Advances in Consumer Research, Volume 37

(Duluth, MN: Association for Consumer Research, 2010)

Preface

The Fortieth Annual conference of the Association for Consumer Research (ACR) was held at the Westin Hotel in Pittsburgh, PA over four terrific days, October 22 to October 25, 2009. This volume is comprised of research presented during the meetings. The volume is organized by type of research submission and includes: Full Competitive Papers; Extended Abstracts; Special Session Summaries; Working Paper Abstracts; Roundtable Summaries; and Film Festival Abstracts.

The conference theme, A World of Knowledge at the Point of Confluence, represented both the vibrant, diverse research presented at the conference, and the geographic beauty of the three rivers that join together in Pittsburgh. ACR2009 had the highest number of submissions and attendees to date. ACR2009 provided a point of confluence for researchers from 32 different countries. Out of over 900 submissions, there were 417 pieces of research accepted for presentation at the conference. The large amount of research necessitated—for the first ACR ever—13 concurrent sessions. It was well worth it to have the exposure to so much strong research representing a broad variety of paradigms and an amazing array of topics on consumers and consumer behavior.

Another first for ACR2009 was the inaugural ACRun. Actually, we had two runs, one for early birds, guided by Joann Peck, and one for those ready to run after a day of sessions, guided by Susan Jung Grant. These three-mile runs along the rivers “at the point of confluence” were well-attended and quite enjoyable. The runs offered time for participants to interact with each other outside of the hotel environment.

We are grateful to many people. The ACR community is hard-working and generous with time and effort. Fifteen Associate Editors guided the acceptance of competitive papers; 67 ACR members served on the Program Committee, providing valuable input on special session proposals; and over 750 members helped review. The names of all these people appear in the ACR2009 Program. We are also very grateful to the past conference chairs, Ann McGill and Sharon Shavitt, and the executive director, Rajiv Vaidyanathan, for their willingness to share their experience and to answer many questions. While we were not feeling particularly thankful last October—just depleted of all executive and other resources—we do sincerely thank ACR President Chris Janiszewski for trusting us with the conference and for supporting us throughout the process.

Lastly, we thank all of you who helped to make ACR2009 a reality by contributing your work, reviewing papers and session proposals, and chairing key components like working papers, roundtables, the film festival and the doctoral symposium. With all of your help, the conference was a success. Now, based on the conference, this volume summarizes the confluence of the very best consumer research to serve as a stepping stone for additional knowledge to come. Happy reading!

Margaret C. Campbell, University of Colorado, Boulder
Jeff Inman, University of Pittsburgh
Rik Pieters, Tilburg University
2009 ACR Conference Co-Chairs and Proceedings Editors

Conference Committees and Reviewers

PRESIDENT

Chris Janiszewski, University of Florida, USA

CONFERENCE CHAIRS

Margaret C. Campbell, University of Colorado, Boulder

Jeff Inman, University of Pittsburgh

Rik Pieters, Tilburg University

ASSOCIATE EDITORS

Hans Baumgartner, Pennsylvania State University, USA

Susan Broniarczyk, University of Texas at Austin, USA

Pierre Chandon, INSEAD, France

Eileen Fischer, York University, Canada

Gerald Häubl, University of Alberta, Canada

Doug Holt, Oxford University, UK

Amna Kirmani, University of Maryland, USA

Davy Lerouge, Tilburg University, the Netherlands

C. Page Moreau, University of Colorado at Boulder, USA

POV: Point of View... Consumers and Ethnographers in Perspective...
“Does Green?”
Remade China: The Re-production of Chineseness in a Multi-Cultural Society

Friday, 23 October 2009
FRIDAY SESSION 1
8:00am–9:15am

- FRI 1.1 *Paper Session:* Saving Money in a Tough Economy: How to Succeed?
- FRI 1.2 *Paper Session:* We are not all the Same: New Issues, Confluence, and Divergence in Consumer Acculturation Studies
- FRI 1.3 *Paper Session:* Attitude Strength and Consistency Between Attitude and Behavior
- FRI 1.4 *Paper Session:* On Being Better (or Worse) Than Others: Illuminating and Eliminating Biases in Social Comparison
- FRI 1.5 *Paper Session:* Positive Emotions Are Like a Box of Chocolates: Without Identifying the Different Flavors You Never Know What Behavior You’re Going to Get
- FRI 1.6 *Paper Session:* Mixed Emotions in Service Experiences
- FRI 1.7 *Paper Session:* Contemporary Topics in Regulatory Focus Research
- FRI 1.8 *Paper Session:* Drivers of Consumer Decision Making
- FRI 1.9 *Paper Session:* Exploring the Links between Stigma and Consumption
- FRI 1.10 *Paper Session:* “Self-ish” Consumer Behavior
- FRI 1.11 *Paper Session:* Who You Are Influences How You Behave: Exploring The Interplay of Personality and Consumer Behavior
- FRI 1.12 *Paper Session:* Talk the Green Talk, Shop the Green Walk?
- FRI 1.13 *Film Festival:* Film Festival Session 1

