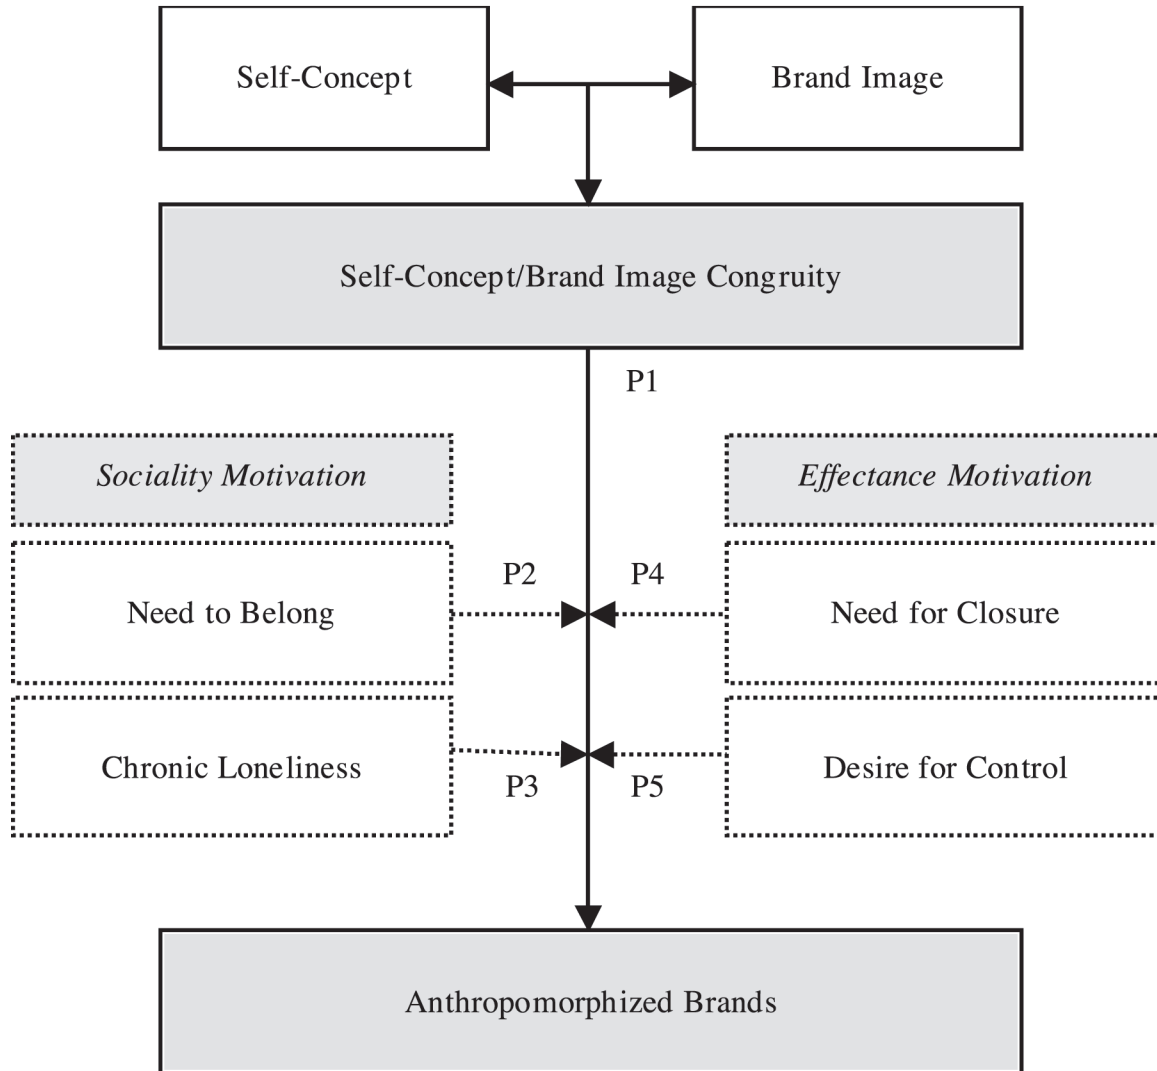

CONCEPTUAL BACKGROUND AND PROPOSITIONS

Anthropomorphization and Anthropomorphized Brands (AB)

Marketing communication efforts have encouraged consumers to view brands in human terms (Aggarwal and McGill 2007; Yoon et al. 2006). There is evidence in the marketing literature that consumers may perceive humanlike features in products and brands (Aggarwal and McGill 2007; Tremoulet and Feldman 2000). The psychological process of imbuing brands with personalities is referred by Aaker (1997) as *animism*. In marketing research, animism and anthropomorphism are frequently used interchangeably to demonstrate the process of product or brand animation. For instance, Fournier (Fournier 1998) refers to theories of animism when discussing the anthropomorphization process. However, social psychologists explicitly differentiate between the two psychological processes. For example, Guthrie (1993) describes animism as a person's wishful thinking of instilling life into objects when some motion or noise from the object is discerned. More importantly, the author defines anthropomorphism as the perception and recognition of humans in objects in the surrounding environment. Additionally, Epley et al. (2007, p. 865) argue that, "anthropomorphism involves more than simply attributing life to the nonliving (i.e., animism)". Consequently, prescribing selective human characteristics to nonhuman objects or merely simply enlivening nonhuman objects (animism) is not synonymous with viewing these objects as complete humans (anthropomorphism).

Furthermore, results of a qualitative study regarding consumer-brand relationship formation conducted by Fournier (1998) show some evidence that consumers may form relationships with brands. Extensive research in consumer behavior supports the notion of the existence of strong consumer-brand relationships (Aaker, Fournier, and Brasel 2004; Aggarwal and McGill 2007; Kim, Lee, and Ulgado 2005). However, Fournier (1998) argues that, in order for a brand to serve as a viable relationship partner and become a legitimate member of a consumer-brand bond, a brand should possess multiple qualities of a human being, embracing emotionality, thoughtful behavior, soul, and feelings. The fact that consumers form strong relationships with brands suggests that individuals perceive these brands as complete humans. Therefore, in the present paper, we apply the notion of anthropomorphization to brands and define anthropomorphized brands as *brands perceived by consumers as actual human beings with various emo-*

FIGURE 1
Conceptual Model

tional states, mind, soul, and conscious behaviors that can act as prominent members of social ties.

More than a decade ago, marketing scholars explored the concept of brand personality (BP) (Aaker 1997). Consumers' perceptions of brand personality became an extensively utilized phenomenon in the practitioners' world. Multiple examples can be identified in the brand world, such as sincere brands (e.g. Hallmark and Ford) (Smith 2001) or exciting brands (e.g. Mountain Dew and BMW) (Aaker et al. 2004). For example, Aaker (1997) states that Dr. Pepper is considered to possess a nonconforming, unique, and fun personality.

In the psychology and marketing literature, personality is commonly defined as the consistency of an individual's behaviors and reactions to surrounding stimuli (Kassarjian 1971). "Anthropomorphism involves going beyond behavioral descriptions of imagined or observable actions" (Epley et al. 2007, p. 865). More specifically, the anthropomorphization of nonhuman objects means perceiving them as absolute humans (Epley et al. 2007). This

involves attributing mind (intentions, effortful thinking, and consciousness) (Gray, Gray, and Wegner 2007), soul (Gilmore 1919), emotional states (Leyens et al. 2003), and behavioral features (Epley et al. 2007). Additionally, anthropomorphism entails the inference process of unobservable human features. Many characteristics of human nature are not readily recognizable, and personality, though being an essential observable part of humans, does not exhaust the transcended concept of humanness (Haslam et al. 2005). Furthermore, Haslam et al. (2005) argue that uniquely human characteristics involve human-nonhuman comparisons, while personality, being the differentiator of humans, is relevant to only person-to-person comparisons. Also, personality develops within the course of life. However, humanness is inherent to humans from the moment of birth. Thus, BP represents only one facet of the multiple components of AB. Additionally, in the marketing literature, BP has been defined as the set of human features that are associated with a brand and strictly applicable to brands (Azoulay and Kapferer 2003). This definition of BP substantially limits the

range of personality characteristics that can be attributable to humans. Therefore, this fact provides additional evidence that the AB concept transcends the construct of BP.

Self-Concept/Brand Image Congruity

Self-concept theory, being the subject of psychological and sociological academic interest for many decades, has multiple implications in marketing research (Aaker 1999; Grubb and Grathwohl 1967; Hong and Zinkhan 1995; Kleine, Kleine, and Kernan 1993; Rocereto, Kwak, and Puzakova 2008; Sirgy 1982). There are many conceptualizations of self-concept in the consumer behavior literature. One such definition is that, "the self is what one is aware of, one's attitudes, feelings, perceptions, and evaluations of one's self as an object" (Grubb and Grathwohl 1967, p.24). Another definition of the self comes from the nineteenth century when James (1890, p.291) conceptualized the self as, "...a sum of all that he (man) can call his, not only his body and psychic powers, but his clothes and his house...". It is obvious from James' definition that the self goes beyond one's personal perception of their own inner state, but includes external elements that a human owns. The self is extremely important and valuable to individuals, and they are expected to behave in ways that protect and enhance their self-concept (Kleine et al. 1993; Sirgy 1982; Underwood 2003; Wallendorf and Arnould 1988). One way to extend and bolster a consumer's self-concept is through the symbolic meanings of brands that consumers possess (Belk 1988; Kassarijian 1971). That is, consumers are able to strengthen their own self-concept by owning brands whose symbolic images are congruent with important aspects of one's own self-concept. Therefore, the present study elaborates on the notion of self-concept/brand image congruity that is defined as the level of congruity between key elements of one's own self-concept and brand image.

The tendency for consumers to utilize brands as symbols in expressing one's self-concept arises from the fact that consumers imbue brands with human personality traits (Aaker 1997). Consumers make evaluations of brands based upon the perceived similarity between their own self-concept and perceived human personalities that they view in brands. If the result of such self-concept/brand image evaluations is positive, that is, in cases wherein consumers perceive the images of brands as being similar to their own self-concept, then they may develop higher levels of brand preferences and brand loyalty and will seek to own and surround themselves with brands that are congruent with their own self-concepts (Grubb and Grathwohl 1967; Hong and Zinkhan 1995; Kassarijian 1971). In the present study, we argue that self-concept/brand image congruity may be positively associated with consumers' perception of AB. We provide the psychological account for the relationship between self-concept/brand image congruity and AB further.

Self-Concept/Brand Image Congruity as an Antecedent to AB

According to Epley et al. (2007), the primary determinant of nonhuman object anthropomorphization is the activation of individuals' self-knowledge or human category knowledge, that is, the accessibility of the human cue at the point of judgment. The elicitation of human knowledge, in general, or self-knowledge, in particular, is based to a great extent upon the physical disability of humans to imagine how to be an object, and individuals' natural tendency to merely experience what it is to be a human due to their sensory limitations (Epley et al. 2007). Guthrie (1993) argues that individuals are extremely sensitive to the availability of any human cue and are very proficient in detecting its presence. Additional reasoning that Epley et al. (2007) provide is that egocentric knowledge is automatically accessible in making judgments for both humans and nonhumans. Psychology literature provides evidence

that supports the notion that self-knowledge operates naturally in the inference processes. For example, Tremoulet and Feldman (2000) show that similarity in motion may stimulate the anthropomorphic processes, and Dennett (1982) demonstrates that facial features or voices may increase the anthropomorphic induction processes. There is a support for the claim that human schema is primed by human cue in marketing literature, as well. For example, in Aggarwal and McGill's (2007) study, the process of product anthropomorphization occurs when human self-schema is activated by the physical appearance of the front of a car that closely resembles the human feature of a smile or of the shape of a bottle that emulates the human physical shape. Furthermore, as the three-factor theory of anthropomorphism postulates, human category or self knowledge application and anthropomorphic inference are likely to be corrected by giving further thought to the object of induction. Thus, when nonhuman information about brands is present, consumers may exhibit the tendency to cognitively process that information and to overcome the anthropomorphic representations of brands in their minds.

Building on the three-factor theory of anthropomorphism (Epley et al. 2007), we argue that when individuals identify that a brand possess aspects of their own unique human personality, the availability of the human cue activates human category knowledge. Sequentially, specific human personality dimension of a brand elicits consumer's self-schema that entails the same personality characteristics (Sirgy 1982). Similarly, previous research has shown that, based on the self-consistency motivation theory (Epstein 1980), consumers approach brands by making comparisons between their own self-concept and the images of these brands (Sirgy 1982). Successively, when making these comparisons, consumers are applying their self-knowledge to brands. When accessible at the point of judgment, human knowledge or self-knowledge may give a consumer a hint to make anthropomorphic inferences about brands. However, at this point, consumers may consider the other non-anthropomorphic brand features that allow for the overcoming and correcting of the initial inference pursuant to AB. For example, consumers may notice some non-anthropomorphic representation in an advertisement, such as the unrealistically fast movements of the image representing the brand in an advertisement that do not resemble the human motion, or a brand message using, instead of the words "family of products" (contains human cue), the words "line of products" (does not contain anthropomorphic cue) (Aggarwal and McGill 2007).

A consumer's consequential psychological process results in making decisions about the level of perceived similarity or dissimilarity between one's own self-concept and the image of a brand that has been defined above as self-concept/brand image congruity. Self-concept/brand image congruity is based on the notion of values that consumers project to brands (Grubb and Grathwohl 1967; Sirgy 1982). Furthermore, voluminous research has shown that brand value is derived from the symbolic meaning of a brand and is embedded in consumers' affective components of their attitudes (Belk 1988; Richins 1994; Wallendorf and Arnould 1988). Thus, when consumers are making comparisons between their own self-concepts and images of brands, they are comparing their own values with those of the values that a particular brand image carries.

On the other hand, marketing researchers have given sparse consideration to the dehumanization theory that has received the vast attention of scholars in psychology and sociology (Haslam et al. 2007). This theory has been primarily applied to explain racial and ethnical intergroup antagonism, conflict, and violence. Haslam et al. (2007) suggest that the dehumanization theory may be applied, not only to the realm of ethnocentric intergroup problems, but also to the interpersonal context, that is, the dehumanization phenomena

can be present in subtle and everyday forms. The central position of dehumanization theory is that if individuals perceive the values of the outgroup as being dissimilar to the values of their ingroup, then they are likely to deprive the outgroup of humanness (Schwartz and Struch 1989). Schwartz and Struch (1989) discuss that values reflect the group humanness and convey the group's humanity. Translated into the interpersonal context, dehumanization theory postulates that when the values of other individuals significantly differ from the values of one's self, then the dehumanization process is likely to occur (Haslam et al. 2007). In the present study, we argue that when consumers' human category knowledge or self-knowledge is primed, they are likely to make anthropomorphic inferences about brands and to perceive these brands as being completely human. Consequently, we posit that dehumanization theory may explain consumer-brand relationships as well. In the light of dehumanization theory, we claim that when brand values are incongruent with consumers' values, consumers are likely to overcome and correct their anthropomorphic inferences of AB. On the contrary, when self-concept/brand image congruity is established, that is, in cases wherein consumers perceive their own values and the values of the images of brands as being congruent, consumers exhibit the tendency to perceive AB without further correction.

Additionally, voluminous research has shown that self-concept/brand image congruity results in affective responses towards brands (Belk 1988; Klein, Kleine, and Allen 1995; Wallendorf and Arnould 1988). Similar streams of research support the notion that consumers experience high levels of attachment toward brands that are most congruent with their own self-concept (Kleine et al. 1993; Richins 1994). In addition, consumers are expected to be more loyal to brands that are more congruent with their own self-concept (Bhattacharya, Rao, and Glynn 1995; Underwood 2003). As ample marketing literature suggests, attitudinal loyalty provides a strong barrier against competitor attempts to persuade consumer switching behavior that is based upon superior functional features of brands or any situational influences (Oliver 1999). Consequently, in the present paper, we propose that consumers' positive affective states "protects" consumers' perception of AB from correction to the perception of non-AB through subsequent possible cognitive non-anthropomorphic considerations. In the absence of congruity, consumers may observe nonhuman features of brands and access some alternate nonhuman representations that may switch their perception of AB to non-AB (Epley et al. 2007).

P1: Self-concept/brand image congruity is positively associated with anthropomorphized brands.

The Moderating Role of Sociality Motivation

Sense of social connection or belonging is one of the most important human values (Kahle, Beatty, and Pamela 1986) and significantly influences one's success and mental health (Adler and Brett 1998). Prior research has shown that individuals satisfy their need for social connections with evident ease, for example, by establishing close connections with religious objects or pets (Epley et al. 2007). Here, we argue that individuals may satisfy their need for social connections through forming affective bonds with AB. First, the state of sociality motivation may increase consumers' social cues accessibility involving humanlike features in brands, influencing the inference process of brand anthropomorphization. Second, sociality motivation stimulates individuals to energetically search for any clues of social connections. Previous marketing research literature suggests that brands may satisfy the need for social connections. For instance, consumers experience the feeling of intrinsic connection through membership in brand communities

(Muniz and O'Guinn 2001). Moreover, individuals whose need for social connection is not satisfied experience the same pain as physical pain (MacDonald and Leary 2005). To recover from this social pain, individuals may tend to anthropomorphize nonhuman objects, and they are more likely to perceive AB. Thus, we propose that consumers who exhibit a high level of the individual need for belonging, and those with higher level of chronic loneliness may have the tendency to anthropomorphize brands.

Need to Belong Generally, the need to belong can be defined as the desire to establish interpersonal attachments (Pickett, Gardner, and Megan 2004). Although the need to belong is an important individual difference variable inherent to consumer behavior literature, it has been neglected in recent marketing studies. However, it has received vast consideration in social psychology. Social psychology researchers have established the fact that individuals' need to belong is the fundamental motivating principle that results in the crucial consequences related to social performance (Smith and Mackie 2000). In support, Leary (1990) argues that the lack of belonging may result in negative outcomes, such as depression, anxiety, or low self-esteem. Prior social psychology research demonstrates that when individuals' needs to belong are unmet, then the social monitoring system assists individuals in adjusting to social information and stimulates the behavior that may lead to social connections (Pickett et al. 2004). Thus, individuals become very attentive and accurate in detecting social cues in the environment. More specifically, Gardner, Pickett, and Brewer (2000) experimentally find that when individuals' need to belong are not satisfied, they exhibit increasing attention toward social vs. nonsocial information. This increased attention to social cues in social psychology literature has been termed as the interpersonal sensitivity that is defined as, "the ability to sense, perceive accurately, and respond appropriately to one's personal, interpersonal, and social environment" (Bernieri 2001, p.3). According to Epley et al.'s (2007) theory, increased sensitivity to social cues may lead to higher degrees of anthropomorphization. That is, consumers who are high in the need to belong may tend to observe humanlike features and human cues more frequently and, therefore, anthropomorphize brands more actively than those who are low in the need to belong.

P2: The relationship between self-concept/brand image congruity and AB is moderated by the need to belong. That is, for consumers who are high in the need to belong, self-concept/brand image congruity will have higher positive association with AB than for their counterparts.

Chronic Loneliness The fact that individuals differ in the extent to which they feel chronically lonely, that is, the degree to which they experience a persistent lack of social inclusion (Pickett et al. 2004), has been well established in the social psychology literature (Cacioppo et al. 2006). Similar to research relating to the need to belong, prior research regarding loneliness provides evidence that when individuals are chronically lonely, they prefer social information within their immediate environment as opposed to nonsocial information (Gardner et al. 2005). Chronically lonely individuals exhibit a tendency to be very creative in instilling humanlike agents within nonhuman objects (Epley et al. 2008). There is support for this notion in the social psychology literature. For example, in their study, Epley et al. (2008) show that after exposure to a loneliness stimuli, individuals tend to perceive gadgets with humanlike features, including the possession intentions, free will, consciousness, and experienced emotion.

Hollywood provides a particularly poignant scenario of the impact that chronic loneliness can have on the likelihood of the occurrence of AB. In the popular movie, *Castaway*, the character

played by Tom Hanks finds himself completely alone on a deserted tropical island following a plane crash. Completely void of any human contact for weeks, he inexplicably befriends a Wilson branded volleyball, whom he affectionately names "Wilson". Throughout his extended solitude and increasing level of chronic loneliness, the character, more and more, views this inanimate object as slowly, yet clearly, evolving into a complete human being. The relationship between the character and the brand becomes so intense that the character is left utterly distraught at the "loss" of "Wilson" at sea.

Therefore, in the present study, we argue that for chronically lonely consumers, anthropomorphic cues are more readily accessible, more easily activated, and are utilized as a path to recover from the social pain caused by social disconnection. That is, chronically lonely consumers are more prone to fulfill the social connection gap with AB and form various types of social relationship with AB. In sum, chronically lonely consumers may tend to be more likely to perceive brands as complete humans, as members of their social ties, and are less likely to overcome or correct their anthropomorphic representations, because such correction of initial anthropomorphic inferences will result in the severance of the pre-established social connection with these brands and cause a recurrence of social pain.

P3: The relationship between self-concept/brand image congruity and AB is moderated by chronic loneliness. That is, for consumers who are high in chronic loneliness, self-concept/brand image congruity will have higher positive association with AB than for their counterparts.

The Moderating Role of Effectance Motivation

The perception of AB by consumers is substantially influenced by effectance motivation—motivation of individuals to act and cooperate effectively in the surrounding environment (Epley et al. 2007). A growing body within psychological research suggests that individuals differ in their motivation to feel efficaciously in their immediate environment (White 1959). Effectance motivation has emerged from the desire of consumers to comprehend and predict their environment, along with an inherent need to reduce its uncertainty. We propose that anthropomorphism satisfies consumers' desire to efficaciously understand the symbolic meanings of brands. Efficaciously motivated individuals, while observing millions of marketing messages in their environment, will tend to seek meaning through the anthropomorphization process. More specifically, Dawes and Mulford (1996) argue that individuals are inclined to anthropomorphize to increase both the comprehensibility and the predictability of nonhuman objects' behaviors in the same way as egocentric knowledge serves as a reference point in making judgments regarding the behavior of another individual. Self knowledge in the anthropomorphic processes increases the individual's controllability of the environment (Burger and Copper 1979) and assists in finding better explanations regarding ambiguous elements within their current environment. Therefore, the extent to which consumers demonstrate their desire to master their environment (Harter 1978) will influence the anthropomorphic tendencies of persons to see humans in brands. In the present study, consumers' effectance motivation is represented by such individual differences traits as the need for closure and the desire for control that may both affect the likelihood of anthropomorphization.

Need for Closure The need for closure is an individual difference trait that explains the extent to which a person desires the precise answer to one's inquiry vs. ambiguity and disorder (Kruglanski and Mayseless 1988). Individuals who are high in the need for closure display the tendency to instantaneously acquire

primarily available cues in their environment and to make judgments based on these cues without engaging in an effortful search for additional and more meaningful information in their environment (Kruglanski and Webster 1996). Thus, individuals who are high in the need for closure are highly motivated to comprehend existing situations and stimuli, immediately abandoning any further cognitive incentives. Considering the apparent ease of self-knowledge accessibility, as has been discussed a forehand, and the ease of seizing upon first available cues, we argue that consumers high in the need for closure tend to perceive brands as humans to a greater extent than those consumers who are low in the need for closure. That is, marketing communication efforts entailing any human cue are utilized by consumers in the formation of impressions and in anthropomorphic judgments about brands. Individuals experience negative affect if their need for closure is undermined or threatened and, therefore, we argue that consumers with a high need for closure exhibit higher sensitivity to any anthropomorphic representations of brands and even facilitate the anthropomorphic representations in their minds. According to Kruglanski and Webster (1996), consumers will be prone to "freeze" their initial anthropomorphic inductions about brands. Thus, those consumers with a high need for closure will not tend to overcome and correct their first anthropomorphic inferences regarding the humanness of brands, because they will rather be motivated to seek a quick, primarily available resolution and, consequently, preserve this resolution from any extant interferences (Kruglanski and Webster 1996).

P4: The relationship between self-concept/brand image congruity and AB is moderated by the need for closure. That is, for consumers who are high in the need for closure, self-concept/brand image congruity will have higher positive association with AB than for their counterparts.

Desire for Control The desire for control construct has received scarce attention in the consumer behavior literature. On the opposite, the construct has been examined by many psychological theorists. For example, Adler (1930) and Burger (1992) propose a striving or motivation of individuals to demonstrate their ability to control the events in their lives. More generally, the concept of control is a commonly accepted driving force of humans that is defined as the psychological need to display the superiority and competence over situations (White 1959). Psychological research has provided evidence that individuals are not identical in terms of the desire for control, and they will exhibit different levels in their general desire to gain control over situations and objects (Burger and Copper 1979). Satisfaction of the desire for predictability of situations and mastery of the environment evokes positive emotions in individuals. For example, previous studies have investigated the role of perceived control in relationship to service quality (Hui and Bateson 1991) where it has been shown that the opportunity to cognitively reinterpret situations and display competence positively affects consumers. Therefore, desire for control motivates consumers to create order regarding the elements of their surroundings, which also allows for the predictability of consequent interactions with brands in the future. In other words, individuals high in the desire for control will tend to predict and comprehend nonhuman objects through the process of anthropomorphization. Consumers with a high degree of the desire for control will possess stronger proclivity to explain brands' behaviors through anthropomorphic representations of brands and, particularly, through attributions of intentions and desires to brands (Burger and Hemans 1988). The result of such attributional activity will facilitate individuals' perception of acting efficaciously in their environment (Epley et al. 2007). Moreover, the existence of hu-

mans in brands for consumers who are high in the desire for control will serve favorably in increasing individuals' desire for efficacious functioning due to the clear understanding of brand behavior at the current stage and in the future. Taken jointly, these results suggest the following proposition:

- P5: The relationship between self-concept/brand image congruity and AB is moderated by the desire for control. That is, for consumers who are high in the desire for control, self-concept/brand image congruity will have higher positive association with AB than for their counterparts.

DISCUSSION

Although marketing practitioners frequently persuade consumers to view brands as if they are real humans, in the present study, we argue that the marketing literature has been lacking the concept of consumers' perception of brands as complete humans. We theoretically introduce the concept of anthropomorphized brands in the consumer behavior literature. We further theorize the important antecedents (i.e., self-concept/brand image congruity) and moderators (i.e., effectance motivation and sociality motivation) of AB. Establishing the notion of consumers' perception of AB discloses new avenues for research pursuant to the creation of consumer-brand relationships and provides new perspectives for understanding these relationships in light of psychological theories of social interaction between consumers and brands. Prior research has shown that the process of brand anthropomorphization occurs in an automatic manner. However, research in social psychology has provided evidence supporting the variability of anthropomorphism. Thus, the major contribution of the present paper is to provide a psychological account for the mechanism of brand anthropomorphization.

Future empirical testing of the propositions defined in this paper should provide significant insights for both academic researchers and practitioners regarding what factors may influence consumers' perceptions of brands as fully, literally humans. The theoretical underpinning of the present paper may shed light into the manner in which self-concept/brand image congruity influences the perception of brands as humans. Furthermore, the theoretical findings of the present paper illustrate a more clear understanding of the manner in which the relationship between self-concept/brand image congruity and AB can be moderated by individual differences of personality traits.

Future directions for marketing researchers might be to delve deeper into the understanding of the drivers of AB. For example, one potential line of research may investigate the manner in which the physical appearance of products or the increasing number of interpersonal contacts may influence the development of AB. Moreover, there are additional avenues for future examination regarding how advertising variables and marketing communication efforts may impact the inferences about AB. Furthermore, future research may better clarify under what conditions consumers may have formed strong bonds with their brands and even have become to identify themselves with these brands, however, still may have not yet transcended their perceptions of these brands as complete humans.

Although, in the present paper, we argue that self-concept/brand image congruity is the driver of AB, future research may be directed towards the investigation of whether similarities between one's own self-concept and the images of brands may not only strengthen the self, but also create 'the other' that is the important part of actualization, maintenance and construction of the self. Specifically, a fruitful line of future inquiry is the examination of the underlying psychological processes that make the anthropo-

morphized brand lead consumer-brand relationships and contribute to consumers' identity transformations under the conditions of the increasing individualization of society.

Additionally, while we argue in the present paper that effectance motivation may moderate the relationship between self-concept/brand image congruity and brand anthropomorphization due to the better prediction and control over brands' unexpected behaviors and contingencies, future research should explore in greater detail a wider range of factors and more specific mental processes occurring in consumers' minds that lead to the intensification of the anthropomorphization processes and perceptions of brands as actual humans with various subject-to-change goals, evolving needs, and relationship effort requirements versus mere perceptions of brands as commercial entities with the dominant goal of delivering market value to their owners. As brands and their products are converting into more sophisticated and intricate entities, consumers may suffer more from being baffled with the escalating brands' complexities. Consequently, during the rapid diffusion of innovation and technologically advanced brands, individuals' effectance motivation may play an especially important role as consumers' need for closure and control is triggered further. Therefore, additional research should address these important questions regarding under what particular conditions do consumers' perceptions of brand as real humans become more difficult than the perceptions of brands as a profit-making unit.

In conclusion, the present paper advances the marketing literature regarding the development of strong consumer-brand relationships. We believe that this study is a first step in gaining a better understanding of the mechanisms that underlie the process of brand anthropomorphization, a process that is a crucial element in establishing legitimate relationships between consumers and brands. The practical implications of these findings show that, in an attempt to create anthropomorphized brands, marketing practitioners may follow the laws and principles of consumers' interpersonal/social relationships with brands in order to eventually push the envelope of brands and human personality.

Brand Avoidance: A Negative Promises Perspective

Michael Shyue Wai Lee, The University of Auckland Business School, New Zealand

Denise Conroy, The University of Auckland Business School, New Zealand

Judith Motion, University of Wollongong, Australia¹

ABSTRACT

Previous research lacks a unifying construct that is both parsimonious enough to account for the multiple reasons that motivate brand avoidance, and flexible enough to remain workable. We address this gap by providing a core construct that may aid in the understanding of brand avoidance. Specifically, we use grounded theory to analyse qualitative data from 23 in-depth interviews, and we introduce the negative brand promises idea as a powerful yet practical metaphor for understanding brand avoidance.

*"Oh my God! Starbucks!!! I hate Starbucks... Oh there are many reasons; they make sh*t coffee. It's horrible! It's really bad tasting coffee, and you can never get a decent size, you can't just get your average normal cup of coffee you have to get a bucket, which then costs twice as much and tastes bad... and the whole multi-national thing... they're really slow... and they're wasteful! They have individual plastic spoons and there's extra packaging and stuff. So Starbucks I avoid, I'd rather not have a coffee than drink a Starbuck's coffee."* CI (First sensitization interview)

INTRODUCTION

The broad domain of anti-consumption, and the specific topic of brand avoidance, is becoming more interesting and important to scholars, managers, and consumers. The quotations above are evidence of this growing interest, as are the increasing number of academic and managerial articles, journal special issues, popular books, magazines, and websites dedicated to the subject area of anti-consumption (Banister and Hogg 2004; Englis and Soloman 1997; Gabriel and Lang 1995; Hogg and Banister 2001; Holt 2002; Klein 2000; Kozinets 2002; Kozinets and Handelman 2004; Lee, Fernandez, and Hyman 2008a; Rumbo 2002; Thompson and Arsel 2004; Thompson et al. 2006; Zavestoski 2002a). Yet, despite this growing interest, the extant literature still lacks a comprehensive, and parsimonious, understanding of anti-consumption and its related topics. Therefore, the purpose of this paper is to explore, in depth, a specific type of anti-consumption, brand avoidance, and in doing so contribute a more complete, integrative, and elegant understanding of the area.

To date, the majority of marketing scholars and practitioners have espoused the many positive aspects of branding and brand equity, and have focused primarily on brands as market-based assets (Srivastava et al. 2001; Srivastava et al. 1998). Consequently, this perspective of brands has resulted in an emphasis on exploring the reasons behind why consumers select brands and how firms can

increase brand loyalty. In consumer research, the notion that people express themselves and construct their identities/self-concepts through the brands and products they use has been well documented (Aaker 1999; Dolich 1969; Grubb and Grathwohl 1967; Heath and Scott 1998; Hogg, Cox, and Keeling 2000; Levy 1959; McCracken 1989; Sirgy 1982; Solomon 1983).

However, equally valid is the idea that some people avoid certain products and brands because of negative associations/meanings (Banister and Hogg 2004; Englis and Soloman 1997; Levy 1959; Thompson and Arsel 2004). Yet, until recently (Banister and Hogg 2004; Kozinets and Handelman 2004; Lee et al. 2008b; Thompson and Arsel 2004; Thompson et al. 2006), the notion of consumers rejecting specific *brands* to avoid adding undesired meaning to their lives has received little attention. As a consequence, the negative characteristics of brands, and their potential to become market-based liabilities for their firm, have not really been explored by marketing academia and practice. This paper directly addresses the issue of negative brand meaning by specifically exploring why consumers avoid certain brands.

When we look closely at the extant literature, it becomes apparent that most studies in the area of anti-consumption actually focus on dissatisfaction with products and services, or counter-cultural phenomenon such as voluntary simplification and consumer resistance (Banister and Hogg 2004; Craig-Lees and Hill 2002; Halstead 1989; Hogg 1998; Kozinets 2002; Oliver 1980; Penaloza and Price 1993; Zavestoski 2002b). Therefore, with the exception of a few researchers (Holt 2002; Lee et al. 2008b; Thompson and Arsel 2004; Thompson et al. 2006), the main unit of analysis in most anti-consumption studies has been general product or service categories, rather than specific brands. Since this research looks at the anti-consumption of *brands*, it is necessary to clarify this concept.

The notion of the brand as a multi-dimensional value constellation is a convincing idea that underlies most conceptualisations of brand (de Chernatony and Dall'Olmo Riley 1998 p. 436-437); and is the notion of brand that we use for this research. This holistic view of the brand is distinct from the traditional product-centric view of the brand (Ambler and Styles 1996) and posits that a brand's value constellation could mean many different things to a consumer, for example: a legal instrument, a logo, a promise/covenant, a risk reducer, an identity, a value system, an evolving entity, or a corporation (Ambler and Styles 1996; Balmer and Gray 2003; Berry 2000; Brodie, Glynn, and Little 2006; Dall'Olmo Riley and de Chernatony 2000; de Chernatony and Dall'Olmo Riley 1998; de Chernatony and Dall'Olmo Riley 1997; Erdem and Swait 2004; Erdem, Swait, and Valenzuela 2006).

A brand is considered a market-based asset, or has positive equity, when it adds value to the company by helping to enhance and sustain cash flow for the company and its shareholders (Srivastava, Shervani and Fahey 1998). However, Keller (1993) states that a brand has customer-based equity when consumers act more, or *less*, favourably to the brand than an identical product or service that is un-named or fictitiously named. Berry (2000), also suggests that brand equity may be positive or *negative*. In considering the importance of brands within marketing, two points become evident. First, it is clear that brands are important to marketers and positive brand equity is a valuable component of a company's brand asset.

¹Acknowledgements: The authors would like to thank Professor Rod Brodie for his comments and the Foundation of Research Science and Technology, project number UOWX0227 for funding for this study.

Second, there is a negative component to brand equity, although this idea has not been sufficiently considered. In exploring the incidents where the association with a brand name actually reduces the worth of, and preference for, an object, this paper contributes to the notion of negative brand equity.

Brand avoidance is defined as a phenomenon whereby consumers deliberately choose to keep away from or reject a brand (Lee et al. 2008b). Two key concepts lie close to the study of brand avoidance. The first is the anti-constellation, which comprise products that are rejected by consumers (Hogg and Michell 1997). Unlike this study, there is less emphasis on brands in the study of anti-constellations. The second concept which closely resembles brand avoidance is the inept set (Narayana and Markin 1975), where the main reasons for negative evaluation have been attributed to a dislike of the advertisement and poor product performance. Another study using two surveys of 100 and 180 consumers concluded that 'extrinsic' factors such as price, availability, and salesperson's recommendations were most likely to influence rejection of a brand (Abougomaah, Schlater, and Gaidis 1987).

We argue that the previous classifications of brand anti-consumption are too simplistic, especially since the rejection of a brand owing to issues of price and availability may not constitute a deliberate act of brand avoidance. This paper demonstrates that there are a myriad of reasons contributing to brand avoidance, and offers a parsimonious, yet flexible, metaphor for understanding brand avoidance.

METHOD

As part of an ongoing project exploring brand avoidance, we used an existing data set gathered by Lee et al (2008). Details of the recruitment method are discussed in their article; therefore we provide more detail regarding our coding process. The lead author applied the grounded theory method of constant comparison to 23 in-depth interview transcripts, in an attempt to abstract from the raw data to a theory of brand avoidance. This technique is similar to other iterative and hermeneutical approaches used in previous studies of anti-consumption (Kozinets and Handelman 2004; Thompson and Arsel 2004; Thompson et al. 2006).

The coding and analysis of the qualitative data first involved the breaking down of the data into smaller units or open coding (Strauss and Corbin 1990; Strauss and Corbin 1998). Practically, this means that for every interview, the lead author read each line of transcription and highlighted all points of interest. At this early stage of analysis, the lead author created codes as frequently as necessary to capture all the possible reasons for avoidance.

The abundant number of codes generated at the end of open coding meant the next logical step in constant comparison was to compare the categories for similarities and differences. Axial coding was used (Strauss and Corbin 1990; Strauss and Corbin 1998), thus, categories that were very similar were collapsed into higher-order categories.

Analysis then progressed to a higher level of abstraction as theoretical coding, or Strauss and Corbin's 'selective' coding (1990), continued. The main emphasis of grounded theory is on how these relationships increase understanding of a particular phenomenon. Figure 1 displays the hierarchical relationships between the four main types of brand avoidance and their sub-themes. It also proposes some relationships between the central themes, revealed in this study, and other pertinent concepts in brand avoidance.

In hermeneutics, 'dialectical tacking' refers to the development of understanding by comparing and contrasting the findings of the present research with existing knowledge (Thompson 1997).

Thus, one of this paper's main contributions is that it integrates the emergent themes into an original theoretical model. This comprehensive approach to understanding brand avoidance directly addresses the limits of previous knowledge, which has been based on studies focusing only on singular reasons for brand avoidance. These new insights into brand avoidance and the study's core category are discussed next.

FINDINGS AND DISCUSSION

Negative brand promises and the four types of brand avoidance.

Our analysis of the data reveal four types of brand avoidance: experiential, deficit-value, identity, and moral avoidance. Figure 1 displays the main reasons motivating each type of brand avoidance, in addition to their sub-themes. For example, unmet expectations motivates most instances of experiential avoidance; but it was poor performance, the extra hassle and inconvenience associated with failed consumption experiences, and an unpleasant store environment that comprised the emic incidents from which the category of experiential avoidance emerged (Lee et al. 2008b).

Experiential Avoidance: Undelivered Brand Promises

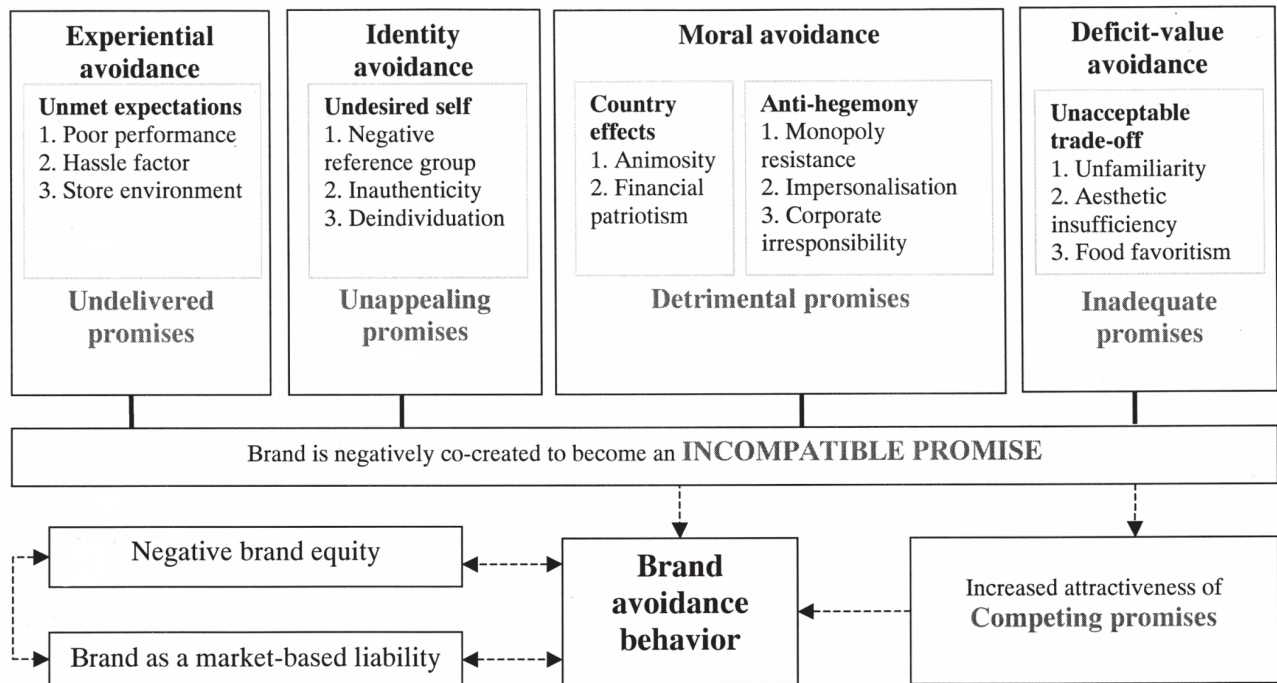

Whilst previous literature from the areas of: disconfirmation and dissatisfaction, (Halstead 1989; Hirschman 1970; Oliva, Oliver, and MacMillan 1992; Oliver 1980; Swan and Combs 1976); negative shopping experiences (Arnold, Reynolds, Ponder, and Lueg 2004; Keaveney 1995); and unpleasant store environments (d'Astous 2000; Turley and Milliman 2000) were used to inform the emergent themes, by further abstracting from the data we are able to provide a new metaphor for understanding these instances of experiential avoidance. We suggest that it is the participant's construction of the brand as an *undelivered brand promise*, which motivates him or her to avoid the brand.

Brands are a multifaceted construct (de Chernatony and Dall'Olmo Riley 1998) and, the brand promise is one important aspect of a brand's constellation of values. The promises framework suggests that the act of branding involves making promises to consumers (Balmer and Gray 2003; Berry 2000; Bitner 1995; Brodie et al. 2006; Dall'Olmo Riley and de Chernatony 2000; Vallaster and De Chernatony 2005). A promise creates a reason to expect something; therefore it is undeniable that brand promises lead to expectations (Gronroos 2006). Indeed, within a consumer's mind, the meaning of a brand is partially made up of a set of expectations about what is supposed to happen when the consumer purchases a brand (Dall'Olmo Riley and de Chernatony 2000). Promises may be explicit or implicit (Gronroos 2006), and when brand promises are delivered in a way that is consistent with consumer expectations, it encourages repurchase (Dall'Olmo Riley and de Chernatony 2000). However, with regards to brand avoidance, if consumers' actual experiences do not match what they have been led to expect by the brand promise, dissatisfaction may result (Halstead 1989; Oliver 1980; Swan and Combs 1976), and brand avoidance may occur (Lee and Conroy 2005; Lee et al. 2008b; Oliva et al. 1992; Thompson et al. 2006).

Thus, one potential disadvantage of branding is that if the company is unable to deliver its promise, it risks disappointing the consumer. Therefore, by heightening consumer expectations, sometimes a brand may be a liability. The following participant clearly illustrates this potential:

I purchased a Sony walkman... maybe after a year, it started rolling [jamming] the tape... So I decided to discard the Sony

FIGURE 1
EMERGENT THEORETICAL MODEL OF BRAND AVOIDANCE

and I didn't get a replacement... sometimes the brand name does not equate to the quality that you'd expect from the brand.
RH Int 12 (Male, 26)

The expectations that RH had of his walkman were created by his interpretation of the Sony brand promise. However, it is clear that the implicit brand promise was not delivered, thereby resulting in future brand avoidance.

Identity Avoidance: Symbolically Unappealing Promises

Identity avoidance occurs when consumers perceive certain brands to be inauthentic, or associate certain brands with a negative reference group. Some consumers may also avoid mainstream brands, believing that the use of such brands detract from their own unique sense of individuality (Lee et al. 2008b). Literature in the area of undesired self (Hogg and Banister 2001; Ogilvie 1987; Sirgy 1982), self-image congruency (Dolich 1969; Graeff 1997; Grubb and Grathwohl 1967; Heath and Scott 1998; Hogg et al. 2000; Sirgy 1982), and disidentification (Bhattacharya and Elsbach 2002; Elsbach and Bhattacharya 2001) helped to inform our understanding of this type of brand avoidance. However, we contribute to the literature by offering the notion of a *symbolically unappealing promise* as a new, and more managerially meaningful, way of understanding identity avoidance. Specifically, we suggest that it is possible for some consumers to perceive certain brand promises as symbolically unappealing, and that such brands have the potential to move them closer towards their undesired selves. Consequently, the consumer disidentifies with the brand's symbolically unappealing promises, and through the process of brand avoidance, the individual is able to manage his or her self-concept, as the following participant illustrates:

It's just not my style... [Amazon-surf/beach wear]... they don't suit what I wear, my image, cause it's not like I'm going

to go walking around in little tank top... I don't have the body for it anymore... you know what I mean?... I'm married now I don't need to attract anyone anymore. VL Int 14 (Female, 28)

VL chooses to avoid this brand because its implicit promise, to provide a young and flirty style, is symbolically unappealing to the self concept she is currently attempting to maintain.

Moral Avoidance: Socially Detrimental Promises

The third type of brand avoidance is moral avoidance. Our analysis of the data suggests that moral avoidance consists of two main reasons for brand avoidance: country effects and anti-hegemony. In terms of country effects, some well known brands (such as Coke and McDonald's) are iconic representatives of the countries from which they originate. When consumers feel animosity towards a country, sometimes their dislike also transfers to the iconic brand of those countries. In other cases, participants who are financially patriotic may avoid brands that they believe will not contribute to the economic development and well being of their country.

Avoidance owing to anti-hegemony, or against domination, is informed by previous work in the area of consumer resistance (Fischer 2001; Holt 2002; Klein 2000; Kozinets and Handelman 2004; Penalzoa and Price 1993; Thompson and Arsel 2004). The data reveal that some consumers avoid dominant brands in order to prevent the development of monopolies, large companies who are suspected of corporate irresponsibility. Typically, only hegemonic and large multi-national companies are held accountable for their actions. The bias against multi-national organisations may be due to their higher visibility, which means they are often under higher scrutiny:

I think that when things are operating on a really big scale like that that they are often doing more damage to the environ-

424 / Brand Avoidance: A Negative Promises Perspective

ment... I'm not saying that all the little guys added up aren't doing damage as well, because probably every little coffee store is doing just as much damage as Starbucks in terms of pollution but I don't know, so that doesn't really make sense does it? But it seems worse when it's like McDonald's. KB Int 10 (Female, 27)

These findings are in line with previous research on consumer resistance, where large and successful companies are more likely to be targets of consumer criticism (Holt 2002; Klein 2000; Kozinets and Handelman 2004; Thompson and Arsel 2004).

Other participants also avoid hegemonic brands because they perceive those brands as being impersonal and disagree with the way in which large brands dehumanize the agents of the brand. For instance, the following participant avoids McDonald's because he prefers to foster a personal connection with local businesses:

You walk into McDonald's... what's the chance that they know who you are... I can send my children down to the fish and chip shop knowing that the fish and chip shop guy knows who my kids are, so if they're not back in half an hour, I can ring him up and say did you see my kids down there? I cannot do that at McDonald's. MT Int 16 (Male, 42)

While the other types of brand avoidance are based on how brand promises impact on the individual's immediate well-being, moral avoidance, on the other hand, is based on the perception of the brand at an ideological level and how it negatively impacts on the wider society.

A further distinction of moral avoidance is the existence of a dominating or oppressive force that the participant resists; for our participants, that oppressive force was normally a hegemonic corporation/brand or another country. This characteristic of moral avoidance is supported by previous literature in the area of consumer resistance and other similar domains (Dobscha 1998; Gramsci 1971; Holt 2002; Klein 2000; Kozinets and Handelman 2004; Moio and Askegaard 2002; Penalzoza and Price 1993; Rumbo 2002). It is this power imbalance, between the multi-national brand and the consumer that makes moral avoidance distinct from other types of brand avoidance.

The final distinguishing criterion of moral avoidance is that it is motivated by the participants' beliefs that they are doing the right thing. In other words, because certain brands are perceived to be oppressive and overly dominant, some participants believe that it is their moral duty to avoid such brands. This ethical component is another integral characteristic of moral avoidance that is not present in the other types of brand avoidance.

Although our findings are in line with previous literature, we suggest that it is the consumer's perception of a brand as a *socially detrimental promise* that drives moral avoidance of certain brands. The promise of fast and convenient food, cheaper prices on mass merchandise, and standardized consumption experiences are not appreciated by all consumers. In fact these brand promises are actually incompatible with some consumers' moral values, and as a consequence, some participants choose to avoid brands for ethical reasons.

Deficit-Value Avoidance: Functionally Inadequate Promises

We expand existing work on brand avoidance (Lee et al. 2008b) by introducing the concept deficit-value avoidance, which occurs when consumers perceive brands as representing an unacceptable cost to benefit trade-off. Previous literature on value and quality help to inform this type of brand avoidance (Dodds, Monroe, and Grewal 1991; Grewal, Monroe, and Krishnan 1998;

Parasuraman and Grewal 2000; Parasuraman, Zeithaml, and Berry 1985; Zeithaml 1988). Some participants avoid budget brands that they construe to be of low quality and, consequently, deficient in value:

I don't go for the real cheap stuff, so I suppose I do avoid them, like No Frills and Basics [budget brands]... if it's real cheap then I don't place much value on it because if it's real cheap then it means that it doesn't cost much to make and it's usually inferior. SP Int 18 (Male, 26)

In contrast, other participants feel that obtaining a product of adequate quality for low cost is a more acceptable trade-off than gaining a high quality product for high cost. Hence, for those participants, it is the premium brands that are unable to provide adequate value:

Sometimes I feel you pay that much just to get the status... 'Oh it's a Sony'... the quality will most likely be the same, but the money we've added doesn't really give you anything, it's just extra profit. KL Int 11 (Male, 20)

Since the symbolic benefit of 'status' appears to be of little value to KL, the extra cost he associates with a Sony product is not perceived to add any tangible benefits to the purchase. Instead, KL believes that the price premium only adds 'extra profit' to the company. Therefore, KL avoids Sony because he perceives the brand as being deficient in value.

From an emic perspective, some participants avoided unfamiliar brands, evaluating such brands to be lower in quality and higher in risk (Richardson, Jain, and Dick 1996), and therefore providing less value when compared to brands with which they were more familiar.

Another sub theme within deficit-value avoidance is aesthetic insufficiency. Some consumers use the appearance of a brand as an indicator of functional value and avoid aesthetically insufficient brands because ugly packaging or a lack of colours signify an inability to satisfy the individual's utilitarian requirements. Socioculturally, much value is placed on aesthetic beauty in society and the halo-effect of attractiveness is well known. Marketers use attractive packaging and models in their promotional campaigns hoping the positive connotations that people have of beauty will be associated with the product (Belch and Belch 2004; Chitty et al. 2005; Solomon 2002). Simply put, from a functional perspective, beauty inspires confidence, while aesthetic insufficiency does the opposite.

However, the data also reveal that some participants will seek aesthetic value as an end in itself, rather than as an indicator of performance:

It's [Budget brands] something that's cheap and nasty it's not nice, I mean the packaging it's just not nice... I know it sounds hopeless, but it's because I know it just looks nicer, so I want it to look nice. SR Int 2 (Female, 40)

Throughout her transcript, SR was dubious that the appearance of a brand could be directly related to its quality; nonetheless she still prefers her things 'to look nice'.

The final sub-theme in deficit-value avoidance concerns a phenomenon whereby consumers avoid food associated with certain value-deficient brands, but are comfortable with purchasing other products bearing the same brand name. We term this phenomenon food favoritism, and research on perceptions of food and safety suggest that when it comes to decisions regarding food

choice, people are more likely to be cautious and use 'better safe than sorry' cues, avoiding the unfamiliar, contaminated, cheap, or harmful (Green, Draper, and Dowler 2003; Occhipinti and Siegal 1994).

Low budget brands... I would buy like pet food and toilet rolls, but when it came to food I wouldn't buy cheap, I'd go for maybe the slightly higher price... probably down to health.
AR Int 4 (Male, 29)

In AR's mind, the No Frills brand promise (lower quality for a cheap price) is adequate for certain products, but inadequate for food.

Overall, the common defining property of the sub-themes in deficit-value avoidance is that they all involve an unfavourable perception of the brand's utility. Thus, from an etic perspective, at the core of deficit-value avoidance is the rejection of a brand because of the unacceptable trade-off that it represents to the participant. In keeping with the negative promises framework, we believe the concept of a *functionally inadequate promise* is a suitable metaphor for understanding deficit-value brand avoidance.

The incompatible brand promise.

As figure 1 indicates, the four negative brand promises that participants are motivated to avoid may be further abstracted into a core category termed an *incompatible promise*. This study employs a holistic definition of brand, whereby brands are considered bundles of meaning, or multi dimensional value systems (Dall'Olmo Riley and de Chernatony 2000; de Chernatony and Dall'Olmo Riley 1998). In line with this perspective, a number of marketing scholars have argued that one important aspect of brand meaning, and marketing in general, is the notion of a brand as a 'promise' or 'covenant' (Balmer and Gray 2003; Berry 2000; Bitner 1995; Brodie et al. 2006; Calonius 2006; Dall'Olmo Riley and de Chernatony 2000; de Chernatony and Segal-Horn 2003; Gronroos 2006; Levitt 1981; Vallaster and De Chernatony 2005; Ward, Light, and Goldstine 1999). As the previous sections have indicated, this idea of the brand as a promise is also particularly useful for helping to understand brand avoidance.

A promise is an assurance or declaration that something will or will not happen and, as a result, promises create a reason to expect something (Gronroos 2006; Merriam-Webster 1998). However, an interesting aspect of promises is that they may be based on real or imaginary resources, and can be either implicit or explicit. Furthermore, like any other form of social communication, promises involve an element of subjective interpretation/evaluation by the parties involved, both before and after a transaction (Calonius 2006; Gronroos 2006). Thus, in the consumer's mind, a brand promise is an assurance that by purchasing a specific brand, certain events should follow.

Since many consumers cannot fully experience nor assess a product or service in advance, many purchase decisions are essentially based on implicit or explicit promises or 'metaphorical reassurances' (Levitt 1981), and, therefore, promises are a crucial component of marketing. This study suggests that not all brand promises are positively interpreted. Instead, some brand associations may be re-constructed in the mind of the consumer to represent a promise of an undesirable outcome; one that is incompatible with the individual's requirements.

We argue that brand avoidance may arise from incidents where brand promises have been undelivered/broken, or when brand promises have been negatively re-constructed in the mind of the consumer to represent an assurance of something symbolically unappealing, socially detrimental, or functionally inadequate. In all

cases of brand avoidance, the brand and what it is interpreted to deliver, is perceived to be incompatible with the consumer's needs or wants. A consequence of this negative re-construction of the brand promise is that the consumer is motivated to avoid the brand.

Increased Attractiveness of Competing Promises.

Most consumer purchase decisions are influenced by both approach and avoidance. So, individuals are pushed away from undesired end states, just as much as they are pulled towards achieving desired end states, and in most cases the two forms of motivation operate simultaneously (Bourdieu 1984; Elliot 1999; Markus and Nurius 1986; Ogilvie 1987; Solomon 2002; Wilk 1997). When a consumer re-constructs a brand's value constellation to represent an incompatible promise, not only may that act lead to avoidance of the brand, but the promises of competitors may also become more attractive to the consumer. As a result, the consumer approaches competing brands to satisfy his or her consumption needs and wants. This preference for competing promises may indirectly exacerbate the avoidance of the offending brand. This proposition is displayed in figure 1 by the arrow leading from competing promises to brand avoidance. The way in which an incompatible promise may motivate consumers to approach competing brands holds an interesting insight for the concept of brand loyalty.

Brand loyalty is a well researched area (Baldinger and Rubinson 1996; Chaudhuri and Holbrook 2001; Jacoby and Kyner 1973; Oliver 1999; Roselius 1971); however, as early as the 1970's, brand loyalty was suggested to consist of both acceptance *and* rejection. Therefore, "not only does [brand loyalty] 'select in' certain brands; it also 'selects out' certain others" (Jacoby and Kyner 1973 p. 2). Similarly, we contend that brand avoidance not only results in the active rejection of certain brands, but at a broader level, it is also a phenomenon that impacts on the attractiveness of competing brands.

Some participants' narratives of brand avoidance were mentioned alongside notions of brand loyalty, which provides an interesting juxtaposition that contributes to the understanding of both brand loyalty and brand avoidance. For instance SR's avoidance of McDonald's does not operate in isolation within the consumption system. What becomes apparent is the inextricable link between the incompatible promises of McDonald's and the increased attractiveness of competing brands:

I like Wendy's because I like their chicken burgers, and just cause they make them fresh they haven't been sitting their for ages. You know at McDonald's they could have been sitting there for a while. At Wendy's they make them fresh and they have fresh salads in them and stuff. I think the quality at Wendy's is better, probably paying more but I think its better quality and they use real chicken. SR Int 2 (Female, 45)

SR's avoidance of McDonald's is mentioned alongside her loyalty for Wendy's. Therefore, is SR's hatred of McDonald's pushing her towards the competing promises of Wendy's? Or is her love of Wendy's pulling her away from the offending brand? The most sensible answer is probably both, since approach and avoidance are able to operate concurrently within each person (Elliot 1999).

Negative Brand Equity.

Another interesting proposition that has emerged from our interpretation of the qualitative data, relates to the resource-based view of the firm (Barney 1991; Barney, Wright, and Ketchen Jr. 2001; Hooley, Broderick, and Moller 1998; Hooley, Greenley, Cadogan, and Fahy 2003; Srivastava et al. 2001; Srivastava et al.

1998), and is illustrated on the bottom left corner of figure 1.

Brand equity was originally defined as a set of assets or liabilities linked to the brand's name that adds value to, or subtracts from, the firm or its customers. Thus, positive brand equity is the added value that the brand provides to the company through the extra money a consumer is willing to pay for the branded service or product (Aaker 1996; Keller 1993). The concept of brand equity as a balance of both negative and positive components has still been relatively ignored in most branding research, with most studies focussing only on the positive components of brand equity.

With regards to the resource-based view of the firm, Srivastava, Fahey, and Christensen (2001) have elucidated the multitude of ways in which a brand is able to enhance shareholder value. Although there is little dispute that a well-managed brand is a market-based asset, there has been scarce discussion over the idea of the brand as a market-based liability. Thus, there still exists a gap in this area, despite the recommended importance of exploring the reasons why a market-based asset might "depreciate, decay, or decline" (Srivastava et al. 2001).

We develop the notion of the brand as a market-based liability by drawing upon Barney's (1991) conceptualisation of a firm's resources, where an asset is described as one of a number of resources that "improve a firm's efficiency and effectiveness" (Barney 1991p. 101). We consider a liability to be the opposite of an asset; and therefore define a market-based liability as anything that decreases a firm's efficiency and effectiveness in the marketplace. This research uses qualitative data in the form of participant quotations to demonstrate that, within the marketing and consumption system, certain incidents may result in a brand promise becoming negatively re-constructed, thereby leading to brand avoidance attitudes and behaviors. A brand that suffers from sustained periods of brand avoidance or failing consumer relationships may develop negative brand equity, since customers consistently react unfavourably to the brand (Aaker 1996; Keller 1993). The brand could then develop negative network equity, as the perceptions and behaviors of additional distributors, retailers, and the market place in general, co-mingle to form an unfavourable impression of the brand. Since the avoided brand decreases a firm's efficiency and effectiveness in the marketplace, the brand might be considered a market-based liability, because it is actually a disadvantage for the company to possess such a brand.

From the firm's perspective, the simplest method of dealing with a market-based liability may be to discard the brand as soon as negative promises begin to develop. However, we argue that the reality of the situation is not black and white. Since negative brand promises are constructed within a complex marketing and societal environment, it is likely that a state of flux exists between the positive brand building efforts of the firm and the negative brand associations that exist within any market. Brand managers should acknowledge that both aspects contribute to the co-constructed meaning of most brands.

MANAGERIAL IMPLICATIONS, LIMITATIONS, FUTURE RESEARCH, AND CONCLUSION

Traditionally, marketing managers have concentrated on strategies that aim to persuade customers to select their brands, but some consumers actively avoid certain brands. Lack of research and knowledge relating to this area means that "conventional brand management literature offers little concrete advice on how brand strategists can proactively diagnose the cultural vulnerabilities that could eventually erode their customer-based equity" (Thompson et al. 2006 p. 61). To this end, we offer the negative promises framework as a tool which managers may use to diagnose any brand avoidance issues that they encounter.

One caveat that accompanies any research using a relatively small number of informants is that the findings must be considered alongside the context in which the study has taken place. In this study, the reasons for brand avoidance emerged from a relatively small group of informants; thus, the findings should only be interpreted as being representative of the participants' attitudes and behaviors. For instance, although several participants expressed an avoidance of McDonald's, this is a successful brand that is clearly satisfying its target market. Therefore, any implications that have emerged from the participants of this study must be interpreted within the context of this research. Thus, we offer a theoretical contribution of why some brands are avoided by some consumers, rather than representative account of brand avoidance in the wider consumer population.

Another limitation of this study, lies in the question: how important is it for managers to deal with brand avoidance? If the majority of target consumers are satisfied with a brand, then there is no need for a company to risk its strategic positioning by addressing people's perception of a brand's incompatible promise. Thus, the brand manager must decide whether the net gain of new customers, as a result of addressing an incompatible brand promise, is greater than the net loss of the original target market. However, it would still be prudent for companies, particularly controversial ones like McDonald's, to monitor the opinion of brand avoiders, if only to be aware of the anti-consumption attitudes directed at their brand. The ability to understand and possibly change brand avoidance attitudes and behaviors in consumers should be considered an important long-term goal of any organisation, even if the number of complaining consumers is relatively small.

Even more managerially useful, would be for future research to interview people who avoid the very brands that have been designed to target them. Many companies use brand guidelines that describe, exactly, the type of person to whom each brand is designed to appeal, such information may be requested from a brand's parent company. Future studies could then recruit participants based on two criteria: (1) they fit a certain brand's target consumer profile and, (2) they actively avoid that brand. Results of such studies, focusing on actual target markets, should help to bridge the gap between the theoretical contributions of this paper and the practical requirements of brand managers.

A final limitation of our study may be that the core concept of an incompatible promise could have been abstracted further to arrive at an even more parsimonious explanation of brand avoidance. For instance, it could be argued that *negative brand meaning* may be the most parsimonious explanation for brand avoidance. Thus, the reason for brand avoidance is because the brand represents negative meaning to the consumer; the implication follows that all a brand manager needs to do is to ensure that their brand meaning does not become negative. Obviously, not only would this be an overly simplistic, and somewhat naive, view of the marketing world, but it is also does not provide a practical way of understanding brand avoidance. Such an abstracted view is too parsimonious and becomes unworkable, particular if it does not elaborate on the elements that constitute negative brand meaning. Although it is important for grounded theory research to abstract from the qualitative data to provide a higher order construct/theory, it is equally important (especially in marketing) that the theory is not too abstract or unworkable. The negative promises framework is a perspective that provides an elevated understanding of brand avoidance but remains practical.

In conclusion, the challenge of balancing between parsimony and complexity has not been successfully negotiated previously in brand avoidance research. The majority of prior studies have been too narrow, failing to account for the myriad of reasons motivating

brand avoidance. Further, the area has lacked a unifying construct that is both abstract enough to account for the many reasons for brand avoidance, yet concrete enough so that managers may find it useful. We address this challenge by offering the notion of an incompatible brand promise as a unifying concept that accounts for the majority of brand avoidance behaviors and attitudes. We suggest that this metaphor provides an elevated, yet workable, understanding of brand avoidance.

“Bye Bye Love”-Why Devoted Consumers Break Up With Their Brands

Andrea Hemetsberger, Innsbruck University, Austria

Christine M. T. Kittinger-Rosanelli, Innsbruck University, Austria

Sandra Friedmann, Innsbruck University, Austria

ABSTRACT

Consumer devotion and brand love have recently attracted rising interest in consumer research. Due to their high emotional attachment, brand devotees love and adore their brands and even fervently defend them against all odds. Yet, some of these relationships break down. This article addresses the question why strong emotional bonds with brands are weakened, and how consumers experience the process of emotional detachment and relationship termination. Phenomenological interviews with brand devotees revealed that—similar to personal relationships—personal transformation and physical and psychological injuries are two main categories of reasons for brand love to vanish.

INTRODUCTION

Apple, the iconic cult brand (Belk and Tumbat, 2005) is undoubtedly one of the brands which is said to be loved by its users and fans. Apple fans are devoted brand evangelists and defend the brand fervently, if necessary. However, even the most convinced Apple devotees were at least irritated by Steve Jobs' pricing policy of the recently introduced Apple iPhone in the US. People were eagerly awaiting the new iconic iPhone. They were spending their nights in front of the stores in order to pay 599 Dollars and get one of the first iPhones. When Apple reduced prices to 399 \$ after two months, some were furious and ended their relationship with the brand, although they still loved Apple. Sounds like personal relationship problems? Probably very much so.

The Apple story is just one out of many examples of brand relationship termination with a loved brand. Literature on brand switching behavior and relationship termination in general is rich (Andreasen, 1984; Schouten, 1991; McAlexander, 1991; Fajer and Schouten, 1995; van Trijp et al., 1996; Fournier, 1998; Mathur, Moschis and Lee, 2003 Perrin-Martinenq, 2004). However, we have only limited evidence of dissolutions of consumer-brand relationships that were once highly emotional and committed partnerships (see: Fournier, 1998; Aaker, Fournier and Brasel, 2004; and Price, Arnould and Folkam Curasi, 2000 about older consumers' disposition of possessions). Firstly, consumers who are highly committed are brand loyal by definition. Secondly, enthusiast consumers and brand devotees are usually much more forgiving and tolerant in case of transgressions from the side of the brand (Fournier, 1998). But when, and under what circumstances do they decide to cut these strong emotional bonds? How do they experience this break up?

This article aims to research and theorize about the termination of strong consumer-brand relationships and contribute to a more thorough understanding of brand love dissolution. To this end we will briefly review the literature on brand relationships and strong emotional bonds with brands in general. We will further summarize literature on possible reasons for brand relationship dissolution, and provide empirical insights into consumer stories of breaking up with a brand they love. In the discussion section we draw a parallel to marital relationship dissolution, and add some thoughts for future research.

STRONG EMOTIONAL BONDS BETWEEN CONSUMERS AND THEIR BRANDS

Susan Fournier's (1998) expanded relationship perspective entailed a wealth of empirical and theoretical insights into emotional bonds between consumers and their brands, which was fuelled from mainly two streams of research. While one of them is rooted in a quantitative view on consumer-brand relationships, and called (product) attachment (Ball and Tasaki, 1992), attachment to brands (Thomson, MacInnis and Park, 2005), or brand love (Ahuvia, 2005), the other stream of research is more qualitative and interpretive in nature and comprises work on brand relationships (Fournier, 1998; Aaker, Fournier and Brasel, 2004), and devotion (Pimentel and Reynolds, 2004; Pichler and Hemetsberger, 2007, 2008). In general, the importance of such relationships for consumers' identity projects, personal style, social categorization, and self-definition is unquestioned.

Brand attachment is a construct which has been introduced in consumer research in order to explain high degrees of emotional attachments to brands (Thomson, MacInnis and Park, 2005). Individuals form attachment to a myriad of objects (Belk, 1988; Wallendorf and Arnould, 1988; Richins, 1994), brands (Schouten and McAlexander, 1995), film series (Kozinets, 2001), places (Maclaren and Brown, 2005), or activities (Hemetsberger, 1999), which evoke feelings of connection, affection, love, and passion. Attachment theory in psychology predicts that individuals who are attached to a person are more likely to be committed to, invest in, and make sacrifices for that person. Emotional attachment to brands is expected to lead to similar results with regard to beloved objects, which has major implications for brand loyalty and emotional commitment, in particular.

Ahuvia (2005) introduced a similar construct, termed brand love. He contends that love objects have a strong influence on our sense of who we are. Hence, they determine our self-concept, contribute to our self definition, and also demarcate the boundaries between ourselves and the identities that we reject. Viewed from this perspective, brand love may actually be highly relevant for times of change, and personal transformation. As a matter of fact, research on brand detachment has found particular life events, and phases of transition to be major causes for brand detachment or brand switching (Andreasen, 1984; Mathur, Moschis and Lee, 2003). It is thus unclear when, and under what circumstances, times of transition foster brand love or rather constitute a peril to the consumer-brand relationship.

Devotion is defined as a somewhat distinct concept in that it concentrates on the private side of consumer-brand relationships on the one hand, and on the behavioral patterns and acts of devotion as a proof for a balanced self- and other-related concerns, on the other hand (Pichler and Hemetsberger, 2008). Devotion is said to be similar to mature love relationships which are defined by passion, intimacy, and dedication. Researchers (Pimentel and Reynolds, 2004; Belk and Tumbat, 2005; Pichler and Hemetsberger, 2007) also emphasize that devotion implies feelings of spiritual and religious excitement, fervor, zeal, and adoration. Similar to love

relationships, brand devotees' adoration is not very likely to vanish out of the blue.

Although Pichler and Hemetsberger (2007), for instance, criticize the view that brand love and consumer devotion may be seen as an ideal state of 'endless love' and highest consumer-brand relationship quality, they leave the question untouched when and why consumers would terminate strong brand relationships, and how consumers emotionally detach themselves from their brands.

TERMINATING BRAND LOVE

Consumers terminate brand relationships and change their brand preferences several times in their lifetime. From research into brand-switching behavior we learn that some consumers tend to get bored more easily with brands and products, are variety seekers (van Trijp, Hoyer and Inman, 1996). Other reasons include marketing strategies employed by marketers, or situational influences. Drawing on literature on interpersonal relationships, Fajer and Schouten (1995) identified three typical patterns of termination: (1) physical separation, (2) new brands replace old ones, or (3) a partner in the dyad reveals or does something to alienate the other. In the case of highly committed partnerships we propose that these patterns are likely to be accompanied by strong triggers, as for instance severe transgressions on the side of the brand, or important transitory stages on the side of the consumer that cause the relationship to deteriorate.

Fournier (1998) suggests two general models of relationship deterioration. The entropy model is based on the assumption that relationships fall apart if they are not actively maintained. As brand devotees are active maintainers by definition, the entropy model as a single cause for relationship termination seems implausible. The stress model (Andreasen, 1984; Fournier, 1998) refers to forceful destructions of brand relationships through brand dyadic, personal, or environmental stress factors which are not relationship specific. Consumers may move to another place where they cannot buy the brand, or other alternatives are found to be even more tempting.

Brand dyadic stress is caused by someone breaking the rules of a relationship, a breakdown of trust, or failure to keep a promise. Other failures refer to poor conduct in the relationship, such as poor brand performance, or a failure to reinforce consumer commitment. Similar failures might also occur in consumer-brand love relationships yet such failures are likely to be forgiven and/or downgraded by real brand devotees (Fournier, 1998). Some relationships even show signs of reinvigoration after such transgressions, primarily with exciting as opposed to sincere brands, and in response to recovery efforts (Aaker, Fournier and Brasel, 2004). Although transgressions vary in severity and cause, all are significant in their potential to affect consumer-brand relationships. 'Sudden death' refers to utterly devastating transgressions which lead to immediate termination of the relationship.

Personal stress factors occur with life disturbances, role changes, or changes in personality, caused by important life events (Andreasen, 1984, Schouten, 1991, Mathur, Moschis and Lee, 2003). Life events and role transitions are associated with significant changes in consumer behavior in general. New brands can help to cope with distress associated with the adoption of new roles and relinquishing old ones. However, loved brands may also serve as a refuge in turbulent times. It is therefore unclear whether, and which life events do actually have an impact on strong consumer-brand relationships.

Termination of brand love is certainly not a spontaneous decision but rather an ongoing process of dissolution (Duck, 1982). Drawing on Duck's work, Fajer and Schouten (1995) describe ending processes of brand relationships as a sequence of break-

down, decline, disengagement, and dissolution. The time needed to end a relationship most certainly depends on whether termination had been triggered by a disruptive event, or had been rather a series of experiences or developments which contribute to a continuous 'fade-out'. It is important to distinguish between relationship termination and brand detachment. Brand relationships may be terminated although consumers are still emotionally attached to the brand; on the other hand, consumers may still stick to a brand but affectively detach from the brand (Perrin-Martinenq, 2004). We argue that it is important to look at the process of relationship deterioration, the idiosyncratic sequence of disturbances and related reactions, in order to understand why love relationships fall apart. We aim to elicit stories of relationship termination; the triggers, reactions, and subsequent processes of dissolution that, in combination, mark the end of a brand love story.

METHOD

Our empirical work followed a 2-step process. First we identified brand proponents who have had strong emotional bonds with brands that for some reason were terminated. Participants were asked to briefly outline their 'love story' with a favorite brand of theirs. To determine whether brand commitment was really strong and emotional we used the brand-relationship-quality dimensions and respective descriptions suggested by Fournier (1998), and additional scale items (Kressmann et al., 2003) and indicators (Aaker, Fournier and Brasel, 2004) for strong brand relationships. Content analysis of the stories, guided and categorized by these dimensions enabled us to decide, if the participants qualified. The final sample consisted of 4 female and 6 male respondents from age 20 to 62, and comprised 10 stories of 10 different passed brand-relationships, including diverse products like cars, clothing, cosmetics, drinks, electronics, and skis. Participants were informed about the goal of the study and ensured confidentiality.

In the second step we conducted phenomenological interviews (Thompson, Locander and Pollio, 1989) to attain first person experiences on the relationships with their beloved brand, and their end. We chose this form of interview to attain deep insights into this very personal, not always easy to verbalize, and in some cases even painful process. To stimulate the expression of emotions undergone during the process we applied the photo-elicitation technique (Zaltman, 1997). Respondents were asked to bring 3 photos or pictures illustrating or symbolizing their brand relationship and their feelings during the termination process. The pictures were used either at the beginning to stimulate stories about the brand relationship, or in the course of the interview. Some respondents used the pictures to express their feelings. If the pictures were not mentioned by the respondent, the interviewer asked for their deeper symbolic meaning, in order to stimulate additional narratives. At the end of the interview the researchers also asked for a picture which is most representative for the ending of the relationship, again with the intention to eventually evoke additional memories or feelings of the detachment process (Zaltman, 1997).

We tape-recorded the interviews and transcribed them verbatim. Analysis followed a two step process (Thompson, 1989). An idiographic analysis documented the single termination experiences including motives, triggers, emotions and processes. Integrative analysis revealed similarities and differences and allowed us to formulate themes, and relate them to processes of brand detachment.

FINDINGS

Consumers' stories of breaking up with the brands they loved revealed how important those brands are for real brand devotees,

and thus how central relationship termination and emotional detachment are for consumers' selves and identities. Some stories sound quite familiar, some are extreme in a way, some seem to belong to the category of 'never-ending stories', and some are even heartbreaking. We found two main categories of relationship termination of brand devotees, which are related to self healing on the one hand and personal transformation on the other hand. In the following we will describe *how* relationship termination develops, and how behavioral (re)actions of both partners and brand detachment are related to relationship ending.

Personal transformation

My™ just couldn't keep up with me and my new life

Sebastian, 29 years old and self-employed with a creative agency told us about his detachment from the Sony brand and his Sony notebook in particular. He had admired Sony since he was a child and all electronic equipment he owned was Sony. His love for Sony culminated in his notebook which he even took along to parties and evenings with friends.

"... at that time I was really crazy. I even took my notebook when going out. I took photos with the first digital cameras and there just was my notebook to transmit them right on spot (to the notebook)... Everybody could have a look and we emailed them immediately. At that time you were really important and cool if you did that. Looking backward I have to say that I had bats in my belfry, but at that time it was important." (...) (My Sony-Laptop) was something like my best friend who I could share with everything and who I took everywhere. (...) Who never lets you down, my Sony Notebook never crashed. Like your very best friend, who you can rely on and who is always with you."

Sebastian's passion for Sony started to lag when he quit his job in an advertising agency (which he had started right after college) and started his own business.

"When starting my own business, I also went through a strong personal transformation. I started to refuse run-of-the-mill products, which somehow everybody seemed to have. ... Now I am self-employed, experienced in my job, I am successful and in this situation I wanted new things, not these ordinary ones. (...) I frequently looked at Apple-ads. After all, their claim is "think different". This seemed like the right motto for me and my life."

During this transition he actually buys an Apple Notebook + iPod and after a while gives away his Sony Vaio as a gift to a friend who needed a computer for college. He describes his feelings when he passed on his Sony to his friend.

"It was quite ok. I already had my Powerbook and was super happy with it. I had my new profession, my self-employment and was full of pleasant anticipation, expecting what future might bring for me. So it was not bad to let loose my Sony. And of course I was happy that my friend would still use it. After all I had been really proud of "the Thing" and I was happy that it is in good hands and that it will be treated with diligence. If I had given it to a stranger it would definitely have been different."

Actually Sebastian never completely detached from his Sony brand but rather decided to let it 'fade-out'. It was quite okay for him; a

new (love) brand replaced the old one (Fajer and Schouten, 1995) but he could not bear throwing it away; it was so much part of him and part of his former life that he wanted his old brand to find a good place, a refuge. Sebastian actually still shows much respect for his former love brand but feels unable to treat it with the same passion as before. Hence, he passes it on in an attempt to help the brand have the life it deserves; a behavior common for brand devotees (Pichler and Hemetsberger, 2008). Price, Arnould and Folkman Curasi (2000) reported similar findings with older consumers who pass on symbolic-laden special possessions to their heirs. Brands may actually want to help with these rituals in order to preserve the object from becoming secularized.

Falling in love with another™

Susanne, 26 works as an office clerk in a medium sized company in a small town in upper Bavaria. Before she was an active athlete within the German Skiing Union and participated in World Series ski-races. She drove "Völkl ski" as a child and also during her career as a ski-racer where she was happy and proud to be selected by Völkl to be sponsored.

"The skis were really great and it fitted so well with my driving style. That simply was mine. They were my one and only. In the evening I brought them along to my room, because I did not want anything to happen to them. (...) They were my sanctuary." (...) we were a team.

When she finished her active racing career she continued to buy Völkl for her private use until she got to know Hermann Maier [Austrian top skiing athlete] who drove Atomic skis.

"I simply adored him. (...)...the way he skied, with all his power. And also this bundle of muscles, that was impressing. ... and he drove Atomic."

She started looking for and test-driving Atomic-skis and Völkl just was not so important any more. For about two years she drove Völkl and Atomic skis and then changed completely to Atomic.

"Now I am a confident driver of Atomic skis. I could not say that I dislike Völkl or so, but that just occurred because I admired Hermann Maier so much. Ok, now I also need Atomic skis. They are, of course, really good skis, nothing can be said against that. It's simply different from driving Völkl. That's how it was."

Susanne actually exhibits typical adolescent behavior where falling in love with someone and adoring him is part of this transitory phase. At first sight Susanne's case looks like a typical brand switching behavior in light of perceived superior alternatives. Yet leaving someone whom she used to love is difficult for her, even if another option seems much more tempting. That is why Susanne actually needs two years of parallel relationship. What is interesting though is that actually the brand testimonial infatuated her which seems decisive for her brand switching behavior. Her admiration for his skiing skills, and the prospect of getting closer to her 'ideal skier self' exceeded the fascination with the new brand. Personified brands are strong attractors. Particularly when they enjoy iconic status, they are seductive and predestined objects for adoration.

De-Glorification

Simone, a student of the social sciences in her early twenties was a Benetton fan from the age of 5. At that age she "inherited" most of her clothes from older friends. When she occasionally got new outfits, she traveled with her Mum to the next small city to go

to a Benetton store. She remained a devoted Benetton customer for many more years, being particularly fond of the quality, the cosmopolitanism, the cultural diversity.

"It was a little bit like a part of me in a certain way, also their advertising campaigns. The cheerful children from the diverse nations, and all dressed up with the bright colors of Benetton. So everywhere on the world children wear these garments and I got to do so as well. I am among them. That's what impressed me when I was a girl."

Towards her high school graduation she started being less satisfied. She has some bad experiences with the quality of the materials and also senses a drawback in style; too dysfunctional for her changing lifestyle (more travel). She starts buying other brands but keeps buying Benetton. After about 2 years she completely turns to other brands without finding any particular favorite. Simone's story elicits a quality of brand love that we may actually call 'glorification' at a rather young age. In the course of the years, and when naivety changes into informed and emancipated consumer decision-making, the brand cannot keep up. Similar to what Belk, Wallendorf and Sherry (1989) have called desacralization, deglorification is a process of brand deterioration, here caused by an eye-opening personal transition into adulthood.

We slowly drifted apart

The following case demonstrates that it may actually be the brand that changes personality in the eye of the relationship partner, which led to a slow but destructive alienation (Fajer and Schouten, 1995). Hans, 62 years old, worked as an engineer and retired last year. For almost his whole life he had a strong emotional bond to Volkswagen (VW), especially the old beetle. He owned beetles, sometimes more than one at a time, and enjoyed almost anything with them like driving, traveling, fixing and tuning it, trading second hand spare parts, Volkswagen ads, and the company behind. VW, especially the beetles were for him exactly what the literal translation of Volkswagen means: a car for all people-solid, sound technology, good value, and suitable for young and old alike. His passion for the brand faded very, very slowly and after 15 years of increasingly ambivalent feelings towards the brand he finally turned his back on VW. He still liked the Golf 1 and 2 model, although he was unhappy that the warranty expired as soon as one fixed anything himself.

"But the (Golf) 3 was not so neat. Actually the time had come then. The (Golf) 2, by the way, I drove it for quite some time; I was quite thrilled. But the 3, it was so bad then, there were complaints all the time so that I had already refused to buy one. Starting with the 4, it was completely over; they got more and more expensive. That had nothing to do anymore with a "Folkeswagen", not to talk about "Folkesprices". No, that's not for me no more. And with these new models, there was nothing you could do yourself, you always had to go to a garage, and that was costly again. Also the others (models), Phaeton or whatever it is called. In my eyes that does not fit VW. Why would VW need a luxury limousine? That sure is not a car for the people, but the others aren't either. So what!"

He still had an old beetle until a year ago but he sold it because he needed the space in the garage and had problems getting spare parts anyway. That was the end of the story. The process of detachment actually started after many years of love and faithfulness. Hans and his VW had a symbiotic relationship of two very stable and dependable personalities. Nostalgia proneness is one of the person-

ality characteristics of Hans thus the relationship ended when the brand became too fierce in its rejuvenation efforts. Furthermore, when the brand refused to let him engage in 'labors of love', he decided to let go. This is actually a commonly observed reaction of brand devotees, who want their brand to develop continuously but who refuse to accept radical changes. This particular process of relationship ending takes years or even decades of slowly drifting apart.

From the Hurt to the Healing Self

The torn self

Maria is 37 and works and lives in her own Living-Design Studio in Munich. Her first true love with an Italian guy entailed her love for "Prosecco Valdobbiadene" (light sparkling wine). This Prosecco "Valdo" saw the two of them through all special occasions of their relationship and was also part of her boyfriend's family life back in Italy. The Valdo actually became the embodiment of this love affair and had a very special significance in her life. The end of this love affair was very painful and disappointing, and also determined the end of her relationship with the Valdo.

"I wanted to ban everything that I related to him (former boyfriend) from my life. Yes, also the Valdo. Once during that time I bought one more bottle together with a girlfriend, because I liked it so much-maybe to drown my grief a little bit. The next morning I had a terrible headache. Maybe it was simply too much (laughs). Anyway, I decided to buy Valdo never again. ... to protect myself a little. ... so that it does not hurt when I see it. Especially at the beginning of the first year (after the break up) it was fairly bad."

During that year of grief she occasionally checks in the stores if the Valdo is still available, but does not buy again.

"I had to separate irrevocably from the Valdo to cope with the whole disappointment and to let bygones be bygones. The memories kept being too strong. Even if I had adored the Valdo; it would not work any more. I would have destroyed myself."

Even today, 7 years after the breaking, memories of this tremendous disappointment come up when by chance she sees a Valdo. As we know from research on special possessions (Belk, 1988), when brands become imbued with strong meanings and memories, they become symbols and manifestations of our experiences. They become part of the extended self thus are hard to let go. The torn self engages in a healing process of emancipation from persons/things that hurt.

A 'healing hand'

Andreas has had a strong emotional relationship with Audi. He is hotelier and this year he is going to celebrate his 50th birthday. He brought the picture of a red heart which symbolized his feelings for Audi, "this strong feeling that I felt for Audi, almost love". He switched from Audi to Ferrari recently, a pretty radical move. Andreas' left leg was severely injured in a ski accident last year which partly explains his dramatic break up with Audi. He underwent a hard process of physical rehabilitation and cannot do his favorite sports like skiing or golfing any more.

"I simply have to avoid sports. (...) I cannot live like I used to live before. I had to realign my life and in the course of it I replaced my Audi and bought a Ferrari. (...) I just hoped that my parting from Audi would ease the farewell from my

PICTURE 1

Manfred sitting on his father's DKW

previous life. That it would be easier for me to recognize the facts. That I would not permanently think of old memories and experiences; simply get more involved with new things."

He also finished the relationship with his wife and experienced hard times. A picture showing a teardrop is what he considers most representative for the whole change process, including the change from Audi to Ferrari. He still holds Audi in high respects and still uses Audis for his hotels, but *"it's not my life to that extent any more"*; for his new, private life it's definitely Ferrari now. From a psychological perspective, Andreas faced a similar challenge of physical and psychological 'healing'. As described by Schouten (1991), consumption activities, including disposition and acquisition, play vital roles in the restoration of harmony to an ambiguous and, in Andreas' case, physically hurt self. He gave up his wife and his Audi—symbols of his old life. Ferrari, a much stronger brand, serves as a support in times of re-orientation, because it could compensate at least his bodily disabilities, and act as a symbol of regaining strength. With Andreas, too, the personifications of the two brands were decisive for his move. In times of troubles you need a helping hand, in times of recovery, Andreas needed a healing Hero.

Breach of faith

Stefan, a passionate biker was sure to own the best road bike of the world. After having desperately longed for an "Eddy Merckx -Bike" (named after the legendary German bike racer Eddy Merckx) he finally bought (credit financed) the "Ferrari among bikes" for 10.000 German Marks. He was very proud and enjoyed the admiration from his fellows and other bikers.

"It was the most exquisite (bike) one could think of. It was the dream of every biker" (...) It meant incredibly much to me. It symbolized success and a great technical standard. It gave me the feeling to be better, more successful and unbeatable against my fellows. Actually it was sheer lunacy to have myself decorated with this device (...) but I was possessed by it."

The "dream" did not last long. Despite being *"death sure to have the very best material"* the frame broke without any premonition on a downhill passage of a dolomite mountains pass and Stefan had a horrible accident. He was catapulted off the road and by great chance survived with minor injuries.

"It was like awakening from a dream. Due to the overturn and the material defect they (my strong feelings) simply vanished.

The great feeling, the dream of being invincible was replaced by sheer fear of this bike."

The reactions from the company were more than disappointing and hardly went beyond the attitude that *"shit happens. There is no 100% safety."* Stefan never again touched this or any other Eddie Merckx bike not to speak about driving one. *"So from blind enthusiasm for the bike I hit the zero point or was even below that."* If the company had reacted differently, he thinks, he might have overcome his fear related to the product. But after this reaction he set seals on this chapter and bought a conventional and simple bike without a "big name" and did not have any problems ever since. Stefan's detachment from the brand could actually have been prevented if the brand had reacted differently. But the brand turned his back on him and Stefan lost his faith in it. From a psychological standpoint Stefan—similar to Andreas—had to cope with substantial fears, which he managed by making a clear cut. However, although Stefan was deeply hurt by the brand in a physical and in a psychological sense, he refrained from buying another "big name". Similar to other cases where the brand spoiled the relationship, consumers' feelings are so deeply hurt that they never again engage in another love relationship within the same product category.

Humiliation and contempt

Manfred, Head of Logistics of a big Bavarian company located in Munich was enthused by the car brand Audi and DKW (the former name of the brand who at that time also manufactured motor bikes). Being a child he already adored his fathers DKW bike (see Picture 1). Right after getting his drivers license he kept owning and loving different Audi models for decades. He was always very proud of his cars and convinced to get good value for money until several problems and unpleasant experiences with his last A6 provoked a revaluation of the brand and finally a break of the relationship.

The problem started on the 3rd day with his last A6. Heading for a meeting he parked in front of his head office and locked the car with the remote key. The car not only locked but opened all 4 windows at the same time. ... Once, twice, three times he tried with the same results and an increasing crowd of spectators was giving him advices. Running late for his meeting he called the hotline that kept being busy. Finally he reached somebody who told him that this was not a new problem and that he should just keep trying.

"I was pissed off. I was the mock of the people. My meeting had long begun and my windows kept opening. I called the hotline again and was told by a friendly voice to disconnect the battery

and boot up the electronic system. Anyhow, the laughs were on the other side and I was humiliated and embarrassed with my new car. That stank!"

Three weeks later he went to the Audi-garage because his back door would not close, or reopened when he closed the drivers-door. The serviceman closed it almost forcibly without checking the mechanism and accused him of not being able to shut doors himself and making up complaints. Manfred ran mad again, and had his problem solved by another mechanic.

"First the window story, then the garage, where they proofed to be extremely arrogant and treated me like I was no Audi-customer at all, though this was my 6th Audi. I was nobody for Audi. Well, so other cars started to attract me; according the motto there are plenty more fish in the sea."

He also started to look at car statistics and tests in magazines and realized that other cars might be better value. When the period of mounting unpleasant events added up to about 2–3 years he broke up with Audi, and ended up choosing a Skoda as his next car.

"I would never have put aside Audi overnight. No, no, I was far too attached to them. But as things go, there is one straw that breaks the camels back."

Manfred's story is the typical story of several severe transgressions from the side of the brand, which eventually leads to relationship termination. What is stunning though is the fact that it took him years to terminate the relationship and detach from the brand. Detachment itself was an active process of looking for a car with purely functional value. No love involved here at all.

Marion, a housewife, 54 years old, told us about her story with the cosmetics mail-order (internet) supplier Yves Rocher (YR) with limited direct distribution in YR-stores in some cities. More than 20 years she loved and used her YR products and convinced many friends of her beloved products.

"I simply could trust the brand and I knew I was right when I used the brand and that they were just the thing for me. These cosmetics very soon became a part of me. It was a ritual to go to the bathroom and use my cosmetics which almost seemed to have waited for me well arranged in the mirror cabinet. (...) It was my one and only. (...) Using the cosmetics in the morning was like the sun rising in the morning, simply fantastic."

When she moved to Skopje, Mazedonia with her husband, the relationship came to a sudden end. After having settled in Skopje she wanted to restock her inventory of personal care items. Her new address was fairly long and did not fit into the online-form provided. So she called an operator for help. After a few unpleasant calls and emails she was informed that there was no solution for this problem and that she could not order to this address.

"I had to abandon the products I needed. That really annoyed me. The whole bureaucracy, I was really frustrated and disappointed. I was angry at YR. I could not order and I will not order because I was so furious. I had ordered for decades and spent a lot of money (...). I was an absolutely loyal customer and this makes me just sad. You do not expect such things. (...) It still offends me, when I talk about it. The whole anger comes back up in me. ...I even asked her, if she could

eventually write the address by hand on the parcel, but even that was too much for them. They told me it's not possible because everything is automatized. Bullshit, nobody can believe that, right?"

On her occasional visits back home in Germany she could actually buy YS products in one of the stores, but now she refuses to buy them.

"I could not even imagine a life without YR products. Now I realized that it does go without. Nobody can take me back to one of the stores... it hurts being disappointed so deeply. I still think a lot of my YR creams and such. For some I still haven't found alternatives ... They are the ones I miss particularly. Nonetheless I will not buy from them again. Who do they think I am!"

At this point of enagement, forgiveness is not possible any more. As Gottman (1993) contends, at this stage of hypervigilance, attribution bias would cause even negative interpretation of positive behavior. Humiliation and contempt are the worst that could happen in a relationship, because they communicate disgust (Gottman, 1993). Inevitably contempt leads to greater conflict and negativity, the remaining wounds are hard to heal, if ever. What is interesting though is that Manfred made a clear cut, whereas Marion is still emotionally attached to the brand. One possible interpretation could be a gender effect. Another interpretation Marion's highly emotional decision to take revenge and not to buy any more. As she immediately terminated the relationship she was lacking time to emotionally detach from the brand. Hence, she reported that she is still suffering from the painful break up.

DISCUSSION

Consumers and brands divorce. Whereas it is not new that consumers are more or less brand loyal, terminating relationships with brands they love is no impulse reaction, goes much deeper in its emotional quality, and—as indicated above—has a deep impact on consumers' lives. Although our research is exploratory in nature, and many more stories might exist, we could carve out two main factors that contribute to the termination of a love relationship with brands: personal transformation and coping with physical and psychological injuries. When consumers break up with their brands, it is always connected to a major life event and/or phase of personal development and emancipation, or with a changing brand personality, which contributes to a growing incompatibility of the consumer and his brand. Hence, our findings support current knowledge, particularly regarding times of transition and changes in consumption patterns (Andreasen, 1984, Schouten, 1991, Fajer and Schouten, 1995), but also clearly transcend what is currently known in literature in at least two ways.

First, the findings indicate that the termination of a love relationship with a brand has to be clearly distinguished from the process of emotional detachment. Consumers may break up but still love their old brands, as is the case with Andreas' Audis, or Marion's story with Yves Rocher. Even in cases where the company has caused relationship termination, it seems hard for consumers to let their love brand go. Vice versa, consumers may need years of detachment from a brand before they actually terminate the brand relationship. As our study shows, emotional detachment is a long (see also Coulter and Ligas, 2000) and active process. The findings indicate that consumers need to actively detach themselves from their love brands, either through cognitive degradation or behavioral engagement in retaliation, searching for alternatives, passing

it on, or similar. These processes of detachment are accompanied by ambiguous feelings and behavior, as exemplified in several cases.

Secondly, we found that breaking up with a love brands exhibits parallels to breaking up with a strong personal relationship. In some cases people fall in love with another brand, which is qualitatively different from a typical 'fling' (Fournier, 1998) where relationship termination is foreseeable; in other cases, proactive sustaining behavior and communication is missing for a long time; other stories reveal that consumers are not willing to accept the personality development of the brand in the course of the years. In cases of relationship endings that are 'caused' by the love brand, transgressions are either severe, causing highly affective reactions, or relationship ending is an extremely long process of steadily growing misfits between the person and the brand. Emotions that were triggered by brand transgressions range from anger and enagement, to grieve, feeling betrayed, or even fear, and eventually lead to relationship termination or even retaliation (Grégoire and Fisher, 2008). Accordingly, triggers that cause such strong emotions are much more severe and usually occur not only once.

Drawing on research about marital divorce, we can distinguish several deteriorating factors, which contribute to the termination of a love relationship. Gottman, in an interview (2007), contended that the best predictors of breakup are 'criticism', 'defensiveness', 'stonewalling', and 'contempt'. Interestingly, all four of these "Horsemen of the Apocalypse" (Gottman, 1993) have been reported by our informants as behaviors enacted by the brands they loved and broke up with, probably the most devastating being stonewalling and contempt as exemplified by the Yves Rocher story. Defensiveness is a rather common 'brand behavior', portrayed by Stefan's Eddie Merckx story, and brought to perfection by Audi's reaction to Manfred's quest for help, which was additionally spiced with criticism.