Friday, 23 October 2009

FRIDAY SESSION 2

9:45am–11:00am

- FRI 2.1 *Paper Session:* Money and People Make Strange Bedfellows
FRI 2.2 *Paper Session:* The Pitfalls of Fame: Insights from Human Brands
FRI 2.3 *Paper Session:* On the Fly: Impression Formation and Updating
FRI 2.4 *Paper Session:* On Being the Same and Different: The Dynamics of Interpretation and Comparison in Consumer Judgment
FRI 2.5 *Paper Session:* How Environmental Cues Impact Consumer Judgments
FRI 2.6 *Paper Session:* Saving for Later or Wasting: A Transformative Research Perspective
FRI 2.7 *Paper Session:* Information Integration in Judgment and Decision Making: New Directions
FRI 2.8 *Paper Session:* Expanding the Research Boundaries of Emotions
FRI 2.9 *Paper Session:* Plates, Smiley Faces and Price Tags: How Contextual Factors Bias Consumption
FRI 2.10 *Paper Session:* Constraints and Consequences: Psychological Reactance in Consumption Contexts
FRI 2.11 *Paper Session:* The Effects of Process and Outcome Simulations on Decision Making
FRI 2.12 *Paper Session:* Unhealthy Behaviors and Outcomes: Personal and Public Policy Implications
FRI 2.13 *Paper Session:* How Pricing Impacts Preferences and Satisfaction
FRI 2.14 *Film Festival:* Film Festival Session 2

Friday, 23 October 2009

FRIDAY SESSION 3

11:15am–12:30pm

- FRI 3.1 *Paper Session:* Multiple Systems for Choice and Valuation: New Perspectives from Decision Neuroscience
FRI 3.2 *Paper Session:* Other People's Things: Perspectives on Ownership Transfer and Sharing
FRI 3.3 *Paper Session:* Social Sources of Persuasion
FRI 3.4 *Paper Session:* Customization and Consumer Choice
FRI 3.5 *Paper Session:* Crossing Thresholds: Research in Life's Transitions
FRI 3.6 *Paper Session:* Charity Begins at Home: Increasing Charitable Donations
FRI 3.7 *Paper Session:* Mind Your Primes and Cues
FRI 3.8 *Paper Session:* Nudging Consumers Towards Healthier Food Choices
FRI 3.9 *Paper Session:* The Interplay between Goal Categories and Effort
FRI 3.10 *Paper Session:* Is Identity Signaling so Great? Limitations and Negative Consequences
FRI 3.11 *Roundtable Session:* Advancing the Production/Consumption Dialectic in Consumer Culture Theory
FRI 3.12 *Paper Session:* It's a Bundle! New Directions for Pricing and Promotion
FRI 3.13 *Film Festival:* Film Festival Session 3

Friday, 23 October 2009

FRIDAY SESSION 4

2:00pm–3:15pm

- FRI 4.1 *Paper Session:* Choices, Judgments and Temperature: From Visceral States to Metaphors
FRI 4.2 *Paper Session:* Having It All: Marketplace Negotiations of Feminism and Women's Roles
FRI 4.3 *Paper Session:* Persuasion, Confusion, and Sponsorship
FRI 4.4 *Paper Session:* Frontiers of Affect and Choice
FRI 4.5 *Paper Session:* Are Crowds Always Wiser?
FRI 4.6 *Paper Session:* Aging Consumers: Perceptions, Attitudes and Choice
FRI 4.7 *Paper Session:* Overconsumption and the Morality of Health
FRI 4.8 *Paper Session:* Choice in Context: The Yin and Yang of Societal and Personal Goals
FRI 4.9 *Paper Session:* The Other Side of the Story: New Perspectives on Word of Mouth
FRI 4.10 *Paper Session:* Beyond Functionality: Aesthetic Considerations in Consumer Behavior
FRI 4.11 *Paper Session:* Improving, Protecting, or Redefining the Self
FRI 4.12 *Roundtable Session:* Towards a Theoretical Vocabulary for Consumer Research on Sustainability
FRI 4.13 *Paper Session:* Preference Reversals and Counterfactuals in Choice
FRI 4.14 *Film Festival:* Film Festival Session 4