Viewed from a positive perspective, brands that are loved can do a lot to support a positive, life-long love relationship by treating consumers with respect and showing affection. Several of our cases indicate that, even after severe transgressions, consumers are reluctant to give up their emotional relationships. Similarly, times of transition could open up new opportunities for consumer-brand relationships and deepen the emotional bonds. Ahuvia (2005) has pointed out the importance of love brands for supporting personal identity that combines potentially conflicting aspects of selves, enable personal growth, and renewal of the self. Future research into consumer-brand relationships that successfully mastered turbulent times could elicit possible courses of action. Future research is also needed to highlight whether gender differences, or other personality characteristics, influence processes of emotional detachment. Love stories and strong emotional relationships might be highly idiosyncratic in their particular development and thus need emphatic brands that are familiar with 'The Art of Loving' (Fromm, 1956).

Exploring Consumers' Conflict Styles: Grudges and Forgiveness Following Marketer Failure

Michael B. Beverland, Royal Melbourne Institute of Technology, Australia

Steven M. Kates, Simon Fraser University, Canada

ABSTRACT

To date, research has not extensively examined consumer conflict styles following a transgression of commercial relationship norms by firms. We examine instances of service failure between consumers and long-time service providers using critical incident interviews with 30 informants. The findings indicate that the decision to perpetuate grudges or forgive service providers following a transgression is moderated by consumers' self- vs. other-orientation, emotional intelligence, and attachment style. The findings provide a new perspective on grudge holding and highlight the dark side associated with strong emotional bonds between consumers and service providers.

INTRODUCTION

One downside to close dedication-based relationships (relationships based on trust and voluntary membership; Bendapundi and Berry 1997) between firms and consumers is that customers in these relationships may react more negatively to severe service failures—"a violation of the implicit or explicit rules guiding relationship performance and evaluation" (Aaker, Fournier, and Brasel 2004, p.2). Bendapundi and Berry (1997, p. 33) propose that such violations lead to "ill-will and consequent negative repercussions." Repercussions may include negative twist behaviors ("unwanted behaviors of resistance against the company"; Arnould, Price, and Zinkhan 2004, p. 784) including long-term grudgeholding, theft, vandalism, negative word-of-mouth, anti-brand websites, and in rare cases physical abuse of service personnel (Andreassen 2001). These outcomes often occur even when seemingly reasonable efforts at service-recovery have been undertaken. Since many service organizations position themselves as sincere relationship partners that espouse consumer centricity (Bolton, Smith, and Wagner 2003) the betrayal of relationship norms potentially represents a significant moment in the consumer-brand relationship (Aggarwal 2004) because consumers place greater emphasis on negative events than on positive performances, and an "updating of expectations may take hold when disconfirmation exceeds a certain threshold" (Rust, Inman, Jia, and Zahorik 1999, p. 90). Such transgressions may result in counterfactual thinking about the service provider resulting in a negative reassessment of the brands' motives (McCullough-Kennedy and Sparks 2003). Moreover, the literature suggests that relationships *are* renegotiated (for the worse) following a transgression regardless of whether service recovery efforts were successfully undertaken (Maxham and Netemeyer 2002).

We examine why some consumers continue to perpetuate grudges against service providers and why and how consumers come to forgive transgressing firms. This paper examines these questions by drawing on the relational conflict literature. Although service provider transgressions have been examined from the perspective of dissatisfaction and justice (Smith and Bolton 2002), research on interpersonal conflict reveals a broader range of conflict responses or styles, and a range of moderators that go beyond concerns of justice to include a complex range of post-betrayal outcomes and moderators. For example, research on the nature of betrayal by romantic partners covers a broad range of possible cognitive, emotional and behavioral outcomes (McCullough et al. 1998). In particular, this research focuses on explaining how and

why betrayed partners may engage in acts that seek to repair or end relationships. Such research helps to explain why some consumers perpetuate grudges following a transgression.

METHODS

Long in-home interviews were performed with consumers, focusing on service brand choice, usage, and instances of serious failure. Service brand consumption is a rich context in which to investigate topics of relationship realignment, dissatisfaction, and forgiveness because consumers establish ongoing relationships with brands or marketing organizations (Fournier 1998). Further, transgressions sometimes occur in marketers' relationships with consumers (Aaker et al. 2004), and consumers adjust their meanings of, and relationships with them, accordingly. Our dataset consisted of thirty interviews with consumers (16 women and 14 men aged between 17 and 61) that had experienced failures in commercial relationships—thus theoretical sampling was employed. To probe into and elaborate on motivations for switching, types of transgressions, and eventual outcomes of transgressions, we employed some projective techniques by providing informants a range of images to help them elaborate on their reactions (Zaltman 2004). In each case we asked informants to discuss the nature of the relationship prior to the transgression, the nature of the transgression and the outcomes. Where relevant, we asked informants to compare the transgressing brand with any new brands that the informant switched to. As well, further probes into informants' emotional responses to transgression addressed personal life themes.

Interviews lasted approximately sixty to ninety minutes and were subsequently transcribed. These interviews were then analyzed by classifying the types of transgressions, processes of dealing with transgressions, and the outcomes that occurred using coding methods described by Strauss and Corbin (1998). Data was read over and analyzed independently by the authors, and then jointly discussed during face-to-face meetings and ongoing email correspondence. Overall, interpretive analysis was performed on the data in order to understand the rich details surrounding types of transgressions and their outcomes, and connecting data derived circumstances to constructs of interest such as relationship change and forgiveness. Finally, categories derived from the data were connected to and enriched by prior research, furthering our understanding of realignment in consumers' relationships service providers. For building theory, attention was paid to those consumption stories that appeared to challenge and extend extant findings (due to space limitations we focus on four informants).

FINDINGS

Consumer Forgiveness

Forgiveness relates to the release of negative feelings associated with a transgression and overcoming such resentments for restoring the relationship to its original state (Sells and Hargrave 1998). In a comprehensive review of the literature Sells and Hargrave (1998, p. 28) identified six necessary conditions of forgiveness: a violation occurs that causes one partner emotional or physical pain; the violation results in a broken relationship between the parties; perpetuation of the injury is halted; a cognitive process is pursued where the painful event or action is understood or

reframed within a fuller context; there is a release or letting go of justifiable emotion and retaliation related to the event; and, there is a renegotiation of the relationship. Of the sampled informants, 16 forgave the transgressor, with nine remaining in the relationship and seven exiting.

In describing examples of forgiveness, informants recounted incidences in a calm manner and although engaging in negative word-of-mouth, they only did so when people asked them about certain service classes. In cases where negative word-of-mouth occurred, the focus was on poor service standards—a functional assessment of the partner's performance. As well, these informants' transgressions involved a pattern of constant failures and in some cases illegal behavior before the consumers decided that the relationship should be terminated. And, these informants often engaged in intense efforts to repair the relationship and reconcile with the transgressor during incidences of failure, often stating how they "followed the rules," or "played their part"—characteristics absent in instances of grudgeholding. Thus, even when exit resulted, these informants met the six conditions of forgiveness identified by Sells and Hargrave (1998).

For example, Peter (WM30) recounted his experience with the National Bank, identifying multiple small failures including sending credit cards to the wrong address, failing to send personal security codes for the card, and poor service-recovery efforts from the bank's credit card center. Such failures had practical repercussions for Peter and his wife because all their credit cards and bank accounts were interlinked—therefore failures often made accessing money difficult, or in cases where new cards had to be sent out, account and internet banking details had to be constantly changed. However, despite these incidences of failure, Peter and his wife kept their anger under control, engaged in efforts at repairing the relationship, and were prepared to extend forgiveness. For example:

"Well their service was terrible! They were rude, unhelpful. Again, we tolerate mistakes, but if the service is good and they try and rectify it, you can be very forgiving, but if they continually, and they did, continually do the same thing and treated us very poorly and we sent them letters about granting my wife access to the accounts and they had it on system, but they always said she couldn't deal with the account. So this went on and on and on, we had really, really had enough."

Peter's passage above was reflective of the stance of many of our informants experiencing small service slippages or failures (anger was followed by a reframing of the event, calming down, attempts to repair the relationship, and eventual exit when it dawned upon the informant that these efforts would not be reciprocated). Peter only sought to exit the relationship after it was clear that his generosity and benevolence within the relationship would not be reciprocated. Peter's unwillingness to exit the relationship immediately was also moderated by his empathy with staff (he described many service personnel as "victims of the system" rather than being intrinsically rude individuals). As such, Peter ultimately attributed fault to the brand *per se*.

"Yes, the bank as an entity, because you can forgive one or two service failures, you know, you can have bad days, you can cop a bad one but generally you don't have them all bad, but it was very consistent and we had enough and it was their system, whatever they did, it was their information system, they always got it wrong. And obviously they didn't have the power to deal with it."

Peter's ability to explain one-off failures as poor timing or bad luck is evidence of his desire to empathize with service staff. However, ongoing failures led Peter to reconsider his stance. Peter's instances of anger and frustration were therefore used to generate counter-factual thinking about the brand (McCull-Kennedy and Sparks 2003), and the likely future experiences—a reexamination of the likely future value of a continued relationship with the offending partner. As such, what were perceived as "one-off" service failures were seen as part of a wider systemic failure that undermined the ability of bank representatives to authentically deliver on their promises. Peter, who defined his expectations of the service provider in terms of "fast, prompt and friendly professional service," realized that these expectations would never be met given the firm's wider problems. However, during this period of time, Peter was still reluctant to leave the bank, describing himself as "too forgiving" and "very patient" and also identifying that although alternatives exist, switching costs in terms of changing account information with employers, suppliers of regular services, and the hassles involved with setting up new phone and internet banking were also involved. For example:

"No, no, we try and get it right. Too much hassle to keep changing banks. As long as they respond and they communicate the problem, or their explanation, and they are up front about it and you know what's going on. Even when it's a human error, you can live with it, as long as they fix it properly."

The final act of betrayal involved a serious violation of customer confidentiality, when a friend working at the bank accessed their account and gave details of their finances to other friends (an illegal act under Australian law). However, even here, Peter's concern that informing the bank would result in the staff member losing their job ("we wouldn't them to lose their job") led him to quietly exit the relationship. Peter forgave because he saw that the outcomes of complaining would impact negatively on the service staff—a result he did not desire because of his empathy with staff. Peter's post-transgression experience was typical of several consumers that emotionally moved on from a negative relationship, rather than ruminating on past events and bearing a grudge. Although Peter will not return to the National Bank in the future, the transgression effectively no longer plays any role in his life.

Peter chose his service providers on the basis of functional performance. In contrast the next example involves a stronger emotional bond between the informant (Tom) and the service provider. Tom (WM18) formed an emotional bond with his chosen service provider, a local retailer of surf equipment because one of his goals was to become a proficient surfer. When he used his new high performance wetsuits it failed dramatically. For example:

"Unfortunately it stretched while I was in the freezing cold water... and let everything in, the water, everything and I froze...came out shaking...and I was numb...I didn't think it would stretch like that but it stretched quite considerably, which they are meant to do, but at the time, I think it was one of my first wet suits, and I didn't think it would because my Rip Curl [wetsuit] hadn't...it did something that was unexpected to me."

Because of this failure, Tom returned to the Billabong retail store and was told most wetsuits stretch and it was necessary for him to buy a new suit. Tom could have reacted angrily (and switched back to Rip Curl or demanded compensation) at this point given that

this retailer prides itself on surfing expertise and could have been expected to advise him to buy a smaller suit first time (wetsuits are an expensive purchase and usually require customers to interact closely with retail staff in order to get the right fit). Instead, Tom reframed the experience and apportioned the blame to himself: "that was just my error that I didn't know. I hadn't researched it well enough and didn't look." He subsequently bought another Billabong wetsuit and vest. Tom has many choices of wetsuit providers and there is a wide range of high quality retail outlets that will ensure he gets a suit suited to his needs. As well, Tom had previously experienced an alternative as a child with his Rip Curl suit. So why did Tom forgive the brand and remain within the relationship?

First, Tom views this experience as part of a learning curve to become a proficient surfer and thus gains value from the experience because he is now better paced to make informed purchase decisions in the future and has actually gained a better wetsuit as a result. Second, although Tom experienced the Rip Curl brand, he did so as a youngster and thus views it as a "kid's brand" rather than a high performance one. Third, retail stores are located close to beaches and therefore employ people who can provide equipment to deal with local wave and weather conditions (whereas stores away from beaches often focus on selling surf-inspired fashion accessories). Thus, by continuing to frequent the retailer he can improve his chances of achieving his goal. Fourth, because of his brand beliefs (partly formed due to his relative novice status as a surfer) he prefers to choose tried and tested brands like Billabong over others. Therefore, despite the seeming available of alternatives, for all intents and purposes, Tom perceives he has little choice of service provider. Research identifies that aggrieved partners extend forgiveness when they believe that there are benefits in doing so, the partner will reciprocate, and there are no alternatives (McCullough et al. 1997). In these cases, aggrieved partners may reframe the transgression and even accept some of the blame for its occurrence (Finkel et al. 2002). This helps explain Tom's conflict style in this case.

Consumer Grudge Holding

According to the literature, there are various forms of forgiveness and alternatives to forgiving a transgression (McCullough, Worthington, and Rachal 1997). For example, an individual may experience unforgiving responses such as harboring a grudge, rehearsing the hurt, perpetuating on negative emotions, seeking revenge, or maintaining estrangement from the transgressor. Unforgiveness and grudge holding following a transgression generally leads to vindictive behavior because transgressions create a "debt" that motivates a person to "get even" with the transgressor through seeking vengeance (Finkel et al. 2002). Unforgiveness could be reduced without explicitly promoting forgiveness, such as by accepting the hurt, reframing the events and circumstances around the offence, seeking justice, managing the stress related to the event, and controlling the anger resulting from the offence (Wade and Worthington 2003).

As noted, 14 informants maintained grudges against the service provider, with eight exiting the relationship and six staying. For example, Jack (WM20s) discussed two poignant examples of exit that remained emotionally charged (these had occurred some time earlier), and in one case, engaged actively in negative twist behaviors. Thus, although the relationships were ended from a commercial standpoint, they still played a prominent role in his life. Jack's examples are more emotionally charged, and he attributes moral failure to the brand and in the case of banks, the product class as a whole. For example:

"Basically what cemented my opinion of the Commonwealth Bank and what convinced me to leave it was the service I got from the staff member in the bank. I was waiting for quite a long time and the staff member was busy with another customer helping them with some new account, but she would dawdle and she wasn't hurrying up at all and I was in the bank for over half an hour, just waiting for her. I was waiting and there was another woman there who was serving someone else as well and that customer actually walked out the door, leaving the one woman free and instead of that woman saying I will be with you in a moment or something like that, she just walked out the back and she didn't come back. And, meanwhile the other person who was serving the one who's dawdling with the new customer, wouldn't look up at me, wouldn't look up at me at all and finally the customer leaves and I walk over there and she didn't apologize for the wait or anything and it's like, well, okay, this is the service you should expect in banks anyway. That was more or less the attitude I got from her and I wasn't impressed with that, so basically if her attitude had have been different, then I guess I wouldn't have been so harsh with the bank. But, basically it cemented my attitude and contributed to my decision to leave it."

Jack's response sits in stark contrast to Peter's more tolerant attitude regarding episodes like this. Jack describes this event as "the straw that broke this camel's back" and then described a long line of seemingly small service failures that were characterized by a lack of customer centricity including poor service in branches, lack of friendliness, and bureaucratic service rules. However, Jack also recognized that he may have been harsh with the bank by judging it based on his encounter with two staff members. Rather than reflect on this seeming rash act he generalizes from this incident first to the bank, and then to all banks as a class.

"I felt angry that the Commonwealth Bank as a corporation had allowed it to get to a stage where they purposely want you to wait in the bank with the aim of not going back to the branch, with you getting fed up with it, so you have to go and use your phone banking or your internet banking and I believe that that's what it's all about, that they are trying to deter you from going in the bank, that's why they keep you waiting and that's why they don't provide the service and people in the finish just give up and don't go into the branches anymore. [I. Can you explain a bit more about giving up?] People think, okay, this is the service that we can expect from banks, so we are not going to put up with it, so we will just, won't go into the branch. [I. Do you think you just had her on a bad day, or do you think she is always like that?] No, no I think it is in regards to banks, yes. Yes, definitely. I think it's, over the years because they have been closing branches and putting off staff, I think that the attitude of the staff and the banks has gotten worse, because they are putting up with so much abuse from the public and I did actually say something to the girl about waiting, about the length of time that I had to wait in the bank and I said, you know, it's nothing against you, but I think it's ridiculous that I had to wait so long and so on. And, she said well, yes I know, but the Commonwealth Bank has actually put off staff and this is the way they like things to be done now and we do apologize for the wait, but they are actually trying to get people to use the phone banking, instead of coming into the branches. And I said, well it's just not good enough, I understand that, but it's just not good enough. I said, you have lost me as a customer

and she, basically, yeah, okay, there goes another one. [I. How did she react, was she angry that you were leaving, or didn't care?] No, she didn't care. It was like okay, yeah, this is number 567 for today...."

Jack's anger generated during the service encounter triggered a cognitive reappraisal of the brand, and then of banks *per se*. Like Peter, Jack engages in counterfactual thinking where he compared his experiences to his expectations of service (McCull-Kennedy and Sparks 2003), the result of which was a realization that there was little value congruence between him and the brand (value congruence is believed to moderate responses to transgressions; Aggarwal 2004; Macintosh and Stevens 2006). Jack considers the failures to be part of a wider systemic problem at the bank, but rather than simply attribute it to poor functional processes, Jack judges the bank's (and product class') motives—by blaming the failure on the greed of the banks and belief that the owners are conspiring to deliberately create a negative experience so they can increase profits by shutting down branches and laying off staff.

"Basically they have just become more money hungry over the years. Their profits are just out of hand, and the media keeps reporting on that obviously, saying that they are in the tens and millions of dollars and so on. And account keeping fees keep going up, they are closing branches all the time and they are trying to force people out of the branches and onto the phone network and the Internet network."

To understand Jack's viewpoint one also needs to consider his attachment to bank. Jack had stronger emotional ties to the Commonwealth Bank. As a schoolboy he had banked his weekly pocket money with this bank as part of a national scheme to encourage savings. As such, the relationship is full of rich self-relevant meanings and memories (cf. Thomson et al. 2005). As a result, Jack built up an expectation that the bank would care for him because of his long loyalty.

"I have always actually banked with them from primary school, that's when my first account started and I was sort of disappointed that with the service I received, they were just prepared to allow me to close my accounts, without any queries with, nothing. I guess because I had been with them for so long that I sort of had a trust that the Commonwealth Bank would be there for me, when I say be there for me, that they wouldn't be as harsh as what I thought they could be, as what I had learnt to believe banks were."

Jack's belief in the benevolence of the Commonwealth Bank as a brand partner was challenged when despite a long period of loyalty, he realized that the bank simply did not care about him either way—reinforced by the service worker's lack of surprise or emotional concern at his request to close his accounts. Such an experience was described by Jack as a "wake up call" to the true nature of banks as commercial entities (despite their espoused rhetoric of partnership). Jack realized that he was not truly in a genuine relationship, and had little influence on the bank, or value to it.

Veronica (WF20s), who describes herself as "not very forgiving" discussed a number of instances of "instant exit"—cases where a small infraction led to immediate exit, at much emotional and practical cost to her. For example, despite knowing that requests for large sums needed to be made 24 hours in advance, Veronica wanted the bank to wave this requirement. Following an initial

rebuff from a service provider and Veronica's anger, a manager relented and waved the wait period as part of a service recovery effort. Yet, Veronica exited.

"I said, "I give you my money and I really don't want to be treated like this." It wasn't about money, it was more about the attitude... It's like they're a bank, but "please don't bank with us, just give us your money." Anyway, I spoke to the manager and I explained that I needed this money urgently, and she said, "that's no problem, you can come back in about an hour and a half and you will have the cash." I was shocked and surprised, because I could not understand on what basis she actually made this decision because all of a sudden I could have anything and in that afternoon I came back, I got my cash and I said, "can I please close the account?" "Oh, why are you doing this?" And I said because I was not treated the way I wanted to be treated."

This seemingly rash decision to exit following one-off "failures" characterized all of Veronica's examples, including product and service providers. For example, she dropped L'Oreal as a brand partner despite many years of preference due to one small failure and a recognition that alternatives are difficult to find in cosmetics given the intimate nature of the product (after two years of searching for a satisfactory alternative to no avail Veronica returned to L'Oreal). Veronica recognizes that she has lost a sense of perspective in her responses yet nevertheless constantly exits relationships following seemingly small slights.

"She was really sorry and she apologized and I was kind of sorry. She was the nice person and I didn't want to be nasty or anything to her. I just said this has happened once and I just—you know, I don't want to deal with you guys, that's it, so she was really upset that I closed the account and afterwards I got a letter from her, where she actually tried to win me back as a customer and I said it's too late, because you could have prevented this from happening that day and now it's just too late, I'm not interested."

Even allowing for the lack of procedural justice, Veronica did not view what was a one-off encounter as the result of a bad experience, or perhaps a trainee staff member's inexperience. Veronica's experience and reaction is also highly emotive. For example:

[I. What was it about that particular situation that prompted the all or nothing decision?] As a customer, you should actually have access to your funds all the time. I knew about the 24 hours notification, but after I asked for a cheque and she said no, then I thought something was wrong, because this is not right and then five minutes later, I speak to her manager and all of a sudden, I get a completely different service and that's what I didn't like. [I. What did you attribute this to?] Maybe lack of knowledge by this person. She should have actually told me I'm not sure or can you come back later and I'll find out, but not just, no, you can't. I just said if I actually have to put in requests 24 hours in advance, then I just don't bank with you, it's that simple... although she kind of didn't deserve that response, they kind of provided this overall image and that's what I associate with the St George Bank. Again, sometimes just individuals standing behind a counter or a person are having a bad day, but I'm a customer and this is a bank and that's all I know. I don't really want to deal with their individual problems or their bad days...."

Veronica's choice of the St George bank is not coincidental. This particular bank positions itself as the "non-bank, bank" (banks within Australia are regularly placed last in consumer satisfaction surveys). In contrast, St George has adopted an emotional branding strategy, positioning themselves around authentic service, customer centricity, friendliness, and at a time when many banks are closing branches, this bank is expanding their branch network. For Veronica, the choice of banking partner was driven by the emphasis they placed on her value as an individual, the strong sense of service and customer centricity and their flexibility in responding to customer needs. Therefore, Veronica's action (identified by her as "unreasonable") can be explained partly by her high sense of entitlement (Exline et al. 2004) and her belief that she has a number of other alternatives in the product class. Thus she reacts to conflict by seeking to dominate the offending partner (Macintosh and Stevens 2006). By exiting, Veronica reaffirms herself as a powerful consumer, even though later on (as with her car repair agency and L'Oreal) she returns to the relationship after failing to find an alternative (in the projective techniques, Veronica referred to a picture of a boxer in a fighting pose to characterize her attitudes to brands). Veronica's use of a fighting metaphor suggests she will be perpetually disappointed in commercial relationships, thus increasing her search and trial costs.

DISCUSSION

Based on the informant passages above we suggest three moderators of consumers' post-transgression conflict style: self- vs. other-orientation, emotional intelligence, and attachment style. First, research on conflict styles suggests aggrieved individuals may respond to transgressions in one of four ways: integration (cooperative behavior with transgressor), dominating (aggressive behavior towards transgressor), obliging (acquiescence to transgressor) or avoiding. These outcomes are moderated by concern for self and others (Macintosh and Stevens 2006; Rahim 1983; Twomey 1978). For example, both Jack and Veronica have a high degree of self-orientation and as such seek to dominate the offending partner, whereas Peter exhibits a high degree of other-orientation and seeks integration and obligation.

Peter's actions may be explained by their over emphasis on other-orientation at the expense of self-orientation. Rahim (1983) proposed that individuals exhibiting a high concern for self and other were likely to engage in genuine efforts at repairing the relationship in order to maximize the benefits to both parties. In cases where other orientation dominates, the aggrieved party may be more forgiving of the aggressor and seek to understand and rationalize the aggressor's actions so they can move forward. This suggests that self- vs. other-orientation may moderate forgiveness outcomes. For example, Sells and Hargrave (1998) suggest that cessation of injury is necessary for forgiveness to occur, yet Peter engages in many actions consistent with a forgiving stance even though he continued to suffer ongoing hurt. By way of contrast, Tom exhibits greater balance in self- vs. other-orientation. In these cases, consumers are predicted to engage in genuine efforts at repairing the relationship in order to maximize the benefits to both parties (Macintosh and Stevens 2006; Rahim 1983; Twomey 1978), just as Tom does.

Second, Peter and Tom's attempts at reconciliation and the ability to put the transgression in perspective and ultimately move beyond it, can also be attributed to a high degree of emotional intelligence, or "the ability to manage one's own emotions and deal with others' emotions in problem solving and decision making" (Yang and Mossholder 2004, p. 594). Yang and Mossholder suggest that emotional intelligence involves four interrelated abilities: accurately appraising and expressing emotions, generating emo-

tions to facilitate thought processes, understanding emotions and emotional knowledge, and regulating emotions in the self and in others to promote emotional and intellectual growth. Such abilities are believed critical to strong relationships because they ensure that task related conflicts do not get blown out of proportion nor become personal. Individuals with strong emotional intelligence are proposed to engage in more cooperative approaches to conflict, whereas highly emotional and coercive responses to conflict are the result of limited levels of emotional processing. Against these criteria, Peter and Tom exhibit high levels of emotional processing and seek to repair the relationship. Thus service failures ultimately do not result in ongoing grudges among these informants. In contrast, Veronica openly acknowledges that she is quick to anger and is "not very forgiving." She also identifies that her reactions may have been unfair given the attempts made at service recovery. These reactions reflect lower levels of emotional processing than Peter or Tom.

Third, we believe that different attachment styles influence forgiveness outcomes. Attachment is defined as "an emotion-laden target-specific bond between a person and a specific object" (Thomson, MacInnis, and Park 2005, p. 77-78). Attachments vary in strength and form part of consumer relationships with brands or service providers (Fournier 1998). In Peter's case, although he had remained in the relationship for some time and valued the bank as a relationship partner, his attachment was defined primarily in functional terms ("fast, prompt and friendly professional service"). Thus, despite ongoing interaction with the service provider, Peter did not form a strong attachment with them (defined by "a rich set of schemas and affectively laden meanings that link the object to the self" Thomson et al. 2005, p. 79), and did not suffer separation distress. By way of contrast, Jack's relationship with the bank was richer in meaning and based on a deeply felt sense of trust—therefore Jack's reaction to the partner's betrayal was ultimately more painful and severe than Peter's. In contrast, Tom's close attachment to the brand and retailer, coupled with his balanced self- vs. other-orientation and strong emotional processing results in forgiveness. Veronica's relationships were also characterized by less rich (in comparison with Tom and Jack) emotional attachments (e.g., her response to strong emotional campaigns such as St George's friendly customercentric bank advertisements and L'Oreal "Because You're Worth It") although unlike Tom and initially Jack, she believes that such brands are easily replaced (Twomey 1978).

Such findings enrich our understanding of consumer grudgeholding and contribute to emerging debates on consumer conflict styles (Macintosh and Stevens 2006). In regards to self- vs. other-orientation we identify that for consumers at either extreme, reconciliation is likely to be difficult. In cases where self-orientation dominates relationships are terminated quickly following a transgression, with the aggrieved party unlikely to seek reconciliation or respond to service recovery efforts. This is particularly so for high self-oriented consumers with low levels of emotional intelligence. In contrast, high self-oriented consumers with stronger emotional intelligence are likely to remain within relationships because they engage in some level of emotional processing that result in them placing the transgression within a wider context of benefits. Consumers high on other-orientation are more likely to tolerate constant errors, forgive small failure, and in cases of severe transgressions (such as Peter) simply exit relationships without holding a grudge (and engaging in costly negative behaviors for the brand).

Research is necessary to confirm the findings herein by using attachment scales (Thomson et al. 2005), conflict orientations (Rahim 1983), and emotional intelligence (Yang and Mossholder 2004). Experimental scenarios of transgressions could be devel-

oped to examine the relationship between personality type and propensity to forgive could be developed. These scenarios could also take into account perceived switching costs (choice of alternatives). Research could also examine barriers to forgiveness such as narcissism. As consumer culture can be characterized by an entitlement mentality (Boyd and Helms 2005), research could draw on narcissism scales to assess consumers' proneness to forgive (Exline et al. 2004).

Salvation of the Second Shift: Are Wives Immune to Monday Blues?

Charles Areni, The University of Sydney, Australia

ABSTRACT

In an internet survey, 702 Australians reported momentary and typical moods for each day of the week (DOW). Both mood measures indicated a gender x marital status x DOW interaction, wherein wives were relatively immune to Monday blues compared to husbands and single adults. Due to traditional gender stereotypes and roles within the household, wives may not associate Mondays with the loss of discretionary leisure and the onset of paid work. Consistent with this explanation, wives reported doing housework on the weekend more frequently than single women and men. They also experienced weekend leisure less frequently and performed substantially fewer hours of paid labor during the week compared to men, although there was no difference between single and married women on either variable. However, none of these variables mediated the gender x marital status x DOW effect on reported moods, suggesting that additional factors underlie wives' immunity to Monday blues.

INTRODUCTION

Stereotypes found in aphorisms (e.g., Monday blues, Wednesday hump day, and T.G.I.F.—Thank God It's Friday), song titles (e.g., I Don't Like Mondays—the Boomtown Rats, Friday on My Mind—the Easybeats, Saturday Morning in the City—Brian Wilson, Gloomy Sunday—Billie Holiday), and literary works (e.g., “something unromantic as Monday morning”—Charlotte Bronte (Shirley), “as lonesome as a Sunday”—Mark Twain (A Connecticut Yankee in King Arthur's Court), “He that laughs on Friday may cry on Sunday”—Proverbs (The Bible)) suggest that some days of the week are consistently better than others. These aspects of popular culture imply that moods vary over the course of a typical week according to a sinusoidal pattern, with a positive gradient between the nadir on Monday and the peak on Friday or Saturday, a transition from the negative to the positive portion of the week on Wednesday (i.e., the hump day), and a steep decline in mood late on Sunday. Day of the week (DOW) stereotypes stem from an assumption that people are generally happier when they are free to choose their activities compared to when they are engaged in paid work (Beatty & Torbert, 2003; Dupre & Gagnier, 1996). The sinusoidal pattern emerges because weekdays (weekends) are associated with paid work (free time) (Zerubavel, 1985), and because people anticipate the number of days before the transition from one to the other (Larsen & Kasimatis, 1990). Hence, Monday morning is the worst part of the week because it is the first work day after two days of free time, and because four work days follow before the next period of free time. Likewise, Friday evening is the best part of the week because it marks the beginning of an extended period of free time (i.e., T.G.I.F.) (Areni, 2008).

Given this explanation for DOW stereotypes, factors affecting the amount of free time experienced on the weekend, and the amount of paid work experienced during the week, should also affect the extent to which Mondays are associated with negative moods. Along these lines, previous studies have shown that men are more prone to the stereotypical weekly mood pattern than women (Rossi & Rossi, 1977; Almagor & Ehrlich, 1990). In short, men have distinct, compartmentalized portions of the week for paid work (i.e., Mon-Fri, 9 to 5) and leisure (i.e., evenings and weekends), whereas these boundaries are blurred for women (Almagor & Ehrlich, 1990; Deem, 1996), who often fulfill multiple social and professional roles simultaneously (Thompson, 1996). Additional research suggests that role conflict is magnified for wives compared

to single women (Stevens, Kiger & Riley, 2001; Roxburgh, 2006). The research reported below uses survey data obtained from a cross-section of the Australian population to test the hypotheses that wives will report less negative moods on Mondays compared to husbands and single adults. The following section expands on this prediction, explaining why wives may be immune to Monday blues compared to single women and men.

WORK TIME, LEISURE TIME AND GENDER INEQUALITY

Perhaps the most fundamental defining aspect of leisure is the freedom or discretion to pursue pleasurable activities (Unger & Kernan, 1983). By this simple definition, contemporary gender roles rob wives of this most basic of human pursuits because of their greater involvement in household production (Hunt & Kiker, 1981), their adoption of multiple, often conflicting, social and professional roles (Thompson, 1996), a perceived lack of freedom to act on their personal wishes (Thompson, Locander & Pollio, 1990), and a tendency to put the needs of others ahead of their own (Meyers-Levy, 1988; Thompson et al., 1990). All of this suggests that wives experience less leisure compared to husbands and single adults (Bittman & Wajcman, 2000; Mattingly & Bianchi, 2003).

Hochschild (1989) coined the phrase “second shift” to describe the fate of working wives who, after a full day of work at the office, come home to a disproportionate amount of household work due to husbands who do not pull their own weight. Despite the social impetus for husbands to increase their share of domestic labor to accommodate the careers of their wives (Thornton, 1989; Mattingly & Bianchi, 2003), husbands often define themselves in terms of their abilities as “breadwinners” for the household (MacMillan & Gartner, 1999; Rogers & DeBoer, 2001; Commuri & Gentry, 2005). Perhaps because of this narrow criterion, husbands do less household work than wives (Hochschild, 1989; Bittman & Pixley, 1997; Roxburgh, 2006), even after correcting for hours of paid labor per week. Some studies have found that wives do more than twice as much household work as their husbands (Bittman et al., 2003), so as wives increase the amount of time spent in paid work, their available leisure time evaporates (Cantwell & Sanik, 1993).

Although wives experience a relative loss of leisure and a higher proportion of housework throughout the week, these gender inequities are more pronounced on weekends, where husbands and children enjoy pure leisure experiences that are often produced by wives' household labor activities (Graham, 1984; Deem, 1996). A husband's experience of drinking a cold beer while watching football on television is produced by a wife who shops for the household (i.e., puts the beer in the refrigerator), pays the utility bills (i.e., supplies the television programming), does the laundry (i.e., provides the clean clothes the husband is presumably wearing), and keeps the children entertained (i.e., stops them from interrupting the viewing experience), among other things. Wives experience free time during different parts of the week compared to husbands and single adults; since they have less free time during the weekend, they squeeze it into weekday evenings, after the kitchen has been cleaned and the children have been put to bed (Hewitt, 1993; Le Feuvre, 1994). Hence, for wives, weekends are less likely to be experienced as two days of free time for leisure activities (Larson & Richards, 1994; Deem, 1996).

Moreover, despite changing gender roles and attitudes toward women pursuing careers, women still work fewer hours per week than men (Coleman & Pencavel, 1993; Roxburgh, 2006), and wives

work fewer hours per week than unmarried women, although the gap is narrowing (Coleman & Pencavel, 1993; Pencavel, 1998). Wives are also less likely to work in traditional “9 to 5, Monday through Friday” positions, instead occupying part time jobs that better accommodate their childcare activities (Presser & Cox, 1997). Wives often choose to participate in paid labor because of financial or marital distress. Indeed, research suggests that wives who increase their participation in paid labor often do so because of unhappiness in their marriage, which is why increases in wives’ paid labor hours is correlated with subsequent divorces initiated by wives but not those initiated by husbands (Schoen, Rogers & Amato, 2006). So wives are less likely to experience Mondays as the beginning of a period of paid work. Many will not begin a full week of work on Monday, and for others, paid work may be a welcome respite from more stressful domestic labor (Larson & Richards, 1994; Deem, 1996).

These gender differences in work and leisure time have been explained in terms of rational allocations of economic resources (Becker, 1981). That is, men spend more hours in paid work because they have greater opportunities to earn money. But this argument seems rather tautological, and even when wives work as many hours and earn as much money as their husbands, they still do more household work, suggesting that gender stereotypes have more to do with this uneven division of domestic labor (Hochschild, 1989; Bittman et al., 2003; Commuri & Gentry, 2005). Wives earning more than 50% of household income may actually do more housework as a consequence (Bittman et al., 2003), because their husbands contribute even less to domestic labor (Brines, 1994; Greenstein, 2000). In other words, a wife who earns more than her husband is “compensated” by having to do even more housework, suggesting a possible ego defense explanation for husbands’ failure to contribute equally to household work. Having children magnifies these differences between husbands and wives (Mattingly & Bianchi, 2003). Research has even shown that married mothers do more household work than single mothers, suggesting that “husbands create more household work than they perform” (Mauldin & Meeks, 1990, p. 67).

In a more general sense, compared to men, and to a lesser extent, single women, wives are less likely to experience the transition from the weekend to the week as a loss of free time to paid work. Instead, household responsibilities permeate every day regardless of how many hours of paid work they perform (Larson & Richards, 1994; Deem, 1996). Since the perceived loss of free time is a critical aspect of Monday blues (Areni, 2008), this suggests that wives should be relatively immune to actual and perceived downward swings in mood from Sunday to Monday compared to husbands and single adults. The research reported below tests this basic hypothesis, and also predicts that wives will report (a) fewer hours of paid labor during the workweek, (b) lower frequencies of leisure experiences during the weekend, and (c) higher frequencies of household production activities during the weekend compared to husbands and single adults. These variables are also tested as mediators of the gender x marital status interaction effect on perceived and actual Monday blues.

METHOD

Design and Procedure

An internet survey was conducted in order to collect data on momentary moods over the course of a week and the typical moods people experience on each DOW. The data were collected from the 5th to the 12th of October in 2005 to avoid public holidays and major sporting events. Husbands, wives, and single men and women

reported their momentary moods once per day at their discretion over one week. On the eighth day, they reported how they typically feel on each DOW. Hence, *mood measure* (momentary, typical) and *DOW* were within-subjects factors, and *gender* and *marital status* were between-subjects factors.

Sample

Seven hundred and two subjects were selected from the panel of an Australian market research company, which included 369 males (52.6%) and ages ranging from 16 to 65. The distribution of ages was approximately normal, with a mean of 38.0 years and a standard deviation of 10.2. There was no significant difference in the mean ages of males and females, and distribution by metropolitan area was uniform when weighted by population. Sixty-nine percent of the subjects were employed in some capacity, 42.5% in full-time work. The remaining 31% who did not report being employed were split between those having home duties (17.5%), retirees (4.3%), and those who were unemployed (9.7%).

Independent Variables

Momentary versus Typical Moods: For the momentary mood measures, subjects were asked “What is your mood like right now?” on seven successive days. On the eighth and final day of the survey, subjects were asked “On a typical (DOW), what is your mood like over the course of the whole day?” This question was repeated seven times for each DOW. The momentary and typical mood measures used the same response format, which is described below.

Marital Status and Gender: Subjects were asked “Which of the following best describes you?” using the response categories “single”, “in a relationship, separate residences”, “in a relationship, living together”, and “married couple”. Given research suggesting that married couples differ from cohabitating couples, who are more comparable to other singles (Stack & Eshleman, 1998), only subjects selecting the last option were classified as married. All other responses were coded as single. Subjects were then prompted with “Are you...” using the response categories “male” and “female”.

Mediating Variables

Hours of Paid Work: Subjects were asked “How many hours per week do you normally work?” using an open-ended response format.

Frequency of Weekend Housework and Leisure: After each of the 7 momentary mood reports, subjects were asked “In what activity are you presently involved?” using an open-ended response format. The responses were coded into 49 categories by two experienced researchers using the Daily Life Experiences (DLE) taxonomy (Stone & Neale, 1982; Stone, 1987). The DLE classifies daily activities into five broad categories (paid work, leisure, family and friends, financial matters, and other), with 14 sub-categories and 49 final classifications. For purposes of this analysis, family and friends was separated into two sub-categories: household work and social leisure. Social leisure, involving discretionary time spent with friends or family members, was grouped with other leisure activities, whereas childcare and other activities involving the care of family members were classified as household work. This resulted in four main categories: paid work, leisure, household work, and other, which was an aggregation of the financial matters and other categories in the original taxonomy.

Two judges independently coded the open-ended responses into the 49 classifications. Inter-coder reliability was assessed for each DOW. Cohen’s K values ranged from .80 on Thursday to .88 on Sunday and Monday. When the data were aggregated up into the

four main activity categories, Cohen's *K* values increased, ranging from .87 on Wednesday and Saturday to .92 on Monday. These results reflect "substantial" to "almost perfect" inter-coder reliability (Landis & Koch 1977, p. 165); differences were resolved via discussions between the author and the two coders. So, subjects reporting momentary moods on a given day also indicated whether they were experiencing leisure or household work at that time. Hence, it was possible to count the number of experiences in each category on the weekend. Since Fridays are experienced as part of the weekend rather than the workweek (Rossi & Rossi, 1977), this research adopted a 3-day definition of the weekend. Subjects could report between 0 and 3 leisure activities and household work activities on the weekend.

Dependent Variable

The two mood measures involved a single, bi-polar response scale in order to reduce subject fatigue given that eight successive daily surveys were required (see Kahneman et al., 2005). Although single, bi-polar measures fail to capture qualitative differences between positive (e.g., pride vs. relief) and negative (e.g., loneliness vs. anger) affective states, previous research suggests "that most moments of experience can be adequately characterized by a single summary value on the GB (good-bad) dimension" (Kahneman, 1999, p. 8). Nine horizontally arrayed circles one quarter inch in diameter were anchored on the left side by "very bad" and on the right side by "very good". Subjects used a mouse to indicate their mood. For purposes of data analysis, the scale was treated as ranging from -4 (very bad) to +4 (very good), with the middle circle taking on the value 0.

RESULTS

In order to test the hypothesis that wives would be relatively immune to Monday blues, a 4-way mixed-factor ANOVA was run with gender and marital status as between-subjects factors and DOW and mood measure as within-subjects factors. Results indicated that the main effects of gender ($F_{1,698}=4.5$, $p<.05$), marital status ($F_{1,698}=7.0$, $p<.01$), DOW ($F_{1,698}=110.5$, $p<.0001$), and mood measure ($F_{1,698}=8.3$, $p<.01$) were all significant. Women ($M=1.60$) reported more positive moods than men ($M=1.37$); married subjects ($M=1.63$) reported more positive moods than single subjects ($M=1.36$); and overall, subjects reported more positive typical moods ($M=1.54$) than momentary moods ($M=1.42$). The DOW effect was more or less consistent with the stereotypical sinusoidal pattern, with moods on Monday ($M=1.10$) significantly lower than moods on Tuesday ($M=1.31$), Wednesday ($M=1.26$), Thursday ($M=1.40$), Friday ($M=1.53$), Saturday ($M=1.60$) and Sunday ($M=1.61$); and moods on Tuesday–Thursday lower than moods on Friday–Sunday, all at $\alpha=.05$.

However, these main effects must be qualified by significant measure x DOW ($F_{6,4188}=71.8$, $p<.0001$), gender x DOW ($F_{6,4188}=2.7$, $p<.01$), and gender x DOW x marital status ($F_{6,4188}=3.6$, $p<.001$) interaction effects. The mood measure x DOW interaction effect revealed that the stereotypical pattern was more obvious for typical moods compared to momentary moods. Specific mean contrasts on each day revealed that typical moods were less positive than momentary moods on Monday (0.57 vs. 1.24) and Tuesday (0.89 vs. 1.47), but more positive than momentary moods on Wednesday (1.29 vs. 1.16), Thursday (1.46 vs. 1.33), Friday (2.05 vs. 1.54), Saturday (2.36 vs. 1.53), and Sunday (2.19 vs. 1.65), all at the $\alpha=.05$ level of significance, except for Thursday, which was significant at $\alpha=.10$. So while there was some evidence for Monday blues in momentary moods, it was more pronounced in typical moods.

Perhaps more importantly, given the focus of the research, the gender x DOW interaction revealed that most of the gender main effect reported above occurred on Monday ($F_{1,698}=6.4$, $p<.01$), where women ($M=1.30$) reported more positive moods than men ($M=0.92$). No other gender differences for the remainder of the week were significant at $\alpha=.10$. This suggests that men are more prone to Monday blues than women, but the gender x DOW x marital status interaction revealed that this conclusion depends on marital status. Paired comparisons revealed that moods declined from Sunday to Monday for single men (1.34 vs. 0.79, $t_{1,224}=4.7$, $p<.0001$), married men (1.81 vs. 1.13, $t_{1,143}=5.9$, $p<.0001$), and single women (1.74 vs. 1.00, $t_{1,160}=5.6$, $p<.0001$), but not for married women (1.66 vs. 1.57, $t_{1,171}<1$). As hypothesized, wives were immune to Monday blues.

The underlying explanation for wives' relative immunity to Monday blues stems from differences in gender roles within the household. Because they do more housework on weekends, experience less leisure on weekends, and work fewer hours of paid labor during the week, wives are less likely to experience Mondays as a loss of free time and the onset of paid work. If this explanation is correct, then hours of paid labor during the week and the frequency of leisure and housework during the weekend may mediate the effects of gender and marital status on Monday moods. In order to explore the first possibility, hours worked per week was included as the dependent variable in a 2-way, between-subjects ANOVA with gender and marital status as the independent variables. Results indicated only a main effect of gender ($F_{1,698}=52.7$, $p<.0001$). Men ($M=33.13$) worked more hours per week than women ($M=16.52$), regardless of marital status. Moreover, when hours worked was included as the covariate in an ANCOVA with DOW and mood measure as within-subjects factors and gender and marital status as between-subjects factors, it was not predictive of moods on Monday ($F_{1,697}<1$) or any other day of the week. So the relative immunity to Monday blues does not apparently stem from wives working fewer hours of paid labor during the week.

To examine whether the amount of weekend housework is related to the gender x DOW x marital status interaction effect on reported moods, frequency of housework was included as the dependent variable in a 2-way, between-subjects ANOVA with gender and marital status as independent variables. Results indicated main effects of gender ($F_{1,697}=36.7$, $p<.0001$) and marital status ($F_{1,697}=23.5$, $p<.0001$). Women ($M=0.87$) were more frequently engaged in weekend housework than were men ($M=0.48$), and married subjects ($M=0.85$) reported housework activities more frequently than single subjects ($M=0.52$). The gender x marital status interaction was marginally significant ($F_{1,697}=3.6$, $p<.06$). Consistent with traditional gender stereotypes, wives ($M=1.06$) reported doing housework on the weekends more frequently than single women ($M=0.66$), husbands ($M=0.59$), or single men ($M=0.41$) at the $\alpha=.10$ level of significance. Frequency of weekend housework was then included as a covariate in a 4-way, mixed-factor ANCOVA with gender and marital status as between-subjects factors and DOW and mood measure as within-subjects factors. However, results indicated that the frequency of weekend housework was not predictive of moods reported on Monday ($F_{1,696}<1$) or any other day. So wives immunity to Monday blues is not explained by the amount of housework done on the weekend.

Frequency of weekend leisure was also included as a dependent variable in a 2-way, between-subjects ANOVA with gender and marital status as independent variables. Results indicated main effects for gender ($F_{1,697}=3.3$, $p<.10$) and marital status ($F_{1,697}=4.7$, $p<.05$). Men ($M=2.02$) experienced weekend leisure more frequently than did women ($M=1.87$) and single subjects ($M=2.02$).

reported weekend leisure more frequently than married subjects ($M=1.86$). However, when frequency of weekend leisure was included as a covariate in a 4-way ANCOVA with gender and marital status as between-subjects factors and DOW and mood measure as within-subjects factors, it was not predictive of the moods reported on Monday ($F_{1,696}<1$) or any other day of the week. So, the frequency of weekend leisure activities also fails to account for the gender x day x marital status effect on reported moods.

DISCUSSION

The results reported above support the hypothesis that wives are immune to Monday blues compared to single women and men, who experienced a marked decline in mood from Sunday to Monday. The explanation given for this immunity stemmed from wives not experiencing Monday as the onset of negatively valued paid work following a weekend of positively valued leisure. Instead, wives were thought to experience all days as complex mixes of leisure and domestic and paid labor, with Mondays even experienced as a relief from the domestic labor of the weekend. However, subsequent analyses did not support this explanation. Hours of paid work during the week, frequency of weekend leisure, and frequency of weekend housework did not mediate the effect of gender and marital status on moods by DOW, suggesting that other factors may mitigate Monday blues.

Despite research indicating changes in attitudes toward more egalitarian gender roles, these results suggest that actual behavior within the household seems to have changed substantially less (Cantwell & Sanik, 1993). Women continue to do more household work than men, and this difference is magnified among married couples. As a result, wives experience less leisure time during the weekend than their husbands do. There is some indication in the literature that the failure of husbands to bring their behavior in line with their supposed attitudes is ego defensive. Contributing more household labor may unconsciously be interpreted as an indication that husbands are inadequate in the traditional role of "bringing home the bacon" (Stevens, Kiger & Riley, 2001). Career-oriented women may feel guilty about being inadequate in their traditional roles as wives and mothers, and domestically-oriented men may feel ashamed about being inadequate in their traditional role as breadwinners.

Along these lines, attitudes toward traditional and progressive gender roles may play a more important role in determining whether Monday mornings are experienced as a loss of freedom or an escape from domestic labor. For a woman adopting a more traditional gender role, domestic labor on the weekend might not be viewed as onerous and paid work during the week may be minimal. On the other hand, a woman with more progressive values may well resent weekend housework, and look forward to resuming her career-oriented work on Monday (Hochschild, 1997). In addition to looking at the allocation of time to household and work-related behaviors, future research might examine attitudes toward gender roles and related issues as potential mediators of Monday blues.

The DOW x mood measure interaction effect reported above indicates that Monday blues and other DOW stereotypes may be more in the mind rather than in the reality of moment by moment affective states. There is some evidence of a weekly mood cycle in the momentary mood reports, but it is at odds with the stereotypical pattern in some respects. Although subjects reported relatively low momentary moods on Monday, which increased substantially on Tuesday, momentary moods were lowest on Wednesday; and though they rose steadily from Thursday to Saturday, momentary moods continued to improve on Sunday, which runs counter to the

stereotypical pattern. By contrast, the typical mood reports followed the stereotypical pattern perfectly, with more pronounced differences between the "good" and "bad" parts of the week. Asking people how they typically feel, on a "Monday" for example, explicitly mentions the DOW, which may activate schemas and stereotypes related to that day. It also encourages people to consider a wide span of previous experiences, and to consider common rather than unique aspects of those experiences. One of the most accessible common aspects of Mondays is the return to paid work after a period of weekend leisure, which should trigger the stereotype, and lead to an exaggeration of how bad Mondays are. By contrast, the momentary mood measure makes no mention of the specific DOW. When asked how they feel at the moment, people are more likely to be influenced by their local surroundings and recently passed and immediately anticipated events, rather than DOW stereotypes. Hence, the stereotypical pattern is relatively muted (Areni, 2008).

It is also intriguing that reported typical moods were more favorable than the actual momentary moods people experienced. Based on momentary mood reports from a number of cultures, Biswas-Diener, Vitterso & Diener (2005) have concluded that "most people are pretty happy" (p. 2005). The caveat suggested here is that people may not be quite as happy as they think. Perhaps this also reflects an ego defensive mechanism. It may be acceptable to admit that things are not going well at the moment, but to admit that things typically do not go well may be threatening to the self. People are motivated to feel good about themselves and others, and typical moods may be more diagnostic than momentary moods as indications of how things are going, so they are biased in a positive direction.

(Waiting) Time Flies When the Tune Flows: Music Influences Affective Responses to Waiting by Changing the Subjective Experience of Passing Time

Charles Areni, The University of Sydney, Australia
Nicole Grantham, Information Tools Pty Ltd, Australia

ABSTRACT

Researchers often focus on perceived (i.e. estimated) duration or deviations from expected duration when examining the effects of atmospheric music on waiting and customer satisfaction. Comparatively little attention has been given to whether an interval feels as though it has “dragged” on versus “flown” by compared to the normal pace of time passage. In a laboratory experiment, subjects waiting for an important event to begin reported more negative affective states when disliked rather than liked music was played during the interval. This effect was completely mediated by their subjective experience of the interval as having passed more slowly or quickly than usual when disliked versus liked music was played, respectively, whereas neither deviations from their expected waiting time nor estimates of actual duration were related to reported affective states.

INTRODUCTION

Previous research has found that perceived waiting time is negatively correlated with overall satisfaction in customer settings as diverse as restaurants (Jones and Peppiatt 1996; Davis and Heineke 1998), supermarkets (Tom and Lucey 1997), video rental stores (Evangelist et al. 2002), banks (Houston, Bettencourt and Wenger 1998), emergency healthcare (Dansky and Miles 1997), general healthcare (Pruyn and Smidts 1998), and airlines (Taylor 1994). Presumably, consumers get annoyed when they have to wait for an extended period (Houston et al. 1998), so longer waits are associated with lower levels of satisfaction (Cameron et al. 2003). The marketing literature has made the distinction between perceived duration and actual duration, and researchers have explored how commercial environments influence the perceived duration of a given interval apart from its duration as measured by a clock or watch (Bailey and Areni 2006; Hornik 1984; Haynes 1990; Taylor 1994; Hui and Tse 1996).

However, most conceptualizations of perceived duration have either involved estimates of the interval in standard time units (Jones and Peppiatt 1996; Dansky and Miles 1997; Evangelist et al. 2002), measures of duration relative to some context-specific expectation (Hedges, Trout and Magnusson 2002; Boudreaux, Mandry and Wood 2003), and/or some combination of the two (Taylor 1994; Tom and Lucy 1997; Davis and Heinke 1998; Houston, Bettencourt and Wenger 1998; Pruyne and Smidts 1998; Roper and Manela 2000; Hedges et al. 2002). These kinds of measures have produced mixed results, sometimes resulting in a direct negative relationship between perceived duration and satisfaction as noted above, sometimes an indirect negative relationship (Pruyn and Smidts 1998; Evangelist et al. 2002), and other times no relationship at all (Boudreaux et al. 2003).

The research reported here posits that an interval may seem long not because it is long or because it is longer than expected given the context, but because time seems to pass more slowly than usual even though the actual duration may be known. Although the first two possibilities have been examined in detail, no research has examined the relationship between whether a given waiting period *feels* as though it has passed more quickly or slowly than usual and resulting affective states. Based on attentional models of time perception, the research presented below argues that, of these three

measures, the subjective experience of the pace of passing time is the most important determinant of affective state in waiting contexts. Consistent with this explanation, a laboratory experiment demonstrates that the effect of atmospheric music on the affective states of respondents waiting for an upcoming event was mediated by their subjective experience of time as passing more quickly or slowly than usual, whereas neither perceived duration nor deviations from expected duration were related to affective state.

SUBJECTIVE EXPERIENCES OF PASSING TIME: ATTENTIONAL MODELS

Attentional models hold that attention is divided between processing temporally-relevant versus temporally irrelevant information. An increase in attention devoted to temporally relevant information results in more information recorded regarding the passage of time (Block 1990). As more and more attention is devoted to the passage of time, perceived duration increases (Zakay 2000). Attentional models are particularly relevant to waiting contexts because people who are waiting for an upcoming event pay closer attention to the passage of time than they would in other situations (Zakay 1990). Attentional models are best captured by the familiar cliché “Time flies when you’re having fun”, and also suggest that time drags when you are not having fun (i.e., waiting). However, in a waiting context, the relationship also operates in reverse; a wait that feels as if it is passing quickly is far less annoying than one which seems to drag on. In other words, attentional models suggest that the effect of waiting on affective states is mediated by the subjective experience of the rate at which time seems to pass. Any stimulus that distracts customers from thinking about the passage of time should speed up the subjective experience of passing time, making the wait seem more bearable. One of the most frequently studied stimuli in this regard is atmospheric music (Baker et al. 2002).

For example, MacNay (1996), North and Hargreaves (1999), Roper and Manela (2000), and Guegen and Jacob (2002) found that respondents reported shorter duration estimates when atmospheric music was present versus absent in a medical exercise facility, an experimental laboratory, a psychiatric care waiting room, and a telephone on-hold setting, respectively. Assuming that music diverts attention away from monitoring time, less temporal information is encoded and elapsed time seems shorter. Yalch and Spangenberg (1990) reported that shoppers under the age of 25 gave shorter estimates of shopping time when they heard Top 40 as opposed to Muzak, whereas the reverse was true for shoppers 25 years of age or older. It is possible that younger shoppers liked and listened to the Top 40 music more, hence diverting attention from the passage of time and reducing perceived duration, whereas the reverse may have been true for older shoppers (Yalch and Spangenberg 1993). Also consistent with attentional models, Lopez and Malhotra (1993) and Cameron et al. (2003) found that respondents’ time estimates were negatively correlated with their reported liking of atmospheric music. Collectively, these results suggest that people exposed to atmospheric music that they like will devote less attention to the passage of time, thus making time seem to pass quickly and the wait seem more bearable (Cameron et al. 2003). This suggests the following two hypotheses:

- H_{1a}: People exposed to music they like during a waiting period will report feeling that time has passed more quickly than usual compared to people exposed to disliked music.
- H_{1b}: The effect of music likeability on affective states will be mediated by the subjective experience of time as passing more slowly or quickly than usual.

Much of the research examining customer satisfaction has adopted a disconfirmation of expectations paradigm, wherein satisfaction judgments are driven by differences between perceptions of the actual service experience and prior expectations of the service (Parasuraman, Zeithaml and Berry 1985). Not surprisingly, previous research on customer waiting has largely relied on measures of perceived duration and/or deviations from expected duration as indicators of the negative effects of waiting on satisfaction (see Houston, Bettencourt and Wenger 1998; Pruyn and Smidts 1998). Many of these studies have found that perceived waiting time is negatively correlated with overall satisfaction in settings as diverse as restaurants (Jones and Peppiatt 1996; Davis and Heineke 1998; Luo et al. 2004), supermarkets (Tom and Lucey 1997), video rental stores (Evangelist et al. 2002), banks (Houston et al. 1998), emergency healthcare (Dansky and Miles 1997), general healthcare (Pruyn and Smidts 1998), and airlines (Taylor 1994). In other words, these studies found that the longer customers think they have waited, the less satisfied they are with their service experience.

Research has also found that various aspects of atmospheric music reduce perceived duration in contexts as diverse as healthcare (MacNay 1996), psychiatric care (Roper and Manela 2000), telephone on-hold (Gueguen and Jacob 2002), university registrations (Oakes 2003), department stores (Yalch and Spangenberg 1990, 1993), supermarkets (Gulas and Schewe 1994), and among students participating in laboratory experiments (Kellaris and Altsech 1992; Kellaris and Kent 1992; Lopez and Malhotra 1992; Kellaris and Mantel 1996; Kellaris, Mantel and Altsech 1996; Hui, Dube and Chebat 1997; North and Hargreaves 1999; Yalch and Spangenberg 2000; Bueno, Firmino and Engelman 2002; Cameron et al. 2003; Mantel and Kellaris 2003).

However, other researchers have reported little or no direct relationship between atmospheric music and perceived duration in contexts such as telephone on-hold (North, Hargreaves and McKendrick 1999), banks (Chebat, Gelinac-Chebat and Filiatrault 1993), gymnasiums (North, Hargreaves and Heath 1998), restaurants (Caldwell and Hibbert 1999), and among students participating in laboratory experiments (Boltz 1998; Brown and Boltz 2002). Moreover, many of the effects reported above are in opposition to the predictions of attentional models (Kellaris and Kent 1992; Hui et al. 1997; Gulas and Schewe 1994; Yalch and Spangenberg 2000), and some involve direct contradictions. For example, Lopez and Malhotra (1992) reported that, compared to disliked music, liked music reduced perceived duration among students participating in a laboratory study, whereas Hui et al. (1997) reported that liked music actually increased perceived duration compared to disliked music. This may reflect the finding that attentional models hold mainly when people focus on the passage of time during the target interval (Block and Zakay 1997), which would be expected of customers waiting for an upcoming event (Zakay 1990; North and Hargreaves 1999), but not necessarily in all retailing contexts (Bailey and Areni 2006).

Moreover, when attentional models do operate, as is the case in waiting contexts, the subjective experience of time passage has a more direct effect on resulting affective states than does perceived duration (Friedman 1990; Flaherty 1999). For example, given certain environmental conditions (e.g., waiting while listening to

disliked atmospheric music), time may feel like it is dragging on even though a customer has a rough idea of how long he has been waiting (e.g., due to periodically checking his watch). In these kinds of situations, subjective experience and not perceived duration would capture the effect of prolonged thinking about the passage of time on resulting affective state. Hence, the following hypothesis is advanced.

- H₂: The perceived duration of the wait period will not mediate the effect of music likeability on reported affective states.

With respect to differences between perceptions and expectations, some researchers have found that waits perceived as exceeding expectations are associated with lower levels of satisfaction in hospitals (Pruyn and Smidts 1998; Boudreaux, Mandry, and Wood 2003), emergency healthcare facilities (Hedges, Trout and Magnusson 2002), airline travellers (Taylor 1994), fast food restaurants (Davis and Heineke 1998), and among students participating in laboratory studies (Kumar, Kalwani and Dada 1997; Hui, Thakor and Gill 1998; Cameron et al. 2003). However, results regarding deviations from expected duration are also equivocal. Other studies have found that negative gaps between perceived and expected wait times did not result in lower levels of satisfaction in hospitals (Boudreaux, Mandry and Wood 2003), banks (Houston et al. 1998), restaurants (Luo et al. 2004), and among students participating in laboratory studies (Hui and Tse 1996). Moreover, research has not examined the effects of atmospheric music on deviations from expected duration because expected duration judgments are, by definition, formed prior to exposure to the wait setting. This limits the effects of any atmospheric variable, and results in deviation judgments being strongly correlated with perceived duration measures. Hence, the following hypothesis is advanced.

- H₃: Deviations from the expected duration of the wait period will not mediate the effect of music likeability on reported affective states.

METHOD

Eighty-six undergraduate students studying business at a major Australian university were recruited for participation in the experiment. Course credit (2%) was offered as an incentive to participate. In addition, respondents who successfully completed the experiment were entered into a draw for 4 prizes of \$500 each. They were told that the study involved knowledge of brand names in various product categories and that they would be required to perform a recall task followed by the completion of a questionnaire. On arrival, they were greeted by a laboratory assistant, asked to sign a consent form, and asked to wait until the study began. When all the respondents for a given session had arrived, the researcher led them in groups of 6–8 into a room set up to appear like a waiting room, with little or no visual stimuli, and no clocks. They were instructed to place all hand bags, backpacks, etc. on a table, to turn off their mobile phones, and to refrain from talking to one another so as not to bias the outcome of the study. The researcher then explained that “the sessions are being run in multiple rooms to save time and things are running a bit behind schedule”, and that he would “return shortly to begin the study when the previous session ends”. The actual time spent in the waiting area was 17.5 minutes. This prevented respondents from guessing correctly simply by rounding up (i.e., 20 minutes) or down (i.e., 15 minutes) to a “standard” time interval. The experimenter began the target period when the last respondent entered the room. He returned to the room after 17 minutes, and distributed the questionnaire containing the

dependent measures. Respondents were instructed to complete the questionnaire 17.5 minutes after the last person entered the room.

Independent Variable: Music Likeability

Several selections of music were selected from two categories, recent number one hits versus uncharted songs from the 1950s. Despite the face validity of the manipulation (i.e., university students would presumably prefer recent number one songs to music created long before they were born), a manipulation check measure prompted respondents with the open-ended statement: "To what extent did you find the music..." and asked them to circle the number corresponding to their perception of the music on five 7-point scales anchored by "unpleasant (1)–(7) pleasant", "unappealing (1)–(7) appealing", "unlikable (1)–(7) likable", "boring (1)–(7) interesting", and "unexciting (1)–(7) exciting". The results of an exploratory factor analysis indicated a single factor solution with an eigenvalue of 3.1 and with all factor loadings exceeding 0.7. Using a mean weighted by factor scores as the dependent variable, a one-way ANOVA revealed a significant effect of music likeability ($F_{1,73}=27.1$, $p<.0001$, $w^2=.27$), wherein the recent number one songs were rated as more likable ($M=4.7$) than the 1950s songs ($M=3.3$).

Mediating Variables

Perceived Duration: Similar to the approaches used by Hui and Tse (1996) and Mantel and Kellaris (2003), the first item on the questionnaire asked respondents: "Without looking at your watch, please estimate how long you have been in this room. _____ minutes _____ seconds." This open-ended approach is common in time perception research because it tends to eliminate any rounding off to the nearest minute (Block (1990).

Subjective Experience of Time Passage: The next two items in the questionnaire measured respondents' subjective experience of time passage using 7-point semantic differential response scales. Both items were based on work by Friedman (1990) and Flaherty (1999). Respondents were prompted with: "During the period I've been in this room:" using a response scale anchored by "time has flown by" (1)–(7) "time has dragged on", and "Since I've entered this room: "time has passed quickly" (1)–(7) "time has passed slowly". The subjective experience measure was the mean of the two items.

Deviation from Expected Duration: The next item measured deviations from prior expectations of duration. Adapted from earlier research by Houston, Bettencourt and Wenger (1998) and Boudreaux, Mandry and Wood (2003), the item prompted respondents with the statement: "The amount of time I've been in this room has been" and used a response scale anchored by "shorter than expected" (1)–(7) "longer than expected". Respondents were instructed to circle the number that best corresponded to their perception of the wait period.

Dependent Variable: Affective state

The affective state measure involved the five items used to measure the pleasure-displeasure dimension of Mehrabian and Russell's (1974) PAD model of affect. This measure has been used in several studies examining retail atmospherics (Donovan and Rossiter 1982; Hui and Tse 1996), and more specifically, the impact of music likeability on time perception and affective states (Cameron et al. 2003). Respondents were prompted with the statements "This question is about how you feel now. For each scale, circle the number that corresponds with your current mood." Five 7-point scales followed, with the anchors: "depressed (1)–(7) contented", "unhappy (1)–(7) happy", "unsatisfied (1)–(7) satisfied", "annoyed (1)–(7) pleased", and "bored (1)–(7) relaxed".

Given the importance of distinguishing among perceived duration, deviation from expected duration, and the subjective experience of passing time, an exploratory factor analysis of the items comprising the mediating and dependent variables was conducted. As shown in Table 1, the results indicated a four factor solution. The five pleasure-displeasure items loaded on the first factor, which produced an eigenvalue of 3.62. Factor loadings ranged from .79 to .87, and communalities ranged from .65 to .79. The two subjective experience items loaded on the second factor, which produced an eigenvalue of 1.82. The factor loadings were .83 and .93 and the communalities were .87 and .91, for the first and second item, respectively. The third factor, which produced an eigenvalue of 1.05, directly corresponded to the deviation from expected duration measure, which had a loading and communality of .97 and .99, respectively; and the final factor, with an eigenvalue of 1.04, corresponded to the perceived duration measure, which produced a loading of .99 and a communality of .98. These results suggest that perceived duration, deviation from expected duration, and the subjective experience of a time interval are distinct constructs with the potential to differentially mediate the effect of music likeability on affective state. Hence, the measures for subjective experience and affective state were the mean scores of the corresponding items, weighted by factor loadings, and the measures for perceived duration and deviation from expected duration were simply the responses to the corresponding single items.

RESULTS

Hypotheses 1–3 were tested via four 1-way ANOVAs with music likeability as the independent variable and affective state, subjective experience, perceived duration and expected duration as the dependent variables; and 3 ANCOVAs with likeability as the independent variable, affective state as the dependent variable and subjective experience, perceived duration, and expected duration as the three covariates. All hypotheses essentially required that respondents exposed to the liked atmospheric music would report more favourable affective states than respondents exposed to disliked music. The results of the first ANOVA supported this expectation. The effect of music likeability on reported affective states was significant ($F_{1,81}=7.2$, $p<.01$, $w^2=.07$), with respondents reporting more positive affective states in the liked condition ($M=4.3$) compared to the disliked condition ($M=3.7$).

Hypothesis 1a predicted that respondents hearing liked music would report that the waiting interval passed more quickly than usual compared to respondents hearing disliked music, and hypothesis 1b predicted that the effect of music likeability on affective state would be mediated by the subjective pace of time passage. A second ANOVA with likeability as the independent variable and subjective experience as the dependent variable revealed a significant result ($F_{1,83}=11.9$, $p<.001$, $w^2=.11$), with respondents in the disliked condition reporting that time passed more slowly ($M=5.0$) than did respondents in the liked condition ($M=3.9$), hence supporting hypothesis 1a. As shown in Table 2, when subjective experience was included as a covariate in an ANCOVA with music likeability as the independent variable and affective state as the dependent variable, it was a significant predictor ($F_{1,80}=19.6$, $p<.0001$), and the effect of music likeability on affective state was all but eliminated ($F_{1,80}=1.4$, $p<.25$). Hence, the effect of music on affective state was mediated by the subjective experience of time passing more slowly or quickly than usual; hypothesis 1b was supported.

Hypothesis 2 predicted that perceived duration would not mediate the effect of music likeability on reported affective states. A third ANOVA revealed that music likeability had little or no effect on perceived duration ($F_{1,84}<1$). Moreover, when perceived duration was included as a covariate in an ANCOVA with music

Mediation Results for Subjective Experience, Perceived Duration, and Deviation from Expected Duration

Model	F stat	p value	Effect	Result
Pleasure = Liking	$F_{1,81} = 7.2$	$p < .01$	$\omega^2 = .07$	H ₁ supported
Pleasure = Subjective Experience Liking	$F_{1,80} = 19.6$ $F_{1,80} = 1.4$	$p < .0001$ $p < .25$	$\omega^2 < .01$	H ₂ supported
Pleasure = Perceived Duration Liking	$F_{1,80} = 1.9$ $F_{1,80} = 7.7$	$p < .19$ $p < .01$	$\omega^2 = .07$	H ₃ supported
Pleasure = Deviation from Expectations Liking	$F_{1,80} = 3.6$ $F_{1,80} = 5.1$	$p < .10$ $p < .03$	$\omega^2 = .04$	H ₄ supported

likeability as the independent variable, it was not predictive of affective state ($F_{1,80}=1.9, p<.18$). Hence, although failing to reject the null hypothesis cannot be construed as supporting a prediction, these results are at least consistent with hypothesis 2. Hypothesis 3 predicted that deviation from expected duration would not mediate the effect of music likeability on reported affective states. A fourth ANOVA revealed that music likeability had a significant effect on expected duration ($F_{1,83}=4.8, p<.04, w^2=.04$). Respondents reported that the wait period was longer than expected when they heard disliked ($M=5.6$) compared to liked ($M=4.8$) music. Moreover, when expected duration was included as a covariate in an ANCOVA it was marginally significant as a predictor of affective state ($F_{1,80}=3.6, p<.06$); however, the effect of music likeability remained significant ($F_{1,80}=5.1, p<.03, w^2=.04$). Hence, these results are consistent with hypothesis 3.

DISCUSSION

The research reported above assumed that the ultimate impact of atmospheric music is on affective state, with the subjective experience of time passage as the mediating variable. However, previous research has examined the mediating role of affective state in accounting for the effect of music on time perception (Wansink 1992; Hui, Dube and Chebat 1997). In order to examine whether

this alternative view applies to the results reported above, affective state was examined as a possible mediator of the effect of atmospheric music on deviation from expected duration and the subjective experience of time passage (it has already been established that music had little or no effect on perceived duration). Two ANCOVAs were conducted with atmospheric music as the independent variable, affective state as the covariate, and deviation from expected duration and the subjective experience of time passage as the two dependent variables.

For the ANCOVA with the deviation measure as the dependent variable, the effect of affective state as a covariate was marginally significant ($F_{1,80}=3.6, p<.06$), and the effect of music was no longer significant ($F_{1,80}=2.0, p<.17$). Moreover, the size of the effect of music declined noticeably when affective state was included as a covariate (from $w^2=.04$ to $w^2=.01$). Hence, consistent with Wansink (1992) and Hui et al. (1997), affective state does mediate the effect of atmospheric music on expected duration. In the ANCOVA with subjective experience as the dependent variable, the effect of affective state as a covariate was highly significant ($F_{1,80}=19.6, p<.0001$). However, the effect of music on subjective experience remained significant ($F_{1,80}=6.0, p<.02$), though the effect size was reduced (from $w^2=.11$ to $w^2=.04$). On the basis of these results one could conclude that the effect of atmo-

spheric music on the subjective experience of time passage is partially mediated by affective state. However, given the conceptual foundation underlying hypotheses 1 and 2, and the result that subjective experience completely accounted for the effect of music on affective state, the more parsimonious conclusion is that former mediates the effect of music on the latter. Hence, attentional models appear to be more useful than other conceptual models for explaining the effects of atmospheric music on affective states in waiting contexts.

A number of other factors have been shown to reduce perceived waiting time in addition to atmospheric music, including giving estimates of the duration of a delay (Hui and Tse 1996; Roper and Manela 2000), involving customers in the provision of the service (Chebat and Filiatrault 1993), giving people tasks to complete during a wait (Dansky and Miles 1997), providing entertainment (Jones and Pepiatt 1996), asking about customers' well-being (Roper and Manela 2000), and avoiding interruptions (Chebat and Filiatrault 1993). The assumption underlying much of this research is that reducing perceived duration will make the wait more bearable and result in higher levels of satisfaction (Jones and Pepiatt 1996; Dansky and Miles 1997).

However, the results reported above question whether this assumption holds. For example, giving repeated updates on the estimated duration of a delay may reduce perceived duration by giving customers a basis for making more accurate estimates, but this may have little or no influence on how much attention is devoted to monitoring the passing time or whether time seems to drag on during the wait. By contrast, engaging customers in conversation will almost certainly divert attention away from monitoring time; this would result in time seeming to pass more quickly than usual, and hence, a more favourable affective state. In short, perceived duration is related to affective state and/or customer satisfaction mainly when attentional models operate.

The research reported above has a number of limitations which should be disclosed and further discussed. Given the goals of this research, the most directly relevant shortcoming is the measure of the subjective experience of passing time. Although perceived duration and expected duration are often measured using single items, the subjective experience of passing time is, on the face of it, a more complex construct, potentially having multiple dimensions. The two items reported here reflect the conceptualization of Friedman (1990) and Flaherty (1999), but a more comprehensive approach would involve the development of numerous potential items, the elimination of items that are not highly correlated with the majority of the items, assessing the dimensionality and reliability of the remaining items, and an examination of the resulting scale on a new sample (Churchill 1979). Future research should proceed along these lines, as better measures of cognitive processes will be needed if research examining the effects of waiting on affective state is to progress further.

The artificial laboratory setting is another potential limitation of this research. Much of the literature in this area involves actual customers waiting in actual retail settings. Although field studies do not necessarily provide higher levels of external validity, they are useful for establishing the relevance of the theory to an actual consumer behavior setting. Finally, the dependent variable in this research was general affective state rather than satisfaction with the waiting experience, as is often used in this area of research. It could be the case that listening to music influenced respondents' affective states directly, quite apart from any influence on the perceived passage of time. Future research should use a more direct measure of whether respondents were satisfied with the wait experience to better test the proposed mediating processes.

Post-Purchase Consumer Regret: Conceptualization and Development of the PPCR Scale

Seung Hwan Lee, University of Western Ontario, Canada

June Cotte, University of Western Ontario, Canada

ABSTRACT

We conceptualize and operationalize a new definition of post-purchase consumer regret. Consumers can regret both the *outcome* and the *process* of their purchase. While previous researchers have identified the existence of these two components, there has been a lack of exploration of how outcome regret and process regret are experienced in a consumer context. In terms of outcome regret, we posit two dimensions: regret due to foregone alternatives and regret due to a change in significance; we believe these influence consumers. In terms of process regret, we expect regret due to both under- and over-consideration during decision-making. We propose and conceptualize these multiple dimensions of post-purchase consumer regret, and report three studies that, taken together, validate a scale for measuring this construct (PPCR). We conclude by identifying possible new research opportunities in this area, outlining why more consumer behavior research can, and should, be devoted to the topic of consumer regret.

INTRODUCTION

When consumers experience regret after a certain purchase, are they regretting what they bought (the outcome), how they bought it (the process), or both? The purpose of our paper is to propose and validate a multidimensional framework for each of these two components of regret. While previous researchers have identified the existence of these two components (e.g. Zeelenberg and Pieters 2006), there has been a lack of exploration of the components of outcome regret and process regret, and how each of these components are experienced in a consumption context. Therefore, we propose a new theoretical definition of post-purchase consumer regret. First, we describe regret in greater detail and also differentiate it from a potentially related construct (disappointment). Second, we conceptually redefine the current definitions of outcome regret and process regret. Third, we present the results of three studies that create a PPCR scale. Fourth, we conclude by identifying implications and questions to stimulate additional research.

CONSUMER REGRET

Regret is an aversive cognitive emotion that people are motivated to avoid, suppress, deny, and regulate should they experience it (Zeelenberg and Pieters 2006). Traditionally, regret has been known to be a painful sensation that arises as a result of comparing 'what is' with 'what might have been' (Sugden 1985). In other words, regret transpires when an obtained outcome compares unfavourably with an outcome that could have been better had the individual chosen differently (Bell 1982; Tsiros and Mittal 2000). This is known as outcome regret (Zeelenberg and Pieters 2006). That is, post-purchase *outcome* regret is a comparison of individual's assessment of the outcomes between what has been bought and what could have been bought.

But recently, scholars have also hypothesized that, independent of outcomes, the quality of the decision *process* can also be regretted (Connolly and Zeelenberg 2002; Zeelenberg and Pieters 2006). Process regret is evoked when an individual compares their inferior decision process to a better alternative decision process. When individuals regret due to process, instead of comparing the outcomes, they compare the decision processes (e.g., I should have checked more stores before buying). These two components of regret can occur independently of one another, which suggest that

it is possible for someone to regret the process, even if the purchase experience resulted in a good outcome. Using Decision Justification Theory (DJT), Connolly and Zeelenberg (2002) argue that individuals regret due to the evaluation of outcomes, and also because of a decision made in an unjustifiable way. DJT postulates that the total amount of regret experienced is a sum of regret experienced as a result of an outcome that is inferior to another outcome that has been rejected, plus the feeling of self-blame for the poor decision process. Below, we go into more depth by closely examining what regret is, and what regret clearly is not.

What is Regret?

Responsibility. Regret arises from individuals expending cognitive efforts to consider the chosen option against the rejected options (Inman, Dyer, and Jia 1997). Individuals must think in order to feel regret. For individuals to experience regret, they have to cognitively process and cross-compare one option (chosen) to another option (foregone). If the result of the comparison is perceived to be unfavorable (i.e. the foregone option is perceived to be better than the present option), then individuals are prone to feeling regret over their actions.

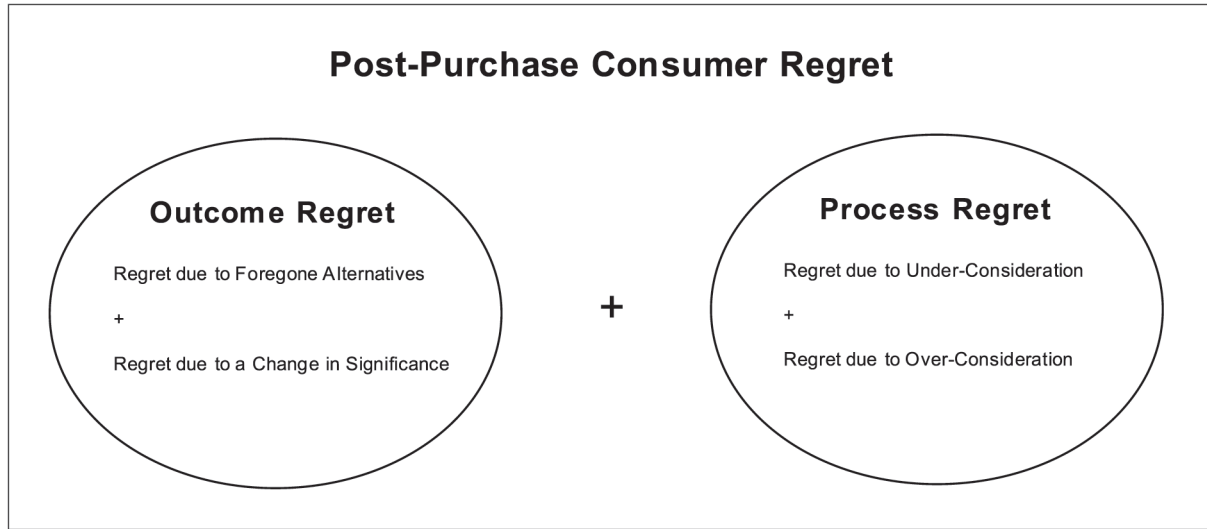

Self-blame is a major component of regret. When individuals perceive that their decision was unreasonable or inexplicable, they tend to feel responsible for making the poor decision (van Dijk, van der Pligt, and Zeelenberg 1999). Sugden (1985) contends that the intensity of regret is often influenced by the level of individual responsibility taken, as well as self-blame. One consistent finding is that regret tends to be greater when individuals had more control over their decisions than when individuals have had little control over their decisions (Gilovich and Medvec 1994).

Counterfactual Thinking. In addition to feeling responsible, in order to experience regret, individuals must also be able to construct alternative scenarios other than the current state (Zeelenberg and Pieters 2006). Counterfactual thinking (CFT) is the process of comparing reality with alternative possibilities by constructing hypothetical scenarios to assess the attractiveness of alternative possibilities (Kahneman and Miller 1986). In essence, CFT is not an evaluation of the outcome, but rather the thought-process of how an outcome could have been prevented or altered to yield a more positive or a negative outcome.

There are two forms, or directions, of counterfactual thinking: upward CFT and downward CFT (Kahneman and Miller 1986). When individuals think about how circumstances could have been worse, it is referred to as downward CFT. Conversely, upward CFT is when individuals think about how circumstances could have been better. Because people engage in greater CFT after a negative outcome than after a positive outcome (Kahneman and Miller 1986), it is likely that people engage in upward CFT more often than downward CFT. And subsequently, when individuals generate upward CFT, it is likely that they will experience regret (Kahneman and Miller 1986).

In the context of consumer behavior, individuals tend to engage in upward CFT after a negative purchase outcome, and CFT helps them analyze what went wrong, to assess why they potentially made a poor choice, and to discover what better opportunities they may have missed. When a negative outcome occurs, people use CFT which can subsequently intensify the feeling of regret (Kahneman and Miller 1986). Indeed, the greater the CFT that

FIGURE 1
CONCEPTUAL MODEL

occurs, the greater the potential for regret to be experienced by the individual (Landman 1993). Therefore, CFT is not only a necessary condition of regret, but also has the potential to influence the magnitude of regret experienced by the individual.

What Regret is Not

Disappointment. Disappointment is an unpleasant feeling induced by the discrepancy between the desired expected outcome versus the actual outcome (Bell 1985). Regret is sometimes used inappropriately as a synonym for other negative emotions, including disappointment. This is because, like regret, disappointment is also a function of post-purchase valuation (Inman et al. 1997). Both are negative-based emotions that are induced by outcomes and risky decision-making. While the two may appear similar, they can be clearly distinguished from one another in three main ways: phenomenology, appraisal patterns and attributions, as well as the varying behavioral consequences of regret and disappointment.

First, building on the idea that specific emotions have distinctive goals, action tendencies, thoughts, and feelings associated with each emotion, Zeelenberg et al. (1998b) compared the phenomenological differences between regret and disappointment (for a review, see Zeelenberg et al. 1998b). Overall, those who experienced regret tended to rethink about past events, while those who experienced disappointment tended to dismiss their negative experience.

Second, in terms of appraisal and attribution, disappointment is appraised as something that caused by events beyond the individual's control, while regret is appraised as something that caused by oneself (van Dijk and Zeelenberg 2002). Zeelenberg and Pieters (2004) posited that one of the major differences between regret and disappointment lies in control. Regret typically arises as a result of having made the wrong decision and is associated with self-blame. On the other hand, disappointment arises as a result of unfulfilled expectations and is associated with blaming others or circumstances beyond individual's control (Zeelenberg et al. 1998a).

Finally, research in emotion theory has shown that discrete emotions have different idiosyncratic behaviors, and behavioral tendencies, associated with them. For example, Zeelenberg and Pieters (1999) conducted multiple studies to assess the differences in consequences between regret and disappointment after a failed service encounter. They found that regret was more associated with

switching behavior than disappointment, while disappointment was more associated with word-of-mouth than regret.

POST-PURCHASE CONSUMER REGRET

As we have argued, Decision Justification Theory suggests individuals can regret due to a) evaluation of the outcomes and b) evaluation of the process (Connolly and Zeelenberg 2002). We believe these two dimensions are themselves multidimensional, and that the total regret experienced by a consumer is a sum of four components. Within outcome regret, we propose that there are two components: regret due to foregone alternatives and regret due to a change in significance. Within process regret, we also propose two components: regret due to under-consideration and regret due to over-consideration (Fig. 1).

OUTCOME REGRET

Regret due to Foregone Alternatives. When individuals regret due to foregone alternatives, they regret that they have chosen an alternative in favour of another alternative. This is perhaps the most classic understanding of post-purchase regret. When the chosen alternative is believed to be inferior to the foregone alternatives that could have been purchased, people are open to experiencing "regret due to foregone alternatives". A key note concerning this dimension is that individuals can compare their chosen alternative to the *known* foregone alternative and/or *unknown* foregone alternative.

People evaluate outcomes by comparing what they have received to what they could have received (Sugden 1985). They feel regret if the foregone outcome is, or is perceived to be, better than the current outcome. Regret is related to choice and the very nature of choice implies that there were other possibilities that could have been chosen over the selected alternative (Zeelenberg and Pieters 2006). These possibilities can be explicitly known to the buyer or unknown to the buyer in which case the person would have to hypothetically construct these possibilities. Traditionally, researchers assumed that outcomes of the rejected alternative must be known to the buyer in order for regret to occur (Bell 1982). Known foregone alternatives are choices that were available to the buyer at the time of the purchase. (e.g., buying A, when one knew about options B and C).

However, studies have suggested that individuals can experience regret even in the absence of known foregone alternatives.

Ritov and Baron (1995) posit that foregone alternatives can be imagined or hypothetically imagined. Regret is not restricted to circumstances in which the outcomes of the rejected alternatives are always known to the buyer (Tsiros and Mittal 2000).

Tsiros and Mittal (2000) developed a model of post-purchase regret by outlining the antecedents and consequences of consumer regret. They demonstrated that regret can still be experienced even when the rejected alternatives are not known to the consumer. These authors argued that when the rejected alternatives are unknown to the buyer, the individual will trigger their upward CFT to construct hypothetical scenarios. Individuals have the tendency to think of outcome scenarios that are often better than the current scenario (Kahneman and Miller 1986). If a person deploys CFT to imagine a better product than the one that they have already chosen, then this person is likely to regret having chosen the current alternative. Therefore, unknown foregone alternatives are choices that were not available to the buyer at the time of the purchase but were hypothetically imagined following the purchase. In this case, individuals wonder whether or not there could have been better options than the one they purchased. (e.g., buying the only option noticed at the time, later wondering whether other options existed). In short, regret due to foregone alternatives is triggered by choice. This phenomenon exists because individuals may make wrong choices and experience regret afterwards, even if the decision at the time seemed to be the right one.

Regret due to a Change in Significance. Researchers have used means-end theory to explain the goal-directed nature of a particular purchase (Zeithaml 1988). In the context of consumer behaviour, the theory suggests consumers tend to judge products based on the ability of the product to fulfill a desired consequence. The level in which the product has fulfilled its desired consequence will act as a cue to determine if the product was a worthwhile purchase.

Regret due to a change in significance is caused by the individual's perception of diminished product utility from the time of the purchase to a certain point in time after the purchase. When an individual buys a product, there is a certain expected use for it. However, if something happens to make the product less appropriate for that use, or the entire usage situation disappears, then the individual is open to feeling regret due to change in significance. If a product was bought for a specific purpose, but the product was unable to fulfill that purpose, then the individual's perception of the product's utility value has changed from time 1 (the time of purchase) to time 2 (time after purchase). That is, in T1, the product carried a purpose, but in T2, the product's purpose has been diminished. Basically, the focus here is whether or not the product has fulfilled the needs of the consumers, when the need has changed.

One of the main distinctions between regret due to change in significance and regret due to foregone alternatives is that the former does not require the comparing of chosen versus the rejected alternatives. In this dimension, the chosen alternative is being compared to itself, but at a different time dimension (T1 vs. T2). Essentially, the product is being compared to what it was at the time of the purchase (T1) to a time when the buyer's perceived utility value of the product has diminished (T2). (e.g., buying a bottle of wine to take to a party that was cancelled).

This dimension has been never explored in previous regret-related literatures. While some may argue that this is a case of disappointment, the distinction needs to be made between the events that have occurred and the purchase that has been made. The buyer may have been disappointed at the series of events that have occurred, but regrets the actual purchase that was made. This dimension highlights that foregone purchase alternatives are not

required for individuals to feel regret after a purchase. Regret due to change in significance is the diminishing change in the individual's perception of product utility value from T1 (the time it was purchased) to T2 (a point in time after the purchase). The greater the utility difference, the greater the regret.

PROCESS REGRET

The two dimensions mentioned above strictly focus on the *outcomes* of a purchase. However, researchers have pointed out that, independent of outcomes, the quality of the decision *process* itself can also engender regret (Connolly and Zeelenberg 2002; Zeelenberg and Pieters 2006). Therefore, it is important to discuss the results of the outcomes separately from the quality of the decision process, and delineate how each of the components separately influences post-purchase consumer regret.

Regret Due to Under-Consideration. When individuals feel regret due to under-consideration, regardless of the purchase outcome, they are sceptical of the heuristic processing that led them to the purchase. Individuals assess the quality of their decision process by examining both implementation/execution and the amount of information they gathered (Janis and Mann 1977). Thus, there are two ways in which individuals can regret due to under-consideration. First, individuals can regret if they feel that they have failed to implement the decision process as they intended it, an intention-behavior inconsistency (Pieters and Zeelenberg 2005). Second, individuals can feel regret if they believe, in hindsight, that they lacked the desired quality and/or quantity of information needed to make a good decision.

People are inherently motivated to do what they set out to do. However, even when behavioral intentions are formed and goals are clearly determined, not all plans go according to plan. Intention-behavior inconsistency is the failure to implement one's behavioral intention in the decision process (Pieters and Zeelenberg 2005). Regret occurs when individuals compare their factual decision process (inconsistent with their behavioral intention) to the counterfactual decision process (consistent with their behavioral intention). When individuals realize that the action that they have taken is not what they intended, they deploy upward CFT to imagine what it would have been like had they executed their desired behavioral intentions. Hence, regret is induced when there is a perceived discrepancy between the intended course of action (how they planned to make a decision) and the actual course of action taken (how they actually made their decision).

Intention-behavior inconsistency can be due to internally or externally attributed causes. When cause is externally attributed, individuals are likely to be disappointed rather than regretful. When cause is internally attributed, individuals believe they put insufficient effort into the decision, or they deviated from their original intentions through irrational decisions. (e.g., buying the first car that one test drove). Individuals can also feel regret due to under-consideration if they believe, in hindsight, that they lacked the desired quality and/or quantity of information needed in their decision-making process. This differs from behavioral intention inconsistency because even if the decision-making process does go as intended, individuals can still feel regret if, in the post-purchase stage, they feel that they have not done enough to make the best decision. Decisions that were well-justified can sometimes appear to be unjustified at a later point in time (Crawford et al. 2002). This means there are likely situations where individuals feel that they could have done more to change the results, even though at the time of the purchase it seemed to be justified.

A critical distinction needs to be made between regret due to unknown foregone alternatives versus regret due to under-consideration. While the two may appear similar in nature, they are

indeed distinct from one another. Thinking about an unknown foregone alternative requires the individual to construct hypothetical products to be compared against the chosen product. Thinking about how one under-considered his/her purchase requires rethinking the buying process. While re-thinking the buying process may lead to the construction of hypothetical products, the two are different from one another because one focuses on comparing the chosen product to a hypothetical product (regret due to foregone alternatives) while the other focuses on comparing the actual decision process to an decision heuristic process (regret due to under-consideration).

In short, regret due to under-consideration is regretting the process of how one arrives at a decision. The consumer can feel regret because what they intended to do was not executed properly and/or the consumer can regret because they feel they should have done more (e.g. more thought, acquire more information, expend more effort, etc.) during decision-making.

Regret Due to Over-Consideration. When individuals regret due to over-consideration, regardless of the outcome, they are regretting that they have put too much time and effort into the buying process. Similar to regret due to under-consideration, this dimension also centers on heuristic processing. However, the critical distinction between the two is that regret due to under-consideration focuses on how one could have done more to *alter* the decision for a better outcome, whereas, regret due to over-consideration focuses on how one could have done less and still achieve the *same* result. Individuals often base their judgment of the quality of their decision process on the amount of information gathered (Janis and Mann 1977). When individuals over-consider their decision process, they are regretting that they have gathered unnecessary information which may or may not have factored into the final result.

In general, more thinking leads to better decisions (Pieters and Verplanken 1995; Pieters and Zeelenberg 2005). Thinking helps individuals search, and weigh the pros and cons of options, which has been known to increase the intention-behavior consistency (Pieters and Verplanken 1995). Thinking also helps individuals achieve a fuller range of objectives, gather more information, and make better arguments in their decision-making process (Pieters and Zeelenberg 2005). Individuals are generally motivated to put extra effort in order to avoid or minimize post-decision regret (Janis and Mann 1977). Therefore, because people behave in a way to reduce future regret, it is common for individuals to avoid or delay their final decision by putting more effort into gathering more information.

However, there comes a threshold where acquiring more information, and expending more effort, does not change or influence the final decision. This means any information that is acquired thereafter can be considered unnecessary and wasteful. Any effort perceived by the consumer as unnecessary effort potentially could be regretted, because the same decision could have been reached with less information and effort. Furthermore, excess information and effort are not the only things that can be regretted when individuals over-consider. Individuals can regret the emotional burden, the cognitive overload, and the stress that was experienced during the decision-making process. (e.g., spending a lot of time looking at alternatives, when the first option was the best choice).

In summary, similar to regret due to under-consideration, regret due to over-consideration is also regretting the process of how one arrives at a decision. Individuals regret having expended too much effort on the decision process, when they could have arrived at the same decision in a shorter amount of time, with less information, or with less effort.

POST-PURCHASE CONSUMER REGRET (PPCR) SCALE DEVELOPMENT

We developed a scale which measures the four components of post-purchase consumer regret as we conceptually defined it above. Previous measures have not sufficed in measuring the multidimensional components of regret, or carried the necessary rigor and the proper validation technique required for developing scales, as proposed by Churchill (1979). Arguably, the closest existing scale that measures experienced regret is the regret experience measure (REM) developed by Creyer and Ross (1999). The REM scale is an 8-item scale that measures level of regret experienced and self-recrimination. However, this measure of regret is uni-dimensional, and it focuses on measuring the level of regret experienced had one chosen differently, and the self-recrimination for selecting the wrong alternative. Other regret scales available were deemed psychometrically insufficient, or were not directly relevant to the consumer behavior context. In this section, we briefly present our scale development process and then discuss the results of our empirical work.

Study 1—Item Generation

A preliminary study involved a focus group of consumers to gain insights in their recent purchasing experience where they regretted a certain purchase. A content analysis of the discussion along with a literature review, brainstorming, and consulting with academics helped generate a total pool of 223 items designed to measure the four facets of post-purchase consumer regret. Following this step, ambiguous items were eliminated as well as those items which were worded with formal academic language, resulting in a revised pool of 174 items.

Study 2—Face Validity

Face validity of the items was assessed in two stages (Bearden, Netemeyer, and Teel 1989). In the first analysis, a marketing faculty was exposed to short descriptions of each of the dimensions and was asked whether or not the item should be retained or removed from the list. Items that received “not applicable” were subsequently removed from the list, leaving us with 153 remaining items. Next, these remaining items were submitted to 10 additional judges (a panel consisting of marketing academics across North America). This panel of judges was also given definitions of each dimension, and were asked to rate each item as “clearly representative”, “somewhat representative”, or “not representative”. For each of the dimensions, items that were deemed to be clearly representative by at least six of the judges were retained. We retained 45 items and the resulting items were arranged in an arbitrary order and interspersed in all subsequent questionnaires to avoid explicit categorization of the dimensions. Each item was formatted into a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree).