Friday, 23 October 2009

FRIDAY SESSION 5

3:45pm–5:00pm

- FRI 5.1 *Paper Session:* Deep Determinants of Value: New Perspectives on the Endowment Effect
FRI 5.2 *Paper Session:* What is the Intelligent Choice? Performance on the CRT and Preferences
FRI 5.3 *Paper Session:* The Constructive Role of Effort in Consumer Choice
FRI 5.4 *Paper Session:* Affective Advertising Effects: Where the Rubber Meets the Road
FRI 5.5 *Paper Session:* The Malleability of Choice Processes
FRI 5.6 *Paper Session:* The Many Faces of Social Influence
FRI 5.7 *Paper Session:* The Buzz about Buzz: Drivers and Consequences of Word-of-Mouth
FRI 5.8 *Paper Session:* For What It's Worth: Valuation of Price and Time
FRI 5.9 *Paper Session:* Looks Matter! Aesthetics, Design, and Consumer Judgments
FRI 5.10 *Film Festival:* Film Festival Session 5

Friday, 23 October 2009

WORKING PAPER SESSION

5:00pm–7:00pm

Saturday, 24 October 2009

FILM FESTIVAL VI-VIII

AND

AWARD WINNING FILMS

8:00am–5:00pm

Black Friday: A Video-Ethnography of an Experiential Shopping Event
Blogs - Consumption, Behaviour, Interaction
Fashion, Consumption and Identity
VINILEIROS – Those Crazy Guys that Love Their Vinyl Records
Brothers in Paint: Practice-Oriented Inquiry into a Tribal Marketplace Culture
Pirates of the Web: The Curse of Anti-piracy Advertising
Restrained Pursuit of Luxury: Wealthy Shanghainese Attitudes towards Upscale Consumption
POV: Point of View... Consumers and Ethnographers in Perspective...
“Does Green?”
Remade China: The Re-production of Chineseness in a Multi-Cultural Society

Saturday, 24 October 2009

SATURDAY SESSION 1

8:00am–9:15am

- SAT 1.1 *Paper Session:* The Role of the Past and Present on Persuasion and Influence
SAT 1.2 *Paper Session:* Greasing the Skids: Fluency and Ease of Processing Impacts
SAT 1.3 *Paper Session:* The Role of Emotions in Self-control Dilemmas
SAT 1.4 *Paper Session:* A Touch of Imagination: The Role of Imagery in Hedonic Consumption
SAT 1.5 *Paper Session:* It's a Two-Way Street: The Influence of Communicators and Recipients in Word-of-Mouth Contexts
SAT 1.6 *Paper Session:* From Ear to Brain, From Heart to Pocket: Branding Challenges and Possibilities in the Music Industry
SAT 1.7 *Paper Session:* Time is More Precious than Money
SAT 1.8 *Paper Session:* Underpinnings of Risky Behavior: Non-health Motives for Health-related Behaviors
SAT 1.9 *Paper Session:* Continuing to Sin or a Reformed Sinner: Examining Sequential Self-Regulation Choices
SAT 1.10 *Paper Session:* Packaging and Sensory Effects on Consumption
SAT 1.11 *Paper Session:* The Shifting Sands of Consumer Culture
SAT 1.12 *Film Festival:* Film Festival Session 6

Saturday, 24 October 2009

SATURDAY SESSION 2

9:45am–11:00am

- SAT 2.1 *Paper Session:* I'm Afraid, But Am I Persuaded? How to Make Fear Appeals More Effective
SAT 2.2 *Paper Session:* Metacognitive Experiences in Number Processing
SAT 2.3 *Paper Session:* Finding the Uncompromising Consumer: A Deeper Understanding of Context Effects on Choice
SAT 2.4 *Paper Session:* All Things New: Originality, Innovation Adoption, and Creative Behavior
SAT 2.5 *Paper Session:* Examining Individual and Situational Drivers of Prosocial Behaviors
SAT 2.6 *Paper Session:* Let the Games Begin: Evaluating Fun Experiences
SAT 2.7 *Paper Session:* Dynamic Influences on Investors' Decisions
SAT 2.8 *Paper Session:* The Role of Stereotypes in Changing Consumers' Attitudes and Behaviors
SAT 2.9 *Paper Session:* Exploring Self-Control: Moving Beyond Depletion Hypothesis
SAT 2.10 *Paper Session:* Visualization, Imagination, and Product Choice: Affective Forecasting of Future Product Consumption and Utilization Experiences
SAT 2.11 *Paper Session:* Virtual Worlds: Balancing Creativity and Motivation
SAT 2.12 *Paper Session:* Self-Identity Across Possessions and Places
SAT 2.13 *Film Festival:* Film Festival Session 7

Saturday, 24 October 2009

SATURDAY SESSION 3

11:15am–12:30pm

- SAT 3.1 *Paper Session:* Setting the Stage: How Frames of Reference May Be Influencing Your Behavior
SAT 3.2 *Paper Session:* When (and How) Does Metacognitive Experience Affect Consumer Behavior?
SAT 3.3 *Paper Session:* Pre-Purchase Planning and Post-Purchase Learning: The Role of Internal and External Factors
SAT 3.4 *Paper Session:* Social Comparison and Negative Emotions: Understanding Regret, Envy, and Schadenfreude in a Consumer World
SAT 3.5 *Paper Session:* The Wellbeing of Subsistence Consumers
SAT 3.6 *Paper Session:* Looking on the Bright Side: The Effects of Optimism on Goals and Behavior
SAT 3.7 *Paper Session:* Multidisciplinary Approaches to Communicating Health Risks
SAT 3.8 *Paper Session:* Deviating from or Resetting Consumers Ethical Standards
SAT 3.9 *Paper Session:* Assimilation and Contrast: Comparison Processes in Judgments and Evaluations
SAT 3.10 *Paper Session:* Cue Substitution: Inferential Processes in Judgments and Experiences of Time
SAT 3.11 *Paper Session:* New or Different Product Evaluation
SAT 3.12 *Paper Session:* Consumer Culture and Branding
SAT 3.13 *Film Festival:* Film Festival Session 8

Saturday, 24 October 2009

SATURDAY SESSION 4

2:00pm–3:15pm

- SAT 4.1 *Paper Session:* Effects of Minor Language Variations on Consumer Persuasion
SAT 4.2 *Paper Session:* Psychological Distance and Metacognitive Experience
SAT 4.3 *Paper Session:* New Insights into Consumers' Inherent Preferences
SAT 4.4 *Paper Session:* Where's My Bailout? A New Look at Factors Affecting Consumer Fairness Perceptions in the Age of Vengeful Populism
SAT 4.5 *Paper Session:* A Voter Among Voters: Political Decisions in the Social Context
SAT 4.6 *Paper Session:* Long-term Decisions and Focusing on the Future
SAT 4.7 *Paper Session:* The Influence of Lay Beliefs on Consumers' Food Consumption Decisions
SAT 4.8 *Paper Session:* Consuming in Self-Defense: Consumer Responses to Self Threat
SAT 4.9 *Paper Session:* In Pursuit of the Prime Suspects: Insights from Second Generation Research on Nonconscious Influences of Consumer Behavior
SAT 4.10 *Paper Session:* Goals' Roles in Consumer Behavior
SAT 4.11 *Paper Session:* Deep Measurement in Consumer Research: The Next Step
SAT 4.12 *Paper Session:* Transcending Culture: Religion and Politics in Consumption
SAT 4.13 *Paper Session:* The Rosy Side of Negative Emotions
SAT 4.14 *Roundtable Session:* Navigating the Networked Rivers of the Social Web: Emerging Themes for Consumer Behavior Research on Web 2.X