Study 3—Item Refinement

Separate item analysis was performed for the remaining 45 items using the responses obtained from a convenience sample of 174 undergraduate students from several northeastern universities. The students were recruited via an opportunity to win a raffle for a movie gift certificate. The purpose of purification study was to verify the existence of the dimensions and to further reduce the number of items to a manageable number.

The correlation of each item with the total score for each of the four susceptibility dimensions was computed. Items that did not have item-to-total subscale correlations above .50 were deleted. In addition, items that did not have statistically higher correlations with the dimension to which they were hypothesized to belong, in

TABLE 1
FINAL POST-PURCHASE CONSUMER REGRET SCALE

<i>PPCR Scale</i>	EFA	CFA
Regret due to Foregone Alternatives (Composite Reliability=0.929, AVE=0.765)		
1. I should have chosen something else than the one I bought.	.782	.862
2. I regret the product choice that I made.	.793	.911
3. I now realize how much better my other choices were.	.714	.824
4. If I were to go back in time, I would choose something different to buy.	.775	.900
Regret due to a Change in Significance (Composite Reliability=0.885, AVE=0.659)		
1. I regret getting the product because it was not as important to me as I thought it would be.	.817	.842
2. I wish I hadn't bought the product because it is now useless to me.	.758	.894
3. I regret my purchase because the product never served its purpose.	.707	.786
4. I regret my purchase because I did not need the product.	.804	.714
Regret due to Under-Consideration (Composite Reliability=0.925, AVE=0.754)		
1. With more information, I feel that I could have made a better decision.	.758	.862
2. I feel that I did not put enough consideration into buying the product.	.754	.871
3. With more effort, I feel that I could have made a better decision.	.745	.879
4. I regret not putting enough thought into my decision.	.708	.861
Regret due to Over-Consideration (Composite Reliability=0.928, AVE=0.764)		
1. I expended too much effort in making my decision.	.856	.815
2. I wasted too much time in making my decision.	.869	.820
3. I think I put too much thought in the buying process.	.894	.933
4. I feel that too much time was invested in getting this product.	.903	.921

comparison with item correlations with the remaining dimension total scores, were also deleted (Ruekert and Churchill 1984). Principal components analysis with varimax rotation was also performed, resulting in a five factor solution. Based on the resulting relative eigenvalues, we retained the first four factors, consisting of items with loadings exceeding .70. These analyses resulted in a reduction of 9 items, leaving 36 items for reliability and confirmatory factor analysis.

The remaining items were examined via confirmatory factor analysis using AMOS version 7.0. First, a confirmatory factor analysis (i.e. a four-factor correlated structure) revealed items with low item reliabilities. In addition, we removed items that potentially cross-loaded onto other dimensions, and we further reduced the

items for parsimony. After this refinement, a second confirmatory factor analysis was performed on the remaining 16 items (four items per factor). The four-factor correlated structure fits the data relatively well ($CMIN/DF=1.965$, $NNFI=.922$, $CFI=.96$, $RMSEA=.075$), thereby indicating unidimensionality (Steenkamp and van Trijp 1991). Composite reliability, average variance extracted, and individual item loadings of the 16 retained items (four items per dimension) are listed in Table 1.

DISCUSSION

We have used the foundation provided by Decision Justification Theory to introduce a new theoretical definition of post-purchase consumer regret. Consumers can regret both the outcome and the

process of their purchase (Zeelenberg and Pieters 2006). We proposed that subsumed within *outcome* regret, individuals can feel regret due to foregone alternatives and/or feel regret due to a change in significance. Subsumed within *process* regret, individuals can feel regret due to under-consideration and/or feel regret due to over-consideration.

With the PPCR scale we have established a concise measure that makes it easy to capture one's level of post-purchase consumer regret. The three studies operationalized PPCR and validated the scale items. Our results are consistent with our conceptual definition, demonstrating a multidimensional factor structure, as well as adequate reliability.

It is important to note that individuals can experience all dimensions of post-purchase consumer regret, or might just experience one (or none) of the dimensions at a certain given time. Furthermore, individuals can experience a particular dimension of regret at a certain point in time and another dimension of regret at a different point in time after purchase. Individuals can also feel different magnitudes of regret arising from each of the dimensions. Therefore, in order to better understand post-purchase consumer regret, it is important to consider each of the dimensions and the magnitude of regret experienced. It is the sum of regret experienced, through each of the four dimensions, that determines how much the individual regrets a purchase.

Future research in this area should focus on continued empirical work with the four dimensions of the PPCR and studying how each of the dimensions functions within a larger nomological network of antecedents and consequences. Additional studies would test convergent and discriminant validity of the dimensions, and also provide evidence of strong nomological and predictive validity. In particular, we encourage researchers to look at post-consumption behaviors such as repeat purchase intentions, change in attitudes toward brands, and complaint behavior. We believe that different dimensions of regret will have unique influences on these post-consumption behavior variables. Also, future research in this area should try to address the following questions. In what circumstances do individuals regret one dimension more than another dimension? Why do individuals feel regret in some ways and not in others? How does time play a role in the magnitude of regret experienced by the individual?

Understanding why consumers regret after a purchase is critical to marketers, as they are constantly looking for ways to minimize the negative experiences experienced by their customers. By having a greater awareness of the different forms of post-purchase regret, businesses can focus on helping individuals attain a better consumption experience. For instance, if marketers know that their customers are experiencing regret primarily due to foregone alternatives, then they can direct their attention to improving their own product and making it more appealing to the customer over other alternatives (e.g. better features, cheaper prices). If they know that their customers are experiencing regret due to a change in significance, then they can direct their attention to devising ways to add more significance to the product (e.g. market multiple uses of the product, add more value to the product, more liberal return policies). If marketers know that their customers are experiencing regret due to process (under-consideration and over-consideration), then they can direct their attention to assisting customers in their decision-making process through helpful customer service, and providing easy accessibility to information to guide them along the way. In sum, if marketers have a better understanding of what is causing consumer to regret over their purchase, then they can place greater emphasis in reducing that particular dimension of regret.

Influencing Willingness to Pay by Supraliminally Priming the Concept of Honesty

Robert Schorn, University of Innsbruck, Austria
Barbara Maurhart, University of Innsbruck, Austria¹

ABSTRACT

Previous research has shown that priming can be used to influence peoples' perception, evaluations, motivations, and even behavior. Most of these studies have been conducted using laboratory experiments. We examined whether supraliminal priming can be effectively applied to affect peoples' behavior in a real consumption situation. In an experiment to test if supraliminally priming the concept of honesty via "mirrored words" influences peoples' behavior, we found that users of a toilet contributed significantly more money for using the bathroom when being primed with the concept of honesty than when that concept had not been primed. Implications and ethical considerations are discussed.

INTRODUCTION

When James Vicary, in 1957, claimed to have increased Coke sales by 18% and popcorn sales by over 50% by secretly flashing the words "EAT POPCORN" and "DRINK COKE" onto the movie screen at a local theatre, people were outraged and alarmed (Weir 1984). Today, we know that it was just a hoax. Nevertheless, numerous studies have been conducted over the last few decades, especially in social cognition research, to demonstrate that priming can be used to influence peoples' perception, evaluations, motivations, and even behavior (see Bargh 2006; Dijksterhuis, Aarts, and Smith 2005 for an overview). For example, Bargh and Pietromonaco (1982) showed that people previously subliminally primed with words semantically related to hostility rated a stimulus person according to the priming words: the more hostile the words presented earlier, the more negative the impression of the stimulus person became. Maxwell, Nye, and Maxwell (1999) demonstrated that, by priming a consideration for fairness, a seller can increase a buyer's satisfaction without sacrificing profit. In simulated negotiations, participants primed to consider fairness demonstrated more cooperative behavior, making greater concessions that led to faster agreement. Fairness-primed buyers consequently had a more positive attitude toward the seller and expressed significantly greater positive subjective disconfirmation of their expectations. Bargh, Chen, and Burrows (1996) found that participants primed with the concept of rudeness, interrupted the experimenter more quickly and frequently than did participants primed with politeness-related stimuli. Furthermore, participants for whom an elderly stereotype was primed walked slower down the hallway when leaving the experiment than did control participants, consistent with the content of that stereotype. Recently, much attention has been focused on the affect of non-conscious influences on consumer behavior and choice, but the field of consumer research is still largely dominated by the rationale of deliberate and cognitive decision-making processes (Bargh 2002). In terms of the latter, a consumer acting as a result of non-conscious stimuli would be succumbing to "hedonic impulses" (Alba 2000; Baumeister 2002). This study evaluates whether supraliminal priming can be used to influence consumer behavior (non-consciously) in a real consumption situation.

"Priming refers to the presentation of a stimulus that either facilitates or inhibits the processing of a subsequent stimulus. The prime precedes the target and has consequences for how well the

target is processed." (Kellogg 1997, 83) Several different types of priming can be distinguished. One basic separation is between direct priming and indirect priming. Direct—or repetition—priming is the facilitation of the processing of a stimulus as a function of a recent encounter with the same stimulus (Cofer 1967; Schacter 1987). In studies in which subjects are free to generate any response they wish to the test stimulus, prior study of items increases the likelihood that those items will be generated as responses. Indirect priming is any change in performance resulting from the presentation of information related in some way (associatively, semantically, graphically, phonemically, or morphologically) to test stimuli (Richardson-Klavehn and Bjork 1988). Here, changes in test results can be observed when information that is related to test stimuli is presented prior to the test. The typical example is the decrease in lexical decision latency as a consequence of presenting associatively or semantically related words prior to the test stimulus; a phenomenon known as associative or semantic priming (Fischler 1977; Meyer and Schvaneveldt 1971). Bargh and Chartrand (2000) refer to three priming techniques: conceptual priming, mindset priming, and sequential priming. In conceptual priming, the activation of mental representations in one context is used to exert a passive, unintended, and nonaware influence in subsequent, unrelated contexts. In mindset priming manipulations, the participant is actively engaged in a goal-directed type of thought in one context, to show that this mindset is more likely to operate later in an unrelated context. Sequential priming techniques test for chronic connections between two representations, across which activation automatically spreads. It is used to study the associative structure of the mind rather than to examine the residual effects of recent experience.

Priming stimuli (or primes) can be delivered in two ways: subliminally or supraliminally. In social cognition research, both forms have been shown to be successful in influencing judgments, motivations, and behaviors (Bargh 1992, 1999). Delivered subliminally, the primes themselves are not accessible to the person's awareness. For instance, they can be presented so weakly or briefly that subjects do not recognize them consciously. If primes are delivered supraliminally, the persons are aware of the primes but not of their potential influence. The "scrambled sentence test" is a very frequently used supraliminal priming technique (Bargh et al. 1996; Srull and Wyer 1979). In an ostensible test to measure language ability, participants are instructed to make coherent, grammatical sentences out of each string of words. The test contains some words related to the concept intended to be primed. Another established supraliminal priming technique is a word-search puzzle where priming words are embedded in a matrix of letters (Bargh et al. 2001). Crossword puzzles are also used to place priming words. While these priming techniques have been used successfully in various laboratory experiments, they seem not to be applicable in most real consumer behavior situations. Our aim was to find and evaluate a priming technique that can be used in real consumption situations, outside the laboratory. A supraliminal priming technique—used in laboratory experiments—but applicable in real consumption situations is where words are mirrored vertically on the baseline. We refer to these words as "mirrored words". Perrig, Wippich, and Perrig-Chiello (1993) used mirrored words in a perceptual priming task. In the learning phase, participants were shown 20 mirrored words for 1.5 seconds each. They were asked

¹This research was supported by OENB-Jubilaeumsfonds 12012

FIGURE 1
Priming stimuli: honest, dishonest, and control stimulus

about how many enclosed areas they were able to find in each mirrored word. In a second—seemingly independent—task, they had to identify words in a perceptual identification task. Words that had been presented as mirrored words before were identified more quickly than those not previously presented.

In our study, we examine whether supraliminal priming can be effectively applied to affect peoples' behavior in a real consumption situation. In a field experiment we test whether priming the concept of honesty would cause users of a toilet at a motorway service area to pay the requested contribution (30 cents) by putting the money voluntarily into a box without being obviously observed. Even though we expect people primed with the concept of honesty to contribute more money, we conservatively formulate a two-tailed hypothesis.

H1: There is a significant difference in money contributed for using a toilet between people whose concept of honesty was primed and people whose concept of honesty was not primed.

Guidebooks about affirmation techniques and autosuggestion recommend that affirmations be formulated positively, without negations or a prefix that negates a word because the unconscious does not consider such a prefix. Irrespective of the scientific credibility of these sources, we examine whether using the word “dishonest” as a prime would influence people when paying the requested contribution. This leads to hypotheses two and three:

H2: There is a significant difference in money contributed for using a toilet between people primed with the word “dishonest” and people not primed.

H3: There is a significant difference in money contributed for using a toilet between people primed with the word “dishonest” and people primed with the word “honest”.

Finally, we investigate whether there is a difference in money contributed between men and women, leading to our fourth hypothesis:

H4: Men and women differ significantly in money contributed for using the toilet.

METHOD

Participants

Participants were all people (1033 male, 896 female) who visited a toilet in a motorway service area over six consecutive days between 10 am and 1 pm or between 1 pm and 4 pm.

Materials

The priming manipulation took the form of words mirrored vertically over the baseline. Three different priming stimuli were used, constructed using the words “honest,” “dishonest”, or a meaningless control word (see figure 1).

Before carrying out the experiment, the stimuli were pre-tested in order to find out whether people could detect a stimulus word. None of the 30 pre-test participants recognized a word. Each of the stimuli was printed in black color on a light brown sheet of paper (297 x 210 mm), compatible with the color of the doors of the toilet cubicles. Each stimulus covered about two thirds of the sheet. The stimuli could be seen as posters, picturing some form of art. They were fixed on the inside of each door of the 22 toilets (14 for women, 8 for men) at the motorway service area. Additionally, a sticker (100 x 70 mm) of black print on white background, compatible with the background surface, was fixed above each of the 11 urinals in the men's bathroom. Each stimulus was placed at eye level. At the exit of each bathroom was a box with a sign requesting people to pay 30 cents for using the toilet. People directly encountered the box before leaving the bathroom.

Procedure and design

Our experiment was carried out at the (only) bathroom of a relatively modern and very clean motorway service area, downstairs from the restaurant. People did not recognize that they participated in an experiment. Our independent variable was the kind of priming condition: honest, dishonest, or control condition. Data were collected separately for men and women. One collection box was located at the women's bathroom exit and another at the exit of the men's bathroom. The amount of money people contributed was our dependent variable. Participants were not directly observed, in order to avoid unintended experimenter effects. When people left the bathroom, they came directly to a corridor leading back to the restaurant. Here, the experimenter (disguised as a staff member obviously working on something) counted the people leaving the two bathrooms. After one hour, the money received was counted and the priming condition was changed. Priming conditions were counterbalanced by time of day and day of the week. In total, 160 people (81 male, 79 female) were randomly selected after leaving the bathroom and were questioned about their satisfaction with the bathroom (cleanliness, etc.). They were also asked, whether they noted something strange. If their answer was yes, they were asked to specify it. None of the 160 people asked appear to have recognized a word in the priming stimuli.

RESULTS

Each of the three priming conditions (honest, dishonest, and control) was observed for a total of 12 hours. As we knew the total

TABLE 1
Descriptive statistics for the three priming conditions

Prime	People	Money received in €	€ per person x 1000	Units of observation
Honest	763	27.96	36.64	12
Dishonest	653	21.72	33.26	12
Control stimulus	513	13.82	26.94	10
Total	1929	63.50	32.92	34

amount of money received and the amount of people visiting the bathrooms each hour, we could calculate an average amount (money/person) for each of the 36 hours of observation (dependent variable). During the experiment, a cleaning lady—obviously uninformed about the experiment—removed the collection boxes from both the men’s and the women’s bathrooms, leaving us with a total of 34 units of observation. For each unit (= hour) of observation we generated a value “€ per person” by dividing the amount of money received within that unit by the amount of people studied within that unit. We call this value “average amount per unit.” These values were then used to statistically compare the different priming conditions.

A total of €63.50 was collected from the 1929 people studied (Table 1). The highest average per person donation was when the “honest” stimulus was used (€36.64 per 1000 people).

To test our first hypothesis, we compared the average donation per sampling unit in the “honesty” primed condition with those of the control condition. Since the distribution of the variable “average amount per unit” was determined to be non-normal and the number of values low, we used non-parametric tests. A Mann-Whitney U test revealed a significant difference ($z=-2.110$, $p=.035$, 2-tailed) between these two conditions. Participants in the “honesty”-primed condition contributed more money (mean rank=14.17) than did participants in the control condition (mean rank=8.30). This result supports our first hypothesis that there is a difference in contributing requested money for using a toilet between people whose concept of honesty was primed and people whose concept of honesty was not primed. People whose concept of honesty was primed by a supraliminal prime contributed significantly more money for using the bathroom.

The average donation per sampling unit in the “dishonesty”-primed condition was compared with that of the “honesty”-primed condition to test hypothesis two. A Mann-Whitney U test did not reveal a significant difference between these two conditions ($z=-1.328$, $p=.184$, 2-tailed). There was no significant difference in contributing money for using a toilet between people primed by the concept of dishonesty and people primed by the concept of honesty.

In order to test our third hypothesis we compared the average donation per sampling unit under the “dishonesty”-primed condition with those of the control condition. The Mann-Whitney U test did not reveal a significant difference between these two conditions ($z=-.198$, $p=.843$, 2-tailed). People whose concept of dishonesty was primed did not differ significantly from people whose concept of dishonesty was not primed (control stimulus).

In testing our fourth hypothesis, we found no significant gender difference for the total experiment (two tailed Mann-

Whitney U test $z=-.034$, $p=.973$), the “honesty”-primed situation ($z=-.160$, $p=.873$), the “dishonesty”-primed situation ($z=-.241$, $p=.810$), or the control ($z=-.313$, $p=.754$).

DISCUSSION

In our experiment to test if supraliminally priming the concept of honesty influences peoples’ behavior, we found out that users of a toilet at a motorway service area contributed significantly more money ($p=.035$) for using the bathroom when being primed with the concept of honesty than when that concept had not been primed. Whereas most priming experiments have been carried out in laboratory situations, we have been able to show that priming can also be applied to real consumption situations.

As many of the established supraliminal priming techniques—like scrambled sentence tests or word search puzzles—seem not to be applicable in most real consumption situations, we have been able to show that mirrored words are both applicable and useful as a priming stimulus. As far as we know, mirrored words have thus far only been employed as priming stimuli in perceptual priming tasks (Hofer 1992; Perrig et al. 1993). We have shown that mirrored words can also be effectively used for conceptual priming tasks. This finding suggests important consequences for the use of supraliminal priming in a variety of consumption environments, including shops, restaurants, and insurance companies, but also in fields such as health care and road safety. Priming for honesty in bathrooms can also be adapted to related situations such as self-service newspaper racks and supermarket checkouts, as well as other situations that seek to maximize honesty; most especially in courts, legal institutions, financial services and tax collection.

Our study only found a significant difference in money contributed between people primed with the concept of honesty and the control group. People primed with the concept of dishonesty did not differ significantly from people primed with the concept of honesty or the control group. One reason for this result could be that the word dishonesty could have been processed non-consciously in an ambivalent manner. It could be that the prefix “dis” was considered differently than the rest of the word, which could have led to the result that some people processed the prime dishonest similar to that of the prime honest. Further research would be necessary to confirm/negate this explanation. A variety of antonyms could be tested: some that differ only by a prefix, as well as others that are completely different, like “crooked” (vs. “honest”). As the amount of money people contributed for using the toilet was quite low in the control group (on average 2.69 cents per person, Table 1), the floor effect could make it difficult to undercut this amount. Another reason for the lack of significant differences could be that people

did not face the stimuli very intensively as they were not instructed to do so, as in many other priming experiments. In almost all experiments using visual supraliminal primes, participants were required to deal with the priming stimuli in some way—like writing the words to make sentences in a scrambled sentence test (Bargh et al. 1996) or counting the closed areas of mirrored words (Perrig et al. 1993)—but in our experiment, people were not actively engaged in dealing with the primes. Some people might only have gone to the bathroom to wash their hands or to freshen up and so may not have encountered the priming stimuli (located above the urinals and on toilet doors). Future experiments should attempt to further minimize the number of participants that do not encounter the priming conditions.

This study shows that the behavior of people can be influenced by supraliminal stimuli whose message can not be detected. The effectiveness of our priming experiment also highlights some important ethical considerations. Because stimuli are not consciously detected, the source of the influence is unknown to the individuals that are manipulated. It is impossible to deliberately avoid being exposed to stimuli that are genuinely undetectable. As the stimuli circumvent certain conscious processes—like critical analysis or evaluation of the context of the stimulus—the possibility of conscious counter-control over subliminal effects is minimal. Because non-conscious influences induce attitude and behavior changes without providing information regarding the source of the influence, people are forced to create post-hoc explanations for their attitudes and behaviors, justifying and rationalizing these attitudes and behaviors to themselves and others (Bornstein 1989).

The aim of this article, and of research in priming generally, should not be to identify techniques that allow companies or other organizations to influence people without their consent or awareness, but to show what kinds of influencing techniques work under what conditions and how misuse can be prevented. For instance, to successfully prime it is critical that people are not aware of how the primes might affect them (Bargh 2002). If people are informed about the function of priming techniques, they can have some control over unwanted influences and so allowing impure manipulations to be thwarted. The results of studies concerning the non-conscious manipulation of people should provide the basis for company policies, as well as political decision making, to avoid the misuse of influencing techniques.

Less is More When Learning By Analogy: The Disruptive Impact of Attribute Information on Consumers' Benefit Comprehension of Really New Products

Amina Ait El Houssi, University of Wollongong, Australia
Kaj Morel, Delft University of Technology, The Netherlands
Erik Jan Hultink, Delft University of Technology, The Netherlands

ABSTRACT

The presented study had two purposes. First, it pursued to demonstrate that it is more effective to use analogies in advertisements for really new products to increase consumers' comprehension of the new product's benefits than not to use analogies. Second, it aimed to test the (counterintuitive) assumption that inclusion of product attribute information in the advertisement in addition to the analogy would actually frustrate benefit comprehension. The results of the experiment showed that advertisements with an analogy lead to greater benefit comprehension than advertisements without an analogy. Further, it is more effective in print advertising in managing consumer learning of the benefits of really new products to use an analogy without than with additional product attribute information. We discuss these findings and outline directions for future research.

INTRODUCTION

New product marketers are constantly seeking ways to ensure that their advertisements not only attract consumers' attention and generate interest, but educates them about their new products' benefits as well (cf. Aaker, Batra, and Myers 1992). Educating consumers is especially relevant in the case of really new products, because such products are relatively complex and often combine several functionalities. As a result, advertisements for really new products typically contain a lot of information. Moreover, this information is likely to consist of technical features and language that consumers are unable or unwilling to understand (Bradley and Meeds 2004; Meeds 2004). In interviews with prospective consumers of several really new products, Veryzer (1998) found that "quite often customers had no experience with the technologies underlying these products and thus they had little or no frame of reference for understanding them" (p.143). Therefore, the communication objective for such really new products should not be on emphasizing the product's new technologies and innovative features. Rather, a more effective communication objective would be to persuade consumers of the new benefits that the new product provides to them (Lee and O'Connor 2003). The question is how marketers should do this?

Recent research in marketing and consumer behaviour has suggested that analogies may be useful to enhance consumer learning of really new products (Ait El Houssi, Morel, and Hultink 2005; Gregan-Paxton, Hibbard, Brunel, and Azar 2002; Moreau, Lehmann, and Markman 2001a; Roehm and Sternthal 2001). Analogies are believed to be effective learning aids because they provide consumers with a familiar frame of reference that helps them to comprehend the unfamiliar new product (Gregan-Paxton and Roedder John 1997). These studies, however, have provided interesting but inconclusive results. Roehm and Sternthal (2001) compared the use of analogy with literal similarity in advertising and demonstrated that messages containing an analogy are better comprehended and are more persuasive, but only when the recipient has expertise with regard to the base. They further found that the effectiveness of an analogy is not only moderated by consumers' ability to map structural relations, but also by the availability of cognitive resources to perform the comparison task. In another

study, Gregan-Paxton et al. (2002) showed that the use of analogy directs consumers' attention to the corresponding relations between target and base. Although it is suggested that the structural relation between the base and the target is more informative about what benefits a product offers (Gregan-Paxton and Roeder John 1997), this assumption has not been empirically tested by Gregan-Paxton et al. (2002). Hence the important question remains whether a focus on corresponding attributes actually enhances consumer's comprehension of the key benefits of a really new product. Answering this question constitutes the first objective of the present study.

Gregan-Paxton et al. (2002) have also shown that analogy triggers selective processing of new product information. They have suggested that analogy can effectively direct consumer's attention to some attributes and away from others. Having said this, we believe that one reason why the use of analogies in previous research (see e.g., Ait El Houssi et al. 2005; Hoeffler 2003; Gregan-Paxton et al. 2002) has not worked as well as expected, may be that the investigated advertisements used attribute information in addition to the analogy. It is proposed here that the inclusion of technical attribute information in an ad copy is likely to prevent consumers from paying sufficient attention to the analogy and thus from forming a concrete representation of the new product and the benefits it offers (Bradley and Meeds 2004). The second objective of the present study is to investigate the plausibility of this proposition by means of an experiment in which consumers' comprehension of a new product's benefits advertised through both an analogy and attribute information is compared with consumers' comprehension of a new product's benefits advertised through an analogy only.

COMPREHENDING NEW PRODUCT BENEFITS THROUGH LEARNING BY ANALOGY

How do analogies assist consumers in comprehending a really new product and in particular its distinctive benefits? In order to answer this question, we first explain how analogical learning is understood to take place.

Analogical Learning

Analogical learning takes advantage of the structural similarities that exist between something that a consumer already knows (i.e., the base domain) and something new to the consumer (i.e., the target domain). It is essential for analogical learning to take place that the knowledge that is transferred from the base to the target domain is predominantly related to a common relational structure (i.e., how the base and target relate to each other) and not to physical resemblance (i.e., how many surface properties the base and target share). Comparing a PDA (target) to a secretary (base), for instance, helps consumers to understand what a PDA does (i.e., performing routine tasks for the individual) in spite of the fact that there are no physical similarities between a PDA and a secretary.

Learning by analogy occurs through a series of three stages: access, mapping and transfer (Gentner 1989; Keane, Ledgeway, and Duff 1994). In the access stage, a relevant base domain becomes active in a person's memory and serves as a source of information about the target. Access is likely to occur spontane-

ously when the target shares a number of surface properties with the base (Gentner, Ratterman, and Forbus 1993). It is characteristic of analogies that the base and target do not share (many) surface properties. This lack of common surface properties makes spontaneous activation of a relevant base less likely (see, e.g., Gick and Holyoak 1980; Reed, Ernst, and Banerji 1974). Therefore, the base is usually prompted by an external source such as a print ad in a marketing communications setting (Gregan-Paxton et al. 2002; Moreau et al. 2001a/b). Once the base has been activated, its content and structure are compared with the target domain in the mapping stage. Unlike access, mapping is characterised by a preference for relation-based rather than attribute-based comparisons between domains (Clement and Gentner 1991; Gentner et al. 1993). Finally, in the transfer stage, the base and target domains are aligned based on the relational commonalities between the two. It is in this stage that learning occurs when knowledge is moved from the base to the target along the paths that have been created during the mapping stage.

Beneficial Effects of Analogies

The basic premise of our study is that using analogies in appeals for really new products may be the most effective tool to direct consumers' attention to and increase their comprehension of the benefits of a really new product. When processing an analogy, cognitive effort is likely to be allocated to the structural relations between the base and the really new product rather than to attribute similarities between them. Hence, an ad containing an analogy will generate greater attention to structural relations than an ad containing merely attributes. Recent research in marketing confirmed that the use of analogies in product descriptions causes consumers to focus on corresponding relationships between the target and the base and to disregard feature similarity (Gregan-Paxton et al. 2002). The focus on structural relationships enhances comprehension of the distinctive benefits of the really new product because structural relations are thought to be more informative than attributes about the benefits that a new product offers (Gregan-Paxton and Roeder John 1997). Support for this hypothesis is found in studies showing that analogies, rather than literal similarity or mere-appearance comparisons, are generally perceived to be more sound (Gentner et al. 1993) and more goal-relevant (Read 1984). An analogy permits the consumer to focus on the shared data structure (between the base and the target) that is sparse enough to allow the learner to isolate the key principles (Gentner 1989). Continuing with our example, a secretary is known for performing many routine tasks and a comparison with a PDA highlights the shared commonalities implying that like a secretary the PDA also performs many routine tasks. Thus, it is reasonable to assume that an analogy increases the salience of the distinctive benefits of a really new product via corresponding relationships with the base domain thereby simplifying the new product. Separate attributes, on the contrary, may complicate encoding relevant information about a really new product in a coherent way. A really new product described by merely attributes will be difficult to understand since it involves complex relationships between largely unfamiliar attributes, technologies and benefits (Menon and Soman 1999). In sum, the use of analogies is likely to promote understanding of the main benefits of a really new product due to an increased focus on and an enhanced elaboration of the key benefits. We therefore hypothesise:

H1: Consumers will better comprehend the distinctive benefits of a really new product from ads featuring an analogy than from ads not featuring an analogy.

Attribute Information as a Disruptive Factor

In practice, companies often communicate attributes when introducing new products (Hoeffler 2003). Since really new products are relatively complex, advertising of these products is especially prone to technical features and language (Bradley and Meeds 2004; Meeds 2004). Including attribute information to an ad containing an analogy may be very demanding for consumers, because most consumers do not have the knowledge to evaluate such technical information. Previous research has demonstrated that even consumers with expertise in the domain of a really new product experience difficulties with comprehending and appreciating the benefits of this type of products (Moreau et al. 2001). The inclusion of technical characteristics of a really new product may induce consumers to focus on what is not known (Lee and O'Connor 2003) and thus impose significant learning requirements upon the consumer (Lehmann 1997).

Roehm and Sternthal (2001) offered evidence that the processing of an analogy is a resource-demanding task. This is because analogies rely on the mapping of structural relations that can be difficult to detect and resource demanding to map. When technical attribute information is presented in an ad that also contains an analogy, consumers' cognitive resources are used to search memory for representations that are capable of making sense of the highly unfamiliar product attributes. Simultaneously, however, substantial resources must be allocated to the processing of the analogy if the analogy is to be successful (Roehm and Sternthal 2001). In other words, consumers' cognitive resources must be divided over the task of comprehending the technical characteristics of the really new product on the one hand, and the task of comprehending the analogy on the other. When the former task demands a great percentage of the available resources, comprehension of the analogy may be compromised. If this happens, the merits of using an analogy are likely to be reduced or even nullified. In support of this account, Gregan-Paxton et al. (2003) found that consumers who processed advertisements containing an analogy recalled significantly fewer new product features than those who processed advertisements without an analogy. In short, we hypothesize that the positive effects of the use of analogies on benefit comprehension will be weakened by the inclusion of attribute information in the advertisement. Hence, hypothesis 2 reads:

H2: Consumers will better comprehend the distinctive benefits of a really new product when it is advertised through an analogy only than through an analogy plus attribute information.

METHOD

Participants

Participants were 122 students from a Dutch high school who participated voluntarily. Sixty-one percent was female and the average age was 16.6 years. They were recruited at the school during breaks and free periods. High school students were selected as they were likely to be interested in the new products examined and they are less likely to have a special interest or expertise in advertising.

Design and Stimuli

The study employed a single-factor (message type: attributes only, analogy only, analogy plus attributes) between-subject design. The design was applied to two really new products. The experimental treatment consisted of exposure to one of the message types for one of the two products. The PH 530 is a mobile phone

with music functionality to mix and create music and ring tones. The RP 530 is a portable pen-like reading device that provides definitions, spelling and pronunciation of words. These two products were selected because they were unfamiliar to participants and because sound analogies were available.

Six different print ads were developed corresponding to the experimental conditions for the two really new products (see Appendix). All versions of the ad were constructed to be as similar as possible to eliminate the lay-out of the ad as a possible confound. No brand names were provided because we did not want participants' judgments to be based on such peripheral cues (Ozanne, Brucks, and Grewal 1992). The original product names (i.e., ReadingPen and Philips 530) were changed to fictitious names (i.e., RP 530 and PH 530, respectively) in order to minimise associations regarding the brand or product name. The ad for the attribute condition and the analogy plus attributes condition consisted of a headline at the top of the page, a coloured picture of the new product at the centre of the page, and a body copy text at the bottom of the page. The analogy was manipulated in the headline (i.e., PH 530: "Be your own DJ"; RP 530: "With the RP 530 you always have your language teacher close at hand"). The body copy text described general features of the new product. The ad version for the analogy only condition lacked the body copy text containing the product attributes.

Procedure

Each participant received a booklet containing the instructions, stimulus and measures. To stimulate realistic viewing conditions, participants were asked to view the ad as they would normally do when reading a magazine. They were allowed to examine the ad at their own pace and they could freely turn back to the ad while filling out the questionnaire. After participants completed the questionnaire, the purpose of the experiment was explained. The whole procedure took less than 10 minutes.

Measures

Benefit comprehension. Inspired by the measure of Roehm and Sternthal (2001), participants were given a list of 11 character-

istics of the advertised products presented in random order (see table 1). This list resulted from a literature search into the attributes and benefits of both new products. Participants were asked to tick the three main characteristics *that were clarified by the ad for the new product* from the list. To reduce possible primacy and recency effects, the first and last characteristic on the list were fillers. Apart from the fillers, the list included three distinct benefits of the new product, three attributes that were presented in the body of the text, and three attributes that the advertised product possessed but that were not mentioned in the ad. The number of benefits from the list marked by participants, ranging from zero to three, determined the degree of participants' comprehension of the new product benefits.

Product familiarity. The use of an analogy is thought to be more effective when consumers have limited or no prior knowledge of the target product. Therefore, participants rated their familiarity with the really new product on a two-item scale ($r=.64, p<.001$) as an additional check that product familiarity was indeed low, as was observed in the pretest: "How familiar are you with the [product]?" (1="not familiar at all"; 7="highly familiar"), and "Have you ever read, seen or heard anything about the [product]?" (1="never"; 7="very often").

Product interest. To ensure the relevance to the sample group participants were asked to rate the extent to which they were interested in the new product presented in the ad on three items ($\alpha=.84$): 1="not interesting at all"/7="very interesting", 1="dislike it very much"/7="like it very much", and 1="does not interest me at all"/7="interests me very much".

Results

To ensure the selected products were relevant to high school students interest in the advertised product was measured. Results show that participants were equally interested in both products (PH 530: 4.5, RP 530: 4.5; $F(1,121)=.04, p=.85$). Product familiarity was measured to control for the degree of participants' familiarity with the new product and an insignificant relationship with benefit comprehension was found (PH 530: $F(1,62)=2.26, p=.14$; RP 530: $F(1,58)=.75, p=.39$). Product familiarity was therefore not included as a covariate in testing the hypotheses. In order to test whether ads

TABLE 2
MEANS OF DEPENDENT VARIABLE IN EACH OF THE EXPERIMENTAL CONDITIONS

containing an analogy generated higher understanding of the benefits of the really new products than ads not containing an analogy (H1), an ANOVA was run separately for both products with message type as the independent variable and benefit comprehension as the dependent variable. Table 2 presents the means of the dependent variable for the experimental conditions for both the PH 530 and RP 530. The analysis yielded a significant main effect for message type for the PH 530 (Attributes: $M=.24$; Analogy plus attributes: $M=1.05$; Analogy: $M=1.76$; $F(2,62)=25.63$ $p < .01$) and for the RP 530 (Attributes: $M=.56$; Analogy plus attributes: $M=.73$; Analogy: $M=1.32$; $F(2,58)=4.55$, $p < .05$). For the PH 530, a Tukey post-hoc comparison test showed that all differences were significant (Analogy plus attributes vs. Attributes: *mean difference*=.81, $p < .01$; Analogy vs. Attributes: *mean difference*=1.52, $p < .01$; Analogy vs. Analogy plus attributes: *mean difference*=.71, $p < .01$). For the RP 530, the Tukey post-hoc comparison test revealed a significant difference between the analogy only condition and the attributes only condition (*mean difference*=.76, $p < .05$). The difference between the analogy only and analogy plus attributes conditions was marginally significant (*mean difference*=.59, $p = .06$). In short, for both really new products, ads featuring an analogy increased benefit comprehension significantly more than ads not featuring an analogy, confirming hypothesis 1. In addition, for the mobile phone, the ad featuring only an analogy boosted benefit comprehension significantly more than the ad featuring an analogy plus attributes. A similar, but not-significant difference was observed for the ReadingPen. Hypothesis 2, therefore, needs to be rejected for the RP 530, but not for the PH 530.

GENERAL DISCUSSION

The presented study had two purposes. First, it pursued to demonstrate that it is more effective to use analogies in advertisements for really new products to increase consumer comprehension of the distinctive benefits of the new product than not to use analogies. Second, it aimed to test the (counterintuitive) assumption that inclusion of product attribute information in the advertisement in addition to the analogy would actually frustrate benefit comprehension. The rationale for this assumption is that inclusion of relatively complex technical attribute information in an advertisement requires consumers to spend a disproportional part of their available processing resources to it in order to comprehend it. As a result, limited attention is dedicated to comprehension of the analogy, decreasing its potential beneficial effects on product benefit comprehension.

With respect to the first purpose, the results showed that advertisements with an analogy lead to greater benefit comprehen-

sion than advertisements without an analogy. These findings provide support for our argument that consumers who process an analogy focus on the relational structures that exist between a base and a target, and that these relational structures are more informative about what benefits a really new product offers than attribute information. Regarding the second purpose, the results showed that ads featuring only an analogy had a stronger positive effect on benefit comprehension than ads featuring an analogy plus attribute information, especially for the mobile phone.¹ This effect may be explained by the availability of cognitive resources theory (Roehm and Sternthal 2001). These authors argue that combining attribute information with an analogy distracts attention away from an analogy, thereby leaving less cognitive resources available for elaborating on the analogy. Indeed, in their study, Roehm and Sternthal found that experts only showed greater comprehension of an analogy and were more persuaded by it when they were able to devote substantial cognitive resources to it. When insufficient cognitive resources were made available for processing the analogy, its beneficial effects were absent.

Although the cognitive resources theory seems a likely candidate to explain our findings, we cannot be too sure about it as participants in our experiment could spend as much time as they liked on processing the ads. Under these conditions, participants had ample opportunity to pay attention to the analogy in spite of the presence of attribute information. Of course, the question remains whether participants will spend as much attention to an analogy when presented with attribute information as they would in the alternative situation where there is only the analogy to process. In the latter situation, participants confronted with the line "Be your own DJ" in the ad for the PH 530 mobile telephone, for instance, would be forced to come up with their own inferences regarding the meaning of this claim. Given the nature of this claim, such inferences would most probably constitute common relations between the base (i.e., a DJ) and the target (i.e., the PH 530) rather than specific attribute information. The fact that participants have to come up with these inferences themselves without any additional help, in contrast to the situation in which attribute information is available, may cause them to experience greater comprehension of the distinctive benefits. Future research is necessary to establish which explanation is most appropriate for our findings.

¹In a pilot study similar to this experiment with a different sample ($n=123$), we also found significantly higher benefit comprehension for the ads featuring only an analogy than ads featuring an analogy plus attributes. This finding thus appears to be rather robust.

An interesting finding that has not been reported earlier, but that should be mentioned here is that although the ads containing an analogy only scored higher on consumer benefit comprehension, consumers found this ad less informative than the ad containing an analogy plus attributes. This finding is surprising because it suggests that while consumers perceive attribute information to be informative, inclusion of such information in an ad with an analogy actually leads to lower product benefit comprehension. This finding may be the result of a kind of 'more is better' heuristic that consumers apply and that, as is the case with most heuristics, is generally effective. In case of the particular circumstances that were investigated in this study more information appears to be worse.

IMPLICATIONS FOR MARKETING AND NEW PRODUCT DEVELOPMENT

This research contributes to a better understanding of consumer comprehension of new product benefits in the context of really new products. Specifically, the results suggest that the use of analogies in ads for these products improves consumer comprehension of really new product benefits, and that adding attribute information to an ad containing an analogy lowers rather than improves consumer comprehension. These results have important implications for marketers responsible for the launch process (or the marketing communications) of really new products. As really new products tend to be complex and consist of several technical features that consumers often do not understand, managers should resist the temptation to communicate the product's new technologies and innovative features to consumers as this communication strategy will only confuse consumers and makes them less likely to adopt. A more appropriate launch strategy would focus on the really new product's distinctive benefits. Our study shows that analogies can be helpful in conveying these benefits to consumers. In order for such a strategy to be successful, companies should spend sufficient time on identifying an analogy that is sound; i.e., a comparison that is strong enough so that the consumer can infer relevant benefits from the base to the really new product. The choice of such an appropriate analogy is not easy. The soundness-rating task of Gentner et al. (1993) and the task that we employed may help companies to identify such strong analogies.

When companies have identified a sound analogy it may be better to only include this analogy in the ad for the really new product without adding attribute information as the results in our experiment show. Although it may seem intuitively more logical that analogies will serve as the "the explanatory context" for the complex attributes (Bradly and Meeds 2004), our findings tell another story. Consumers usually spend little time on processing an ad. According to Chisolm (1995) newspaper ads are looked at for an average of 0.84 seconds. It may therefore be more useful when consumers spend this limited time and their available cognitive resources on processing the analogy, rather than be distracted by the often long list of technical features.

Overall, our research provides valuable information for marketers on how consumers react to really new products. The results reinforce a broader strategic lesson that marketers should prepare the customer cognitively for really new products (Hoeffler 2003; Moreau et al. 2001b). This cognitive preparation can, for example, be achieved by visualisation exercises (Dahl and Hoeffler 2004) but also by the use of sound analogies as our results show. Although the last word has surely not been written on the use of analogies in communicating really new product benefits, our results showed that a DJ and a language teacher were helpful in comprehending the distinctive benefits of a mobile phone with music functionality and a portable pen-like reading device that provides definitions, spell-

ing and pronunciation, respectively. We are looking forward to new research that will investigate if and when other analogies such as, for example, a guardian angel or a sheep are helpful in explaining the distinctive benefits of a car safety protection system or an autonomous lawn mower to consumers, thereby hopefully improving the market success of such innovative products.

The Role of Exploration in Creating Online Shopping Value

Catherine Demangeot, University of Strathclyde Business School, UK

Amanda J. Broderick, Coventry University Business School, UK

ABSTRACT

This study draws attention to the integrating role of exploration in online shopping. Online, the shopping experience, product search and product information search all happen through the exploration of different pages of a website. A survey among 301 respondents who first navigated an online bookstore for eight minutes was analyzed using structural equation modeling. Results show that exploratory potential (the perceived ability of a retail website to provide scope for further exploration) plays a central role in creating utilitarian and hedonic value, which in turn contribute to site commitment. Further, sense-making potential only produces utilitarian value if mediated by exploratory potential, thus further reinforcing the notion that exploratory potential is the real 'killer attribute' of a retail website.

INTRODUCTION

This paper demonstrates the importance of exploratory potential for online research by examining its explanatory power on shopping behavior. Environmental psychologists Kaplan and Kaplan (1982) suggest that exploration is, alongside sense-making, a major human need in an environment. Thus, if one considers the screen on which the successive pages of a retail website are displayed as an environment, consumers perceive the succession of pages in terms of their exploratory potential and their sense-making potential (Demangeot and Broderick, forthcoming). Exploratory potential is defined as the perceived ability of the site to provide scope for further exploration over and beyond what is visible to consumers on the page they are viewing, and sense-making potential is defined as the perceived ability of a retail website to facilitate the consumer's orientation, navigation and task accomplishment.

Exploration can apply to the retail environment, the shopping experience, the product range available on the website, or the information available about a particular product. It can happen at the level of an individual page, whose different components and overall design can be inviting, and at the level of the whole site, when the depth of content prompts the discovery of more material and the overall 'feel' of the site enriches the navigation experience. Thus, this paper contends that exploration is an important concept in studying online consumer behavior, because it reflects the manner in which, fundamentally, the shopping experience and product information search take place in the online context, as a result of the internet medium's characteristics.

Most studies of online consumer behavior have echoed discrete streams of the consumer behavior literature, focusing on separate elements of the overall shopping experience. In particular, Hoffman and Novak (1996) discuss the distinction between surfers and goal-directed online users, echoing the distinction made by Bloch, Ridgway, and Sherrell (1989) between browsing and pre-purchase information search. Klein (1998) and Li, Daugherty, and Biocca (2001) have considered the manner in which products may be experienced differently online and offline, adding to the literature concerned with different types of product experiences (Hoch, 2002; Singh, Balasubramanian, and Chakraborty, 2000; Wright and Lynch, 1995). Several authors have also considered the atmospheric qualities of online shopping environments (e.g. Eroglu, Machleit, and Davis, 2003; Richard, 2005), leaning on the extensive body of literature on the use of the 'silent language' of environmental cues to produce desirable consumer responses (Kotler,

1973; Mehrabian and Russell, 1974; Turley and Milliman, 2000). However, none of these studies takes account of the fact that in an online context, the processes of shopping, assessing product range and gathering product information are one and the same, consisting of clicks and searches.

In this paper, the concept of exploration is used to integrate these different streams, reflecting the reality that when shopping online, information search, product experience and store navigation are performed in the same manner. The paper investigates the behavioral consequences of the exploratory potential of a retail website. It first outlines the study's conceptual framework, before presenting the method and measures chosen. The main results are reported and implications are drawn. Finally, limitations are acknowledged and directions for further research suggested.

CONCEPTUAL FRAMEWORK

Online exploration

The rationale for studying the concept of online exploration stems from the common manner in which online, consumers shop, navigate the virtual environment, find products and gather product information.

Online, the process of acquiring product information and shopping generally is fundamentally different from offline. Because it is not possible to survey a whole website at once, consumers have to find their way, form impressions and gather information by progressing through consecutive clicks and searches. Besides, electronic data is stored and can be retrieved in a manner which gives shoppers access to quasi-unlimited amounts of information from a variety of sources (the marketer, other users, experts, opinion leaders etc.). The data can be accessed immediately (via competently-executed searches) or can facilitate, through a series of hyperlinks, in-depth information gathering, to browse or make a purchase decision. Thus, the scrolling up or down of long pages or the clicking of successive hyperlinks are different forms of exploration, of the virtual shop, of the product range or of a particular product's information. Offline, the gathering of information from different sources is carried out as a series of discrete activities (reading a review, visiting a shop to ask questions to the sales assistant, consulting a colleague or friend); it involves different people and takes place in different locations. Shopping online can encompass, in the same locus, the simultaneous performance of activities which, offline, are separate in time and place. The ability to do this is likely valued by consumers, since it greatly reduces the effort and costs of searching for information (Nelson, 1974).

Information can be accessed at very little cost and in any sequence, because searches can return both the expected product or information, and a series of alternatives, and because individual product pages often provide links to other products. Thus, the distinction between browsing and pre-purchase information search is less pronounced online than offline. Consequently, the distinction in the literature between browsing and pre-purchase information search (Bloch et al., 1989), may be less relevant online. In fact, consumers likely switch from one mode to the other during the course of one shopping navigation, committing some information to memory (or, for instance, to the website's 'wish list') while concurrently deciding to make a particular purchase. The concept of exploration encompasses both motives.

The activity of shopping and the products for sale are experienced differently online and offline in two major ways. First, the online retail environment itself is less intuitive than a real shop; it is only revealed to the consumer one page at a time, and navigated virtually, with the help of informational cues. Hence, a sense of the 'depth' of the website and its product range is acquired not through a visual assessment of the volume of the store or a walk around the aisles, but by calling up a succession of two-dimensional pages. To move on from the scene and information on the screen, it is necessary to click on a hyperlink or perform a search. The concept of exploration is appropriate because it accounts for the fact that online, retail environment, products and product information do not appear to consumers all at once, but they are explored in the same manner, by calling up a succession of pages or scrolling up and down the same page.

Second, the products are not physically present, and experiencing them consists in clicking on different parts of a screen, to look at different images, perhaps simulate their manipulation (as, in the case of cameras, clicking on a hotspot to zoom in or take a photograph), watching a video or obtaining more textual information. Klein (1998) shows how goods which offline cannot be experienced before they are purchased, may, online, have more attributes which can be searched and assessed. Similarly, online user reviews enable consumers to obtain a vicarious experience of goods such as experiential goods, which can be difficult to assess offline (Varlander, 2007). Further, Senecal, Kalczyński, and Nantel (2005) found that consumers who consult product recommendations display a more complex shopping behaviour (in terms of number of pages visited, the linearity of the navigation pattern, and the number of product pages visited) than those who did not consult recommendations, suggesting that they use product recommendations as just one of several factors contributing to their decisions. This behavior is different from offline, where recommendations are often used to reduce decision-making effort and time (Solomon 1986).

Demangeot and Broderick (forthcoming) have conceptualized exploratory potential to reflect four dimensions: (1) *visual impact*, defined as the attention-grabbing, aesthetic visual diversity of individual pages; (2) *experiential intensity*, defined as the ability of the website to produce an involving shopping experience; (3) *marketer informativeness*, defined as the extensiveness of marketer information available on the site; and (4) *non-marketer informativeness*, defined as the extensiveness of product information available on the site, which originates from non-marketer sources, and is used differently than marketing information by consumers (Solomon, 2004). In essence, visual impact and experiential intensity describe the shopping and environmental exploration, while marketer informativeness and non-marketer informativeness concern the informational exploration. Further, the distinction between visual impact and experiential intensity reflects the distinction between perceptions at the level of an individual page and at the level of the entire navigation, experienced as a succession of pages. Other studies have considered the entertaining (e.g. Kim and Stoel, 2004), aesthetic (e.g. Yoo and Donthu, 2001) or informational (e.g. Loiacono, Watson, and Goodhue, 2007) qualities of retail websites. However, the construct of exploratory potential, while encompassing these three dimensions, has the advantage of integrating them since they are all apprehended by consumers through the same process of exploration. Therefore, they are expected to have a common core, motivated by people's fundamental need to explore environments (Kaplan and Kaplan, 1982). Demangeot and Broderick's (forthcoming) study found empirical support to the conceptualization of exploratory and sense-making potential as higher-order constructs.

They conceptualized sense-making potential as reflecting two dimensions: (1) *page clarity*, defined as "the ease with which one can grasp the organization of the scene" (Kaplan, 1992); and (2) *site architecture*, defined as the shopper's perception of the organization of the different pages of the website as a coherent, understandable whole. The distinction between the two dimensions again reflects the distinction between the level of an individual web page and the succession of pages visited during a shopping navigation.

There is an obvious tension between the needs to make sense and to explore, since attempts to facilitate sense-making can reduce an environment's exploratory potential and vice versa. However, both needs have to co-exist: while familiarity is sought after, it also breeds contempt (Kaplan and Kaplan 1982), and exploration satisfies the need for stimulation (Berlyne, 1960).

Several studies using the Technology Acceptance Model (Davis, Bagozzi, and Warshaw, 1989) have found an antecedent-consequence relationship between the model's two main constructs: perceived ease of use and perceived usefulness (Henderson and Divertt, 2003; Karahanna and Straub, 1999). Ease of use is similar, conceptually, to sense-making potential, and usefulness is similar to exploratory potential. It is possible that, as is the case between ease of use and usefulness, sense-making potential is an antecedent of exploratory potential, because the online environment needs to make sense first, before its exploratory qualities can be apprehended fully. Thus:

H1: A retail website's sense-making potential is a predictor of its exploratory potential.

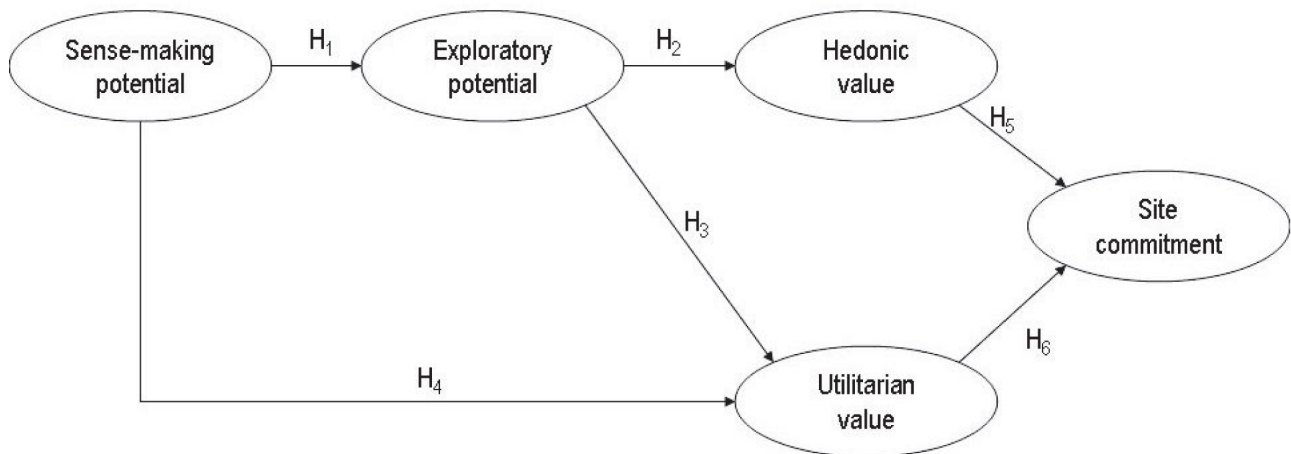

Online exploration and shopping value

Value is considered as a main outcome of shopping experiences (Babin, Darden, and Griffin, 1994; Holbrook, 1986). Since people shop to satisfy a variety of needs, some of which are independent of the acquisition of products (Bloch et al., 1989; Tauber, 1972), shopping value encompasses an appreciation of the whole experience rather than just the success of the shopping trip or navigation with regard to product acquisition (Babin et al., 1994; Diep and Sweeney, 2008). The outcome of a shopping trip or navigation may result in both utilitarian and hedonic shopping value (Babin et al., 1994). Utilitarian value is defined as "an overall assessment of functional benefits and sacrifices" (Overby and Lee, 2006, p. 1161) and hedonic value as "an overall assessment of experiential benefits and sacrifices, such as entertainment and escapism" (Overby and Lee, 2006, p. 1161). Thus, consumers shopping online can potentially draw utilitarian value, if they have gained more from the navigation than the costs expended (financial, time, cognitive), as well as hedonic value, if the experience was rewarding in its own right.

The exploration of landscapes is involving (Kaplan and Kaplan, 1982) and similarly, shopping navigations can be involving due to the medium's potential for interactivity and vividness (Fortin and Dholakia, 2005). More complex information displays (Gammack and Hodgkinson, 2003) and image interactivity (Kim, Fiore, and Lee, 2007) increase attention and involvement. The mere presence of involvement suggests that the experience is hedonically rewarding (Bloch and Richins, 1983). Consumers may be able to enjoy a lively interaction with the website or with the product without proceeding with a purchase, and this in itself can produce hedonic value (MacInnis and Price, 1987). Exploratory potential can provide further product knowledge for its own sake, and be perceived as an intrinsically rewarding experience. Thus:

H2: A retail website's exploratory potential provides consumers with hedonic value.

FIGURE 1
CONCEPTUAL MODEL

Furthermore, the involvement elicited by the exploratory potential of a website makes consumers pay more attention (Celsi and Olson, 1988), which facilitates instrumental tasks (Hoffman and Novak, 1996). Cognitively involved consumers are known to increase information processing abilities and search for more information (Beatty and Smith, 1987). Further exploration of the site and interest in looking at more products and more information can lead consumers to find more suitable products, thus making the shopping trip also more successful in utilitarian terms (Kroeber-Riel, 1979). Thus:

H3: A retail website's exploratory potential provides consumers with utilitarian value.

Further, when consumers perceive the website to be easy to make sense of, they are likely to find products or product information more easily. As they accomplish what they set out to do, the navigation will likely produce some utilitarian value (Babin et al., 1994). Hence:

H4: A retail website's sense-making potential provides consumers with utilitarian value.

Value and site commitment

Each online shopping navigation is a 'moment of truth', which will influence the consumer's future intentions and behavior. Obtaining consumer commitment as a result of any site navigation is important (Christopher, Payne, and Ballantyne, 2002), since it explains future behavioral intentions (Park and Kim, 2003). Whether consumers purchase or not during a particular navigation, the ongoing relationship between consumer and retail website—or absence thereof—is subject to the consumer's site commitment. In this study, site commitment is defined as the degree to which the consumer is willing to remain associated with the retail website. It indicates a future-focused assessment of a consumer's recent navigation, linking past and future behavior (Park and Kim, 2003). Because shopping value, whether hedonic or utilitarian, is a positive outcome and increases shopper satisfaction (Babin et al., 1994), it is likely to produce approach behaviors (Jones, Reynolds,

and Arnold, 2006). Therefore the following hypotheses are formulated:

H5: Hedonic value drawn from navigating a retail website is positively related to site commitment.

H6: Utilitarian value drawn from navigating a retail website is positively related to site commitment.

The conceptual model shown in Figure 1 summarizes the six hypotheses derived.

METHOD AND MEASURES

To test the conceptual model, data were collected from a sample of 301 respondents recruited on a voluntary basis among the students and staff of a British university. Respondents were asked to shop at an online bookstore (www2.uk.bol.com) for eight minutes, then answer a questionnaire about that particular navigation experience. The duration was established based on the need for respondents to get to know the site well enough to answer specific questions about its attributes, while keeping the overall duration under 25 minutes.

A relatively unknown site was chosen (only 7.3% of the sample reported having visited it once or occasionally; no-one was a regular user) to capture instant, 'fresh' perceptions, thus overcoming validity concerns expressed about the likely halo effects of studies which call on consumers' memory to describe past experiences (Chen, Wigand, and Nilan, 1999; Lowrey, Otnes, and McGrath, 2005). To maximize the 'naturalness' of the shopping exercise, the site was chosen in a product category which students and university staff typically purchase; the setting for the navigation (computer lab, desk or home) is typical of the setting the respondents use when they shop online; and the instructions themselves asked the respondents to shop "as [they] would normally shop online if [they] were at home, in an internet café or at [their] desk", thus they clearly aimed to induce the sense of shopping, rather than just aimless or experimental browsing.

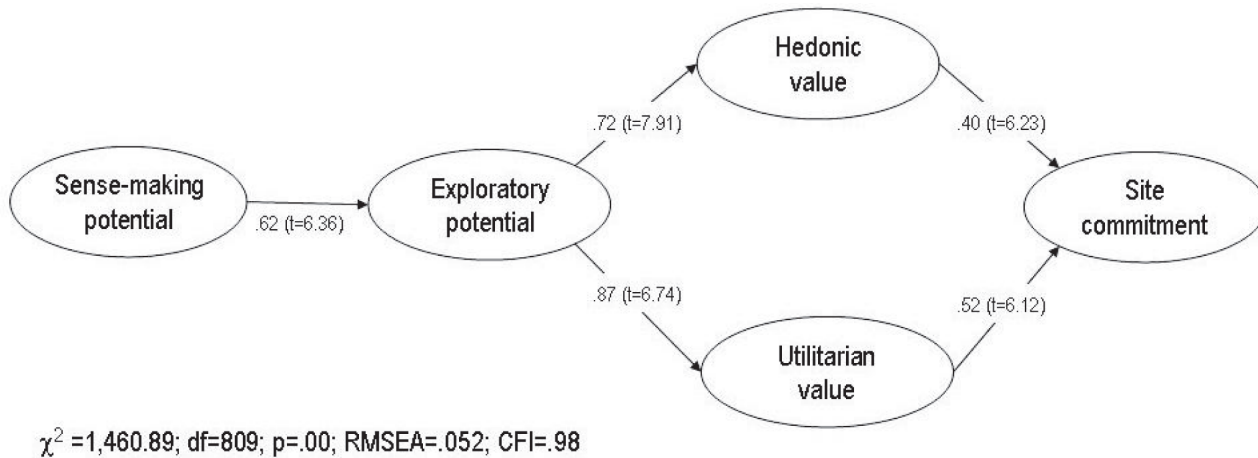

Exploratory potential and sense-making potential were conceptualized as higher-order constructs. They were operationalized as such, and to measure their respective dimensions, the scales

TABLE 1
 PSYCHOMETRIC PROPERTIES OF THE MEASURES OF EXPLORATORY POTENTIAL AND SENSE-MAKING POTENTIAL

Construct/dimension	CR	AVE
Exploratory potential (second-order construct, 4 dimensions)	.76	.46
Visual impact (4 items)	.87	.63
Experiential intensity (4 items)	.79	.48
Marketer informativeness (5 items)	.82	.49
Non-marketer informativeness (3 items)	.81	.59
Sense-making potential (second-order construct, 2 dimensions)	.79	.67
Page clarity (3 items)	.86	.68
Site architecture (6 items)	.86	.51

CR: composite reliability; AVE: average variance extracted

FIGURE 2
 FINAL MODEL RESULTS

developed and validated in Demangeot and Broderick (forthcoming) were used. The psychometric properties of the two higher-order constructs and their respective dimensions are summarized in Table 1.

To measure hedonic and utilitarian value, Babin, Darden, and Griffin's (1994) scales of 11 and 4 items respectively were used. To meet the unidimensionality requirement (Gerbing and Anderson, 1988), the hedonic value scale was reduced to 6 items, consistent with other studies (e.g. Babin, Chebat, and Michon, 2004). To measure site commitment, items from existing scales (Agarwal and Karahanna, 2000; Coyle and Thorson, 2001) were combined with items developed during a previous, qualitative exploration stage. As recommended by Baumgartner and Steenkamp (2001) to reduce the possibility of response bias, items were ordered randomly and all scales contained both positively- and negatively-worded items.

The Appendix, which details the items retained to tap each measure, shows that all measures display strong psychometric

properties. Discriminant validities between all measures of the model were assessed and supported by, first, ensuring that a confidence interval of two standard errors on either side of the correlation coefficients did not include 1, and second, through the testing of nested models to confirm that correlation coefficients between each set of factors were significantly different from 1 (Anderson and Gerbing, 1988).

FINDINGS

The path model was tested using structural equation modeling, and produced strong goodness-of-fit indices ($\chi^2 = 1,459.65$; $df = 808$; $p = .00$; $RMSEA = .052$; $CFI = .98$). Of the path coefficients freely estimated, all except one have strong values, significant at the .001 level. However, the path from sense-making potential to utilitarian value is not significant. Its coefficient (-.04) has a t-value of -.59. As a result, the model was re-specified to exclude that path. The results of this final model are shown in Figure 2.

Hypothesis 1, which posits a positive relationship between sense-making potential and exploratory potential, is supported, with a path estimate of .62 ($t=6.36$; $p<.001$). When a website makes sense, it is more likely perceived to be worth exploring too. Hypothesis 2 posits a positive relationship between exploratory potential and hedonic value, and it is supported by a path estimate of .72 ($t=7.91$, $p<.001$). When consumers are on a shopping website which has exploratory potential, they draw hedonic value from it. Hypothesis 3, which posited a positive relationship between exploratory potential and utilitarian value, is supported by a path estimate of .87 ($t=6.74$, $p<.001$). This supports the argument that when consumers navigate a site which has potential for exploration, they gain utilitarian value, possibly because the site's exploratory attributes enable them to achieve such shopping objectives as purchasing the most suitable item, being able to compare between several products, or being able to inspect products by clicking on them, etc.

Hypothesis 4 which suggested that sense-making potential is an antecedent of utilitarian value, was rejected. This was an unexpected, yet most interesting finding. The entirety of the effect of sense-making potential on utilitarian value is mediated by exploratory potential. Consumers therefore do not appear to draw *any* value from sense-making attributes if they cannot use them to explore the site. Sense-making potential may be a necessary condition for consumers to be able to explore a site, but it is not sufficient for them to draw value from their visit or form a commitment. This is consistent with Kaplan and Kaplan's (1982) argument that people are not satisfied with just making sense of an environment. They quickly become bored and seek exploration as a way to expand the boundaries of their world.

Hypothesis 5, which posited a positive relationship between hedonic value and site commitment, is supported by a path estimate of .40 ($t=6.23$; $p<.001$). Similarly, Hypothesis 6, which posited a positive relationship between utilitarian value and site commitment, is supported, with a path estimate of .52 ($t=6.12$; $p<.001$). These results suggest that consumers form a commitment to a site based on both kinds of value.

DISCUSSION AND CONCLUSION

Several implications arise from this study. First, the results confirm and further reinforce the notion that exploration plays a central role in providing consumers with shopping value. The strength of the relationship between exploratory potential and both kinds of value, and the absence of a direct relationship between sense-making potential and utilitarian value suggest that exploratory attributes are essential for consumers to draw value from their navigation. Exploratory potential, then, plays a significant role in producing shopping value, and may be thought of as the 'killer attribute' of retail websites. Thus, exploratory potential is the most strategic attribute of retail websites, because by producing shopping value, it creates commitment to the site.

Exploratory potential was found to reflect both spatial exploration and informational exploration attributes. Exploration applies to both the virtual environment and to product-related information. The internet, with its unique characteristics, presents marketers with different opportunities to create a shopping environment and manage product communication, which are equally worth exploring. Online, products can come to life through telepresence (Steuer, 1992); for the first time in consumers' lives, all sources of information they value most (personal, marketer, opinion formers, other users) are available at once; the quantity of information is potentially quasi-unlimited, and it can be searched effectively. The potential for the exploration of online shopping environments can

only grow, as technology and increasing bandwidth provide more ways to bring environments and products to life.

Second, the study found that hedonic value and utilitarian value contribute to site commitment in similar proportions. This is an important finding because although the utilitarian benefits of online shopping are well known (e.g. convenience, absence of crowding, access to more information and access to a wider product range), and the limitations of virtual experiences compared to direct ones have been considered (Grewal, Iyer, and Levy, 2004), online shoppers nevertheless appear to place a high value on hedonic factors when considering their future relationship with a retail website. Online also, the ability to stage intrinsically rewarding experiences is likely to be a source of competitive advantage (Pine and Gilmore, 1998). Marketers' ability to provide, on each visit, a shopping experience which produces high levels of both hedonic and utilitarian value is especially important online where, unless they form the intention of returning to a site during a navigation, shoppers are unlikely to 'stumble into it' again with the ease one stumbles into a store in the high street or a mall.

Managerially, the model developed and tested implies that a major concern of online marketers should be to create and design retail websites which facilitate exploration. The model also suggests ways in which they can manipulate the design of their websites to produce stronger customer commitment. In particular, exploratory potential, which is central to gaining consumer commitment to the site, was found to concern both the shopping environment itself, and the product information. Consequently, as they work closely with IT and design professionals, marketers can use these concepts to ensure that the results of site development or re-designs do indeed result in higher perceptions of exploratory potential. As technology evolves, they will have to keep finding new ways to facilitate the exploration of their online environments and of their products and information.

The study's results need to be considered in the context of its limitations. First, the use of a convenience sample of university students and staff limits the generalizability of its findings. Students have been exposed to virtual environment for a higher proportion of their lives, and are more computer literate and avid online shoppers than average consumers (Marsh, Case, and Burns, 2000). In this respect though, they are perhaps more representative of tomorrow's consumers, and should be a prime concern to marketers, as they consider the future of online retailing.

Second, due to their age and lighter time pressures, students may also have more exploratory behavior tendencies. This could have raised the observed levels of hedonic value. Further research could consider the possible moderating effect of exploratory behavior tendencies. Baumgartner and Steenkamp (1996) have found that both exploratory information seeking tendencies and exploratory acquisition of product tendencies affect actual exploratory consumer behaviors. This begs the question of whether these two constructs moderate the relationship between sense-making and exploratory potential (consumers with high levels of exploratory behavior tendencies may seek and therefore be able to identify exploratory cues more proficiently than others), or between perceived exploratory potential and hedonic value.

A third source of vulnerability lies in the single context (online bookstores) in which the measures and overall model have been developed and tested. Replication applied to a different product category might return different strengths in relationships. In particular, exploratory attributes may have less importance on websites selling less gratifying product categories such as groceries or computer accessories. However, because all online shopping necessitates exploration to move from one webpage to another,

exploratory potential is expected to remain a crucial attribute of all retail websites.

A further avenue for future research would be to establish whether, when consumers are in a hurry to make a decision, exploration may be a hindrance. Offline, Chernev (2006) found that, while consumers relish the flexibility offered by large assortments, they are more confident—when the time comes to make a choice—when choosing among smaller assortments. However, it is possible that the manner in which information is stored, searched, sorted and categorized online, can assist consumers in making sounder decisions among larger assortments, by reducing the amount of cognitive processing required to compare between items of a similar nature. There may also be circumstances when the relationship between sense-making potential and exploratory potential does not exist or, even, is reversed. For instance, in the case of highly technical or really new products, one could conceive that making sense of the site and its information is the result of exploring it more.

Fourth, while the use of an ex post facto design precludes any claim of causality, a number of measures were taken to limit the influence (confound) of extraneous elements—the respondents navigated the same site, at the same download speed, with the same browser display and for the same duration. Nevertheless, a true experimental design would be useful to study the impact of cue manipulations on consumer responses.

Importantly, in view of the central role played by exploration in online shopping behavior, the concept requires further theoretical development. A qualitative approach would be useful in further understanding and distinguishing between different exploration situations during the course of an online shopping navigation. Observational methods, for example by tracking the different pages visited during a single shopping navigation, could help researchers understand consumers' trajectories during a shopping navigation, and perhaps associate different types of trajectories with distinct behavioral outcomes. Further research is also needed, to extricate the possible role of such phenomena as learning, internal information search, information overload, on the relationship between exploratory potential and site commitment.

By highlighting the central role of exploratory potential in committing consumers to a site, a major contribution of this study is to draw attention to the integrating role of exploration in online shopping, and re-focus the main challenge of online retailing as the design of virtual retail environments and the communication of product information in a manner which invites exploration. The consumer behavior literature, which so far has focused mostly on goal-directed search (Janiszewski, 1998), will need to turn its attention towards the exploratory manner in which online, goal-directed shoppers and browsers alike shop and search for products and information. This will become especially important if consumers keep using the internet as part of a cross-channel strategy (Muse, 2006).

In conclusion, this study has revealed, and its findings further emphasized, the central role played by exploratory potential as it increases commitment to a retail website by producing both hedonic and utilitarian value. Further research on the exploratory potential of retail websites holds a great deal of promise, since one can only assume that the constantly evolving technology will provide ever more opportunities and novel ways for retailers to increase the potential for exploration on their website. Furthermore, as internet speeds increase and internet use becomes more widespread and more second-nature to consumers (as the young 'generation internet' comes of age and becomes the consuming majority), the relative importance of sense-making and exploratory potential

is likely to irrevocably and permanently tilt towards exploratory attributes.

APPENDIX
MEASURES USED IN THE MODEL AND THEIR PSYCHOMETRIC PROPERTIES

Construct/item wording	CR	AVE	Completely stand. loading (t-value)
Visual impact-4 items	.87	.63	
The website had a visually pleasing design			.86 (t=12.70)
This website was dull visually (R)			.82 (t=12.11)
The website was aesthetically appealing			.82 (t=12.25)
This site had no visual impact (R)			.67 (*)
Experiential intensity-4 items	.79	.48	
This website replicated the kind of experience I have when I shop			.69 (t=9.31)
The experience of shopping was not there when I navigated on this site (R)			.75 (t=9.89)
When I navigated this website I felt I was shopping for real			.71 (t=9.50)
This website was incapable of reproducing the experience of shopping (R)			.62 (*)
Marketer informativeness-5 items	.82	.49	
There was enough information on this website to assess the products			.57 (t=9.89)
I could learn a lot about the products			.64 (t=11.42)
The information on this website was helpful			.73 (t=13.39)
The information on this website was useful			.71 (t=12.89)
This website adequately met my information needs			.81 (*)
Non-marketer informativeness-3 items	.81	.59	
This site had customer reviews of products			.82 (t=12.14)
From this site it was impossible to see what other users thought of the products (R)			.70 (t=11.25)
This website only gave me its own product information, and not other users' impressions (R)			.79 (*)
Page clarity-3 items	.86	.68	
There was too much text on the screen (R)			.86 (t=16.53)
There was an awful lot of things on every page (R)			.75 (t=14.18)
The pages on this website were too crowded (R)			.85 (*)
Site architecture-6 items	.86	.51	
During the navigation, I felt confused (R)			.70 (t=11.16)
I felt lost on this website (R)			.67 (t=10.81)
My interaction with this website was clear and understandable			.73 (t=11.59)
The web pages were easy to read			.69 (t=11.01)
The content on this site was clear			.77 (t=12.20)
The organization of the information presented on the screen was confusing (R)			.71 (*)
Utilitarian value-4 items	.79	.49	
I accomplished just what I wanted to on this navigation			.76 (t=8.23)
I couldn't find what I really needed on this website			.79 (t=8.36)
While shopping I found just the item(s) I was looking for			.71 (t=7.99)
I was disappointed because I would have to go to another site to complete my shopping (R)			.49 (*)
Hedonic value-6 items	.88	.55	
The navigation on this website was truly a joy			.78 (t=13.88)
Shopping on this website truly felt like an escape			.77 (t=13.71)
I enjoyed this navigation for its own sake, not just for the items I may have purchased			.66 (t=11.43)
I had a good time on this site because I was able to act on "the spur of the moment"			.74 (t=13.12)
During the navigation I felt the excitement of the hunt			.74 (t=13.15)
While shopping on this site I felt a sense of adventure			.77 (*)

APPENDIX (CONTINUED)
MEASURES USED IN THE MODEL AND THEIR PSYCHOMETRIC PROPERTIES

Construct/item wording	CR	AVE	Completely stand. loading (t-value)
Site commitment–7 items	.94	.70	
I will visit this site first when I want to buy books			.79 (t=12.97)
I plan to use this website in the future			.91 (t=14.71)
I intend to continue using this website in the future			.94 (t=15.22)
I expect my use of this website to continue in the future			.91 (t=14.79)
I am unlikely to use this website again (R)			.78 (t=12.75)
I will recommend this site to other people			.82 (t=13.37)
I would have only good things to say about this website			.69 (*)

$\chi^2=1,259.50$, $df=783$ ($p=.000$); $RMSEA=.045$; $CFI=.98$; $n=301$

Culinary Culture, Gastrobrands and Identity Myths: ‘Nigella’, An Iconic Brand in the Baking

Paul Hewer, University of Strathclyde, UK
Douglas Brownlie, University of Stirling, UK

INTRODUCTION

“They say that stars give you something to dream about...[the] screen idols are immanent in the unfolding of life as a series of images. They are a system of luxury prefabrication, brilliant syntheses of the stereotypes of life and love. They embody one single passion only: the passion for images, and the immanence of desire in the image. They are not something to dream about; they are the dream. And they have all the characteristics of dreams” (Baudrillard 1988, 56).

In his perceptive and persuasive rendering of the nature of consumer society and its obsession with fame and celebrity, McCracken (2005) states that “the celebrity world is one of the most potent sources of cultural meaning at the disposal of the marketing system and the individual consumer” (ibid, 113). Indeed, as Pringle (2004) so bluntly puts it, ‘celebrity sells’. While both authors transport us back to the 1960s and McLuhan’s powerful analysis of the “transforming power of media” (1964, 20), Pringle offers a managerial take on the growing complexity of the media environment, where media fragmentation, global reach and the explosion of celebrity culture go hand in hand. Olsen (1999) trenchantly observes that by virtue of the global distribution of its manufactured media product, the US Film and TV media industry is effectively assembling a “Hollywood Planet”. Pringle takes the view that “the celebrity phenomenon has largely been created by [US] movies and television [although] there is no doubt that other media have play[ed] a significant part” (ibid, 10).

To consumer researchers it will come as no surprise that, while generating enormous growth in the demand for media content, rapidly circulating flows of mass media product have bombarded us with stories and images of many manufactured celebrity figures. But, by adding to the growing media clutter, this has made it increasingly difficult for brands to gain and hold consumer attention. In what he terms the ‘era of consent’, where brands increasingly need consumers’ permission to communicate with them, Pringle (2004) concludes that commodity celebrities “who themselves have a high standing in the public eye, [provide] one of the more powerful tools for brand [building]” (ibid, 50). Hence, equally unsurprisingly, building brand visibility through harnessing the ‘cut through’ of celebrity iconography continues to make sound commercial sense.

Paradoxically, while celebrity ‘product’ feeds off fame, it is also embedded within the constitutive logic of promotional culture, for which exposure to the glare of media attention is a mode of economic production (Wernick, 1991). It recursively organises the conditions of possibility of celebrity, not merely as media product and content, but as a medium of communication. And if the message or meaning content is celebrity, while the medium is also celebrity, we then have an example of McLuhan’s pronouncement that “the medium is the message” (1964, 13). This is also an instance of what Baudrillard refers to as ‘the implosion of meaning’, where the message and “all the contents of meaning are absorbed in the dominant form of the medium. The medium alone makes the [communications] event-and does this whatever the contents” (1983, 100). In more prosaic words, commodified celebrities, whose fame derives from carefully calculated media activity and self-presentation, must also manipulate media attention to develop and sustain the visibility and viability of their own marketplace

visibility and viability. Celebrity may be commonly understood as a highly prized, if fleeting, condition that attaches itself to an object of media attention, but as Cashmore and Parker (2003) advise, “...it is [the] commodification of the human form [...] the process by which people are turned into “things”, things to be adored, respected, worshipped, idolized, but perhaps more importantly, things which are themselves produced and consumed” (ibid, 215). The celebrity of celebrity and its product, celebrity, function in fiercely contested cultural domains where competing celebrity brands nurture the visibility of their visibility, while leveraging it to penetrate the ambient noise of competing media products. Thus are the thematic features of the celebrity and the *celebritized*¹ brand not only the product of careful composition and premeditation, but of recursively organized modes of production built around everyday conventions that articulate celebrity, so giving a media object meaning within specific social relations. So, as the opening extract suggests, celebrity is not simply something to dream about; it is the dream.

Pringle (2004), like Rein, Kotler and Stoller (1987) before him, situates managerial interest in branding technology in the device of personalization by means of which commodities come to acquire extraordinary, figurative meanings. Brand identity is made intelligible through the symbolizing capacity of consumers. This feeds into and off iconic media content that promotes chains of associations between face, figure and personality. McCracken (1989) describes as ‘meaning transfer’ the personification by means of which product properities become associated with desirable qualities of the commodified celebrity character. A process of appropriation takes place. McCracken’s argues that celebrities are “key players in the meaning transfer process” (2005, 112) and that “celebrity endorsement and the marketing system are cultural undertakings in which meaning is constantly in circulation” (ibid, 113). He sets out a three-stage process through which “culture and consumption interact to create a system of meaning movement [whereby] some of the meanings of the celebrity [become] the meanings of the product” (1989, 314). Sternberg (1998) describes this transfer as ‘iconographic work’, where, through a combination of facial expression, costume, bearing, gesture, voice and word,

¹We use the terms *celebritized* and *celebritization* in this sense: that if we understand the brand as ‘media object’-the object or thing that is itself the product of media attention paid to it-an example of what Lury refers to as “*the broadcast distribution of commodities*” (2004,6); and the media object feeds off and into circulating cultural codes, unstable subject positions circulating around, eg, gender roles and identity, or in our case ‘domesticity’; and those subject positions are temporarily stabilized through the deliberate media manipulations of branding and personification; and where, as a media brand a subject position itself is framed and narrativised through the lens of celebrity iconography; then, the cultural logic of celebrity (including the celebrity of celebrity), organized recursively as a mode of production, works through discursive practices of *celebritization*. So, *celebritization* describes what happens when the logic of celebrity is exploited as a mode of production in the service of marketing ends. In this sense the cultural logic of celebrity (and of the celebrity of celebrity) is at the core of consumer society, for, as Warhol famously remarked in 1968, ‘in the future everyone will be world-famous for fifteen minutes’.

celebrities personify sought-after brand features or attributes. In another article, he observes that “everywhere we look, goods and services are suffused with images [and] capitalism is burgeoning from the calculated production of meanings” (1999, 3). Marketplace activity that draws upon cultural resources to ‘thematize a commodity’ so to heighten its meaning is understood by Sternberg as “iconic production” (ibid, 3). He argues that the activity of loading everyday consumer products with evocative meaning, with what Jameson (1991, 91) refers to as a ‘sign flow’ or ‘inner logic’, generates the brand content that animates desire. We suggest that if the commodified celebrity can be understood as a medium of translation, then the brand itself can be seen as a media object, an essential interface in the cultural logic of consumption.

The purpose of this paper is to explore ways in which celebrity functions as a mode of economic production whereby cultural resources, especially differentiating subject positions currently in circulation, are *celebritized* in pursuit of rhetorical appeal. We explore these issues through developing case material from an investigative site that consists of the branding of a celebrity chef through a collection of superior photographic print images situated within a contemporary ‘lifestyle’ cookery book. We take the photographic content of the cookbook, the representations of the commodified celebrity, as constructed spaces or environments with *celebritizing* characteristics.

Within the built environments of the photographic images we argue that representations perform iconographic work as spatialized forms of discursive practice, allowing us to explore the work of celebrity as the content of those images. In other words, the images make available for inspection models of *celebritized* social relations, in this case framed by the narratives into which particular representations of domesticity have been inserted. As in a previous study (Brownie and Hewer 2008) we investigate the mediating role played by the cookbook as cultural artefact, seeing it as a way of further circulating powerful cultural codes of masculinity in pursuit of commercial success. In the context of this study we focus on domesticity as an unstable symbolic form which is put to cultural work, appropriated towards the production of meaning and the amelioration of cultural anxieties within the landscaped environments of the images.

CCCT*2

Within discussions around CCT (Arnould and Thompson 2005) we note that the notion of celebrity seems curiously absent, with exception possibly of O’Guinn (1991) and Schroeder (2006). This strikes the authors as strange, given the fact that contemporary consumer culture is literally awash with commodified celebrity product (Wicks et al. 2007) labouring to help us fashion consumer selves with their wiles, charms and managed identities. To the list of celebrity feminine ‘cooks’-the term ‘chef’ reserved for their hypermasculine male counterparts-Martha Stewart, Elizabeth David, Fanny Craddock and Delia Smith, must surely be added that of *Nigella*, (to not italicize it would surely be a sin!). *Nigella* joins that long list of celebrity actresses: Marilyn Monroe, Rita Hayworth, Audrey Hepburn to name but three; and celebrity divas, Madonna and Kylie-all of whom exist in the hallowed territory of fame, celebrity stardom and fandom. Residing in a mythic land in which one’s surname becomes entirely unnecessary, redundant to communicate the appeal, magnetism and sway held and wielded by such iconic celebrity characters.

We argue in this paper that the iconicity of the *Nigella Brand* has as much to do with the *recipies* (Brownlie and Hewer 2008; Holt 2004) which it offers for rethinking feminine identities, domesticity and womanhood within contemporary consumer culture. Hence to explain the attraction, the constructedness of the *Nigella Brand* and

its marketplace appeal, we consider the cultural logic of celebrity, unpacking the role that celebrities play in assuaging doubts and managing cultural anxieties, what Holt (2004) refers to as “meaningful stories, myths that work as salves for contradictions in the nations’s culture” (ibid: xi). While we pay tribute to the insightful work of Holt (2004), especially his concepts of cultural branding and identity myths, in exploring the cultural meanings that celebrity brands circulate, we also recognise the significance of thinking of them as constituting a particular form of *Myth Today* (Barthes, 1985). In this regard, we also draw upon the inspirational work of McCracken who suggests that since “all of us labor to fashion manageable selves, it is inevitable that we should cultivate a knowledge of this [celebrity] world.” (1989, 318).

THERE’S SOMETHING ABOUT NIGELLA

“This is a book about baking, but not a Baking Book. The trouble with much modern cooking is not that the food it produces is not good, but that the mood it induces in the cook is one of skin-of-the-teeth efficiency, all briskness and little pleasure. Sometimes that’s the best we can manage, but at other times we don’t want to feel stressed and overstretched, but like a domestic goddess, trailing nutmeggy fumes of baking pie in her languorous wake...” (Lawson 2000, inset page to front cover)

The *Nigella* brand includes all manner of cookware items, from swanky red measuring cups to nifty serving hands, from cookie cutters to an all-purpose pot (well who needs lots of pots cluttering up the kitchen when you can have one), and a wipe-clean laminated shopping bag adorned with cocktails and delectable deli goodies, or as she explains on *Nigella.com* “I have a terrible habit of walking around town with tatty plastic bags and this is my attempt to rehabilitate in style. I can get a spare pair of shoes, books, magazines, emergency rations and the usual rubbish in here, and it actually looks good on the arm too: no more bag lady.” (*Nigella.com*, accessed 28/11/07).

This *Living Kitchen* cookware range is available globally from selected retail outlets. It generates annually more than seven million pounds. The product range is enlivened by a number of glossy-stylized cookbooks (Lawson 2000, 2001, 2007), which can be likened to the ‘How To’ manuals of yesteryear, presenting ready-made solutions or ‘salves’ to our cultural doubts and anxieties-like those of *How to Eat*, *How to be a Domestic Goddess*. This also includes a variety of TV programmes and accompanying books which are exported overseas, from those of the *Nigella Bites* (2000) era, to the most recent offering, *Nigella Express* (2007). Herein, viewers and readers are transported to that fantasyland where the impossible is made possible³-a land in which it is possible to not only *have your cake and eat it*-but a land in which we are drawn into a particular version of feminine identity, a branded subject position around which it is possible to do the cooking whilst caring for others, to give others pleasure, if that choice works for you. However, it is not necessary to be chained to the kitchen sink catering for the needs of others to feel loved, loving and needed. It is also possible to choose to care for yourself, say through taking trouble to feed yourself and choosing food you like rather than deferring to the choices of significant others. In constructing her version of the celebrity chef, pleasures of cooking, eating and caring

²CCCT, ie Consumer Culture Celebrity Theory!!

³For copyright reasons we are unable to reproduce the images from the book here. To view the images seek out Lawson (2007) or *Nigella.com*.

are linked in representations of domestic life which admit the importance of caring and hedonism to dealing with the conflicts and anxieties experienced by working women.

In Nigellaland we are transported to a magical place of plenty, a consumer culture where supermarkets reign supreme; a land in which you can literally *express* it all (but at a cost). This narrativization seeks to assuage any doubts or anxieties experienced by her cash-rich, time-poor, viagra-induced cosmopolitan constituency. This is a hegemonic land of taste and distinction (Bourdieu, 1984), where everybody has that most desired and cherished of kitchen adornments the salt pig (and it has to be full size measuring 16cm x 18cm), to those not in the know a pot for holding salt, but for Nigella aficionados this commonplace object is magically transformed through the story-telling capabilities of our 'brand author':

"I am a complete *Maldon* salt addict, and like to be able to keep my salt out at grabbable distance near the stove at all times. Again, the salt pig I own is functional, but no more, and I wanted one as a part of the range, one I really wanted to live with and take pleasure from just seeing it on the kitchen top."

Woodside et al. (2008) argue that storytelling plays a central role in how people relate to one another and that brands are important actors in the myths that inform such stories and move people to action. Building on this line of thought, we suggest that GastroBrands are thus constructed around their story-telling potential; stories which inevitably do a seamless job of promoting particular 'brand authors' in their pursuit of difference.

ALL ABOARD THE NIGELLA EXPRESS

All aboard the *Nigella Express* then, a homey spectacular realm in which the kitchen becomes a magical familial and social place. A site not simply for domestic toil and drudgery; but a space for self-fulfilment, emancipation, calculated hedonism and premeditated fun. Here we are being sold a particular version of commodified pleasure and liberation: where the gals all look great, even in the morning, and even when making the meals for her imaginary cosmo gastronista guests, for (yummy) dad and for the (yummy) kids. This is a magical liminal realm where the washing-up never needs doing; a land where the inevitable messiness of everyday living and cooking is banished never to be seen; a land where the clamouring pressures of kids and the daily grind of employment are remarkably and effortlessly erased. A glamorous and all too seductive version of femininity and homeyness then, where the mundane and ordinary are never allowed to set foot. Within this gastroporn vista the character of Nigella rules, as a celebrity we all love to hate. And perhaps it is this collectivized hatred that propels the brand and its all too seductive and sex-suggestive myths. In a contemporary consumerland where size zero's rule the celebrity zeitgeist, Nigella stands out in her all too retro-voluptuousness. For her 2000 cookbook offering *How to be a Domestic Goddess*, the inset pages contain golden-hued (sepia would be just too old-looking) images of what can only be likened to 1950's *Stepford Wives* revelling in the delights of taking the Sunday roast from the oven, exuding poise, grace and what can only be described as ecstatic delight at the marvels of deftly wielding a rolling pin and measuring milk from a *milk bottle* (and look what happened to those objects). The blurb for the book offering reads:

"This is a book about baking, but not a Baking Book. The trouble with much modern cooking is not that the food it produces is not good, but that the mood it induces in the cook is one of skin-of-the-teeth efficiency, all briskness and little pleasure. Sometimes that's the best we can manage, but at

other times we don't want to feel stressed and overstretched, but like a domestic goddess, trailing nutmeggy fumes of baking pie in her languorous wake..." (Lawson 2000, inset page to front cover)

So what the Nigella brand offers we might argue is a particular version of 'doing domesticity'; her currency and widespread appeal the result of the Nigella brands' ability to navigate, negotiate and even side-step tricky cultural and feminist contradictions, especially that of drudgery of the domestic sphere. Or as Nigella exhorts in the introduction for *How to be a Domestic Goddess*:

"I neither want to confine you to kitchen quarters nor even suggests that it might be desirable. But I do think that many of us have become alienated from the domestic sphere, and that it can actually make us feel better to claim back some of that space, make it comforting rather than frightening. In a way, baking stands both as a useful metaphor for the familial warmth of the kitchen we fondly imagine used to exist, and as a way of reclaiming our lost Eden." (Lawson 2000: vii).

Here the brand liturgy (in its earliest form) considers the salve (Holt, 2004) for the anxieties of domesticity as female identity to flow from the mythical craft and comforts to be had from baking and enjoying the fulfillment that comes from caring for others and giving them pleasure. In this manner, the success of *Nigella* the celebrity brand cannot simply be explained by recourse to her perceived credibility, or her trustworthiness, expertise, attractiveness, or even her beauty, as the Brand Management literature (Keller 2004: 376) would have us believe.

Rather the *Nigella* brand exploits multiple competing subject positions in circulation around the identity myth of domesticity. Representations assembled from those subject positions suggest a new narrative of domesticity for the time-starved, body-conscious, self-indulgent contemporary woman. Thus constructs a version for our post-feminist, post-gender, postmodern times that, while sounding overwrought and precious, also strikes an alluring and comforting note. That is to say, the *Nigella* brand does not simply reiterate such brand propositions and values. Rather it performs and enacts such propositions of culinary sexyness and culinary homeyness to thereby rolling-pin out any of the inherent contradictions of our mundane, firefighting, reality tv, work-obsessed everyday lives. The brand, especially in its later form, responds to such collective existential and ontological dilemmas over experiences of time scarcity and stress generated by juggling the roles of worker, wife, parents and yummy mummy (O'Donohoe 2007), to name but a few. Moreover, Nigella's celebritized brand of domesticity generates compensatory resources—Holt's salve (2004)—to help readers respond creatively to erasing the existential tensions and anxieties commonly experienced in their everyday lives. Suggestive perhaps of Baudrillard's (1988) notions of the constraint of pleasure and the view of consumption as a form of production (1988). The introductory blurb of the latest extension of the brand, the *Nigella Express* (2007) cookbook thus reveals:

"The Domestic Goddess is back but this time it's instant. Nigella and her style of cookery have earned a special place in our lives, symbolising all that is best, most pleasurable, most hands-on and least fussy about good food. But that doesn't mean she wants us to spend hours in the kitchen, slaving over a hot stove.

Featuring fabulous fast foods, ingenious short cuts, terrific time-saving ideas, effortless entertaining and simple, scrump-

tious meals, Nigella Express is her solution to eating well when time is short.

Here are mouthwatering recipes, quick to prepare, easy to follow, that you can conjure up after a long day in the office or on a busy weekend, for family or unexpected guests. This is food you can make as you hit the kitchen running, with vital tips on how to keep your store cupboard stocked, freezer and fridge stacked. When time is precious, you can't spend hours shopping, so you need to make life easier by being prepared. Not that the recipes are basic-though they are always simple-but it's important to make every ingredient earn its place in a recipe. Minimise effort by maximising taste. And here too is great food that can be prepared quickly but cooked slowly in the oven, leaving you time to have a bath, a drink, talk to friends, or do the children's homework. Minimum stress for maximum enjoyment..." (www.nigella.com/books/detail.asp?area=5&article=3510)

As a slogan for the brand 'Minimise effort by maximising taste' ain't a bad one. And seeking clarity through recourse to Bourdieu on habitus and social class, especially in his discussion over the role of the new petite bourgeoisie, we might suggest that an ethics of consumption is being enacted:

"Seeking its occupational and personal salvation in the imposition of new doctrines of ethical salvation, the new petite bourgeoisie is predisposed to play a vanguard role in the struggles over everything concerned with the art of living, in particular, domestic life and consumption, relations between the sexes and the generations, the reproduction of the family and its values...the new ethical avant-garde urges a morality of pleasure as duty. This doctrine makes it a failure, a threat to self-esteem, not to 'have fun'...The fear of not getting enough pleasure, the logical outcome of the effort to overcome the fear of pleasure, is combined with a search for self-expression and 'bodily expression and for communication with others ('relating'-exchange), even immersion in others (considered not as a group but as subjectivities in search of their identity)." (1984, 366-367).

This is perhaps why the naturalistic *denouement* for every TV programme always has to be the ritualistic display of food as a means for, what Maffesoli (1996) might refer to as, our *being-togetherness*-a culinary gift which makes material the ineluctable and ephemerality of the everyday as a form of *immersion in others*. Communicating and conveying those all-important ethical brand qualities of taste and distinction, but achieved with minimum effort and toil, justified and legitimated visually as doing one's bit for the greater good of others, especially the voracious gastronomists of dinner-partyland.

As a brand then, the Nigella Brand ain't that shy about coming forward; ain't that shy about maximising its brand assets (as they say in the Brand Management textbooks, cf. Keller 2004); ain't that shy about responding to any lingering doubts over the earlier *Domestic Goddess* message, with its all-encompassing, all-too-labour-intensive, back-to-the-kitchen mentality. But most importantly, the Nigella Brand works hard to enjoin us against the choices and dispositions of the *necessary*, an all too terrifying place signalled as Bourdieu suggests by a "resignation to the inevitable." (1984, 372). Instead, through living the *Nigella* way, we might say that the everyday becomes a site for the re-chantment of the labour of identity, pleasure and fun around an ethics of consumption and the all too consuming delights of the spectacular.