Saturday, 24 October 2009

SATURDAY SESSION 5

3:45pm–5:00pm

- SAT 5.1 *Paper Session:* Morality, Suspicion, and Modification: New Directions After 15 Years' Persuasion Knowledge Research
- SAT 5.2 *Paper Session:* The Distinct Effects of Hope in Consumption
- SAT 5.3 *Paper Session:* Why Reproduction Involves More Than Sex: The Diverse Effects of Mating Motivation on Consumer Behavior
- SAT 5.4 *Paper Session:* It's Not What You Think it Is: Insights into Consumers' Perceptual Biases in Response to Brand Strategies
- SAT 5.5 *Paper Session:* Effects of Social Influence on Consumer Spending Decisions
- SAT 5.6 *Paper Session:* The Consequences of Being Naughty
- SAT 5.7 *Paper Session:* Consumer-Generated Advertising: Creators and Spectators
- SAT 5.8 *Paper Session:* Emotional and Motivational Drivers of Our "Want" and "Should" Desires
- SAT 5.9 *Paper Session:* Consumer Strategies to Track Spending
- SAT 5.10 *Paper Session:* Tough Choices and Comparisons
- SAT 5.11 *Film Festival:* 2009 AWARD WINNING FILMS

TABLE OF CONTENTS

PRESIDENTIAL ADDRESS

<i>The Consumer Experience</i>	1
Chris Janiszewski, University of Florida, USA	

Special Session Summaries

SPECIAL SESSION SUMMARY

<i>Planning to Save Money Seems to be a Good Thing: But is it Always?</i>	7
Julia Belyavsky Bayuk, University of Delaware, USA	

Framing Goals to Increase or Decrease Personal Savings: The Effect of Specific Goals and Construal Level
Amar Cheema, University of Virginia, USA
Gülden Ülkümen, University of Southern California, USA

Letting Good Opportunities Pass Us By: Examining the Role of Mindset during Goal Pursuit
Julia Belyavsky Bayuk, University of Delaware, USA
Chris Janiszewski, University of Florida, USA
Robyn LeBoeuf, University of Florida, USA

When Seeing is Believing: Visualization Effects on Regulating Savings Behavior
Eunice Kim, Yale University, USA
Ravi Dhar, Yale University, USA

SPECIAL SESSION SUMMARY

<i>We Are Not All the Same: New Issues, Confluence, and Divergence in Consumer Acculturation Studies</i>	10
Søren Askegaard, University of Southern Denmark, Odense, Denmark	

She, Who Has the Spoon, Has the Power: Immigrant Women's Use of Food to Negotiate Power Relations
Zuzana Chytkova, University of Pisa, Italy
Nil Özçaglar-Toulouse, Université de Lille 2, France

Cross Generation: Cultural (In)visibility in the Consumption of Second Generations
Luca Massimiliano Visconti, Bocconi University, Italy

Deciphering the Socio-Temporal Dimensions of Consumer Identity Development: A Cultural Genealogy
Lisa Peñaloza, EDHEC Business School, France

From Resistance to Integration: Changing Consumer Acculturation Practices of Immigrants
Mine Üçok Hughes, Woodbury University, USA

SPECIAL SESSION SUMMARY

<i>Attitude Strength and Consistency Between Attitude and Behavior</i>	15
Kalpesh Kaushik Desai, State University of New York at Binghamton, USA	

Internal versus External Informational Sources: Causes and Consequences for Attitude Certainty and Attitude-Behavior Consistency
David Dubois, Northwestern University, USA
Derek D. Rucker, Northwestern University, USA
Richard E. Petty, Ohio State University, USA

A Field Examination of the Influence of Brand Equity on Behavioral Loyalty and Factors that Moderate this Relationship
Kalpesh Kaushik Desai, SUNY-Binghamton, USA
Vijay Hariharan, SUNY-Buffalo, USA
Jeffrey Inman, University of Pittsburgh, USA
Debabrata Talukdar, SUNY-Buffalo, USA

Fragile Enhancement of Attitudes and Intentions Following Difficult Choices

Ab Litt, Stanford University, USA
Zakary L. Tormala, Stanford University, USA

SPECIAL SESSION SUMMARY

On Being Better (or Worse) Than Others: Illuminating and Eliminating Biases in Social Comparison 20
Ellie Kyung, New York University, USA

Biases in Social Comparisons: Optimism or Pessimism?