CELEBRITIES, FEMININITIES AND THE DRAMATISATION OF THE SPECTACULAR

Within the cultural studies literature on celebrities, Chaney (2002) argues that "celebrities work at the dramatisation of mundanity" (2002, 113). In this way such manufactured characters are said to embody that thin line between communicating and displaying, for all to see, the ordinariness of the everyday and the flight to the spectacular and extra-ordinary. In being able to blur this distinction then rests their appeal. Likewise, Bell and Hollows (2005) explore how celebrities (or 'lifestyle experts') take upon the role of "advising us on consumer choice—*interpreting* the lifestyle landscape for us rather than dictating how to live" (2005, 15, italics in original). They continue by suggesting: "Voice and manner are important here, too, in making expertise ordinary, which also means making it accessible and inclusive." (2005, 15). Perhaps this is why *Brand Delia*⁴ was doomed to fail for the late nineties and early noughties, as all too schoolmarmish, and all too hectoring Nanny Mummy. *Brand Nigella* also treads a tricky line here as a cultural intermediary. But it is clearly the case that her TV gastro-makeover programmes (as do the images within the book) work hard at the dramatisation of mundane spaces, such as the kitchen, garden and dining room table, coupling this with her own silky dulcet tones, cover-girl looks, friendly and flirtatious affectations which work hard to convey the possibilities of the spectacularity of the domestic sphere. In this light, it's useful to turn to Cashmore and Parker's (2003) assessment of the appeal of *Brand Beckham* as a bringing together of seemingly contradictory representations of masculinity "that contradicts, confuses and conflates all in one. He is 'new man' (nurturer, romantic, compassionate partner) and 'new lad'/'dad-lad' (soccer hero, fashionable father, conspicuous consumer—some would argue, all round, cosmetically conscientious 'metrosexual') while demonstrating vestiges of 'old industrial man' (loyal, dedicated, stoic, breadwinning)." (2003, 225). Perhaps we can say that the *Nigella* brand works in a similar way, syncretically blurring the distinctions, the apparent inconsistencies of traditional-stay-at-home-mummy (caring, pinny bedecked-homemaker), with professional-entrepreneurial mummy (smooth operator, woman-on-top, out-competing men), but also managing to conflate such modes of femininity with that of yummy-mummy (sexy, desirable, clad in designer-clothes).

Nigella also has the perfect credentials for that of a Celebrity Gastronista—a colourful and tragic past. Prior to publishing her swathe of cookery books (2000, 2001, 2007), as Nigella Lawson she was not only the daughter of the UK Chancellor of the Exchequer during the Thatcher years, Nigel Lawson, she was also the food writer for that ultimate fashionista publication *Vogue*. The death of her first husband, journalist John Diamond, and subsequent second marriage to Charles Saatchi is further evidence of her strong media appeal. Her continuing appeal is also assured in blogland, as the range of Nigella's books remain popular in those all-important Amazon reviews with *How to be a Domestic Goddess* scoring a cool 44 out of 51 reviews at the all-important Five Star level. *Nigella Express* appears less popular, but still 21 out of 38 reviews rated it at Five Star. One such review on Amazon.com is typical of most and suggests on the theme of Nigellahood:

"We all adore (or want to be) Nigella in our house! We love time spent fiddling around with a zillion ingredients, gallons of cream and a dozen eggs BUT this is fabulous too!!"

⁴Delia Smith is a well-known UK cookbook writer, whose most famous book *Delia Smith's Complete Cookery Course*, published originally in 1978, but since reprinted over 20 times stands not so proud on many a budding cooks' top shelf.

I have two children who love tasty food (who doesn't?) and I needed some new ideas for quick meals! You will find plenty of them in this book and your kids will love trying out some new flavours!! Popular with my two are the white bean mash, chicken schnitzel with bacon and green eggs and ham (frequently accompanied by the Dr Seuss story of the same name!).

Don't be put off by the "Express" element of the title! This is a great book with just enough Nigella chat to also make it a good read when you're not cooking." (<http://www.amazon.co.uk/Nigella-Express-Lawson>).

A review which 104 out of 118 fellow readers found 'useful'. Another reviewer was less popular and suggested a counter side to her appeal:

"Nigella herself is possibly the most irritating person on TV today-her simpering, her over-the-top adjectives and her ridiculous outings with her 'friends' who have obviously never set eyes on her before make me reach for the off button. BUT I have to admit that her recipes in this new book are terrific." (<http://www.amazon.co.uk/Nigella-Express-Lawson>)

For us, such vitriol and loathing serves to merely add more vitality and dynamism to the relationships (Fournier, 1996) and connections, consumers generate around the *Nigella brand*.

CONCLUSIONS

By way of a contribution we argue that what makes the *Nigella* brand phenomenon of interest to consumer researchers is not only that it employs circulating subject positions of domesticity and feminisms, but that it is playful with them. It self-consciously nudges away at their assumed limits, subtly disrupting uncontested norms, bending them ever so gently to the imperatives of wider contemporary debates about domestic lifestyles. And in offering resources to help undo, or at least resist embedded assumptions about socially acceptable forms of domesticity, we argue that the 'Nigella Express' cookbook also offers material that is suggestive of strategies for the transformative performance of domesticity. We find that the content of those strategies is generated by means of images informed by ideas that turn on the blurring of boundaries between the pursuit of pleasure through caring for others, and the pursuit of pleasure through caring for the self (which in some cases is achieved through caring for others); between the leisured self and the employed self; between the public world of the workplace and the intimate, private world of domesticity; between the stressed, time-short self and the self-indulgent self; between the controlled self and the decontrolled, calculated hedonist self; between self of deferred pleasures and the self of immediate gratifications; between the cooking as pleasure self and the cooking as additional hassle self. It is then possible to understand those images as sites for rethinking, not only how domesticity is performed, but also how we seek to fashion seductive representations of such conduct. Deeply rooted anxieties can surround the disruption of even apparently minor details defining social differentiation, especially fears over the balance achieved between restraint and self-indulgence, between giving and taking pleasure and what that might say about your ability to conduct yourself in a recognizably acceptable way within contemporary consumer culture.

Defining the Brand Hero: Explorations of the Impact of Brand Hero Credibility on a Brand Community

Toni Eagar, Australian National University, Australia

ABSTRACT

This article presents a definition of brand hero based on the literature surrounding celebrity endorsement with particular emphasis on source credibility and attractiveness. Three brand communities and their brand hero(es) were analyzed using an ethnographic-grounded theory approach. Findings indicate that brand hero credibility does not solely include expertness, trustworthiness and attractiveness but is complicated by the inter-relationship between the brand, community and hero to include the attributes of integrity and affinity. These are key constructs in the effectiveness of the brand hero in motivating the brand community to act for the benefit of the brand.

INTRODUCTION

While the nature of celebrity is often lamented in modern society (Caughey 1987) marketers have held a positive view of celebrities as potential tools for gaining and holding the attention of potential customers through a focus on celebrities as endorsers of a product or brand (McCracken 1989). However, there is a gap in the research in understanding the nature of brand community celebrities, which are people who are recognized by the brand community for their role within the brand's creation. This article seeks to offer an alternative perspective to that outlined by celebrity endorsement. Through the application of the source credibility framework a more comprehensive understanding of brand hero effectiveness is achieved. The difference in source and audience effects has a profound impact on the application of brand hero credibility. This article will define the concept of brand hero in order to understand the issues surrounding credibility.

THE LITERATURE

A feature of modern society is the rise of fan culture within popular media, which has led to an increasing interest in consumption related social networks, such as brand communities. A brand community is "a specialized, non-geographically bound community, based on a structured set of social relations among admirers of a brand" (Muniz and O'Guinn 2001, p.412). Brand community research has focused on how brand communities positively influence marketing outcomes in terms of brand commitment and meaning, and also for the consumer in the development of self and social identity (McAlexander, Schouten and Koenig 2002, Muniz and Hamer 2001, Muniz and O'Guinn 2001, Muniz and Schau 2005). However, while there has been acknowledgement that there are celebrity influences within a brand community (Belk and Tumbat 2005, Muniz and Schau 2005) there has been little research into the relationship between brand community members and these celebrity figures.

In contrast, there has been extensive research into the area of using celebrities to endorse a brand or product in marketing communications, specifically in advertising. McCracken (1989, p.310) defines a celebrity endorser as "any individual who enjoys public recognition and uses this recognition on behalf of a consumer good appearing with it in an advertisement". A basic assumption of this definition is that a celebrity's public recognition is developed separately from the brand and this recognition is then used to endorse a brand. From this assumption of externally developed recognition, celebrity endorsement research has focused on finding appropriate celebrities and presenting them in persuasive and

symbolically representative communications with the brand (McCracken 1989). This has overshadowed study of internally generated celebrities whose public recognition is tied to their role with the brand, thus issues of appropriateness and symbolic congruence are not relevant.

A number of endorsement roles that the celebrity can fulfill have been identified; (1) the celebrity is an expert; (2) is associated with the manufacturer in some long-term capacity; or (3) has no special knowledge, or association with, the product in question (Friedman, Termini and Washington 1976, McCracken 1989). The first role of celebrity endorser as expert can be applied to the brand hero. The brand hero derives their perceived expertise from their involvement in the creation or production of the brand. However, the literature in celebrity endorsement tends to use examples of experts external to the brand, such as a racing car driver endorsing motor oil (McCracken 1989), where their perceived expertise is a consequence of their profession and would impart knowledge about motor products. The second role of the celebrity endorser in association with the manufacturer in a long-term capacity also can be applied to the brand hero concept. For example, singer Kylie Minogue has a long-term relationship with lingerie maker Holeproof in a capacity of designing a range of co-branded lingerie; she doesn't just endorse the product but is involved in its creation. In terms of brand heroes where the brand is the sole creation of that celebrity the association between the celebrity and the manufacturer is indelibly linked. However, not all brand heroes require a long-term relationship, for example, a director may have only worked on one Star Trek movie to be considered a brand hero for the Star Trek brand community. The third role includes only celebrities well-known from external sources, which does not fit within the brand hero concept (McCracken 1989), examples of this include Christina Aguilera and LL Cool J, both singers, appearing in television commercials for Virgin Mobile. Neither celebrity has a special association with the brand through expertness or through a long-term association, as these were one-off appearances. This final role has no equivalent to the concept of brand hero, where the core assumption is some special association to the brand in a capacity internal to the creation or production of the brand.

There have been three main approaches to celebrity endorsement developed. The first two approaches are similar in their application and rely on the target market viewing the celebrity as either a credible source of information or as an attractive source. The third is referred to as the 'meaning movement' approach, where a celebrity is an appropriate endorser when there is congruence in the symbolic images evoked by both the celebrity and the brand. The 'meaning movement' approach may be of importance in understanding the effectiveness of a brand hero, but it is beyond the scope of this article. Source credibility states that the celebrity will be viewed as a credible source when it is perceived that celebrity has the ability to make valid assertions (expertness), and a willingness to make valid assertions (trustworthiness) (McCracken 1989). Source attractiveness has been considered as a separate factor in explaining source effectiveness (Kahle and Homer 1985) or as an additional component of credibility (Kamins 1990). Attractiveness as an indicator of credibility is considered the most appropriate conceptualization, as the focus for brand heroes is not physical attractiveness, but rather their attractiveness is a function of their contribution to the brand's success. However, the nature of brand

FIGURE 1
CASE SELECTION CRITERIA AND CASE SITES SELECTED

	Single Brand Hero	Multiple Brand Heroes
Single Role	Discworld	The Brumbies
Multiple Roles	\	Star Trek

hero credibility is somewhat different which will be explored further in the findings section.

The definition of celebrity does not fully encompass the brand hero concept, as the special association the brand hero has with the brand means that other factors beyond mere recognition are present. The definition that is most widely used is “celebrity is a person who is known for his well-knownness” (Boorstin 1964, p.57). In particular, the key-determining factor of a brand hero being influential in a brand community is their perceived credibility with the brand and the community. However rather than being limited to expertness, trustworthiness, and attractiveness, for the brand hero, credibility takes on additional dimensions as the relationship between the brand, brand community and the brand hero create a more complex relationship of perceptions than the simple brand-endorser memory matrix proposed by McCracken (1989). The findings presented will discuss how current definitions of endorser credibility apply to the brand hero context. Also, credibility will be extended to include the added complexity of the brand community situation and the effect this has on brand community outcomes.

METHOD

The objective of this article is to define the concept of the brand hero and the outcome of credibility on brand hero effectiveness. A qualitative approach was applied as the nature of understanding brand hero credibility is exploratory. Both the grounded theory approach, particularly the principles of building theory from data through constant comparison and theoretical sampling (Glaser and Strauss 1967), and ethnography, and its concern for culturally based patterns of behavior (Goulding 2005) were applied in this research. Theoretical sampling of cases was conducted for analysis (Glaser and Strauss 1967), where sampling was based on a single/multiple role by single/multiple brand hero matrix, with three sites selected that are discussed below, see Figure 1. The analysis method applied was derived from grounded theory, with data being open-coded, then built into categories that through systematic comparison were developed into theoretical constructs and relationships.

Site 1: Discworld

The principal site of investigation was the Discworld brand community. Terry Pratchett as the author of Discworld books represents a single brand hero with a single role. Discworld is a fantasy-comedy series that has sold over 40 million books worldwide. There are 38 books, aimed at adults, in the series. Data collection was ethnographically based with the researcher forming an embedded role in online and real-world Discworld communities. This involved participant observation in online forums and real-world conventions, and in-depth interviews with brand community members and Terry Pratchett

Site 2: The Brumbies

The Brumbies are a rugby union team that competes in the Super14 competition comprising teams from Australia, New Zealand and South Africa. The Brumbies have multiple brand heroes that perform a single role as players. Data collection involved participant observation of fans at games held in Canberra, Australia over a three-year period.

Site 3: Star Trek

Star Trek has multiple brand heroes who have multiple roles from actors, directors, authors and creators of the television series, books and movies. Star Trek is one of the most successful television science fiction series ever, with continuous production of Star Trek related entertainment since the sixties. Data collection was non-participant in nature and involved analyzing the question and answer sessions that were held online at the official Star Trek website (www.startrek.com) between community members and various Star Trek celebrities.

WHO IS THE BRAND HERO?

The different sites of investigation underlined the differences that exist between the traditional conceptualization of the celebrity endorser credibility and how credibility is applied to brand heroes. Figure 2 shows the attributes of the brand, the brand hero and the

FIGURE 2
THE ATTRIBUTES OF BRAND HERO CREDIBILITY

brand community that combine to create brand hero credibility. The findings suggest that while the brand hero needs to be seen as an expert and trustworthy, these concepts take on different dimensions in the brand hero context as the brand hero is placed within the milieu of the brand community. As the relationship is more complex there are also additional dimensions to brand hero credibility that will be presented. The findings from the analysis of the different brand community sites indicate that credibility is extended through brand hero integrity and affiliation.

Brand Hero Integrity

The research revealed that for the brand community one of the key brand hero attributes was integrity. The celebrity endorsement literature refers to source credibility in terms of expertness and trustworthiness. Expertness is defined as the perceived ability of the celebrity to make assertions about a product, and trustworthiness is the perceived willingness of the celebrity to make valid assertions (McCracken 1989). These definitions have an underlying assumption that the celebrity's credibility is based on their activities external to the brand, which is then matched-up to the brand and the message (McCracken 1989). Such an assumption does not take into account the credibility that a celebrity might attain through their association with the brand. For instance, Terry Pratchett the brand hero to the Discworld brand community hardly needs to establish his expertness in the Discworld brand or in the fantasy literature product category as his creation of the brand itself has established his legitimacy. When respondents were asked whether they believed Terry Pratchett was a celebrity the responses were mixed but respondents referred to his credibility as an author and his integrity as a representative of the Discworld brand.

“Yes essentially Terry Pratchett is a giant of literature, he’s a god. There’s nothing else you need to say about Terry Pratchett in my mind he’s a giant of literature he’s something out there, I don’t need him in my life, he’s there. His books are in my life and occasionally I go to his lectures and go ‘oh wow this is fascinating’ it really is.” (Chris, Personal Interview)

The statement by Chris indicates that Terry Pratchett’s credibility is enhanced because of his perceived status in the product category. One of the core aspects of brand hero credibility is the belief that they represent the top of their field. This status in the field is often expressed in comparative terms between competing brands and brand heroes.

“I completely agree with what Terry Pratchett says. Sorry, but JK is not the only author in the world, and she’s a long way short of the best authors around. I am a big Harry Potter fan, but she in no way compares to the Discworld series. She has only wrote one series of books about one main group of characters, and it will be interesting to see where her writing goes after here. Will she be able to take the world that she has invented for HP and write about different people, or will we be stuck with the same people & personalities. Pratchett’s discworld series has many different characters with different stories that all somehow complement each other. You very rarely meet a character that you feel you have already encountered in a different person. Lets just look back in twenty years, and see whether there is still such a great demand for the discworld series, & discworld memorabilia, and compare it to how JK is doing.

Mind you, the Harry Potter books are so similar to the star wars series, that maybe we’ll be up to the prequels by then!!!” (Harry Potter Forum post in TP vs JKR Thread)

For the Discworld community, as a smaller brand in the market, most of the comparisons are made with the largest brand, Harry Potter (Muniz and Hamer 2001, Muniz and O’Guinn 2001). When comparing Terry Pratchett’s status to J.K. Rowling the consensus of the community was that he was the better author and deserved more success but that J.K. Rowling was an adequate author who had won the ‘lottery’, as one online member described it. So for the brand hero the issue of expertness not only depends on their ability to make assertions but also on their perceived status within the product category based on their contribution to the

brand's success. This linking of expertness to the brand's success is also present in understanding the notion of trust in source credibility.

"He doesn't strike me as a kind of arrogant celebrity and I think he would be interesting. I think he writes books because he genuinely wants people to read them not because he's cashing in. I don't get that impression, I don't think he could write the books as well as he does if he was just going: 'Right, I could do with another half mil so you know I'll churn another one out'. I think he genuinely wants you to read them. If you're intelligent you realize that if you're going to make money out of people they're going to have some demand on you." (Tegan, Personal Interview)

For Tegan, Terry Pratchett represents someone who is credible because his motivation for producing Discworld is a love of the brand and the fans. This perception imbues a great deal of trust in Terry Pratchett's management of the brand. Other respondents referred to the notion of 'selling out' and that Pratchett never would, an example of this is in the denial that any Discworld figurines would ever be sold at McDonald's as Happy Meal toys. There was vehement denial that Pratchett would ever allow his brand to be used in such a way, one respondent said that he would have to be 'dead and buried, very dead and very buried before Discworld would be sold out' (David, Personal Interview) and even then another respondent believed that Pratchett's wife and daughter would not 'sell-out' the brand in this way as 'they love it too much' (Sandra, Discworld Convention). The belief that the brand hero creates and manages the brand for the benefit of the brand and its values underpins perceptions of brand hero credibility. So for the brand hero, credibility is defined as the perceived integrity of the brand hero in maintaining the brand's values.

Brand Hero Affiliation

Besides the integrity of the brand hero in maintaining the brand's values another aspect of brand hero credibility related to their attractiveness to the brand community. Source attractiveness as a component of credibility refers to the celebrity's perceived familiarity, likeability and similarity (McGuire 1985). In terms of the brand hero the most salient attractiveness dimension was similarity, where the brand hero had to demonstrate a similar sense of being affiliated to the brand and the community as that felt by the brand community. Familiarity and likeability were not useful constructs in the brand hero context, as familiarity was a part of the brand community experience and likeability was based on a sense of affinity, so they are not covered further. Similarity of perceived affinity was achieved in two ways, (1) the demonstration of a long-held affinity to the brand, and (2) the appearance that the brand hero was just another fan. In order for the brand hero to be accepted by the community the brand hero needed to show that on some level they were 'just like the community members'.

In the first instance when a potential brand hero was presented to the community the brand hero was required to demonstrate that they held the similar affinity with the brand as that of the brand community. This was prevalent in the Star Trek brand community where there are a number of brand heroes who perform different roles within the brand. A case that demonstrates this was the Question and Answer (Q&A) session held between the online Star Trek community and the director Robert Wise. This brand hero only had one instance of contributing to the Star Trek brand through his direction of the first Star Trek movie. Many of the questions asked of this brand hero revolved around Robert Wise establishing his credentials as a Star Trek fan.

"Had you ever seen any "Star Trek" show before Paramount asked you to direct the Motion Picture?" (Romain NIGITA, Robert Wise Q&A, 02.05.2004)

"Mr. Wise, did you have anything to do with the 1983 TV version, aka the Special Longer Version? Did you re-edit the film specifically for television and video? What prompted the 1983 longer version? Thanks," (James B., Robert Wise Q&A, 02.05.2004)

As Robert Wise had only a brief association with the Star Trek brand the questions that the brand community asked him revolved around his work in the brand and his history with the Star Trek brand. In this Q&A session only one question was asked about Robert Wise's career outside of Star Trek, this in contrast with Leonard Nemoj (Dr. Spock, a long running character from the original television series and movies) where half the questions asked concerned his life outside of Star Trek, with questions such as:

"Your voice talent is excellent. Will we be seeing more voice work from you?: (designationlocutus, Leonard Nemoj Q&A, 03.04.2003)

"As a writer and advanced amateur photographer myself for many years now, there are many questions I would like to ask you about your passion for still photography, culminating in your latest, and remarkable, "Shekhina" project. For example, how did your interest in photography evolve, and did you begin with 35mm?" (gundar Leonard Nemoj Q&A, 03.04.2003)

This was interpreted to indicate what Leonard Nemoj had already established his affiliation with the Star Trek brand and as such the community did not need to ascertain his commitment to the brand. The less the brand hero is viewed as having a similar affiliation to the brand the more likely the brand community is to attempt to establish this credibility. So for Robert Wise, who had little long-term affiliation with the brand there was a need to establish the perception of him being committed to the Star Trek brand. Whereas, a brand hero like Leonard Nemoj with a long history of Star Trek involvement did not need to establish his brand affiliation.

The second aspect of brand hero affiliation is the appearance the brand hero is just another fan. This goes beyond merely establishing an affiliation for the brand as discussed previously, but includes those aspects of brand community involvement that define membership activities. For example, Terry Pratchett was considered a credible Discworld community member because he would behave just like any other fan at community events.

"Now, the question is, why does he do it? Why give up three days of precious free time to spend them in a field with people who would buy your books anyway? Even if it did increase sales, the amount would be a drop in the ocean compared to what he's selling already. So I'm left with the notion that he enjoys it. He walks around, chatting to fans, occasionally being photographed but not, I hope, being hassled too much. He doesn't appear to have an entourage (we saw him walking down from the top barn to his car on Sunday morning, presumably to pick up something) or to have any security worries (if he had any 'mindes', they were very well hidden) and because he acts like a 'regular person', that's how he gets treated. It might be that he feels he 'owes' it to the fans to turn

up at events like this. In the Q&A, he was asked whether he was going to be at the Australian Convention, and after saying that the date had been changed a couple of times already, he said that whatever date it finally ended up on, he'd be there, because "they've gone to so much trouble" (and that he never misses a chance to go to Australia). I don't know of any author with a comparable level of sales who gives so much time to keeping fans happy." (Diane L, alt.fan.Pratchett, 05.08.2005)

For this Discworld brand community member they perceive that Terry Pratchett is motivated by enjoyment of fan contact rather than by commercial concerns. In her mind this gives added credibility and appeal to Pratchett as a brand hero. The 'regular person' aspect of his credibility presents a persona that the brand community is able to identify as someone similarly committed to the community and the brand. This was also evident in the Brumbies case where the captain, Stirling Mortlock was sidelined due to injury. He demonstrated his commitment to the brand by acting as the waterboy for half the team's season. He also demonstrated an affinity for the community while being the waterboy by interacting with the crowd. For example after an apparently incorrect line call the following exchange occurred:

"Ref are you blind?!" Male 20s
 "Ref you can borrow my glasses if you like!" Male 40s
 "This guy is useless, isn't he?" Stirling Mortlock to the men yelling
 "You should get out there, Waterboy! We need you!" Male 20s

Such exchanges create a sense of the brand hero being on the same side as the brand community, that they are all working together for the benefit of the brand. A similar affinity was found in the Star Trek community:

"What can the fans do to help get more publicity for *Star Trek: Enterprise*?" (Pam, Scott Bakula Q&A, 19.11.2003)

This apparent sense of affinity of the brand hero for the brand community and the resultant expectation from the brand community that they are working with the brand hero for the benefit of the brand is a crucial function of a brand hero. While the celebrity endorser is attempting to persuade the audience (McCracken 1989) the brand hero is attempting to motivate a communal effort between themselves and the brand community for the benefit of the brand. The broader scope of brand hero credibility, that extends to encompass aspects such as integrity and affinity are important considerations in developing effective marketing strategies using a brand hero to communicate to a brand community. The implication of these findings will be discussed in the following section.

IMPLICATIONS AND FURTHER RESEARCH

The results of this research indicate that while the celebrity endorsement literature offers a key foundation in the consideration of the brand hero concept it does not fully encompass the phenomenon. While brand heroes display some similarity to celebrities in their attributes to celebrities these are influenced by the more complex nature of the interaction between the brand, the brand community and the brand hero. This apparent feedback in effects offers an alternative perspective for the study of celebrity endorser effectiveness, which would be a valuable addition to the increasing amount of research in the 'meaning movement' approach (McCracken 1989). McCracken (1989) proposed transference of

meaning between the celebrity and the brand, however, the current research suggests that the transference may be two-way and include social or group meanings. Further research is needed to analyze reciprocity in meaning transference and the effect that social/group meaning has on this relationship.

The definition of the brand hero is distinct from celebrities, as brand heroes are well known by the brand community for their role in the creation, production or consumption experience of a brand. This is in contrast with the common approach to celebrity as something that happens separately to a brand. The findings show that the brand hero has a great deal of influence in providing the motivation for the brand community to engage in behaviors for the benefit of the brand. This sense that the brand hero and the brand community are working together for the continued success of their brand is something that has been alluded to in previous research (Belk and Tumbat 2005, Muniz and Schau 2005), however, it is something that requires further research. This communal effort goes beyond simple persuasion or communicating with the brand community but may form a fundamental core of social identity, where a brand hero may be the most effective tool a marketer could use in developing and maintaining a group of highly committed customers.

The concepts of expertness, trustworthiness and attractiveness as indicators of source credibility are adapted and extended to include brand hero integrity and affinity in the brand hero context. The additional concepts of integrity and affinity are important considerations. The brand hero needs to represent themselves as a symbolic agent of the brand and community's values. Further research is needed on how marketers can build this brand community celebrity, in particular how do you build celebrity for a brand hero while emphasizing the brand hero's credibility? The notion of 'selling out' is inherently anti-corporate or anti-marketing, marketers need to understand how they can create integrity and affinity without creating the perception of 'selling out'. A starting point for this research would be in defining the term 'selling out' and under what conditions the perception of 'selling out' occurs.

Additional research is also required into the effect that brand heroes have on brand community outcomes. This research indicates that being perceived as credible leads to the perception of a communal effort to advance the brand. Important areas of study would be in the nature of the relationships formed between the brand hero and the brand community and an investigation into the effects on community identity and involvement. This additional research would assist marketer's in understanding the nature of the brand hero as a brand community communication source and also the limits that marketers have in controlling the brand hero and in turn the brand community.

The research is limited by the three cases chosen, which represent certain types of brand communities and brand heroes. Further research is needed to ascertain whether the influence of a brand hero is community or hero determined, and a wider selection of brand community sites is required to achieve this. This study is further limited by not including the 'meaning movement' hypothesis in defining brand hero effectiveness. While the current study focused on brand hero credibility, further research into the symbolic transfer of meaning between the brand and the brand hero would be a valuable and interesting extension of the current study. However, understanding the nature of brand hero credibility, in terms of integrity and affinity, is important to our knowledge of the brand community phenomenon. Brand heroes are influential tools in the creation and management of social networks around consumption objects.

When the Brand is Bad, I'm Mad! An Exploration of Negative Emotions to Brands

Simona Romani, DEIR, University of Sassari, Italy

Hamdi Sadeh, Al Quds Open University, Palestine

Daniele Dalli, DEA, University of Pisa, Italy

ABSTRACT

This paper attempts to identify the nature and characteristics of individual negative emotions to brands and the antecedent conditions which affect them. Using introspective essays with consumers in two very diverse cultural contexts (Italy and Palestine), our findings reveal that the negative emotions of dislike and anger are experienced to a much greater extent than others, such as sadness, fear, disappointment. At the same time, we observed the presence of three conditions which consumers focus on and react to in the context of brand, noting that these systematically relate to specific negative emotions.

Lastly, we examined the consistencies and differences between our qualitative results and those of previous quantitative research conducted on negative emotions in general.

INTRODUCTION

The website called "Hatebook", a parody of the famous "Facebook", can be seen to presently be enjoying much success on the internet. Identical to its reputable cousin, but red in color, this site presents itself by way of an elucidatory phrase: "Hatebook is an anti-social utility that disconnects you from the things YOUHATE".

Its users, who are called haters, do not spare anyone and free rein is given to gossip and backbiting. It is possible to hate anything and everything and to do it in company is considered to be much more rewarding. Not by chance, upon entrance, pops up the message: "welcome to the site of bad".

Examination of whether these "hate clans", created "to get rid of all annoying things around you", include some specifically dedicated to brands, revealed that there were indeed 45 with those most targeted featuring a number of classic cases such as Starbucks, Microsoft, Pepsi, and McDonalds, but notably also Burberry, D&G and Vuitton, etc.

For example, in the description of the "I hate Starbucks" clan, the founder, *bartbrains*, writes: "Do you think that Starbucks are not really selling coffee but something like water with syrup, cream and sugar? Do you miss the taste of real coffee? Do you think that people go to Starbucks just to be in fashion? Then this clan is for you".

Similarly, on the hate-board of the "I hate Microsoft" clan Rocker wrote 2007-11-25 at 01:05:55 h. "Linux Rules. Fuck Windows"; coolzone wrote 2007-11-13 at 14:28:49 h. "I HATE BUGS, IHATE microsoft's BSOTD!!" and josefstalin wrote 2007-11-03 at 12:36:18 h "All capitalist pigs should suffer for their lack of equality".

These cases demonstrate that, while it is possible for consumers to like or even love some brands, have an emotional attachment to or in any case generally positive feelings toward them, at the same time it is also true that consumers can express negative feelings, such as hate, dislike, anger, etc.

Yet most prior examination of consumer-brand relationships has given little consideration to these negative aspects.

This is not to say that negative feelings have not featured in certain brand research; some studies touch upon phenomena closely related to negative emotions and feelings (e.g. Holt 2002; Hollenbeck and Zinkham 2006), but an explicit development of the topic is still notably lacking in the literature.

Above all, the research available on negative emotional reactions to brands is significantly limited, especially in comparison with that conducted on those positive. In terms of negative emotions regarding brands, the almost exclusive focus on brand dissatisfaction is far outweighed by the wide range of positive responses explored-e.g., brand love (Shimp and Madden 1988; Whang, Allen, Sahoury, and Zhang 2004; Carroll and Ahuvia 2006; Keh, Pang and Peng 2007), brand attachment (Thomson, McInnis, and Park 2005; Thomson 2006; Park, MacInnis and Priester 2007), brand passion (Fournier 1998), brand satisfaction (Oliver 1997; Fournier and Mick 1999; Giese and Cote 2000) and brand delight (Oliver, Rust and Varki 1997; Durgee 1999; Swan and Trawick 1999; Kumar, Olshavsky and King 2001).

In addition, there is limited marketing research addressing the situational conditions, or antecedents, associated with specific consumption emotions (as exceptions, see Folkes 1984; Folkes, Koletsky and Graham 1987; Nyer 1997; Ruth, Bruner and Otnes 2002; Soscia 2007).

This paper aims to address these research gaps in an attempt to identify the nature of individual negative emotions to brands and the antecedent conditions that cause them.

This investigation would provide considerable insights, on a theoretical level, in order to better understand and explain consumer-brand relationships; what's more, this type of knowledge could be of great benefit to brand managers who need to enhance their understanding of the situational conditions associated with negative emotions in the selected targets and to verify the possibility of devising specific countermeasures.¹

In comparison with the prevailing research on emotions and appraisals this study employs a non traditional approach based on unstructured introspective essays involving consumers in two extremely diverse socio-cultural contexts: Italy and Palestine.

This approach allows for stepping back from the dominant paradigms to investigate and describe negative emotions to brands from the firsthand viewpoints of those directly involved (analogous logics are present in, among others, Fournier and Mick 1999 and Kwortnik and Ross 2007). Our goal can therefore be seen to be threefold: 1. develop a realistic account of negative emotions to brands as they arise in everyday life, 2. identify relevant antecedent conditions capable of generating varying negative emotions to brands, and 3. compare this knowledge with prevailing paradigms on emotions in order to reveal possible similarities and differences.

EMOTIONAL RESPONSES AND CONSUMPTION

Emotions can be said to have a specific referent (e.g. consumer is angered by poor shop service).

More explicitly, emotions arise in response to an appraisal of something of relevance to one's well-being. As specified by Bagozzi, Gopinath and Nyer (1999) "appraisal" means an evaluative judg-

¹In some situations, negative emotions toward a brand could actually be the result of a particular brand positioning strategy that necessarily implies a negative reaction from some specific targets considered not interesting by the company.

ment and interpretation thereof, while “something of relevance” implies a personally experienced incident or episode, an action performed or result produced by oneself, or changes in an object person of thought with personal meaning.

It is important to consider that although types of events or physical circumstances are frequently associated with particular emotional responses, there is not a direct, causal relationship between the two but rather the latter is the result of each individual’s unique psychological appraisal, evaluation and interpretation of the former.

It is possible for the same stimulus to be interpreted in a number of ways, thus giving rise to various emotions: a parent’s forbiddance of his/her child buying a desired product could be interpreted by the child as an unforeseen and intolerable obstacle, perhaps producing anger; or it could well be construed as a way of limiting personal independence, possibly generating sadness. Thus, the resulting emotion is essentially an experience of the emotion producing situation and its potential positive or negative significance for the individual person, and so, varying emotions can be said to be characterized by different situational meaning structures (Frijda 1986).

This central role of appraisal in the formation of emotions has led to the definition of what are aptly called appraisal theories in psychology (e.g., Frijda 1986; Lazarus 1991; Ortony, Clore, and Collins 1988; Roseman 1991; Roseman, Antoniou and Jose 1996; Smith and Ellsworth 1985).

Appraisal theorists maintain that cognitive elements are: a) an integral part of the emotion, in that each emotion corresponds to a specific meaning structure or cognitive examination of the situation; and b) the direct cause of the emotional experience and behavior.

A distinctive feature of appraisal theories is the number and type of cognitive elements that give rise to discrete emotional responses. The literature is extremely rich, but there is also a strong degree of convergence between the different approaches (Scherer 1988; Watson and Spence 2007).

While the confines of this paper do not allow us to present a full review of these theories, we do focus on their use for studying negative consumption emotions, their cognitive appraisal and possible effects.

Folkes (1984) and Folkes, Koletsky and Graham (1987) manipulate the three principal dimensions of causality (locus, stability and controllability) in order to examine their relation to anger. It is clear that respondents in situations where product failure is due to a firm’s controllable actions report higher levels of anger than when it is consumer-related or beyond the firm’s control. Also, anger stemming from failure on the part of the service provider can be seen to be associated with increased negative post-purchase consumer behavior (refund, demanding apology, complaining, etc.).

Likewise, Nyer (1997) manipulates certain appraisals (goal relevance and congruence, attribution and coping potential) ascertaining that various combinations can influence respondents’ anger and sadness in the evaluation of computer products. These emotions are also shown as determinants of post-consumption behavior such as negative word of mouth.

More recently, Soscia (2007) demonstrates the correlation between two different appraisals (goal congruence and agency), guilt and also certain post-consumption behavior such as negative word of mouth and customer complaint.

Ruth et al. (2002), further demonstrate the systematic relationship between nine cognitive appraisals from Ellsworth and Smith (1988) and six specific negative emotions (fear, anger, sadness,

guilt, uneasiness and embarrassment) in a consumption context, making use of variance and multiple discriminant analysis.

However, these studies focus on emotions generated by general consumption situations—subjective states that occur when considering, buying or using a product—and not on those specifically elicited by brands; it is possible, therefore, that additional research is required to identify a specific set of negative emotions in relation to brands.

In fact, in the case of a specific focus on emotions in relation to brands we can expect much more emphasis on emotions brought about by reactions to the object and its possible meanings rather than on emotions determined by decision making processes and subjective experiences that characterize consumption situations considered in a broader and more generic sense.

Additionally, it is worth noting that previous research has been experiment-focused or correlational in nature, providing evidence regarding the possible systematic relationship between appraisals and certain negative consumption emotions, based on existing psychological theories; however, a thorough examination of negative emotions as experienced and expressed through the consumer is lacking. Those concerned with marketing have yet to accurately and comprehensively assess these types of emotions in the context of normal everyday life and with regards to brands.

Consequently, this study attempts to address the following research questions:

1. What kind of negative emotions do consumers experience in relation to a specific brand?
2. What are the relevant antecedent conditions capable of generating various negative emotions to brands?
3. And finally, is it possible to relate this set of conditions to salient cognitive appraisals, or an interpretation of situations according to the likely impact on one’s well-being (Bagozzi et al. 1999) as documented in various emotion appraisal theories put forward by a number of authors?

METHODOLOGY

In order to address these research questions and further our knowledge of the nature and characteristics of consumer negative emotions to brands, this study employs a projective method. This technique has proven useful in a variety of contexts where more traditional quantitative and qualitative methods fail to achieve an adequate understanding of consumer behavior processes and consumption symbolism (among others, Belk, Ger and Askegaard 2005; Havlena and Holak 1996; Zaltman and Coulter 1995).

Our informants consisted of consumers in both Italy and Palestine. The Italian consumers totaled one hundred and fifteen male and females (equally distributed) aged between 18 and 51 and the Palestinian consumers numbered fifty six (equally distributed) aged between 20 and 25.

Our main intent in selecting these two cultural contexts was to avoid the narrow confines of an individual, typically western country, with an interest in broadening the scope of our data rather than necessarily creating the basis for a cross-cultural, comparative investigation.

We made use of introspective essays as a qualitative, projective method. These essays allowed us to evoke consumers’ feelings and emotions without their being directly guided by an interviewer (Lupton 1996). They were requested to write down the name of a brand capable of generating negative emotional responses, specify these feelings, and provide an open and detailed account of the reasons for their reactions.

Questions and responses were in Italian or Arabic, where appropriate. The essays were analyzed independently by two of the native tongued authors, and additionally we collectively re-evaluated our interpretations a number of times.

Not surprisingly, we found both similarities and differences between the two locations, and naturally, our findings are particular to the culture and people studied. However, we found that some differences had more to do with emphasis and specifics than essential content. Indeed, an initially extensive list of areas of difference was progressively reduced during our collective meetings.

From this iterative process, we are able to present our findings by way of topic, noting cultural differences in the presence of systematic evidence.

FINDINGS

Our findings are divided into two parts, beginning with a description of the nature of negative emotions to brands as experienced by our informants and then turning to the antecedent conditions of their occurrence. The latter gives place to most of the discussion about possible cultural effects on emotions toward brands. Following these two sections, we then discuss the possibility of relating this set of conditions to the salient appraisals well documented in emotion appraisal theories by certain authors and consider the potential implications for brand theory.

Dislike and anger as main negative emotions to brands

Firstly, it is worth noting that, with rare exception, respondents were able to effectively describe the emotions they felt toward the brand and differentiate not only between the different basic positive and negative emotional states, but also those more analogous such as sadness, anger, dislike, etc.

Indeed, after focalizing on their chosen brand, respondents' accounts often concentrate on one particular emotion, describing it in detail and generally keeping it separate from others that can be considered similar in terms of valence, yet distinct in terms of nature and content.

We witness in both research contexts that respondents are by and large spontaneously drawn toward one specific negative emotional state and much less frequently inclined to describe a combination of such emotions.

It appears, therefore, that each emotional state is distinct and characterized by something peculiar to it; a set of psychological sensations capable of making it possible to distinguish one from another.

The two fundamental groups of negative emotions consumers experience to brands can be seen to be centered around dislike and anger.

Dislike emotions² are typical, affective and aesthetic reactions to brands based on evaluations of unappealingness, which are, in turn, dependent on personal attitudes and tastes.

These emotions are characterized by different levels of intensity, covering a continuum of feelings from simple dislike and to the extreme and global, negative emotion of hate. The typical emotion terms within this range chosen by consumers to express their negative feelings toward brands are aversion, distaste, disgust and revulsion.

*So, I felt dislike and distaste toward this brand (P-M, 18)
I don't trust this brand and I honestly, really hate it (P-M, 20)*

Consumers also report feeling cross, irritated, spiteful, indignant toward a brand, expressing prototypical features of the emotion anger.

I feel very cross, irritated and spiteful toward all the Tuna Marina brand products (P-M, 21)

I feel indignant and hostility toward the Coca Cola brand, for many reasons (P-F, 21)

The role assigned to other negative emotions such as sadness,³ fear and disappointment⁴ is extremely marginal.

Our findings corroborate the suggestion by Bagozzi et al. (1999) that the dominance of the dissatisfaction construct in marketing is possibly due more to its being the primary emotion to receive attention rather than constituting a unique, fundamental construct in and of itself, and that, therefore other negative emotions could be of equal or even greater importance in consumption contexts.

Antecedent conditions of negative emotions to brands

The three main brand-related antecedent conditions which consumers can focus on, evaluate and react to, are the:

- physical object
- symbolic cultural object
- agent

Physical object

Whilst acknowledging the central role of a product's symbolism in consumption culture, it is also essential to recognize that its physical attributes and functions continue to play an important role. In fact, consumers' negative feelings can result from an attenuation of their relationship with a brand due to an intentional or inadvertent disruption in its conduct (Fajer and Schouten 1995; Fournier 1998). Such a breakdown can have a multitude of causes, including the undoubtedly important role played by unmet promises by marketers in terms of brand performance, as reported below:

I literally hate Clinique products. They're really expensive, and claim to be hypo-allergenic, but I still got an allergic reaction. I felt totally cheated. I mean, I'd practically thrown my money away for nothing (I-F, 20)

Additional factors also capable of generating consumers' negative feelings toward brands are changing consumer needs, criteria of liking or even the appearance of potentially superior alternatives:

I really don't like Onyx. It's okay for a young adolescent target, but it doesn't go with my way of dressing. When I was younger, I liked the brand a lot, but then I grew up and their stuff just stayed the same. I think it's a brand that needs updating (I-F, 25).

I really don't like Lotto products! They've hardly changed in years, and have never known how to reinvent themselves in any way (I-M, 19)

²This concept of dislike differs from that put forward by Dalli, Romani and Gistri (2006). In that case dislike was a global, negative consumer response to a brand and not a group of emotions, as in this paper.

³Sadness is often associated with anger; this mix of emotions will be discussed subsequently.

⁴The absence of this emotion, usually present in consumption situations (Zeelenberg and Pieters 1999), could be explained by the fact that disappointment is specifically related to decision making whereas here consumers' accounts that focus on decision processes related to brands are decidedly marginal.

In the above cases the brand is considered as a physical object with material characteristics and functionalities with the negative consumer reaction resulting from its relative unattractiveness.

In addition to this type of negative consumer responses to brands that is common to both Italian and Palestinian respondents, we see an interesting phenomenon emerging solely for the latter. It appears that Palestinians' resentment toward the state of Israel leads to their denigrating the quality of Israeli products and services, perceiving them as personal and culture specific, and consequently disliking these particular brands.

This can be seen to be especially true for products such as food and services, which are particularly culturally imbedded and difficult to disconnect from those who produce them; Palestinian consumers' animosity can be seen to have a significant negative impact on their perception and assessment of the quality of Israeli products.

I hate all of this Israeli brand's products and I don't like seeing any of them on the Palestinian market. I view this brand as an enemy of Palestinian, and so I advise everyone I know not to buy any of its products. I don't trust them either because they could contain toxic substances, especially given Israeli policy (P-F, 19).

This kind of milk is produced in Israel for children. One day, I bought it for my little brother from an Israeli market and it was wonderful. When my mother asked me to buy another carton, and I bought it in a Palestinian area, it gave him many health problems. This must be due to Israel's mean and devious policy of allocating toxic containers to Palestinian markets and harmless ones to their own. I hate this brand because of its differentiation policy and the fact that it isn't concerned about children's health. (...) I won't trust any Israeli brands in the future (P-F, 23)

This type of negative response to brands, due to the presence of animosity toward an ethnic group, resulting in negative product-quality judgments is also documented by Shoham et al (2006) in a comparable cultural context. This study examines Jewish Israeli reactions to Arab Israelis regarding the purchase and consumption of products and services produced or marketed by the latter.

Here, this result is extremely noteworthy given that previous research (Klein 2002; Klein, Etterson and Morris 1998) concludes that such animosity has no effect on product/brand judgments and emotions.

The symbolic cultural object

It appears that people buy brands for something other than their mere physical attributes and functions (Levy 1999).

Consumers attach positive and negative meanings to their consumption choices in order to create and maintain social and cultural identities (McCracken 1986); they also use these meanings to establish similarity and difference and in doing so, call for inclusion within or exclusion from particular social settings.

Wilks (1997) provides an example of this, demonstrating that distaste and refusal are often given greater importance than taste and choice in their being more effective as social indicators, despite the fact that likes tend to be much easier to communicate than dislikes.

Hogg's research can also be considered from the viewpoint that consumers' anti-choices are aimed at creating distance from the undesired self they want to be disassociated from (Banister and Hogg 2004; Hogg and Banister 2001). According to Hogg's findings, consumers are able to define themselves by means of the formation of distaste and associated negative stereotypes.

In their written reports, a number of consumers can be seen to express negative feelings toward brands that, due to their symbolic associations, are not self-expressive or are connected to one or more specific stereotypes or social groups from which they want to distance themselves.

The sense of dislike expressed below by Rossana is based on the fact that she cannot identify with the brand's image and, furthermore, that the brand actually appears to her to be associated with a profile she finds objectionable: showgirls. It is clear that this brand does not contribute to her identity construction and, in addition, is capable of shifting her identity toward an undesired self.

I really don't like Monella Vagabonda! I consider it to be a brand that doesn't represent me at all; a brand for showgirl types! (I-F, 21)

On the other hand, the negative feelings expressed below by Angela toward Paciotti depend on an association between the brand and particular stereotypical characteristics of the typical user. Angela believes that those who possess Paciotti products have character traits she dislikes. In terms of emotion, the effect is stronger, resulting in "disgust".

The brand Paciotti really disgusts me! In my experience, people who wear these shoes are usually loutish and pay a lot of attention to appearances (I-F, 27)

Generally speaking, at times brands represent actual or ideal human profiles from which consumers want to distance themselves since they dislike them as such or because of their specific traits and characteristics. In this sense, by association, brands are capable of conveying negative or positive symbolic meanings, and are used as a means for communicating one's idiosyncrasies to others.

As a matter of fact, our informants from Italy and Palestine can be seen to significantly differ with regards to this dimension. While many Italian subjects make reference to brands as carriers of negative symbolic meanings, no Palestinian expresses such attitudes.

This asymmetry can be explained in a number of ways. Firstly, the situation in the Palestinian territories (the Israeli occupation and acute social and economic recession) can be said to be devastating, with harsh and continual threats to social, cultural and even physical conditions. Understandably, the vast majority of Palestinians concentrate on their primary needs for survival and not on desires (Annajjar 2007; Abdelhameed 2004). Consequently, they attach little or no importance to differentiation, inclusion or exclusion as a matter of cultural and/or symbolic identity construction mediated by consumer goods and brands.

From the situation above it follows that Palestinians live according to a commonly shared subsistence or survival existence that is not a matter of choice as in affluent Italy, but of providence: these consumers are condemned to considering solely the functional aspects of consumption and not those symbolic. In this sense there is little differentiation between these "consumers" and—even for religious or moral beliefs—they give no importance to material goods as a means for social and cultural distinction.

In addition, the Palestinian community can be said to be a sort of tribal community in which everyone is strictly embedded in a complex network of clans and sects. They have no additional "need" for inclusion/distinction as occurs in western societies where individuals have lost their sense of belonging and ask for "linking value" (Cova 1997). They do not "need" goods or services to feel closer to other consumers, since their self is already well-

rooted in a specific tribal structure (Abdelhameed 2004; Alsorany 2006; Annajjar 2007; Helal 2005; Helles 2003).

Moreover, this tribal configuration has the effect of reducing the individual dimension of living: personal expression undergoes “communal” processes such as discipline, obedience and self-sacrifice for group benefit. Individual identity depends on integration within the group structure and—almost by definition—one’s clan or tribe affiliation ensures no need for further “distinction”.

In other words, if properly integrated within the social structure, one’s culture becomes an integral part of belonging to a group, removing the need for “individual” expression.

The agent

According to that presented above, it is evident that consumers attach functional or symbolic properties to the brand as an inanimate object. However, recent studies have developed a richer and more variegated picture of the consumer-brand relationship: the brand’s role appears to be more complex than it used to be. Researchers have put forward the idea of the brand as an active partner in a dyadic relationship (Fournier 1998), a real agent. Consumers actively infer and construct brand meaning, generating emotions toward them, but it can also be argued that brands have their own attitudes to their target markets, which iteratively affects consumers’ evaluations (Dall’Omo Riley and de Chernatony 2000; McEnally and de Chernatony 1999). This premise is based on the fact that brands act by way of their “parent” company’s actions, such as the everyday execution of marketing strategies and overall (in)activity related to social, ethical and/or political issues.

Following this line of reasoning, brands are considered not only for what they represent, symbolize and communicate, but also for what they actually do with this active role being played mainly through their company’s actions. Consumers make little or no distinction between the brand and its manufacturer and the brand becomes a sort of synonym for the company: the company is perceived as the brand and the brand as the company (Aggarwal 2004). When something occurs that is perceived as incorrect, consumers say “brand x did this, brand y did that”, explicitly referring to the brand when speaking about company behavior.

As a result, consumers commit themselves to brands that behave in ways that give the appearance of their sharing common views and values, whilst they are troubled by those seen to have an incorrect conduct, evading the civic responsibilities expected of a community pillar (Holt 2002).

The following excerpts are clear examples of this aspect: consumers explicitly associate regrettable behavior and even forethought and hypocrisy to brands. Brands are capable of doing bad things and it appears they can do it purposefully and with satisfaction.

I feel indignant toward Nestlé. I can't stand its opportunistic and unethical behavior and the fact that it tries to conceal this by using a false and misleading exterior appearance (I-F, 22) Sometimes they like making people angry with them. I am angry and indignant because of their shameful advertisements. They should respect the regional culture and religion of where they are broadcast (P-M, 20)

In the Palestinian reports the brand’s country of origin can be seen to be of great relevance in this perspective. Respondents express strong negative emotions toward brands manufactured in “enemy” countries for political (e.g. Israel or the USA) as well as religious reasons (e.g. Denmark for its publication of cartoons perceived as offensive to Muslims). These consumers recount

feeling negative emotions to brands that come from these countries because of their very origin. In these cases, it is not company behavior, but that of certain individuals from the country in question that is extended to the population as a collective subject (the Americans/Danish do this or that) and even to the country itself as an agent (the U.S./Denmark did something).

I feel really cross, irritated, and spiteful toward all products with the brand-name Tuna Marina; simply because it's Israeli (P-M, 21)

I feel indignant and hostile toward Coca Cola, for many reasons; firstly, it is an American company (P-M, 21)

I feel angry and annoyed with this brand because of its country's disrespect for Muslim feelings and Islam.(P-M, 19).

In short, brands can be conceived as agents: they are given the “personality” to do things, put ways of behaving in to practice. They can also be considered as representative of collective agents (people, countries). This occurs when consumers associate specific events and individual conduct with “collective” properties of the community/country of origin on an ideological, ethical and/or religious level and when their normative implications are perceived as different from those of the consumer.

In these circumstances, the brand acts as an agent and, as such, is able to elicit emotions that can differ from those elicited by the brand as an object, as is apparent in the discussion below.

Relating brand negative emotions and appraisal theories

Analysis of our data reveals that the brand-related conditions on which consumers focus, or an individual’s interpretation of brand were often related to particular emotional responses. More specifically, in both research contexts, we see the majority of dislike emotions being associated with the brand perceived as a physical object and those of anger with its interpretation as an agent.

This product is a replacement of an Israeli one called “Tapozena”. Marawi is not a good choice.

The bottle shape is unattractive, the taste is bad, and bearing these qualities in mind, the price is high. Therefore, I dislike and feel distaste toward this brand's product (P-M, 18).

I feel indignant toward Nestlé. Of all the multinationals it is the symbol of exploitation, abuse of power and a total lack of ethics. Also, it produces so many products that at times it becomes impossible to avoid buying one of them (I-F, 27)

In the Italian context, dislike emotions can also be seen to be related to the brand interpreted as a symbolic cultural object.

These systematic relationships between negative emotions and an individual’s brand interpretation strongly relate to salient appraisals documented by various emotion theories.

As observed primarily by Ortony et al (1988), but also, with slight differences, by a number of authors (among others, Ben-Ze’ev 2000; Roseman et al. 1996), the group of dislike emotions result primarily from reactions to objects qua objects whose intensity tends to be influenced by the “unappealingness” of the item of interest.

We found this salient appraisal to be consistent with our data since the majority of dislike emotions are related to an interpretation of a brand as an inanimate object with utilitarian and functional and/or symbolic values. In addition, respondents’ reports on disliked brands can be seen to closely relate to the characteristic feelings, thoughts, action tendencies and goals of dislike identified by Roseman, Wiest and Swartz (1994). A number of respondents

describe sentiments like wanting to reject and distance themselves from the brand, as illustrated below:

I hate Datch! I would never wear it. It's a rough and vulgar brand...in fact it's represented by a big-head like Costantino. I wouldn't ever want anyone to think that I identify with that style, I'd feel terrible. (I-M, 28)

On the other hand, anger emotions differ from those of dislike since they derive from disapproval of someone else's questionable actions (and their consequences) rather than a global and detailed evaluation of an object's appealingness (Ortony et al. 1988). Anger is the classic example of emotions that are "other oriented" (Smith and Ellsworth 1985; Roseman et al. 1996), that is, generated from others' responsibility. As with dislike, this involves a negative evaluation, but it is the appraisal of particular actions performed by others rather than of an object.

Once again, we found this salient theoretical appraisal of anger emotions to be consistent with our data, since consumers' interpretations consider the brand as an active agent (Fournier, 1998) by way of its administering managers' activities or country of origin's policies. Consumers can be seen to feel anger when these actions are considered unfair and/or questionable.

Respondents' reports on brands capable of generating anger can also be seen to correlate closely with hypotheses upheld by Roseman et al. (1994) that considers it to be an emotion that involves the desire to attack in order to injure someone else.

Indeed, we see that respondents can feel extremely negative towards brands whose behavior they consider unfair, and wish to seriously damage them, as illustrated below:

Buck is just one of the Danish brands about which I couldn't care less about quality. I feel hate and aggression toward all Danish products because of the great insult to the Prophet Mohammed in a Danish newspaper. This offends over one billion Muslims. Indeed, this was condemned and denounced by the Muslim world by way of an economic boycott of Danish brands. So, let this be a lesson to those who attempt to insult Islam in the future. I boycott Danish brands, and I urge all my friends and relatives to do likewise until the government of Denmark apologizes to the Muslim world. I despise all Muslims who buy any Danish brands, considering them to be disloyal to Islam (P-M, 23).

Whereas in the presence of dislike emotions individuals are inclined to avoid confronting the brand, in the case of anger they often wish to correct the brand's behavior, at times through extreme action or forms of punishment, in order to be able to (re)create a possible relationship with it.

Lastly, some consideration can be given to sadness; this particular emotion is marginally present in consumers' descriptions, but when it is, it is rarely alone, and often associated with anger. Consumers that disapprove of a brand's culpable actions are often contemporarily unhappy about the related undesirable events that could derive from them.

I feel anger and indignation toward Adidas, but also sadness. I saw a documentary in Germany, about how Pakistani children of three years and up make Adidas shoes and other items that I could never buy (I-F, 26)

The emergence of this emotional mix in respondents' descriptions is somewhat unaligned with the theoretical models presented

by various appraisal theorists, which tend to emphasize the underlying differences that exist between these two emotions. Ortony et al. (1988) are the only authors that consider a possible association between these two emotional states. Nevertheless, this evidence is somewhat weak and additional research is required to investigate this issue further.

CONCLUSION

Using a qualitative projective method, we found that similar consumer negative emotions to brands occur in two diverse cultural contexts. Our findings demonstrate that the negative emotions of dislike and anger are experienced to a greater extent than others, such as sadness, fear and disappointment. At the same time, we observed the presence of three conditions on which consumers focus and react to in the context of brand, noting that these systematically relate to specific negative emotions.

Lastly, we examined the consistencies with and differences between our qualitative results and those of previous quantitative research conducted on negative emotions in general.

This study complements research on specific negative emotions in the context of consumption. Our findings also prove to be consistent with past causal research on individual consumption emotions such as anger, where we observed the salience of other-oriented responsibility and control, as does Folkes (1984), Nyer (1997) and Ruth et al. (2002).

In addition, we are contributing to that line of research by providing a foundation for studying under-considered consumption emotions, such as dislike.

However, this paper's main contribution is on the subject of brand, by providing preliminary and relatively new evidence for the vastly under-researched phenomenon of negative emotions to brands. A particular aspect of our findings can also be said to be intriguing from a theoretical standpoint. The fact that anger and dislike are the negative emotions most commonly experienced by consumers, both in isolation and combination with others, offers ample space for reflection on the possibility of enriching the analysis of negative emotional paths in the consumer-brand relationship, given the, until now, sole consideration of dissatisfaction as the typical negative emotional response to brands.

The expansion of this investigation could have important theoretical, but also managerial implications given the importance of limiting, or even better, avoiding the diffusion of negative emotions toward brands for their managers.

This study's use of a projective method allows for advantages in collecting data about actual rather than prompted or manipulated emotions. However, this needs to be further complemented by alternative projective as well as qualitative methods, in order to evaluate the strength and validity of our results and the possibility to enrich them. Additional research is in progress to address these issues.

Salsa Magic: An Exploratory Netnographic Analysis of the Salsa Experience

Kathy Hamilton, University of Strathclyde, UK

Paul Hewer, University of Strathclyde, UK

“The anticipation of the night, Your skin prickling with electricity thinking about going dancing... The feeling in your stomach as you enter the dancehall and look around. The first beat of the drum reverberating around your soul. The automatic smile when you see people enjoying themselves. The wonder and amazement at all the bodies moving so well and so naturally. Being kissed by the magic in the air from all the chemistry, charisma and the good energy flowing all around. The nervousness of my first dance, yet the beautiful realisation that my body and soul remembers what to do and shall guide me through it. The ‘thank God’ feeling that my body and mind can take me to that beautiful place of euphoria again that comes from dancing” (Male, Salsa Dancer, Australia).

INTRODUCTION

This is a paper about the promise of dance as unfolding social drama. Such promise has clearly been recognised in attempts to represent dance cinematically: from Powell and Pressburger’s *The Red Shoes*, to the classic *Singin in the Rain*; from Fred Astaire in *Shall We Dance* (or even Richard Gere in the 2005 remake) to the disco inferno of Tony Manero swinging his butt to recognition in *Saturday Night Fever*. Representations of dance as re-enchanting and reinvigorating have always remained to the fore within cinematic discourses. This rich potential has also been recognised in TV advertisements, with the Apple iPod ‘Silhouettes’ campaign clearly feeding off such liberatory experiences. In this paper we foreground one such dance technique, that of Salsa, to reveal and explore the appeal of the experiences provided by this dance form. We suggest that the scene has grown significantly over the last ten years from its roots in the Caribbean (mainly Puerto Rico and Cuba) and initial transfer to New York and Los Angeles to a phenomenon sweeping the world. As a global export (Madrid 2006) the appeal of Salsa appears much more than this culturally, especially when we turn to the significant rise in popularity achieved by this dance form. Here we can draw attention to the continuing emergence of a gamut of Salsa Congresses, Latin Dance clubs and classes springing up across the globe in countries as diverse as the UK (Evening Chronicle 1998; Sunday Times 1999), Singapore (Singapore Times 2004), Ghana (Africa News 2006), the US (Miami New Times 2000; New York Times 2007) and Canada (Montreal Gazette 2006; Vancouver Sun 2005); to even the success of the Broadway musical *In the Heights* and Jennifer Lopez starring in *El Cantante*, which depicts the life of 1970s Salsa songster Hector Lavoe. Or even *Dirty Dancing 2* subtitled *Havana Nights*, where formal ballroom dancing in the form of Katey meets the steamy passionate embrace of Javier in the Cuban dance halls of the 1950s.

DANCE WITHIN CONSUMER RESEARCH

Within consumer research what strikes the authors as somewhat surprising is the lack of studies which have taken dance seriously, the absence of studies made more explicit by the value of those exceptions (Wort and Pettigrew 2003; Goulding et al 2002; Goulding and Shankar 2004). For us this absence is troubling, as we explore how as a research context a turn to dance forms, cultures and representations would appear to offer us much potential to reinvigorate our own understanding of consumer cultures (see Featherstone 1991) and ways of theorizing consumer culture. A dance turn within consumer research necessitates we take seriously

notions of (tribal) aesthetics (Maffesoli 2007) and ephemeral communities (Hamera 2007), but also notions of embodiment (Featherstone 1991; Frank 1991; Goulding et al 2002; Joy and Sherry 2003). Dance then promises transformation and transcendence, but also as Frank reveals is communal, bringing forth particular “forms of dyadic associatedness which transcend the individual body to that of the other” (Frank 1991, 80). The experience of embodiment offered through a turn to dance becomes all important for a rethinking of consumers, especially as what we glimpse through attention to dance and the performative realm is a reconsideration of the “human body as a moving agent in time and space” (Thomas 2003, 78). A moving body which questions notions of fixed structures, where agency becomes the ability to “negotiate movements within those structures” (McDonald 2004, 200). The moving body in other words becomes pivotal in exploring consumer culture afresh, suggestive of rethinking our relationship with this world, and the imagined limits cast upon that relationship. For as Meamber and Venkatesh indicate: “the body is a site of exploration and experimentation...a way to understand, explain, refashion our notion of our world.” (1999, 194).

Both Turner (1991) and Featherstone (1991) draw upon the work of Foucault to explore notions of the regimentation and disciplining of the body, as he suggests “Bodily domination is never imposed by some abstract societal Other; only bodies can do things to other bodies. Most often, what is done depends on what bodies do to themselves” (1991, 58). For Featherstone, we might suggest that *bodies matter* (to take a line from Judith Butler 1993) within consumer culture, especially evinced through notions of the performing self where management of one’s appearance and look become paramount. Or as Bourdieu expresses: “The body, a social product which is the only tangible manifestation of the “person” is commonly perceived as the most natural expression of innermost nature...The legitimate use of the body is spontaneously perceived as an index of moral uprightness, so that its opposite, a ‘natural’ body, is seen as an index of *laisser-aller* (‘letting oneself go’)” (1992, 193). For Foucault (1990, 152) then a turn to bodies and their histories becomes a turn to the body as the site for the deployment of power/knowledge relations, but also to reimagine the body as simply unfinished business that is unstable and therefore constitutive in constructing potential resistances.

It is here that the significance of dance as a cultural form and sensibility reveals itself, not simply individual leisure time but a form of letting oneself go, a space for constructing resistance, offering transcendence and transformative potential through becoming “other”, for as Carter (1996) suggests: “The spatial aspects of movement and the situation of the action in the performing space can also be considered for their significance in forming or replicating notions of gender” (1996, 50-51). Dance then as a performative act reveals its significance, the ability to blur and overcome (if only symbolically) contradictions, its ability to provide as Turner reveals a “liminal period...betwixt and between one context of meaning and action and another” (1982, 113). For as Hamera suggests “They [Dance techniques] offer vocabularies for writing, reading, speaking and reproducing bodies. In doing this, they do much more: organize communities around common idioms, rewrite space and time in their own images, provide alibis, escape clauses, sometimes traps, sometimes provisional utopias” (Hamera 2007, 208).

Wort and Pettigrew (2003) explore such symbolic and material refashionings through a group of Australian womens' experiences of belly dancing to challenge the assumptions around this dance form. They argue that participation is performed by women to "fulfil their own needs for femininity and sensuality, rather than being an activity designed for the male gaze" (2003, 190). Belly dancing thus becomes a way of "dabbling in the exotic" (ibid, 190), but also for the women a way "to come to terms with the shapes of their bodies" (ibid, 190). In this way, Wort and Pettigrew draw attention to the transformative potential of dance, as illustrated through the importance of adorning their bodies with accoutrements such as costumes but also the application of henna and their associated beauty rituals for making material this transformation from their everyday to dance selves. But perhaps more importantly, as a form of transcendence achieved through a "connection" with other women (ibid, 191). Or as McRobbie proposed: "Dance is where girls were always found in subcultures. It was their only entitlement" (1993, 25). On this entitlement, she continues by writing about the rave experience for women: "This gives girls new-found confidence and a prominence. Bra tops, leggings and trainers provide a basic (aerobic) wardrobe. In rave (and in the club culture with which it often overlaps) girls are highly sexual in their dress and appearance... The tension in rave for girls comes, it seems, from remaining in control, and at the same time losing themselves in dance and music" (1993, 25).

The work of Maffesoli (2007) explores a similar theme but from another conceptual position; he explores the nature and "advent" of the tribal aesthetic itself where he seeks to explain the emergence of this logic, that is to say, aesthetics are defined in terms of their etymological meaning as "people feeling emotions together" (Maffesoli 2007, 27). More so, he argues that the tribal aesthetics speak of an ecological dialectic versus that of simply economic means-ends activities—a spirit which captures the sense of aesthetics as expressing a "passion for life" (ibid, 27), where "situations are the only things of any import" (ibid, 29), since within such contexts (Maffesoli uses the example of the "orgy") lies the possibility for the "loss of oneself in another" (ibid, 30), or better, of a "re-enchantment of the world" achieved essentially through the collapse of the individual and the foregrounding of "shared passion and social empathy" (ibid, 30). The approach of Maffesoli then takes seriously the social sphere as the starting point for any investigation of tribal aesthetics, or as he explains:

"Big meetings, large gatherings of all kinds, group trances, sporting events, musical excitement and religious or cultural effervescence—all raise the individual to a form of plenitude that s/he cannot find in the grayness of economic or political functionality. In each of these phenomena, there is a sort of magic participation in strange things and strangeness..." (ibid, 32).

Salsa dancing then can be understood as one such instance of *social effervescence* where the consumer moves beyond their position of isolated individual through involvement and participation with the emergent social. Parallels can be drawn with the work of Goulding et al. (2002) and Goulding and Shankar (2004) which employs notions of Maffesoli's (1996) neotribalism to explore the emergent rave scene—"the music, the laser light shows, and in some cases the ingestion of drugs like ecstasy and cocaine, and the nature of the dance itself" (Goulding and Shankar 2004, 649)—for producing new dramas and communities constructed around a particular dance form. Or as Sash, one of the respondents better articulates: "You have enough hassle all week at work. What you want to do at the

weekend is break free of all that, go a bit mad, get it all out of your system, dancing is like a release, you can lose yourself... On Friday the fun starts early" (Goulding et al 2002, 275). Dance in other words becomes a useful context to explore the intimacies and embodiments brought into being through such new communities, or as Hamera reveals: "It is a testament to the power of performance as a social force, as cultural poesis, as communication infrastructure that makes identity, solidarity and memory sharable. Communities are danced into being in daily, routine labor, time and talk... emerg[ing] at dance's busy intersections of discipline and dreams, repetition and innovation, competition and care" (Hamera 2007, 1).

METHODOLOGY

In this section we reveal the methodology adopted to obtain the "deep contextualization of meaning" (Cova, Kozinets and Shankar 2007, 9) necessary for a fuller and richer understanding of Salsa. The material presented in this paper was collected through a netnographic analysis of an online salsa forum (<http://www.salsaforums.com>). Drawing on the excellent work of Kozinets (1997, 1998, 2001, 2002) we argue that a netnographic analysis is able to transcend the 'limits of asking' through observation of people's talk. Salsaforum is an international forum that attracts people from all over the world. The forum began in February 2004 and a testament to its growing popularity is the fact that there are now 3382 registered users, who have made a total of 74638 postings since its outset. Members vary dramatically in the usage of the forum; some have not made any postings and the most active user has made a total of 7265 posts, averaging 4.92 posts per day (figures correct on 14 March 2008). The forum provides an arena for members to discuss salsa music, share salsa video clips, announce events and offer reviews of salsa clubs, DVDs etc. For our analysis, we focused on the "Just Dance" section of the forum. There are a total of 1750 discussion threads in this section of the forum covering a wide range of salsa dance issues. Some threads only receive a few replies while others have received almost 1000 replies. Interpretation was constructed around moving between individual postings, chunks of postings, entire discussion threads and the emergent understanding of the complete data set (de Valck 2007). In addition, our interpretation of the Salsa experience is also aided by knowledge gained through participant observation and interviews. The posting presented at the beginning of the paper highlights a number of issues that will now be explored. Specifically the findings are organised into three key experiential themes: the first exploring the salsa experience; followed by understanding the "magic" of the salsa dance floor; finally, we explore the apparent interaction between the music, the self and the body engendered by the salsa experience.

'JUST DANCE': THE SALSA EXPERIENCE

From our analysis of the internet forums, a key experiential theme is that Salsa appears as a shared experience that links individuals together resulting in a relaxed, friendly and comfortable atmosphere on the salsa forum. The forum is viewed as a place where salseros (salsa dancers) can seek advice, support and encouragement from other salsa lovers in all corners of the world. As one participant suggests:

I love this forum 😊. This place can even out the wildest of emotional roller coasters and hopefully has kept some people going when they might otherwise have given up.
(UK, male)

Others concur that the forum provides a helpful support network and analysis reveals that members use the forum as a venue to share positive (e.g. the perfect dance) and negative (e.g. embarrassment at being abandoned mid-song on the dance floor) salsa stories. There is evidence of a sense of camaraderie amongst forum members, as demonstrated through the incessant use of compliments, both written (such as “well said”) and symbolic (smiling or bowing emoticons) during discussions as members praise each other for what are perceived to be beautiful or inspiring words. For example, as one of the participants suggests:

You can tell from all your posts here that you would be GREAT to dance with. You have a passion for dancing and music plus you appreciate and understand your partner. A winning combination 😊😊 (male, Australia)

This camaraderie is extended to newcomers who often receive words of welcome after their initial postings. As a result of the powerful and often poetic communication between members, the forum serves, we argue, as a rich repository of cultural meanings seeking to embody the social dramas (Turner 1982) of contemporary consumer culture.

“BEING KISSED BY THE MAGIC IN THE AIR”: CONSTRUCTING MAGICAL EXPERIENCES ON THE DANCE FLOOR

The passion felt for salsa shines through in both observation in salsa classes and clubs and analysis of the forum postings. In addition to well-being and health benefits created by physical movement, Salsa is also seen as an activity that has “the power to generate so much happiness.” One member defines a salsa “fix” as “THAT euphoric, satisfying feeling” while another suggests that salsa “gives me all the energy in the world. It makes me feel alive!” One of the reasons for this feel-good factor is because salsa dancing results in a sense of escape from the mundane realities of everyday life and provides relief from feelings of stress or tension (similar to Goulding et al 2002). More so, in terms of the way in which space appears as a social construct, the dance floor is viewed as somewhere that can be separated from the rest of the world akin we would suggest to Turner’s anti-structure “wherein human beings stripped of their roles, statuses, memberships, and moralities, are in communion as human selves—against the demands of organization and structure” (1982, 113). Or, the signature of one of our forum members more succinctly conveys this idea: “Mild-mannered corporate guy by day...raging Salsero by night.” The salsa dance floor offers dancers the possibility of being transported to a liminal space: “another world—where there’s no pain, suffering, worries that life abundantly confronts you with.” In this world salseros experience a sense of peace, it is a world where “everything is effortless, no performance anxiety, no feelings of superiority or inferiority.” The following two postings provide effective illustrations of this otherworldliness associated with the salsa dance floor:

Participant 1: I love it when everything around me seems to disappear, when there’s just me, my dance partner and music. In those moments I feel so much passion, so much energy... I truly feel life in my veins. That’s better than...well...anything! (Male, Slovenia)

Participant 2: It offers an environment where you can walk in feeling like a nobody, or maybe just down after a hard day, and walk out feeling completely special and very much appreciated. The best thing is that it comes with no strings attached and there seems to be an understanding and respect for the bound-

aries that separate the dance floor from the rest of the world. For five minutes you can loose yourself and focus all your attention on another human being! (Male, UK).

A vital space of emergence and possibility, for example, a number of salseros compare the emotions generated through salsa with the experience of falling in love suggesting that the “spirit of salsa” makes “time stand still” as people lose themselves in the moment. One forum member commented that: “Looking back on some of the best dances; they now seem like dreams. Maybe they happened maybe they didn’t.” In this way, the dance floor becomes a sacred place (Belk 1989) to be imagined and eulogized.

Some salseros extend their love of salsa from the dance floor to other aspects of their lives. Some suggest that salsa “starts to become a part of you” while others go further and suggest that it becomes a lifestyle and an overarching guiding philosophy:

Participant 3: “Salsa isn’t about girls, it isn’t about who is looking at you, it isn’t about patterns/moves, it isn’t about partying, it isn’t stepping. It is about LOVE, it is a lifestyle where salsa is your world and your mate the subject of all interactions within that world and its love.... It is a lifestyle, a lifestyle, it is nothing less...”

For some, devotion to salsa dancing not only encroaches on lifestyle but can actually become a way of life in its own right (de Burgh-Woodman and Brace-Govan 2007).

The previous postings place especial emphasis on the relationship between the dancing couple which is described by the forum members as a “mysterious union,” “gratifying connection” and “magical moment.” In an ideal partnership “you cease being two people dancing with each other, and become a couple dancing together.” This highlights the central role of the social in the salsa experience, defined by one forum member as follows: “Social-in dance terms?-The ability to participate, engage in, and collaborate, with someone-known or unknown- who is of a like disposition”. The reference to “like disposition” in this definition does not refer to demographic or socio-economic characteristics, rather, salsa appears to attract people from all walks of life who are connected through their love of the dance. The internet forum makes possible a sharing of this interest, but also a global connection where talk of people’s salsa experiences is central. As one member suggested, salsa provides an opportunity for “Meeting and dancing with a wide variety of people that I normally would never meet in my nerdy, high-tech world.” It is precisely this tendency that caused Gilroy (1991) to comment that the dance floor could be viewed as a cultural space marked by an absence of the usual hierarchies of society. It could be suggested that salsa provides an opportunity to break down barriers as it creates an automatic link and point of communion between dancers:

Participant 4: “It’s always funny, when I’m hanging out with my salsa friends, to see the puzzled looks on people’s faces. They’re like...what are all of these black, white, latino (you name it) folks doing hanging out together. In fact, we were asked what group we were from or the reasons we were hanging out! LOL It’s all about the dance and the music, baby!”

Salsa congresses are a popular venue for meeting other salsa aficionados and appear to provide a chance for people from many different countries to congregate. It is commonly suggested that even language differences do not inhibit union through salsa; the dancing is the central element. Thus the dance floor offers a space

that is beyond the barriers that may typically prevent meaningful interaction in everyday life. As one member suggested, salsa is “the global language of dance.” Indeed communication through dance is sometimes deemed superior to oral communication offering a way to “perfectly capture and convey something you could never express with words.”

The above definition of social also suggests that even complete strangers can be united through salsa. Observation at salsa clubs indicates that partner switching is the norm as participants rarely dance with the same partner for two songs in a row. As one forum member suggests, “the more you dance with people you don’t know, the better.” Stories of dancing with strangers then appears to offer the potential to generate deep emotions, as articulated in the comment below:

Participant 5: That surprise dance. Someone you’ve never met before, maybe never even seen dancing, asks you to dance, or you ask them, and from the first step, you’re in tune with each other. It just feels so “right” it makes me wanna laugh (and cry) my way across the dance floor. (UK)

As such, the dance floor becomes a space where norms of touch are challenged and where the relationship between private and public space is blurred (Bringinshaw 2001). The presence of “chemistry” between a couple, even those who are strangers off the dance floor, leads to a particularly intense emotion. This was defined by one Salsero as follows: “Chemistry is when both partners are listening, and both are hearing. Chemistry is nuance, appreciated and acknowledged.” The difficulty of putting this chemistry into words motivated participants to use various metaphors to express and understand such extraordinary experiences: “When that spark ignites it’s great; it’s like a story being read for the first time” and “We’re painting a story together and the dancefloor is our canvas.” Thus in Maffesoli’s (2007) words, in order for the “loss of oneself in another,” there needs to a connection between two people through the sharing of emotions and particular dance experiences. Salsa draws our attention to the boundaries of the body, and the extent to which such boundaries are fluid and can be blurred and merged (Bringinshaw 2001). Whereas Douglas (1973) maintains that physical bodily experiences are modified by the social body through adherence to social norms, we suggest that the salsa dance floor may be viewed as one space where this modification is less evident. Whereas bodily behaviour in public spaces is often rule-governed as individuals maintain “territories of the self” (Goffman 1966), in salsa dancing, that personal space can expand to include the extended body, that is, the body of the other.

“MY BODY AND SOUL REMEMBERS WHAT TO DO AND SHALL GUIDE ME THROUGH”

The interaction between the music, the self and the body is of central importance in salsa dancing. The previous section highlighted the strong emotional bonds that exist on the dance floor. It appears that connections between the couple are accentuated through the music. As one forum member suggests: “The two of you have become *one* WITH the music.” Music is seen as powerful and energising and as a force that vitalizes the body:

Participant 6: To me, as soon as “the right music” comes on (has to have that certain groove), it touches me deeply, it pulses through me, like electricity, and I want to become one with it. The pleasure I get from the music alone is intense, very much like....you know what I mean ;-)... and if I can dance and click with someone it becomes perfect. I go straight to heaven.

Participant 7: my ultimate goal is to be a true representation of the music that is being played.... on the moment, creative, imaginative, response to the music, that is what I strive for every time I walk in a dance floor someday someday (male).

While mastery of the steps undoubtedly makes participants feel good, especially when learning a new move for the first time, this is not deemed to produce the best style of dance. Rather many believe that truly good dancers are those who not only listen but “feel” the music in their “heart and soul” and are capable of translating such emotion into movements of the body. Even those who do not understand the Spanish lyrics, can be guided by the emotion in the singer’s voice. As another Salsero remarked:

“In fact, when a person is deeply in touch with feelings and the music, changes in a song never heard before are felt way before they happen, they all have nothing to do with technique nor musical knowledge of salsa, rather ability to feel...”

In salsa dancing, the accounts suggest that people’s bodies can be one step ahead of levels of consciousness as people become caught up in the vitality and spontaneity of the “materiality of being-together” (de Certeau 1996, 75). It is this process that leads to self-expression as salseros interpret the music in different ways. As one member suggests, “we aren’t robots, we are all different, so shouldn’t we all display the true US on the dancefloor?” An important goal for many salseros is to achieve flair or “sabor,” that is “an innate response to self expression that can not be taught through a set of physical rules” as participants attempt to “find yourself in the dancefloor” and contact with “inner dancers.” Indeed, one member comments that “Even though this is a partner dance, I would say the most important thing I have learned is to dance for myself.” The dance floor appears as a space characterised by a freedom of expression and freedom of movement and the release of aspects of the self that are often hidden to others:

Participant 3: I like the fact that people get to enjoy you and vice versa. Sometimes the you on the floor can be more ‘you’ than the person off the floor just like an artist might express the deepest part of themselves through their paintings but nowhere else. (Female, UK)

Thus “the way people treat their bodies reveals the deepest dispositions of the habitus” (Bourdieu 1992, 190). Similarly, Fraleigh (1995, 19) suggests, “We dance to enact the bodily lived basis of our freedom in an aesthetic form.... We move for the moving, but more, we dance for the dancing.” In other words, salsa appears to provide a form of freedom from everyday constraints where movement is not directed at instrumental or practical goals but rather is channeled into forms of self-expression and action centered upon pleasure and enjoyment. Salsa is a way to allow self-expression and emotion to escape or “burst” as a “radiating essence.” In this sense, Salsa can be seen as a medium of expression through the communicative body, that is, a body in process of creating itself (Frank 1991).

As social drama, salsa dancing appears to demand that participants are in touch with their inner emotions. One forum member provides a particularly rich description of the way in which this may conflict with societal expectations and norms:

“society at large does not teach us how to become in tune with our feelings but rather, how to look to the outside and be lost

in exoteric ideals; a material world that is only to be happy with external possessions. Hence, we go on following what society tells us and forget about the innerself and feelings..." (male)

This member suggests that those who focus on technique rather than letting the music move them are driven by "instant gratification," a central driver of consumer society (O'Shaughnessy and O'Shaughnessy 2002). They are driven to dance in such a way that fits with others' expectations rather than attempting to dance in tune with their inner selves which would enable "real achievement" in the future. The issue of rationality versus emotion is central to this discussion and Salsa appears as a way to fulfil the "emotional hunger" (Cushman 1990, 600) generated by consumer culture. Or as our participant continues:

"while the mind is busy thinking the body can't feel. The mind is blocking the body from feeling.....Listen to your soul not what step the brain thinks you should do...."

Dancing comes from the soul, not the mind, but to a thinking society such a belief doesn't come easy to stress.....So, while we are taught the do this and do that, our soul has been waiting to be let loose. Our mind (ego) needs something to feel good about, that something happens to be patterns and the thought of achievement through more and more complicated patterns. While the ego rules there isn't telling someone that true fulfillment comes from the soul."

These posts generated a great deal of enthusiasm with forum members suggesting that "his inspirational words are like diamonds" and "jewels". Others agreed that the best dances are those when the moves "just happen". Dancers who are driven by the head are bound by "limits, correctness, and rationale" and therefore fail to realise that "true greatness [comes] from that something inside of you." Creativity is therefore not as constrained as one might imagine (cf. Madrid 2006). As Frank (1991) suggests, for the communicative body, discourses enable more than they constrain. Thus once primary steps have been learnt, salseros can allow their bodies to "play with the music" and thereby overcome the cultural contradictions that they experience in their everyday lives through the medium of dance.

CONCLUSIONS

"The presumption of bodies already in motion, what dance takes as its normative condition, could bridge the various splits between mind and body, subject and object, and process and structure that have been so difficult for understandings of social life to navigate." (Martin 1998).

From the ecstatic bodily gestures of the shaman to the magic of ritual within archaic cultures dance has always been central for the construction, production and reconstruction of our notions of society. From the hypnotic beats of Salsa music and its associated global marketing industries, to its continued representation and commodification within films and advertising, to the multitude of global clubs, congresses and dance classes; Salsa culture has always offered a rich and fertile ground for the transcendence of cultural forms. Our exploratory study foregrounds the lack of attention with the CCT tradition (Arnould and Thompson 2005) to notions of the body and embodiment (Joy and Sherry 2003); Goulding et al (2002) make a similar point on the importance of the body. On the basis of our exploratory netnographic study of the salsa experience we reveal in this study how dance forms such as salsa are rooted in a renegotiation of the relationship with our own bodies and those of others. That is how dance responds to and may

compensate for a need for movement within our everyday lives; moving bodies are always then about a release and transcendence, even when such movement is underscored with a dance technique which is itself disciplining. The desire to dance then responds to a reclamation and renegotiation within the confines of existing structures; navigating and traversing within the confines of those structures whilst offering a partial imaginative release through resolving cultural contradictions on the dance floor. Through touch, sustained eye contact and a "magical" connection with others; through the creation of art with one's body; and through the tendency to forget what one looks like in order to follow one's "inner dancer" to the beat of a style of music which is "infectious". We start to see how dance, but also through the discourses constructed around it, promises a kind of transcendence, an attempt to rethink the rules of association with not only others, but also ourselves within consumer society. Whereas conventional thinking dictates that the body mediates the relationship between self identity and social identity (Goffman 1966), it appears that salsa dancing offers the opportunity for a union between the outer representational body and the subjective experiential body (Thomas 2003). Using Csikszentmihalyi's (1990) terminology, we can suggest that's salsa dancing offers a "flow experience," that is a state of total involvement where one moment flows holistically into the next without conscious intervention (cited in Celsi et al. 1993). More so, we might concur with Turner when he suggests that: "The group or community does not merely 'flow' in unison at these performances, but, more actively, tries to understand itself in order to change itself" (Turner 1982, 101). Herein lies the promise of salsa, as for some, the experiential consumption of salsa provides meaning in life and offers enjoyment and ecstasy through connection (Belk 1989) and "rare imaginative transcendences" (Turner 1982, 101). More so, the online interactions makes possible a continued dialogue around such experiences, where we witness the group generating new forms of understanding and knowledge.

Dance then comes to be seen as a reflexive form of knowledge enacted in and through our bodies, where the settled and fixed is disturbed and placed in motion. Here the importance of dance for an understanding of consumer culture reveals itself. While others may rule out the possibility of escape from consumer culture (Arnould 2007); a turn to dance brings in its gyratory wake a reimagining of consumer action embedded within not only economic and market forces. Rather we see how dance embodies an unquenchable thirst to escape beyond the mundane, a desire for "freedom", especially if understood as the continual and never-ending "attempt at self-disengagement and self-invention" (Rajachman cited by Sawicki 1991, 101). In our minds this speaks of how dance makes possible shared passions, exhilarations and desires lacking from people's everyday lives, compensating and granting them a space for articulation and expression. Whereas previous research has suggested that high octane white knuckle experiences such as skydiving (Celsi, Rose and Leigh 1993) and white water rafting (Arnould and Price 1993) may offer such an opportunity to transcend mundane experience; here we suggest that salsa dancing can result in total absorption as the dance floor becomes a "beautiful place of euphoria." While at the same time we acknowledge and appreciate the role of consumer culture itself in this economy of passions and desire, since it is the character of contemporary consumer culture which furnishes and makes possible the emphatic and constant rejoinder to seek out desire, producing the will to desire desire and passion itself. But to end, we argue that what dance ultimately makes possible, is what de Certeau refers to as a "materiality of being-together" (1996, 75). That is, through its emergent qualities, and brought into being by the sensual and exotic qualities of the music, but also most importantly through the synchronic movements of the

dancers themselves to produce a community space for rethinking the social and notions of shared emotions through a dance form which is itself affiliative and sharable. By way of closure, the promise of dance then can be understood as a social drama which through its performances serves to, as Turner suggests: “keep us alive, give us problems to solve, postpone ennui, guarantee at least the flow of our adrenalin, and provoke us into new, ingenious cultural formations of our human condition and occasionally into attempts to ameliorate, even beautify it” (1982, 110-111).

Exposing the 'Credogenic' Environment: Where does Responsibility Lie?

Isabelle Szmigin, The University of Birmingham, UK
Deirdre O'Loughlin, University of Limerick, Ireland

ABSTRACT

This paper explores the nature of the consumption environment of credit, termed the 'credogenic' environment and identifies its key players including financial services providers, regulators and consumers. Perspectives from both students and key informants from a range of consumer and debt advice agencies, regulatory bodies and banks in the UK and Ireland are presented. The pervasive culture of credit and the issue of responsibility emerge as key themes. While there is recognition of marketing's role in creating and sustaining the credogenic environment, there are differing views regarding lender and borrower responsibility and accountability. The adequacy and effectiveness of current legislation is questioned.

INTRODUCTION: THE MARKETING ENVIRONMENT

While the marketing environment is recognised as a critical factor for both management and customers, it is a relatively underexplored and underdeveloped concept. The ideological power of neo-liberalization has resulted in the 'exaltation of the individual' (Evans, 2002:56) in marketing discourse, while the influence of marketing to shape and control the consumption environment has been largely ignored. A case in point has been what we term the credogenic environment, where the continued availability of credit for many of those already in debt inevitably affects the choices they make and their perception of their financial situation. The term 'credogenic' is purposely derived from another term describing a particular environment in which marketing could be seen as complicit. This is the obesogenic environment (Swinburn *et al.* 1999) whereby a surfeit of fat, sugar and salt and a lack of physical exercise have led to an increase in obesity. In particular, Swinburn *et al.*, (1999) highlight the importance of the physical, economic, social and cultural environments of most industrialised countries and we suggest that a similar argument could be made regarding the proliferation of credit and the acceptance of high levels of debt in western societies today. This paper begins by acknowledging the nature and importance of this credit environment in terms of how it is constructed and examines how much real freedom and choice consumers have in their behaviour within it. We consider research which identifies the individual's cognitive limitations faced with a complex purchase such as credit before presenting a more detailed analysis of the current credogenic environment with a particular emphasis on the growth of consumerism and the pervasiveness of the culture of credit across all strata of society. Empirical research with regulators, representatives of financial institutions and advisory agencies and one potentially vulnerable group (students) is presented to identify roles and responsibilities.

THE ENVIRONMENT AND CONSUMER CHOICE

The dominant neo-liberal view coming from standard welfare economics is that of rational, well informed consumers. Consumers are, however, still constrained by their own cognitive limitations and product complexity. Complexity is an important issue in terms of how much real control consumers have. It has been suggested that consumers cannot rationally process all the information neces-

sary to optimize their behavior (Hanson and Kysar, 1999). This argument could be made for the consumption of credit where increasing product complexity and limited financial literacy resulting in poor financial decision-making is a growing cause for concern (Atkinson and Kempson, 2004). Thus, any argument for consumer empowerment has to be framed within the complexity of the context.

Furthermore, we also have to consider how people frame choices in relation to their needs now and in the future. If we use too much credit today it is unlikely that we do it while considering the implications for our future needs. This reflects Pigou's (1920) defective telescopic faculty whereby most people prefer present pleasures to future satisfaction. Increased choice today has little regard for the future; we must instead consider how the individual's imperfect faculty operates in the sophisticated marketing environment alongside a rampant consumer culture where pursuit and possession of goods is all important (Roberts and Jones, 2001). The evaluation of a product's potential harmfulness is not always clear-cut as the marketing of seemingly beneficial products can sometimes become damaging because of the particular characteristics of the consumer (Rittenburg and Parthasarathy, 1997) who through their lack of knowledge, experience or maturity may abuse or misuse the product (Cui and Choudhury, 2003). For example, university students accept bank loans to enable them to study and support themselves at university but in doing so they are required to assess their financial capabilities in terms of budgeting for this commitment and forecast their ability to pay in the future once employed. While the use of credit cards to finance consumer purchases has become 'a way of life' (Hayhoe *et al.* 2000), it has been suggested that the dramatic growth in credit card usage among college students in the US is placing them at greater risk for high debt levels and misuse and mismanagement of credit after graduation (Lyons, 2004). If young people enter the market place unable and ill-equipped to manage the further demands and attractions offered by the credit industry their future may already be blighted. Thus, the ethical evaluation of many products depends on their interaction with consumer characteristics and marketing practices (Cui and Choudhury, 2003).

THE CREDOGENIC ENVIRONMENT

Higher levels of credit consumption and debt accumulation have led to an economic and, importantly, psychological transformation in society from a saving to a spending culture (Griffiths, 2000; Berwick, 2004). This in turn, appears to be accompanied by a change in consumer behaviour and attitude where debt has become perceived as part of normal modern life (Lea *et al.*, 1993). Recent statistics show that Ireland is ranked first in terms of personal indebtedness compared to euro area countries using personal-sector credit to GDP and GNP ratios (ECB, 2007). Similarly, secured and unsecured debt figures in the UK have reached £1.2 trillion (Datamonitor, 2006) with UK consumers accounting for two thirds of all outstanding credit card debt in the EU (Fleet Street Letter, 2007). Alongside changing behaviour there has been an increasing level of aggressive unethical and undesirable marketing practices (Burton, 2008), a rise in 'predatory lending' to vulnerable groups (Hill and Kozup, 2007) and promises of 'easy money'

TABLE 1
Profile of Agency/Supply-side Participants

Position	Institution

Director	British Bankers Association, UK
President, Students' Guild	University of Birmingham, UK

(Griffiths, 2000) by traditional and non-traditional financial institutions. In this credogenic environment the decision to take on credit is strongly shaped by a desire to attain a lifestyle (Chien and Devaney, 2001) in order to satisfy a range of hedonistic and utilitarian desires in turn shaped marketing practice.

Coupled with the increased range and access to credit, there is also a high level of asymmetric information between borrower and lender (Oxera, 2004) which is particularly relevant for people who may be classed in the "vulnerable" category, such as students and low-income groups. A recent Irish study found that debt among low-income consumers includes a greater element of "middle-class, lifestyle-related" consumption and debt including credit card debt and luxury goods debt, which is often driven by aggressive marketing tactics and increased access to credit, coupled with pressures from a consumption-driven society (O'Loughlin, and O'Brien, 2006). While the life-cycle hypothesis of saving (Modigliani, 1986) suggests that people in the early stages of their career may have more favourable attitudes towards spending and borrowing, assuming future strong earnings (Chien and Devaney, 2001), more recent research suggests that indebtedness may move across lifecycle stages (Soman and Cheema, 2002), signalling that young people will continue to carry debt throughout their lifecycle. Taking a student perspective, O'Loughlin and Szmigin (2006) found that changing expectations and intense promotion of unsolicited and unsecured credit by financial providers signals a pattern of attitude tolerance and debt-accumulating behaviour among students that will ensue throughout their adult lives. The empirical part of this paper presents findings from in-depth discussions with students in the UK and Ireland, considered to be a particularly susceptible consumer group, in addition to key informants who are directly engaged with the credogenic environment from a policy, practice and advisory capacity. The research illustrates the nature and pervasiveness of the culture of credit and outlines a range of

views with regard to where and how the ultimate responsibility for managing the current credogenic environment should lie.

METHODOLOGY

The study focused on exploring the level and division of responsibility held by key players including consumers, government agencies and financial providers in the credogenic environment and the power relations therein through an inductive exploratory approach (Miles and Huberman, 1994; Zaltman, 1997; Silverman, 2000).

A purposive sample of 5 UK and 6 Irish agency and supply-side key informants were selected across a range of key Irish and UK banking representative bodies, government support bodies, debt advice bureaus, consumer agencies and student representatives.

In addition, a range of consumer interviews were conducted with a purposive sample of 3rd level students based at the University of Limerick, Ireland and Universities of Bath and Birmingham, UK across a range of demographics, (age, gender, geographic and economic background). A purposeful sampling method was used to recruit 20 UK and Irish students in total, 10 from each country. As one of the key areas of interest was range and use of credit, including attitudes and behaviour in relation to credit cards, each student in the sample was recruited on the basis of credit card ownership.

Personal interviews were chosen as the most appropriate means of data collection for sensitive financial issues due to their superior ability to build depth and intimacy (Denzin and Lincoln, 1994) and optimally reveal participant in-depth insights and interpretations (Carson et al. 2001) in relation to credit and debt consumption. Following Miles and Huberman (1994), the transcripts were independently coded by both researchers and the themes were subsequently discussed and agreement was reached in terms of any differences in interpretation.

DISCUSSION OF FINDINGS

Ease of Access to Credit

Most of the students in this study found it easy to access both loans and credit cards from their banks. Importantly, many students are opening a bank account for the first time and it gives banks the opportunity to market further products to them:

'It wasn't me going out and saying I need a credit card, it was more, there's an option of getting a credit card, why not?' (UK, Male)

'It was very easy for me to obtain a credit card, I wasn't going to have it but they said to me I might as well have it because it's there' (UK, Female)

Neither student has intended to obtain a credit card but accepted them when offered. They readily, and perhaps with little thought, accepted them. The possible consequences of getting into the credit card 'way of life' (Hayhoe *et al.*, 2000) are highlighted by the representative from the National Debtline who expressed her concern that people as young as 18 were calling on their service:

'It's so easy to get and people are starting off a lot younger and they're just acquiring more credit and then inevitably, they reach a point where they can't pay it and it might not be because their income drops but it just can't sustain it' (Training Information Officer, National Debt Line)

She continued by saying that young people do not necessarily have the 'training' to know how to deal with the credit offered them and then they accept more credit until they are no longer able to cope, thus echoing the issue of financial capability and literacy highlighted in the literature (e.g. Atkinson and Kempson, 2004).

The director from the British Bankers Association also pointed to a supply side issue in relation to the ease of credit for young people by pointing out that credit could be acquired from many sources so no one provider really knew how indebted a customer was. In addition he recognised that students were a particularly attractive marketing proposition:

"If they're promising in terms of university calibre then of course they have a future potential, and it's that future potential that makes them such an attractive marketing proposition" (Director, British Bankers Association).