Geeta Menon, University of Pennsylvania, USA
Ellie Kyung, New York University, USA
Nidhi Agrawal, Northwestern University, USA

It's Not Just Me: The Role of Inferences about Reference Distributions on Estimates of One's Own Comparative Performance

Andrew Gershoff, University of Texas at Austin, USA
Katherine A. Burson, University of Michigan, USA

Overconfidence and Entry into Competitions: Reconciling Discrepant Results

Daylian M. Cain, Yale University, USA
Don A. Moore, Carnegie Mellon University, USA
M. Keith Chen, Yale University, USA

SPECIAL SESSION SUMMARY

Positive Emotions Are Like a Box of Chocolates: Without Identifying the Different Flavors You Never Know What Behavior You're Going to Get 24
Lisa Cavanaugh, University of Southern California, USA
Barbara Fredrickson, University of North Carolina, USA

Feeling Good and Doing Better: How Specific Positive Emotions Differentially Influence Consumer Behavior

Lisa A. Cavanaugh, University of Southern California, USA
James R. Bettman, Duke University, USA
Mary Frances Luce, Duke University, USA

Opportunity Knocks: Other-Praising Positive Emotions in Action

Sara B. Algoe, University of North Carolina, USA
Jonathan Haidt, University of Virginia, USA
Shelly Gable, UC Santa Barbara, USA

Why Different Positive Emotions Have Different Effects: An Evolutionary Approach to Discrete Positive Emotions and Processing of Persuasive Messages

Vladas Griskevicius, University of Minnesota, USA
Michelle N. Shiota, Arizona State University, USA
Samantha Neufeld, Arizona State University, USA

SPECIAL SESSION SUMMARY

Exploring the Links between Stigma and Consumption 28
Elizabeth Crosby, University of Illinois at Urbana-Champaign, USA
Cele C. Otne, University of Illinois at Urbana-Champaign, USA

Consumption as a Strategy for Stigma Management

Elizabeth Crosby, University of Illinois, Urbana-Champaign, USA
Cele C. Otne, University of Illinois, Urbana-Champaign, USA

The Voices of Trailer Park Residents: Towards a Multidimensional Understanding of Stigma

Bige Saatcioglu, HEC Paris, France
Julie L. Ozanne, Virginia Tech, USA

From Individual Coping to Collective Action: Stigma Management in Online Communities

Daiane Scaraboto, York University, Canada

Eileen Fischer, York University, Canada

Understanding Stigma and Coping Strategies across Resource and Literacy Barriers: A Cross-Cultural Comparison

Madhu Viswanathan, University of Illinois at Urbana-Champaign, USA

SPECIAL SESSION SUMMARY

Talk the Green Talk, Shop the Green Walk? 32

Gary Bamossy, Georgetown University, USA

Basil Englis, Berry College, USA

Green Dilemma: Libertarian Values Trump Communal Values

Basil G. Englis, Berry College, USA

Gary Bamossy, Georgetown University, USA

Change Is In the Air?

Steven French, Natural Marketing Institute, USA

Dispersed Practices and Cultural Models: Implications for More Sustainable Electricity Consumption

Eric J. Arnould, University of Wyoming, USA

Melea Press, University of Wyoming, USA

SPECIAL SESSION SUMMARY

Money and People Make Strange Bedfellows 36

Deborah Small, University of Pennsylvania, USA

Social Rejection and Desire for Money

Kathleen Vohs, University of Minnesota

Xinyue Zhou, Sun Yat-Sen University

Roy Baumeister, Florida State University

Putting the "Social" in Prosocial Spending: Interpersonal Giving Promotes Happiness

Michael I. Norton, Harvard Business School

Lara Aknin, University of British Columbia

Elizabeth Dunn, University of British Columbia

Reminders of Money Weaken Sociomoral Responses

Nicole Mead, Tilburg University

Kathleen Vohs, University of Minnesota

Krishna Savini, Stanford University

Tyler Stillman, Florida State University

Roy Baumeister, Florida State University

Fatal (Fiscal) Attraction: Tightwads and Spendthrifts in Marriage

Scott I. Rick, University of Michigan

Deborah A. Small, University of Pennsylvania

Eli J. Finkel, Northwestern University

SPECIAL SESSION SUMMARY

The Pitfalls of Fame: Insights from Human Brands 37

Marie-Agnès Parmentier, HEC Montréal, Canada

The Ties that Bind: Consumer Engagement and Transference with a Human Brand

Cristel Antonia Russell, University of Auckland, New Zealand

Hope Jensen Schau, University of Arizona, USA

Branded Like Beckham? An Examination of Dynamic Processes in Human Branding

Marie-Agnès Parmentier, HEC Montréal, Canada

Eileen Fischer, York University, Canada

Taking Stock in Martha Stewart: A Cultural Critique of the Marketing Practice of Building Person-Brands
Susan Fournier, Boston University, USA

SPECIAL SESSION SUMMARY

On Being the Same and Different: The Dynamics of Interpretation and Comparison in Consumer Judgment 41
Femke van Horen, Tilburg University, The Netherlands