That students require money to support their education at a time when they will be limited in terms of how much they can earn makes them an easy target for marketing and in particular for point of sale offers. None of the student participants had been rejected for loans or credit cards. But while the financial providers' telescopic abilities forecast that students are likely to be earning reasonably within a relatively short period of time, they do not accommodate the potential financial difficulties such students may face during their studies or already be in. Although previous studies (Mendoza and Pracejus, 1997) have recognised that students may display a future temporal orientation associated with holding more credit cards, debt still requires careful management in the period before future earnings are realised.

Marketing and Responsibility

Students were aware of and critical about the marketing they encountered. They suggested that marketing messages often only gave them one side of the agreement:

"You know, it's like we are giving you the freedom to do all this but actually on the sly we are keeping you hostage for the next few years until you pay us back" (Irish, Female).

Another student suggested that providers present a picture of 'free' money to students:

"For me, they make it out as if this is free money, you don't really need to worry about it, spend it on what you want we'll sort you out a good deal, have a good time, that's probably the way they market, and I don't think it's a good way because it comes across as free money, not you've got to think about the consequences" (UK, Female).

That the marketing of credit may play on a consumer's desire to engage fully with a culture of materialism (Calder, 1999) was recognised by all of the agency and supply participants. The policy officer from Consumers Advice described a recent piece of research they had conducted which had identified what she referred to as the 'seven deadly sins of credit marketing':

'It's all about how easy it is and it's all appealing to people's aspirations and also particularly in the loans, they say; 'why don't you take out a little bit more? Go on, spoil yourself!' (Senior Policy Advisor Citizens Advice)

The British regulator was more circumspect in his comments, recognising the importance of education for individuals but also acknowledging that the decision as to whether or not to take credit is theirs:

'Our job is to make sure that people understand the decisions that they need to take in relation to taking on debt and the consequences of it and make sure they've got enough information and the tools available to make those decisions, not to tell them what their decisions are' (Consumer Sector Team Manager, Financial Services Authority).

The idea that there is a responsibility to ensure people understand what they are getting themselves into was echoed by the director of the British Bankers Association, who suggested that some kind of interrogation was needed to assess whether the finance was needed and the nature of repayment fully understood at the time of purchase:

'(We should) provide them with more understanding...how could I best help you in any future credit you might want to take, and I'd say, do you need it, do you understand it and can you afford it?' (Director, British Bankers Association).

In conclusion the supply side participants echoed the students' comments in relation to the freedom extended to them in terms of being able to engage with a product for which they did not necessarily have enough information and understanding to recognise their future obligations. This supports the notion that the effective evaluation of complex products such as credit is dependent on both the vulnerability of the consumer, marketing practice (Cui and Choudhury, 2003) but also meaningful consumer information and advice.

Individual Responsibility

Despite the fact that many financial providers aggressively promoted credit offerings to consumers and were perceived to be

"putting an idea in a student's head", many students acknowledged their responsibility. This individual level responsibility related to assessing the level of credit each person required and ensuring that he/she did not incur unmanageable debt. Several students emphasised the importance of the individual assuming the responsibility for taking on credit, over-spending and paying back the debt:

"[It's a] nightmare... I think people take too much credit out- they go beyond their means and it can be a downward spiral into debt and you shouldn't really take it up unless you need to... that's my thoughts really" (UK, Female)

"Yeah, I don't believe in any of this crap when people sue for spending too much and being in debt and get it written off. No, you spend, it's your own fault you pay it back" (UK, Female)

Both comments suggest a high level of awareness and maturity regarding their role and responsibility in relation to credit and debt which they clearly feel should not be passed on to others to manage. Some students recounted bad experiences from which they had learned to manage their finances better. For example one student recalled her immature behaviour:

"I should have just paid off the minimum payment but I thought if I don't think about it it's not there" (Irish, Female)

Since this time, however, she has set up a minimum payment to leave her account each month. Conversely, other participants recounted stories of how they or their peers assumed little or no responsibility for their spending and instead relied on parents to support them and pay off any debts they incurred:

"No, some of my friends... they will just go into a shop and spend all around them. Some of them have their parents... they just pay it back for them" (Irish, Female)

Similarly, others spoke of their "nice parents" and that they were "spoiled" as their parents not only paid off their loans and debts but also provided them with an allowance.

While some students freely used their parents as a source of non-repayable income to finance their lifestyle, others recognised the extensive support provided by their parents and were very mindful of taking responsibility for their own debt.

"My family do so much for me already. The student debt that I will pick up is my own responsibility I mean I can't ask them to go off paying other parts after they do everything, all the other financial things for me" (UK, Male)

While previous research has shown that parental attitudes to finance offer a context to their children's behaviour (Hesketh, 1999), this can also contain mixed messages with regard to the use of credit (Atkinson and Kempson, 2004). The role of parents in this study was complex with some being very active, even cutting up their children's credit cards following excessive use, while others regularly paid off debts of hundreds of pounds.

The concept of responsibility varied across participants with some acknowledging and exercising individual responsibility while others focused more on the instant gratification of spending and supporting their lifestyle (Webley and Nyhus, 2001), without reflecting on the long-term consequences of debt, instead relying on their family to "bail them out" if they incurred unmanageable debt. There were clearly major economic differences amongst students that reflected how they were able to behave with regard to debt as

is reflected by this comment from the President of the Students' Guild:

'The amount of people I know who take all their student loan out and put it in a high interest bank and Mum and Dad give them money every month and have a copy of their parent's credit card so that they can just go and spend.' (President, Students' Guild, University of Birmingham)

From a supplier perspective, the notion of individual responsibility was also met with mixed responses with some emphasising that "responsibility works both ways" (Financial Advisor, Ireland). Another suggested that "there has to be responsible lending and there has to be responsible borrowing" (Director of Consumer Information, Financial Regulator, Ireland). Individual level responsibility was also contingent on the consumer being fully informed and equipped to make the best financial decision and there was acknowledgement by some that not only were financial products complex but that financial capability varied, signalling the "need for better financial literacy from school age" (Director, Office of Director of Consumer Affairs, Ireland). Others believed, however, that there was sufficient consumer information and public awareness in addition to legislation in regard to credit and debt and that it was the responsibility of the individual to exploit resources available to them:

"We give them information and leaflets—we don't tell them what to do... regulation should be minimised" (Consumer Sector Team Manager, Financial Services Authority, UK).

While the notion of individual responsibility unveiled disparate thoughts from both consumers and supply-side participants, it did not detract from the shared view that increased access and consumption of credit was pervasive. Those involved directly with indebted individuals recognised a change in culture regarding the acceptance of credit with young people becoming socialized into the normalization of debt (O'Loughlin and Szmigin, 2006), such that they 'carry this philosophy with them' (Financial Advisor, Ireland). However, successfully or not students manage their current situation their attitudes and behavior are likely to continue to develop in a pattern which may be difficult to change and adjust leading to a life-long relationship with debt (Soman and Cheema, 2002).

CONCLUSIONS AND IMPLICATIONS

This paper has argued for the importance of understanding the environment in the modern consumption context. The case study of the credogenic environment effectively illustrates the nature of the power relationships which support the continued dominance of marketing's role in a neo-liberal context. Despite the exaltation of the individual as rational and well informed, the challenges facing consumers to exercise true choice and freedom within this arguably marketing-governed environment are clear. Reflecting many western societies, the consumer and supplier research highlights the pervasiveness of the culture of credit in Ireland and the UK which is predominantly fueled by increased access to and intensive marketing and promotion of "easy credit" and "free money". This is particularly concerning given the individual cognitive limitations associated with a complex purchase such as credit which may be particularly acute for susceptible groups such as students, where their ability to evaluate and act responsibly may be unfairly tested. The consumer and supplier research clearly highlights that students are perceived as an attractive marketing proposition and targeted at

the point of sale with unsolicited seemingly harmless credit offerings, often without clear explanation of the long term implications. The direct consequence is a "buy now pay later" culture and the normalization of debt, some of which becomes unsustainable for consumers such as students who may not have the present ability, if perhaps the future potential to repay their debts. That consumer agencies report increased usage of their services by consumers as young as 18 is testimony to the power of the credogenic environment, within which a sophisticated financial marketing force continues to offer attractive credit options while failing to include the consequential dark side to credit which is unmanageable debt.

The issue of where responsibility should lie for creating and sustaining this credogenic environment unveiled much debate and diverse perspectives among both consumer and supply-side participants. On one hand, there was clear consensus among both groups of participants regarding marketing's dominant role in creating a consumerist society in actively promoting a lifestyle to consumers which in turn was facilitated by a range of credit options offered by financial providers. On the other hand, there were mixed views regarding the extent to which responsibility should be assigned at the individual consumer level, particularly as the issue of varying levels of financial capability and literacy was a key factor. Regarding the issue of lender responsibility, recent Irish legislation has been introduced through the Consumer Protection Codes (2006) which have outlawed many unethical lender practices such as unsolicited limit increases and pre-approved loans. Reflecting similar initiatives in other countries, this may go some way towards providing augmented regulation of the credit-led environment which is focused on protecting the consumer rather than on crippling the supplier. As for individual responsibility, while the notion of financial education from an early age and ongoing "training" of consumers as suggested by participants is part of the solution, there does not appear to be sufficiently meaningful or accessible information in the public domain. Indeed, considering many of the students were offered credit at the point of sale, it is perhaps here that attractively packaged and promoted credit offerings should be accompanied by simple but hard-hitting guidelines and warnings regarding the total cost of repayment and penalties.

Classifying Customers with Multidimensional Customer Contact Sequences

Sascha Steinmann, University of Goettingen, Germany
Guenter Silberer, University of Goettingen, Germany

ABSTRACT

We used a multidimensional sequence alignment method to cluster customers ($N=151$) of a German tour operator according to the multidimensional sequences of their customer contacts (dimension 1), their functions (dimension 2) and importance of the customer contact (dimension 3). In doing so, we obtained four clusters. Results reveal differences in the customers' behavior concerning the customer contacts and their functions in the whole purchase process, as well as between the customer segments identified. Customer segmentation based upon demographic or psychographic variables would not have been able to enrich the knowledge of the customers in this manner.

INTRODUCTION

Knowledge of one's customers is a strategic success factor for any supplier. The fundamental element for the attainment of customer knowledge is the contact between the retailer or service provider and her/his customers in the different channels of the marketing and distribution system. Not only are the kind and number of the customer contacts in a specific process phase relevant to this, but also their functions and importance to the customer, not to mention the sequence of these three dimensions during the purchase process. Such multidimensional sequences have practically been ignored in previous marketing research, especially the problem of collecting, connecting and analyzing the relevant data from the different marketing and distribution channels in all phases of the purchase process to present a single, unified view of the customers (Payne and Frow 2004).

However, it can be assumed that multidimensional customer contact sequences (MCCS) are of great relevance to marketing: for example, it can be expected that different contact sequences are accompanied by different product purchases or e.g. in the tourism industry through the booking of different journeys and that different customers have different sequences according to their individual behavior. Knowledge of these connections facilitates the purposeful control of the customers throughout the purchase process by the retailer or service provider and thus extends his/her commercial possibilities to interact with customers within the bounds of marketing. Furthermore, such sequences can provide important insights into potential existing cross-channel synergies (Verhoef, Neslin, and Vroomen. 2007). Hence, an analysis of the multidimensional sequence of the customer contacts (dimension 1), their functions (dimension 2) and their importance (dimension 3) could provide crucial insights into customer behavior, as well as the needs and preferences of the customers over time, as it has become routine for the consumer to use different channels in the purchase process to approach a retailer or a service provider (Rangaswamy and van Bruggen 2005). Therefore, this study contributes to the marketing literature by addressing how the MCCS can be measured and form the basis for multidimensional customer segmentation. Besides this we are also interested in evaluating possible determinants and effects of the customer contacts, their functions and importance.

CONCEPTUAL BACKGROUND

Customer Touch Points and Customer Contacts

It is increasingly common for firms to employ online distribution channels alongside its offline distribution channels and further

marketing channels to rely on these complex combinations as a source of competitive advantage and better serve their customers needs and preferences (Geykens, Gielens, and Dekimpe 2002). In such environments, many customers have become multi channel users. They realized contacts between the firm and themselves at different contact points (e.g. store, agency, homepage) in the different phases of the purchase process. Therefore, there are many opportunities to establish contacts between a supplier and customers in the different process stages.

In retailing, we can differentiate the pre-purchase, purchase and post-purchase phases, but in other branches or when we are interested in specific problems or research questions it is more meaningful to use a more detailed modeling of the process. For example, with regard to tourism industry differentiation into five successive process phases (the pre-booking, booking, pre-journey, journey and post-journey phase) including all customer contacts is reasonable. Furthermore, we can distinguish the variability of the contact points (personal, semi-personal and impersonal contacts) (Silberer, Steinmann, and Mau 2006). Payne and Frow (2004) define these categories of customer contacts as a continuum of forms ranging from the physical to the virtual contact.

Functions and Importance of Customer Contacts

Every customer contact fulfills different functions in the various process phases. Consequently, speech, sale and service functions can be distinguished (Simons and Bouwman 2004). Therefore, the functions of the customer contacts in the different channels range from general and selective information regarding the desired product or service, price comparisons and purchasing up to using different kinds of customer services as well as advisory and complaining. Hence, in the contact, not only is purchasing a product of relevance to the customer, but also information and communication prior to, during and following the purchase (Wallace, Giese, and Johnson 2004). According to the media-richness theory (Daft and Lengel 1984), during the process customers will subsequently find it easier to establish contact with a supplier in a way that best fits their needs. This requires that the respective channels and their combination to be capable of fulfilling customer needs and preferences concerning the desired functionality in the different process phases.

According to Payne, Bettman, and Johnson's (1993) concept of adaptive decision-making, a customer shifts between the pre-purchase to the purchase phase from an attribute-based search to an alternatives-based search as she/he progresses in the decision-making process. Thus, the customers will be less focused on information gathering but more focused on comparing the alternatives they have decided to consider. In the case of complex products or services such as vacations, these alternatives are complex bundles of attributes and benefits that need to be processed. In cases where many relevant aspects of the decision cannot be controlled, customers seek some kind of help in the decision-making, and hence the customer is more likely to use the desired benefit as the basis to evaluate the characteristics of the different contacts points and the importance of the specific contact in the purchase process (Frambach, Roest, and Krishnan 2007). However, there are channel related differences in fulfilling customer's needs and preferences across the purchase process, including richness of information presented (Daft and Engel 1984) and accessibility or convenience (Ward

2001). For example, on the internet products cannot be physically examined, which leads to less product information than in the case of brick-and-mortar stores (Venkatesan, Kumar, and Ravishankar, 2007). Therefore, the internet is often considered to be risky for purchasing (Alba et al. 1997). Conversely, the offline channels are amongst other things characterized by richer information on the product (Venkatesan et al. 2007). Verhoef et al. (2007) used an extended version of the theory of reasoned action (Fishbein and Ajzen 1975) in their model for explaining the interdependencies of customers' channel choice across different process phases. Their results show that customers can benefit from the channel related differences within the purchase process by using the channels according to their individual channel behavior (see also Silberer et al. 2006) because channels do not differ in their functionality but also in their ability to fulfill individual customer needs to the same extent across the different process phases (Balasubramanian, Raghunathan, and Mahajan 2005). Research also shows that benefits and therefore the importance of the several contacts sought change across the process phases (Mittal, Kumar, and Tsiros 1999).

Concerning the booking of a vacation, we can expect personal contacts in offline channels to be more likely and more important to the customer than semi- or impersonal contacts because personal advisors are in the best position to help the customers identify and explain the important aspects in the pre-purchase and purchase phase. Because of the limited functionality of the mostly impersonal contacts in online channels compared to face-to-face contacts in offline channels, many customers commonly use the internet as an information source in the purchase process. Especially in the case of complex products or services, customers have to come to categorize it in their minds as an important information source, not as a shopping revenue (Balasubramanian et al. 2005; Verhoef et al. 2007). The previous comments show that not only does the usage of the different contact points by the customers differ during the purchase process, but it also supports the assumption that the functions, as well as the importance of the customer contacts, also change during the purchase process. We assume that this is reflected in the multidimensional customer contact sequences (MCCS).

Customer Segmentation

For our study, research regarding different approaches for customer segmentation is of particular interest. Ruiz, Chebat, and Hansen (2004) and Ganesh, Reynolds, and Luckett (2007) provide an overview of a large number of empirical studies on this topic. The procedure for the formation of customer segments can thus be divided into two different approaches. Demographic variables (e.g. age and gender) on the one hand and on the other psychographic variables (e.g. motives or attitudes) are drawn upon for the segmentation. By doing so, the constituted customer groups reveal *who* is buying in the investigated stores and *why*. The customer's actual buying behavior during and after the purchase, however, is hardly taken into account, i.e. *how* the customers inform themselves prior to purchase, *how* the purchase in the store goes and *how* the relationship between retailer and customer is organized after the purchase. Kim and Park (1997) classified the customers of food stores by the frequency of their visits. Ruiz et al. (2004) use the behavior during a shopping trip, and that only related to a visit in one store or shopping mall, as a basis for customer segmentation. Although they had partially different results in the end, the mentioned studies show the usefulness of customer segmentation based on their customer's behavior. However, different essential aspects are not taken into account: the specified studies only examine the behavior in a specific channel of a supplier *in* the purchase phase. It should be expected that different behavior during the purchase is reflected in different behavior *prior* to and *after* the purchase.

Another aspect deals with the variables used in the segmentation analysis: to consider only the behavior leads to the neglect of other contacts between customers and suppliers. However, as shown by studies mentioned first, such contacts are important influential factors for customer behavior.

According to Hägerstrand (1970) customer behavior can be viewed as a sequence of interdependent actions over time. However, customer behavior in the studies mentioned is mostly treated as a chain of independent activities. Thus, the sequential order and obvious relations of the activities are often neglected. Therefore, Abbott's (1995, p. 94) statement "We assume intercase independence even while our theories focus on interaction" regarding social science is also largely true for marketing research concerning the segmentation of the customers with regard to their individual behavior through the phases of the purchase process. Therefore, in the aforementioned approaches important aspects reflecting the customers' behavior are not addressed.

The sequential behavior of the customers throughout the purchase process also in different channels has barely been taken into account in the formation of segments. For marketing purposes, Larson, Bradlow, and Fader (2005) for example used a sequence-analytical clustering approach to evaluate the shopping behavior in a supermarket for the foundation of customer segments. Silberer et al. (2006) used the sequence of the customer contacts in retailing to evaluate differences in the customer's behavior with regard to the whole purchase process. Segmentation of this kind can give a retailer or service provider important insights into the requirements, preferences and behavior of the customers over a period of time. By tracking the multidimensional customer behavior across channels, firms can improve their understanding of their customers' decision-making and develop a basis for creating strong relationships and improving retention (Dholakia, Zhao, and Dholakia 2005).

The previous discussion shows that not only do the customer contacts (dimension 1) differ across the successive phases of the purchase process, they also support the assumption that the functions (dimension 2), as well as the importance (dimension 3) of the customer contacts, also change during the purchase process. The actual behavior of the customers over a period of time is taken into account for the customer segmentation through the use of the multidimensional customer contact sequences. This facilitates a differentiation of customers that is not possible on the basis of demographic or psychographic variables. Such insights are an important confirmation as to the usefulness of customer segmentation regarding the multidimensional customer contact sequence.

METHOD: MULTIDIMENSIONAL CUSTOMER CONTACT SEQUENCES

Measures and Procedure

The aim of this segmentation is to identify powerful customer clusters which are very similar with regard to their individual behavior reflected in their multidimensional customer contact sequence in the purchase process. We investigated multidimensional customer contact sequences regarding the five different phases of the purchase process in the tourism industry—pre-booking, booking, pre-journey, journey and post-journey phase—with a German tour operator based upon a structured questionnaire (comparable to Silberer et al. 2006). To support the recollection of events dated far away back a proceeding was chosen that took pattern from cognitive psychology (Ericsson and Simon, 1980; Anderson, 1995). Therefore, the questionnaire leads the customer through her/his memories step by step—starting with events that are most accessible to him because they are closest to the interview (post-journey phase)—up to those situations that are initially difficult to remember

without any support because they date a long way back (booking and pre-booking phase).

The surveyed multidimensional sequences included the different customer contacts (dimension 1: e.g. advertising, travel agency staff, tour guide), their functions (dimension 2: general and selective information, price comparison, booking, advisory and complaining) as well as the importance (dimension 3) of the different customer contacts across the purchase process. The importance of the customer contacts was inquired on a six-step rating scale ranging from 1=*entirely unimportant* to 6=*very important*. To ensure the recording of the multidimensional customer contact sequence over the whole purchase process, only those customers were recruited who had actually finished a journey booked with the tour operator. Furthermore, we only surveyed customers who booked a journey in the last 6 months prior to the study to ensure that they could still remember it well.

In the final questionnaire, not only the multidimensional contact sequences actually realized were examined but also possible determinants (previous bookings, price category, journey category, internet affinity, and demographic variables) as well as final variables (customer satisfaction, intention of recommendation, intention of repeat booking, trust).

A total of $N=151$ customers of the tour operator took part in the survey. Every participant in the survey was entered in a lottery, where two wellness weekends and tickets to a German leisure park were drawn. Women represented 44.2% of the sample. The average age=51.12 ($SD=13.52$) years.

Multidimensional Sequence Alignment and Sequence Clustering

The Sequence Alignment Method (SAM) was originally developed in molecular biology to compare DNA or protein sequences (Sankoff and Kruskal 1983). The idea of the SAM is to equalize two different sequences with regard to the operations insertion, deletion and substitution. Mostly the weight of one is assigned to the operations insertion and deletion, for substitutions the sum of the consecutive operations deletion and insertion (Joh et al. 2002). Usually there are different ways to transfer one sequence to another in the aforementioned operations, therefore the minimal sum of the weighted operations, the Levenshtein distance (Levenshtein 1966), is commonly used as similarity measure for the considered sequences.

In this study, the customer behavior is not represented as the customer contacts by a single attribute. To gain deeper insights in the differences of customer behavior and powerful clusters, the multidimensional customer contact sequences were characterized by three dimensions: the customer contact sequence (dimension 1), the sequence of the functions related to the customer contacts (dimension 2), and the sequence of the importance (dimension 3) of the contacts to the customers. The easy way to compare such sequences is to calculate the Levenshtein distance for each dimension separately and then add up the measured distances of all the dimensions. This approach is based on the assumption that all attributes are independent. In our case, this clearly is not true because there are obviously dependencies between the customer contacts, their functions and their importance. Therefore the calculation of measured attributes for each dimension would distort the result. To avoid such distortions with regard to the different measurement scales of the dimensions, we used a multidimensional approach proposed by Joh et al. (2002) which identifies elements that can be aligned simultaneously without calculating the costs twice, called "optimal trajectory multidimensional SAM" (OTMSAM). Joh et al. (2002) proposed to treat the operations that are applied to the elements of a dimension belonging to the same

event to be treated as a single operation. This integrated operation combines a set of elements that can be aligned simultaneously as if it were one element. Such sets of elements are called a segment. In the case of no interdependencies, the resulting alignment cost equals the simple sum of uni-dimensional optimum alignment costs. Any costs-savings are indicative of interdependencies across the dimensions underlying the activity-travel patterns. In general, the alignment of two multidimensional activity patterns will involve varying degrees of cost reductions. The stronger the interdependencies between attributes, the higher the cost reduction. For a more detailed description see Joh et al. (2002). The distances were calculated with the Software DANA as a basis for our cluster analysis using the Ward Method. The results of our cluster analysis show that the differentiation into four clusters proved to be the optimal cluster solution.

RESULTS: MULTIDIMENSIONAL SEQUENCE CLUSTERS

Description of the Clusters using Constituent Variables

In order to describe the clusters, the active variables that have entered the cluster analysis are cited. The clusters identified are therefore described using the customer contact sequences (centroids) typical for them (see table 1).

The typical representative of the first cluster has two contacts with the travel agency staff in the booking phase. These contacts were used for "selective information" and for the "booking" of the desired journey. In virtue of the minimal customer contacts in this cluster, it is not surprising that they were rated as "very important" contacts. The centroid of cluster 2 shows that these customers realized contacts in all different phases of the purchase process. They sought contact with the travel agency staff in the pre-booking phase for "selective information". During the booking phase they used the catalog to obtain "general information" combined with the travel agency staff for "selective information" and the "booking" of the desired journey. Prior to their journey they used the tour operators catalog and the travel vouchers to get "general" and "selective information" about their travel destination and for recreational activities. All contacts in this phases were "very important" to the customers. During their vacation these customers contacted the tour guide for a "price comparison" of different recreational activities. In the post-journey phase they realized a contact with the travel agency staff to obtain "advice" on different problems. The contacts in the journey and post-journey phase are of significantly lower importance to these customers. The customers in the third cluster sought their first contacts in the booking phase. They used the tour operators catalog combined with the travel agency staff for obtaining "general and selective information" about the travel destination and different hotels as well as the "booking" of the considered journey. It is noticeable that the catalog is of much lower importance to these customers compared to cluster 2. As in cluster 2, the customers from cluster 3 also used the tour operators catalog and the travel vouchers for "general and selective information" about the travel destination and for information about recreational activities, but evaluated these contacts as less important. During the journey and in the post-journey phase, these customers display a similar behavior regarding their realized contacts than the customers in cluster 2. Customers in cluster 4 used the tour operators catalog for obtaining "general information" and a "price comparison" of the tour operator's different offers and only contacted the travel agent only for the "booking" of the desired vacation. During their vacation they sought contact with the tour guide for "general and selective information" and the "booking" of recreational activities. In the post-journey phase they used their travel vouchers and

the catalog for “advisory” functions or, maybe, finding a telephone number to contact the tour operator, but such contacts were only of low importance.

Description of the Clusters using Contact-related Variables

For the description of the cluster solutions within the four clusters, selected differences regarding the three dimensions of the MCCS are referred to here in the different phases of the purchase process which differentiate the clusters (see table 2). The results in describe the clusters by way of different customer contacts in the purchase process. Overall, the customers in the first cluster realized the fewest number of contacts with regard to the whole purchase process as well as concerning the proportion of contacts in different process phases, except the booking phase, compared to the other clusters. In the pre-booking phase the high proportion of contacts with the tour operators-advertising in the travel agency is remarkable for the customers in cluster 3. The customers of the other clusters realized such contacts significantly less. We obtained similar results for catalog contacts in the booking phase.

The customers in all clusters mostly booked the desired journeys in the travel agency having personal contacts with the travel agency staff. Prior to the journey the customers in the second cluster had the highest proportion of contacts concerning the stated contacts. We obtained similar results in the journey phase. In the post journey phase, only the customers in cluster 2 only had considerably more contacts with the travel agency staff compared to cluster 1 and cluster 3. Customers in cluster 1 hardly had any contact with the stated contact points. The customers in cluster 4 used the catalog and the travel vouchers most often, the proportions distributed equally across the stated contact points here. All these results are reflected in the first dimension of the centroid-sequences of clusters.

The differences in the functions of the customer contacts provide important findings regarding the intention of the contacts during the overall purchase process (see table 3). In the pre-booking phase we obtain highly significant differences regarding the function “general information” of the tour operator’s catalog. Customers in cluster 1 and cluster 4 used the catalog the least for this function, but the customers of cluster 1 used the catalog for more differentiated functions than the customers in cluster 4. They also used the catalog for “selective information” and “price comparison”.

The same behavior was obtained for the customers in cluster 2. Concerning the catalog functions we obtained a similar result in the booking phase. There are no significant differences between the clusters regarding the functions of the travel agency staff in this phase, but it is remarkable that these contacts had to fulfil most different functions. The customers of all clusters used them for “general and selective information” regarding the tour operator’s offers, the travel destination, and recreational activities, as well as for “price comparison”, “advice”, and, of course, for the “booking” of the desired journey. We did not obtain any significant differences in the functions of all contact points during the journey. In this phase the customer contacts, especially contacts with the tour guide, were mostly used for “selective information” and the “price comparison” of recreational activities as well as for “advice” and “complaining”. After the journey, our results show significant differences in the functions of the contacts with the travel agency staff. The customers of cluster 2 and cluster 4 mostly used this contact point for “advisory” functions, while the customers in cluster 1 and cluster 3 mostly had contact for “complaints” in this phase.

Overall, the customers of cluster 2 evaluated the contacts as most important compared to the other clusters (see table 4). Interestingly, this is the only cluster that evaluated the contacts in the pre-

Note: ^a inquired on a six-step rating scale: 1 corresponds to *entirely unimportant*, 6 corresponds to *very important*

booking phase as the most important, while for the customers in the other clusters the contacts in the booking phase were of the highest importance.

Prior to the journey, we obtained significant differences with regard to the importance of the tour operator's homepage. Regarding the customers in cluster 1, this contact point was of considerably lesser importance compared to the other clusters. During the journey the tour guide was the most important to cluster 2. After the journey our results show significant differences in the importance of contacts with the tour operator's catalog and homepage. In this phase the contacts with the travel agency staff were of great importance to all customers, probably due to the fact that this contact point was mostly used for "advice" and especially for "complaining". Finally, table 5 characterizes the clusters of the different segments by its size and essential demographic reference numbers.

We also analyzed the behavior of the customers in our cluster solution regarding the customer contacts, their functions and importance over time. As expected, we obtained significant differences in the customer behavior in each cluster across the successive phases of the purchase process. For the customers in cluster 1, we found highly significant differences concerning the number of contacts across the different phases (*Hotelling's Trace* $F(4, 41)=26.152$; $p<.001$) but no significant differences with regard to the functions and importance of the customer contacts. Only 64.4% of these customers realized contacts in the pre-booking phase and after the booking of the vacation, they also have a significantly lower proportion compared to the other clusters ($p<.001$). In cluster 2, we detected significant differences in the customer contacts (*Hotelling's Trace* $F(4, 28)=3.182$; $p<.05$) and highly significant differences for the functions (*Hotelling's Trace* $F(4, 12)=16.001$; $p<.001$). Compared to the others, these customers had the highest proportion of contacts in the pre-booking phase (93.8%), the pre-journey phase (98.9%) and also during the journey (94.6%). For cluster 3, we obtained a similar pattern concerning the customer contacts (*Hotelling's Trace* $F(4, 41)=10.797$; $p<.001$) and the functions (*Hotelling's Trace* $F(4, 14)=22.589$; $p<.001$). We also

found such characteristics for the customers in cluster 4 (customer contacts: *Hotelling's Trace* $F(4, 26)=4.308$; $p<.01$; functions: *Hotelling's Trace* $F(4, 11)=11.971$; $p<.01$). According to cluster 1, there are no significant differences in the importance of the contacts across the purchase process phases.

Determinants of the Multidimensional Customer Contact Sequence Clusters

As we have already illustrated, different factors can determine contact sequences. In this context, the duration of the purchase consideration, the price of the journey and the journey category are conceivable. Furthermore, the time of day and the day of the week can be regarded as determinants for customer contacts. However, only the most important differences between the cluster solutions of both segments are considered more closely here (see table 6).

Effects of the Multidimensional Customer Contact Sequence Clusters

Besides the determinants, the effects of the MCCS on final variables such as customer satisfaction with the tour operator's prices, the journey, and the tour operator's service across the successive phases of the purchase process are also of great interest. We were also interested in the satisfaction with the reachability of the tour operator, as well as the satisfaction with the tour operator compared to other tour operators. Furthermore, we examined the effects of the customer contacts on the intent to recommend, willingness for repeated bookings, perceived risk and trust (see table 7).

DISCUSSION AND CONCLUSIONS

The results of our study demonstrate that the customers can be classified with regard to their multidimensional contact sequences. These indicate differences in the purchasing process, as for example our results on differences in the customers' behavior concerning the usage and functions of the different contact points across the purchase process suggest between the customer clusters identified. Customer segmentation based upon demographic or

psychographic variables would not have been able to enrich the knowledge of the customers in this manner.

In observing the differences between all of the results, we can classify each cluster with a name—even if simplified: customers in the first cluster could be characterized as “satisfied repeat bookers” in view of their very high proportion of previous bookings with the tour operator, low number of contacts, and the results concerning the final variables. The second cluster can be categorized as “information seekers”, as the customers in this cluster already had the highest proportion of contacts, especially with the tour operator’s catalog, in nearly all phases of the purchase process bar the post-journey phase. In the pre-booking and booking phase, they mostly used the different contact points for “general and selective information” on the tour operator’s offers and the travel destination. Prior to their journey and in the journey phase, they sought information regarding recreational activities. In view of the proportion of contacts with offers through the tour operator’s advertising in the pre-booking phase, and with regard to the results concerning the final variables, the customers in the third cluster can be referred to as “unsatisfied offer bookers”. Finally, customers from the fourth cluster could be classified as “complicated travelers”. They have the highest proportion of contacts in the post-journey phase, not to mention a high proportion of contacts with the tour guide during their vacation. The contacts in these phases mostly served “advisory” or “complaining” purposes.

This new kind of information puts a supplier in a position to adapt the establishment of individual customer contact points to the different customer segments and guide customers via contacts in the purchase process. Knowing these segments and their sequences enables the retailer to anticipate further contacts and offer suitable measures. If the supplier pursues a particular strategy with regard to the sequence of the contacts, these results provide information on the proportion of the customers who behave accordingly. Therefore, the balance between the aspired and actual sequence of the customer contacts could be used to monitor the marketing communication, as well as the whole marketing strategy. The multidimensional contact sequences could also provide crucial insights into potential existing cross-channel synergies. Such insights will contribute to an approach towards optimal multi channel integration as well as an optimal multi channel mix and also a successful CRM. This will increase customer satisfaction as well as gaining profitable and long-term customer relationships.

There are also important implications for marketing science as individual customer contacts or parts of the purchasing process have primarily been explained through partial theories in previous research (Kumar and Venkatesan, 2005). However, the differences identified in the multidimensional customer contacts sequences cannot be explained with such approaches. A comprehensive theory is necessary which, ideally, would integrate all the individual phenomena from the purchasing phases and can explain the differences of the customers in their contact sequences. Besides this, our results also imply the application of other sequence analytical methods, such as Markov-Models, for predicting customer behavior as well as the cluster membership based on the multidimensional sequences. Furthermore, we only analyzed customer contacts and contact sequences in one branch with one tour operator, so a lot of research in other branches is necessary to generalize our findings.

ABSTRACT

This investigation focuses on the role of the media in the acculturation processes of Maghrebins in France. It seeks to assess the extent to which the media are an agent for acculturation in this specific immigrant population. We carried out thirteen in-depth interviews with a varied sample group, using an interpretative approach. We considered three types of media in this research: the 'French' media, the 'Arab' media, and the 'ethnic' media produced in France but directed at the Maghrebins. Results are then presented and discussed. The limits of this research are underlined, and some future openings for research are proposed.

INTRODUCTION

Immigration is a study topic for human and social sciences. Demographers thus take an interest in population movements; historians are interested in the spread of cultures and in colonisations; anthropologists see immigrants as 'the others'; and sociologists investigate the social transformations brought about by the arrival of immigrants. More recently, marketing researchers have become interested in immigration, initially because immigrants represent a market and because understanding the acculturation process is key to penetrating that market, but also from a point of view of transformative research, since this understanding makes it possible to improve immigrants' well-being.

Most studies of consumer acculturation have studied immigrants in the US, while relatively less attention has been paid to immigrants living in Europe (e.g. Askegaard et al. 2005; Lindridge et al. 2004; Jamal 2003). France has the highest rate of immigration in Europe (INSEE, 2006). Immigration in France, which originally was chiefly motivated by economic considerations, is now motivated more by family reunification. According to INSEE,² mainland France had 4.9 million immigrants in mid-2004, representing 8.1% of the population. In light of France's republican and egalitarian tradition and its chosen position as a strong and centralising nation state, immigration is currently a hot topic for debate (Hetzl 2003). The recent creation of the 'Ministry of Immigration, Integration, National Identity and Co-development' has been seen by some as going against the founding principles of the French Republic, intended to be universalist and egalitarian. The debate is heating up even further with the increasing emergence of 'communitarian' behaviours or the protest movements in the suburbs of major cities that have large immigrant populations.

The media is playing a part in this change. Thus, France has seen the recent appearance of newspapers and magazines (such as *Amina*, *Jeune Afrique*, *Salama*, *Arabies Magasine* and *Yasmina*) and radio or television stations are specifically targeted at ethnic populations. This rapid growth in the number of media making use of the ethnic variable as a criterion for defining their target market raises numerous questions. In particular: which role will these media play in the acculturation process for immigrants? Marketing

literature presents the media as an essential agent for acculturation, but this significance is supported by little empirical work. This article is intended to assess the extent to which the media constitute an agent for acculturation in a specific immigrant population: that of Maghrebins in France. According to INSEE (2006), maghrebins immigrants are the largest immigrant population in France (with the exception of intra-EU immigration). They represent a growing market for marketers, since in 2005 the number of immigrants originating from the Maghreb was 1.5 million, 220,000 more than in 1999 (+17%). The fact that the Maghreb is composed of three countries (Algeria, Morocco and Tunisia) means that it represents certain homogeneity of cultural identity. This shared culture is first and foremost based on the Berber origin of most of the region's inhabitants—even if many of them do not speak Berber. In addition, all the inhabitants speak Arabic (a language that has been spoken in the region for thirteen centuries) in classical and/or dialect form. Classical Arabic is essentially a vehicle for Islam, the religion shared by Maghrebins and for official institutions such as schools and the public administration. However, dialectal Arabic is the mother tongue and language used in everyday life by the majority of Maghrebins.³ Finally, these three countries share a common history with France, linked initially with colonisation (19th and beginning of the 20th Century) and then to immigration (essentially since 1960). The majority of French people tend to react to this strong shared identity by stigmatising these three countries on account of their 'Arab-Muslim' identity, and this stigmatisation in turn reinforces the 'homogeneity' of Maghrebins' identity in France.

In order to study the role of the media in the acculturation process of Maghrebins in France, we will first address the theories of acculturation and the role that the media play in this regard. We will then present the methodology and the main results of our qualitative study. Finally, we will end this article with a discussion, including the main limits of this research and the avenues of research.

Immigration and research into consumer behaviour

Most research into consumer behaviour studies the process by which individuals adapt to a culture different from their own, by concentrating on two phenomena: assimilation and acculturation. Research employing the assimilationist approach studies how individuals adjust to a new culture by how quickly they appropriate elements of that new culture, at the expense of their own culture of origin (Deshpande et al. 1986; Hirschman 1981; Kim et al. 1990; Wallendorf and Reilly 1983). Since the 1990s, research has concentrated on the acculturation approach. According to this doctrine, different individuals adapt to different extents and borrow elements from their own culture of origin as well as from their host culture (Berry 1980; Jun et al. 1993; Mendoza 1989; Peñalozza 1994). More recent work has focused on the 'swapping' between the culture of origin and the host culture, and this movement has given rise to

²INSEE is the French National Institute for Statistics and Economic Studies.

³The significance of its proximity to classical Arabic depends on the sociocultural position of the speaker.

different acculturation models (Askegaard et al. 2005; Lindridge et al. 2004; Oswald 1999; Üstüner and Holt 2007).

However, all this research takes the work of Berry (1980) as its source, which assigns different degrees of acculturation to individuals based on the extent to which they associate themselves with their culture of origin and their host culture. There are therefore four modes of acculturation: assimilation, integration, separation and marginalisation (Berry 1980). Integration is the situation in which immigrants partially maintain the cultural integrity of their ethnic group and partially demonstrate an increasingly marked participation in their new society. In this situation, immigrants retain their identity and certain other of their own cultural characteristics (languages, dietary customs, religious festivals, etc.) whilst simultaneously taking part in economic, political and legal structures with the other ethnic groups in the new society. On the other hand, immigrants are considered to be assimilated if they abandon their cultural identity in favour of that of the host society. They do not wish to retain their cultural identity and actively seek contact with the host culture. Separation describes the situation of individuals who do not seek to establish relations with the dominant community and who wish to keep their cultural identity. They preserve their culture of origin and their practices and keep themselves apart from the dominant group. Marginalisation is where immigrants lose their identity (often as a result of assimilationist policies practised by the dominant group) but yet do not have the right to participate in the running of institutions and the life of the dominant group.

For some researchers, acculturation manifests chiefly at a behavioural level. The authors first addressed linguistic preferences (Hui et al. 1992; Valencia 1985), particularly at work, at school, within the familiar or in situations where there is confrontation with the media, together with shopping behaviour. Other works (Gentry et al. 1995; Jun et al. 1993; Laroche et al. 1991; Valencia 1985) have studied the choice of neighbourhood (ethnic/non-ethnic) and friends, the celebration of religious festivals and the choice of holidays and social activities, together with the issue of mixed marriages. Peñaloza (1994) stresses however the limits of an approach that measures the degree of adherence or integration of a minority to a dominant culture without examining the nature of this process, and omits to take account of the influence of marketing strategies on the process of adaptation amongst the populations studied. That author states that in a globalised world with porous frontiers, the presence of transnational consumers and products has an effect on local consumer cultures. In the host society, some immigrants tend to consume products attached to their culture of origin, thereby displaying ethnic consumption, whereas others appropriate or do not hesitate to opt for products representing the dominant culture; they thus demonstrate a considerable degree of cultural change and are progressively becoming more and more acculturated, at the expense of their culture of origin. The individual characteristics of immigrants (demographic, geographic, linguistic and the date of their arrival) are determining factors in the process of consumer acculturation, as are the various agents of acculturation: family, friends, religious institutions, the media and the institutions of the culture of origin and the host society (see Ogden, Ogden and Schau 2004). Within this context of acculturation, this paper will concentrate on the specific agent of the media.

THE MEDIA: AN AGENT OF ACCULTURATION?

Since the inaugural work of Nagata (1969 in Lee 1989), many researchers (Hui et al. 1998; Lee 1989; O'Guinn and Faber 1985; O'Guinn et al. 1986; Kim, Laroche et al. 1990; Peñaloza 1994, etc.) have presented the media as a crucial element in the acculturation process. However, relatively little research (Kara and Kara 1996)

has been devoted to studying the impact of the media on acculturation.

The media can have an effect on two levels. On the one hand, they enable immigrants to become symbolically familiar with their host society (Lee 1989). This is however not a question of intense, concrete contact with the new society. By making use of the radio, the television, magazines, newspapers, cinema, theatre, museums or lectures, immigrants can acquire certain closeness to the host society (Tzu 1984). They learn which products they 'must use and own' in order to be properly looked on as a member of the dominant society (O'Guinn et al. 1985; O'Guinn et al. 1986). This is especially important where the immigrants do not have a comfortable command of the language of the host country. Television can be a solution to this problem, since images enable a relative understanding to be gleaned (Lee 1989). Garcia (1982) has shown the preference of Mexican-Americans for the media over and above other agents as a source of information and advice. Similarly, Lee (1989) shows that television is perceived by Chinese immigrants in the USA as a reliable source of information and an easily accessible agent of acculturation when learning the lifestyle and values of the host country. Indeed, Lee and Tse (1994, 68) write that: "exposure to mass media, [...] contributed to attitudinal and/or behavioral change. It appears that acculturating individuals' adoption of the majority norms may be related to their exposure to mass media".

Moreover, immigrants seek to remain in contact with their country of origin via forms of media that are relevant to their ethnic cultural community. This research can be interpreted as the need to return to the well-known and the familiar, and as being linked to the pleasure of hearing one's language of origin or of coming back into contact with familiar cultural elements. It may also be a question of the need to stay informed of what is going on in the country of origin. This research into contact via the media is not limited to the initial phase of arrival in the host country. In their consumption of ethnic media, immigrants can seek out this contact even several years after their immigration. In their work on immigrants from Hong Kong to Canada, Lee and Tse (1994, 68) report that: "even after living in Canada for at least seven years, the long-time immigrants spent 41% of their media time on ethnic media".

Over the course of immigrants' settlement in the host society, they are bathed in an intensive consumption of dominant media, at the expense of ethnic media. Immigrants are therefore simultaneously in contact with the media from the host country and the media from their country of origin. The media should thus be distinguished more precisely according to their target language and their relationship with Maghrebin immigrants. As part of this research, we will consider three types of media.⁴

- the 'French' media: French-language television channels, radio stations, newspapers and magazines targeted at the French population living within the country;
- the 'Arab' media from the countries of origin: Algerian, Moroccan and Tunisian national newspapers from the countries of the Maghreb that are sold in France and channels; and radio stations broadcast from Arab countries such as Al-Jazeera. These media are essentially targeted at the populations living in the Maghreb or in Arab countries.
- 'Ethnic' media produced in France but for the Maghrebin minority in France. These media cover subjects of interest to the Maghrebin community living in France.

⁴Only television, radio and the press will be considered here, since cinema and posters are of very secondary importance as media.

How do Maghrebin immigrants living in France consume these different media, and to what extent do these media contribute to their acculturation process? This was the key question addressed by this research.

METHODOLOGY

In order to answer these questions, it would have been limited for us to restrict ourselves to a quantitative study of the consumer behaviour of Maghrebin immigrants in France. It is not sufficient to know whether these immigrants are aware of the different media and whether they consume them; the method of that consumption and the relationship these immigrants have with the media—the way they integrate them into their life and their identity—must also be known. A qualitative approach was therefore required. We decided to carry out in-depth interviews with a varied sample group of Maghrebin immigrants in France, using an interpretative approach.

We carried out 13 in-depth interviews of an approximate length of 90-120 minutes with Maghrebin immigrants aged between 19 and 54; 12 of these immigrants are from the middle class backgrounds, and one is from lower class. In total, thirteen people were approached for a total of 21 hours and 26 minutes' interview time. We favoured variety of information over choosing a representative sample of the population. For this reason we opted for a theoretical sampling process by trying to vary the gender, age and generation of the people involved. The theoretical sampling was achieved after the 13th interview, since the accounts received displayed a considerable degree of diversity and the last interviews contributed relatively little new information (Glazer and Strauss 1967). This figure is higher than the minimum recommended by McCracken (1988) and is within the range of 3-20 interviews for interpretativist research (Fournier 1998; Thompson and Haytko 1997).

Our interviews were carried out in the north of France, a region marked by an initial economic Maghrebin immigration for the purpose of working in the textile or mining industry; these immigrants were subsequently joined by the immigration of their families. The Maghrebin immigration is in fact the result of multiples waves of migration motivated by economic, political or family considerations. According to INSEE data (1999), Algerians form the majority of Maghrebin immigrants in France (44%, or 574,208 immigrants), followed by Moroccans (40%, or 522,504 immigrants) and then Tunisians (16%, or 201,561 immigrants). Over the course of their settlement in France, Maghrebins have spread throughout the whole of France. Of the thirteen people, nine are Algerian, two are Moroccan and two are Tunisian. The sample is composed of seven women and six men. Seven arrived in France at various ages and have been living in France for between 5 and 44 years; they form the first generation. The others, born in France, are deemed to be the second generation. We took into account their place of residence in France and their background (rural/urban) in their country of origin.

The interviews were recorded and transcribed in their entirety. The interviews touched on several aspects pertaining to the dominant culture and the culture of origin (their arrival in France, the story of their immigration, and their current life in France). In terms of life in France, the interviews sought to understand the immigrants' sociability, their cultural practices in the host country, their consumption of media and how they perceive, identify and define themselves in French society.

The relationship with the media was studied via different themes. The respondents were asked to speak about programmes they watched, stations to which they listened and newspapers and magazines that they read. The discussion on the media led the

respondents to voice the reasons that drive their choices of the French or Arabic media.

Some of them are of an identity concern:

"I watch French TV because I'm French, because it's my life, because France is my country." (Faiçal, 23 years old, 2nd).

Others are related to nostalgia to the language:

"It's nice to watch Tunisian TV from time to time, to hear people speaking with Tunisian accents, but that's the only reason." (Kamel, 23 years old, 2nd).

Whereas for some immigrants, the media choice is a sign of their acculturation in the host society:

"I'll never switch on an Arab channel, ever. To start with, I don't understand literary Arabic, and also because I prefer to watch French TV, because I'm French and that's all there is to it." (Faiçal, 23 years old, 2nd)

We analysed the comments of our thirteen respondents using an interpretative approach. By alternating between the specific case of each interview and the interviews taken as a whole, and by making use of literature, we sought to understand the role of the media in acculturation, and whether this role appears as major as the literature stemming from research done in non-French-speaking contexts suggests (Jamal 2003; Kim and Kang 2001; Lee and Tse 1994; Peñaloza 1994; Samad 1998).

MAIN RESULTS

The profile of media consumption shown by the interviews as a whole does not seem to depart significantly from that of the French population as a whole. Television is a very widespread medium and was appreciated to varying degrees in the interviews, with some people criticising the choice of programmes available, but everyone watched it (with the exception of students who did not have a television set in their student accommodation, but who nevertheless had the opportunity to watch it whenever they returned home to their family). In the minds of the respondents, it is thus the most significant medium in the minds of the respondents. Radio is seen as a medium to be used as an accompaniment, to be listened to in the car, or in the background at home, but also a medium that enables people to stay informed (the news station France Info). More people are familiar with the press than actually read it: the respondents cited titles of daily newspapers and magazines, but then said that they read newspapers only very occasionally, with the exception of the free ones given out in the metro. People seem to be more regular readers of magazines, since magazines address the interests of their readers (Femme Actuelle, France Football, Sciences et Vie, etc.). Finally, the younger respondents referred to the internet: some visit newspaper sites to read the news, and others use it to find Arab music.

We will focus on three types of media as defined above: French media, Arab media and ethnic media, by following the comments made by our respondents more closely than we will follow their consumer behaviour itself.

With regard to French media, which are the media consumed most heavily by all the respondents, comments on television showed two opposing viewpoints. For some people, the choice of a programme or a French channel was simply a matter of personal taste, and bore no connotations of integration or involvement in French society.

TABLE 1
Informants Characteristics

Names	Sex	Age	Arrival date	Generation	Origin	Occupation	Language ability	Education level
Dorsaf	F	35	1992	1 st	Tunisian	Benevolent (NGO fields)	French, Tunisian dialect, Classical Arabic	University
Louiza	F	26	Born in France	2 nd	Algerian	Cashier	French	High school
Faiçal	M	23	Born in France	2 nd	Moroccan	Student	French, Moroccan dialect	University
Farid	M	19	Born in France	3 rd	Algerian	Student	French	University
Kamel	M	23	Born in France	2 nd	Tunisian	Student	French, Tunisian dialect	University
Warda	F	21	Born in France	2 nd	Algerian	Student	French	University
Samir	M	35	2002	1 st	Algerian	Waiter	French, Algerian dialect	University
Mohamed	M	53	1963	1 st	Algerian	Professor/researcher in Physics	French	University
Zora	F	54	1978	1 st	Algerian	Maintenance staff	French, Algerian dialect	Graduate school
Rachida	F	52	1955	1 st	Algerian	Nurse	French	Second grade
Lynda	F	23	1989	2 nd	Algerian	Student	French	University
Chérif	M	34	2001	1 st	Algerian	Security gard	French, Algerian dialect Classical Arabic	University
Nourah	F	20	Born in France	2 nd	Moroccan	Student	French, Moroccan dialect	University

“Sometimes there are good programmes on, with good guests, so I watch them. It depends on the programme. When there is something I like on one of the channels, I’ll watch it. I like M6 on Sunday nights when there is something good on like ‘Zone Interdite’ or something like that; it depends on the programme. If there’s a film on that I like, I’ll watch that too.” (Louiza, 26 years old, 2nd)

“I put on any channel at all, really, and I fall asleep in front of it after half an hour.” (Rachida, 52 years old, 1st)

“Actually I channel-hop; I don’t have a favourite channel either but I guess I watch M6 the most because I think it’s the channel that shows the most entertainment programmes.” (Nourah, 20 years old, 2nd)

Others have a more all-encompassing view of the consumption of French television channels and associate it with a strategy of integration. Television characterises the society that is accepting them and they find it perfectly understandable to incorporate it into their media habits, since they feel themselves to be members of French society. It is via this form of communication that the respondents are in contact and in step with their surroundings and what makes up their daily lives. This is what Peñaloza (1994) calls an agent for acculturation.

“French channels are about my life after all, since they mean something to me and they talk about what is happening in France. I feel more affected by what is happening in France, and France is important to me because it’s my country, and I spend more time following events in France.” (Dorsaf, 35 years old, 1st)

These media represent their present-day and everyday life in a country that most of them think of as their own.

“Things about the French system, because I do live in this country, after all, I feel it important to follow the French media in order to be aware of things even if only from a political and administrative point of view, in society.” (Lynda, 23 years old, 2nd).

Some people go further and appear aware of the role played by the French media in general, and television in particular, in their acculturation process.

“It depends how you think of yourself and which attitude you adopt. If you think of yourself as once an immigrant, always an immigrant, you’re obviously going to be interested by everything to do with your home country, so as long as it’s about your home country, you’re happy, which is not at all the case for me. Or you might think to yourself that you’re here but you’re different; for example, I’m here but I’m different, but first and foremost I’m here, so obviously whatever goes on in France is of interest to me.” (Dorsaf, 35 years old, 1st).

The newspapers and magazines that are read cater more for the interests of their readers: older people read daily regional newspapers, students read the economic press, and football fans read sports journals. With regard to the radio, some people listen to it very occasionally, whereas others mentioned a list of stations to which they listened, but comments on the radio were very limited, and the immigrants did not seem to attach any particular importance to it.

With regard to Arab media, the role discovered was different. These constitute an invaluable source of information on political events and on troubles and unrest, both in the world at large and more specifically in Arab countries in particular. This preoccupation with politics was shared by all the respondents, although their comments were particularly alarmist with relation to Algeria. All respondents relied mainly on the Arab channels in order to avoid being cut off from the Arab-Muslim world.

“Al-Jazeera is an information channel, so they take the time to go into things in detail, and to examine issues from different angles and discuss them at length, so you don’t take what they tell you at face value: it does more than just present the information; there are analyses and everything; so it’s very important, when you think that on the other hand it’s not a channel...I mean it doesn’t do all that because it’s an Arab channel, or because it’s a famous channel; it also presents analyses about the Israelis and the Americans and everything. It does nonetheless handle information in a way that seems objective to me; in any case they give everyone the right to express themselves.” (Dorsaf, 35 years old, 1st)

“I watch Tunisian television, and a bit of Al-Jazeera to find out what’s going on in the Middle East.” (Kamel, 23 years old, 2nd)

Arab television also has another function entirely: as an integrator within the family itself. For the second generation, who do not always have a good command of Arabic, watching television with those from the first generation is an essential form of sharing. The process of acculturation is different between the 1st generation and the 2nd generation, which creates a distance between parents and children. French and Maghrebin societies keep these groups apart by virtue of the specific experiences that each of them has had: children have not experienced what their parents have in their country of origin, and parents do not experience what their children are going through on a daily basis. Young people are aware of this distance and try to diminish it by watching Maghrebin television with their parents from time to time, particularly during religious festivals (Ramadan). They use Algerian or Moroccan television as a means of bridging the gap between themselves and the first generation, even though some admit that they do not understand everything or that the content is of no interest to them. For the respondents from the second generation, it is a question of ‘respect’ for their elders: they symbolically try to be close to their parents, to share some aspects of their parents’ original culture to which these young people are not accustomed in their daily lives. Thus, the country, which can sometimes be a source of differences between the two generations, can sometimes be a means of reuniting them.

“I only watch it when my father watches it; I wouldn’t switch on something like that myself.” (Faïçal, 23 years old, 2nd),

“When my parents are around and I feel like spending some time with them. There are programmes in Arabic on the Algerian channel, and there are sketches, that I sometimes watch with them, or alternatively when something major is happening in Algeria or whatever, or when my parents tell me that such-and-such is happening.” (Louiza, 26 years old, 2nd)

Arab television is also a cultural echo for people who live in France but are very attuned to their culture of origin. It is also a means of heightening the sensitivity of children to certain cultural aspects, such as their language of origin, that they only rarely get the opportunity to hear in the home. Religious festivals are particularly appropriate occasions:

“We all end up watching during Ramadan because the whole family comes together for dinner. There are some nice things on in Ramadan, so we watch as a family, and it’s enjoyable.” (Louiza, 26 years old, 2nd)

Finally, the media mirror immigrants’ shifting identities. Some respondents clearly state that they use their choice of channels or programmes as a way of asserting their own identity:

“Arab channels are an insight. I’m more interested in what’s going on in France, and of course what’s going on in the world, although now the world has become a village, but it’s really a matter of choice. France is important to me because it’s my country, so events in France are the ones I follow the most regularly. Arab channels are an insight as well as an entertainment; they are an insight into a world that is no longer my world but that still has something to offer me, as well as meeting my cultural expectations and expectations in terms of information, and they mean I can stay in touch with the pace of life going on over there, of which I’m still a part in a way.” (Dorsaf, 35ans, 1st)

However, this attitude was not shared by all the respondents; some made less consistent use of the Arab media because they had got accustomed to their life in France in terms of culture, specifically their consumer culture.

The situation is basically the same with regard to newspapers, with the added issue that a command of written Arabic is required. Immigrants who read newspapers written in the Maghreb or in Arab countries and ‘imported’ to France do so because these newspapers present information in a different way from French newspapers. Comments from these immigrants share the same underlying search for a connection with their identity is present in their comments. Finally, with regard to radio, no respondent mentioned any stations broadcast from the Maghreb or from any Arab country as forming part of their listening habits.

With regard to ethnic media, the situation is different, because television is absent from the choice of media available. There is no channel targeted specifically at Maghrebins in France. The analysis covered solely newspapers, magazines and radio stations. These media appear to be relatively poorly known, especially the press. No respondent mentioned any ethnic magazines without being prompted. Most of them were completely unaware of their existence. However, the media targeted at a Maghrebin public in France are both numerous and (above all) varied. Some are information magazines, others are women’s magazines and yet others discuss culture. They are targeted at Maghrebins from France, not just Maghrebins who live in France. These magazines represent the Maghrebin community in France and cover current affairs topics such as mixed marriages, relationships between ‘Maghrebin’ women and ‘French’ men and discrimination, as well as cultural activities including music, cinema or shows intended for Maghrebin audiences from France, not to mention articles on beauty products sold in France and made from plants that come from the Maghreb. Their content therefore differs radically from that of the Arab media, which discuss the life of Maghrebins living in the Maghreb. When respondents learned of the existence of these newspapers and magazines, they immediately showed an interest.

“I could identify with the feelings they talked about, and with their way of thinking, because I’ve got a side to me like that.” (Lynda, 23 years old, 2nd),

“Ah, now that’s interesting; that way we can stay informed about other things than the regular news about all the troubles

and everything going on back at home. Like here, for example—look, they're talking about cookery, and since I like cooking and everything, it's very interesting to watch the recipes and things, all the things you can watch." (Zora, 54ans, 1st)

With regard to ethnic radio, only the radio station 'Pastel FM' was mentioned by the respondents in their comments. 'Pastel FM' is a formal communication medium for France's Maghrebin community. This station addresses some aspects of Maghrebin culture, chiefly cinema and music. Information on the release dates for films at the cinema (such as for the film *Indigène*,⁵ which was mentioned by several respondents) or concerts by Maghrebin groups is given out via this radio station. However, the majority of ethnic information is transmitted via informal networks, which use word of mouth and social connections. These informal networks are used almost exclusively to transmit information about religious events (demonstrations of solidarity, social debates on religious themes, etc.) and the celebration of religious festivals. For most Maghrebins in France, the ethnic cultural activities in which they are involved are connected with religion and the practice thereof.

DISCUSSION AND CONCLUSION

This research worked from literature on ethnicity in marketing and focused on the potential role of the media in the acculturation process of Maghrebin immigrants in France. The results obtained largely corroborate the earlier work done in this field. The media have a strong presence in the life of this immigrant population, and above all are very varied: alongside traditional French media, this population consumes Arab media (chiefly television programmes, more rarely newspapers, and hardly ever the radio) and marginally consumes ethnic media, despite the fact that these media are theoretically targeted at them. The media definitely play a role in acculturation, which takes two complementary forms: the French media enable Maghrebin immigrants to gain a better understanding of the society in which they live, whereas the Arab media give them the opportunity to remain in contact with their country and culture of origin. Encouraging as these results are, they do however raise numerous questions, which we will discuss in this last section. First of all, however, the unique aspects of our research need to be set out, since this is the first study of its kind on Maghrebins in France in marketing literature; previous research has dealt with Mexican (e.g. Garcia 1982) or Chinese (e.g. Lee 1989) immigrants in a North American context.

The first unique aspect is the Arabic language, which lends itself very poorly to the written press. It is not uncommon for a spoken language to differ from its written equivalent, but with Arabic, a Moroccan, a Tunisian and an Algerian will all speak a very different dialect from the language they will find printed in a newspaper or a magazine. There is therefore a considerable problem in terms of making newspapers accessible, since a certain degree of education is required. Classical Arabic thus makes it more difficult to maintain links with the culture of origin. On the other hand, the use of classical Arabic promotes communication across national frontiers, and enables Maghrebins to follow programmes broadcast by an Egyptian or Saudi channel. Moreover, classical Arabic is strongly linked to Islam. The second-generation immigrants who participated learned Arabic either within the French school system (as a foreign language) or, more frequently, in schools dedicated to Islam, since a fluent command of Arabic is

essential in order to read the Qur'an. This situation is by no means exceptional; for example, Hebrew is linked with reading the Bible in the Jewish faith, but it also has repercussions on relationships with culture. Thus, one of the female respondents who rejected Islam as a religion ended up rejecting Arabic as a language as well, and as a result found herself cut off from the culture entirely. Finally, the last unique aspect of this research pertains to the historic relations between France and the Maghreb in a colonial context. French was the language of the elite in these three countries, and a large number of people in the Maghreb still speak the language, including the current political and economic elite. Needless to say, this makes French extremely important as a language, and enables second-generation immigrants who do not speak the relevant national dialect to enter into contact with their family or with certain media published in French (e.g. the *Le Matin* newspaper in Morocco). It goes without saying that the combined effect of these elements makes it difficult to extend this research to other immigrant populations in other countries without taking the necessary precautions.

The first question raised by our results pertains to the actual content of the media that are intended to transmit a vision and the behavioural codes of the host society. Thus, a number of our respondents mentioned that they chiefly watched American series on television (*Columbo*, *Desperate Housewives*, *One Tree Hill*, etc.). As Hirschman (1988) showed in her work on the competing series of 'Dallas' and 'Dynasty', series such as these do illustrate codes and methods of consumption, but these codes are completely different from French codes. In addition, the respondents highlighted, totally consistently, the difference between the Egyptian series broadcast on Maghrebin television and the methods of behaviour—not to mention the expressions—observed in those societies. First-generation immigrants however appear relatively enthusiastic consumers of this type of programme, certainly more so than their descendants. Although we reasonably can state with regard to information and news that the medias of each of the countries—the country of origin and the host country—participate in a process of acculturation between the two cultures, numerous television programmes tend more to broadcast a 'universal' or generic culture, using American society and culture as its reference.

The second question relates to the similarities and differences observed between the consumption of media within the French population and that within the Maghrebin immigrant population. Of course, since an interpretative approach is being used, this does not involve making a quantitative comparison; rather, the determining factors for the consumption of media must be established. Cultural capital, and thus to a certain extent social class (Bourdieu 1984), appear to be essential elements in terms of determining the consumption of media amongst both French people and immigrants. Although television reaches all populations, the number of media consulted increases in proportion to the level of education, and the media become more diverse: newspapers and the internet play an increasing role, and the type of channels watched changes. Age is another dividing factor: older people (generally first-generation immigrants) say that they read the regional press (*La Voix du Nord* in our study), whereas younger people use the internet to look for information.

The third question relates to the issue of ethnic media. These seem to be largely unfamiliar to respondents, particularly with regard to magazines and newspapers. Two reasons can be put forward to explain this unfamiliarity: either these ethnic media have not benefited from sufficient publicity and distribution, or they genuinely do not respond to a latent need in the Maghrebin immigrant population. The second scenario obviously raises questions of its own: does it indicate that being a Maghrebin immigrant in France

⁵A French film about North African soldiers sent to liberate France from Nazi occupation during World War II. The five actors are all descendants of Maghrebin immigrants.

today does not confer any particular status and does not give rise to any requirements sufficiently specific to create an independent need for media? This question needs to be examined in more detail.

Finally, the central question raised by this research is that of the relationship between acculturation and media. Should the media be considered as an agent of acculturation or rather as an indicator of it? The literature insists that the former role is correct; our research indicates that the latter concept is also worth consideration. However, it is not so much the quantity of media consumed as the type and variety of these media that counts when assessing the degree of acculturation. The quantity of media consumed is in fact linked to the cultural capital of the individual concerned and it increases in proportion to the level of education. Variety here must be defined as a recourse to media that fall within the different categories we identified during this research: French, Arab and ethnic. Separated immigrants are more likely to consume Arab media, whereas assimilated immigrants will restrict themselves to French media. Consumption of the broadest variety of media will most likely be observed amongst integrated immigrants, who will simultaneously consume French media (because they feel affected by what goes on in France), Arab media (in order to stay in contact with the Arab-Muslim culture) and ethnic media (because they have to face problems specific to them). Furthermore, the generation effect must be taken into account: for people who arrived in France as adults (1st generation) and whose mother tongue is Arabic, the acculturation of these individuals seems to be indicated by their consumption of French media. For young people born of immigrant parents (2nd generation), on the other hand, who can speak and read French more spontaneously, it is more their consumption of Arab or ethnic media that acts as a gauge of acculturation. The development of a gauge for assessing the degree of acculturation via the variety of media consumed thus appears to be a promising topic for future research work.

Adolescents Yet Again Speak of Fashion: An Account of Participation and Resistance

Cagri Yalkin, King's College, UK
Richard Elliott, University of Bath, UK

EXTENDED ABSTRACT

This paper aims to examine the female adolescent friendship groups' consumption of fashion from a perspective of participation and resistance in the marketplace, and intends to build a case for analyzing the consumption of fashion and 'peer pressure' outside of the traditional belonging vs. independence dichotomy; both in order to bring a new perspective to the adolescents' relationship with the market and one another, and to fill the gap arising from the absence of the female adolescents' voice from the resistance literature.

Resistance to marketing efforts (Dobscha 1998) and to the domination of corporations (Holt 2002), and the emancipatory efforts to avoid the market (Kozinets 2002) have been studied and given way to new conceptualizations regarding the general issues of resistance and emancipation. Although Thompson and Haytko (1997) have studied the interpretive acts of naturalizing, problematizing, juxtaposing, resisting, and transforming in the case of fashion, their analysis is based on adult informants' narratives. Understanding how fashion and related marketing communications fit into adolescents' daily lives and how they are employed in the process of participating in and/or resisting fashion will fulfill some of the gaps in the literatures of both adolescents' consumption practices and marketplace resistance. Taking into account the above-mentioned gaps, we explored the resistive/participative practices of adolescent consumers by making use of adolescents' narrations of fashion and its communications. The extended case method (Burawoy 1991) was used, based on three friendship groups (popular, unpopular, normal), and two 12.5-13 year-old adolescents from each friendship group were interviewed; the data was analyzed using a hermeneutic approach (Thompson 1997). The name and nature of the groups emerged from the preliminary conversations with the adolescents, and were later used to define cases; the three groups' understanding of the social spaces they occupied at school matched one another.

The key results of data analysis are twofold: the first is that the adolescents narrate readings/acts of both resistance and participation in fashion; they use several tactics to resist the hegemonic practices and images of fashion. The second, and unexpected, key result is that the patterns of reading and the resistive/participative acts described seem to be consistent within friendship groups; small friendship groups act as micro-interpretive communities (Fish, 1980; Kates 2002; Yannopoulou and Elliott 2008).

The data analysis revealed three resistive tactics used by the adolescents: the trivialization of fashion, ascribing tyrannical qualities to fashion, and surrealizing the images in fashion and beauty communications. Trivializing fashion or projecting it as a not-so-important part of one's life and consumption practices has as its main building block the claims of *not-following* fashion seasonally, if at all, and *'just wearing what I wanna wear'*. Similar to the way Dobscha's (1998) informants who defined themselves as "I'm not a consumer", the adolescents defined themselves as "I'm not into fashion". However, these claims do not exclude them from consuming fashion. Secondly, seeing fashion and its related beauty imagery as one of the root causes of the 'size zero' buzz, the adolescents ascribed tyrannical qualities to fashion, blaming it for the eating disorders they see both around themselves and in distal references such as Kiera Knightley: *'It is a dangerous industry because fashion is super skinny people, which is forcing people just to feel*

bad about themselves if they are slightly over weight or something'. Finally, regardless of the 'interpretive position' (Thompson and Haytko 1997), the adolescents surrealize the images in fashion and beauty communications as a form of passive resistance. However, this derealization emerges not as a suppressive force in that its way of existence (surreal imagery) is the very tool used by adolescents in order to resist fashion communications, evident in such quotes as *'They [models] are just impossibly thin, impossibly happy... They just don't seem like real people to me'*; echoing deCerteau's (1984) viewpoint that subversion can be found in people's daily practices, tactics that are grounded in the signification system foreign to the system they have no choice but to accept.

Penaloza and Price (1993) argued that the range of actions viewed as resistance was narrow and that altering the meaning of consumption and consumption objects were neglected. Trivializing the meaning of consuming fashion and treating fashion imagery as surreal classify as attempts at altering the meaning of consumption (e.g. Wallendorf and Arnould 1991). As the accounts of resistance seem to be embedded in the grander act of participation, as "the effective strategies and tactics of consumer resistance are limited to those stemming from outside the market" (Penaloza and Price 1993), and as the adolescents are still taking part in the fashion 'system', their resistive interpretations/acts are not likely to have large-scale effects on the way they are treated by fashion communication and marketing; although this does not exclude the presence of 'agency' in the adolescents' narratives.

Adolescents continuously took up of different interpretive positions from which to ascribe meanings to their fashion behaviors and to describe the motivations for others' fashion behaviors (Thompson and Haytko 1997). There seem to be different meanings attached to some of the resistive acts at the micro-group level: how the 'popular' girls view resistive actions versus how the 'unpopular' group views resistive actions differ. There is a difference between how friendship groups read the resistive/participative practices of the other friendship groups, giving way to sanctions that further induces differentiation of friendship groups, which resonates with the viewpoint that it is the form of resistance that is sanctioned, not resistance itself. The adolescent identities seem to be located within micro-communities of interpretation and practice (friendship groups); the self has been integrated with the social and the material (Elliott 2004). Finally, the female adolescents view fashion as dominant because it is what is available; given that the informants are very young, they have still not experimented with alternative shops or ways of getting dressed, and to them, fashion is dominant not because it is capitalism's tool, as consumption is seen by the respondents in Dobscha (1988) and Holt (2002), but because it is what makes clothes *available*.

Overall, Thompson and Haytko's (1997) study on the interpretation of fashion and Murray's (2002) re-interpretation are contrasted by the adolescents' interpretations in that the interpretive positions need not be individualistic, they can rest on a common point of reading. While this study does not argue that a friendship group 'causes' a particular interpretive strategy and the accompanying resistive/participative practices to emerge, it suggests that the friendship groups as micro-interpretive communities should be explored. Understanding close-friendship groups as the context within which the complex background of established cultural meanings and belief systems are formed and as a part of cultural

background (Thompson 1997) leads the way to conceptualizing close-friendship groups as interpretive communities (Yannopoulou and Elliott 2008), which follow-up research will explore.

The Effect of Parenting on Adolescent Susceptibility to Peer Influence: Mediating Role of Self-Esteem

Zhiyong Yang, University of Texas at Arlington, USA
Michel Laroche, Concordia University, Canada
Ashesh Mukherjee, McGill University, Canada

EXTENDED ABSTRACT

Individuals are often influenced by the opinions of peers, such as their friends, activity partners, and colleagues at work (Price and Feick 1984). This is especially true during adolescent years, a time when individuals are particularly sensitive to ideas and trends popular among their peers (Bachmann, John, and Rao 1993). Peer influence on adolescents has significant marketing and public policy implications, since many adolescent decisions ranging from brand choice to substance abuse are affected by the opinions of peers (Kandel 1996; Rose, Boush, and Friestad 1998; Wooten and Reed 2004). In fact, peers influence not just adolescents' choices at the brand level, but also their attitudes towards retailers, amount of money spent shopping, and attitudes towards consumption in general (Batra, Homer, and Khale 2001; Mangleburg, Doney, and Bristol 2004). Peer influence is also viewed as one of the most important factors, if not the most important one, to affect adolescent smoking or other forms of consumer misbehaviors (Akers and Jensen 2006).

Acknowledging the important role peers play in individuals' consumption-related decisions, previous research in marketing has validated the fundamental role of susceptibility to peer influence (SPI) and its powerful impact on consumer behavior, where SPI is defined as the tendency for individuals to look to standards from peers to develop their own motivations, attitudes, and behaviors (Bearden, Netemeyer, and Teel 1989). Despite the vital role SPI plays in understanding consumer behavior, little research has been conducted to investigate the driving forces of susceptibility. This issue is important because knowing about the key antecedents of SPI allows researchers and practitioners can develop effective intervening strategies to alter individuals' vulnerability to peer influence.

In the present research, we fill this gap through examining the effects of parenting strategies on SPI among adolescents. Specifically, we develop an integrative model of adolescent susceptibility to peer influence that includes parenting strategies (parental responsiveness and parental psychological control) as driver, adolescents' self-esteem as mediator, and stage at adolescence as moderator of susceptibility to peer influence. The overarching finding in our studies is that responsive parenting decreases susceptibility by bolstering adolescents' self-esteem, while psychologically controlling parenting increases susceptibility without influencing adolescents' self-esteem. This is especially true for children at their mid- and late-adolescence stages. Notably, these results were observed in both cross-sectional (Studies 1 and 2) and longitudinal data (Study 3), as well as data from both adolescents and their parents. Implications of the results for improving the effectiveness of parent-oriented anti-smoking campaigns are discussed.

Building Consumption Skills through Teenage Empowerment: A Powerful and Invisible Determinant of Customer Relationships

Wided Batat, University of Poitiers, France

EXTENDED ABSTRACT

Social networking and Web 2.0 enable young people to connect and collaborate easily and productively, online tools and spaces allow them to create collective knowledge about any consumption subject. The Internet and the mobile phone have become a central force that fuels the rhythm of teenage daily life. Among other things, there has been significant growth over the past five years in the number of teens who play games on the Internet, get news, check-in and shop online. In addition, the changing media landscape has become a battleground for the adolescents' share of voice. The 'YouTube' generation uses many forms of media simultaneously and average over six hours a day using the various forms (Hempel and Lehman 2005). Consequently, authors argue that today's teenagers are more competent than their parents in dealing with media and digital products (McDonnell 1994; Tapscott 1998) as their consumption learning is mostly made by practising social and entertainment activities *via* digital equipments and media which enable them to develop consumption skills. However, modern-day adolescents are competent or vulnerable consumers, depending on their age, gender, family, social background, consumption experience and other influences on their daily lives (Tufte 2003). In order to develop a better understanding of young consumers' empowerment, who represent the most highly sought for researchers and marketing practitioners, it is important to explore teens' competencies as consumers of media and new technologies. By examining how teens aged 11-15 define a competent consumer and how they perceive themselves as competent consumers within their own normative framework of new technologies' usages, we should be better able to understand the consumption behaviours they exhibit, the purchase decision they make and the limitations they feel they must overcome to become fully competent consumers. In order to examine these issues, the exploratory research was the best means for getting at these unspoken cultural and social patterns that shape consumer behaviour. The main thrust of this research involved 20 French schoolchildren aged 11-15 both boys and girls for 6 months (from January to June). This study was delimited to the schoolchildren population enrolled at Sainte Marthe Chavagnes elementary school in the city of Angoulême (south west of France).

The key findings for this study illustrated the behaviours associated with competent consumers and areas for improvement as competent consumers. Moreover, the study showed that teenagers are not mere followers of marketing strategies and they develop consumption skills in relationship to their experience, their peers and media which are more often associated with their consumption learning. We believe that nowadays teenagers are active participants and producers of their cultural consumption processes and that state of things can also be seen in the consumption of entertainment electronic technologies. In answering the question of competencies and savvy teens, our investigation gives evidence about the process of skills' construction within the consumption of digital product by the schoolchildren aged 11-15. Hence, teenagers' perception of the competence that they must have to be able to consume lies first and foremost on skills associated with preventive behaviours.

Being responsible consumer also means having the ability to resist to marketers influences. In order to do so, getting information,

evaluating and comparing the options, looking for the best price-quality ratio and the awareness about the environment' protection are one of the characteristics of a competent and responsible consumer. The present exploratory research seems to confirm that the mother and specifically the father remain the most influential consumer learning agent, in addition of peers, media, Internet, learning through trial and error, observation and the virtual peers *via* blogs. Therefore, the consumption skills emerge within the teens' experience of the purchase and the use of new technologies within their entertainment activities (playing video games) as well as their social activities (chatting on the Internet). Therefore, for companies understanding individuals' experiences remains the foundation for innovation and empowering young customers to communicate the message will become a vital part of both brand value and customer relationships management (CRM).

More Than Meets the Eye: The Influence of Implicit Self-Esteem on Materialism

Ji Kyung Park, University of Minnesota, USA
Deborah Roedder John, University of Minnesota, USA

EXTENDED ABSTRACT

One of the most consistent findings reported in the materialism literature is the link between self-esteem and materialism, with lower feelings of self-worth related to higher levels of materialism (Chaplin and John 2007; Richins and Dawson 1992). Material goods are viewed as a way for individuals with low self-esteem to cope with or compensate for doubts about their self-worth.

However, recent self-esteem research suggests that the relationship between self-esteem and materialism may be more complicated than current findings suggest. Two forms of self-esteem have been identified: explicit versus implicit self-esteem (Greenwald and Banaji 1995). *Explicit self-esteem* is defined as conscious evaluations of the self, whereas *implicit self-esteem* is defined as unconscious evaluations of the self. Consistent with Wilson, Linsey and Schooler (2000)'s dual attitude model, people can have two different attitudes toward the self, such as implicit versus explicit self-esteem. In fact, explicit self-esteem is only weakly correlated with implicit self-esteem, which is considered a distinct dimension of self-esteem (Bosson, Brown, and Zeigler-Hill 2003).

In this article, we propose that explicit self-esteem alone is not sufficient to capture the relationship between self-esteem and materialism, and that implicit self-esteem is an important determinant in the adoption of materialism. We report three studies that demonstrate the usefulness of this construct for understanding materialism. Each of the studies and findings are described below.

Study 1: The Joint Effect of Implicit and Explicit Self-Esteem on Materialism

Prior research has found that individuals with high (explicit) self-esteem exhibit lower levels of materialism. However, individuals with high (explicit) self-esteem are not a homogeneous group. In fact, this group includes two distinct subgroups of individuals: those with *congruent high self-esteem* (high explicit/high implicit self-esteem) and those with *discrepant high self-esteem* (high explicit/low implicit self-esteem).

Not surprisingly, these two groups exhibit different behavioral patterns. Individuals with discrepant high self-esteem have underlying negative self-feelings associated with low implicit self-esteem. To conceal such nagging self-doubts, these individuals use various forms of self-enhancing strategies. Relative to individuals with congruent high self-esteem, they tend to exhibit overt grandiosity, higher levels of narcissism, and indirect forms of self-enhancement, such as out-group derogation and in-group biases (Bosson et al. 2003; Jordan et al. 2003; Kernis et al. 2005). In sum, individuals with discrepant high self-esteem possess some of the same characteristics usually attributed to individuals with low (explicit) self-esteem, with both groups engaging in self-enhancing strategies to compensate for negative self-feelings.

Thus, we predict that individuals with discrepant high self-esteem will exhibit higher levels of materialism than individuals with congruent high self-esteem. We measured intact levels of implicit and explicit self-esteem, comparing how combinations of these types of self-esteem relate to materialism. Explicit self-esteem was measured using the Rosenberg Self-Esteem Scale (Rosenberg 1965); implicit self-esteem was measured using the self-esteem Implicit Association Test (IAT; Greenwald and Farnham 2000). As a measure of materialism, we used a qualitative task in which levels of materialism were revealed by asking participants to

construct a collage to answer the question: "What makes me happy?" (see Chaplin and John 2007).

The results support the idea that materialism depends not only on the levels of explicit self-esteem, but also on implicit self-esteem. Contrary to prior materialism research, individuals with high (explicit) self-esteem are not always immune to the appeals of materialism. Indeed, individuals with discrepant high self-esteem (high explicit/low implicit self-esteem) are more materialistic than individuals with congruent high self-esteem (high explicit/high implicit self-esteem).

Study 2: The Causal Impact of Implicit Self-Esteem on Materialism

Next, we proceed with our examination of implicit self-esteem by examining the causal relationship between implicit self-esteem and materialism. In Study 1, intact levels of implicit and explicit self-esteem were measured rather than manipulated, leaving open the possibility that materialism affects implicit self-esteem rather than the reverse. In Study 2, while measuring the intact levels of explicit self-esteem, we primed high implicit self-esteem through subliminal evaluative conditioning (Dijksterhuis 2004).

The results replicated those of Study 1. High implicit self-esteem priming reduced materialism; indeed, among participants with high explicit self-esteem, those in the control group who did not receive a prime were more materialistic than those primed with high implicit self-esteem.

Study 3: Why Does Discrepant High Self-Esteem Cause Materialism?

Individuals with discrepant high self-esteem, who tend to have relatively strong materialistic tendencies, present the most interesting case when compared to prior materialism research. In Study 3, we explore why discrepant high self-esteem can lead to materialism in more detail. They tend to use self-protective and self-enhancing strategies, not only to compensate for underlying negative self-feelings, but also to deal with threats to the self (McGregor et al. 2005). Because these individuals are concerned about protecting their exaggerated self-images, they overly react to self-threats.

We thus predict that individuals with discrepant high self-esteem will respond to a situation where a self-threat is present by focusing on material possessions as a self-enhancing behavior. Further, we expect their response to self-threats to be unique, in that not all individuals with low implicit self-esteem will react this way. We manipulated the level of self-threat in performing a memory task. As in Study 1, we measured the intact levels of explicit and implicit self-esteem, and used Richins and Dawson (1992)'s materialism scale as a measure of materialism.

We found that individuals with discrepant high self-esteem exhibit defensive responses to threats to their self-image. When a self-threat was present, individuals with discrepant high self-esteem exhibited heightened materialistic tendencies, which was not the case for individuals with low explicit and low implicit self-esteem.

Summary

Prior research has found that individuals with high self-esteem are less materialistic than those with low self-esteem. We add to these findings by distinguishing two types of self-esteem—explicit

and implicit self-esteem—and demonstrating that they have a joint influence on materialism. Specifically, we find that individuals with high explicit self-esteem vary in their tendency to self-enhance through material things as a function of their levels of implicit self-esteem. Thus, contrary to prior research, individuals with high explicit self-esteem can be susceptible to materialism.

The Bi-directional Effects of Consumption and Well-being; An Empirical Examination

Vincent-Wayne Mitchell, City University London, UK

Jing Yang Zhong, City University London, UK

EXTENDED ABSTRACT

The present study seeks to investigate how much people have to spend in order to achieve happiness; and how much happy people are more likely to spend. The concept of life satisfaction occupies a central place in marketing theory, and the model has been successfully applied to Quality-of-Life (QOL) issues (Day 1987; Lee, et al. 2002; Leelakulthanit, Day, and Walters 1991). However, individuals' actual consumption has not been linked to well-being issues and fully investigated in consumer behavior.

The theoretical foundation of the present study is the integration of subjective well-being (SWB) bottom-up and top-down theories. Bottom-up theories propose that "SWB is caused by the (summation of) pleasurable and unpleasurable moments and experiences, and a happy individual is happy simply because he or she experiences many happy moments" (Brief et al. 1993:646). This suggests that an individual's level of overall happiness is primarily predicted by his or her objective life circumstances such as the consumption behavior in this context (Feist et al. 1995). Top-down theories, by contrast, assume "there is a global propensity to experience things in a positive way, and this propensity influences the momentary interactions an individual has with the world. In other words, a person enjoys pleasures because he or she is happy" (Diener 1984:565). From this perspective, a person's overall well-being is the cause rather than consequence of his or her experience of specific phenomena such as specific consumption experiences (Feist et al. 1995; Headey, Veenhoven, and Wearing 1991). That is, we argue there is a bi-directional causality between SWB and consumption on hedonic products. In the present study, we look at two consumption categories, that of leisure consumption and durables consumption. This is because the increases of the consumption on these two categories are the highest for the past 4 decades in the UK (Porritt 2003), and they are important to consumers in modern life.

Data for this study are from the British Household Panel Survey wave 10-15 which were collected in late 2001-early 2002 for wave 10, in late 2002-early 2003 for wave 11, and so on. The observations for these 6 waves are over 50,000. Methodologically, panel data is the way of establishing the directional causality, which is the key aspect of the present study (Graham, Eggers, and Sukhtankar 2004). In the present study, subjective well-being is measured with the inverse of the 'caseness score' form of the multi-item scale GHQ12, ranging from 0 to 12. It is widely recognized to be a reliable measure of psychological well-being (Argyle 1987). Leisure consumption includes a) consumption on leisure activities, entertainment and hobbies; b) consumption on eating out. Variables a) and b) are ordinal in nature and ranging from 0, 1 (under £10) until 12 (over £160). Consumption on hedonic durables is measured with consumers' annual expenditure on each and aggregate of the 7 household hedonic electronics in the past year. Control variables include gender, age, age², marital status, household size, number of children and pre school children, education, vocational qualification, job status and the partner's job status, property ownership, health status, household net wealth, household annual income, and region in accordance with existing literature on consumption (Ameriks, Caplin and Leahy 2002; Oropesa 1995). Random-effects ordered probit estimations and panel fixed effects estimations are

employed to test the directional causations. Stata 10 is used for the data analysis in this study.

Our ordered probit estimations reveal that compared to spend nothing on leisure per month, leisure consumption at all other categories significantly affect a consumer's well-being. For example, the increase of leisure consumption from under £10 to over £160 per month weakly decreases the probability of being less happy, but strongly increases the probability of being in the highest well-being level (by 7.25% on average). However, consumption on hedonic durables does not affect well-being. These results seem to indicate that rather than deriving satisfaction from consumption activities as suggested in existing theories, only spending on experiential hedonic products correlate with being active and social contribute to well-being.

For the other causal direction, our ordered probit estimations suggest compared to well-being at reference level 0, well-being at levels over 3 all report highly significant effects on leisure consumption. For example, when well-being increases from level 1 to 12, people are 5.63% less likely to spend nothing per month on leisure, while they are 1.53% more likely to spend £50-£59 per month. The estimates for the effects of SWB on eating out and aggregate leisure consumption reveal qualitatively similar results. Additionally, we also find that when an individual's SWB increases from 0 to 12, the weighted average leisure consumption increased by approximately 20%. Our findings indicate compared to unhappy consumers, happy consumers enjoy more and are more likely to spend on hedonic products, but they do not tend to spend too much or buy very expensive ones. The findings seem to indicate that happy consumers spend on hedonic products primarily for meeting intrinsic goals such as intrinsic fun, regulating emotions (consumption on hedonic durables), social connectedness, and physical health (leisure consumption) which can be at no-cost or low-cost, rather than for extrinsic goals such as social comparison, material symbols, and identity seeking which are much more expensive, and they do not prefer expensive indulgent hedonic products.

Theoretically, this research extends well-being research into the consumer behavior area, and supplements the consumer literature that short-lived emotions influence consumers' temporal buying intention such as self-gifting, impulse buying, and compulsive buying and reaction to marketing stimuli. We suggest chronic well-being has potential impacts on consumers' general consumption behavior, especially on hedonic products, and the consumption it leads to is primarily goal pursuit and oriented. One implication for marketers of hedonic products is that happy consumers could be their target audience. Consumers can also use the results to guide their consumption behavior to improve their long-term happiness and quality of life.

Imagery-Text Congruence in Online Commerce and its Influence on Attitude Formation: A Processing Fluency Account

Thomas J. L. van Rompay, Twente University, The Netherlands

Peter W. de Vries, Twente University, The Netherlands

Ad T. H. Pruyn, Twente University, The Netherlands

EXTENDED ABSTRACT

Recent research indicates that design features of products and (online) environments may influence consumer choice and attitude formation (e.g., Griffith 2005; Mandel and Johnson 2002). Part of this influence relates to whether, and the extent to which, meanings connoted across different design elements match or mismatch (e.g., Van Rompay and Pruyn *in press*). For instance, online environments comprise many different elements (e.g., color, layout, textual information, and visuals) whose connotations require integration in order for a consumer to form an opinion or make a (purchase) decision. The authors propose that meaning (in)congruence impacts the relative ease with which informational elements are integrated. Ease of information integration, in turn, is expected to shape consumer response. To test these predictions, an experimental study is reported in which meanings connoted throughout product visualization and product description on a hotel booking site were manipulated.

In motivating these predictions, of particular interest is recent theorizing on processing fluency (e.g., Lee and Labroo 2004; Reber, Schwarz, and Winkielman 2004). The kernel of this proposal holds that people evaluate stimuli more positively the more fluently they can be processed. Arguably, meaning congruence also impacts processing fluency. For instance, when confronted with online vendor sites connoting various meanings through text (e.g., product description) and visuals (e.g., thumbnails of products), consumers face the task of integrating these various meanings into an overall impression in order to assess product quality and relevance, and to decide on purchase. Compared to highly incongruent information, matching or congruent information connoted by different website elements requires less integration, and, thus, makes the target product's meaning easier to grasp (cf. Lee and Labroo 2004).

Based on the above, it was predicted that online vendor sites in which product description and product visualization connote congruent meanings pose less information integration requirements, i.e., are more easily processed, compared to websites connoting incongruent meanings through product description and visualization. In line with the proposed relation between processing fluency and product evaluations, fluent processing was, in turn, expected to positively affect consumers' attitude towards the product presented. Since meaning integration requires, at least to some extent, elaborate processing, it was predicted that congruence effects would be particularly pronounced for participants high in need for cognition, as opposed to participants low in need for cognition.

To test these hypotheses, an experimental study was conducted in which participants were asked to evaluate a hotel booking site in which meaning congruence was manipulated. Based on pretesting, three hotel images were selected; a hotel image connoting coziness, a hotel image connoting modernity and a hotel image neutral with respect to these constructs. Similarly, two hotel descriptions were selected either stressing the hotel's cozy atmosphere or its modern atmosphere. By cross pairing the product visualizations and product descriptions, six versions of the website

were created, crystallizing in a 3 (Product appearance: cozy versus neutral versus modern) * 2 (Product description: cozy versus modern) * 2 (Need for Cognition: low versus high) between-participants design. Dependent measures comprised measures of processing fluency and attitude formation.

Results indicated that meaning congruence, as opposed to meaning incongruence, indeed facilitated processing and positively affected attitude formation. Hence, processing fluency and attitude ratings were highest when a modern hotel appearance was accompanied by a hotel description stressing the hotel's modern atmosphere, and when a cozy hotel appearance was accompanied by a description stressing its cozy atmosphere. In contrast, websites connoting incongruent meanings through text and visuals received lower ratings on the fluency and attitude measures. In line with predictions, congruence effects were particularly apparent for participants high in need for cognition. Furthermore, using moderated mediation analyses (Muller, Judd, and Yzerbyt 2005), it was shown that meaning congruence indeed impacts attitude formation via processing fluency, confirming that meaning congruence is an important antecedent of processing fluency and via this route affects consumer attitude formation.

The findings reported are of practical relevance, not in the least because product descriptions and product visualizations are the two most important sources of product information on online vendor sites. Considering that this particular type of service (i.e., a hotel booking site) is also high in experience characteristics (i.e., the service can only be evaluated after consumption; Klein 1998), the importance of information congruence is all the more apparent. Under these conditions in particular, information gathering to reduce uncertainty and perceived risk associated with the wrong choice (e.g., booking a modern hotel high in formalized procedures when looking for a warm and personal atmosphere) benefits from information congruence.

Taking note of these considerations, the findings reported can be integrated with, seemingly contradictory, findings from research addressing congruence effects in advertising (e.g., Heckler and Childers 1992; Lee and Mason 1999). Findings from these studies indicate that text-image incongruence in ads may attract attention and positively affect consumer response in low involvement situations. The results reported here indicate that, when consumer involvement and perceived risks are high, information incongruence should be avoided. Nonetheless, incongruence may yield positive effects when applied to peripheral or stylistic website elements (e.g., color, layout or typeface) that are not central to information processing (cf. Eroglu, Machleit, and Davis 2001). In addition, future research should explore to what extent moderators such as browsing intentions and online experience qualify congruence effects.

Awaiting further studies addressing these and related issues, in the meantime the findings presented testify to the importance of careful consideration of textual and visual elements comprising the online environment, and stress the importance of website design in general.

How a Consumption Failure Influences an Observing Customer's Attribution and Perceived Service Quality: The Role of Regulatory Focus

Elisa K. Y. Chan, The Chinese University of Hong Kong, China

Lei Su, The Chinese University of Hong Kong, China

Lisa C. Wan, The Chinese University of Hong Kong, China

EXTENDED ABSTRACT

Past literature has largely focused on how a failure in consumption influences customer satisfaction and behavioral reactions to the company (e.g., Folkes and Graham 1987; Smith, Bolton, and Wagner 1999), but very little attention has been paid to examine how a failure influences other customers (or potential customers) who are not directly involved in a consumption failure. Interestingly, existing marketing literature regarding the role of other customers has investigated how the presence of other customers influence decision making of customers involved in a consumption context (e.g., Argo, Dahl, and Manchanda 2005); however, the reciprocal influence that the customer involved has on other customers has remained untapped. This research attempts to fill this gap by examining how customers react to an observed consumption failure. It also highlights the moderating influences of regulatory focus on observing customer's attribution behavior and perceived service quality. It reports a study that tested several hypotheses.

Research Hypotheses

According to defensive attribution theory (Walster 1966), when observers witness a negative event in a context that is relevant to them, feeling of threat would arise. This feeling would then lead to attribution driven by self-protective motives. These defensive attributions may also be subjected to the influence of perceived personal similarity with the target person involved in an incident (Shaver 1970). Drawing on the defensive attribution theory, we argue that an observing customer will attribute more (vs. less) responsibility to the service provider if the customer involved in the failure incident is similar (vs. not similar) to him/her. These attributions, in turn, will influence an observing customer's perceived service quality of the company. In addition, an individual's regulatory focus may moderate this pattern of attribution due to their differences in sensitivity to loss (prevention-focused) versus gain (promotion-focused). Since prevention-focused (vs. promotion-focused) customers are more sensitive to loss, they are vigilant against harmful consequences of a similar service failure that might befall them. It follows that in a similarity condition, prevention-focused (vs. promotion-focused) customers may attribute more responsibility to the company, and therefore possess a poorer perceived service quality.

The research hypotheses are summarized as follows:

H1: When there is perceived personal similarity with the customer involved, an observing customer will attribute more responsibility to the service provider

H2: The effect of perceived personal similarity on responsibility attribution will be moderated by regulatory focus. (a) When there is perceived personal similarity, prevention-focused (vs. promotion-focused) observing customer will attribute more responsibility to the service provider, and (b) When there is no perceived personal similarity, regulatory focus of an observing customer will have no effect on responsibility attribution.

H3: The effect of perceived personal similarity on perceived service quality will be moderated by regulatory focus. (a) When there is perceived personal similarity, prevention-focused (vs. promotion-focused) observing customer will have a poorer perception of service quality, (b) when there is no perceived personal similarity, regulatory focus of an observing customer will have no effect on perceived service quality, and (c) this effect is mediated by attribution.