The Color of the Chameleon Depends on the Prime Type
Americus Reed II, University of Pennsylvania, USA
Mark Forehand, University of Washington, USA
Andrew Perkins, Rice University, USA

On Subtle Themes and Blatant Features: The Effect of Imitation-Type on Evaluation and Choice of Copycats
Femke van Horen, Tilburg University, The Netherlands
Rik Pieters, Tilburg University, The Netherlands
Diederik A. Stapel, Tilburg University, The Netherlands

When Bodily Sensations Elicit Context Effects: The Moderating Role of Physical Distance
Joan Meyers-Levy, University of Minnesota, USA
Rui (Juliet) Zhu, University of British Columbia, Canada

SPECIAL SESSION SUMMARY

How Environmental Cues Impact Consumer Judgments 45
Leonard Lee, Columbia University, USA
Michel Tuan Pham, Columbia University, USA

Positive Effects of Negative Publicity
Jonah Berger, University of Pennsylvania, USA
Alan Sorensen, Stanford University, USA
Scott Rasmussen, Stanford University, USA

When does Priming Cause Us to Value or Devalue a Brand?
Amy Dalton, Hong Kong University of Science and Technology, China
Gráinne Fitzsimons, University of Waterloo, Canada
Gavan Fitzsimons, Duke University, USA
Tanya Chartrand, Duke University, USA

The Effect of Music on Retrieved and Constructed Preferences
Leonard Lee, Columbia University, USA
Manoj Thomas, Cornell University, USA

Shaping Customer Satisfaction through Self-Awareness Cues
Michel Tuan Pham, Columbia University, USA
Caroline Goukens, University of Maastricht, The Netherlands
Jennifer Ames Stuart, Bayer Healthcare, USA
Donald Lehmann, Columbia University, USA

SPECIAL SESSION SUMMARY

Plates, Smiley Faces and Price Tags: How Contextual Factors Bias Consumption 49
Meng Zhu, Carnegie Mellon University, USA

What is Beautiful Tastes Good: Visual Cues, Taste, and Willingness to Pay
Collin Payne, New Mexico State University, USA
Brian Wansink, Cornell University, USA

Can Pictures in Advertisements Curb Consumption?
Meng Zhu, Carnegie Mellon University, USA
Darron Billeter, Brigham Young University, USA
J. Jeffrey Inman, University of Pittsburgh, USA

The Ironic Effect of Efficacy on Consumer Consumption
Rajesh Bagchi, Virginia Tech, USA
Amar Cheema, Washington University/University of Virginia, USA

SPECIAL SESSION SUMMARY

Constraints and Consequences: Psychological Reactance in Consumption Contexts 53
Amit Bhattacharjee, The Wharton School, University of Pennsylvania, USA

Financial Incentives and Consumer Product Choices
Marco Bertini, London Business School, UK
Utpal (Paul) Dholakia, Rice University, USA

Escaping the Crosshairs: Reactance to Identity Marketing
Amit Bhattacharjee, University of Pennsylvania, USA
Jonah Berger, University of Pennsylvania, USA

Feeling the Pressures: Considering the Context-Dependencies of Reactance Motivation in Underage Alcohol Consumption
N. Pontus Leander, Duke University, USA
Tanya Chartrand, Duke University, USA
James Shah, Duke University, USA
Gavan Fitzsimons, Duke University, USA

SPECIAL SESSION SUMMARY

The Effects of Process and Outcome Simulations on Decision Making 57
Michal Herzstein, University of Delaware, USA

The Journey to Goal Attainment: When Process Focus is Engaging
Michal Herzstein, University of Delaware, USA
Aparna Labroo, University of Chicago, USA

Using Process-Focused vs. Outcome-Focused Thought to Enhance Consumer Judgment
Jennifer Escalas, Vanderbilt University, USA
Mary Frances Luce, Duke University, USA

Process- versus Outcome-focused Simulation and the Evaluation of New Products: The Temporal Effects on the Affective and Cognitive Dimensions
Min Zhao, University of Toronto, Canada
Steve Hoeffler, Vanderbilt University, USA
Gal Zauberman, University of Pennsylvania, USA

SPECIAL SESSION SUMMARY

Multiple Systems for Choice and Valuation: New Perspectives from Decision Neuroscience 60
Ab Litt, Stanford University, USA