Method and Results

A total of 100 undergraduate students (61% females) of a University in Hong Kong participated in the study. Participants were randomly assigned to either a similarity or non-similarity condition, and their regulatory orientation scores were measured. Median split was used to classified participants into prevention-focused and promotion-focused orientation. Finally, a total of 92 undergraduate students were used to test the hypotheses.

The results from an experiment provide general support for the hypotheses. In general, participants attributed more responsibility to the service provider in the similarity condition (vs. non-similarity condition). As predicted, prevention-focused participants attributed more responsibility in the similarity condition than did promotion-focused participants. No significant difference between the two groups was found in the non-similarity condition. Moreover, participants perceived poorer service quality in the similarity condition (vs. non-similarity condition). In particular, prevention-focused (vs. promotion-focused) participants perceived service quality to be poorer in the similarity condition, and no significant difference between the two groups was found in the non-similarity condition. More importantly, results indicated that attribution partially mediated the effect of regulatory focus on perceived service quality in the similarity condition.

Two Types of Language Bias in Word of Mouth

Gaby A. C. Schellekens, Erasmus University, The Netherlands

Peeter W. J. Verlegh, Erasmus University, The Netherlands

Ale Smidts, Erasmus University, The Netherlands

EXTENDED ABSTRACT

Product-related conversations, or word of mouth, form an important part of consumers' responses to products and services. While the role of language in other areas of consumer behavior has received considerable attention (Luna and Peracchio 2005; Tavassoli 1999), there has been no research on the role of language in word of mouth. Language is fundamental to word of mouth and the study of language use could uncover fundamental psychological processes and gain insight in the context of word-of-mouth communication (Fiedler 2008).

To study the role of language in word of mouth, we made use of the framework provided by the Linguistic Category Model (Semin and Fiedler 1988). The linguistic category model has been used to study a variety of aspects of language use in interpersonal behavior. It distinguishes four categories of interpersonal terms based on the sentence verbs and predicates from the most concrete level (*descriptive-action verbs*) to the intermediate (*interpretive-action verbs* and *state verbs*) to the most abstract level (*Adjectives*). The use of more abstract language increases the extent to which a description is informative about the subject, as well as increased temporal stability and perceived likelihood of repetition of the behavior that is being described (Semin and Fiedler 1988). In general, people are unaware of the level of abstraction they apply, and cannot access their reasons for choosing a certain level of abstraction (Franco and Maass 1996).

Research in social psychology has demonstrated a linguistic expectancy bias (Wigboldus, Semin and Spears 2000). That is, behavior is described more abstractly when it is congruent (rather than incongruent) with one's expectations of the actor. Up till now, this bias has only been demonstrated with interpersonal behavior and has never been examined for communication about inanimate objects. Even though many of peoples daily conversations are about objects, such as product related conversations. This paper intends to fill this gap and examines the *linguistic expectancy bias* in word of mouth. In addition, and perhaps even more importantly, we will focus on the role of the receiver. In social psychology, language abstraction has mostly been studied in settings where participants are asked to describe the behavior of an actor (often depicted in a cartoon). In word-of-mouth communication, however, product experiences are communicated to another consumer. Research has frequently shown that receivers have a strong impact on the nature of word of mouth (e.g., Brown and Reingen 1987). We therefore extend the concept of linguistic expectancy bias to include the perceived or inferred expectations of the receiver. We will show that a *receiver's* attitude toward a product or brand will influence the abstraction level that is chosen by the sender of a word-of-mouth message. We label this phenomenon the "*receiver linguistic expectancy bias*".

Experiment 1 demonstrates the linguistic expectancy bias in word of mouth. In the experiment the product attitudes about fictitious brands (positive vs. negative) and product experiences (positive vs. negative) were manipulated and the participants were asked how they would communicate the product experience to another person by choosing from several predetermined product descriptions according to the levels of the linguistic category model (Semin & Fiedler, 1988). Consistent with our hypotheses, study 1

revealed the linguistic expectancy bias in word of mouth: product experiences congruent to ones product opinion were communicated more abstractly, compared to expectancy incongruent experiences. More specifically, favorable product experiences were communicated more abstractly by participants with a positive product attitude compared to a negative attitude, and unfavorable experiences were communicated more concretely by participants with a positive compared to a negative product attitude. The findings of experiment 1 were replicated in two additional studies. The first one demonstrated the linguistic expectancy bias with existing brand attitudes (using actual brand names, such as Nike and Apple Ipod) and the second replication showed the linguistic bias with an open-ended response format as dependent variable, in which participants' responses were coded according a schema developed by Semin and Fiedler (1988).

Experiment 2 demonstrates the *receiver linguistic expectancy bias*. It was expected that characteristics of receivers affect the language that senders use to describe their product experiences. We anticipate that people will use more abstract or more concrete language to accommodate the receiver's expectations about a product.

In the experiment, the participants were asked to communicate a product experience to a receiver of whom they knew the product attitude. We found that positive experiences were communicated more abstractly when the receiver held a more favorable (vs. unfavorable) attitude of the product under consideration. Likewise, negative experiences were communicated more abstractly when receivers held a less favorable (vs. favorable) attitude of the product. This bias parallels the "classical" linguistic expectancy bias, but has its cause in a different source, namely the attitude of the receiving party.

Our research sheds new light on the oft-studied topic of word of mouth, by providing insights into the subtleties of product-related conversations. We provide a first application of the linguistic category model outside the context of (inter)personal behavior, and demonstrate a linguistic expectancy bias for inanimate objects. Secondly, we propose and demonstrate a receiver linguistic expectancy bias. Our studies show that language abstraction is responsive to the influence of the communication context: a communicator's use of language abstraction is biased to fit the expectations of the receiver. Opportunities for future research are identified in the paper.

Selective Consumer WOM Communication and Its Consequences

Yu Hu, Salem State College, USA

EXTENDED ABSTRACT

Consumers' interpersonal, word-of-mouth (WOM) communications have long been recognized as an effective channel to disseminate market information (Frenzen and Nakamoto 1993) and, perhaps more importantly, to influence consumers' product judgments and choices (Herr, Kardes and Kim 1991). Accordingly, much of the research attention has been focused on the recipient of the WOM message (i.e., the *audience*). However, for an interpersonal social interaction like WOM, surprisingly very little is known about the effect of WOM on the communicator of the message (i.e., the *speaker*). Specifically, two issues are largely overlooked: First, the speaker's retelling of past experience to an audience is not a verbatim recall of what has happened (Marsh 2007); instead, the speaker's message construction is a selective process, a process that is under the influence of many individual and situational forces. Second, this selective communication process itself might drive important cognitive changes in the minds of the speaker. In other words, communicating consumption experience with others might affect the speaker's subsequent judgments of the experience itself.

For the WOM speaker, communications of consumption information with others can serve many different interpersonal or situational goals, such as self-presentation, impression management, or entertainment, and more importantly, accuracy is often not the main objective; thus, the communicated message should not be a simple relay of the stored knowledge. In fact, message modifications, such as interpretation, evaluation, exaggeration, omission, or even falsification (e.g., Argo, White, and Dahl 2006; Sengupta et al. 2002) are ubiquitous in consumers' daily conversations. "This means, in effect, that one has to lie. We must leave out the details that don't fit, and invent some that make things work better (Schank and Abelson 1995, p. 34)."

Borrowing a term from social psychology (e.g., Higgins 1992), I use *audience-tuning* to refer to the WOM speaker's adaptive message construction behavior, in which the speaker tailor his/her message to suit the audience's characteristics or meet situational demands. I posit that the speaker's audience-tuning behavior not only affects the quantity and quality of the WOM messages transmitted to the audience but also has a significant cognitive impact on the speaker's subsequent memory and judgments of the communication topic. As Schank and Abelson (1995, p. 58) put it, "We lose the original and keep the copy". That is to say, as a consequence of the communication, the speaker's recollections or evaluations of the consumption knowledge might be realigned with the contents of the communicated messages.

Many researchers have reasoned that memory differences after communications could be attributed to the fact that communicators selectively rehearsed certain aspects of the past events during communications and the rehearsals enhanced the subsequent retrievals of those details. In addition to the rehearsal mechanism, McGregor and Holmes (1999) proposed a heuristic explanation that people develop a heuristic version or interpretation of the past events to effective retelling of past story and this interpretation heuristics directly biased later judgments and remembering of those events. Regardless, either due to enhanced rehearsal or heuristic interpretation, selectively modifying past experiences to serve communication purposes is bound to have a cognitive impact on the speaker.

In an effort to provide empirical evidence of WOM speakers' message modification behavior and its consequent cognitive changes,

this research developed a memory-based, two-step experiment approach. Subjects first learned some evaluatively complex (positive, negative and ambiguous) product information and formed initial judgments. After a brief delay, they were supraliminal primed with different social relations: best friend vs. stranger (i.e., communal vs. exchange relation; see Clark and Mills 1979, 1993). Immediately afterwards, in an ostensibly unrelated task, they were asked to freely communicate the product information to a relation-ambiguous audience. Subjects' responses revealed the following patterns: Those primed with a best-friend audience communicated more negative product information than those primed with a stranger; they were also more likely to negatively interpret ambiguous information.

Twenty-four hours later, product attitude was reassessed via an online questionnaire. Results showed a significant attitude change. More importantly, subjects in the best friend condition presented significantly decreased evaluations of the product, which could be attributed to the fact that these participants recounted significantly more negative product information during the communication stage and this selective rehearsal affected their subsequent judgments. Interestingly, audience-tuning behavior did not seem to have an evaluative impact on subjects in the stranger group: Although they rehearsed more positive product information than those in the best friend condition, they seemed to have a mechanism in place to filter out or not register the audience effect during either the message production process or the later reevaluation of the product. This unexpected finding pointed to a promising direction for future research. For example, if it is reasonable to expect that the speaker needs to monitor the retelling-induced cognitive change, then what factors would contribute to the enhancing or discounting of this ability? What are the roles of the audience in this monitoring process?

The intended contribution of this research is twofold. First, by priming a common relationship variable to demonstrate the WOM speaker's selective message construction and the resultant cognitive changes (and non-change), this paper attempts to raise researchers' attention to the social co-construction nature of consumer WOM behaviors. It is necessary for researchers to adopt a broader, interpersonal, co-constructive view of the WOM behaviors and to identify the antecedents and consequences of this complex process (see Pasupathi 2001 for a review). Second, as a meaningful addition to the WOM research methodology, this research introduces a new memory-based experimental approach that could be used to systematically investigate the process of WOM communications and its consequences.

The Interpersonal Determinants of Sniping in Internet Auctions

Michael A. Kamins, Stony Brook University, USA

Avraham Noy, University of Haifa, Israel

Yael Steinhart, University of Haifa, Israel

David Mazursky, Hebrew University of Jerusalem, Israel

EXTENDED ABSTRACT

The current research explores the intrapersonal and social factors of the sniping phenomenon. Sniping occurs in on-line auctions when the auction closes at a specified pre-determined time (a "hard close"). Sniping is placing a bid on an item in the very ending stages of the auction in an attempt to win the auction, while leaving other bidders a short period of time or no time to respond.

Four studies were conducted to examine the social factors affecting the sniping strategy. The first study was based on on-line survey among 144 eBay bidders. Its findings pointed out that consumers perceive sniping to be an effective auction strategy by which the bidders can achieve a higher probability of winning the auction at a lower price. The second study was based on an on-line auction simulation setting among 62 participants. Its results revealed that participants were more likely to snipe when there was a higher number of other bidders showing an interest in the auction than when the number was low. The last two studies were conducted in actual eBay auctions. The third study was conducted among 141 eBay bidders in the presence of high or low counter. eBay counter is a visual representation of the number of viewers who inspected the specific item. The results demonstrated that the tendency to snipe was higher in case of high counter (many other potential bidders) than in case of low counter. The fourth study was conducted among 286 eBay bidders. The findings indicated that when the auction displayed the counter, sniping took place more often in public auction (i.e. when knowing the bidders' identity) compared to private auctions (i.e. when the bidder's identity is concealed). However, when the counter was hidden, there was not a significant difference in the percentage of sniping.

The findings of this research shed new light on the determinants affecting bidding behavior, specifically—sniping in internet auctions. The research also uncovers extant beliefs that bidders have about sniping effectiveness. It would be interesting to further explore the boundaries of the social impact on sniping. It can be implemented through controlling for other factors which earlier studies observed that they have an effect on sniping. The closing rule of the auction and the experience of the bidders are such factors which come to mind. These studies will enable the researchers to evaluate boundary conditions regarding the effect of the other bidders on sniping behavior as well as the interaction among the factors.

Consumer Emotional Intelligence: A Comparison between the U.S. and China

Robert Jewell, Kent State University, USA
Annie Peng Cui, West Virginia University, USA
Blair Kidwell, University of Kentucky, USA
Desheng Wang, Shandong University, China

EXTENDED ABSTRACT

Consumption decisions often satisfy consumers' various psychological needs and serve a social purpose by reflecting ties to one's family, community, and cultural groups. These distinct orientations may provide important insights into how consumers process emotional information and how they use that information to make brand decisions. In this research, we explore the antecedent role of consumer emotional intelligence on decision making differences between collectivist and individualistic orientations; specifically Chinese and American consumers. Further, we compare the consumer emotional intelligence scale across these two distinct cultures to better understand its validity and dimensionality.

In the present paper, we first highlight the importance of cross-cultural instrument testing, followed by a brief discussion of CEI and its measurement. Then, we compare differences in the CEI instrument across a US and Chinese sample, followed by an examination of the influence of CEI on brand selection.

Emotional intelligence is defined as one's ability to recognize, perceive, and effectively use emotional information, such as the meaning of emotions, emotional patterns, and emotional relationships (Caruso, Mayer, and Salovey 2002, Mayer and Salovey 1997). Emotional intelligence operates in a complementary fashion with the more traditional, cognitively-based knowledge in decision making. That is, emotional intelligence is conceptualized to supplement rather than supplant cognitive intelligence in decision-making contexts (Mayer, Salovey, and Caruso 2004). Research has consistently indicated that emotional intelligence predicts performance beyond the effects of cognitive intelligence (Mayer et al. 2004).

Recently, a scale has been developed that evaluates emotional intelligence specifically as it relates to consumer domain-specific issues such as product choice (Kidwell, Hardesty, and Childers 2008). The Consumer Emotional Intelligence Scale (CEIS; www.ceis-research.com) was developed to measure the domain of consumer decision making. The CEIS is comprised of four specific branches; *perceiving*, *facilitating*, *understanding*, and *managing* emotion.

Research on culture has shown that differences exist on a number of dimensions. For example Hofstede has found that cultures tend to differentiate along five dimensions: power distance, individualism versus collectivism, masculinity versus femininity, uncertainty avoidance, and long- versus short-term orientation (Hofstede 2001). With respect to the difference between the U.S. and China, the dimension that is most-often invoked is the individualism versus collectivism dimension. Individualist societies are believed to be characterized by low identification and loose integration into social groups. The implication is that people in individualist societies are largely on their own in terms of dealing with issues and problems. Conversely, those in collectivist societies are characterized by strong identification and a high degree of cohesiveness with social groups. The implication is that that people in collectivist societies perceive individual issues and problems as problems for the group to solve (Hofstede 2001).

With respect to emotional intelligence, such a taxonomy of cultural differences may suggest, on the one hand, difference

between U.S. and Chinese consumers. China, representing a more collectivist society, may reward emotional intelligence to a higher degree than an individualist society such as the U.S. Thus, one expectation related to emotional intelligence may be that consumers in China have higher levels of emotional intelligence. Moreover, the emotional skills necessary to function in a collectivist society may be qualitatively different than the skills necessary to function in a collectivist society. Thus, with respect to emotional intelligence, the expectation may be that rather than the amount of emotional intelligence, the structure of emotional intelligence would be different between China and the U.S.

On the other hand, there is reason to believe that cognitive representation and cognitive processing characteristics, such as intelligence, are invariant with respect to culture (Sternberg 2004). That is, perhaps the ability to perceive, use, understand, and manage emotions is a fundamental characteristic of the human condition. With respect to emotional intelligence, such a perspective would lead one to predict structural invariance for CEI as it pertains to a comparison between U.S. and Chinese consumers. Given these two distinct yet equally viable possibilities, we view this study as exploratory. As a result, we make no specific hypotheses or predictions as to the nature of the similarities or differences between China and the U.S. with respect to emotional intelligence; we will allow the question to be addressed empirically.

To examine the construct of CEI and its structure in two countries that are culturally distinct, we conducted two studies in China, representing a collectivistic culture, and the United States, representing an individualistic culture. The results of our studies suggest that the basic structure for the Chinese data indicated a good model fit with the CEIS model proposed by Kidwell, Hardesty and Childers (2008). This supports the notion that CEI is a general construct that appropriately applies to consumers in a country that is culturally distinct from the U.S., where the scale was developed. Thus, we can conclude that the construct itself and its four-factor structure are robust and have a high external validity. This finding is further supported in a choice task that indicates that consumers high in emotional intelligence evaluate attribute information more objectively than consumers with lower levels of emotional intelligence.

Our second important finding indicates that although the basic structure for the Chinese data showed a good model fit, there is a clear indication of structural difference between the two samples. In particular, the dimension of *Understanding* determines the difference between the Chinese and the U.S. samples. One possible explanation might be that Chinese consumers, coming from a collectivist culture, may pay more attention to the contextual cues when giving the task to understand and process the information presented than American consumers. This may lead to a different perception of the same scenario between Chinese and American consumers, which eventually presented via their answers.

The present study suggests that consumer emotional intelligence provides a unique lens for researchers and marketers to study consumers from different cultures. Future research should explore this construct in other cultures, group dynamics, and other marketing applications.

The Effect of Culture on Sequential Choice in Group Settings

Song-Oh Yoon, Korea University, Korea
Kwanho Suk, Korea University, Korea
Seon Min Lee, Korea University, Korea
Eunyoung Park, Korea University, Korea

EXTENDED ABSTRACT

Past research has indicated that people tend to seek variety in their choices. This effect has been demonstrated in both intrapersonal and interpersonal choices, although variety-seeking has been shown to result in lower overall satisfaction with their choices (Ariely and Levav 2000). Many of these findings are explained by people's desire to portray a positive self-image by appearing unique (Ariely and Levav 2000; Ratner and Kahn 2002). However, the findings of some cross-cultural studies have challenged the generalization of such assessments (Kim and Markus 1999). According to these studies, variety-seeking is less pronounced in Eastern cultural members, as they share different assumptions regarding uniqueness and individuality. Specifically, in contrast to the more individualistic Western culture, where uniqueness and being different from others are considered positive traits, negative associations are attached to uniqueness and individuality in the more collectivistic Eastern culture.

While past research has provided insights into cultural influences on variety-seeking behavior and the underlying motivations, its implications with regard to consumer's interpersonal decision have yet to be clearly understood. This is mainly because past cross-cultural studies in this area have focused on individual choice situations (Kim and Markus 1999). In particular, it is still ambiguous as to whether the negative meanings associated with uniqueness in Eastern culture will result in a mere lack of conscious attempts to vary their choice from those of others (i.e., lack of variety-seeking) or it will result in greater efforts to conform to others' choices in interpersonal decision situations. One line of research (e.g., Markus and Kitayama 1991) suggests that individuals from collectivistic cultures are expected to follow others' choices when the choice is made in a group setting, since being similar to others and conformity to group is an important cultural value in this context. However, another research finding (e.g., Kim and Drolet 2002) suggests that other's choices would exert minimal effects on the individual's choice, because choice is not an act of self-expression for collectivistic cultural members. Accordingly, members of collectivist cultures will not necessarily make similar choices with those of others, while the amount of variety-seeking behavior is less, compared to individualistic cultural members.

Therefore, the primary purpose of current research is to test these two competing predictions. In particular, we focus on the impact of others' choices on conformity-seeking tendency among individuals from collectivist cultures. We also attempt to examine the conditions under which such cultural orientations have particularly profound impacts on individual's choice. In line with previous research highlighting that culture is not a constant meaning but often dissipates or activates depending on situational demands (Briely and Aaker 2006), we show that culture has greater implications for choice only when individual's choice is made based on cultural, rather than personal, knowledge. Finally, we investigate the potential differences between Eastern and Western cultural members in the emotional consequences of aligning one's behavior (e.g., choice) with cultural norms. Unlike the members of Western culture, whose emotional well-being has been shown to be lowered after complying with cultural norms (e.g., variety-seeking), individuals in Eastern culture are not expected to experience such

reductions in emotional well-being, as aligning oneself with cultural norms (e.g., conformity) is more consistent with their definition of personal happiness.

We test our predictions in two studies, involving real restaurant order data and a field study. In the first study, the analysis of 517 meal order slips, representing 1,475 diners from two local restaurants in Korea, showed that real tables dining in a group tended to choose less varied dishes as compared to what would be expected from a random sampling of population of all individual choices across tables (i.e., simulated data representing menu selections in the absence of any group influence). Similar findings are observed in restaurants that differ in terms of cuisine, average dish price, and familiarity to participants. Next, we replicate our findings in a setting that allows more experimental control. In our field experiment, we manipulate the conditions in which individuals choose their options, such that in one condition they select their options under group influence (i.e., sequential choice condition) and in the other condition, group is dissolved and thus the choice becomes a strictly individual one (i.e., individual choice condition). We found that Koreans tended to select options identical to those of their group members when they make selections collectively as opposed to individually. We further show that, unlike previous findings based on individuals from Western cultures, adherence to the cultural norm (i.e., conformity) did not result in lower overall satisfaction with their chosen options for Koreans. Lastly, we show support for the hypothesized mechanism underlying the above effects, by demonstrating that the tendency to seek variety or conformity is associated significantly with decision maker's individualistic-collectivistic dispositions.

Do Ethnic Marketing Efforts Pay Off?: Interaction Effects of Accommodated Brand and Price on Product Evaluation and Purchase Intention

Manuel Michaelis, University of Muenster, Germany
Hai Van Duong Dinh, University of Muenster, Germany
Tobias Heussler, University of Muenster, Germany
Mareike Meyer, University of Muenster, Germany
Dieter Ahlert, University of Muenster, Germany

EXTENDED ABSTRACT

In the course of history, especially through globalization and the coalescence of many different countries to confederations (e.g., the European Union), migration has become a common phenomenon all over the world—resulting in large ethnic groups in many domestic markets. As a result of this changing ethnic landscape, marketers increasingly target ethnic groups with culturally accommodated marketing. Consequently, consumer researchers are engaged with the questions of whether ethnicity is a viable variable to segment markets, and whether targeting ethnic groups with culturally oriented marketing pays off. In spite of this growing interest in ethnic marketing, research in this field is still fairly limited, even in the U.S. where ethnic marketing has evoked most attention (Burton 2000). Furthermore, the range of issues addressed in the studies is narrow. First, due to the dominance of U.S. research papers, studies focus on ethnic groups in the U.S. Second, most of these studies focus on ethnic advertising and neglect accommodation options of other marketing tools, such as culturally oriented brands (Burton 2000). Last, in large part the studies are limited to efforts to determine behavioral differences between consumers of various cultural groups, and trying to account for these to cultural factors (Holland and Gentry 1999; Hirschman 1981).

Extending our knowledge about consumer responses to ethnic marketing, our contribution to the literature is threefold. First using an accommodated brand we analyze a marketing tool other than advertising. Second, we differentiate between consumer affective, cognitive, and conative responses to ethnic marketing measures. Third, we investigate the specific impact of an accommodated brand on price premium options for a German ethnic group.

Drawing on accommodation theory (Holland and Gentry 1999) and existing findings of research on ethnic marketing, brand, and price, we derived our hypotheses. We propose that culturally accommodated brands improve cognitive and affective product evaluation as well as purchase intention. Moreover, we propose that accommodated brands moderate the relationships between price and cognitive product evaluation, affective product evaluation, and purchase intention.

We tested our hypotheses in collaboration with a German mobile telephone service provider, gathering data from 100 Turkish respondents, and using a scenario-based experimental fixed-factor 2 x 2 between-subjects research design. Our stimuli were four different fictitious products which were presented randomly to the participants. Price (high vs. low single surcharge per call to Turkey) and brand (neutral vs. Turkish brand name with Turkish national symbols) were selected as independent variables, whereas the phone rates were reduced to four fixed connections for the ease of presentation to the test subjects (calls on German landline and all German mobile networks, calls on Turkish landline, calls on all Turkish mobile networks, single surcharge per call to Turkey).

The effects of accommodated brand and price on the dependent constructs were tested by conducting a MANOVA. The results indicate significant main effects and a significant interaction effect. In order to determine the effect of the stimuli on each dependent

construct we conducted Follow-Up-ANOVAS, which revealed that the affective product evaluation and the purchase intention were both influenced by an interaction effect (brand x price). In contrast to our proposition, we did not find a significant interaction effect on the cognitive product evaluation. Moreover, we found no significant direct effect of brand on cognitive product evaluation. Last, we conducted post-hoc tests to determine whether the hypothesized effects work in the proposed direction. In the case of a high price, the accommodated brand has a positive impact on the affective product evaluation as well as on purchase intention, whereas, in the case of a low price, mean values do not differ significantly from those when no accommodation takes place. Thus, ethnical accommodation at lower prices does not have a significant impact on affective product evaluation or on purchase intention.

Our results have implications for marketing management. In the case of low prices ethnic marketing efforts increase neither affective product evaluation nor purchase intention because the price dominates other cues (here: brand) which affect consumer response. In the case of high prices, purchase intention is higher with accommodated brands than with brands that have not been accommodated. Consequently, cultural adaptations allow higher prices, justifying expenditure on ethnic marketing efforts. As a result, accommodated branding tends to pay off, particularly in situations of larger targeted ethnic groups and those with higher purchasing power.

The effect of price level and branding on cognitive product evaluation is less clear. In contrast to our hypothesis, we found no effect of price and brand on cognitive product evaluation. Holland and Gentry (1999) give a reasonable explanation of this result. Due to the mere exposure effect, accommodation may have an affective response even if consumers do not consciously recognize the targeted marketing efforts (here: accommodated brand). In contrast, recognition is a prerequisite for consumers to evaluate products cognitively. Therefore, more research is needed to understand the underlying process of product evaluation in an ethnic context. Further research could also draw on Oliver's loyalty model, which differentiates between four stages of loyalty—cognitive, affective, conative, and action loyalty (Oliver 1997; Evanschitzky, and Wunderlich 2006)—to extend our knowledge of consumer response to ethnic marketing.

As with all empirical studies, this study has limitations. The key limitation here is the design as a laboratory experiment. In order to extend an examination of the results, the experiments can be replicated with heterogeneous samples (field experiments). Moreover, replications with different ethnic groups and in different service industries are needed in order to confirm our findings.

Seize The Day! Encouraging Indulgence for the Hyperopic Consumer

Kelly L. Haws, Texas A&M University, USA

Cait Poynor, University of Pittsburgh, USA

EXTENDED ABSTRACT

The luxury market in the United States alone generated over \$445 billion in 2005 (Mintel 2005). Though some luxury items are associated with frivolity, there also appear to be short and long-term benefits associated with indulgence, beginning with the enjoyment of everyday pleasures and extending to profound effects on life satisfaction (Kivetz and Keinan 2006). However, recent research suggests that consumers may display what has been called “hyperopic” behavior, exhibiting aversion to luxury-related products and actions. Some degree of hyperopia may exist in a broad segment of the population. Therefore, both in order to enhance consumer well-being and provide guidance for luxury marketers, understanding ways in which consumers and marketers can alter such hyperopic tendencies, within reason, is important (Kivetz and Simonson 2002). In the present research, we measure hyperopia as an individual difference, identify mechanisms which drive hyperopic behavior and validate prior assumptions about its nature. We then examine how the level at which goals or purchases are construed can impact the behavior of hyperopic consumers, helping those with high levels of hyperopia to overcome their aversion to indulgence and learn to “Seize the day.”

In the present research, we use a 6-item measure of hyperopia based on the work of Kivetz and Simonson (2002) and examined further by Kivetz and Keinan (2006). This scale captures hyperopia’s main characteristics: First, hyperopia lowers a consumer’s present likelihood of pursuing and consuming indulgences. Second, hyperopic individuals acknowledge their own difficulty with indulgence, and therefore should be capable of reporting these tendencies. Third, the hyperopic tendency to consistently forego indulgence can lead to retrospective regret and a sense of missing out on life (Kivetz and Keinan 2006).

In our first study, we measure individual level hyperopia and examine its relationship to basic outcomes. We propose that consumers high in hyperopia will generally consider a given set of products as more luxurious than will consumers low in hyperopia. Furthermore, we demonstrate that even when controlling for differences in perceived level of luxury, high hyperopia consumers have lower purchase intentions for luxuries than consumers low in hyperopia. Study 1 also provides evidence that high hyperopia is different from excessive self-control, suggesting that hyperopia is distinct from excessive levels of self-control.

Studies 2 and 3 seek to demonstrate a construal based level remedy for hyperopic consumers. In Study 2, we asked participants to adopt and elaborate on an indulgence goal:

Imagine that you have decided that although your financial future is important, you really should enjoy life more by worrying less about how you are spending your money or sticking to a particular budget, and instead focus more on the overall enjoyment of your life.

Immediately following these instructions, the level of construal at which participants were to consider the indulgence goal was manipulated using a laddering technique based on Fujita et al. (2006). For the low-level construal condition, participants were asked to consider *how* they might pursue the goal. For the high-level construal condition, participants were asked to consider *why* they might pursue the goal.

We then assessed perceived ease of achieving the indulgence goal. Results showed a significant interaction of hyperopia level

and the level at which the goal was construed. Closer examination of this interaction reveals that the effects of construal were primarily among high hyperopia participants. When high hyperopia participants construed the indulgence goal at a higher level, they exhibited a significantly higher sense that they could pursue the goal in question than did those construing at a lower level.

In study 3, we manipulate the construal of an indulgence product through marketing communications. Specifically, participants read about a BMW, either in terms of specific, concrete attributes or higher-level benefits. Then, embedded among a series of distracter questions, we measured their sense that the car constituted a good investment (i.e., that it was consistent with long-term gains) and their purchase likelihood for the car. As in study 2, the ad containing the higher-level construal significantly increased perception of the vehicle as a good investment among high hyperopia consumers. This perception, in turn, mediated an increase in purchase likelihood among that group.

Overall, we reveal that hyperopia operates at a fundamental, perceptual level, creating an upward tendency in the degree to which a given item is seen as luxurious. Furthermore, hyperopic consumers express lower purchase intentions for luxury products, even when controlling for their own luxury perceptions. Studies 2 and 3 reveal that construal level moderates the effect of trait hyperopia. Importantly, we demonstrate that this occurs by altering the extent to which the luxury is seen as a long-term investment or gain, and is, therefore, consistent with the hyperopic consumer’s tendencies. Thus, the present research provides insight into means of overcoming hyperopic tendencies (Kivetz and Simonson 2002). These theoretical contributions suggest that marketing communications can externally influence construal levels in ways that make luxury products less unappealing to the high hyperopia consumer. Practically, the present research suggests that retailers and consumers can create situations which are conducive to the hyperopic individual’s ability to occasionally “Seize the day!” and make the most out of the opportunities life has to offer.

Schedules of Reinforcement, Learning, and Frequency Reward Programs

Adam Craig, University of South Carolina, USA
Timothy Silk, University of British Columbia, Canada

EXTENDED ABSTRACT

Recent studies have applied principles of operant conditioning to provide insight into consumer behavior in response to frequency reward programs (FRP's). Operant conditioning describes how both animals and humans acquire (learn) behavior through punishments and reinforcements experienced while behaving successively in the environment. With FRP's, consumers are rewarded each time they shop at a particular company, repeatedly purchase a product, or fly with a specific airline. They also avoid the loss of potential rewards by being loyal to the program. In all cases, effort (usually measured in time or dollars spent) is rewarded in the hope that consumers will exhibit loyalty and continue their purchasing efforts.

Consumer research on FRP's has focused primarily on fixed ratio (FR) reinforcement schedules. For example, Kivetz et al. (2006) employed a FR10 schedule that rewarded consumers after every 10 purchases and found that operant effort (i.e., the rate of purchase) increases as perceived distance to the goal decreases. While consumer research has reliably demonstrated that FR schedules can accelerate purchases, it has yet to examine other types of schedules found to generate higher response rates in other research domains. Research in operant conditioning and neuroscience has shown that variable ratio (VR) schedules generate faster rates of response than fixed ratio (FR) schedules using the same number of reinforcements (Ferster and Skinner, 1957). This implies that VR schedules have the potential to generate higher revenues with no increase in the cost of rewards. The current research examines the impact of variable ratio schedules in an FRP context.

The different response rates for FR and VR schedules is attributed to differences in the rate of learning each schedule. Fixed schedules are learned relatively easily since the reward recurs consistently after every *n*th purchase. Once the schedule is learned, subjects accelerate their behavior as they approach the next reward (i.e., as the psychological distance to the next reward decreases). However, participants in FR schedules tend to exhibit periods of inactivity immediately following a reward when the perceived distance to the next reward is at its greatest.

In contrast, VR schedules are learned less easily because the timing of each reinforcement varies over successive trials. The impeding affect of variability on learning is supported by research on multiple-cue learning (e.g., Mellers 1980), which shows that people have difficulty learning patterns that contain small amounts of error or randomness. The number of rewards administered by a VR schedule is the same as with an FR schedule, but the exact timing of the rewards in the behavioral sequence varies randomly. Because the reward occurs randomly and can be acquired (potentially) after any single operant response, perceived distance to the reward decreases, motivation to respond increases, and participants respond without cessation. This eliminates the post-reward pause observed with FR schedules, resulting in higher response rates. Variability also influences preference for reinforcement schedules. Wilson et al. (2005) find that people forecast that they will be happier when the timing of reinforcements is predictable. Yet, paradoxically, positive moods (Wilson et al. 2005) and neural responses (Berns et al. 2001) tend to last longer when the timing of reinforcements is uncertain.

Consistent with Wilson et al. (2005), we predict that consumers will prefer FRPs that administer rewards on a more certain or

predictable schedule when given a choice among reward schedules. Consistent with Ferster and Skinner (1957), we predict FRPs that employ VR schedules will produce faster rates of purchase. The results of two experiments demonstrate the predicted response paradox: consumers predict they will purchase more and be more satisfied with predictable fixed ratio schedules, yet response rates are fastest when rewards are administered using unpredictable variable ratio schedules.

Experiment 1 examined consumer's self-predicted behaviors in response to three reinforcement schedules under consideration at their favorite coffee shop. The study employed a within-subjects design involving 33 undergraduates. Subjects were presented with descriptions of three reinforcement schedules: (1) FR5, (2) VR5 with high variability, (3) VR5 with low variability. As expected, consumers' predicted satisfaction and predicted purchase frequency were inversely related to the variability of the schedule.

Experiment 2 examined whether VR schedules generate faster, more frequent responses than FR schedules. Experiment 2 also examined whether increasing the variability of reward timing results in slower rates of learning and faster response times. One hundred and forty-four subjects were randomly assigned to one of four reinforcement schedules: (1) FR5 in which participants were rewarded after every 5th trial, (2) VR5 with low variability in which participants were rewarded after every four to six trials, (3) VR5 with high variability in which participants were rewarded after every two to eight trials, and (4) a no-reward control condition. The VR5 schedule with high variability generated the fastest rate of response, followed by the VR5 schedule with low variability, the FR5 schedule, and the no-reward control condition. Differences in response rates were attributable to differences in the rate at which consumers learned the schedules and anticipated rewards. Further, the rate of learning was inversely related to the variability of reward timing. In summary, the findings suggest that variable ratio schedules may be more profitable despite consumers' preferences for predictable rewards.

The Anticipation of Chosen Pleasures: Temporal Variations in the Valuation of Delayed Consumption

Elaine Chan, Hong Kong University of Science and Technology, Hong Kong, China
Anirban Mukhopadhyay, University of Michigan, USA

EXTENDED ABSTRACT

Consumers often make purchase decisions now for products and services to be consumed in the future. Research on the valuation of delayed consumption has mixed findings. Discounted utility theory (Ainslie 1975) demonstrates that delayed consumption is valued less than immediate consumption (“discounting”). However, other research (Loewenstein 1987) indicates that individuals may savor the pleasantness of future consumption, implying that delayed consumption is instead valued more (“anticipation”). This research investigates the conditions under which individuals discount versus anticipate future consumption, and proposes that the extent of intrinsic motivation towards the consumption is an important moderating factor. Specifically, we predict that two variables—autonomy, as manifested by choosing agent, and perceived control, as manifested by length of delay—which we predict influence intrinsic motivation and hence the temporal valuation of delayed consumption.

Extant research has demonstrated that choosing one’s option provides autonomy and increases motivation to persist at the chosen activity (Deci and Ryan 1985). We therefore hypothesize that when individuals choose their own consumption, the associated autonomy provides intrinsic motivation to engage in the consumption, and a goal of consumption is activated. If this goal is not satiated over time, its intensity may increase (Bargh et al. 2001), leading to anticipation. In contrast, if the consumption is chosen by someone else, the lower autonomy and correspondingly intrinsic motivation will lead not to anticipation, but rather discounting of the delayed consumption—causing evaluations to decrease with time.

However, two factors may be at play here. When the delay extends beyond a certain point, individuals may perceive other uncontrollable external factors decreasing their perceived control over the consumption thereby reducing the intrinsic motivation. Hence as the length of delay increases, the positive effect of autonomy on intrinsic motivation may get swamped by the increasingly negative effect of decrease in perceived control. As a result, beyond a certain point there should be a net negative effect on intrinsic motivation. Therefore, we hypothesize that when individuals make their own choices, the valuation of delayed consumption will first increase and then decrease as the temporal separation between choice and consumption increases.

We tested these hypotheses in three experiments. In experiment 1, participants were told that a drama festival was due to start either the same day or one week later. They then read descriptions of three dramas, of which one had been pretested to be significantly more interesting. Next, half the participants chose which drama they would like to watch, while the other half were told which drama their friend had chosen for them (the “more interesting” option). Subsequently, they were asked to imagine that the drama was to start in a few hours but there was a thunderstorm outside (as in Gourville and Soman 1998). Given this scenario, participants were asked how likely they would go to watch the drama. As predicted, results revealed that intention increased with delay in the self-choice condition, but decreased in the other-choice condition.

Experiment 2 used real delays between choice and consumption, and included an additional longer delay condition. We also directly manipulated inherent interest to test whether the anticipation effect

is driven by intrinsic motivation. We expected that the inverted u-shaped relationship between evaluation and time would occur only for consumption that is of high (vs. low) inherent interest. In contrast, evaluations should decline with time when someone else chooses the option, regardless of the level of inherent interest. The fourth aim of this experiment was to test the proposed mediating effect of intrinsic motivation. Similar to experiment 1, participants were told that a music festival was to be held either the same day, one week later, or two weeks later. Inherent interest was manipulated using genre: participants in the high [low] interest condition read about two pop [classical] music concerts. The procedure was the same as before: participants either chose the concert for themselves or were told which concert their closest friend had chosen. Subsequently (vs. after a week / two weeks), participants reported their evaluations and intrinsic motivation towards the concert. Consistent with our prediction, when they chose their own concert, there was a significant quadratic trend (i.e. more positive evaluations in the short-delay than in no-delay and long-delay conditions) but only in the high interest condition. When the concert was chosen by someone else, there was a linear trend such that participants in the no-delay condition reported more positive evaluations than in the delay conditions. Further, as hypothesized, this effect was fully mediated by intrinsic motivation.

Experiment 3 aimed to further increase confidence in the inverted u-shaped relationship in the self-choice condition by using real decisions as well as delays. We also wanted to investigate the effect on post-consumption evaluations. Participants were first asked to choose between two variants of chocolate. Then, either immediately, one week, two weeks, or one month later, they provided their pre-consumption evaluations. Finally, after tasting their chosen chocolate, they reported post-consumption evaluations. Replicating the previous pattern, pre-consumption evaluations showed a significant quadratic trend such that evaluations were more positive in the one-week condition than in the same day, two-week and one-month conditions. As before, this effect was mediated by intrinsic motivation. In contrast, post-consumption evaluation measures revealed an ironic negative effect—participants evaluated the chocolate more *negatively* in the one-week condition than in the other three conditions. Evidently, those who anticipated more prior to consumption reported lower post-consumption evaluations.

Taken together, our results demonstrate that when consumers make their own choices, there is an inverted u-shaped relationship between pre-consumption evaluation and delay. We also show that the anticipation effect is driven by consumers’ intrinsic motivation towards the consumption, and thus only occurs for consumption that is of high inherent interest. When somebody else makes the choice for them, evaluations decline as consumption is delayed. The moderating effect of choice on the discounting and anticipation effects; the fact that this is due to differences in intrinsic motivation; and the inverted u-shape of the anticipation effect; the three are key contributions of this paper.

The Role of Goals in the Relationship Between Counterfactual Thinking and Behavioral Intentions

Anu Sivaraman, University of Delaware, USA
Parthasarathy Krishnamurthy, University of Houston, USA

ABSTRACT

This paper focuses on why and how counterfactual thinking (CFT) affects information processing and behavioral intentions. Earlier research has indicated that CFT influences the ability to discriminate between superior and inferior arguments, but did not directly examine the underlying process. Also, even when CFT affects future behavioral intentions, it is not clear how it does so. Across three studies we find that the underlying process is more akin to elaboration than priming. Also, we find that, when CFT influences behavioral intentions, it does so by increasing goal strength.

Counterfactual Thinking as a Post-hoc Consumption Expectation

Jessica Y. Y. Kwong, The Chinese University of Hong Kong, China

Candy K. Y. Ho, The Chinese University of Hong Kong, China

EXTENDED ABSTRACT

Consumer expectation of a consumption experience is seen as pivotal in determining consumer responses to the consumption experience because it serves as a comparison standard against which the consumption is evaluated (e.g., Oliver 1980; Oliver and DeSarbo 1988). Research to date has conceptualized consumer expectations as a set of prior beliefs about a product or service (Olson and Dover 1979), indicating that they are formed before consumption. While these prior expectations are useful as generic and relatively stable standards for evaluating any consumption experience, they might be too general for assessing one particular incident. We argue that after receiving an outcome, consumers may also retrospectively generate case-to-case “customized standards” to evaluate that particular consumption incident. These instantaneous standards are highly contextualized that they may be relevant to the current situation only, and may even be contradictory to general preexisting expectations. In the present research, we investigate consumers’ retrospective construction of a “customized standard” for a particular consumption instance and examine its effects on consumer responses to the consumption.

It is proposed that in instances of negative consumption experience, consumers’ counterfactual thoughts of “what the company *could* have done” serve as a retrospectively constructed expectation of “what the company *should* have done” and determine consumers’ postpurchase responses. Counterfactual thinking is the imagination of alternatives to a factual event in which the factual outcome is undone by altering an antecedent event. For instance, a customer who finds that a fast food shop has stopped selling food just a few minutes before he/she arrives may generate a counterfactual thought that he/she would have made the purchase had the counter extended the service hours just a little bit longer. At that instance, the customer may take that hypothetical action that the company could have done, that is, close later, as what the company should have done. By underscoring what the company should have done and yet failed to do, company-related counterfactuals signal the company is at fault. This will lead to negative reactions toward the company.

We further propose that the extent of negative reactions toward the company depends on the ease of generating those counterfactual actions. The easier it is for the consumers to imagine a company could have done something differently, the stronger is the belief that the company should have acted accordingly. Hence, we hypothesize that consumers would react more unfavorably towards the company in situations where it would be easier to generate company-related counterfactual thoughts.

In addition, we also hypothesize that consumers’ negative reactions will be tempered in the presence of self-related counterfactual thoughts. For example, consumers may react less negatively to the fast food shop when they dropped by somewhere (e.g., grocery store) on their way to the fast food shop than when they did not. The counterfactual of not visiting another place suggests the self as another antecedent that could have turned the situation around. People in general have a tendency to discount the weight of one antecedent given another (Kelley 1972). Thus, the impact of the company-related counterfactual thoughts on consumers’ reactions may depend on the availability of other company-unrelated counterfactual thoughts, such that this effect

may be attenuated when it is easy to generate company-unrelated counterfactual thoughts, such as those related to oneself.

We assessed our ideas using scenario experiments, in which undergraduate students participated for course credits. Study 1 tested the effect of company-related counterfactuals on consumers’ postpurchase responses. In the scenario, the ease of generating company-related counterfactuals was altered by temporal closeness. It was easier to generate such thoughts when the temporal closeness for the counterfactual actions was high than when it was low.

Consistent with our contention that temporal closeness should facilitate the construction of company-related counterfactuals, participants in the temporally-close condition (vs. the temporally-far condition) elicited a significantly higher proportion of company-related thoughts. Parallel to our predictions, participants in the temporally-close condition reported significantly higher dissatisfaction toward the company and also higher negative postpurchase intentions than did those in the temporally-far condition. More important, these findings could not be explained by the idea that consumers’ reactions are driven by their prior beliefs about the consumption experience. In fact, the findings were in a direction opposite to those predicted by consumers’ preexisting beliefs.

Study 2 was conducted to show that the impact of company-related counterfactuals was attenuated by the presence of self-related counterfactuals. The study independently manipulated the ease of generating company-related counterfactuals and that of generating self-related counterfactuals.

Consistent with study 1, participants who generated more company-related counterfactuals reported greater dissatisfaction and negative postpurchase intentions towards the company. However, as our discounting argument predicted, this pattern was attenuated among those who generated a higher proportion of self-related counterfactuals. The thought protocols yielded further support that the participants relied on the post-hoc-generated company-related counterfactuals as the standard for evaluations. Again, the results were opposite to the predictions derived on the basis of consumers’ preexisting general beliefs.

To conclude, this research highlights the role of post-hoc-constructed expectations in influencing consumers’ responses from a counterfactual thinking perspective. Results from two studies provide converging evidence that counterfactual thoughts of what the company could have done to bring a better outcome set as post-hoc standards for evaluations. The easier is this process, the more dissatisfied are the consumers. This tendency, nevertheless, is attenuated when company-unrelated counterfactual thoughts, such as those related to the consumers themselves, are generated simultaneously. Findings in the current studies could not be readily explained by consumers’ prior expectations. This highlights the uniqueness of post-hoc expectation as standards for evaluations.

The Role of Alternative Causes and Disabling Conditions on Consumers' Acceptance of Product Claims

Elise Chandon, Virginia Tech, USA
Chris Janiszewski, University of Florida, USA

EXTENDED ABSTRACT

Causal conditional reasoning involves making inferences on the basis of an "if p then q" statement (i.e., a conditional premise), where p is the antecedent (i.e., cause) and q is the consequent (i.e., effect). In the field of marketing, product claims often take the form of a conditional premise. The goal of advertisers is to convince consumers that brands are a "true" cause of beneficial effects. For instance, Crest toothpaste uses the slogan *Crest fights cavities* in an attempt to persuade potential customers that if they use Crest toothpaste, then they will not develop cavities.

Product claims can be formulated in many different ways. First, product claims can either focus on the presence (i.e., usage) or absence (i.e., non-usage) of the brand and the resulting impact on the effect. Second, ad claims can lead with the cause (e.g., *Pantene Pro-V: For hair so healthy it shines*) or the effect (e.g., *How do you spell relief: R-O-L-A-I-D-S*). Manipulating these two variables (usage or non-usage of the brand and presentation order) offers four possible ways to express a product claim. Examples of product claims that fit into each of these classifications (see Table).

Prior research investigating a person's willingness to accept a causal claim has focused on two types of counterarguments (Cummins 1995; Cummins et al. 1991; Dieussaert, Schaeken, and D'Ydewalle 2002): the availability of alternatives causes and the availability of disabling conditions. An alternative cause is a possible cause that can generate the effect and a disabling condition is a situation which prevents the effect from happening despite the presence of the cause. A person's ability to think of *disabling conditions* can make a claim less believable. For example, knowing that people with high sugar diets are more likely to have cavities may decrease a person's willingness to believe that Crest prevents cavities. The presence of disabling conditions cast doubt on the sufficiency of the cause (e.g., using Crest). Second, the person's ability to think of *alternative causes* can make a claim less believable. For example, knowing that good oral hygiene also prevents cavities may reduce a person's willingness to believe that Crest prevents cavities. The presence of alternative causes casts doubt on the necessity of the cause.

We contend that the persuasiveness of a product claim will depend on the accessibility and diagnosticity (e.g., Feldman and Lynch 1988; Wyer and Hartwick 1980) of disabling conditions and alternative causes. Experiment 1 investigates the diagnosticity of disabling conditions or alternative causes for assessing the believability of a conditional premise. We ask participants to read a conditional premise, to list disabling conditions or alternative causes, and to make a conditional inference. We show that listing disabling conditions influences the acceptance of a modus ponens (MP) and a modus tollens (MT) conditional premise, but not an affirmation of the consequent (AC) and a denial of the antecedent (DA) conditional premise. Similarly, we show that listing alternative causes influences the acceptance of an AC and a DA conditional premise, but not a MP and a MT conditional premise.

Experiment 1 focused on documenting the types of counterarguments (i.e., reasons) that influence the acceptability of a conditional premise. In effect, it investigated the diagnosticity of specific type of counterarguments. Yet, when a person assesses the

validity of an advertising claim, counterarguments are self-generated. Are there factors that influence the type of counterarguments that are accessible (Rholes and Pryor 1982; Roese, Sanna, and Galinsky 2005)? The conditional reasoning literature is silent on that issue but there is suggestive evidence in the counterfactual literature that the accessibility of different types of counterarguments will depend on the framing of the causal claim (Roese, Hur, and Pennington 1999).

In experiment 2, we investigate the joint influence of the accessibility and diagnosticity of disabling conditions or alternative causes on the believability of a causal claim. We show that a claim framed as achieving a gain is more believable in a MP argument format (e.g., "If you use a deodorant soap, then you will remove body odor.") than a DA argument format (e.g., "If you do not use a deodorant soap, then you will not remove body odor."). In contrast, a claim framed as preventing a loss is more believable in a DA argument format (e.g., "If you do not use a deodorant soap, then you will not prevent body odor.") than a MP argument format (e.g., "If you use a deodorant soap, then you will prevent body odor.").

The results show a complex, but predictable, pattern of acceptance of product claims depending on the claim frame and the argument format. Most importantly, the results show that one argument format (i.e., MT) is not universally the best argument type. It is also interesting to note that a number of existing product claims are being stated in a manner that limits their acceptance.

Is that Bargain Worth My Time?

Ritesh Saini, George Mason University, USA
Raghunath Singh Rao, University of Texas at Austin, USA
Ashwani Monga, University of South Carolina, USA

EXTENDED ABSTRACT

Consumers love bargains. The possibility of cheaper products urges people to drive to far-flung outlet malls; the prospect of getting a discount makes them clip and save coupons; and the promise of instant savings at the time of purchase is reason enough to sign up for the store-specific credit card. But how far are consumers willing to go in order to get such bargains? Consider an example of two stores: Store A sells a shirt for \$20 but Store B sells the same shirt for \$10. Would a consumer, who is already in Store A, be willing to take a five-minute drive to Store B in order to save \$10? Furthermore, would the consumer be willing to drive to save \$10 if the price at Store A were \$60?

Traditional economic theories suggest that consumers should base this decision simply on how much they value the benefit of \$10 versus the cost of a five-minute drive (Stigler 1987). However, research on relative thinking suggests that a discount of \$10 seems *less* appealing if the price is \$60 rather than \$20. In other words, people demonstrate relative thinking (Azar 2007; Thaler 1980; Tversky and Kahneman 1981). This notion is significant for marketers because it implies that, given a fixed sales-promotion budget aimed at increasing store traffic, a manager ought to make discounts more attractive by applying them on products that are priced low rather than high. We delineate the conditions under which this strategy would make sense, but also other conditions in which managers ought to do the opposite. We show that a \$10 discount can sometimes seem *more* appealing on a price of \$60 rather than \$20.

Relying on the strength of multidisciplinary research, we rely on a mathematical model to derive new predictions that we then test in behavioral studies. Our theorizing involves a consideration of referent thinking, which involves the reference price that one expects to pay (Kalyanaram and Winer 1995; Winer 1986). We employ an analytical model to study how two behavioral tendencies—relative and referent thinking—interact when they are jointly incorporated into the prospect theory value function. This leads to three novel predictions: (1) A relative-thinking effect will emerge when the actual price turns out to be the same as expected. That is, consumers will be more willing to seek a bargain on a product that is priced low rather than high. (2) A referent-thinking effect, which is opposite to the relative-thinking effect, will emerge when the actual price deviates from the expected price. That is, consumers will be more willing to seek a bargain on a product that is priced high rather than low. (3) A relative-thinking effect will emerge yet again when actual prices become extremely discrepant from the reference price.

The above predictions are supported in three laboratory experiments that employ an infrequently-purchased product category (blankets) and a frequently-purchased product category (gasoline). An additional study attests to the counter-intuitiveness of our results and provides evidence that these effects might be occurring without people being aware of them. Specifically, when a group of participants were given details about one of our experiments and asked to predict what the results would have been, they suggested a pattern that was consistent with relative thinking, but opposite to the referent-thinking results that we actually found.

From a theoretical standpoint, we help better understand the factors that determine the effectiveness of bargains such as price

promotions. We also help provide a more nuanced view of prior research on relative thinking (Tversky and Kahneman 1981). To research on internal reference prices (Kalyanaram and Winer 1995), we add the notion that the influence of reference prices stretches beyond perceptions of actual prices; they also change perceptions of promotions that are offered on those prices. Finally, we present a framework that affords wide applicability. For instance, our framework can be extended to incorporate time-money differences (Okada and Hoch 2004; Saini and Monga 2008) in order to examine how bargain-seeking behavior varies with whether the cost of seeking a bargain is in terms of time or money. Similarly, it can help understand the effect of other consumer benefits, beyond the monetary promotions that we studied.

From a managerial standpoint, our results offer direct suggestions regarding enhancing the effectiveness of a fixed sales promotion budget by considering not only product prices, but also the deviations of those prices from expected prices. Depending on the situation, a fixed sales-promotion budget should sometimes be allocated to cheap products (loss leaders) but to more expensive products (big-ticket items) at other times. Finally, recommendations arise in terms of when promotions ought to be framed in absolute terms (\$X off), and when in relative terms (Y% off).

The Differential Promotion Effectiveness on Hedonic versus Utilitarian Products

Yuhuang Zheng, Tsinghua University, China

Ran Kivetz, Columbia University, USA

EXTENDED ABSTRACT

Prior research in social sciences (e.g., Kivetz and Simonson 2002; Kivetz and Zheng 2006; Maslow 1970; Prelec and Loewenstein 1998; Weber 1998) suggests that consumers feel more difficult to justify spending money on hedonic than utilitarian products because of the inherent disadvantages of hedonic luxuries compared with utilitarian necessities. Consequently, we propose that consumers have a stronger need for justification and are more likely to rely on external justifications such as promotions to help them make a purchase decision when buying hedonic products than buying utilitarian ones. Therefore, it is predicted that promotions have a stronger effect on the purchase likelihood of hedonic rather than utilitarian products. This and other related propositions are tested in a series of studies using a variety of promotion programs and product categories in different price ranges.

Study 1 tests the proposition that promotions have a stronger effect on the purchase likelihood of hedonic products than utilitarian ones in three separate tests using different types of products. In each test, respondents were randomly assigned to one of the four conditions in a 2 (product type: hedonic vs. utilitarian) X 2 (promotion availability: available vs. unavailable) between-subjects design. Consistent with our hypothesis, in all three tests, promotions had a stronger positive effect on the purchase likelihood of the hedonic products than utilitarian products (all p 's < .05). Specifically, in the first test (DVD movie vs. ink cartridge), for the hedonic product (DVD movie), promotion had a significant positive effect on the purchase likelihood (13% vs. 47%, $p < .001$). In contrast, for the utilitarian product (ink cartridge), promotion did not have a significant positive effect on the purchase likelihood (77% vs. 87%, $p > .1$). The difference in the observed promotion effects between hedonic product and utilitarian product conditions is statistically significant ($p < .05$). Similarly, in the second test (LCD TV vs. desktop PC), for the hedonic product (LCD TV), promotion had a significant positive effect on the purchase likelihood (46% vs. 81%, $p < .001$). In contrast, for the utilitarian product (desktop PC), promotion did not have any effect on the purchase likelihood (78% vs. 78%, $p > .1$). The difference in the observed promotion effects between hedonic product and utilitarian product conditions is statistically significant ($p < .01$). Finally, in the third test (Time Out New York magazine vs. Time magazine), for the hedonic product (Time Out New York magazine), promotion had a significant positive effect on the purchase likelihood (12% to 42%, $p < .01$). In contrast, for the utilitarian product (Time magazine), promotion did not have a significant positive effect on the purchase likelihood (54% vs. 37%, $p > .1$). The difference in the observed promotion effects between hedonic product and utilitarian product conditions is statistically significant ($p < .01$).

Study 2 further tests the proposed conceptualization by holding constant the product in all conditions while manipulating consumption goals (hedonic vs. utilitarian) across conditions. Specifically, Study 2 employed a 2 (consumption goal: hedonic vs. utilitarian) X 2 (promotion availability: available vs. unavailable) between-subjects design. The results show that while promotions had a significant positive effect on the purchase likelihood of a digital camcorder when the consumption goal was hedonic (for vacation) (32% vs. 68%, $p < .001$), the same promotion did not have a significant effect on the purchase likelihood of the same camcorder when the consumption goal was utilitarian (for study) (63 vs. 74%,

$p > .1$). The interaction effect between promotion availability and consumption goal was significant ($p < .05$).

Study 3 was designed to test the conceptualization by investigating the differential effects of promotions when a product is purchased for self compared to when a product is purchased as a gift for others. Specifically, Study 3 employed a 2 (hedonic product vs. utilitarian product) X 2 (promotion available vs. promotion unavailable) X 2 (for the self vs. for others as a gift) between-subjects design. Consistent with the proposed conceptualization, the results demonstrate that for hedonic products, promotions had differential effects on the purchase likelihood of the hedonic product when it was purchased for the self (25% vs. 73%, $p < .001$) compared to when it was purchased as a gift for others (71% vs. 86%, $p < .1$) (interaction effect $p < .05$). In contrast, for utilitarian products, there was no significant differential effects of promotion on the purchase likelihood of the utilitarian product when it was purchased for self (20% vs. 40%, $p < .05$) compared to when it was purchased as a gift for others (46% vs. 61%, $p < .1$) (interaction effect $p > .1$). The 3-way interaction effect between product type, promotion availability and whether the product is purchased for the self or for others as a gift was marginally significant in the predicted direction ($p < .1$).

Study 4 investigates the underlying psychological processes of the differential promotion effectiveness by examining the moderating role of justifications in the positive effect of promotions on purchasing or choosing hedonic products. Specifically, Study 4 employed a 2 (justification availability: available vs. unavailable) X 2 (promotion availability: available vs. unavailable) between-subjects design. The results show that while promotions have a strong positive effect on the purchase likelihood of hedonic products (28% vs. 75%, $p < .001$), such effect is eliminated when consumers are asked to carefully think of reasons before they make their decisions (50% vs. 56%, $p > .1$). The interaction effect was significant in the predicted direction ($p < .01$), supporting the moderating role of justifications in the positive effect of promotions on the purchase likelihood of hedonic products.

In sum, the findings of Studies 1-4 are consistent with our proposed conceptualization that consumers find it more difficult to justify spending money on hedonic luxuries for themselves and therefore they have a stronger need for and are more sensitive to external justifications such as promotions. In the final section, we discuss the implications of the findings for marketing managers and for the literature of sales promotion.

Gambling for a Discount: Preferring Discount Per Item to Discount Per Purchase?

Bernadette Kamleitner, University of London, UK
Mandeep K. Dhama, University of Cambridge, UK
David R. Mandel, DRDG Toronto, Canada

EXTENDED ABSTRACT

Price discounts are a well-studied promotional method (e.g., Hardesty and Bearden 2003). How discounts are offered has an influence on consumers' deal perception (e.g., DelVecchio, Krishnan, and Smith 2007). Although various discount frames have been investigated, there remains a paucity of research on risky discounts. These are discounts that are determined by a chance procedure (e.g., 'scratch & save' cards). Research on risky discounts is needed because they are actually offered and because they differ from other discount formats in at least one important respect: even after choosing a product, consumers do not know how much discount they will receive. Consumers receiving risky discounts are playing a gamble with an unknown outcome.

To enhance our understanding of risky discounts we assess in three studies whether consumers prefer to get risky discounts per purchase or per item and why they prefer one discount format over the other. In fact, these options differ with regard to several respects (e.g., saving distribution) but they do not differ with regard to expected values.

Study 1 was conducted in an environment where risky discounts are offered, in Canada. 150 participants completed a questionnaire on a 'scratch & save' card discount policy. According to this policy customers pick a card and scratch it to reveal their particular discount rate. Each card informs about possible discount rates (e.g., 10%, 25%, 50%) and their associated probabilities. Participants were asked to choose between getting such a discount per item (i.e., separate cards for each item) or per purchase (i.e. one card overall). Options do not differ with regard to expected value. After choosing a discount format, participants were asked to report their main reason for their choice.

A significant majority of participants (82%) chose the item-specific discount. The main reason given was that participants thought that this option would be more likely to provide them with a higher discount. Some thought they would get a higher discount overall, others thought that they would get a higher discount at least once, but most did not further clarify their claim. Some of those choosing the purchase-specific discount also did so because they believed that purchase-specific discounts would be superior with regard to expected discount. However, most choosing the purchase-specific discount did so because they preferred to keep things simple.

Participants of Study 1 were familiar with risky discounts in general but they were not familiar with item-specific discounts. To ensure that results were not due to a familiarity bias Study 2 replicated Study 1 in a country where purchase-specific and item-specific risky discounts are equally novel to consumers, the UK. 67 participants participated in an exact replication of Study 1. Again, a significant majority of participants (67%) preferred the item-specific discount. The differences in reasons mentioned across options largely corresponded to those established in Study 1. Most participants preferred one discount per item because the probability of receiving a higher discount was perceived as being higher, i.e. participants appeared to be more hopeful.

Study 3 aimed to corroborate these findings using a different design. 54 participants read a scenario that was based on the discount policy used in the previous studies. Participants were told that one shopper, Susan is offered one 'scratch & save' card for her purchase of four items whereas another shopper, Molly, is offered

four cards for the same items. Participants answered four questions designed to shed light on their underlying preferences: They had to indicate whether Susan, Molly or both equally would (a) be more hopeful when starting to scratch, (b) have better chances to get an overall discount of more than 25% off, (c) and of at least 50% off, and (d) spread more positive word-of-mouth communication about the shop. Separate analyses for each of these questions show that item-specific discounts are perceived as inspiring more hope, as more likely to lead to a higher discount and as more likely to lead to positive word-of-mouth communication.

Across studies we found that consumers prefer risky item-specific discounts to risky purchase-specific discounts, mainly because they seem to inspire more hope. Interestingly, this hope does not seem to relate to actual characteristics of savings distributions. In study 3, consumers were not able to realize actual changes in overall outcome probabilities that result from splitting a purchase-specific discount into multiple discounts per item. Rather, across studies many consumers seemed to be hopeful either because of a biased perception of probabilities or because the item-specific discount option led to a shift in mindset: many consumers choosing the item-specific discount seemed to aim to at least once "hit the jackpot" rather than making a good deal overall. From a retailer's perspective, offering item-specific risky discounts is rational as long as discount administration is feasible. In particular the observed shift in mindsets may lead to more satisfied consumers: In the case of purchase-specific discounts, only those getting an overall high rare discount will be especially satisfied. In the case of item-specific discounts, all those getting a high discount on one single item will be satisfied.

Considering that not everyone preferred item-specific discounts and that there is still much to learn (e.g., verifying the observed preference across product categories and different amounts of items) we recommend offering a choice between purchase-specific and product-specific risky discounts rather than forcing consumers into one discount format. Risky discounts make it possible to offer consumers such a choice.

Neuroscience in Marketing and Consumer Research: Using Functional Magnetic Resonance Imaging

Martin Reimann, Stanford University, USA
Andreas Aholt, University of Hamburg, Germany
Carolin Neuhaus, University of Bonn, Germany
Oliver Schilke, Stanford University, USA
Thorsten Teichert, University of Hamburg, Germany
Bernd Weber, University of Bonn, Germany

EXTENDED ABSTRACT

Advances in brain imaging have made it possible for researchers to enhance their knowledge about how the brain functions. Recently developed forms of neuroimaging, such as functional magnetic resonance imaging (fMRI), allow for a direct measurement and localization of brain activations. In some respect, fMRI may be considered superior to more traditional measurement approaches, such as questionnaire surveys, in that it promises: (1) the ability to provide confirmatory evidence about the existence of an intrapersonal phenomenon; (2) the generation of a more fundamental conceptualization and understanding of underlying processes; and (3) the refinement of existing conceptualizations of various phenomena.

Although the use of neuroscientific methods has a long history within the social sciences, e.g. in the discipline of neuropsychology, applications in the field of consumer neuroscience are still relatively scarce. While consumer neuroscience—also referred to as neuromarketing—has excited growing interest in recent times, both in the business practice and as a focal point of academic research, its use is still far from being wide-spread among marketing and consumer behavior scholars. A possible diffusion barrier may be that familiarity with neuroscientific methods in the consumer behavior area is low, making it difficult for most researchers to properly evaluate its use. Exacerbating this problem of limited familiarity, existing applications of neuroimaging in the consumer behavior area have used the technique inconsistently and, at times, inappropriately.

The purpose of our research is to provide insights into the field of fMRI, which is the most frequently-used neuroscientific methodology in marketing and consumer research in past years. We will focus on the advantages it provides and the problems it faces. Moreover, we will suggest guidelines for how to implement fMRI in marketing and consumer research.

An Innovative Approach Examining the Asymmetrical and Nonlinear Relationship between Attribute-Level Performance and Service Outcomes

Xiaomeng Fan, Purdue University, USA
Sandra Liu, Purdue University, USA
Michael Zhu, Purdue University, USA

EXTENDED ABSTRACT

Studies in customer satisfaction suggest that the relationship between the attribute-level performance and overall satisfaction/behavioral intentions may be nonlinear; attributes with differing characteristics can affect customer satisfaction differently. This study employs an innovative approach for a step-by-step evaluation of said relationships within a hospital service context.

Conceptualization

The prospect theory predicts that people follow an S-shaped value function when making decisions under risk. This curve changes from a reference point, steeper for losses than for gains, indicating a negative asymmetrical effect. In addition, the curve suggests a diminishing sensitivity of service outcomes to attribute-level performances, with changes at higher levels of positive/negative performance failing to influence service outcomes as dramatically as changes at the intermediate range.

However, empirical studies have revealed that both directions of asymmetrical effects (positive/negative asymmetry) and types of nonlinear relationships (increasing/diminishing sensitivity) vary depending on the nature of service attributes. For example, Anderson and Mittal (2000) posited that attributes with satisfaction maintaining qualities often exhibited negative asymmetrical effects, because these could be viewed as core attributes and were taken for granted by consumers. Moreover, higher order constructs were likely to have a decreasing sensitivity towards extreme levels of performance on these attributes. Meanwhile, for attributes with satisfaction enhancing qualities, positive performance was rarely expected by the consumer. Thus, changes in the positive domains of these attributes would bring about greater impacts than would changes in the negative domains and might create increasing rates of improvement on service outcomes.

In our study regarding the relationship between attribute-level performance and patient behavioral intention in terms of the likelihood to recommend the hospital (LTR), attributes are established through four aspects: Physiological Care, Psychological Care, Physical Environment, and Spiritual Care, and these specific attributes each has a particular nature. For instance, "competence" under Physiological Care may have satisfaction maintaining qualities, given the essential importance of this attribute to hospital services. LTR is expected to drop significantly if staff "competence" is viewed negatively. Meanwhile, attributes reflecting Spiritual Care may have a satisfaction enhancing nature, since these have been less addressed in hospitals previously and patients may be surprisingly delighted by positive experiences on these attributes. Therefore, we hypothesize that these attributes can be classified into three types according to the direction of asymmetrical effects: for Type I attributes, LTR can only be influenced if negative performances are encountered; for Type II attributes, LTR can only be influenced if positive performances are encountered; for Type III attributes, both positive and negative performances can significantly influence LTR. We then hypothesize that Type I and Type III attributes will display diminishing marginal returns on LTR, given the satisfaction maintaining qualities of these attributes; Type II attributes will be perceived as "delights" for customers, providing an increasing marginal return of LTR.

Method

Telephone-survey data was gathered from 2000 inpatients hospitalized in 2006. Patients were asked to indicate their experiences with 24 descriptors of hospital services on a seven-point likert-like scale and were also asked to rate, on an eleven-point scale, how likely they would recommend the hospital.

Five hidden aspects of hospital services were extracted through an exploratory factor analysis: "Compassionate Care", "Mutual Communication", "Procedure Efficiency", "Reputation", and "Spiritual Care". A score for each factor was generated by taking the weighted average of ratings on items under the corresponding factor and ranged from 1 to 7. The authors then centered these scores, creating five new variables representing performances on each factor.

Next, a three-step approach was utilized to examine the asymmetrical and nonlinear relationships existent between performance on each aspect of hospital services and LTR. First, the original scale measuring attribute performance was divided into four parts: "extreme-positive", "low-positive", "low-negative", and "extreme-negative". Second, on each of these parts, LTR was regressed along the perceived performance on the individual aspect of hospital services. If either low-negative or extreme-negative performance was significant in predicting LTR, while neither part of the positive domains could influence LTR, said aspect of hospital service belonged to Type I attributes. If either part of the positive domains was significant in predicting LTR, while neither part of the negative domains could influence LTR, said attribute belonged to Type II. It was also possible to find some attributes on which both positive and negative performances could influence LTR. These attributes belonged to Type III. To assess nonlinearity (increasing/diminishing sensitivity), the regression coefficients on low versus extreme levels of perceived performance were compared by using Z-Test. Finally, for each attribute, the curves representing the relationship between LTR and attribute-level performance were delineated in both the positive and negative domains.

Major Findings

Spiritual Care was established as a Type II attribute; negative performance did not have a significant impact on LTR, but positive performance could significantly enhance LTR. Z-test also indicated an increasing rate of improvements of LTR as the Spiritual Care performance approaches "perfect". The other four aspects of hospital care are regarded as Type III attributes, since both the positive and negative domains of perceived performances on these attributes could have a significant impact on LTR. However, Type III attributes did not relate with LTR in an S-shaped value function. For "Mutual Communication" and "Compassionate Care", LTR was particularly sensitive to extremely negative performance and exhibited decreasing sensitivity towards the extreme upper end of positive domains. For "Procedure Efficiency", LTR also demonstrated particular sensitivity towards extremely negative performance, while maintaining a linear relationship with perceived performance on its positive domain. For "Reputation", LTR indicated decreasing sensitivity towards extreme values within the negative domain, but had a linear relationship with attribute-level

performance on the positive domain. Finally, no care aspect was identified as a Type I attribute.

Based on these research findings, we advocate that for hospitals that wish to advance from "good" to "great", the priorities of service improvement programs should target levels of "Spiritual Care", since continuous improvements on this attribute will bring increasing marginal returns of LTR.

The “Right” Consumers for the Best Concepts: A Methodology for Identifying Emergent Consumers for New Product Development

Donna Hoffman, University of California, Riverside, USA

Praveen Kopalle, Dartmouth College, USA

Thomas Novak, University of California, Riverside, USA¹

EXTENDED ABSTRACT

Consumer firms are generally interested in learning which consumers might be the “right” ones they might use to further develop product concepts and improve their chances for success in the marketplace. Which consumers are the most appropriate to engage in the product development process is important because while new product development is a major activity of firms (Chandy and Tellis 1998), most of the 25,000 products introduced in the United States each year fail (Goldenberg, Lehmann, and Mazursky 2001). While much research has emphasized improving current new product concept techniques (e.g. Dahan and Hauser 2002; Dahl and Moreau 2002; Green, Krieger, and Vavra 1997), except for the lead user approach (von Hippel 1986), little work has focused on *which* consumers to use in the new product development process, particularly in the consumer goods industry.

We propose such a methodology to identify these “right” consumers. We argue that the right consumers possess what we call an “emergent nature,” i.e., the ability to process information in a synergistically experiential and rational thinking style, and exhibit a unique set of personality traits such that interactions among them in a new product development context will produce a product that mainstream consumers would find more appealing and useful relative to one that is developed by mainstream or even innovative consumers. We draw on information processing theory to develop the emergent nature construct and test our hypotheses in four studies.

A considerable body of research in dual-processing theory has differentiated among two types of information processing styles: experiential thinking style and rational thinking style (e.g. Epstein 1994; Pacini & Epstein 1999; Slovic 1996; Smith and DeCoster 2000) and substantiated the existence of individual differences in these two thinking styles (Epstein, Pancini, Denes-Raj, and Heier 1996; Pancini and Epstein 1999; Norris and Epstein 2003a, 2003b). Rational thinking style involves goal-directed, active, logical processing, and permits consumers to make optimal judgments about the utility of adopting a particular product innovation. Experiential thinking style, on the other hand, involves holistic, emotional, associative processing. Immediate experience is critical for experiential thinking, while logic and evidence are critical for rational thinking. The two thinking styles are not mutually exclusive processing styles; empirically they tend to have a very small positive correlation. Epstein and his colleagues have shown that these two processing styles reliably relate to a variety of psychological constructs (e.g. Pacini & Epstein 1999), with rational thinking style appearing to be adaptive for good judgment in specific decision-making situations, and an experiential style adaptive for interactions and creative pursuits.

Novak and Hoffman (2007) suggest that some tasks “might demonstrate *synergistic* effects” in which *both* experiential and rational situation-specific thinking style might correlate positively with performance. We propose that consumers with an emergent

nature are high in both experiential and rational thinking style and are able to use the two thinking styles in a synergistic manner. That is, we argue that *emergent nature is defined largely by the complementary interaction between the experiential and rational thinking styles*.

We propose that emergent consumers, owing to the synergies among their thinking styles, are able to engage successfully in both idea generation to enhance the original concept and logical analysis to refine and develop the concept further. In other words, emergent consumers are able to synergistically apply intuition and judgment to improve product concepts. Consumers with a high emergent nature develop an intuitive, almost “instinctive” understanding, i.e., visualizing the latent uses of a new product, through a sequence of small scale, affective, and associative perceptions. They are able to generate these ideas focused on the future because they possess a high degree of experiential processing ability. The experiential system generates the “gut feelings” underlying the intuitive understanding of the potential usefulness of a new product concept. Following this automatic, associative stage, emergent consumers, owing to their high degree of rational processing ability, then employ a rational thinking style in a conscious, logical and analytic effort to evaluate and refine the concept. In our conceptualization, the thinking styles work together in a complementary and iterative fashion, where a rational effort to analyze a product concept may activate further implicit, experiential associations about that concept, followed by another round of rational analysis, and so on. The essence of emergent nature is that consumers so possessed are able to inform their experiential impressions and associations with rational evaluation and judgment and vice versa.

The results from Study 1, a comprehensive calibration and validation phase involving scale development and construct measurement, provide strong support for the idea that emergent nature is a useful construct in the product development context. We have developed a highly reliable and valid scale to measure emergent nature in consumers and showed that the emergent nature construct is empirically distinct from other product development constructs such as lead user status, as well as dispositional innovativeness (Steenkamp and Gielens 2003).

In study 2, five mutually exclusive groups of consumers, including those high on emergent nature, lead user status, and dispositional innovativeness, develop a new product concept using an online bulletin board methodology, and in studies 3 and 4, those concepts are market tested demonstrating that consumers high on emergent nature can develop product concepts that are perceived by typical consumers as significantly better than concepts developed by groups high on domain-specific lead user status or dispositional innovativeness.

The strong showing of the concept developed by the high lead user group reinforces research that argues that lead users represent a good segment for developing radical new product concepts (von Hippel 1986). It also provides strong face validity to our results. We also note that we have developed a highly reliable and valid scale to measure domain-specific lead user status in a consumer context and marketing researchers may also find value in this scale.

Although work remains to be done, the idea of identifying and using emergent consumers in the development of consumer prod-

Effects of Lower and Higher Quality Brand Versions on Brand Evaluation: An Opponent-Process Model Plus Differential Brand-Version Weighting

Timothy B. Heath, Miami University, USA
Devon DelVecchio, Miami University, USA
Michael S. McCarthy, Miami University, USA
Subimal Chatterjee, Binghamton University, USA

EXTENDED ABSTRACT

Despite threats of image dilution, sellers commonly extend brand names to lower quality (*Charmin Basic*, *Levi Strauss Signature*, *BMW 1-Series*, etc.). To assess potential outcomes of such strategies as well as underlying processes, this study tests the effects on overall brand evaluation of middle-quality brands also offering versions of either lower or higher quality.

Experiments 1 and 2

An exploratory choice experiment comparing control conditions within two product classes (target brands offering a single middle-quality product) with experimental conditions (target brands also offering a lower-quality or higher-quality version) found no effect of offering lower-quality versions. However, offering a higher-quality version bolstered choice of the middle-quality offering in one of the two product classes tested. A small follow-up experiment extended this by having participants rate the brands on various perceptual dimensions. Consistent with the choice results, offering higher quality improved perceptions of brand knowledge and perceived marketplace respect, whereas lower-quality versions failed to have an effect.

These opening experiments implicate opponent processes in the context of lower-quality versions. Whereas quality-association effects should be negative due to brand associations with lower quality, variety effects should be positive because additional offerings signal greater knowledge of production processes (expertise), increased ability to produce and market a range of products, greater sensitivity to diverse consumer tastes, etc. These potential positive effects may then temper the negative effects of brands offering lower-quality versions (although both effects should be positive in the case of higher-quality versions). Experiment 3 was then conducted to replicate the brand-quality asymmetry with better measures of underlying processes.

Experiment 3

Methodological Overview. Two-hundred-forty-eight upper-classman at a large U.S. university were randomly assigned to conditions. A 7 (brand-quality levels: control plus six experimental conditions) by 2 (product-class: pasta sauce, portable CD players) by 2 (name: *Formaggio's* or *Giovanni's* pasta sauce, *Acoustix* or *Earshot* CD players) between-subjects design was used. In addition to the control condition that included only the flagship product (e.g., *Giovanni's* pasta sauce), the six experimental conditions added (1) a brand version one level up in quality (*Giovanni's Tuscano*), (2) one two levels up in quality, (3) versions at both one and two levels up in quality, (4) a brand version one level down in quality (*Giovanni's Basiqué*), (5) one two levels down in quality, and (6) versions at both one and two levels down in quality.

Participants imagined living abroad where they were venturing into an early shopping experience there. They viewed a table of brands listed by brand name, price, and average quality rating ostensibly from a survey of the retailer's customers, and then rated the target brand on three items per each of the following: brand attitude, prestige, innovativeness, and ability.

Results and Discussion. Experiment 3 replicated the brand-quality asymmetry. Whereas higher-quality versions significantly improved brand attitudes as well as perceived brand prestige, innovativeness, and ability, lower-quality versions had (1) null effects on brand attitude, (2) smaller negative effects on perceived brand prestige, (3) smaller positive effects on perceived brand innovativeness, and (4) null effects on perceived brand ability.

Consistent with the opponent-process model, lower-quality versions reduced perceived brand prestige but increased perceived brand innovativeness. The opponent-process model was also supported by the fact that statistically controlling for perceived innovativeness eliminated the asymmetric effects of higher-quality and lower-quality versions on brand attitude

Experiment 4

Although the prior experiments implicate a robust brand-quality asymmetry, Experiment 4 proposes and tests a process in addition to opponent processes: Consumers may "discount" or under-weight lower-quality versions when judging brands. Even if a flagship brand adds lower-quality versions, the brand continues to offer the same quality offerings as before, thereby suggesting no change in the brand's ability to design, produce, and market quality products, and no change in the brand's commitment to offering quality products. However, when brands offer higher-quality versions, these versions signal the greater skill necessary to produce and market such products, as well as an organizational commitment to offering higher-quality products.

Method. Experiment 4 replicated Experiment 3's procedures using only a single additional higher-quality or lower-quality version to simplify. To enhance generalizability, Experiment 4 used different product classes (restaurants and beers) plus both real and fictitious brands (*Metro* was the new (fictitious) target brand in both product categories, and real target brands were *Ruby Tuesday* in restaurants and *Fosters* in beers). Experiment 4 supplemented Experiment 3's measures with questions assessing how much weight participants in experimental conditions accorded the flagship brand version when evaluating brand liking, prestige, expertise, and innovativeness (constant-sum to 100).

Results and Discussion. The brand-quality asymmetry again arose across multiple measures as well as within both real and fictitious brands (although effects were weaker within real brands, they remained statistically significant). Unlike Experiment 3, however, none of the perceptual measures could statistically account for the asymmetry in brand attitudes. Nonetheless, consistent with an opponent-process account, lower-quality versions reduced perceived brand prestige significantly. Whereas higher-quality versions consistently improved brand perception and evaluation, lower-quality versions failed to change brand attitudes, perceived brand innovativeness, or perceived brand expertise.

Regardless of the dimension being judged, consumers reported giving greater weight to higher-quality versions than to lower-quality versions. Higher-quality versions were also weighted as much or more than flagship versions, whereas lower-quality versions were consistently rated less than flagship versions. It

appears that consumers do, in fact, consider lower-quality versions less relevant to brand evaluation than flagship and higher-quality versions.

Discussion

Four experiments find that higher-quality brand versions boost brand image and evaluation more than lower-quality brand versions damage them. This brand-quality asymmetry emerges in part from lower-quality versions stimulating both negative and positive effects that then partially cancel out one another, and in part from consumers seeing lower-quality versions as less relevant to brand evaluation than higher-quality brand versions. It appears that offering higher-quality versions has multiple positive effects, whereas offering lower-quality versions has a mix of positive, negative, and null effects that fail to threaten brand image as much as negative quality-associations alone might otherwise suggest.

Are Well-Known Brands Held to a Higher Standard of Performance: The Moderating Influence of Pre vs. Post Purchase of the Product

M. Deniz Dalman, Binghamton University, USA
Kalpesh K. Desai, Binghamton University, USA
Manoj K. Agarwal, Binghamton University, USA

EXTENDED ABSTRACT

Prior research in branding has clearly demonstrated the multitude of benefits (e.g., inclusion in consideration sets, greater advertising efficiency) that well-known brands (or WKB) enjoy over less known brands (or LKB) (Feinberg et. al. 1992; Johnson et. al. 2006; Park and Srinivasan 1994). With some exceptions, most such research focus either on the pre- or post-purchase stage and that too for either WKB or LKB. In the current research, we fill this important gap in the literature by comparing the relative evaluations of WKB and LKB in both pre- vs. post-purchase stages. Similarly, the current research fills an important gap in the satisfaction literature (Caruana, Money, and Berthon 2000; Oliver and Swan 1989) by highlighting the moderating impact of brand equity on the influence of deviation of objective performance of a brand relative to its claimed performance on consumer satisfaction.

Consider a consumer choosing between a laptop manufactured by SONY, a WKB, and AVERATEC, a LKB. SONY is likely to be priced higher compared to AVERATEC due to its strong brand equity. Each brand makes specific claims about the battery life that its product will provide. Brands often claim a specific level of performance on an objective attribute (e.g., battery life and laptops). However, because of manufacturing and usage variability, consumers will experience uncertainty about the actual performance relative to the claimed level. Thus, the actual performance delivered by a brand could be higher or lower than the claimed level. We argue that at the pre-purchase stage, consumers will entertain lower level of uncertainty about the WKB's (vs. LKB's) performance relative to the claim because of its strong brand equity. This will result in WKB having a competitive advantage in the pre-purchase stage in terms of preference and buying likelihood even if both LKB and WKB claimed the same level of performance on an objective attribute. However, based on the literature in standards of judgment and stereotyping (Biernat, Manis, and Nelson 1991; Linville and Jones 1980) we posit that the LKB will have an advantage in the post-purchase stage (i.e., after using the product) because WKB will be held to a higher standard of performance. More specifically, if both brands exceed their claims, LKB will be rewarded more than WKB. If both brands fail to meet their claims, WKB will be punished more than LKB.

Results of the first study employing two category replicates of tires and online web service confirm our hypotheses in the pre-purchase and post-purchase stages and confirm the uncertainty of performance underlying the evaluations in the pre-purchase stage. In Study 2, we establish the robustness of the effects by replicating the Study 1 results for both categories. The regression analyses confirmed our posited process underlying the evaluations in post-purchase stage. Specifically, it showed that it is the deviation from claim that influences the satisfaction and not the deviation from participant's expectation formed during the pre-purchase stage. The results show that WKB is held to a higher standard than LKB for the same deviated level of performance—if both brands exceed their claims, LKB is evaluated more favorably than WKB. However, when both brands fail to meet their claims, WKB is punished more than LKB.

Along with important managerial implications, this research has important theoretical implications for both the satisfaction and brand equity literature. Regarding the former, we show that, contrary to the satisfaction literature, it is not the deviation from the expectation (which we controlled for in this study) that influences the levels of satisfaction for a given performance but it is the different evaluations of the same deviated performance of brands varying in their brand equities. As for brand equity literature, we show that while WKB have advantages over LKB in the pre-purchase stage, WKB are held to a higher standard and thus they have less room for error in the post-purchase stage. Managers of such brands should carefully manage the expectations of consumers in the post-purchase stage. LKB should take full advantage of being held to a lower standard of performance in the post-purchase stage. However, managers of such brands need to be more conservative when they are deciding the claimed level of performance to communicate to consumers and should work to reduce the perceived uncertainty in performance of such claimed performance in the pre-purchase stage.

Self-Regulation and Consumer Ethnicity: Resisting Undesirable Eating Temptations

David J. Moore, University of Michigan, USA

ABSTRACT

Intense emotional distress is capable of depleting one's capacity for self-control, thus increasing one's vulnerability to yielding to an undesirable eating temptation (Baumeister and Heatherton 1996). This study found that Caucasian women, compared to their African American counterparts, engage in more weight reduction activities, but nevertheless, experience greater emotional concern about gaining weight, and this elevated level of emotion helped to undermine self-regulation. Furthermore, African American women displayed greater transcendence—a more positive attitude toward disappointment in achieving immediate weight reduction goals, and this, in turn, boosted self-regulation. Implications for marketing and public policy are also discussed.

Pledges and Competitions as Health Interventions

Sekar Raju, Iowa State University, USA
Priyali Rajagopal, Southern Methodist University, USA

EXTENDED ABSTRACT

Public policy makers have attempted to influence the development and prevalence of healthy eating habits through various recommendations with respect to food content. While these efforts have contributed to increased awareness and knowledge of what constitutes healthy eating, research has documented that just this increased knowledge may be insufficient to motivate people to eat in healthier ways (e.g. CDC 1996). Further, little is known about how children of different age groups react to such interventions. Children and young adults are important groups to address in the context of healthy eating because past research has shown that these groups fail to meet the recommended daily consumption levels of fruit and vegetables in the United States and because eating patterns that are established in childhood tend to persist throughout life, indicating the importance of starting healthy eating habits early (Lien, Lytle, and Klepp 2001). Our research aims at understanding two different public policy interventions (pledges and competitions) that can be used by marketers and public policy makers to increase healthy eating attitudes and behaviors amongst school and college age students. We report the results of two empirical studies conducted amongst school children and college students.

Study 1

Objective: To compare the relative effects of pledges, and competitions on healthy eating choices amongst school children and understand how the age of the child plays a role in the effectiveness of the intervention.

Study background and design: A total of approximately 31,000 public school students in grades one to eight participated in this longitudinal field study conducted over a six month period. Schools participating in this study were provided an enhanced lunch menu consisting of an additional serving of a fruit and a vegetable during the study period.

Method: Schools were randomly assigned to one of three study conditions-control, pledge, or competition condition. The second independent variable was age, a measured variable. Grades 1 through 3 were coded to represent younger children and grades 4 to 8 were coded to represent older children. Incentives were offered to all the students in the study and were small in nature (e.g. pencils). The baseline condition participants received only the incentive instructions. The pledge condition participants were told about the incentives and asked to make a personal pledge to eat healthier by signing their name on a special poster prepared for the occasion and placed in the classroom for the duration of the study. The competition condition participants were told about the incentives and were also told that they were in a friendly healthy eating competition with students from other participating schools.

Procedure

Six weeks prior to the start of the main study, baseline consumption of fruits and vegetables were recorded. For a one week period, the same enhanced menu that was used during the main study was provided to students in the participating schools (BE). The following week, the enhanced menu was withdrawn but student's fruits and vegetable consumption with the regular menu was recorded (BR). These two baseline measures allowed us to account for any variation in novelty and availability effects. The main study was conducted over six consecutive weeks and the

consumption of fruits and vegetables was recorded for each day of the week for each student in each school. At the end of the sixth week, all students were told that the healthy eating program had ended. In the week immediately following the main study, the enhanced menu was again provided and consumption recorded to track immediate follow-up behavior (IF). Finally, ten weeks after the completion of the main study, long-term follow-up behavior (DF) was tracked by offering the enhanced fruit and vegetables menu for a week and recording the consumption. Therefore, the study was designed as a 3 (study condition: control, pledge, or competition) x 2 (age: younger or older children) x 8 (study week: W1-W6) mixed design. Study condition and age were between-subject variables and study week was a within-subject variable.

The data was collected at the individual level, but due to privacy concerns, aggregated to the homeroom level.

Results

A repeated measures ANOVA conducted on the two baseline measures BE and BR revealed no significant differences between the measures ($M_{BE}=.45$, $M_{BR}=.45$, $F(1, 673)=.46$, $p>.10$).

The data was subjected to a two-way ANCOVA with experimental condition and grade as the between-subject variables, study week as the within-subject variable, change in consumption of fruits and vegetables over the baseline period as the dependent variable, and enrollment size as the covariate. The results revealed a significant three-way interaction between study condition, age, and study week ($F(11.7, 3902)=2.83$, $p<.001$; $\chi^2=.01$). To understand the nature of the three-way interaction better, the data were analyzed separately for the younger and older children.

Younger children

The results of a one-way ANOVA revealed that the increase in the proportion of competition condition participants taking fruits and vegetables was greater than pledge condition participants for younger children. The data relating to the follow-up period revealed that the increase in the proportion of students taking fruits and vegetables continued to be significantly greater for the competition condition participants compared to the pledge or control conditions. However, the difference between the pledge and control conditions became non-significant. These results suggest that in the follow-up period (both immediate and delayed), the competition condition participants maintained their consumption of fruits and vegetables, but the pledge condition participants dropped to a level not different from the control condition participants.

Older children

For the duration of the six study weeks, there was a significantly larger increase in the proportion of pledge condition participants taking fruits and vegetables compared to the competition condition participants, except in weeks three and four where the results were not significant. Similarly, the difference between the pledge and control condition participants was also significantly different for all the study weeks. Taken together, these results suggest that the increase in the proportion of pledge condition participants taking fruits and vegetables was greater than competition condition participants for older children. In the immediate and delayed follow-up period, the difference between the pledge and competition conditions became insignificant indicating that the

effects of the intervention did not extend beyond the intervention period.

Our results hold important implications for health educators, marketers and public policy makers since they suggest that different interventions may be appropriate for children of different ages.

The Effect of Past Usage Pattern on Preference for Current Tariff: Can I Control Myself?

Young-Soo Kim, KAIST Business School, South Korea

Do-Hyung Park, LG Electronics Inc., South Korea

EXTENDED ABSTRACT

In spite of the importance of past usage patterns on tariff choice, in our knowledge, there are few studies investigating the effect of past usage patterns on tariff choice. The purpose of this article is to examine the relationship between past usage patterns and current tariff choice by using self-control theory.

Past usage patterns of consumers may range from being stable to fluctuating. Depending on the past usage pattern which tariff, pay-per-use or flat-rate tariff, will be preferred? We try to explain consumers' tariff choice by using self-control and perceived risk of tariff choice failure. Basically, when the pattern is stable a person tends to choose pay-per-use tariff if their usage is less than the minimum beneficial rate for flat-rate tariff or choose flat-rate tariff if their usage is excessive in order to maximize economic utility. However, a person can not be sure of next usage of certain content if variance of the past usage pattern is high, which results in that he/she is concerned about self-control for future usage as well.

Our study focuses on the case in that the past usage pattern is fluctuating. This research proposes the two different mechanisms depending on the self-controllability when the past pattern is fluctuating. Specifically, if consumers think themselves to have the high level of self-controllability, they choose the tariff that fits the norms of each content usage. Otherwise, they choose the tariff based on the risk related to the failure of tariff choice.

According to prior research on self-control, hedonic contents make people feel guiltier as the usage volume increases (e.g., Kivetz and Simonson 2002; Prelec and Herrnstein 1991; Thaler 1980). Therefore, in general, people strive to decrease the usage volume of hedonic contents as possible and increase the usage volume of utilitarian contents (e.g., Ainslie 1975; Hoch and Loewenstein 1991; Trope and Fishbach 2000; Wertenbroch 1998). Thus, if people perceive that they can control their future usage, utilitarian contents users are more likely to choose flat-rate tariff to increase the usage volume. On the other hand, hedonic contents users are more likely to choose pay-per-use tariff in order to decrease the usage of hedonic contents.

The decrease in the self-controllability of future usage leads him/her to focus on a future tariff choice failure which is either the case of that he/she chose pay-per-use tariff but used more than their estimated usage rate or the case that he/she chose flat-rate tariff but used less than their estimated usage rate. In the case of the hedonic content, if consumers who chose pay-per-use tariff are unsuccessful in the choice, they can not justify the added costs easily. In contrast, if consumers who chose flat-rate tariff experience the tariff choice failure, they can justify the unused usage more easily. Finally, it is predicted that consumers exposed to the fluctuated usage of hedonic contents are more likely to prefer flat-rate tariff to pay-per-use tariff. In the case of the utilitarian content, if consumers who chose flat-rate tariff are unsuccessful in the choice, they can not justify the unused usage easily. In contrast, if consumers who chose pay-per-use tariff experience the tariff choice failure, they can justify the added costs more easily.

Study 1 examined the effect of past usage patterns on preference for two tariff options and the moderating role of a content type. Participants were given the scenario in which they have been using an online web site providing online contents. Depending on the manipulation of content type, they were involved in the online site offering either hedonic or utilitarian contents. After, the table

showing the past pattern of each content usage was provided. The data of the table had twelve month usage in terms of time. After exposed to the stimuli, participants were asked to evaluate preference for the two different tariffs. Study 1 showed that when the past usage pattern had high variance, preference for tariffs is different depending on the content type. Specifically, hedonic content users preferred flat-rate tariff, while utilitarian content users preferred pay-per-use tariff.

Study 2 was initiated in order to support our theory more strongly by conducting the experiment to manipulate the level of self-controllability. We hypothesize that utilitarian contents users are more likely to prefer flat-rate tariff than the hedonic contents users do when they have the high level of self-controllability. On the other hand, hedonic contents users are more likely to prefer flat-rate tariff than the utilitarian content users do when they have low level of self-controllability. In study 2, the same pattern of past usage with the target usage of 30 hours was provided across all conditions, but the average usage was different from 25 hours per month to 35 hours per month. We intended for participants in the utilitarian content condition to experience failure in self-control given the past usage pattern with 25 average hours per month whereas success in self-control given the past usage pattern with 35 average hours per month. As hypothesized, in the case of the high level of self-controllability condition, participants exposed to the utilitarian content reported a higher score of preference for flat-rate tariff than those exposed to the hedonic contents. As for the case of the low level of self-controllability condition, participants exposed to the hedonic contents reported a higher score of preference for flat-rate tariff than those exposed to the utilitarian contents

Contributions made by the present research are twofold. First, we examined how consumers' preference between the two tariffs changes when the overall past usage pattern has high variance. Second, we proposed the underlying mechanism to explain consumers' tariff choice by using perceived risk and self-control. In study2, we showed that if people perceive that they have control over their future usage, they choose the tariff that fits the norms of each content usage even when the past usage pattern is highly fluctuating. On the other hand, if people perceive that they have less control over their future usage, they choose the tariff based on the risk related to the failure of tariff choice.

The Social Construction of Consumer Needs: A Case Analysis of the “Healing Boom” in Japan

Takeshi Matsui, Hitotsubashi University, Japan and Princeton University, USA

EXTENDED ABSTRACT

This paper examines the development process of the healing boom, the largest consumer culture in Japan at the turn of the century, which developed consumers’ collective sense of consumption environments and oriented their experience and lives (Kozinets 2001). Since the late 1990s, many firms in different industries launched a large number of “healing” products and services; such a category had not existed until this boom. The more the boom developed, the wider the category of healing products and services expanded. Finally, hair dryers that generate negative ions, talking stuffed dolls, tourist resorts, spa, and compilation CDs of easy listening were advertised as “healing” products or services.

Due to the massive launch of “healing” products and services, the meaning of healing was drastically changed. According to Kojien 5th edition (1998), the most authoritative Japanese dictionary, *Iyasu* (heal) means to cure somebody’s disease or injury, satisfy hunger, or mitigate emotional pain. *Gendai Yōgo no Kiso Chishiki* (Encyclopedia of Contemporary Words) 2003 Edition explains that *Iyashi Sijō* (healing market) is a market of goods and services that are useful for creating psychological security, and nowadays, various kinds of consumer goods such as books, music, paintings, movies, massage, drink, food, and clothing, which help us relax, fall under this rubric.

This study argues that this linguistic change is evidence of the cognitive institutionalization of healing, which means that healing is accepted as an objective reality among the members of society (Berger and Luckmann 1966). Neo-institutional sociology has been interested in this cognitive process (DiMaggio 1997; DiMaggio and Powell 1983; Meyer and Rowan 1977; Powell and DiMaggio 1991; Zucker 1983). Agents such as firms and consumers take some actions not because of rules or obligations forced by their society but because such an action is taken for granted as the way we do these things (Scott 2008).

To analyze the interplay among corporate behavior, media discourse, and consumer needs, this study adopts two concepts from neo-institutional sociology: firms’ mimetic isomorphism and the media’s theorization. Mimetic isomorphism is the mechanism that forces organizations to imitate other organizations’ behavior that they perceive as successful when the relationship between means and ends is uncertain (DiMaggio and Powell 1983). Successful products or services are now easily imitated by their competitors because marketers’ ceaseless effort to offer hit products or services always faces uncertainty about the relationship between means (the 4Ps) and ends (sales and/or profit). The imitative process in the healing boom can be considered as a typical instance of mimetic isomorphism. Theorization is the self-conscious development and specification of abstract categories and the formulation of patterned relationships such as chains of cause and effect (Strang and Meyer 1993). *Nikkei* newspapers, the counterpart of *Wall Street Journal*, theorized that people bought healing products because they hoped to eliminate their stress. This causal explanation triggered imitative behavior by firms.

This study includes three content analyses. First, in order to understand firms’ mimetic isomorphism, all healing products and services launched were listed by investigating 5,371 articles of *Nikkei* newspapers published from 1982 to 2007. Second, in order to understand the media’s theorization, a qualitative content analysis on the contents of *Nikkei* articles was conducted. Third, to

understand the views of ordinary people on healing (cognitive institutionalization), the study analyzed the environment of ideas to which ordinary magazine readers were exposed. A content analysis on 8,038 article titles from 466 types of magazines published from 1984 to 2007 was carried out. Content analysis was adopted because it is a useful research tool to understand consumption value through time (Tse, Belk, and Zhou 1989).

Three cognitive institutionalization processes are found. First, it is now taken for granted that healthy people have the need to be healed. Second, it is also considered natural that these needs can be satisfied by purchasing and using healing products or services. Third, the new expression *Iyashi-kei* (healing kind) began to be used frequently for describing certain kinds of laypersons who just help us relax and are not religious persons or healers. Most celebrities considered as *Iyashi-kei* are young actresses, which endorses the implicit shared views on the gendered division of labor: women heal men. In summary, consumers’ needs for healing are socially constructed by media discourse and the imitative behavior of firms.

Why Do People Shop Second-Hand? A Second-Hand Shoppers' Motivation Scale in a French Context

Dominique Roux, Universite Paris 12- IRG, France
Denis Guiot, Universite Paris Dauphine (DRM-DMSP), France

EXTENDED ABSTRACT

Despite the marked interest in second-hand markets and thrift shopping (Bardhi and Arnould 2005; Belk, Sherry, and Wallendorf 1988; Sherry 1990; Soiffer and Hermann 1987), no measurement tool has been developed to capture the range of motivations that drive consumers to buy second-hand. In particular, little can be predicted either in term of behavior related to second-hand buying, or of the consequences that stem from it. This study thus offers a measure of second-hand shoppers' motivations, the types of products they bought and of channels they frequent as well as with other economic or ludic practices such as recycling and browsing.

We first show that second-hand commerce has ancient roots in France and is experiencing comparable growth to Anglo-Saxon contexts: proliferation of garage sales, expansion of specialized second-hand stores, and growing use of the Internet. Then, in line with previous research (Bauhain-Roux and Guiot 2001), we assume that purchasing second-hand consists both of not buying new and of resorting to forms of supply that have their own distinctive characteristics. As Westbrook and Black' (1985) contribution on shopping, we assume that motivations toward second-hand buying conform to this combination of reasons that encourage consumers to look for original and less expensive products and to prefer the informal and recreational world of certain places of exchange. The concept of motivation thus appears to be a wide-ranging tool for studying second-hand buying, both in regard to products and distribution channels.

Following Churchill's (1979) paradigm revised by Rossiter (2002), we develop a measure of motivations toward second-hand buying within a French socio-cultural context. We define motivations for second-hand buying as the psychological and material impulses that orient individuals toward second-hand products and/or channels. As previous research was carried out in Anglo-Saxon contexts and only within specific channels, a preliminary qualitative study was deemed necessary to explore the motivations of French purchasers. We identified six main areas of motivation, broken down into 15 sub-dimensions and 77 items: an economic dimension (I) is reflected by four factors: the search for a fair price (1), bargain hunting (2), the wish to pay less (3), and the allocative aspect of price (4); a recreational dimension appears to be linked both to the second-hand product offering (II)—the originality of the products (5), nostalgia for items from the past (6), self-expression (7), and congruence sought with the items purchased (8)—and also to the characteristics of certain shopping outlets (III) such as social contact (9), stimulation (10), and treasure hunting (11); a power motive (IV) is also revealed by the way purchasers control the power of sellers by means of bargaining (12), and through a wish to escape from conventional channels (13); ethical and ecological motives (V) show concerns of certain purchasers in regard to recycling and avoidance of waste (14); and finally, "anti-ostentation" motives (VI) for some respondents reveal the conscious and voluntary rejection of everything associated with fashion and mass consumption (15).

Two data collections gathered from 708 second-hand buyers enabled us successively to calibrate and replicate the scale. Scale purification was achieved through an initial data collection (224 Parisians), and exploratory and confirmatory factor analysis. We

examined the hierarchical structure of the scale, its reliability, and its convergent and discriminant validity. The findings reveal a hierarchical structure characterized by two second-order factors, one corresponding to economic motives—with 3 subfactors: "fair price", "ethics and ecology" and "distance from the system"—and the other to recreational motives—with 4 subfactors: "treasure hunting", "originality", "social contact" and "nostalgia". An alternative first-order model comprising 7 correlated sub-factors was tested and rejected in favor of the hierarchical structure hypothesis.

We successfully replicated the hierarchical model on a validation sample of 484 Parisians with the same survey conditions. A measurement model using the 7 dimensions and 21 items remaining after the purification stage provides a satisfactory goodness-of-fit to the data. Reliability was estimated through Jöreskog's (1971) indices (>.70). Observation of factor contributions (all significant and >.669), application of the Fornell and Larcker (1981) procedure, and comparison of nested structural models indicate that the convergent and discriminant validity conditions are satisfactorily met. The nomological and predictive validities were assessed by testing the relations between second-hand shoppers' motivations and the types of products bought and channels frequented, as well as behaviors related to economic and recreational motives such as recycling (Leonard-Barton 1981) and browsing (Lombart 2004). Three types of effect corresponding to the different dimensions of the construct were assumed:

- H1*: Economic motives for second-hand buying are positively linked to recycling behaviors, measured by items included in the voluntary simplicity scale (Leonard-Barton 1981)
- H2*: Recreational motives for second-hand buying are positively linked to browsing behaviors, (defined as wandering around for pleasure and without any specific intention of buying, Lombart 2004).
- H3*: Motivations for buying second-hand are positively linked to the frequency of buying second-hand products and to the number of second-hand product channels visited.

The results confirm the stability of the causal model with significant structural coefficients enabling all the hypotheses to be validated. Additionally, the capacity of the scale to explain the choice of products bought and the second-hand channels frequented was tested by logistic regression, while controlling the effects of age, income and educational level. 10 of the 32 product categories and half the 11 channels proposed show correct classification percentages by logistic regression. Finally, the scale successfully captures a variety of motives that give rise to a specific form of purchasing. It incorporates motivations toward products and channels and no longer relies on contextualized approaches. It also lends itself to different uses involving a total score corresponding to all dimensions of the aggregated construct, as well as disaggregated scores. It can further be used to explain variables linked either to the economic or recreational dimensions such as preferences toward private labels, sensitivity to brands or perceived market authenticity. New avenues of research are also envisaged on possible links between the second-hand shopping motivations and

emerging phenomena such as sustainable or socially responsible consumption, dissatisfaction with the market system, and consumer resistance.

The Meanings of 'Kod-sa-na-faeng'- Young Adults' Experiences of Television Product Placement in the UK and Thailand

Amy Rungpaka Tiwaskul, University of Surrey, UK
Chris Hackley, University of London, UK

EXTENDED ABSTRACT

"... when I see they use it in *Sex and the City*, I feel like if I use it I can be like Jessica Parker ... Jessica guarantees it."
(Female, Thai, 24)

Young adults around the world have a commonality in their experience of brands and marketing practices. Product placement has no direct translation in Thai, it is known as 'kod-sa-na-faeng' or 'implicit advertising'. This is partly because product placement and sponsorship are not separate categories on Thai television but aspects of the same practice. Nevertheless, consumers in Thailand, as well as those in the UK, are well aware of the various promotional techniques deployed in their television viewing. Television offers a powerful medium for the promotion of brands. Consumers often have an intimate engagement with their favourite television shows. Television is a medium conducted in a localised vernacular. In Thailand and the UK even where syndicated foreign shows or advertisements are broadcast they are framed by localised announcements and locally produced shows. TV is often engaged with on a daily basis in domestic environments. It has the dual quality of both normalising and glamorising consumption practices. Brands are ubiquitous in television as they are in everyday life: studio directors need brands in order to populate storylines with familiar objects which connect with the viewers' own reality. Television is consequently an ideal vehicle for product placement, yet its role as a vehicle for consumer cultural meaning transfer (McCracken, 1988) and a resource for personal identity projects in an international context is still relatively under-researched.

Previous studies have begun to conceptualise some of the dynamic characteristics of product placement in, for example, explorations of the influence on consumer attitudes towards the brand of the connection between plot and brand (Russell, 2002), character-product associations (Chang and Roth, 2000) and the alignment of consumer attitudes towards the placed brand with those of a character with whom viewers identify (Russell and Stern, 2006). However, most previous studies have been attitudinal and individual in orientation (e.g. Karrh 1994, 1995, 1998; Balasubramanian, 1991; Vollmers and Mizerski, 1994; Nelson, 2002; Gupta et al., 2000; Nebenzahl and Secunda, 1993). So far, more studies have focused on movies as a television as a product placement medium than television (exceptions include LaFerle and Edwards, 2006; Russell, and Puto, 1999; Russell et al, 2004; Tiwaskul et al., 2005) but thus far phenomenological approaches have been rare and non-US national contexts have seldom been explored in their consumer cultural context.

Attempts to define and categorise product placement practices suffer from the limitation that they do not take account of differences in regulation and practice in different countries. For example, Balasubramanian (1994), Gupta and Gould (1997), Ford (1993) and Baker and Crawford (1995) suggest that product placement is 'paid for' with cash or other considerations going to the studio, usually in the person of the producer or broadcaster. This ignores two issues: one is the fact that many brands appear in entertainment as content simply directors need them. Placements give a brand much-needed visibility and credibility regardless of whether payment was made and public relations agencies go to great lengths to bring about 'coincidental' placements. The second issue is that, in

the UK, product placement is common but brand owners are forbidden by current regulations from paying programme makers. Instead, they pay product placement agencies who use their contacts with studios to push their clients' brands into programmes as freely supplied scene props.

This paper describes research among consumers in two differing cultural contexts, the UK and Thailand. In each country the media infrastructure is mature with many domestic television shows being made. Each country has a vital consumer culture and lively interest in brands both domestic and non-domestic (although in Thailand consumer culture is concentrated in the major urban centers where buying power is highest). One important difference between them is that in Thailand television product placement is well-established and although there is media censorship there are relatively lax regulations governing placement practices. In contrast, in the UK under current regulations television programme makers are forbidden from receiving payment from brand owners for featuring their brands as scene props or in storylines. Nevertheless, this does happen legally under the 'free prop supply' system. It is widely assumed that UK regulations will soon change to allow paid-for placements. The UK thus has an immature and highly regulated television product placement environment while Thailand has a mature and relatively under-regulated one.

This paper draws on interviews and written narratives from a selective sample of UK-based and Thai-based television-viewing young adult consumers supplemented by interviews with leading practitioners. Taking an interpretive theoretical stance, the findings suggest that young adult consumers in both countries are similarly attuned to television product placement incidents: they seek them out, describe them vividly, and clearly enjoy their sophistication in discerning not only brands, both global and local, but also the marketing techniques by which brands are inserted into their entertainment. Consumers displayed a high degree of reflexive self-awareness in being aware of their subjective responses to brands placed in television shows and articulating the underlying motivations for their affective response. Specifically, they deployed their knowledge and awareness of brands in identity strategies. The paper develops these themes using direct quotes and then draws on the findings to develop and integrated discussion around international consumers' experience of television of product placement, identity, brand symbolism and the movement of consumer cultural meaning.

A Multivariate Model of Partitioned Country-of-Origin on Consumer Quality Perceptions

Md. Humayun Kabir Chowdhury, East West University, Bangladesh

EXTENDED ABSTRACT

A substantial body of literature has accumulated showing that consumers adjust their attitudes toward a product according to its country-of-origin (Chao 1993; Cordell 1992; Han 1989; Han and Terpstra 1988). This bias may be categorized as either "home country bias" or "foreign country bias". With "home country bias" consumers prefer products made in their own country to identical products made in foreign countries. "Foreign country bias" exists when differential differences are expressed for products made in different foreign countries (Schooler 1965; Wang and Lamb 1983).

Understanding consumers' opinion toward products from various countries can be useful in developing multinational strategic marketing policies. If country-of-origin is to be used as a competitive tool, managers must also understand the mechanism of country-of-origin on consumer quality perceptions. Research on evaluation of foreign products infers that the producing country affects consumers' judgments of product quality (Bilkey and Nes 1982; Hong and Wyer 1989). For example, a country's image regarding workmanship and technological advancement logically will be projected onto the features of products produced by that country. Product quality evaluation is conceptualized as the attitudes consumers hold towards their targeted products.

The main objective of this research was to examine the cognitive processes by which country-of-origin information influences consumer's evaluation of a product. In doing so, structural equation modeling approach has been used to test a hypothetical model containing relationships among psychological constructs including country associations, the evaluation of the product's functional characteristics and appearance and the quality perceptions with regard to the product. The second objective was to develop a better understanding of the country-of-origin effect by separately examining the effects of the country-of-design (COD), the country-of-assembly (COA), the country-of-parts (COP), and consumer brand image (CBI) of a product.

To study the psychological process by which the country-of-origin associations are integrated in the formation of related behavioral deliberation, a hypothetical structural model was developed. The model contained eight theoretical constructs. These constructs were considered to be latent psychological variables that cannot be measured directly and without error. Instead, each of them has to be measured indirectly through multiple indicators. The eight constructs of the hypothetical model may be grouped into the following three categories:

- Evaluation of the country-of-Origin associations;
- Evaluation of the product; and,
- Evaluation of the quality.

Therefore, current study dealt with eight constructs and their observed measures. The questionnaire contained multiple measures of all seven latent variables of the model. The selection of these indicators was based on an extensive literature review. All measures used in the present study had already been used and found to be valid and reliable indicators in one or more previous studies. The main sources used in this selection process were: Inch and McBride (1998), Parameswaran and Yaprak (1987), Bandyopadhyay and Banerjee (2002), Ahmed and d'Astous (1999), Han and Terpstra (1988). For all these directly observed variables, ratings were

obtained on a seven-point scale ranging from 7="Strongly Agree" to 1="Strongly Disagree".

Since COD, COA, COP and CBI deal with overall country and brand image, description and scales for each construct thus contained the same contents except the specific country name. For example, a description for COD such as "Japan has designed a television —" has been changed into—"China/Bangladesh has designed a television —". Similarly, the description for COA is—"China assembled the final product—" has been changed into—"Japan/Bangladesh assembled the final product—" . Finally, the description for COP is—"Major parts have been produced in Bangladesh" has been changed into—"Major parts have been produced in Japan/China".

The data were first tested for reliability using Cronbach's alpha to assess reliability. Internal consistency (reliability) values of the measurement items were assessed before entering into the structural analysis. Data were analyzed via structural equation models using Amos (Analysis of MOment Structures) 5.0.

The Maximum-Likelihood Method was selected as the method of model estimation. The fit of the structural model was estimated by various indices, and the results demonstrated good fit. For models with good fit, most empirical analyses suggest that the ratio of chi-square normalized to degree of freedom (χ^2/df) should not exceed 3.0 (Carmines and McIver 1981). In addition, the obtained goodness-of-fit (GFI) measure was 0.92 and the adjusted goodness-of-fit (AGFI) measure was 0.89, respectively, which are both higher than the suggested values. The other two indices of good fit—the normalized fit index (NFI) and the comparative fit index (CFI) are recommended to exceed 0.90. The results also meet these requirements. Finally, the discrepancies between the proposed model and population covariance matrix, as measured by the root mean square error of approximation (RMSEA), are in line with the suggested cutoff value of 0.08 for good fit (Byrne 1998).

The results of this study provide evidence that country associations can influence product responses. Moreover, when COD, COA, COP and CBI associations are available to consumers, these associations appear to affect product responses in different manners. The results raise the possibility that countries that already have positioned themselves around a reputation for technological innovation or other skills and abilities related to product development and manufacturing may expect consumers to transfer those associations to new products from the country.

Changing Mealtime Rituals: The Mediating Influence of the Television on Family Dynamics

David P. Chitakunye, Keele University, UK

Pauline Maclaran, Keele University, UK

EXTENDED ABSTRACT

Eating at home has always been regarded as a time when all family members come together from their diverse and separate activities to affirm their relatedness and love (Levy 1996). Yet traditional mealtimes have become more fragmented with members of a family often eating at different times to suit their own personal schedules (Warde 1997). Although food meanings, and the rituals and practices in which these are embedded, contribute to family identity and domestic life (Charles and Kerr 1988), our knowledge is still limited as to how these are changing, and how material objects, such as the television or computer games, are influencing these changes.

Whilst the family serves as a consuming, producing, distribution and socialising unit interacting with other elements of society (Price and Epp 2005), consumer researchers have devoted relatively little attention in understanding them. Extant research has investigated food consumption behaviour with particular focus on specific consumption events such as Thanksgiving Day (Wallendorf and Arnould 1991); Christmas (Hirschman and LaBarbera 1989); public eating venues (Fischer and Wayne 1999); food culture of particular societies or ethnic groups (Hetzel 1999); and consumer micro-cultures (Thompson and Troester 2002). Yet, apart from Hirschman et al. (2004), there has been a paucity of consumer research that examines the differing contexts of eating, and how these affect the meanings attached to food consumption. Importantly, in relation to this study, there is silence about the actual practices in regard to eating together as families (Murcott 1997).

Given this background, our present purpose is to explore how the television is mediating family mealtime relationships, and their concomitant rituals. In particular, we are interested in naturalistic everyday food consumption practices in the domestic context of consumption, rather than specific consumption events or food consumption in public places.

This study uses an interpretive research strategy. Stage 1 of the research was school-based and gathered data from school children aged between 13 and 17 through observation, semi-structured and in-depth interviews as well as visual diaries. Stage 2 was an observation during family mealtimes; we talked informally with family members. The research followed a theoretical sampling approach for recruiting informants, i.e. a sample that typifies the population, the theoretical category or the phenomenon to be studied and was chosen purposefully with consideration to representativeness (Mason, 2002; Silverman, 2000). In addition, online research was used to sensitise the researchers to the culturally resonant categories (Hirschman et al. 2004). In total the dataset so far consists of 13 personal interviews, 9 online interviews, 23 visual diaries, and mealtime observations with 3 families. The data analysis is following the principles for the analysis and interpretation of qualitative data as recommended by Spiggle (1994) and others (Strauss and Corbin, 1998; Arnould and Wallendorf, 1994), and continuing in an iterative fashion across offline and online environments.

Two overarching conceptual categories are used to organise our interpretation of the meanings of mealtime rituals, and how these are mediated by the television: (1) the formal environment for food consumptions; and, (2) the informal environment for food consumption. Our findings show that when eating in a formal environment, such as the dining room, the table is usually set in a specific way, making it easier to maintain a routinised seating order,

which may also be hierarchical, for example, with a father or mother at the head of the table. This formal configuration facilitates interactions between family members which take place on a face-to-face basis, with few external distractions. Appropriate eating and serving utensils (e.g. knives, forks, plates, dishes etc) will also be used. By contrast, the informal environment (usually a lounge or 'den') tends to be dominated by the television, with seating arrangements organised accordingly in order to ensure good viewing. In this environment it is not always convenient to use traditional eating or serving utensils and it thus encourages a more relaxed style of consumption. The seating of family members often follows a random pattern, depending on who comes first into the room, and an available seat's proximity to the television. Because everyone faces the television rather than each other, conventional mealtime interactions may prove difficult, not least because family members will usually be absorbed in what is happening on the television.

Drawing from these findings, we argue that, family identity may be enacted through everyday mealtime interactions and the various communication processes therein that include parents, children, television, the Internet and so forth. Of particular importance in our findings, is the link between food, family identity and domestic life, and how this is mediated by the television in several ways. Our study demonstrates how the mealtime reality of everyday life is frequently shared with the television. We argue that the television is becoming part of the nucleus family. Just as people share not only food, but also conversation and a social life, so too, does the television become part of that social life when informants' conversations are centred on television programmes, rather than on other family members.

Ties that Bind and Blind: The Negative Consequences of Using Social Capital to Facilitate Purchases

Bryan R. Johnson, Pennsylvania State University, USA
William T. Ross, Jr., Pennsylvania State University, USA

EXTENDED ABSTRACT

Conceptualization

As the fabric of civilization, social relationships play an important, yet often subtle, role in society. Relationships bind individuals together by facilitating correspondence and collaboration among them. Because of their intrinsic function in social interactions, relationships have the capacity to impact numerous aspects of human behavior, including those related to consumption. Consequently, given the influence of these ties, many consumers draw upon social connections as they purchase everyday products and services (Beaty et al. 1996; DiMaggio and Louch 1998; Frenzen and Davis 1990). Accordingly, the purpose of this paper is to examine the impact of using these social relationships to make purchases. While scholars have recently begun to address the basic questions of whether and why consumers leverage personal relationships in the marketplace, very little has been done to determine the implications of such actions for consumers.

To highlight the consequences of incorporating social relationships into consumption experiences, we draw upon social capital theory, which posits that individuals obtain benefits or returns as a result of their social relationships with others (Lin 2001; Portes 1998). Generally speaking, social capital theory focuses on how the resources embedded in social relationships provide benefits to individuals. These resources, such as advice, information, and ideas, are considered social because they can only be accessed through direct and indirect ties with others. Hence, to possess social capital, one must possess relationships with others; it is only through social interactions that the benefits of social capital can be realized (Lin 2001; Portes 1998).

Like most social capital research conducted in the social sciences, research on social capital in the consumer domain has focused primarily on the positive benefits of this behavior, while largely ignoring the hidden liabilities that may be associated with leveraging social relationships for personal gains. Consequently, our main objective is to identify the negative outcomes of social capital mobilization for consumers drawing upon their relationships to make purchases in the marketplace. Ultimately, uncovering and explaining these negative outcomes is important if scholars are to understand this meaningful social dimension of consumer behavior.

Method

To understand the consequences of leveraging social relationships in the marketplace and to expand and refine social capital theory in the consumer domain, we utilize the grounded theory approach (Glaser and Strauss 1967; Strauss and Corbin 1998). We conducted semi-structured depth interviews with 19 U.S. consumers, who were purposively selected using established theoretical sampling techniques. Our analysis employed *open coding* to identify important concepts in the data and *axial coding* to identify how emerging codes related to larger categories of interest (Strauss and Corbin 1998). We followed the "constant comparative approach" (Glaser and Strauss 1967) to ensure that the emerging theory was well-grounded in the data. This method of data analysis led to rich conceptual density among our categories and allowed us to refine our code list, yielding a core set of categories regarding the

consequences of social capital mobilization. In order to ensure trustworthiness of the data, we conducted member checks with study participants, as advocated in previous research (Belk, Sherry, and Wallendorf 1988; Lincoln and Guba 1985).

Findings

The fundamental premise of social capital theory is that individuals obtain returns from leveraging their social relationships. However, we have suggested that these returns may, at times, be negative. As expected, during the course of our interviews, we uncovered experiences in which negative outcomes unexpectedly occurred as a result of social capital mobilization.

Our analysis identified three categories of these negative outcomes: *recourse bridling*, *trust decay*, and *relationship atrophy*. These outcomes are important because they have not previously been connected to individual social capital theory. Identifying such experiences extends and refines social capital theory, both within marketing and in the larger social science arena.

Recourse bridling occurs when consumers face challenges during the consumption experience, yet they feel constrained from addressing them, given the relationships involved. This bridling effect likely occurs due to the perceived discomfort associated with confronting friends, as well as the perceived awkwardness that may result in future social interactions. *Trust decay* also results as a consequence of problems that arise when using personal relationships to facilitate purchases. When things do not work out as anticipated, many consumers lose trust in their friends' judgments and subsequently discount their recommendations and opinions in future interactions. Finally, *relationship atrophy* occurs when problems associated with the transaction permanently tarnish the relationships involved. When problems arise and expected benefits fail to materialize, individuals are often put in the unfortunate position of making a choice between the anticipated benefits and the relationship. When anticipated benefits win out, relationships degenerate.

Surprisingly, we find that many consumers underestimate the risks involved with leveraging their relationships for personal gains. Nearly all participants failed to contemplate the possible impact of negative experiences on the relationships involved. Instead, they tended to fixate completely upon the potential benefits available to them. Our data suggest that consumers' ability to foresee these negative consequences is a function of their experience using social capital. Consequently, those with more experience may be more adept at calculating the true cost of using their social connections, as they are more likely to have experienced negative consequences in the past.

Ultimately, this study makes several important contributions. It highlights the notion that social capital may not be the panacea it was once believed to be. Although social capital mobilization frequently results in positive outcomes for individuals, there are situations in which it has negative consequences. In addition, this study identifies the different categories of negative outcomes typically experienced by consumers when employing social capital in the marketplace.

Interestingly, these consequences are typically unanticipated and frequently take consumers by complete surprise. Ironically, the same social forces that facilitate access to resources can also

constrain and impair those who seek them. Collectively, these findings add depth to our understanding of social capital theory, both within marketing and in the larger social science arena.

The Comparative Mindset: From Animal Comparisons to Increased Purchase Intentions

Alison Jing Xu, University of Illinois at Urbana-Champaign, USA
Robert S. Wyer, Jr., Hong Kong University of Science & Technology, China

EXTENDED ABSTRACT

Xu and Wyer (2007) found that when consumers consider their preference for one of a set of products without having decided whether they want to buy anything at all, they develop a “which-to-buy” mind-set that increases their likelihood of ultimately making a purchase both in the present situation and in other, unrelated situations. In one study, for example, more participants reported a willingness to purchase a vacation package if they had previously reported a preference for one of two computers than if they had not. In another experiment, participants who stated preference for five pairs of products or services were significantly more likely to purchase candies that were on sale after the experiment than were participants who had not made preference judgments before. Thus, merely stating a preference for choice alternatives in one product domain not only can increase the willingness to make a purchase in other hypothetical situations but also can have an impact on actual purchase behavior.

Preference judgments are only one type of comparative judgments, however. In the present research, we proposed that a which-to-buy mind-set may be a manifestation of a more general, comparative mind-set that, once activated, persists to influence decisions and behavior in other situations in which comparison processes come into play. Furthermore, this mind-set may be activated by making different kinds of comparative judgments in non-product domains.

Four experiments examined these possibilities. Participants in the first experiment received information about two vacation packages, A and B. One group of participants indicated which vacation they preferred. A second group of participants, however, indicated which vacation they disliked more. Then, both these participants and control participants (who had not been exposed to the vacation packages) received information about two computers and indicated whether they would want to purchase A, to purchase B, or to defer making a choice. Compared with control participants who had not made judgments of vacation packages, participants who either made preference or dislike judgment of vacation packages were more likely to choose one of the computers rather than defer choice.

In experiment 2, some participants were exposed to pairs of animals (e.g., elephants, hippos, etc.) and asked to indicate which animals in each pair they preferred. Other participants were asked to compare the animals with respect to a specific attribute (heaviness, jumping ability, eye sight, etc.). Then, both these participants and control participants who did not make judgments of animals performed the same computer-decision task we employed in Experiment 1. Both groups of participants who made comparative judgments of animals expressed a greater willingness to buy one of the computers than control participants.

Furthermore, a third experiment showed that participants who had made comparative judgments of animals were actually more likely than control participants to purchase one of several products (candy, potato chips, etc.) that were on sale after the experiment.

Experiment 4 manipulated the comparative mind-set by asking participants to make a series of similarity judgments on countries, educational institutions, etc. Making these similarity judgments reflected the nature of making directional comparisons suggested by Tversky (1977). These participants also expressed greater willingness to purchase a computer in the subsequent choice task than were control participants.

The Illusion of the Illusion of Control

Francesca Gino, University of North Carolina, USA
Zachariah Sharek, Carnegie Mellon University, USA
Don A. Moore, University of California, Berkeley, USA

EXTENDED ABSTRACT

In the 1970s, New York City installed buttons at intersections with traffic lights. Helpful signs instructed pedestrians: "To cross street, push button. Wait for walk signal." Pedestrians in New York routinely assume that pushing the button speeds the arrival of the walk signal. As it happens, their faith is misplaced. Since the late 1980s, traffic signals in New York have been controlled by a computer system that determines when the walk signal is illuminated (Luo, 2004). Pushing the button has no effect. But the city has not paid to remove the signs or the buttons, and pedestrians push the buttons anyway. Are they suffering from the illusion of control?

According to Langer (1975), people are suffering from the illusion of control when they behave as if they have control when in fact they do not. Many studies have shown how easy it is to get people to behave as if they think they have control over purely chance outcomes (see Thompson, Armstrong, & Thomas (1998) for a thorough review). These experimental paradigms set up situations like New York City intersections, and then point the finger of bias at people who press the "walk" button when given the chance to do so. But is it any surprise that when people have zero control, they are more likely to overestimate than underestimate their control?

A simpler alternative explanation is that people have an imperfect sense of how much they control probabilistic events—when they have very little control, they tend to overestimate it. This alternative explanation implies the need for an experimental condition that is missing from most research on the illusion of control: A high control condition. If people with no control systematically overestimate their control when they have little because they are unsure about how much control they have, then they should systematically underestimate their control when they have objectively high control. This is the hypothesis we test in our experiments.

In two studies, we manipulated whether control was objectively high or objectively low and asked participants to estimate their control. Our main goal was a critical test of the claim that people generally overestimate their control. As predicted, people overestimated their level of control in the low control condition and underestimated it in the high control condition. These results are consistent with our hypothesis and suggest that people systematically overestimate their control when it is objectively low and systematically underestimate it when it is objectively high.

The first study used a novel paradigm that allowed us to manipulate the actual amount of control participants had over a feature of a task in which they were engaging. The results show that when participants had low control (15%) they tended to overestimate it, but that when they had high control (85%) they tended to underestimate it. The second study replicates this result using the classic button-light paradigm in which participants are given a button that may or may not influence the chances that a light comes on subsequent to them pressing the button. Again, when the button provided them with high control (80%) over the light's onset, they tended to underestimate that control. When the button provided them with low control (20%) over the light, they tended to overestimate that control.

Our studies offer little evidence of systematic overestimation of control. Indeed, the only circumstance in which we found that our participants overestimated their control was when they had very

little and our measure made it difficult or impossible for them to underestimate their control. We offer an alternative account for findings that people overestimate their control when control is low: It is common for people to be uncertain about how much control they have. Consequently, when control is objectively low people tend to overestimate it. By focusing on domains in which people have little control, prior research has created the illusory impression that overestimation of control is more frequent than it actually is.

The Impact of Social Categorization on Persuasion Attempts

Mirjam A. Tuk, University of Groningen, The Netherlands

Peeter W. J. Verlegh, Erasmus University Rotterdam, The Netherlands

Ale Smidts, Erasmus University Rotterdam, The Netherlands

Daniel H.J. Wigboldus, Radboud University Nijmegen, The Netherlands

EXTENDED ABSTRACT

Research examining social categorization effects on persuasiveness, has mainly focused on understanding the precise impact of persuasion attempts from in-group members on attitudes. It has been argued that in-group membership can serve as a cue for systematic processing (Mackie Worth and Asuncion 1990; Van Knippenberg 1999), because in-group members are more similar and usually share the same opinions. This causes people to process information from in-group members in a more systematic way than information from out-group members. As a consequence, people are relatively more persuaded by strong arguments from in-group members than by weak arguments from in-group members, whereas they are relatively unpersuaded by both strong and weak arguments from out-group members. This implies that persuasion attempts from out-group members are relatively less influential than persuasion attempts from in-group members, and do not (or to a lesser extent) influence attitudes.

However, research examining the impact of out-group members within other domains, suggests that people do show strong reactions towards out-group members. People have a strong tendency to differentiate themselves from out-group members in terms of resource allocation (less points or credits for the out-group), and evaluations of group members (evaluate in-group and out-group members as even more different than they already are; Jetten, Spears and Postmes 2004). Furthermore, recent research examining the impact of group membership in relation to product evaluations (Berger and Heath 2007; Escalas and Bettman 2003, 2005; White and Dahl 2006, 2008), shows that people tend to avoid products that are associated with dissociative out-groups.

The above described research shows that people tend to differentiate themselves from out-groups in terms of resource allocation and product preferences, but remains silent about the precise impact of persuasion attempts from out-groups. In the current research, we examine whether out-group members are either less persuasive (i.e., have relatively less influence on attitudes, as is suggested by the research showing stronger persuasion effects of in-group members) or whether people differentiate their attitudes after persuasion attempts from out-group members (as is suggested by the research showing differentiation tendencies in other domains). A crucial test to gain more insight in the exact impact of persuasion attempts from out-group members, is to examine the impact of persuasion attempts that differ in opinion valence. A differentiation effect does not predict differences in responses to weak versus strong arguments from out-group members, and this previously found result is thus in line with both a differentiation effect and a difference in persuasiveness effect. However, a differentiation effect predicts that people will report attitudes that are clearly different from the one stated by the out-group member. This implies reporting a positive (product) attitude after a negative recommendation, and a negative attitude after a positive (product) recommendation. If the out-group member is less persuasive than the in-group member, this does not predict a flip of attitudes in a direction that is clearly different from the out-group member, but rather a relatively neutral opinion.

We tested these predictions with four experiments. In the first three experiments, we manipulated recommendation valence (positive versus negative) and group membership (in-group versus out-

group). Across these three experiments, we used different manipulations of group membership. This had two purposes, first of all, this increases the reliability and generalizability of the results. And second, the type of group manipulation is quite easily open to alternative explanations (unknown to the researchers, a particular group might for example be a dissociative out-group for the participants). Showing the hypothesized effects with different types of group manipulations (one of which was a minimal group paradigm; Billig and Tafel 1973) rules out such group specific alternative explanations. In these three experiments, respondents read the (positive or negative) opinion of either an in-group or an out-group member about a specific painting. After seeing a picture of the painting themselves, respondents were asked to indicate their opinion about this painting (seven-point scale, 1=ugly, 7=beautiful). Results of the three individual studies showed that people were more positive about the painting after a positive in-group recommendation than after a positive out-group recommendation (in line with previous research). These studies also showed that people were more positive about the painting after a negative out-group recommendation than after a positive out-group recommendation, which is in line with a differentiation effect. Furthermore, a pooled analysis over these three studies also showed that respondents were more positive about the painting after a negative out-group recommendation than after a negative in-group recommendation. Together, these studies and the pooled analysis over these three studies provide convincing evidence that people react to persuasion attempts from out-group members by differentiating their own attitude away from the out-group member, and that this effect is caused by pure social categorization.

Remarkably, none of the studies showed any difference in attitude after the positive versus the negative in-group recommendation. In the final experiment, we examined whether this was caused by a lack of salience of shared (in)group membership (Wilder 1984). We argued that a recommendation from an in-group member can be perceived on a more interpersonal level as a recommendation from a stranger rather than on an intergroup level (as a recommendation from a fellow in-group member). Confronting people with the existence of the out-group should make the intergroup context relatively more salient and subsequently also highlight the fact that someone belongs to the in-group. In this study, we confronted half of the respondents with out-group members, and we found the expected effect of recommendation valence (more positive after a positive than after a negative in-group recommendation), which was again absent in the condition where respondents were not confronted with the out-group.

These set of studies showed that out-group members have an important impact on attitudes in an unexpected manner. This is important to take into account with regard to persuasion attempts (such as word of mouth) and advertisement campaigns, just like the finding that in-group membership only has an impact on attitudes when an intergroup context has been made salient.

The Persuasive Role of Incidental Similarity on Attitudes and Purchase Intentions in a Sales Context

Lan Jiang, University of British Columbia, Canada
Darren Dahl, University of British Columbia, Canada
Amitava Chattopadhyay, INSEAD, Singapore
JoAndrea Hoegg, University of British Columbia, Canada

EXTENDED ABSTRACT

The study of similarity in persuasion has a long history. The majority of research in this area has been conducted to examine the role of attitude similarity between individuals, but this research has recently been extended to examine the role of incidental similarity, i.e., chance similarities between individuals that provide little relevant information and few implications in a specific context (Burger et al. 2004). For example, a shared birthday with another individual provides no diagnostic information regarding compatibility as business partners.

In most instances, logic would indicate that incidental similarities should not play a significant role in social environments. However, existing research has shown that incidental similarity can play a role in social situations and can increase liking, persuasion, and cooperative behavior between individuals (e.g., Burger et al. 2004). In this paper we extend these initial findings for incidental similarity to an interpersonal context. Specifically, we examine the effects of incidental similarity shared between a salesperson and a potential consumer in an actual face-to-face sales situation. Further, we provide an explanation for how and why incidental similarity can have a persuasive influence, in this instance. To do this, we draw on the theoretical framework of a need for belongingness (Baumeister and Leary 1995), where people strive to achieve social connectedness with those around them. This framework is particularly relevant in an interpersonal situation, which is the context of our investigation.

Four experiments show our contributions: 1) we establish social connectedness as an important underlying mechanism for the effect of incidental similarity. While previous research (e.g., Brendl et al. 2005) has shown that self-esteem enhancement can underlie incidental similarity effects, we show that in the interpersonal context social connectedness drives the effects of incidental similarity and that our results cannot be explained on the basis of self-esteem, 2) we identify two boundary conditions that qualify our findings: the valence of sales person's behavior towards an unknown other and the length of the interpersonal relationship as being critical moderators to the process we outline. We show that when the need for social connectedness is mitigated, i.e., when the salesperson is disliked or when the relationship is not expected to continue, the positive effects of incidental similarity are lost.

We propose that discovering an incidental similarity with a negative or disliked other will decrease the need for connectedness and cause individuals to distance themselves from the similar other. Since connectedness can underlie the relationship between incidental similarity and attitudes/purchase intentions, we expect that distancing in the sales context investigated will mean negative implications for attitude formation and the resulting purchase intentions. We also expect the negative outcome caused by an incidental similarity during an unpleasant social interaction to be mitigated when the social interaction is brief and unlikely to continue.

Using an actual sales situation, Study 1 tests for the effects of incidental similarity in a service context and identifies the role of

connectedness in the process. We manipulated incidental similarity through shared birthday. After a sales promotion for a personal training program, consumers who accidentally found out that they share the birthday with the trainer reported a more favorable attitude towards the program as well as a higher intention to enroll in the program. The direct measure on the sense of connectedness and the mediation analysis corroborated our hypothesis that social connectedness could be the underlying mechanism for the incidental similarity effect.

Study 2 further validates the role of connectedness by comparing the effects of incidental similarity for individuals differing in their chronic tendency to connect with others. We found that people who have a low social connectedness orientation are least influenced by the shared birthday and on the other hand, people with a high social connectedness orientation are influenced most strongly.

Study 3 tests the potential boundary condition for the observed effect of incidental similarity by identifying the importance of the valenced behavior of the referent other in achieving both a social connection and an effect for incidental similarity. We showed a reversed effect of the shared birthday when the salesperson displays some negative traits during the promotion. When participants discover that they share the same birthday with a person who is rude, the similarity no longer helps establish connection and instead it makes them feel more disconnected. The decreased feeling of connectedness leads to a more negative attitude towards the program and lowers their intention to purchase.

Our final study tests another possible boundary condition of the incidental similarity effect—the anticipated length of the interpersonal relationship with the salesperson. We show that this negative effect that was realized was mitigated when the social interaction was just a brief encounter with no future interactions expected. In non-aversive conditions, an incidental similarity increased attitude favorability and purchase intentions even when the interaction with the similar other was a brief encounter.

To our knowledge, this research is the first empirical test of social connectedness as a theoretical explanation for when and why individuals will be affected by an incidental similarity. Drawing from the theory of belongingness (Baumeister and Leary 1995), we tested two features of the need for belongingness, the valence of the interaction and the length of the relationship, as moderators for incidental similarity effects. Our results not only confirmed the impact of these two situational factors, but also extended Baumeister and Leary's (1995) proposition by demonstrating a negative effect of incidental similarity in an aversive condition.

From a managerial perspective, our research provides insight into the power of cultivating similarity between consumers and sales agents in the retail context. Matching sales people with consumers to enhance shared similarity is an obvious recommendation for marketing practice. Our research suggests that even matching based on incidental similarities may have an influence on consumer decision making. It is important to note however, that salespeople that share a similarity also have the capacity to alienate consumers if their behavior is perceived to be negative.

Contagious Likes and Dislikes—Neighborhood Effects in Attitudes and Preferences

Jayati Sinha, University of Iowa, USA

Dhananjay Nayakankuppam, University of Iowa, USA

EXTENDED ABSTRACT

We examine the influence of neighborhood effects on attitudes and preferences. Specifically, does exposure to the attitudes of others in a group influence one's own attitudes and preferences? The primary goal of the present research was to explore how individual attitudes are shaped by neighborhood effects—that is, people living in close proximity could influence each others attitudes and preferences. By neighborhood effects, we refer to interdependencies between individual attitudes and the attitudes of others in a group. Said differently, exposure to others' attitudes and preferences influences one's own attitudes and preferences. Specifically, we suggest that there are (a) *direct influences* (e.g., a neighbor provides information and/or opinions about some issue or product) as well as (b) *indirect influences* (where no direct information needs to be exchanged).

The notion of direct influences is suggested by the effects such as the *group polarization* phenomenon (Moscovici and Zavalloni, 1969) and the *chameleon effect* (Chartrand and Bargh, 1999). A sizeable body of social psychology literature has demonstrated that an individual's attitude toward a given issue tends to polarize during a group discussion with other people who hold a similar opinion on that issue (Myers, 1978; Myers and Lamm, 1976). We base the hypothesis regarding the indirect influence from recent work in social psychology (Ambady and Rosenthal, 1992; Ambady et al., 1999) which suggests that there are domains where people are remarkably accurate at gleaning information from very little information.

We show that neighborhood effects do emerge for issues where one is exposed to group attitudes. More intriguingly, neighborhood effects also emerge for issues where one was never exposed to group attitudes. We suggest that this is due to the fact that exposure to some group attitudes allows individuals to make shrewd guesses about group attitudes on other issues that were never discussed. Further, these guesses bias one's own attitudes.

We present evidence for one mechanism through which neighborhood effects emerge, namely that exposure to the preferences of others (which is more likely when individuals are in close contact) influences one's own preferences. Thus, Bill telling Bob about his attitude towards Scott's lawn feed changes Bob's attitude towards Scott's. More startlingly, we show that it does not require exposure to the attitude towards the target object. Neighborhood effects emerge even for non-discussed target objects. Exposure to attitudes towards some objects appears sufficient to allow individuals to make fairly shrewd guesses about attitudes towards other objects, which in turn influence their own attitudes. That is, Bill telling Bob about his attitude towards Scott's lawn feed changes not only Bob's attitude towards Scott's lawn feed, but also Bob's attitudes towards other issues such that Bob's and Bill's attitudes converge even on non-discussed issues (such as Scott's lawn mowers).

Strong Attitudes Versus Strong Situations: Social Pressure on Recycling

Iris Vermeir, University College Ghent & Ghent University, Belgium

EXTENDED ABSTRACT

Previous researches show contradictory results concerning attitude strength, social pressure and attitude-behavioural consistency. Either strong situations (Wallace et al. 2005) or strong attitudes (Pomerantz et al. 1995) predict attitude-behavior consistency. We argue that these contradictory results could be explained when personal factors like perceived control and self-monitoring are taken into account. The purpose of this study is to investigate the relation between attitudinal (attitude strength), contextual (social pressure) and personal (self-monitoring and perceived control) variables in influencing attitude-behavior consistency. More specifically, we investigate if the level of self-monitoring and perceived control could influence the predictive value of attitude extremity (as a measure of attitude strength; Krosnick et al. 1993) and social pressure on the attitude-behavior consistency.

Openness to social pressure is not at the least influenced by personal characteristics like self-monitoring. High self-monitors are particularly sensitive to others in social situations and use the expressions of others as guidelines for their own behavior (Gangestad and Snyder 2000). Hence, in strong social pressure situations, attitudes of high-self monitoring respondents shouldn't necessarily determine behavior (H1a). While, for low-self monitoring respondents, strong attitudes could overcome social pressure (H1b). Low-self monitors perform behavior according to their own beliefs, instead of paying attention to beliefs or behaviors of others (Gangestad and Snyder 2000).

Previous research already demonstrated a decreased attitude-behavior consistency due to a lack of perceived control (Vermeir and Verbeke 2006). Individuals have to feel they are able to act environmentally conscious in order to intend environmental behavior (Knussen et al. 2004) or actually perform this behavior (Tanner 1999). Hence, we can expect that strong attitudes would not be followed if perception of perceived control is low, regardless of social pressure (H2a). When perceived control is high, attitude strength can be a determinant of behavior, especially in low pressure situations (H2b).

In order to test our hypotheses, an experiment was set up concerning recycling of soda cans. To manipulate social pressure, participants studied research results –ostensibly the results of a recent study on student opinion– that indicated that an in-group (defined by connectedness to the group) strongly or weakly engaged in recycling behavior. Manipulation checks confirmed that our respondents experienced high (versus low) social pressure when recycling behavior described in the text was high (versus low).

In total, 284 students participated in our experiment in exchange of a reward. When entering into the room, respondents were offered a soda. First, participants were asked attitudinal questions on recycling. Attitudes toward recycling were measured using a four-item semantic differential on a 7-point scale. Attitude extremity was used as a measure of attitude strength. Extremity scores were created by computing the absolute value of the deviation of each attitude score from its conceptual midpoint (cfr. Fabrigar, Petty, Smith and Crites 2006). Next, participants were asked to carefully read a text on recycling behavior of 18-25 year old adults. After completing some filler items, respondents indicated their perceived level of control to engage in recycling behavior and completed the self-monitoring scale (Snyder and Gangestad 1986). A median split was performed to identify low/high self-monitors and low/high perceptions of control. Next, respondents were asked

to go to another room to collect their reward. On their way to the other room, respondents could dispose of their cans on their own, without any peers around. They could drop their soda can in either an ordinary bin or a recycling bin (meant for cans). Both bins were equally visible. About 45% of our respondents (N=119) used the ordinary bin, while 141 respondents (55%) used the recycling bin. The soda cans were marked so we could link each soda can to a corresponding number on the questionnaire.

Results showed that attitude strength and social pressure do indeed influence attitude-behavior consistency. In general, respondents who experienced high (versus low) social pressure, did act more on their positive recycling attitudes. However, strong attitudes were not always associated with high consistent behaviors. High self-monitoring respondents who experience high social pressure do not differ in their attitude extremity according to their behavioral pattern, confirming our first hypothesis (H1a). Furthermore, we found that attitude extremity did not differ for consistent and inconsistent respondents who did not experience high social pressure. High self-monitoring respondents who act consistently with their attitudes do not have stronger attitudes compared to inconsistent respondents regardless of social pressure. Possibly, high self-monitoring respondents have a natural tendency to act on their expressed attitudes, regardless of their strength and regardless of contextual factors. We found that low self-monitors, who are more prone to follow their own ideas, follow their attitudes when they are strong (versus weak), especially when there is no social pressure. However, social pressure does seem to influence low-self monitors on some occasions: low-self monitors who experience social pressure to act on their positive attitudes, do engage in recycling regardless of the strength of their attitude (rejecting H1b). These results show the vast influence of social pressure in determining behavior, even for low-self monitoring respondents.

Furthermore, respondents who feel they can decide for themselves if they engage in recycling, engage in recycling behavior when their attitudes are stronger (versus weaker), especially when they do not experience social pressure (confirming H2b). Respondents who feel they have less control over their recycling behavior, do act on their recycling attitudes when they experience high social pressure and when their attitudes are stronger (versus weaker) (partly rejecting H2a). Moreover, under conditions of social pressure, respondents with high perceived control, act consistently on their positive attitudes, if their attitudes are strong (versus weak). Although the latter result was only marginally significant, these results show that strong attitudes can predict attitude-behavioral consistency regardless of the perception of control when they experience high social pressure. When less social pressure exists, low (versus high) control makes attitude strength less a determinant of behavioral consistency (partly confirming H2a). Possibly, these respondents do not engage in recycling behavior because they have no control over their behavior on one hand and because there is no social pressure to act on their attitudes.

The Emotional Information Processing System is Risk Averse: Ego-depletion and Investment Behavior

Bart De Langhe, RSM Erasmus University, The Netherlands
Steven Sweldens, RSM Erasmus University, The Netherlands
Stijn Van Osselaer, RSM Erasmus University, The Netherlands
Mirjam Tuk, University of Groningen, The Netherlands

EXTENDED ABSTRACT

Previous research has shown that self-regulatory strength is crucial to exert willpower. It has been found that a depletion of self-regulatory resources very often leads to detrimental behavior such as overeating and impulsive buying (Vohs and Faber 2007; Vohs and Heatherton 2000). However, not much is known about how the availability of these resources is related to risky decision making. The current research shows that a state of ego-depletion leads to higher levels of risk aversion in mixed gambles (involving mixtures of gains and losses).

Risk aversion for mixed gambles refers to the tendency of people to reject a gamble with an equal chance to win or to lose, even when the expected value of gambling is higher than the expected value of not gambling (Tversky and Kahneman 1992). Recent developments in the field of neuroscience and psychology indicate that anticipatory emotional reactions that are elicited by features of the risky decision alternatives are crucial in understanding risk taking and risk seeking (Damasio 1994; LeDoux 1996; Loewenstein et al. 2001).

In the current research, we adopt a dual-process framework that distinguishes between a rational (cognitive) and an experiential (emotional) information processing system (Epstein and Pacini 1999), in order to explain greater risk avoidance in a state of ego-depletion. In a situation where one has to make a choice between a risky and a less risky alternative, both the rational and the experiential system generate an "advice" concerning the most desirable behavior. The outcome of the rational system is determined by a cognitive assessment of probabilities of decision outcomes and outcome severity, whereas the outcome of the experiential system is determined by an automatic retrieval of accumulated knowledge from previous experiences. Since the experiential system attaches greater weight to previously experienced negative contingencies than to previously experienced positive contingencies of the choice options (De Houwer, Thomas, and Baeyens 2001), it guides the decision maker away from risky alternatives.

Given that the rational system is the slower, analytical system it is in an ideal position to monitor and inhibit the output of the faster, associative experiential system. However, building on previous research that puts forward self-regulatory resources as the necessary fuel for the rational system (Vohs 2006), we hypothesize that a depletion of self-regulatory resources impairs the inhibiting capacity of the rational system. As a consequence, the output of the experiential system is weighted more heavily in the final decision, resulting in more risk averse behavior among ego-depleted individuals.

Two experiments provide support for this reasoning. In both experiments, the availability of self-regulatory resources was manipulated by a modified version of the Stroop task (Stroop 1935). Inhibiting first responses (which is the general purpose of this task) has been shown to consume self-regulatory resources (e.g., Inzlicht and Gutsell 2007; Muraven, Tice, and Baumeister 1998; Wallace and Baumeister 2002), and is therefore an effective way of inducing a state of ego-depletion.

In Study 1, the Stroop task was followed by an investment task which has previously been used to compare decision making of

patients with lesions to the brain's emotional circuitry and patients with substance dependence to decisions made by a normal control group (Shiv et al. 2005a; Shiv et al. 2005b). The task consists of 20 decision rounds in which one can choose between investing \$1 or not investing \$1. An investment decision is followed by a coin toss; heads results in losing the \$1, tails results in gaining \$2.50. If a participant decides not to invest, the game advances to the next round. Since the expected value of risk seeking behavior (invest) is higher than the expected value of risk averse behavior (not invest), a rational decision maker should always decide to invest. Participant's predisposition to rely on experiential processing was measured with the experiential subscale of the Rational-Experiential Inventory (Pacini and Epstein 1999).

As the experiential system is an associative information processing system that generates emotional responses based on previous outcomes, we only expected it to influence investment decisions of depleted participants after some experience with the task at hand (i.e. in the second block of 10 trials). Additionally, we expected a moderation of the effect by experientiality. Indeed, if the weighting of the outcomes of the experiential system is dispositionally low, the rational monitoring system should still be able to override the responses generated by the experiential processing system.

As predicted, the three-way interaction between state of self-regulation (control; depleted), experientiality (high; low) and decision block (first block of 10 decisions; second block of 10 decisions) was significant. After having gained some experience with the investment task, ego-depleted participants with a tendency to rely on their experiential "hunches" clearly showed higher levels of risk aversion.

The goal of the second study was to demonstrate that a lower availability of self-regulatory resources can be beneficial for decision making in a situation where the expected value of risk avoidant behavior is higher than the expected value of risk seeking behavior. After completing the modified Stroop task, participants continued with the Iowa Gambling Task (see Bechara et al. 1994, for exact procedures and pay-off structure). Participants had to choose 100 times between cards from four different decks. Two decks are low-risky decks with a high expected value, and two decks are high-risky decks with a lower expected value. Results showed that ego-depleted participants selected significantly more cards from the low-risky decks with a higher expected value.

In sum, in two experiments we showed that a lower availability of self-regulatory resources increases risk aversion in mixed gambles (study 1 & study 2). This finding can be explained by an increased weighting of experiential processing in decision making (study 1) and implies that ego-depletion is not always detrimental for decision making, but can also guide people towards more beneficial choice options (study 2).

A Model of Investment Decision-Making: How Adaptation to Losses Affects Future Selling Decisions

Carmen K.M. Lee, VU University Amsterdam, The Netherlands
Roman Kräussl, VU University Amsterdam, The Netherlands
André Lucas, VU University Amsterdam, The Netherlands
Leonard J. Paas, VU University Amsterdam, The Netherlands

EXTENDED ABSTRACT

The well-known disposition effect postulates that investors tend to sell their winners (appreciated investments) too soon and hold their losers (depreciated investments) for too long (Shefrin & Statman, 1985). The prominent explanation for this disposition effect is based on prospect theory (Kahneman & Tversky, 1979), which posits that investors are more risk-averse in the domain of gains and more risk-seeking in the domain of losses. Thus, when facing paper gains, investors tend to be risk-averse implying the tendency to sell their winners. By contrast, when facing paper losses, investors tend to choose the risky option and hold on to their losers. However, it is not clear why and when investors eventually do sell at a loss. The aim of the present study is to address this gap in the current literature by integrating a theory of adaptation, adaptation level theory (Helson, 1964), a theory of reference point dependence, prospect theory (Kahneman & Tversky, 1979), and a theory of dual process decision-making, cognitive-experiential self-theory (Epstein, 1994) to propose a model of investment decision-making.

Our model disentangles the effects of time in losing position and size of loss on reference point adaptation. The adaptation of the reference point (from prospect theory) can be modeled as changes in adaptation level (from adaptation level theory), which are determined by time and size of each stimulus. These are linked to the investor's decision-making process using the framework of cognitive-experiential self-theory, which suggests there are two systems in decision making: experiential and rational (Epstein, 1994). The experiential system can automatically and effortlessly process information. Also, it interacts with the rational system as a source of intuitive wisdom and creativity. On the other hand, the rational system is a deliberative and effortful system, processing at high levels of abstraction and handling long term delay of gratification.

In the integration of prospect theory, adaptation level theory and experiential self-theory, we develop on the results of a recent study by Arkes, Hirshleifer, Jiang and Lim (2008). They find investors adapt to financial gains and losses as their reference point shifts after the value of the investment increased or decreased. However, the link between reference point adaptation and decision-making is still lacking. Therefore, we conduct an experimental study to examine how the adapted reference point influences one's emotions and expectation about an investment's future performance, and eventually leads to the decision to hold or to capitulate a losing investment.

We hypothesize that (H1) the size of total loss and the time in losing position are negatively related to an individual investor's adapted reference point; (H2a) the adapted reference point is positively related to one's optimistic expectations towards the losing investment; (H2b) in turn, more optimistic expectation leads to a smaller probability of an investor's capitulation of the losing investment; (H3a) the size of previous loss is negatively related to one's positive emotion towards the losing investment; (H3b) in turn, more positive emotion leads to a smaller probability of capitulation. We ran an experiment, in which 111 participants

incurred various sizes of stock losses over a course of maximum 10 investment periods. At the end of each period, participants received information of the stock's performance. Before making the decision to hold or to capitulate on the stock, participants answered several questions concerning their emotions, expectations and adaptation to losses.

We applied the partial least squares (PLS) approach to estimate the proposed model. Significant effects were observed from both time in losing position and size of total loss on reference point adaptation. We show that the investors' adapted reference point significantly shifts downwards when total loss and time in losing position increase. These experimental results give support to hypothesis 1. Moreover, a higher adapted reference point predicts more optimistic expectations about the stock's future performance, while a larger previous loss predicts more negative emotions. These results give support to hypotheses 2a and 3a. To test hypothesis 2b and 3b, we examine the relation among emotion, expectation and the decision to hold or capitulate on a losing investment. More optimistic expectations about the stock's future performance are positively and significantly related to the tendency to keep the losing investment, although a more positive emotion does not significantly predict a stronger tendency to hold. Thus, hypothesis 2b is supported, but hypothesis 3b is not.

Our results are consistent with Arkes et al. (2008) that investors do adapt to losses, but we contribute to the existing literature by demonstrating that a lower adapted reference point is predicted by a larger size of total losses and/or a longer time in losing position. Moreover, our results add more insight into the separate effects of time in a losing position and the size of investment losses as we have disentangled the unique effect of past stimuli and time. We also show that adaptation of the reference point indirectly affect an investor's decision to hold or to capitulate on a losing investment, thus, we have demonstrated the link between reference point adaptation and decision-making.

Cost-Benefit Associations and Their Influence on Loan Experience

Bernadette Kamleitner, University of London, UK

Erik Hoelzl, Universitaet Wien, Austria

Erich Kirchler, Universitaet Wien, Austria

EXTENDED ABSTRACT

Most decisions are determined by costs and benefits. We investigate whether it matters to which degree consumers mentally associate costs and benefits of a transaction. In 1998 Prelec and Loewenstein suggested that the pleasure of consumption decreases, if thoughts related to consumption strongly evoke thoughts of payment. Also, they suggested that the pain of paying decreases, if thoughts related to payment strongly evoke thoughts of consumption. Or to put it differently: if the benefits of a transaction make people think of the cost, the benefits themselves become devaluated. If the cost of a transaction make people think of the benefits, the cost become less onerous. To ascertain whether cost-benefit associations (CBAs) really have these suggested consequences it seems necessary to assess and manipulate the actual degree of cost-benefit associations. Even though some studies have drawn on Prelec and Loewenstein's concept of coupling (Gourville and Soman 1998; Heath and Fennema 1996; Kivetz 1999; Soman and Gourville 2001) they did not directly measure cost-benefit associations. Rather, it has been assumed that certain differences in transaction characteristics lead to differences in cost-benefit associations (e.g., assuming weak CBAs due to price bundling Soman and Gourville 2001) which in turn contribute to differences in consumer evaluations and behaviour (for an exception, see an interview study by Kamleitner and Kirchler 2006). We aim to fill this gap.

In three studies, we assessed the consequences of cost-benefit-associations on consumer evaluations of a personal loan. Personal loans were chosen as a context because buying a good on a loan entails several consumption and payment episodes over a long time period. Consequently, costs and benefits are likely to be salient and in turn loan users are likely to be able to report on CBAs.

Study 1 was a field study among 143 personal loan users. CBAs were assessed by two straightforward items asking for the strength of each direction of association (e.g., 'When I think of the loan I always also think of the goods I bought with it'). Subjective evaluations of the loan and the good were assessed as dependent variables. Separate regressions were run to predict both dependents. The subjective burden of the loan significantly regressed on the degree to which the benefits evoked thoughts of the cost (B2C-association) whereas it did not regress on the degree to which the cost evoked thoughts of the benefits (C2B-association). This result holds even if possible income effects are controlled for. Contrary to that, the subjective evaluation of the loan financed good does not relate to the degree of CBAs. Hence neither of the assumed consequences was observed. Strong B2Cs did not reduce the utility of consumption and strong C2Bs did not reduce the burden of the loan. Rather, strong C2Bs seemed to relate to the burden of the loan. The more the benefit (i.e. loan financed good) made people think of the cost (i.e., loan), the more burdensome the loan was experienced.

To make sure that CBAs have a causal impact on subjective evaluations, Study 2 manipulated CBAs in a paper pencil experiment. 128 Participants were asked to immerse into a short scenario about a person who took up a loan for a car. In particular, the scenario contained two short episodes and thoughts the person had during that episode. Wording of the thoughts was varied so that both directions of CBAs were manipulated independently. After immersing into the scenario, participants were asked to provide subjective evaluations of loan and car. A manipulation check

indicated that the manipulation was successful. A 2x2 MANOVA tested for an effect of B2C- and C2B-associations on evaluations. As in Study 1, there only was a main effect of the B2C-association. If benefits strongly led to thoughts of cost, the loan was experienced more burdensome and the car was experienced less positive than if this association was weak. In sum, Study 2 reconfirms and adds to findings of Study 1. As in Study 1 B2C-associations had an effect on loan burden. In addition, the hypothesized effect of B2C-associations on the utility of the good was observed.

Study 3 was designed to assure generalizability across designs and samples. 235 people participated in an online experiment: Participants were asked to imagine that they had among other goods a loan-financed car. They then had to work through several slice-of-life episodes, some of them featuring the car or the loan. Slight changes in wording and in accompanying pictures were successfully used to prime B2C- and C2B-associations. Subjective evaluations were again assessed. Results of a 2x2 MANOVA are in line with the previous studies. There was only a main effect of B2C-associations. The subjective loan burden was higher if the car strongly evoked thoughts of the loan. No effect on the subjective utility of the car was observed.

To conclude it seems that—at least with loan-holders—CBAs do not have the consequences often assumed. This finding is of practical importance and it is worthwhile to investigate why we did not observe the theorized relations, e.g., strong B2Cs had a consistent effect on cost rather than benefit perception. One possibility is that associations are influential because of a meta-cognitive impact. Strong associations can increase the cognitive accessibility of the associated concept. Accessibility in turn may act as cue to the affective quality of the concept (e.g., Wanke, Bohner, and Jurkowsch 1997). For example, if a good strongly evokes thoughts of payment, consumers may focus on their intense thoughts of payment and interpret them as indicative of a massive pain of paying. The current studies allow for this possibility. Future research is needed to show to which degree our findings can be generalized across transaction contexts, measurements and manipulations.

Effects of Belief in Global Citizenship on Branding Discourse in the U.S. and Russia

Yuliya Strizhakova, Michigan Technological University, USA

Robin Coulter, University of Connecticut, USA

Linda Price, University of Arizona, USA

EXTENDED ABSTRACT

Global brands appeal to managers because of their ability to provide economies of scale and secure high brand equity. Their appeal for consumers is more widely debated, especially in emerging markets where global brands are frequently blamed for disruptions of local value systems. Past research (Appadurai 1990) suggests that the potential of global brands to transform cultural meanings depends on whether consumers believe that global brands can provide them with the means of participation in the global consumer culture and expression of their identity. Holt, Quelch, and Taylor (2004) posit: *global brands create an imagined global identity that [the consumer] shares with like-minded people* (p. 71); they report that approximately 12% of consumers across 12 countries prefer global brands for this reason.

Drawing on research on branded products, globalization, and consumer culture as related to developed and emerging markets, we attempt to further explicate the concept of belief in global brands as a passport to global citizenship. Specifically, we posit and test relationships between several concepts, including: belief in global citizenship, the symbolic use of branded products as a means of identity, and the importance of branded products. We further consider the effects of cultural openness and consumer ethnocentrism on belief in global citizenship. The overarching goal of our research is to move beyond preference prediction for global brands and to assess effects of belief in global citizenship on a symbolic system of meanings consumers associate with branded products in developing and developed cultures. We consider belief in global citizenship as an antecedent to the symbolic meaning of personal identity that branded products project and to importance that consumers assign to branded products. Effects of consumer ethnocentrism and cultural openness on belief in global citizenship are also examined.

Our research takes an adapted etic approach (Douglas and Craig 2006) and focuses on the global youth segment in one developed (U.S., n=218) and one developing (Russia; n=292) market. College students in the two countries were asked to complete a questionnaire that presented them with shortened measures of consumer ethnocentrism (Shimp and Sharma 1987) and cultural openness (Sharma et al. 1995). Based on past research (Alden, Steenkamp, and Batra 1999; Holt et al. 2004; Steenkamp, Batra, and Alden 2003), we developed three items to measure belief in global citizenship. We also developed fifteen items to measure the meaning of personal identity of branded products (five items each to reflect the meanings of self-identity, group-identity, and status). Because of past challenges with self-reported general measures of consumer involvement with branded products in emerging markets (e.g., Coulter, Price and Feick 2003), we developed an index measure of branded product importance for each individual based upon his/her expressed importance for branded products in ten product categories (i.e., mineral water, soda, beer, coffee, cigarettes, chocolates, personal care/cosmetics, clothing, automobiles, and televisions).

We used structural equation modeling (AMOS, 7.0) to address our goals and hypotheses. The models exhibited configural and metric invariance (Steenkamp and Baumgartner 1998), which allowed us to make model comparisons between the two countries. Both pan- and intra-country analyses were performed. As pre-

dicted, belief in global citizenship was a strong positive predictor of the brand meaning of personal identity, and this effect was stronger in Russia. The meaning of identity increased importance of branded products to an equal degree across countries. Both cultural openness and consumer ethnocentrism had positive effects on belief in global citizenship, but, contrary to our prediction, the effect of cultural openness was stronger in the U.S. and the effects of ethnocentrism were not different across the two countries. Consistent with past research, there was a moderate negative correlation between consumer ethnocentrism and cultural openness in the U.S. (Sharma et al. 1995; Shimp and Sharma 1987), but we found no relationship between these two concepts in Russia.

Our work draws attention to belief in global citizenship and importance of branded products, and examines relationships between these concepts, as well as their relationship to symbolic meanings associated with antecedents of ethnocentrism and cultural openness. Our research identifies several important opportunities for future research. First, we show that young consumers in the U.S. and Russia vary in the extent to which they believe in belongingness to the global world and view global brands as symbols of identity meanings. Global brands empower branded product discourse by enriching meanings of brands and facilitating consumer involvement with branded products. Second, we find that individuals in the U.S. and Russia who are culturally open and those who are patriotic about their locally-made products are likely to believe in global citizenship. The latter finding speaks to the notion of emerging "glocal" identities of young consumers, especially in developing markets where global brands signal a path for national empowerment and value sharing. Future research should examine potentially different, possibly curvilinear relationships between ethnocentrism and belief in global citizenship in samples of more ethnocentric consumers and over time. Finally, the relative novelty of brands and branding in Russia makes the constructs of culture and consumer culture rather distinct. Multinational corporations and local firms need to be aware of consumer's limited understanding of branding and determine appropriate local mechanisms to further develop consumer culture.

The Demand for Counterfeits-An Extended TPB Approach with Empirical Evidence from Seven Countries

Elfriede Penz, Wirtschaftsuniversitaet Wien, Austria
Barbara Stoettinger, Wirtschaftsuniversitaet Wien, Austria

EXTENDED ABSTRACT

This paper aims to broaden the knowledge on why consumers buy counterfeit products, a global concern to manufacturers of original products. Extended through the concept of self-identity, the Theory of Planned Behavior is used as theoretical underpinning in a seven-country study. Overall, findings support the usefulness of the extended TBP to explain the demand for fakes in a multi-country setting. A more in-depth look into individual linkages reveals national idiosyncrasies and provides interesting avenues for future research.

Introduction

The trade with counterfeit products has been growing dramatically across the globe, and manufacturers of the original products find themselves in a constant battle against this malpractice. In order to curb the demand for counterfeits, the knowledge on what drives customers to buy the copy rather than the original is crucial. As pointed out in the literature (Eisend & Schuchert-Güler, 2006), the knowledge base in the field is still fragmented and lacks theoretical substantiation. Thus, with our contribution, we aimed at extending existing research in various ways: (1) responding to the frequent call for more theoretical underpinning by using the Theory of Planned Behavior (Ajzen, 1991) as a framework, (2) extending it with the concept of self-identity and (3) applying the model to a multi-country sample to meet frequent calls for more cross-national research in this area (Fullerton & Punj, 1997; Husted, 2000).

Conceptual Background

In consumer misbehavior research, which uses the purchase of counterfeits as one of its classic examples (Fullerton & Punj, 2004; Green & Smith, 2002), the TPB was used previously (d'Astous, Colbert, & Montpetit, 2005); yet only in the context of software and music piracy, i.e., product categories with highly functional benefits (e.g., Kwong & Lee, 2002). For the product categories that we selected for our research; counterfeits of widely used branded products (such as textiles, handbags, accessories), the TPB was not used so far as a theoretical framework.

Branded products are used to improve the self-concept through the transfer of attributed meanings and thus the enrichment of self-value. People who are buying branded products are especially concerned about the impression they make and more sensitive to interpersonal rejections (Ang, Cheng, Lim, & Tambyah, 2001; Nia & Zaichkowsky, 2000). For this process to work, interaction with others is necessary. Others deliver meaning to brands, as brands are interpreted differently by different consumer groups (Hogg, Cox, & Keeling, 2000).

Through the concept of subjective norm, the TPB takes the role of social influences on the purchasing behavior into account (Terry, Hogg, & White, 2000). Theoretically, the purchase of counterfeits is based on similar contentions: buying fake products means getting the prestige of branded products without paying for it (Cordell, Wongtada, & Kieschnick, 1996), thus indicating suitability of TPB also in our research context. Recently, concerns were raised that subjective norm exhaustively covers external influences on purchasing decisions (Thorbjørnsen, Pedersen, & Nysveen, 2007). Research strongly points towards self-identity as a meaning-

ful extension of the TPB (Armitage & Conner, 2001; Mannetti, Pierro, & Livi, 2002; Thorbjørnsen et al., 2007). In that respect, self-identity has been used in purchasing settings, where ethical considerations are an important influence (Shaw & Shiu, 2003; Sparks, 2000). While buying counterfeits represents unethical consumer behavior, the underlying arguments related to self-identity may apply similarly in our research context.

Methodology

Based on existing literature and the contentions outlined above, a model was developed. Attitudes towards counterfeits/counterfeiting, the subjective norm (operationalized in three ways: as direct social influence through immediate peers, interpersonal influence susceptibility, consumer motivation), perceived behavioural control, perceived access to counterfeits and price consciousness were outlined as drivers of intention. Ethical disposition, self identity and fashion consciousness were modeled as antecedents. The model was tested at two different price levels (counterfeit is significantly/slightly cheaper than the original).

We tested our theoretical model in seven countries, namely Mexico, Thailand, Ukraine, Slovakia, the U.S., Austria and Sweden. Country selection is based on Husted's (2000) work who identified three factors as important drivers of the demand for counterfeits (GNP per capita, distribution of income, individualism). Data were gathered by means of a questionnaire survey. After pre-testing and checking for content validity of the measures, the final questionnaire was made available in the languages pertinent in the countries chosen. Linguistic equivalence between the different versions was established through back-translation (Brislin, 1970).

Findings and Discussion

As results show, the general model structure we proposed appears to be universal with an acceptable fit across the seven countries and the two different price levels. So, with our research goals in mind, the extended Theory of Planned Behavior on an overall level serves well as a theoretical framework to predict the demand for counterfeits across countries.

A more in-depth look into individual linkages revealed a multi-faceted picture. While attitudes do have an effect on intentions to purchase, linkages differ in strength on a country basis. This holds even truer, when it comes to the antecedents to attitudes. Influences other than attitudes turned out to be more stable across countries when predicting purchase intention. Perceived behavioural control was a particularly important influence on the intention to buy. Similarly important and consistently, price consciousness does NOT influence the intention to buy. This contradicts the conventional notion and arguments put forward in the literature. The access to counterfeits turned out to be influential in explaining intentions to buy, yet less strongly and consistently than the other two factors.

The importance of social norm as proposed in TPB holds true to a large extent. Particularly, the immediate social environment plays an important role, while on a more general level (interpersonal influence susceptibility, consumer motivation) the impact of social norm is fading. Self-identity does not impact intention directly, but very much indirectly via the subjective norm.

In terms of future research, given the national idiosyncrasies, it appears called for to investigate in more depth how attitudes are formed on a national level and in what way the antecedents proposed influence this formation. Moreover, deepening the insights into how and on what level self-identity and subjective norm are related and influence other constructs would contribute to the theoretical advancement of TPB. Finally, while the general model structure appears to be universal, the specific variable values at national levels point to cultural influences. Exploring and explaining these national/cultural idiosyncrasies will be helpful to deepen the understanding of why consumers buy fakes.

An Exploratory Study of Media Multitasking Practices and Experiences among Young Consumers

Andrew Rohm, Northeastern University, USA
Fleura Bardhi, Northeastern University, USA
Fareena Sultan, Northeastern University, USA

EXTENDED ABSTRACT

An increasingly important line of inquiry in consumer behavior is the study of the ways consumers multitask across multiple forms of media in a simultaneous fashion (Pilotta and Schultz 2005). Simultaneous media consumption, which we call media multitasking, is a phenomenon born from the plethora of media and communications platforms available and easily accessible to consumers, especially among young consumers. The media landscape and delivery system itself has changed dramatically in recent times. Contemporary media employs multitasking formats, such as television newscasts displaying multiple messages on one screen, enabling viewers to access several different news items simultaneously. Further, consumers are no longer passive media spectators, but interact with media in co-production settings, such as seen with consumer-generated advertisements or text-message voting for a favorite singer in television shows such as *American Idol*. However, marketing research continues to examine media consumption and treat marketing communication issues under a sequential, traditional marketing communication model where the consumer is a passive receiver of one type of media at one time. This study represents a first attempt to examine the phenomenon of media multitasking and its implications for marketing communication concepts and strategy.

Media multitasking, the simultaneous consumption of multiple media platforms seems to be the norm, especially among young Gen Y consumers who have grown up amidst today's vast media landscape. According to a nation-wide survey study reported by *Time* magazine, Americans aged 8 to 18 not only consume the greatest amount of media, but through electronic media they can compress 8.5 hours worth of media time a day into a 6.5 hour time-period through simultaneous consumption (Wallis 2006). This study attempts to a) examine media multitasking behavior among young consumers and b) provide an understanding of their motivations, experiences, and coping with media multitasking.

The study of multitasking has primarily been the domain of cognitive psychology, concluding that multitasking threatens consumers' task effectiveness, learning and well being. However, the cognitive perspective ignores the socialization aspect of behavior. Mick and Fournier (1998) illustrate the ways individuals attempt to cope with the ubiquity of technology. Consumers may also develop specific skills with which to manage and even automate performance involving multiple tasks (Kanfer and Ackerman 1996). In some instances, consumers may be more effective while multitasking when they are able use technology to complement or supplement other media (Sinan, Brynjolfsson, and Alstyn 2007; Jenkins 2006). For example, consumers may seek to complement and add depth to their media experience by searching for results of a sporting event online while they are simultaneously watching the event on television. Therefore, consumers may adopt multitasking strategies in order to increase comprehension and effectiveness in the consumption of online and offline media. Highly practiced skills, such as sequential or simultaneous multitasking across sources of media, may be developed as strategies to deal or cope with vast amounts of media communications sources or outlets (Sinan, Brynjolfsson, and Alstyn 2007). In what he refers to as the participatory culture,

Jenkins (2006) also suggests that because of the rise in access to digital media, particularly among the youth market, multitasking and attention should not be viewed as an "either, or" proposition, given that the nature of attention to media among young consumers has changed to that of continuous partial attention. In other words, consumers born and raised during the Internet era are perhaps becoming more skilled at navigating between and effectively managing multiple sources of information and media content.

The goal of the study is to examine the experience of media multitasking from the perspective of the young Gen Y consumer. Therefore, we selected as a purposeful sample for the study 64 undergraduate students at a university in the northeastern U.S. The students were also screened on their media consumption to insure that they continuously participate in media multitasking. As this is an exploratory study, a qualitative approach was taken. Data were collected through semi-structured interviews and collages developed to portray their media consumption.

We found that media multitasking is a normal activity in students' lives driven by a) the ease of accessibility and the interactive nature of contemporary media; and b) the participatory culture in which they live. For Gen Y, work, leisure, socialization, and personal self-development are closely related with exposure to various media and communications technologies. We found that most media multitasking evolved around the offline (television) and the online (computers). Consistent with past research, our findings suggest that television is typically consumed as a background media, whereas online sources (e.g., the Internet) act as foreground media characterized by discrete burst of engagement and attention. Two types of media multitasking behaviors emerged that differ in terms of the role of the consumer as either *active participant* or *passive victim*, as well as in terms of the individual's level of attention and engagement. The first type of media multitasking behavior involves *strategic switching* between various media platforms. The second type of multitasking is a passive mode of behavior, characterized by the individual constantly tuning in and out various media with the goal of simply being "always on".

Media multitasking is considered by our informants as paradoxical. Our data suggests that the multitasking experience parallels a subset of consumer paradoxes of technology developed by Mick and Fournier (1998): efficient/inefficient, connectivity/isolation, and freedom/enslavement. To cope with these paradoxes consumers develop various coping strategies (Mick and Fournier 1999) from restriction of media usage to the refinement of personal media consumption practices. The majority of our informants claimed that, while they were aware of personal issues and challenges associated with their media consumption, they have become effective multitaskers as a result of their active participation as consumers of contemporary media and the associated role of media as a socialization agent within the youth participatory culture. Based on these findings the paper provides implication for theory and practice.

The Role of Symbolic Consumption in Identity Projects: The Case of Fostered Children

Margaret K. Hogg, Lancaster University, UK

Maria G. Piacentini, Lancaster University, UK

Sally Hibbert, Nottingham University Business School, UK¹

EXTENDED ABSTRACT

Consumption impacts identity projects especially when it facilitates, accelerates, ameliorates or impedes identities in transition. Earlier studies have largely examined identity transitions within the context of privileged groups of consumers, to the relative neglect of less privileged consumer groups. Negative experiences such as stigmatization can impede identity transitions by interrupting the acquisition not just of an adult identity, but also of some of the essential consumer skills for operating in the marketplace, thus threatening self-esteem. The empirical context represented by less privileged groups such as fostered children, for instance, could offer significant additional theoretical insights into the impact of consumption experiences on identity projects. The literatures on transition and emerging adulthood informed our examination of the lived experiences of young fostered people.

Young people in the transition to adulthood in post-industrial societies have the opportunity to explore a wider range of potential identities because the current cultural environment is less normatively structured (Bauman 2001; Cote 2002). While this brings opportunities for self development, the task of configuring a coherent identity that will provide the basis for adult roles in work, family and home life, often creates a psychological burden (Schwartz et al. 2005). Evidence suggests that a sense of agency and the ability to exercise free choice are crucial to successfully undertaking future adult roles such as parenthood, employment and marriage (Schwartz 2004); and yet the ability to exercise agency and free choice are not necessarily enjoyed by all sections of society, often reflecting structural inequalities in the marketplace. During their transitions to young adulthood, fostered children often face the additional burden of managing social stigma and stereotyping in their identity projects because "at its core, the experience of stigma is fundamentally a threat to the self" (Crocker and Garcia 2006: 289).

We used a range of contacts (e.g. charities that support fostered young people; a lobbying organisation run by care-experienced young people; and support workers) to recruit sixteen young adults for group and individual interviews over an eight month period. All participants were aged between 16 and 21; and had either left care to live independently or were preparing to do so. A token incentive was paid to each participant. Focus group discussions with nine participants lasted between sixty and ninety minutes; and were held in single-sex groups (four men and five women). Nine individual interviews were held (7 women and 2 men). Each interview lasted between one and two hours. Open-ended questions were used to elicit the experiences of young fostered adults, and about how the fostered children had coped with those experiences in the transition to adulthood. Intratextual and intertextual interpretive analyses (Adkins and Ozanne 2005) were used, moving between deductive and inductive approaches. The interview framework was used for deductive analysis around themes such as experiences of leaving

care. Inductive analysis was used to identify emergent themes (e.g. different views of the self; vulnerability; and coping strategies).

These fostered children's experiences showed how consumption was used to achieve selfhood and personal identity (Hirschman and Hill 2000); the role of the material in identity formation processes; and particularly the creation of meaning via consumption including symbolic consumption and the extended self (Belk 1988). For the purposes of this paper, we follow Thompson (2005) and focus on three participants' stories (Veronica, Theresa, Krista) to illustrate the major themes which emerged from our overall data set about symbolic consumption in relation to transitional objects; precious possessions and relationships; and identity threats from stereotyping (that is, the fear that one's behavior will confirm an existing stereotype of a group with which one identifies).

At times of transition, possessions play an important role, symbolising relationships and helping to enhance feelings of psychological well-being during liminality (Noble and Walker, 1997). Our informants tended to have few material goods but these were very important to their psychological well-being, reinforcing the importance of transitional objects as identity markers. Krista's desk was a transitional, almost epiphanic (Woodward 2001) object, that had moved with Krista from her care home into her new flat, marking also her transition to adult status by living independently, and managing her household expenses via careful budgeting (e.g. the desk demonstrated her ability to save and to allocate resources carefully). This suggests scope for seeing the extended self (Belk 1988) in a much more nuanced way within the context of individuals' earlier consumption and attachment histories. In the context of the vulnerable youth coming out of foster care, the role of possessions is particularly important, confirming the role of symbolic consumption in transitions (Gentry et al. 1995; McAlexander 1991; Price et al. 2000; Roster 2001; Schouten 1991; Young 1991). Our research also builds on Hirschman and Hill's (2000) work on the role of possessions and the impact of restricted consumption on identity; and resonates too with recent work on refugees (Parkin 1999) who share characteristics in terms of the uncertainty of life, the transitoriness of possessions, and the brittleness of relationships.

Their children were sacred possessions, representing very important attachment objects for the fostered young women who themselves had experienced very poor histories of attachment in their own young lives. Veronica's story about the birthday party she had held for her daughter Megan illustrated how symbolic consumption was used to mark her precious daughter's birthday, and inscribe familial relationships. Veronica could thereby demonstrate that she had the means to be an indulgent, as well as caring, mother, and thus pass one of the key tests of adult identity (i.e. parenthood, George 1993).

Symbolic consumption emerged as a response when an identity threat was perceived from stereotyping, even when a young person's foster care status was concealed. For Theresa it was very important to be able to 'pass as normal' and to be accepted as a mother. She felt her physical appearance was instrumental in allowing her to disconnect from an earlier negative identity that might be attributed to her; and her physical appearance was closely tied to her self-esteem. Theresa fought hard to conceal aspects of her past that directly related to her being fostered (particularly the

¹Acknowledgements: The authors would like to thank all the young people who participated in this study as well as the U.K. national children's charity, Barnados and the local government Morecambe Leaving Care Team (U.K.) for their generous assistance. We would also like to thank Russell Belk and Pauline Maclaran for their comments on earlier drafts of this paper.

people who had constituted her social network when she was fostered). Her appearance served to 'disguise' her from past social ties; she had changed her hair colour and had facial piercings to avoid being recognized by former friends. She was particularly anxious to protect her child and her partner from her past. This earlier youthful (negative) identity was in tension with the adult (positive) identity that she was trying so hard to move towards, particularly that of a caring mother who could be a good role model for her child.

Stories from fostered children show how they employ symbolic consumption in their strategies to resist and counteract the threats from their earlier negative identities as 'fostered children' as they forge new identities as young emergent adults and consumers. From their stories we see how they employ contingencies of self-worth in order firstly, to enhance their self-esteem in the key transitions to establishing an adult identity (becoming parents and establishing family life); and secondly to counter feelings of low self-esteem which contribute significantly to consumer marginality, vulnerability and disadvantage.

The Roles of Affective and Cognitive Components of Attitudes in the Context of High-Stakes Healthcare Decisions

Tracey King, American University, USA

EXTENDED ABSTRACT

This study is an attempt to shed light on the interplay of affective responses and cognitive beliefs in determining consumer attitudes towards high-stakes healthcare decision behaviors. High-stakes consumer decisions are defined as those involving subjectively important and risky outcomes (Kahn and Baron 1995; White 2005). The primary goal is to test the hypothesis that affective responses, compared to cognitive beliefs, are more important in determining attitudes towards hormone replacement therapy (HRT) use. Using structural equations modeling, attitudes and intentions towards HRT use are predicted within a network of relationships based on the theory of planned behavior framework (Ajzen 1991). The basic theory of planned behavior model was expanded to include the separation of affective and cognitive predictors of attitude towards HRT use (Edwards 1990).

One particular high-stakes decision context in which consumers are actively determining their choice of treatment is the decision of whether or not to use HRT. This treatment involves both risks and benefits, remains controversial among healthcare professionals, and is a decision almost every female consumer makes as she reaches menopausal age. In the literature on high-stakes decision making, it is argued that individuals may have a tendency to make these types of decisions using heuristics or general rules of thumb, including an overall affective reaction (Kunreuther et al. 2002; Loewenstein et al. 2001). Although there have been a number of studies that examine the cognitive influences on attitudes and intentions towards HRT use (Spatz et al. 2003), there is only limited research that considers the importance of affective responses in determining attitudes towards HRT use.

A sample of women (N=369; median age=51) provided the data to test the above hypothesis and the relationships in a model predicting intentions to use HRT. The respondents were administered a questionnaire containing self-report measures for constructs including (1) cognitive beliefs (e.g., "I think that using HRT is safe (vs. unsafe)"; $\alpha=.81$) (2) affective responses (e.g., "Using HRT makes or would make me feel anxious (vs. not worried)"; $\alpha=.83$), (3) subjective norms (e.g., "People who are important to me would encourage me to use HRT"; $\alpha=.93$), (4) perceived behavioral control (e.g., "I am confident that I could use HRT if I wanted to"; $\alpha=.86$), (5) attitude towards HRT use (e.g., "My overall attitude towards HRT use is favorable (vs. unfavorable)"; $\alpha=.96$), and (6) intentions towards HRT use (e.g., "I expect to use or continue to use HRT in the future"; $\alpha=.99$). All items were measured using 7-point semantic differential or Likert scales.

The first step in the analysis of the conceptual model and hypotheses tests was to assess the properties of each measurement instrument by performing a confirmatory factor analysis (CFA) using LISREL (Jöreskog and Sörbom 1996). The fit indices of the measurement model showed good fit ($\chi^2=279.46$, $df=120$, $p<.01$, CFI=.98, RMSEA=.60) and the validity and reliability of the measures were confirmed. The next step was to examine the structural relationships in the model and assess model fit. The fit indices showed that the model had an acceptable fit ($\chi^2=194.36$, $df=124$, $p<.01$, CFI=.98, RMSEA=.61) based on the criteria published by Jaccard and Wan (1996).

The structural results indicate that attitude ($\beta=.49$, $t=11.78$, $p<.01$) and subjective norms ($\gamma=0.40$, $t=9.57$, $p<.01$) both had positive and significant effects on intentions to use or continue to

use HRT. However, perceived behavioral control ($\gamma=.07$, NS) had a nonsignificant effect on intentions to use or continue to use HRT. The path between affective responses and attitude towards HRT use was also positive and significant ($\gamma=.82$, $t=14.17$, $p<.01$). However, the path from cognitive beliefs to attitudes towards HRT use was positive but nonsignificant ($\gamma=.09$, NS).

The results provide support for the hypothesis that affective responses are a stronger predictor of attitudes compared to cognitive beliefs. Although the nonsignificant relationship between cognitive beliefs and attitudes towards HRT use was surprising, it is consistent with research on high-stakes decision making that shows that ambiguity as to what would constitute a 'right' answer can lead individuals to make choices by focusing on affective cues instead of cognitive beliefs (Kunreuther et al. 2002). To formally test this assertion, feelings of attitudinal ambivalence were measured using a four-item scale ($\alpha=.76$) regarding how 'torn' one feels about the behavior. When entered into a linear regression, cognitive beliefs are shown to be a significant predictor of attitudinal ambivalence ($\beta=.13$, $t=2.12$, $p<.05$) whereas affective responses are nonsignificant ($\beta=.04$, $t=.65$, NS).

The Role of Cultural Identity and Personal Relevance on Risk Perception and Avoidance

Chrissy Mitakakis, Baruch College, USA

EXTENDED ABSTRACT

In the globalized world that we now live, the media keeps warning us about health threats such as the avian flu, mad cow disease, E.coli, etc. from different countries. It is generally assumed that perception of risk among citizens depends largely on the perceived likelihood of occurrence of the threat (Luce and Kahn 1999; Menon, Block, and Ramanathan 2002). However, little is known on whether risk perception depends on how culturally similar the origin of the threat is to one's own? For instance, would Californians feel more at risk if the health threat originated in England versus in Japan, although both countries are advanced and at almost the same distance? This paper attempts to answer these important questions.

Scholars investigating the psychological closeness phenomenon suggest that people are more likely to assimilate self-evaluation to the standard if they feel psychologically closer to him or her (Brown et al. 1992). Along similar lines, Teigen's (2005) proximity heuristic theory in judgment of risk suggests that perceptions of proximity influence people's perceptions of their own and other people's risk. He exemplifies this proximity phenomenon by saying that the death of a close relative is more threatening than the death of a distant one, even when genetics is not the cause of death. A somewhat opposing view to the heuristic proximity theory is the one on defensive processing of threatening messages. Liberman and Chaiken (1992) suggest that threatening messages that are personally relevant may lead people to engage in defensive and biased processing in an attempt to reduce the threat. In this case, we can expect that health risky situations that are perceived to be highly personally relevant may lead to message avoidance or denial of susceptibility and hence reduce the perception of risk.

It is common knowledge that people feel psychologically closer to culturally similar groups. We propose that this feeling of closeness with the origin of a threat increases one's perception of risk and behavioral intentions. However, when personal relevance is increased, it can lead to a rejection of the risk.

In this research, using a context of people being affected by contaminated beef and dairy products, we conducted three studies to examine consumers' perception of risk from potentially consuming the contaminated food and their consequent willingness to engage in behaviors to avoid the risk. We demonstrate that when the risk is highly likely to occur, perceived risk and behavioral intentions are high only when the threat originates in a culturally similar country. However, when risk is less likely to happen, perceived risk and behavioral intentions are unaffected by the cultural similarity with the originating country. Furthermore, we show that even in the case of a culturally-dissimilar country, perceived risk and behavioral intentions can be high when the threat is high, provided that personal relevance is also high. In the case of the culturally-similar country, when personal relevance is high, it lowers their perception of risk and behavioral intentions.

Participants in studies 1 and 2 were given a fictitious news article that reported a food contamination in a foreign country and some citizens in that country being affected as a result. Likelihood of threat occurrence was communicated by manipulating the strength

of the warning issued by local (Canadian) health officials about the possibility of food imported from that country being contaminated. In study 1, our data show that when the contaminated food was said to be imported from a culturally similar country (UK), consumers perceive a greater risk and behavioral intentions when the likelihood of threat occurrence is high and a lower risk when the likelihood of threat occurrence is low. However, when the contaminated food was said to be imported from a culturally dissimilar country (France), risk perception and behavioral intentions were low regardless of the likelihood of occurrence of the threat. These results indicate that the likelihood of threat occurrence impacts risk perceptions and behavioral intentions only when the threat originates in a culturally similar context. When the origin of the threat is seen as culturally distant, consumers underestimate the risk and are less willing to engage in behaviors to avoid the risk even when the risk is highly likely to occur.

In study 2, we manipulated personal relevance by the news article specifying that the persons affected by the contaminated food were students (high personal relevance) or not specifying (low personal relevance). We demonstrate that when the origin of the threat is a culturally-dissimilar country, perceived risk and behavioral intentions are high when the likelihood of threat occurrence is high only in the highly personally relevant condition. Interestingly, in the case of the culturally-similar country (UK), when the victims were reported to be students, perception of risk and behavioral intentions drop in the case of high likelihood of threat occurrence. We argue that this happens because consumers activate a defensive mechanism (Liberman and Chaiken 1992) that makes them reject the threat as not being credible. The results of study 2 mirror study 1 when the victims were said to be just people.

In study 3, using Germany as our culturally similar condition and Spain as our culturally dissimilar condition, we were able to replicate the findings from studies 1 and 2. This was done to eliminate any potential dissociative biases arising from English Canadians' perceptions of France.

This paper makes two important contributions. First, it demonstrates the moderating role of cultural similarity in perception of risk and behavioral intentions to avoid the risk in the face of an external threat. Second, it shows that when the message concerns a possible negative outcome, increasing the personal relevance of the threat results in rejecting the risk, counter to common knowledge that communications need to help the consumer relate to them in order to be effective.

Certainty Appraisal and Health Communications

Canan Corus, St. John's University, USA

EXTENDED ABSTRACT

Introduction

Individuals employ defensive mechanisms when faced with health information that might perturb their sense of security. Efficacy of health communications are undermined as high risk individuals who are the target of most campaigns are also those who are most likely to reject or ignore them (Block and Williams 2000). Recent research suggests that aversion towards relevant health information is diminished under positive emotions. If the benefits of negative information are essential, as in the case of self relevant messages, then positive affect acts as a resource for buffering the mood hurting influence of threatening information, while under negative affect, one lacks the confidence to deal with the adverse emotional effects of threatening health information (Raghuathan and Trope 2002).

Conceptual Framework

This research examines the role of discrete incidental emotions on the effectiveness of health communications. Certainty appraisal (Smith and Ellsworth 1985) differentiates emotions on the basis of predictability that they convey about the environment. For example, when people feel angry, they report thinking that the situation is unpleasant but that they are certain and confident about what is happening. In contrast, when one feels anxious, the situation is unpleasant but also less predictable.

It is proposed that emotions high on certainty appraisal can provide the confidence to cope with the insecurity instigated by relevant but threatening health messages. Previous research shows that high certainty (e.g., anger, pride) makes one feel more resilient to risk (Lerner and Keltner 2001) or assess the situation as manageable (Johnson and Stewart 2005). It is proposed that those feeling certain might conclude that they need not refrain from processing an aversive but useful message. On the other hand, individuals feeling uncertainty associated emotions (e.g., anxiety, hope) are motivated to decrease their uncertainty (Raghuathan and Pham 1999). We suggest that the threatening nature of highly relevant health information is likely to be in conflict with uncertainty reduction goals, leading to decreased processing of this information. Thus, we suggest that when a health message is highly self-relevant, uncertainty related emotions will impede processing whereas certainty related emotions will facilitate processing of relevant health messages.

A different mechanism is likely to be at work when the health risk is *not* self relevant and therefore *not* as threatening. We predict that when relevance is low, the projected effect of the message for one's affective state will be less influential (Andrade 2005). Therefore, the message's implications for one's uncertainty related goals will be less relevant. In this case, emotions low (high) on certainty appraisal signal insufficient (sufficient) confidence about the surroundings, leading to increased (decreased) processing. These predictions would be in agreement with Tiedens and Linton (2001) findings that certainty related emotions lead to heuristic processing.

Studies 1-3

When individuals are at low (high) risk, those who are induced with uncertainty (certainty) related emotions will process a health related message to a higher extent compared to participants who are

induced with certainty (uncertainty) related emotions. The first 2 studies directly test this hypothesis.

In study 1 participants were induced to feel anger (negative-certain emotion), pride (positive certain emotion), worry (negative-uncertain emotion) or surprise (positive -uncertain emotion). They then read an article about Chlamydia, a prevalent STD. Individuals were categorized as high versus low risk according to their past sexual behavior. The dependent measures were: message related thoughts, correct answers to a quiz about the article and a message persuasion intention measure. As expected, High risk individuals showed higher message recall and were more persuaded under certainty related emotions while the opposite was true for low risk individuals.

Study 2 replicates the results of study 1. In this study, perceived vulnerability was manipulated by conveying either high or low prevalence of the health threat. Further, emotions different from those in study 1 were used (i.e., hope and happiness). The procedure and dependent variables were similar to those of study 1 but this study focused on a different health issue, Hepatitis C. The results of study 1 were replicated. Further, in study 2, we wanted to rule out alternative explanations which may involve other relevant appraisals (i.e., pleasantness, situational control and intensity). Hence, we regressed vulnerability and a composite appraisal measure on the dependent variables. Results show that certainty was the *only* emotional dimension that interacts with vulnerability in the predicted direction. The regression results confirm that in the high risk condition, the more certain participants felt about the situation (i.e., higher certainty appraisal) the more they processed the message. Thus, it provides further support for the proposed effect that high certainty provides encouragement for processing useful but intimidating health information.

Study 3 not only extends the findings to a different health context (i.e., caffeine consumption) but also provides evidence that the demonstrated effects are indeed a function of the threatening nature of health related information. In this study, participants are presented with negative as well as positive information on caffeine consumption. Inducing four negative emotions that range in their certainty appraisals (i.e., fear, sadness, anger, disgust) we show that emotions that are associated with higher certainty increase individuals recall of negative information as compared to positive information and this effect is reversed for uncertainty related emotions.

Conclusion

In sum, the findings support the proposition that certainty-related emotions provide confidence to attend relevant but threatening information. Whereas, when feeling uncertain emotions, reading threatening health information clashes with uncertainty reduction goals, decreasing message processing and persuasion. These findings are in agreement with affect regulation theories and extend them to involve emotional uncertainty as an emotional state to be "repaired", by avoiding further uncertainty or striving for reassurance. The implications of this research concern the context (e.g., emotion laden program) in which a health message should be placed as well as its tone (e.g., high vs. low threat) that should be used in that context.

The Effects of Retrieval Ease on Health Issue Judgments: Implications for Campaign Strategies

Chingching Chang, National Chengchi University, Taiwan

EXTENDED ABSTRACT

A common opinion among psychologists studying metacognition is that “there is more to thinking than thought content” (Schwarz, 2004, p. 332). The literature on metacognition suggests that recall tasks render two types of information accessible: the retrieved content and the subjective experience of retrieving the content (see Schwarz, 1998, 2004, for reviews). Both types of information can influence judgments. Content-based thinking models (e.g., Wyer & Srull, 1989) hold that the more instances of an event that individuals are asked to recall, the more instances they will retrieve, and the higher they will thus estimate the frequency of the event to be. In contrast, metacognition models suggest that the more instances individuals are asked to recall, the more difficulty they will experience with retrieval (Schwarz, 1998, 2004). This subjectively experienced retrieval difficulty is then taken as an indicator that such events do not happen frequently.

Accordingly, thinking about the severity of a disease can render two types of information available: the retrieved consequences of the disease and the ease or difficulty with which they were brought to mind. Rothman and Schwarz (1998) found that, when asked to list many as opposed to a few factors leading to a disease, participants experienced more difficulty with the retrieval task, decreasing their perceived vulnerability to the disease. By extension, when people are asked to list possible outcomes or symptoms regarding an ailment, the difficulty with which such information comes to mind should affect their judgments of the ailment’s severity. This question was tested in the first experiment of the present study.

In order to maximize willingness to seek treatment, it is also crucial to increase perceived self-efficacy in dealing with an ailment. Thus it is relevant to ask whether the difficulty of retrieving prevention or treatment options influences perceived self-efficacy. This issue was addressed in the second experiment.

When thinking about health issues, people often consider the severity of the issue. If it is difficult to retrieve many instances of serious consequences, the issue should be seen as less serious. Therefore, it is important for health campaigners to work to reduce ease of retrieval effects by reminding people about the severity of health issues. Experiment three addressed the prediction that when public service announcements (PSAs) render more information accessible, subjective experiences will not be used as judgment inputs and the retrieval ease effect will be weaker.

Experiment four focused on the idea that, for issues of higher general concern, people will tend to engage in content-based processing. This mode of processing should also be more prevalent among individuals who are particularly concerned about the specific target health issue. When individuals who are thus motivated to engage in content-based processing attempt to list many disease consequences, they should perceive the disease as more severe and their vulnerability to it as higher, and find the health message to be more effective.

In sum, the present study had four objectives: first, to test for ease of retrieval effects on issue severity when the retrieval task involves listing disease consequences; second, to examine ease of retrieval effects on self-efficacy when the retrieval task involves listing prevention or treatment options; third, to test whether making more relevant information accessible attenuates the effects

of retrieval ease; and finally, to examine the effects of retrieval ease when PSAs encourage content-based processing.

Findings supported the predictions. In the first experiment, ease of retrieval was manipulated by asking participants to list either a high or low number of consequences of an ailment. As expected, retrieval difficulty resulted in lower perceived disease severity. In the second experiment, ease of retrieval was manipulated by varying the number of disease prevention or treatment measures participants attempted to list. As predicted, retrieval difficulty resulted in lower self-efficacy regarding prevention and treatment. In two additional experiments, participants viewed a public service announcement (PSA) highlighting the consequences of contracting a particular disease. Ease of retrieval effects were observed only when the manipulation involved irrelevant information (number of prevention/treatment options) and not relevant information (number of consequences). Furthermore, when the health issues were of greater concern, content-based rather than experience-based judgment appeared to be stimulated, and attempting to list more disease consequences resulted in higher ratings of disease severity.

Toward a More Comprehensive Theory of Attitude Change: The Effects of Inter-Attitudinal Concept Structure on Attitude Dynamics

Leslie D. Dinauer, University of Maryland University College, USA

EXTENDED ABSTRACT

Theories of inter-attitude relationships and attitude change have failed to identify the architecture of inter-attitudinal structures and then clarify its relationship to attitude and belief change. Such a failure is critical to consumer researchers for whom understanding attitudes is a primary pursuit. This theoretical study examined two competing models of inter-attitudinal structure that explicitly address the influence of inter-attitudinal structure on attitude change dynamics: a hierarchical model (Hunter, Levine, Sayers, 1976, 1984; Poole and Hunter, 1979) and the Galileo spatial-linkage model (Woelfel and Saltiel, 1988; see also Kaplowitz & Fink, 1988; Woelfel & Fink, 1980). The results should inform consumer attitude research and lead to more accurate measurement of consumer attitudes, as well as to the production of more effective persuasive messages.

Each of the models in the study posits an inter-attitudinal structure that makes a number of predictions regarding how attitude change occurs between and among associated concepts. In a hierarchical model, a change in attitude toward a concept in a hierarchy is hypothesized to be constrained by the structural relationships of the hierarchy (i.e., one's attitude towards animals in general is not affected by a change in one's attitude towards dogs). In the Galileo spatial-linkage model such constraints are loosened and it is hypothesized that attitude change toward any concept in a group of linked concepts will result in absolute change across all linked concepts.

The between-subjects experiment in this study presented participants with pictures of either an *explicit* hierarchy (i.e., one that consists of concepts that are super- and subordinate to each other as a result of their denotative meanings) or an *implicit* hierarchy (i.e., one that consists of concepts that are not obviously super- and subordinate to each other as a result of their denotative meanings; however, when people are asked to organize a set of concepts that form such a hierarchy, the super- and subordinate relationships emerge) and then measured participants' attitudes after they processed a persuasive message. To accomplish this, three hundred ninety-one students enrolled at a large eastern university were randomly assigned to one of 26 questionnaire conditions: 2 (Hierarchy: explicit vs. implicit) x 2 (Priming: primed vs. unprimed) x 3 (Persuasive Message Target: Superordinate concept vs. Subordinate Concept 1 vs. Subordinate Concept 2) x 2 (Question Order: ascending vs. descending) plus two control groups. They were exposed to the randomly assigned hierarchy exposure and priming conditions and consequently administered the questionnaire. Additionally, prior to the study, ten pilot studies ($N=271$) had been conducted that determined the content of the explicit and implicit hierarchies and the measurement instrument used in the study.

Adjusted geometric mean distances among nine experimental concepts as measured in the questionnaire were input into the Galileo computer program V56 (Woelfel, 1993). This generated 14 multidimensional spaces, one for each of 2 x 3 x 2 experimental conditions plus two controls. The program rotated each space to the same orientation and transformed it to a least-squares best fit so that the spaces could be similarly aligned and visually compared. The first two dimensions in each space accounted for at least 79% of the variance of the real space involved as per Miller's (1988) procedures to check the reliability of the paired-comparison judgments.

Thus, the true spaces were very close to two-dimensional and the generated spaces were relatively accurate representations of the arrangements of their respective concepts. This "true" two dimensionality increased the validity of conclusions drawn from examinations of the graphs, however, supplemental analyses of variance and structural equation modeling offered additional support.

Analyses of the multidimensional cognitive spaces show that linguistic organizational structures influence attitude change. However, it is the Galileo spatial-linkage model that provides a theoretical structure which makes the more correct set of predictions about how concepts affect one another. The results also support the spatial-linkage model's suggestion that such inter-attitudinal change is constrained less by a concept's relative position in the structure and more by the strength of the concept's association with other concepts in that structure. Furthermore, within these inter-attitudinal structures, concepts directly targeted by a persuasive message often exhibit less attitude change than related concepts.

The results hold several important implications for consumer researchers, and should lead to more accurate measurement of consumer attitudes, as well as to the production of more effective persuasive messages across consumer influence areas. First, the results support the Galileo model's operationalization of a process of inter-attitudinal influence that has been previously described but for which no consistent cognitive mechanism has been suggested. For example, Converse's (1964) renown and popular discussion of belief systems in mass publics proposes that people's attitudes and beliefs are enmeshed in a greater network of peculiar, often irrelevant, ideas that exert influence over the network. The Galileo spatial-linkage model provides a model of cognitive processing that explains why such influence occurs. Moreover, because the model suggests that this influence is not uncommon, support for the Galileo model as demonstrated in this study also suggests that consumer attitude researchers should pay more attention to the seemingly irrelevant attitudes that might provide access to a difficult to reach attitude of interest.

Because the results suggest that it is possible to affect attitudes indirectly, there are tremendous implications for those in the applied consumer research field who design persuasive messages about sensitive topics (e.g., obesity, debt). For example, the results of the study suggest that talking to individuals about specific purchases, as opposed to talking about shopping in general, may be more effective as a debt counseling strategy. Moreover, simply the act of making accessible an individual's specific shopping-related cognitive space, and revealing the implicit associations to him or her, may increase the effectiveness of debt counseling by creating a new awareness of the previously unknown links and influences between attitudes and behaviors.

The Illusion of Avoiding Bias: How Correcting for Perceived Bias Can Make a Recommendation More Effective

Francine Espinoza, University of Maryland, USA
Rebecca Hamilton, University of Maryland, USA

EXTENDED ABSTRACT

Based on previous research, we expect that consumers would be more influenced by a recommendation coming from a trusted source (e.g., a friend) than by a recommendation coming from a distrusted source (e.g., a salesperson; Wilson and Sherrell 1993). However, we demonstrate that this is not always the case. Research on bias correction shows that individuals correct for perceived bias in their judgments by making adjustments in the direction opposite to which they believe the context is influencing their judgments (Wegener and Petty 1995). Because consumers may naturally resist a recommendation from a distrusted source, attempting to remove bias from their judgments may, ironically, increase rather than decrease the effectiveness of a recommendation from a distrusted source. As a result, a recommendation from a distrusted source can become not only more effective, but just as effective as a recommendation from a trusted source.

We examine three potential explanations for the moderating effect of correction on source trustworthiness effects: Changes in perceptions of ulterior motives of the recommender; changes in overall attitudes towards the recommended product; and changes in judgment (attitude) certainty. Building on previous research (Tormala and Petty 2002, 2004, Tormala, Clarkson, and Petty 2006) we propose that judgment certainty is mediating the effect.

We focus on the role of certainty because research suggests that attitude certainty can change as a result of consumers' observing their reactions to a persuasive attempt (Tormala and Petty 2002, 2004). Assuming that correction instructions motivate individuals to observe their reactions and to resist the influence of a recommendation (Briñol et al. 2004), we predict that asking consumers to correct their judgments will change the certainty with which participants hold their judgments. Therefore, we propose that certainty, rather than perceived ulterior motives of the recommender or overall attitudes toward the products, will mediate the effect of source trustworthiness and correction on willingness to buy.

Study 1 ($N=71$) employed a 2 source trustworthiness (friend vs. salesperson) \times 2 correction (no-correction vs. correction) between-subjects design and a jacket purchase scenario adapted from Campbell and Kirmani (2000). A 2 \times 2 ANOVA reveals an interaction ($F(1, 67)=4.53, p<.05$) suggesting that correction eliminated the effect of source trustworthiness. Participants were more willing to buy a product when the trusted source (friend) recommended it, than when the distrusted source (salesperson) recommended it ($F(1, 30)=8.61, p<.01$). However, when participants were instructed to correct their judgments (based on instructions adapted from Wegener and Petty 1995), the effect of trustworthiness was no longer significant ($F(1, 37)=.01, p>.90$). Notably, no significant effects emerged for the overall attitude measure (all $p>.12$), and although the salesperson was perceived to have more ulterior motives than the friend ($F(1, 67)=48.86, p<.001$), the effect of correction was not significant ($p>.33$).

Study 2 ($N=267$) employed a 3 source trustworthiness (federal agency vs. control) \times 2 correction (no-correction vs. correction) design. Participants read a pamphlet describing the benefits of phosphate detergents and learned that the pamphlet was either produced by a federal agency or by the manufacturer (Briñol, Petty, and Tormala 2004). The correction manipulation was adapted from study 1.

As predicted, an interaction between source and correction in a 3 \times 2 ANOVA ($F(1, 259)=4.13, p<.02$) indicates that, in the no correction condition, participants were more willing to buy the product when the trusted source recommended it than when the distrusted source recommended it ($M_{\text{agency}}=5.15, M_{\text{manufacturer}}=4.35, M_{\text{control}}=5.02$), $F(1, 130)=5.43, p<.26$). Correction eliminated this difference ($M_{\text{agency}}=4.58, M_{\text{manufacturer}}=4.89, M_{\text{control}}=5.17$), ($F(1, 129)=1.36, p>.26$). A 3 \times 2 ANOVA with certainty as dependent variable reveals a similar interaction ($F(1, 259)=5.43, p<.01$).

We conducted regressions to test mediation by certainty. In the first regression, the interaction between source and correction ($t=2.83, p<.005$) affected the dependent variable willingness to buy. In the second regression, the interaction between source and correction ($t=2.47, p<.02$) affected the mediator variable attitude certainty. In the third regression, attitude certainty ($t=3.27, p<.001$) affected willingness to buy, and the interaction between source and correction was no longer significant ($t=1.79, p=.08$, Sobel $z=2.41, p<.01$). These results support the mediating role of certainty.

Study 3 ($N=163$) provides further support for the process mechanism by manipulating certainty subliminally and holding the source of the recommendation constant. Using a 2 certainty (uncertainty vs. certainty) \times 2 correction (no-correction vs. correction) design, we first subliminally exposed participants to certainty and uncertainty-related words. Then, participants indicated their willingness to rent an apartment recommended by a realtor. If certainty affects behavioral intentions, we should detect a difference in willingness to rent the recommended apartment in the no correction condition. If, as proposed, correction changes certainty, after correction the change in certainty should be reflected in the behavioral intentions measure.

As predicted, a significant interaction between certainty and correction on behavioral intentions in a 2 \times 2 ANOVA ($F(1, 159)=5.41, p<.02$) suggests that, in the no correction condition, participants primed with certainty had more favorable behavioral intentions towards the recommended apartment than participants primed with uncertainty ($M_{\text{certainty}}=5.02, M_{\text{uncertainty}}=4.16$), ($F(1, 86)=5.26, p<.02$). When participants were instructed to correct, this difference was eliminated ($M_{\text{certainty}}=4.18, M_{\text{uncertainty}}=4.54$), ($F(1, 73)=.99, p>.3$).

Across three studies, we show the basic effect and support mediation by judgment certainty. The results contribute to the bias correction literature by suggesting a new process mechanism through which correction operates to influence judgments, and to persuasion research by showing one condition in which behavioral intentions can change directly as a function of certainty, while attitude favorability remains unchanged.

Feeling Fatigued Leads to Feeling Certain: Regulatory Resource Depletion and Attitude Certainty

Echo Wen Wan, University of Hong Kong, China
Derek D. Rucker, Northwestern University, USA
Zakary L. Tormala, Stanford University, USA
Joshua J. Clarkson, Indiana University, USA

EXTENDED ABSTRACT

This research examines the impact of regulatory resource depletion on attitude certainty. Regulatory resources have been conceptualized as a pool of resources that people use to override urges or exert controlled behavior (Baumeister et al. 1998). Attitude certainty is the subjective feeling of conviction one has about one's attitude, or the extent to which one believes one's attitude is correct (Gross, Holtz and Miller 1995). We focus on studying how regulatory resource depletion affects attitude certainty in the absence of differences in attitudes. We also uncover the mechanism using measured and manipulated approaches and demonstrate that differences in certainty have a meaningful effect on behavior.

Previous research has established attitude certainty as an independent construct from attitudes (Bassili 1996; Rucker and Petty 2004). Attitude certainty is particularly interesting for consumer research because *behavior* is influenced not solely by one's attitude but also the certainty placed in that attitude. In particular, attitudes held with high certainty serve as stronger guides for judgment and behavior.

Past research has shown that depletion significantly impacts consumer behavior such as impulse purchases (Vohs and Faber 2007). Recently Wheeler, Briñol, and Hermann (2007) found that depletion leads to poorer resistance against the counterattitudinal message when individuals were allowed to vary the effort exerted to counterargue. Our research focuses on the situation where depleted individuals are sufficiently motivated to exert equal effort on the subsequent task as non-depleted individuals and thus generate similar thought profiles (Muraven and Slessareva 2003). In such situations depleted and non-depleted individuals should have processed the same information to the same degree, which would produce similar attitudes. However, under such circumstances we asked whether depletion might affect attitude certainty.

Intuitively, one might expect that depleted (vs. non-depleted) individuals would perceive processing messages as more difficult. Based on prior findings that processing ease is associated with attitude certainty (Haddock et al. 1999), depletion might undermine attitude certainty. However, we propose that depletion might actually lead to greater attitude certainty. Research has shown that depleted (vs. non-depleted) individuals perceive themselves as exerting greater effort overestimating the amount of time they spend (Vohs and Schmeichel 2003; Wan and Sternthal 2008) on the same task. Previous studies suggest that people might use the amount of time or effort spent as indicators of the thoroughness of information processing (Vonk and van Knippenberg 1995). And the perception of thoroughness of thinking is associated with attitude certainty. For example, Berger and Mitchell (1989) suggest that repeated ad exposures enhanced individuals' product-related processing and thus their attitude certainty. Furthermore, recent research suggests that *perceived elaboration* (one's subjective assessment of how carefully one has processed information) affects attitude certainty even when there are no differences in actual elaboration (Barden and Petty forthcoming).

Drawing on the work linking depletion to perceived elaboration and the work linking perceived elaboration to attitude certainty, we predict that in situations where depleted individuals are

motivated and able to process messages extensively, depletion will increase attitude certainty, and this effect is accounted for by an enhanced perceived elaboration among depleted individuals.

Three experiments tested and supported these propositions. In all experiments, participants first completed a depletion manipulation, followed by reading an ad message about a consumer product. We strived to hold the actual amount and type of thinking constant across conditions in multiple ways: First, we induced high motivation to process by emphasizing the importance of the task. Second, we held actual ad exposure time constant. Finally, to test the success of our efforts we included measures that prior research has shown to be sensitive to differences in actual information processing.

In experiment 1, participants completed either a depletion manipulation, read an ad about one brand of answering machine, reported their attitude and attitude certainty, and reported their perceived elaboration and processing ease. The results show that depleted and non-depleted participants did not differ in their attitudes or processing ease. However, depleted participants were more certain of their attitudes and perceived their information processing as more thorough than non-depleted ones. Perceived elaboration mediated the effect of depletion on attitude certainty.

Experiment 2 used a different depletion manipulation in a different product category and with a different ad exposure time. In addition, we added two independent variables. One manipulated the naïve theories about the relationship between depletion and perceived elaboration. This tested whether varying the relationship between depletion and perceived elaboration affected certainty, and thus provided a moderation approach to testing the role of perceived elaboration. The other varied the argument strength in the message to test whether actual processing between depleted and non-depleted was constant. As another means of testing individuals' actual processing, we included a thought listing measure. The results showed that attitudes only differed between strong and weak arguments conditions, but depletion had no effect. The naïve theory results showed that manipulating the relationship between depletion and perceived elaboration affected attitude certainty, supporting the perceived elaboration mechanism. Moreover, both depleted and non-depleted participants had more favorable thoughts in the strong than weak argument conditions.

Experiment 3 tested the behavioral consequence of our effects following the same procedure as used in the strong argument condition in experiment 2 except that no naïve theory was manipulated. At the end participants made a real purchase decision. The results showed that 1) the attitude-purchase correlation was significantly stronger among depleted (vs. non-depleted) participants; 2) among participants holding positive attitudes, depleted (vs. non-depleted) individuals chose to purchase the snack more frequently; and 3) these effects were mediated by difference in attitude certainty. Depletion led participants to be more certain, and thus they became more likely to act based on attitudes.

Our research contributes to literature on regulatory depletion and persuasion by revealing a hidden effect of depletion on attitude certainty. We also enrich the understanding of attitude certainty by showing that a subjective perception of elaboration (vs. objective differences) impacts attitude certainty. Finally, this research finds

evidence that consumer behavior (e.g., actual purchase) can be affected by depletion due to the variation in attitude certainty.

This Brand is Me: A Social Identity Based Measure of Brand Identification

Amy E. Tildesley, University of Queensland, Australia

Leonard V. Coote, University of Queensland, Australia

EXTENDED ABSTRACT

Of particular importance to practitioners and academics in the marketing field is the ability to recognize, analyze and utilize information regarding the voluntary relationships that consumers engage in with the brands they purchase. Fournier (1998) and Aaker (1999) make an explicit plea to researchers regarding the need for research in marketing to examine the deep, enduring brand relationships that lead to beneficial outcomes for firms. Accordingly, recent consumer behavior research has investigated the psychological connections individuals build with brands, brand communities and the brand relationships that surpass loyalty (Carroll and Ahuvia 2006; Fennis and Pruyn 2007; Fournier 1998; McAlexander, Shouten, and Koenig 2002). One commonly accepted perspective stemming from the consumer behavior literature is that products and brands are able to fulfill the self-definitional needs of consumers (Belk 1988; Dolich 1969). This notion has proliferated a variety of academic fields of study including possessions as extensions of self (Belk, Bahn, and Mayer 1982; Kliene, Kleine, and Allen 1995), brand personality (Aaker 1997; Kassarian 1971), relationship marketing (Fournier 1998), the congruence or fit literature (Birdwell 1968; Dolich 1969; Gardner and Levy 1955) and more recently, consumer-company and brand identification (Bagozzi and Dholakia 2006; Bhattacharya, Glynn, and Rao 1995; Bhattacharya and Sen 2003). Thus, the self-concept related benefit of brands is well accepted in the literature; however, the numerous and varied manifestations of the construct have perpetuated a fragmented and inarticulate area of study.

This paper purports that strong consumer-brand relationships may be attributed to theories of social psychology, namely, social identity and self-categorization theory. The basic premise of these theories is that individuals group within society to achieve meaningful self-definition through intergroup homogenization and intra-group difference (Tajfel 1978, 1982). Social psychologists have historically applied these theories to an organizational context (Brown et al. 1986; Hogg and Abrams 1988) and concurrently, organizational behaviorists adopted theories of social psychology to explain desirable employee behavior such as employee citizenship and conscientiousness (Ashforth and Mael 1989; Bergami and Bagozzi 2000; Cheney 1983). Thus, organizational identification has received much academic attention in recent years (Dutton, Dukerich, and Harquail 1994; Pratt 1998; Riketta 2005; Van Dick 2001). Following this and entering the realm of marketing, Bhattacharya and Sen (2003) introduced the concept of consumer-company identification and posit that individuals, regardless of formal membership ties, are able to identify with companies.

Unfortunately, identification theory in marketing remains in its infancy. This may be partly attributed to the theoretical foundation of consumer-company identification being somewhat detached from the marketing literature and companies being the incorrect focus in marketing. Brand identification is the focus of few studies, and has never been conceptualized as a construct truly separate from that of organizational identification. Equally as problematic, the operationalization of the construct is inconsistent, underdeveloped, and always adapted from the organizational literature. The aim of the present research was threefold: (1) to conceptually develop brand identification by firmly grounding the construct in the social psychology literature, and hence to establish it as distinct from organizational and consumer-company identifica-

tion, (2) to establish a valid and reliable measure of brand identification, and one appropriate for a branding context and, (3) to compare the new measure to existing measures of identification used in the marketing literature.

Drawing on domain sampling theory, three components of brand identification were developed that were thought to capture the entire domain of the construct. Specifically, brand identification was hypothesized to consist of a self-brand connection component, to reflect the process of social classification and affiliation, a brand salience component, to capture of the importance of the brand to one's self-identity and finally, a brand signaling component, to reflect the utility of the brand in signaling one's self-identity to others. Studies using data from twelve samples and over 2,000 subjects were conducted to refine and validate the final 11-item measure of brand identification.

In the initial scale purification studies, the scale was refined using factor analyses on multiple samples. Subsequently, antecedents and outcomes of brand identification were proposed and the scale was shown to have nomological validity. The developed scale was found to have the same antecedents as established identification scales; however, the outcomes differed substantially. In particular, one component of the developed scale, self-brand connection, was shown to consistently outperform the other two components of the developed scale as well as the established scales. Specifically, the self-brand connection component explained more variance in a set of outcome variables including loyalty, willingness to pay a price premium, and brand advocacy and defense. In a test of known-group validity, it was shown that the new scale was able to distinguish between those who should score highly on the scale and the general population. The brand identification scale was then subject to two quasi-experimental studies to test its predictive ability. The first study demonstrated that consumers with high levels of brand identification were more resilient to negative information about the brand. In the second study, a choice task demonstrated that brand identification was positively related to brand preference.

Overall, the evidence obtained from the studies in this paper for the validity and reliability of the brand identification scale is encouraging. Marketers intuitively understand the importance of brands and the possibility of consumer identification with brands and as such, the identification concept is quickly becoming a recurrent theme within much of the consumer behavior and marketing literatures. Despite this, more work needs to be done in testing our conceptions of brand identification and the role it plays in shaping consumer behaviors. The brand identification measure reported in this paper is offered to the field as an impetus to further empirical work and theory testing, with the ultimate aim of truly understanding brand identification and its importance.

Is Consumer Culture Theory Research or Realpolitik? A Sociology of Knowledge Analysis of a Scientific Culture

Matthias Bode, University of Southern Denmark, Denmark
Per Østergaard, University of Southern Denmark, Denmark

EXTENDED ABSTRACT

When Consumer Culture Theory (CCT) was introduced by Arnould and Thompson (2005) it was part of a branding strategy to create legitimacy for interpretive research. The general direction of these branding procedures is a necessary step towards a more developed discussion of academic research as they explicitly take into account the “realpolitik complexities” of science (Arnould and Thompson 2007, 6). Unfortunately, the discussion rests upon unreflected assumptions about the relationships between theory/knowledge and the status and social reproduction of academic cultures. The goal of this paper is twofold. First, the CCT discussion is embedded in a wider theoretical and empirical frame of academic cultures. As the higher education landscape is confronted with severe challenges of globalization, underfinanced mass universities and a managerial spirit with a drive for efficiency and productivity (Henkel 1997; Becher and Trowler 2001), a thorough research stream is exactly focussing on the link between science and the real world context. Second, it is intended to make the inherent logic of thought procedures in the CCT construction explicit by a deconstructive reading (Atkins 1983; Harland 1987). It is revealed how CCT represents a different perception of knowledge compared to the way knowledge was perceived among research taking part in The Interpretive Turn (Sherry 1991). The latter was focused on groundbreaking research and less interested in the realpolitik consequences, which is opposed to the CCT focus on realpolitik in its strive for legitimacy. It is shown how there have been an ongoing discussion in the sociology of scientific knowledge (e.g., Becher and Trowler 2001; Henkel 2000; Pickering 1992) about the consequences in scientific cultures when they are confronted with the requirements of the real world. This is a debate that is not reflected in CCT and there is a lot to be learned from that stream of research.

The basic insights are based on a multi layered conception of dynamic scientific cultures that emerge from the informal, scientific community as a network, incorporating direct and indirect interaction with other colleagues outside of the local academic institution. If we want to deliberately change and manage these cultures, it is not enough to focus on individual academics in their assumed loyal commitment to the community. Rather, the individual academic is an actor, embedded in a system of internal and external variables. Primarily, there are micro layers of individuals, meso layers of institutions and discipline, and macro layers of national and international relationships. Instead of presupposing a homogeneity of interest and orientations, the heterogeneity of the specific constellations of institutional, disciplinary and national cultural layers and the individual researcher’s negotiation of value tensions has to be taken into account.

The deconstructive analysis of CCT is done on the basis of Greimas’ (e.g., 1987; 1990) semiotic square. It is shown how CCT reveals the classical dichotomy between knowledge and power. It is a dialectical contradiction, which are the constituting elements for the university as an institution. The Interpretive Turn can be seen as a scientific culture where there was no interest in being pragmatic and thereby a strive for recognition from the mainstream. Instead there was a tendency to stay outside the mainstream in an isolated position with no power. Arnould and Thompson (2005; 2007) want to change that by introducing CCT. Where the former stream of

research had an idealistic attitude towards doing research, CCT is instead focused on the pragmatic aspects in order to get legitimacy from the mainstream and thereby being a part of the power game in the discipline. To do this the CCT researchers must leave their idealistic and isolated position and instead participate actively in realpolitik. There are logically some inherent dangers in these different movements. The Interpretive Turn has been characterized by groundbreaking research and it can be difficult to continue this kind of research if the researchers become a part of the mainstream and the power position, which is characterized by a “suppose to know” attitude. There is no easy solution to the dilemma of whether to choose the power position or to stay isolated in the knowledge position. One answer to the dilemma is a new way of dealing with this kind of research. Instead of being in one of the camps we think there is a third position in between the two camps, which we define as reflexive research. It is the pragmatic position striving for an idealistic mentality among the researchers. It is a position with a focus on pragmatic aspects of research, but at the same time leaving room for the anarchistic nature of groundbreaking research. Reflexive research is characterized by a meta-level where the scientific culture openly can reflect upon the how-to dealing with the conflicting reality of today’s research landscape.

Potential Contributions from Contemporary Social Science Literature: Expanding Cultural Understanding in Consumer Research

Kivilcim Dogerlioglu-Demir, Washington State University, USA
Jeffrey Radighieri, Washington State University, USA
Patriya Tansuhaj, Washington State University, USA

EXTENDED ABSTRACT

Prior research has examined the state of culture based consumer research (Sojka and Tansuhaj (1995), yet to our knowledge there are no published works that study the issue from a cross-disciplinary and non-marketing/consumer perspective. The purpose of this paper is to review and integrate recent cultural research in social science disciplines in order to gain insights into theories and related concepts that will help further our understanding of consumers in diverse cultures.

Two independent judges reviewed 323 articles from the top ten cited journals in five social science disciplines: anthropology, psychology, communication, philosophy and sociology. We aim at exploring and assessing the breadth, not depth, of knowledge in contemporary social science research. Therefore, articles published in the past two years (2006 and 2007) were included in order to identify contemporary research. Our analysis includes studies between cultures and nations as well as investigations within one culture or nation. The articles were coded on additional criteria, including cultural dimension, format (conceptual vs. empirical), and method (qualitative vs. quantitative).

Our findings reveal some prominent cultural themes in each discipline. While contemporary sociology papers tend to focus on transnational migration and role of religion, communication research centers on race and racial bias. Recent anthropology articles tend to emphasize macro issues of imperialism and capitalism. Philosophy papers focus on the meaning of globalization, diversity and sympathy. Psychology research examines acculturation, discrimination, and ingroup/outgroup issues. The main recent theme that seems to cut across all disciplines is globalization and its differential effects on various peoples across the globe.

Identified articles were content analyzed by the judges and classified into six dimensions: 1) language and communication, which includes studies that explore the cultural functions of communication; 2) religion and beliefs, covering studies that have theological and ethical perspective on cultural issues; 3) ethnicity, race and nationality, which comprises research that emphasizes race, ethnicity, acculturation, and nationality; 4) family and gender, examining marriage, sexual identity, and family issues; 5) government and law including works that focus on legal structures as they affect everyday life; and 6) regionalization and globalization, reflecting studies that examine the origins and consequences of integration of economies and political systems and their repercussions on individuals.

Relevant theories and concepts were identified and discussed for each dimension. In the language and communication dimension, we discuss two particular theories: cultural sensitivity/centered approaches and pictorial realism. Moral cosmology theory was chosen as a significant contribution in the religion and values dimension. The ethnicity, race, and nationality dimension provides the largest quantity of relevant theories, including dramaturgical theory, "I-know-you-but-you-don't-know-me," cultural frame switching, social unity, and material cultural evolution concepts. Applicable theories in the family and gender dimension include the demand/withdraw pattern of communication and transformative processes. In the government and law dimension, resistance and affect control theory seem to have a high potential for providing a

significant contribution to consumer research. Finally, in the regionalization and globalization dimension, the theory of globalization of law and authenticity were identified and discussed as applicable and useful for introducing to the consumer research in marketing.

Our research suggests the presence of a bias toward the United States and its respective cultural groups. Future research should entail more work in South America, Africa, and Eastern Europe. In addition, more research on religion and beliefs could provide significant contributions to the field. While the family has been researched in the social sciences, it has not received much attention in consumer behavior. In addition, more work is needed in sexual identity issues. Finally, consumer research has also not addressed regionalization and globalization in any serious manner. We cannot ignore such a global phenomenon and how it affects consumers at the macro and micro levels (i.e., collective consumer trends such as hypermodernism in China, versus changes in individual consumer attitudes, values and behavior changes).

With this study, we hope to provide consumer researchers with new and exciting research directions that might help us better understand consumer behavior in diverse settings. Despite repeated calls, cross-cultural consumer research continues to use nationality as a proxy for culture. We wish to reemphasize the need to move away from treating culture and nationality as equivalent. Amid globalization, we can also learn from the same weakness shown in social science research, the need to reduce our bias toward focusing mostly on studying America or the American culture. Finally, scholars have stressed the need for consumer research to become more interdisciplinary (Deighton 2005; Mick 2006; Shimp 1994; Wells 1993), yet these calls have gone unheeded. The ultimate goal of this work is for the reported results and suggestions to serve as a starting point for researchers to begin to move the field toward a multidisciplinary emphasis.

The Impact of Family Micro-Environments on Children's Consumer Socialization

Ben Kerrane, Bradford University, UK
Margaret K. Hogg, Lancaster University, UK

EXTENDED ABSTRACT

The purpose of this paper is to explore the family environment in which children learn to become consumers. It aims to contribute towards filling the significant gaps which exist in our current understanding of the role that the family environment plays in the socialization of children (Roedder John, 1999). This paper also offers support for Cotte and Wood's (2004) assertion that parents can create different family environments for their children, and explores the possible implications of such environments in terms of consumer socialization.

With the family described as *the* socialisation unit (Commuri and Gentry, 2000), it is perhaps surprising that relatively little is known about how such a social environment impacts on the consumer socialization process. Moschis and Churchill (1978), too, point towards the importance of the family in the consumer socialization process, and Moschis and Churchill (1978) offer their classic conceptualization of consumer socialization.

Theories such as *parental socialisation style* (Carlson and Grossbart, 1988) and *family communication pattern* (Carlson et al., 1994) have been presented which aim to shed greater light on the family socialization environment. However, such theories have failed to adopt an internal focus. Instead, families are often compared to one another, and consumer research has ignored the possible differences which may exist within the same family.

Research in the fields of genetics and behavioural psychology suggest that multiple environments, or *familial micro-environments* (Harris, 1995), exist within the same family. This study, therefore, seeks to explore the family environment in greater detail in relation to the consumer socialization of children. A wide variety of family forms were chosen as the sites of consumption due to marketing's preoccupation with nuclear family types (Commuri and Gentry, 2000), and the voices of children alongside adults are actively sought.

Six families were recruited to participate; one lesbian headed family with both adopted and biological children; one blended family; a family headed by a cohabiting couple; a family headed by a single mother; and two nuclear families. Each family member was invited to take part in the research process in a move away from the early family studies which recruited only a limited number of respondents. Generally every family member who was living in the family home chose to participate, although there were a few exceptions (most notably with very young children, adolescent children and certain fathers who chose not to be involved).

Consent was sought from both parents and children alike to participate in phenomenological interviews and family observation. The families were seen between three and five times over a period ranging from four to twelve months. The interviews were conducted in the family home, where a parent or guardian was always present, and interviews were conducted with individuals and family groups depending on which family members were available.

The interviews were recorded and transcribed. The data was analysed following Spiggle's (1994) data analysis steps in which marginal notes were made on each transcript. This allowed similar topics to be grouped under broader emergent themes. Each family was analysed initially on an idiographic basis and then across-family analysis occurred which allowed for global themes to emerge. The interpretation of the interview texts used a hermeneu-

tical approach (Thompson, 1991; Thompson, Locander and Pollio, 1990) which involved an iterative process of moving back and forth within and across interview texts and between transcripts and the literature.

Across all six family cases significant differences were found to exist *within* the families studied. Family members, parents and children alike, treated various family members in different ways, creating very unique familial micro-environments for the family members. Two family cases, in a similar vein to Thompson (2005), are presented; the Baldwin family story to illustrate the differences in the family environment that are created by parents; and the Jones family story to illustrate how children themselves can treat their fellow siblings in different ways.

The familial micro-environments which exist within each family story suggest that one universal family environment does not exist. Empirical support is not found to support the universal parental socialization style and family communication pattern that Carlson and Grossbart (1988) and Carlson et al. (1994) respectively present. Rather, different socialization tendencies exist within the same family, with parents and children acting as important socialization agents within the family for other children.

The unique familial environments fostered by parents (*paternal micro-environments*) and children (*fraternal micro-environments*) impact the consumer socialization environment in families, and the *antecedent variables* and *socialization process variables* which Moschis and Churchill (1978) identify, and thus the learning outcomes for children within families. A child's familial micro-environment affects the opportunities which are made available to the child to discuss consumption related issues, and thus the ability to acquire consumer skills.

Consumer Socialization: The Role of Hunting and Gun Rituals in Becoming a Man

Jon Littlefield, Berry College, USA

Julie L. Ozanne, Virginia Polytechnic Institute and State University, USA

EXTENDED ABSTRACT

The modern practice of recreational hunting is a domain that has been understudied in the sociological and anthropological literature and completely neglected in the consumer research literature. Anthropology has largely focused on the history of hunting as interpreted via modern day hunter-gatherer societies as a means of studying human development, while sociology has focused on the extremities of the hunting culture such as poaching or on the ethics of hunting or eating meat. The neglect in consumer research is particularly surprising for two reasons. First, hunting in pre-historic times represents the earliest representation of key consumption and acquisition activities. While today we shop, previously we hunted. And activities such as sharing meat that continue to exist today, both among modern hunters and among still-existing hunter-gatherer societies, suggest remnants of one of the earliest forms of exchange. Second, hunting is an area in which study of the extended consumer socialization process in families—typically between fathers and their sons—can be examined. New hunters, along with their male mentors, undergo a years- or decades-long process of socialization into the skills, social norms, and values of the hunting culture. This socialization process, along with the ensuing expression of masculinity by hunters, is the focus of this study.

Children develop through both cognitive and social means and both have been suggested as important foci for the study of consumer socialization (Moschis and Moore 1979; Roedder John 1999). In consumer research, however, the cognitive development of socialization has attracted the most attention. In this stream of literature, socialization is envisioned as progressing through a series of three stages that are related to the child's age (Roedder John 1999): a perceptual stage focused toward "immediate and readily observable perceptual features of the marketplace" (186), an abstract analytic stage where the child shifts to more symbolic thought where s/he can see multiple perspectives, and a reflective stage in which the child is able to grasp not only functional meanings of the consumption experience but also its more subtle social meanings. This approach sees the child attaining specific skills at universal stages with this progression depending on the complexity of the child's existing cognitive structures and is based on theory developed originally by Jean Piaget (1963). In contrast to this Piagetian perspective, we find that an explanation that explicitly includes the influence of family members and other mentors more richly explains the socialization process into hunting.

The primary method of data collection was semi-structured, in-depth interviews of approximately two hours with twenty-seven adult male hunters and a wildlife manager, including interviewing separately 5 fathers and sons who hunt. The secondary method was participant observation of the hunting community, including hunter safety classes, hunting and gun shows, informal interviews with hunting-related retailers, and participation in hunting trips. A hermeneutical analysis of the text was conducted, based on the assumption that consumers' personal histories are embedded within a context of personal meanings expressed by "culturally shared narrative forms" (Thompson 1997, 439-40), involving an *intra*-textual analysis resulting in a written interpretation of each informant and an *inter*-textual analysis comparing themes across informants.

Our findings suggest that consumer socialization can be conceptually expanded to include the dynamics by which social influ-

ences such as family impact the process through which young men learn to hunt, making use of Lev Vygotsky's theory of development (Vygotsky 1978; Tudge and Scrimsher 2003) that stresses the importance of interpersonal interaction in the socialization process. Hunters progress through four distinct stages that are characterized by support, challenge, and encouragement by their mentors. *Pre-hunters* accompany their mentors hunting, participating in scouting and retrieving activities, while *neophytes* have proven they are responsible enough to carry a loaded gun. *Apprentice* hunters hunt independently without their mentors, exhibiting camaraderie and challenge with their peers, and *competent* hunters have moved past the need to prove themselves and have achieved actualization of their masculinity in ways discussed in the following section.

Competent hunters negotiate masculinity in ways that relate both to the mediating role that equipment plays in constructions of the "extended self" (Belk 1988) and to the primary motivation achieved from participating in the activity of hunting. Their equipment meanings vary on a continuum between meanings that are intrinsic to the equipment (e.g., accuracy, technical aspects) and meanings that are extrinsic to the equipment (e.g., personal history, nostalgia). The second factor relates to the approach to the hunt, which varies from a focus on the experience of the hunt (a process orientation) to a focus on the final kill (an ends orientation).

Thus, four subgroups of hunters emerged: traditionalists, gearheads, experientialists, and transcendentalists, and we found that masculinity is both expressed and understood differently by the four types of hunters. For *traditionalists*, hunting is deeply intertwined with rural family traditions and results in easily achieved close male social bonds. Technology mediates the hunting experience for the *gearhead* through mastery of equipment in both skill development and customization, he expresses his masculinity through his desire for control, order, precision, and accuracy, and is unique among hunters in his focus on a hierarchy based on technical expertise. Masculinity for the *experiential* hunter harkens back to finding his particular place in both the natural and the social worlds. Rather than dominating nature, the experiential is interconnected with nature. *Transcendental* hunters represent a category of masculinity that affirms emotional bonds to both family and nature by using their family socialization and life long hunting experience to achieve a balance between stereotypically feminine characteristics of empathy and caring and a stereotypically masculine activity of hunting and killing in competition with other men.

The “Proper Meal” and Social Capital in Urban China

Ann Veeck, Western Michigan University, USA

Hongyan Yu, Jilin University, China

Alvin C. Burns, Louisiana State University, USA

EXTENDED ABSTRACT

The concept of a “proper meal” has been studied as a symbol of the family and as a means to identify the roles and the power structure of family members as they negotiate the divisions between the public and private spheres for decades (e.g. Murcott 1982; Charles and Kerr 1988; DeVault 1991). Building on the “proper meal” literature, this study investigates conceptualizations of the “proper meal” in urban China. Via interviews with twenty Chinese families, we examine how activities related to domestic meals serve to generate and transmit social capital (Bourdieu 1984, Coleman 1988, Putnam 2000) during this era of dramatic economic and social change.

Descriptions of what constitutes a proper meal in western studies generally start with the dishes necessary for a nutritious meal. For example, British studies in the 1980’s found that a proper meal had to be home cooked and consisted of meat, potatoes, vegetables, and gravy (Charles and Kerr 1986; Murcott 1982). In the U.S. DeVault (1991) also found strict definitions related to the appropriate constitution of meals, although the particular choice of dishes could vary according to the families’ ethnicities. Earlier studies also emphasized that for a meal to be proper it was expected that a woman had cooked the meal at home and that all family was in attendance (Charles and Kerr 1988; DeVault 1991; Murcott 1982). More recent conceptualizations on meal norms have found more forgiving standards on the composition of the meal, as well as more sharing of meal tasks by younger couples (Bugge and Almas 2006; Makela 2000; Marshall and Anderson 2002).

Representations of the “proper meal” are useful for studying how family routines facilitate the transmission of social capital. Social capital is defined as a set of resources that accrue to individuals as a result of their membership in particular social groups, with the most fundamental group in most societies being the family (Bourdieu 1984, Coleman 1988, Putnam 2000). The form of social capital transmitted among family members would be what Putman (2000) would call ‘bonding,’ or exclusive, social capital that would reinforce the solidarity and mutual benefit of being a member of the family. Social capital has been seen as a conceptual tool for understanding the nature of family life and the communities in which they are imbedded (e.g. Edwards 2004; Putnam 1998).

This research is part of a larger study of family meals, conducted in Changchun, Jilin Province, P.R. China, that has included focus groups, family interviews, food shopping trip observations, and a household survey over a multiple year period. For this research, we conducted interviews with twenty families who had at least one child living at home in their home. The interviews included numerous questions about family meals, including the participation of family members in activities surrounding breakfast, lunch, and dinner and perceptions and attitudes towards food-related tasks and meals. We analyzed the interviews to identify definitions of the “proper meal,” and to pinpoint how family meals served to transmit social capital.

An analysis of data related to definitions of the proper meal found the following components to be most salient: 1) food, 2) atmosphere, 3) mood, 4) conversation, and 5) participants. As in other studies of “proper meals” (e.g. Murcott 1982; Lupton 2000), family members defined a proper meal as having food that is tasty and nutritious as a fundamental requirement. A pleasant, or perhaps

special, atmosphere was also cited as being important, with family members retaining a relaxed and happy mood. Quite a few participants noted the need for good conversation that was about light and happy topics, with an avoidance of stressful topics, particularly related to work. Finally, and most importantly according to many of the respondents, all of the family members had to be present for the meal to be “proper.”

Via the definitions of “proper meals” provided by the families we interviewed, along with elaborations on how domestic meals actually functioned in their lives, we were able to identify how social capital might be generated and transmitted via these food-related activities. In the end, we coined and categorized three distinctive forms of social capital that were propagated via family meals, and, by extension, family life: identity capital, moral capital, and emotional capital. The first form of social capital that we identified as being enhanced through shared meals is identity capital, which functions to provide feelings of belonging and purpose to family members. The second form of social is moral capital, which serves to transmit proper mode of conduct and values to family members. A final form of social capital is emotional capital, which allows the transmission of feelings of love and emotional support to family members

With a sample consisting of twenty intact families, this study omits the viewpoint of individuals who live outside these strict boundaries. The conceptualization of a “proper meal” might be seen quite differently by residents of Chinese cities who are, for example, very rich, or single, or migrant workers, or any number of characterizations that were not represented in our sample. The study of the formation of social capital using other family forms and household types would provide wider understandings of the place of family in society.

The Self-Activation Effect of Advertisements: Ads Can Affect Whether and How Consumers Think About the Self

Debra Trampe, University of Groningen, The Netherlands
Diederik A. Stapel, Tilburg University, The Netherlands
Frans W. Siero, University of Groningen, The Netherlands

EXTENDED ABSTRACT

One of the signature strengths of the advertising industry lies in its ability to transfer seemingly mundane objects into highly desirable products. Products can transform into different entities once they are placed in advertisements. In their everyday appearance, products are relatively distant, self-defining stimuli: Shoes are for walking and cars are for driving. However, the meaning that is conveyed by such products can change dramatically once they are placed in an advertisement. Then, these products can become consumer products, things that can be bought and owned. Then, shoes and cars are for buying. To give an example, the meaning signaled by a high-heeled shoe in an advertisement is radically different from the meaning that is conveyed when one encounters the exact same shoe outside of its advertisement context. In the latter situation, the shoe is a relatively distant, neutral product. However, in the former advertisement context, the shoe is a desirable, potentially self-relevant product that one can buy and that suggests a possible self-image of beauty and attractiveness.

The present paper looks at important but understudied consequences of the different meaning that advertised versus non-advertised products can convey. In three experiments, we test the proposed self-activation effect of advertisements, which suggests that the different meaning products convey once they are placed in an advertisement can trigger important self-processes. By postulating the self-activation effect of ads, we suggest that when placed in an advertisement context, products become potentially desirable consumer products that address people in their capacity as consumers—people who buy and own things, and thus make specific consumer choices and decisions. Moreover, we expect this effect to be especially true for hedonic products, but not for more utilitarian products. Specifically, we suggest that advertised hedonic products, as opposed to non-advertised hedonic products, can affect both *the extent* to which individuals think about the self, and *how* they think about the self.

Interestingly, the relevant literature has not yet explicitly acknowledged the idea that the meaning that is conveyed by advertised products may be very different from the meaning that is conveyed by non-advertised products. However, previous studies have focused on how advertisements can employ all sorts of techniques to convey their message in an implicit fashion, such as implicatures (Phillips 1997) and stylistic properties (Peracchio and Meyers-Levy 2005). Contemporary consumer research acknowledges that advertisements can possess symbolic features and that advertisements are often highly stylized representations that compel consumers to engage ads as symbolic systems (Aaker 1999; Philips and McQuarrie 2004; Scott 1994; Solomon 1983). That is, rhetorical theory posits that advertisements can convey meaning that goes beyond their physical characteristics and as a consequence, consumers must draw upon associations and cultural knowledge to grasp the implicit meaning the ad conveys. However, past studies have commonly focused on how the content of ads can affect product perceptions, evaluations, and processing style. In other words, most consumer research has studied variations within consumer situations, rather than variations between consumer and non-consumer situations. Or, using Folkes' (2002) words "... little

consumer research directly compares consumption with non-consumption or customer with non-customer behavior". The present paper attempts to fill a void in the current literature by making comparisons between consumer and non-consumer situations.

Taken together, the results of three experiments indicate that very subtle manipulations (merely adding a brand name and a relatively simple background) can interact with the hedonic level of the products to transform products into advertised consumer products. The consequences of this change in meaning were found to be substantial. First, Study 1 found that a hedonic product that was placed in an ad activated the self (as exemplified by an increase in the salience of first-person pronouns), as compared to the same hedonic product when it was not advertised. That is, when research participants had been exposed to an ad featuring eye shadow (a product previously rated as relatively hedonic), they were more likely to translate fictitious words as first-person pronouns than when they had viewed the eye shadow without the ad context.

Study 2 was designed to address the self-evaluative consequences of Study 1's finding that ads can interact with the hedonic level of products to activate the self. Study 2 revealed that ads for hedonic products (as opposed to a more utilitarian product) were used as a standard against which consumers evaluated the self. Specifically, individuals were found to evaluate their self-image more negatively when they had viewed, for example, a high-heeled shoe (a product previously rated as relatively hedonic) in an ad than when they were exposed to the exact same shoe when it was cut out from its advertisement context.

Further support for the notion that the activation of the self is an important underlying mechanism was provided by Study 3's finding that experimentally activating the self interacted with the hedonic level of products to produce similar effects on self-evaluation as did exposure to advertised products. That is, when the self was directly activated, exposure to the hedonic products in ads resulted in more negative self-evaluations than when the self was not activated.

To sum up, the three experiments provide evidence for the self-activation effect of ads: placing products in an advertisement context can interact with the hedonic level of products to activate the self, and as a consequence, ads can exert self-evaluative effects on consumers. By demonstrating this, the current studies contribute to the literature on visual imagery in ads. This literature has revealed important knowledge about how consumers draw meaning from ads. The current studies add to this research body by demonstrating that an advertisement context itself can also serve as a "figure of thought" that should not be processed literally, but rather by using implicit associations and knowledge. Stated differently, the current research adds to the existing literature on rhetorical theory by examining how people interpret themselves on the basis of advertisements, rather than looking at how people interpret the advertisement on the basis of themselves (i.e., their knowledge structures).

My Brand and I: The Impact of Self-Construal on Self-Brand Closeness

Jia Liu, Monash University, Australia

Dirk Smeesters, Erasmus University, The Netherlands

Els Gijsbrechts, Tilburg University, The Netherlands

ABSTRACT

Three studies demonstrate that consumers with independent self-construals are more inclined to incorporate brands into the self and hence maintain close connections with them than consumers with interdependent self-construals. We demonstrate the underlying role of self-expression in explaining this effect. Unlike interdependent consumers, independent consumers have a high need for self-expression, and are inclined to use brands to communicate the self, which should further strengthen their self-brand connections.

Imagining the Self: The Effect of Self-Focus and Visual Perspective on Persuasion

Massimiliano Ostinelli, McGill University, Canada

Ulf Böckenholt, McGill University, Canada

EXTENDED ABSTRACT

When evaluating products, consumers often imagine future consumption-related behaviors (e.g., MacInnis & Price, 1987; Shiv & Huber, 2000). Drawing on James's (1982) classical distinction between the "Me" and the "I", we suggest that when projecting themselves into the future, consumers can focus either on their *future being-self*, by reflecting on what consumption can make them become (e.g., a better student, an expert, a caring parent), or their *future experiencing-self*, by anticipating the thoughts, feelings, and emotions they will experience in a consumption episode (e.g., the excitement of a snowboard downhill, the relaxation of a spa).

To persuade people to engage in the imagined behavior, images of future being-selves have to successfully convey how the scene pictured enhances one's sense of self, whereas images of future experiencing-selves have to transmit the feelings and emotions that could be experienced in a particular situation. We propose and provide evidence that the persuasiveness of being-selves and experiencing-selves is moderated by visual perspective in imagination.

Future selves can be imagined through a *first-person* perspective, when people visualize the scene through their own eyes, or a *third-person* perspective, when people visualize the scene through the point of view of an external observer (e.g., Nigro & Neisser, 1983). Empirical findings indicate that the adoption of a specific vantage point can determine the inferences people make about their future selves. In particular, the third-person perspective leads to more dispositional attributions (e.g., Frank & Gilovich, 1989) and highlights the broader meaning of an imagined situation (Libby & Eibach, 2004 cited in Libby et al. 2005; Vasquez & Buehler, 2007). On the other hand, the first-person discloses more information about future states of mind (i.e., affective reactions and psychological states) experienced by a person (McIsaac & Eich, 2002).

We propose that the third-person perspective, by highlighting the broader meaning of a behavior and its dispositional consequences, is more suitable to imagine future being-selves, whereas the first-person-perspective, by disclosing more information about one's state of consciousness, is more suitable to imagine future experiencing-selves.

Moreover, although people can deliberately decide to adopt a specific visual perspective (Nigro & Neisser, 1983), we suggest that unfamiliar scenarios, being imagined through a constructive process that focuses attention on the spatial relation between the self and its surrounding environment, tend to be visualized through a third-person perspective. This, in turn, increases the persuasiveness of future being-selves over experiencing-selves.

Three studies were conducted to test our hypotheses. Study 1 had a 2 (visual perspective: first vs. third) x 2 (self-focus: being vs. experiencing) between-subjects factorial design. Participants were presented with a short description of a new book that provided techniques to improve performance at school and imagined either themselves having a better way of studying, mastering course material, and becoming an expert in a subject domain (being-self) or the feelings of getting a good grade on a difficult exam (experiencing-self). The visualization task was performed either through a first- or a third-person perspective. As expected, future being-selves led to significantly more favorable attitudes toward the book when imagined through a third- as opposed to a first-person

perspective, whereas the experiencing-self-focus led to directionally (although not significantly) more favorable attitudes when the scene was visualized through a first-person as opposed to a third-person perspective. Further analysis suggested that vividness of imagination, but not ease of imagination, mediated the interaction effect between self-focus and visual perspective on attitude.

Drawing on empirical evidence suggesting that near-future events are more likely imagined through a first-person perspective than distant-future events (Pronin & Ross, 2006), Study 2 replicated findings from Study 1 through a naturalistic manipulation of visual perspective. Participants imagined enjoying an exotic vacation (experiencing-self) either in the near-future (a week later) or in the distant-future (three years later). As expected, the vacation was more likely imagined through a third-person perspective in the distant-future than in the near-future condition. Moreover, participants who adopted a third-person perspective liked significantly less the vacation destination than those who adopted a first-person perspective. A distribution of products test (MacKinnon, Lockwood, Hoffman, West, & Sheets, 2002) showed that temporal distance had a significant indirect effect on attitude via visual perspective, although its direct effect on attitude was not significant.

Study 3 analyzed the impact of scenario familiarity on visual perspective and future selves' persuasiveness. The experiment had one between-subjects factor (scenario: familiar vs. unfamiliar) and one within-subject factor (self-focus: being vs. experiencing) design. Participants were asked to imagine either incorporating the product into their daily routine (familiar scenario) or an original use of the product (unfamiliar scenario) and evaluated the product by focusing either on their being- or experiencing-selves (within-subject factor). In the being-self-focus, respondents were first asked to consider the extent to which the e-book reader made them more efficient/effective and then rate the product attractiveness by focusing on that particular aspect of their imagination. In the experiencing-self-focus, respondents were asked to consider the extent to which they experienced positive emotions and feelings while using the product, and rate the product attractiveness by focusing on that particular aspect of their imagination. As expected, the unfamiliar scenarios were more likely imagined through a third-person perspective than familiar ones. Moreover, the e-book reader was evaluated significantly more positively in the being-self-focus than in the experiencing-self-focus when the scene was visualized through a third-person perspective but no significant differences were found when the scene was visualized through a first-person perspective. This finding suggests that the attractiveness of future being-selves over experiencing-selves was enhanced by the adoption of a third-person perspective. Although the direct effect was not significant, a distribution of products test (MacKinnon et al., 2002) showed that familiarity had a significant indirect effect on attitude via visual perspective.

This work has two main implications for product positioning and advertising. First, marketers can manipulate visual perspective to match future self-focus; situations that draw attention on one's being-self (e.g., future achievements, symbolic consumption) are more attractive when visualized through a third- rather than a first-person perspective, whereas the opposite is true for future experiencing-selves (e.g., the excitement of a snowboard downhill). Second, marketers can draw attention on either being- or experiencing-self to match the visual perspective in imagination. As shown

in Study 3, unfamiliar consumption imaginations, such as the use of a radical new product, are more effectively promoted by drawing consumers' attention on their being-selves (e.g., becoming more efficient) rather than on their experiencing-selves (e.g., experiencing positive feelings).

Public Commitment Leads to Weight Loss

Stephanie Dellande, University of New Orleans, USA

Prashanth U. Nyer, Chapman University, USA

EXTENDED ABSTRACT

In compliance dependent services (CDS), e.g., weight loss programs, the client is expected to continue to perform for himself or herself once away from the service provider in order to ensure positive outcomes and customer satisfaction (Dellande and Gilly 1998). Given that the customer of CDS must provide the inputs as well as create a major portion of the service, it is important to understand the underlying motivation-compliance process. Motivating the customer to comply with his or her service roles becomes all-the-more difficult/important when the customer must carry out his or her roles for extended periods of time. The research objective of this investigation is to explore aspects of motivation in long-term customer compliance behavior. We examine public commitment and its influence on motivation, and the effect of these on customer compliance behavior in a weight loss program. Further, we investigate the role of susceptibility to normative influence (SNI), to understand the underlying relationship between public commitment and customer compliance behavior.

Conceptualization

This paper investigates the role of public commitment in influencing motivation and compliance behavior in weight loss. In addition, susceptibility to normative influence (SNI) is also examined. The theoretical model suggests that public commitment to weight loss leads to long-term weight loss compliance behavior; further, weight loss motivation partly mediates the effect of public commitment on weight loss and SNI moderates the effect of public commitment on weight loss. As such, we offer the following hypotheses:

- H1: Higher levels of public commitment to a target behavior will result in higher levels of compliance with that behavior.
- H2: The effect of public commitment on long-term customer compliance behavior will be, in part, mediated by weight loss motivation.
- H3: Susceptibility to normative influence (SNI) will moderate the relationship between public commitment and compliance such that, at high levels of susceptibility to normative influence (SNI), the positive influence of public commitment on compliance will be strengthened.

Method

Design

The study uses a 3 x 2 full factorial design manipulating three levels of public commitment (no public commitment, short-term public commitment, and long-term public commitment), and a median split to generate two levels (low and high) of Susceptibility to Normative Influence (SNI).

Subjects

The subjects in this study were 211 women between the ages of 20 and 45 enrolled in a women's weight loss program at a center in southern India. The subjects were selected from clients who signed up for a 16 week weight loss program designed to help clients lose modest amounts of excess weight (typically 15 to 20 pounds). Weight loss goals were set for the 8th week and the 16th week of the 16 week program. The weight loss goal for the follow-up visit held during the 24th week was the same as the week 16 goal, i.e., participants were expected to maintain their weight loss during

the eight week period following the program.

Subjects completed a survey that included measures of susceptibility to normative influence (SNI), and weight loss motivation using modified versions of the sub-scales from Snell and Johnson's (1997) Multidimensional Health Questionnaire. Versions of this survey were also administered during the 4th week and during the 12th week of the 16 week program. During the second and third administrations of this questionnaire an additional question was included to assess the manipulation of public commitment. Subjects were randomly assigned to one of three manipulated experimental conditions in a 3x2 full-factorial experimental design.

In this study we investigated the effect of long-term versus short-term public commitment, and consequently public commitment was manipulated as follows. Each subject in the long-term public commitment condition had their weight loss goal, and their name printed on an index card and displayed in a locked glass-faced bulletin board for the duration of the 16 week program. Subjects in the short-term public commitment condition had their weight loss goal and their name displayed in the bulletin board for the first three weeks of the program. Subjects in the no public commitment condition did not have their information posted in the bulletin board. After eliminating participants who did not complete the entire 16 week program, 211 subjects remained.

Subjects were weighed at the start of the program, eight weeks into the program, at the end of the 16 week program, and once more during the follow-up visit during the 24th week. The percentage of weight loss goal achieved (WL) was computed for each of these weigh-ins and these form the major dependent variables in this study. Thus a subject with weight loss goals of 10, 20 and 20 pounds (for weeks 8, 16 and 24) who achieved weight loss of 9, 16 and 14 pounds respectively, would have WL scores of 90%, 80% and 70% for the three weigh-ins.

Major Findings

In this study, we investigated the effect of making public "the commitment" to lose weight. Subjects who made a long-term public commitment to a weight loss goal were found to have achieved greater results compared to subjects who made a short-term public commitment, and compared to those who made no commitment at all. Further it was found that weight loss motivation partly mediated the effect of public commitment on weight loss. Higher levels of public commitment resulted in increased weight loss motivation which in turn resulted in increased levels of weight loss. In addition, the personality trait *susceptibility to normative influence* (SNI) was found to be a moderator of the effect of public commitment on weight loss. Subjects high in SNI were more likely to be affected by public commitment, compared to those lower in SNI. Finding significant differences in compliance behavior lends greater support to our hypothesis that the "public-ness" with which a commitment is made will have a significant and favorable impact on long-term compliance behavior.

Does Precipitation Affect Consumers' Smoking Tendency?

Yinlong Zhang, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Smoking consumption perhaps is the most striking example of a harmful pattern of consumer behavior. Yet, smoking consumption is still very common in developed markets, nearly 25% of the U.S. population smokes tobacco despite the well-known negative consequences (Centers for Disease Control and Prevention, 1997), and its usage seems to be getting increasingly higher in emerging markets (World Health Organization 2004).

Due to the health and social significance of smoking consumption, over the years academic attention has been paid to understand the determinants for smoking consumption tendency. Different literatures seem to emphasize the relative importance of different factors. For example, the economic literature has mostly stressed that economic factors such as prices as the most critical driver for smoking consumption. While the social psychology literature tends to recognize that psychological, and interpersonal social determinants are important in understanding the smoking consumption, the role of social environmental factors such as family or peer group has been demonstrated as extremely important determinants. But, the role of natural environment factors such as temperature or precipitation has not been systematically investigated. These factors arguably are the very important factor in explaining consumers' consumption activities (Parker 1997), so the current research aims to offer an initial step to understand the impact of these factors in smoking consumption.

Starting with two secondary data sources, we show that measure of precipitation correlates significantly with percentage of adult smokers at both country and state levels, even after controlling for many plausible alternatives. This relationship was further confirmed with a survey on smokers' belief and their smoking tendency. Next, we present data from two experiments in which we manipulated perceived precipitation to determine its effect on smoking consumption. From the two experiments, we show that manipulations of imagined rainy weather influence intention to engage in smoking consumption in predictable ways, and this influence is mediated by negative mood, moderated by smoking status and whether smokers are in hedonic or utilitarian processing objectives.

When is a Salad Not a Salad? The Impact of Product Category on Perceived Nutritional Value

Caglar Irmak, University of South Carolina, USA
Beth Vallen, Loyola College, USA

EXTENDED ABSTRACT

The American marketplace has been inundated with “healthy” alternatives to “unhealthy” foods. For instance, smoothies are positioned as healthy alternatives to milkshakes and salads are suggested as replacements for burgers. While salads and smoothies sound like healthy options, objective nutritional information, such as caloric content and number of fat grams, might indicate that they are not really healthier choices. Yet when we do not have complete access to this information, it is hard to decipher the nutritional difference between a healthy option and its unhealthy counterpart. Instead, we may rely on cues to infer an item’s nutritional value. Under certain conditions, however, using cues to infer the healthiness of food items may lead to increased consumption of unhealthy foods. For example, recent research demonstrated that when a fast-food restaurant claims to serve healthy food (e.g., Subway), consumers are more likely to underestimate the caloric content of main dishes and to choose higher-calorie side dishes, drinks, or desserts compared to when no such claims are made (e.g., McDonald’s; Chandon and Wansink 2007). Essentially, the healthy claim associated with the restaurant creates a “health halo,” such that all restaurant items are perceived as healthy, irrespective of their objective nutritional content.

In the present research, we demonstrate that the product category associated with a food item provides another cue that consumers use to infer the healthiness of the item. For instance, imagine that you are ordering dinner from a restaurant menu that presents the items under different category titles (e.g., pastas and salads). Our results suggest that you will perceive a food item that is presented in a relatively healthier food category (e.g., salad) to be healthier than a food item with identical ingredients that is presented in a relatively less healthy food category (e.g., pasta). Moreover, we show that these effects are more likely to be demonstrated by those who are more knowledgeable about nutrition (i.e., experts) because they are more likely to rely on category-based heuristics to form inferences about products (Sujan 1985; Sujan and Dekleva 1987). In four studies, we demonstrate that product category information may bias experts’ perceptions of the nutritional value of food items, such that food items that belong to relatively healthy categories are perceived to be more nutritious than those that belong to less healthy categories. These perceptions of nutritional value, in turn, impact consumption behavior.

In the first two studies, participants were presented with a dish containing identical ingredients, but with different product category assignment as communicated by the item name (i.e., salad vs. pasta or veggie links vs. sausage links). They then evaluated the item’s healthiness and nutritional value and responded to items assessing nutrition expertise. As expected, the results showed that while novices showed no difference in their nutrition perceptions of the items, experts perceived the items assigned to healthier categories (i.e., salad and veggie links) to be significantly healthier than the items assigned to less healthy categories (i.e., pasta and sausage links).

In the third study we sought to investigate the proposed categorization process underlying the effects observed in the prior studies. To do so, we manipulated the processing approach of study participants. After providing participants with the same pasta-salad pair used in study 1, half of the participants engaged in an effortful, piecemeal process by estimating the healthiness of each ingredient

of the food item before evaluating its overall healthiness. The remaining participants engaged in a holistic, categorization process by estimating the healthiness of each ingredient after they evaluated the overall healthiness of the food item. In line with the categorization explanation, the results show that when individuals first estimated healthiness of each ingredient (i.e., piecemeal process), neither novices nor experts perceived any significant difference between the healthiness of the two items. On the other hand, experts—but not novices—considered the salad to be healthier than pasta when they evaluated perceived healthiness of the item before its ingredients (i.e., categorization process).

In our final study, we explored the impact of food category assignment on various product inferences as well as consumption quantity. We provided participants of this study with a sample of an actual confectionary product identified as either “Candy Chews” or “Fruit Chews” and measured perceptions of nutritional value, attitude towards, and purchase likelihood of the item, as well as the amount of the product consumed. As in prior studies, when the category name was associated with healthfulness (i.e., Fruit Chews), experts perceived the item to be healthier. They also expressed more positive attitudes towards and showed stronger intentions to purchase the item. Importantly, these inferences translated into behavior; nutrition experts consumed greater quantities of the item when it was positioned as a member of a relatively healthy category. Novices, on the other hand, did not demonstrate these category-based inferences nor was their consumption influenced by the category manipulation.

Together, these findings demonstrate that perceptions of the nutritional value of food items with identical ingredients can differ depending on the food category in which they are presented. For experts, food items that belong to relatively healthy categories are assumed to be more nutritious, are liked more, and are more likely to be purchased than items with identical ingredients that belong to less healthy categories. In turn, these items are likely to be consumed in greater quantities. Novices, on the other hand, are far less likely to rely on category-based heuristics. Ironically, this suggests that the knowledge that was acquired to make informed decisions may accentuate the impact of health halos created by food categories. These findings contribute to the emerging body of literature that examines cues that consumers utilize to infer unknown information about food items (e.g., Chandon and Wansink 2007) by showing that product category information—which might simply be provided by the item’s name—can drive health perceptions of food items and resulting consumption behavior.

Inferred Informational Cascades and Their Effects on Choice: The Relative Stocking Level Effect

Jeffrey R. Parker, Columbia University, USA
Donald R. Lehmann, Columbia University, USA

EXTENDED ABSTRACT

Consumers use multiple heuristics in making (sometimes non-optimal) choices. Here we introduce another heuristic, the *relative-stocking-level* effect, which consumers use to choose among similar alternatives. Specifically, we present evidence that consumers use the relative stocking level of available alternatives to infer the popularity of those alternatives and then use the inferred popularity as an input in making choices, leading them to select the less stocked alternative. We suggest that even though consumers do not directly observe the behavior(s) of their predecessors, they use stocking levels to infer it, ignoring other information (e.g., brand and quality) and potential extremeness aversion; a process we call an *inferred informational cascade*. In other words, this paper investigates whether informational cascades manifest themselves in the absence of direct observation.

Participants in four studies made choices between intra-category products, each of which was stocked at a different level. A separate study (not reported here) also examined the effect of different stocking levels when options were presented individually and found no evidence of a stocking level effect, demonstrating that it is a relative effect and, hence, not the same as a scarcity effect.

In study 1, participants chose items from three product categories (white wine, red wine and cheese) where two similar alternatives were available. Across categories, 79% of respondents chose the lesser-stocked alternative. Importantly, of those choosing the lesser-stocked alternative, 52% reported perceived popularity of that alternative as the main reason for their choice, supporting the inferred informational cascade explanation. Interestingly, participants choosing the more-stocked alternative often gave product appearance (the label) as an explanation which, since items here (and in the other studies) were rotated (balanced) in the treatments, seems to have been a convenient, and possibly post hoc, rationalization.

Study 2 extended study 1 by increasing the number of alternatives per category. Participants were asked to choose one white wine and one red wine with each category offering three alternatives stocked at three distinct levels. Replicating the results of study 1, participants preferred products that were relatively less stocked. Across categories, 53% of participants chose the least-stocked alternative, 32% chose the mid-stocked alternative and 15% chose the most-stocked alternative. A binary logistic regression revealed that stocking level was a significant predictor of preference. As in study 1, participants choosing the lesser-stocked alternatives largely indicated they had done so based on perceived popularity. Importantly, participants in this study most frequently chose the extreme option, counter to what extremeness aversion would predict.

Neither of the first two studies provided participants with information about the products other than their stocking levels and a small picture of the items. Such information could potentially reduce or eliminate the relative-stocking-level effect. Therefore, in study 3, brand information was introduced. Participants were asked to choose from six different product categories (paper towels, toilet paper, air freshener, shampoo, deodorant and spray cleaner). To simplify administration, the brands were combined into two equally appealing groups of products. One brand from each category was placed in Group A, and one in Group B. For example, the two brands of paper towels were Scott (which was placed in Group A) and

Bounty (which was placed in group B). Pretests indicated that the brands in each group were equally recognizable. As in study 1, all choices were binary. Participants made their choices either from sets where both products were equally stocked (these choices were used to determine baseline preferences in each category) or where one product was less stocked. Across brands, 53% of participants preferred Group B products when both products were equally stocked, which is not significantly different from chance. However, when the brands in Group A were less stocked, they were preferred by 60% of the participants. Similarly, when the brands from Group B were less stocked, they were preferred by 63% of the participants. Overall, lesser-stocked brands were preferred by 62% of the participants. Therefore, the relative-stocking-level effect still exists in the presence of well-known brands.

Finally, in study 4 we directly tested whether participants were making quality inferences based on perceived popularity. If participants make a quality inference, and use this information to make a selection, this would suggest our explanation of inferred informational cascades is at best an indirect effect (with stocking leading to a popularity inference which, in turn, leads to a quality inference). Thus, each participant was provided a quality rating for each of the alternatives. If a quality inference is driving the relative-stocking-level effect, then participants' choices should be random when the products are of equal quality. However, even when both alternatives were of equal quality, 78% to 85% chose the lesser-stocked product, replicating the findings of study 1. When the lesser-stocked alternative was of higher quality, 93% of participants preferred it. Most interestingly, when the lesser-stocked alternative was of lower quality, 27% of participants still preferred the lesser-stocked alternative. Thus, the relative-stocking-level effect is not dependent on quality inferences.

Taken together, the four studies present evidence that a relative-stocking-level effect exists and that it is robust in the face of extremeness aversion and brand and quality information. That participants choose the alternative they believe to be most popular, and do so despite information suggesting this might be suboptimal, supports our contention of the presence of an inferred informational cascade.

This type of consumer behavior may have significant practical implications for managers such as optimal stocking quantity and restocking timing. Further, retailers could potentially use this information to direct customers to more profitable private labels. It also suggests consumer welfare may be decreased when consumers utilize the "relative-stocking-level" heuristic. Finally, our findings suggest that consumers do not have automatic negative reactions towards either the brand (e.g., "This brand must not be good if they don't keep it in stock.") or the store (e.g., "This store is disorganized.") when a product is not fully stocked. Instead, it seems that consumers find imperfect stocking levels to be positive information.

CAM: A Spreading Activation Network Model of Subcategory Positioning when Categorization Uncertainty is High

Joseph Lajos, INSEAD, France

Zsolt Katona, INSEAD, France

Amitava Chattopadhyay, INSEAD, France

Miklos Sarvary, INSEAD, France

EXTENDED ABSTRACT

In this era of digital convergence, consumers often encounter new, hybrid products that do not fit unambiguously into their existing mental categories. For example, when consumers encountered the Motorola Envoy, which would later be acknowledged as the first personal digital assistant (PDA), they had difficulty categorizing it, since it shared features with portable computers and organizers, yet was distinctly different from products in both categories (Keller, Sternthal, and Tybout 2002).

When consumers encounter a new product, such as the Envoy, which has features that differ significantly from existing categories, they respond by creating a new subcategory (e.g., the PDA subcategory) within their existing category structure for products (Sujan and Bettman 1989). If the new product could conceivably be placed into more than one category due to similarities (e.g., shared features) with several categories (i.e., categorization uncertainty is high; Gregan-Paxton et al. 2005), consumers must determine where to position the new subcategory. For example, upon encountering the Envoy, which shared features with both portable computers and personal organizers, consumers had to decide under which of these two categories to position the new PDA subcategory.

Understanding how consumers determine where to position a new subcategory is important, since new products, including really new products, are often derived from existing product categories (Goldenberg, Mazursky, and Solomon 1999). A recent example is Sony-Ericsson's Walkman phone, which also functions as an mp3 player, camera, pedometer, and organizer.

Furthermore, consumers' categorization decisions can have striking implications for firms. Research has shown that consumers use information contained in product categories to make inferences about the features, functions, and performance of new products, and to predict the retail store departments in which they will be stocked (Gregan-Paxton and Moreau 2003). Furthermore, the manner in which consumers categorize products affects their thoughts about, attitudes toward, and overall evaluations of these products (Moreau et al. 2001b; Sujan 1985; Sujan and Bettman 1989), their memory for product features (Gregan-Paxton and Moreau 2003; Sujan and Bettman 1989), and their likelihood of recalling and subsequently choosing the products in memory-based choice (Nedungadi 1990).

In this paper, we address the question of how consumers position subcategories for new products when categorization uncertainty is high by developing and testing an analytical process model. The Category Activation Model (CAM) differs from extant models of categorization in two important ways. First, whereas extant models primarily seek to describe how category knowledge is represented and to predict into which categories objects will be placed, the goal of the CAM is to predict where entire new subcategories will be positioned. Second, whereas extant models are largely based on the notion of selective attention, the CAM relies on category accessibility.

We build on previous research that shows that priming a category increases its accessibility and subsequent use (Herr 1986, 1989). We assume that when a category is accessed (e.g., by thinking about a product in the category), some of the resulting

activation remains with the category and the rest spreads through the entire network. Furthermore, we assume that the increase in activation that results when a category is accessed increases the probability that a new subcategory will be positioned under it. Combining these assumptions, it follows that if we accurately describe the process by which activation spreads through the network, we should be able to predict the probability that a new subcategory will be positioned at any relevant location within the category structure. We show that these probabilities depend on the existing link structure, since these links determine how activation spreads through the network. Our model leads to the following hypothesis:

- H: The probability that an individual will position a new category subordinate to a particular category i is proportional to the relative number of categories that are already subordinate to i .

We find support for this hypothesis in three studies. First, in a pilot study, we performed a preliminary test of our hypothesis by asking participants to build category structures for 100 products and then examining some properties of the structures that they formed. The results indicated that these structures were congruent with the CAM, and that those participants who spent less time on the task were more likely to rely on the heuristic represented by the CAM.

In study 1, we formally tested our hypothesis in the context of a new, hybrid product, and also tested our proposition that accessibility underlies the effect. In the experiment, we varied the relative number of subcategories that were subordinate to two parent categories. The results indicated that, following a neutral prime, participants were more likely to position a new subcategory for a new, hybrid product under the parent category to which more subcategories were connected. Furthermore, we found that first priming the parent category to which fewer subcategories were connected using a proofreading task eliminated this effect, providing evidence in favor of accessibility.

However, one could argue that the results of study 1 were driven by differences in perceived category breadth or abstraction, rather than accessibility, across the subcategory numerosity conditions. In study 2, we ruled out perceived breadth as an alternative explanation by manipulating subcategory numerosity and the breadth of each category independently. The results indicate that subcategory numerosity influenced participants' positioning of a new subcategory, above and beyond any effect attributable to differences in category breadth.

The CAM provides a means for firms to assess how consumers are likely to position a subcategory for a new product. A firm could then use this prediction to estimate the level of marketing effort that would be needed to alter or support the manner in which consumers position the subcategory, to the firm's advantage. Furthermore, the CAM suggests one means by which such influence might be exerted. Since, based on our findings, consumers will be more likely to position a new subcategory within a category that already has many subcategories, it follows that advertising that prompts

consumers to think about several subcategories within a particular domain should increase the likelihood that they will position the new subcategory within that domain.

The Effect of Adding Features on Product Attractiveness: The Role of Product Perceived Congruity

Matteo De Angelis, Luiss Business School, Italy
Gregory S. Carpenter, Northwestern University, USA

EXTENDED ABSTRACT

Manufacturers offer consumers an ever-increasing number of features to differentiate products. Even simple devices often add a relatively broad range of features. Research shows positive (e.g., Carpenter et al. 1994) and negative effects of adding features (e.g., Mick and Fournier 1998). However, all studies assume that buyers make calculations based on perceived benefits and costs associated with additional features. Using the cost-benefit framework, scholars (Thompson et al. 2005; Gill 2008) show that the outcome of the calculation depends on the context of evaluation.

We propose that calculation buyers make, weighing benefits and costs, depends on more than simply the benefits, the costs, and the context; it depends on the cognitive resources applied. We argue that the resources consumers apply to the evaluation of the added features depend on the number of features, the similarity between the features and the brand, and the time frame over which consumers anticipate making their choice. Contrary to many scholars, we specifically examine the case of one versus more additional features, and explore the role of time frame in buyers' evaluation, examining how varying the future time horizon affects buyers' valuation of added features.

When valuing novel features, consumers may rely on their existing knowledge about the brand. Consumers confronting a brand with a small or large number of new features may react depending on their ability to resolve the apparent incongruities between new features and brand. The value they attach to the features may depend both on the number and their perceived brand congruence. When exposed to congruent features, consumers need not expend great cognitive effort to resolve incongruity. As a result, as the number of congruent features increases consumers should perceive an overall benefit from such an increase, increasing valuation. When exposed to moderately incongruent features, consumers face a dilemma, because resolving such incongruities requires effort, but this resolution leads to enhanced evaluation (Mandler 1982). However, this effect should exist for any small to modest number of features. Finally, resolution of highly incongruent features would require making undesired structural changes to the schema: the resources required exceed those available, leading to consumers not positively valuing the newly added features. This should be true for one or more extremely incongruent features.

Next we focus on the case in which new features' number is high. Previous analysis suggests that consumers avoid spending the resources necessary to resolve the incongruity when the number of incongruent features is high. But evidence suggests that consumers apply more resources in some instances. Then, what is the impact of added resources on the valuation of a large number of added features? When the features and the brand are highly congruent, applying additional resources should produce no difference, because features do not need extensive elaboration. The same is predicted when features are highly incongruent, because of the undesired, structural changes to the schema required. When features are moderately incongruent, things change. Encouraging people to think carefully about new stimuli results in resolution of moderate incongruity and greater preference (Meyers-Levy et al. 1994; Maoz and Tybout 2002). The nature of that effect will, however, vary with the resources applied to the task. With greater resources, buyers will more easily be able to reduce the incongruity,

leading to more detailed information processing and more positive evaluation.

Further, are the cases where a larger number of moderately incongruent features is preferred to a smaller number? One possible answer is provided by temporal construal theory, according to which the outcomes of increasing the number of moderately incongruent features may differ depending on the temporal frame of consumers' evaluation. Liberman and Trope (1998) argue that distant future events are more abstract, whereas near future events are more concrete. Hence, when focused on near future, consumers will develop a concrete construal of the product: as the number of incongruent features increases, perceived difficulty to reconcile more features with the current configuration of the product increases, and product evaluation should not increase. However, when considering a number of moderately incongruent features in a distant time frame, consumers will develop a more abstract construal of the product, focusing on higher-level considerations, related to the desirability to have more features. Consequently, product evaluation increases as the number of features increases.

We tested these predictions in three experiments. The first one focused on the interaction between number and congruity of features. Pre-tests identified the brand (Apple), the product (Ipod Nano), and three features for each of three congruity conditions (high, moderate, low). A 2x3 was employed, in which the number of new features (one, three) and their product congruity were manipulated. Subjects were asked to rate the attractiveness of the Ipod Nano compared to \$200 cash. Results showed that product attractiveness increased as the number of congruent features increased, whereas it did not increase as the number of moderately or extremely incongruent features increased.

The second study was a 2x3 in which level of resources (high, low) and congruity were manipulated, whereas the number of features was set at three. We found a significant difference in evaluation between high and low resources only when features were moderately incongruent.

The third study was a 2 x 2 design, in which temporal construal (near, distant future) and number of new moderately incongruent features (one, three) were manipulated. An increase in product evaluation as the number of features increased was observed only in the distant future.

This contribution of this paper consists in suggesting that the perceived costs and benefits associated with adding multiple product features depend on the resources consumers are willing to devote to the evaluation and on the level of abstraction at which costs and benefits are considered. All else equal, greater number of features and greater perceived incongruence between features and brand increase the perceived cost of the features. But those same features are perceived to be less costly or more valuable when consumers devote more resources to considering them or when they do so at a higher level of abstraction.

Preference Fluency in Sequential Customization: The Unexpected Ease or Difficulty of Product Feature Decisions

Keith Wilcox, Baruch College, The City University of New York, USA
Sangyoung Song, Baruch College, The City University of New York, USA

EXTENDED ABSTRACT

Product customization has become so ubiquitous that companies in thousands of different categories tailor some aspect of their product designs to meet individual customer needs. To date, a significant amount of academic research on customization has focused on finding ways to develop better customization recommendations in order to create a stronger fit between firms' product offerings and customer preferences. Inherent in much of this research is the assumption that consumers have stable preferences that, once revealed, will allow managers to better anticipate customer needs and achieve a strong competitive advantage. However, other research on the construction of preferences suggests that customer preferences are not well-defined and that factors, which seem unrelated to consumer preferences, may influence product customization decisions. For example, individuals will retain more optional features while customizing a car when they are endowed with a fully-loaded model and asked to reject features from the car compared to when they begin with a base model car that requires them to add features (Park, Jun, and MacInnis 2000).

Building on recent research in sequential decision-making and processing fluency, this current research identifies preference fluency—the subjective feeling of ease or difficulty experienced while making a decision—as another factor that affects customer preference during product customization. Previous research on preference fluency (Novemsky et al. 2007) has found that increasing the difficulty of a decision, without changing the content of decision-makers' thoughts, can have a substantial impact on preference. However, the effect of fluency on judgment may have less to do with the level of difficulty, and more to do with whether there is a discrepancy between the experienced difficulty and an expected baseline value (Whittlesea and Williams 2000). Thus, increasing the difficulty of a decision may not lead to preference fluency if individuals expect the decision to be more difficult. Interestingly, this also suggests that altering individuals' expectations may lead to preference fluency without changing the actual difficulty of a decision.

We conceptualize product customization as a sequential decision-making process where individuals use their experiences from earlier decisions to form their expectations for subsequent decisions. We find that when the difficulty of subsequent customization decisions deviates from that of initial decisions, it creates a discrepancy between consumers' actual and expected decision difficulty. This, in turn, results in preference fluency and leads individuals to select more premium features during customization compared to when they perform a similar task where the level of difficulty is expected. Thus, we demonstrate that the sequential nature of customization processes can lead to preference fluency without changing the actual difficulty of consumers' decisions.

In study 1, we compare consumer preference for laptop computer features when there is low versus high discrepancy, which we manipulated via option framing. Respondents were presented with one of four configurations of a laptop computer (two high discrepancy and two low discrepancy configurations). In one high discrepancy configuration, respondents were endowed with an initial set of features that they were asked to reject before adding a subsequent feature set. In the other high discrepancy configuration, respon-

dents were asked to add the initial feature set before rejecting the subsequent feature set. We then compared preferences in these configurations to those in two low discrepancy configurations where the framing of features remained constant (i.e., respondents only added or rejected the two feature sets). We found that participants' choices in the high discrepancy customization processes were consistent with enhanced or reduced preference fluency. In study 2, we directly link discrepancy to preference by holding the framing of alternatives constant and manipulating expectations. To manipulate expectations, we provided respondents with consensus information about whether other people found the subsequent feature set to be easier than the initial feature set. The results provided additional support for our discrepancy theory. When people expected a decision to be more difficult than it actually was, the unexpected ease of the decision led to choices that were consistent with enhanced fluency. Similarly, when individuals expected a decision to be easier than it was, the unexpected difficulty of the decision resulted in choices that were consistent with reduced fluency.

This paper contributes to our understanding of preference fluency in decision-making. While previous research has shown that preference fluency will arise when the difficulty of a decision increases, we demonstrated that preference fluency is not only determined by the difficulty of the decision, but by the extent to which it deviates from individuals' expectations. We believe these findings have important managerial implications as well. Previous research has suggested that endowing consumers with a premium version of a product may be the managerially optimal solution because they will retain more higher-priced, higher-performance features compared to the basic model (Park et al. 2000). However, it may be difficult to implement this idea in practice since the higher initial price of the premium model is likely to decrease the likelihood that consumers will consider that model. This paper demonstrates that individuals will select as many (and in some cases more) higher-priced, higher-performance features as the premium version when they are initially endowed with a mid-priced, standard version, which may be a more attractive option for customization.

Effects of Consumer Co-Production on Perceived Authenticity of Consumption Experience and Input Product

Magne Supphellen, Norwegian School of Economics and Business Administration, Norway
Sigurd V. Troye, Norwegian School of Economics and Business Administration, Norway

EXTENDED ABSTRACT

In two studies we examine the effects of *prosumption* (Toffler 1980; Xie, Bagozzi, and Troye 2008) on the perceived authenticity of a food product (taste and input product). Prosumption (*production + consumption*) is “value creation activities undertaken by the consumer that result in the production of products they eventually consume and that become their consumption experiences” (Xie et al. 2008, p. 110). We suggest that subjective feelings of authenticity are stimulated when consumers actively participate in the value-creation process (prepare food) and that this sense of authenticity transfers to the outcome (the taste of food) and the input product (a dinner toolkit). It is further suggested that stronger perceptions of authenticity are obtained when consumers are highly involved with the prosumption domain (cooking). Specifically, we tested the following hypotheses:

- H1: Consumer prosumption has a positive effect on outcome authenticity, i.e. self-produced outcomes will be perceived as more authentic than ready-made solutions of comparable quality
- H2: Consumer prosumption has a positive effect on perceived authenticity of the input product
- H3: The positive effects of consumer prosumption on perceived authenticity of outcomes (H1) and input product (H2) will be more pronounced for consumers who are highly involved in the prosumption domain compared to those who are less involved.

Study 1: Effects of Real Prosumption

Participants and Design

A professional research agency recruited subjects randomly from a Scandinavian city ($n=98$; 52.4 percent females, mean age: 33). All participants were users of the focal product category (Asian food). The study used a 2 (Low prosumption/High prosumption) by 2 (Low involvement/High involvement) between-subjects design. The product was a Tikka Masala dinner toolkit.

Stimuli, procedure and measures. The experiment took place in a laboratory kitchen with 8 pairs of ovens. In the Low Prosumption condition ($n=47$), the food was ready-made and subjects only heated and stirred the food. In the High-Prosumption condition ($n=51$), subjects were asked to fry meat and prepare the meal as prescribed on the product package (the package contained coco milk and dehydrated sauce and rice).

Before tasting the food, subjects filled in a small booklet of measures on perceived prosumption level (manipulation check) and demographic questions in an adjacent room. While subjects filled in this questionnaire, their casseroles were secretly swapped with food prepared by our chef. Subjects were let to believe that they were going to taste the food they had prepared themselves. Next, subjects were instructed to taste the food.

After the taste session, subjects responded to a questionnaire with measures of outcome and input authenticity and prosumption domain involvement. Outcome- and input authenticity were measured on two seven-point semantic differential scales (not at all authentic–very authentic; not really Indian–really Indian). Product domain involvement was measured by three items on seven-point scales.

Results of study 1

Manipulation checks. The manipulation of prosumption was successful ($F(1,82)=5.679$, $M_{\text{high prosumption}}=3.492$ vs $M_{\text{low prosumption}}=2.881$, $p<.05$).

Test of hypotheses. In line with H1, we find that subjects who prepared the dish themselves, rate the taste as more authentic than subjects who tasted ready-made food ($M_{\text{HighPros}}=4.66$ vs $M_{\text{LowPros}}=4.37$, $F(1, 81)=3.93$, $p=.051$). A similar, but even stronger effect is observed for authenticity of the input product (the Tikka Masala toolkit), lending support to H2 ($M_{\text{HighPros}}=4.76$ vs $M_{\text{LowPros}}=4.14$, $F(1, 81)=4.86$, $p=.00$). Also, the Prosumption level x Domain involvement interaction is significant for both taste authenticity ($F(1, 81)=11.83$, $p=.00$) and product authenticity ($F(1, 81)=4.43$, $p=.04$). The patterns of means and the results of contrast analyses are consistent with H3 for both variables.

Study 2

Participation involves three aspects that may partly determine perceived authenticity of the outcome. First, the prosumer gains insight into how the dish is made. Second, it allows an association between the self and the outcome. Third, what is self-made is also hand-made. In study two we used a scenario manipulation to assess whether “self-made” had an effect over and beyond the effect of the outcome being “hand made”.

Participants and Design

Subjects were 240 bachelor students in an introductory marketing course. Two subjects did not use Asian food and were removed from the analyses. In line with previous research (Bendapudi and Leone 2003), prosumption was manipulated by means of scenarios. All scenarios focused on the same product as in study 1 and described a situation in which friends were expected to visit in 90 minutes. Three scenarios described three different prosumption conditions: 1) food purchased from a firm specializing in delivery of fast food (low prosumption), 2) food prepared by a friend (handmade, low prosumption), or 3) food prepared by the subject (high prosumption). After reading a scenario, subjects tasted the food (prepared in the same way as in study 1) and responded to a questionnaire with the same measures as in study 1.

Results Study 2 and conclusion

Manipulation checks. The prosumption manipulation was successful ($F(2,236)=7.631$, $p<.05$; $M_{\text{self-made}}=2.753$; $M_{\text{made by friend}}=2.259$, $M_{\text{purchased}}=2.162$, $p<.05$ for both contrasts).

Test of hypotheses. The main effect of prosumption on outcome authenticity (taste authenticity) was not significant ($F=1.980$, $p=.139$). Thus, H1 was not supported ($M_{\text{self-made}}=3.97$; $M_{\text{made by friend}}=3.65$, $M_{\text{purchased}}=3.80$). ANOVAs for the effects of prosumption on input product authenticity (H2) and the interaction between prosumption and domain involvement on outcome- and input authenticity (H3) revealed no significant findings (all p -values $>.30$).