Brain Processes Underlying the Influence of Prior Gains and Losses on Decisions under Risk
Kaisa Hytönen, Erasmus University Rotterdam, The Netherlands
Guido Baltussen, Robeco, The Netherlands
Martijn van den Assem, Erasmus University Rotterdam, The Netherlands
Vasily Klucharev, Erasmus University Rotterdam, The Netherlands
Ale Smidts, Erasmus University Rotterdam, The Netherlands
G. Thierry Post, Erasmus University Rotterdam, The Netherlands

Impatient No More! Impulsivity in Choice Depends on How you Frame the Question
Bernd Figner, Columbia University, USA
Eric Johnson, Columbia University, USA
Amy Krosch, Columbia University, USA
Jason Steffener, Columbia University, USA
Eustace Hsu, Columbia University, USA
Elke Weber, Columbia University, USA

Distinguishable Neural Circuits for Motivation and Valuation Underlying Decision Making

Ab Litt, Stanford University, USA
Hilke Plassmann, INSEAD, France
Baba Shiv, Stanford University, USA
Antonio Rangel, California Institute of Technology, USA

SPECIAL SESSION SUMMARY

Other People's Things: Perspectives on Ownership Transfer and Sharing 65
Zeynep Arsel, Concordia University, Canada

Identity and Self-Territory in Second Hand Clothing Transfers
Dominique Roux, IRG-Université Paris-Est, France

Exploring the Social Dynamics of Online Bartering
Zeynep Arsel, Concordia University, USA

Market-Mediated Collaborative Consumption in the context of Car Sharing
Fleura Bardhi, Northeastern University, USA
Giana M. Eckhardt, Suffolk University, USA

SPECIAL SESSION SUMMARY

Customization and Consumer Choice 69
Aner Sela, Stanford University, USA

Contingent Consumer Response to Self-Customization Procedures: Implications for Decision Satisfaction and Choice
Ana Valenzuela, Baruch College, USA
Ravi Dhar, Yale University, USA
Florian Zettelmeyer, University of California–Berkeley, USA

Negative Effects of Explicit Customization on Perceptions of Opportunity
Aner Sela, Stanford University, USA
Itamar Simonson, Stanford University, USA
Ran Kivetz, Columbia University, USA

Menu Customization and Calorie Estimation Biases in Consumer Choice
Alexander Chernev, Northwestern University, USA

SPECIAL SESSION SUMMARY

Nudging Consumers Towards Healthier Food Choices 73
Pierre Chandon, INSEAD, France

Vicarious Goal Fulfillment: When the Mere Presence of a Healthy Option Leads to an Ironically Indulgent Decision
Keith Wilcox, Babson College, USA
Beth Vallen, Loyola College, USA
Lauren G. Block, Baruch College, CUNY, USA
Gavan Fitzsimons, Duke University, USA

Rejection is Good for Your Health: The Influence of Decision Strategy on Food and Drink Choices
Jane Machin, Virginia Polytechnic Institute and State University, USA
Yong Wan Park, Virginia Polytechnic Institute and State University, USA

Linearize This! Why Consumers Underestimate Food Portion Changes and How to Help Them
Pierre Chandon, INSEAD, France
Nailya Ordabayeva, INSEAD, France

SPECIAL SESSION SUMMARY

The Interplay between Goal Categories and Effort 77
Antonios Stamatogiannakis, INSEAD, France

Maintenance versus Attainment Goals: Why People Think it Is Harder to Maintain their Weight than to Lose a Couple of Kilos

Antonios Stamatogiannakis, INSEAD, France
Amitava Chattopadhyay, INSEAD, Singapore
Dipankar Chakravarti, Johns Hopkins University, USA

Recurring Goals and Learning: The Impact of Successful Reward Attainment on Purchase Behavior

Joseph Nunes, University of Southern California, USA
Xavier Drèze, University of Pennsylvania, USA

The Fruit of Labor Effect

Monica Wadhwa, Stanford University, USA
Remi Trudel, University of Western Ontario, Canada

SPECIAL SESSION SUMMARY

Is Identity Signaling so Great? Limitations and Negative Consequences 81
Rosellina Ferraro, University of Maryland, USA

Signaling Identity through Brands: The Role of Perceived Authenticity

Rosellina Ferraro, University of Maryland, USA
Amna Kirmani, University of Maryland, USA
Ted Matherly, University of Maryland, USA

Read the Signal but Don't Mention It: How Conspicuous Consumption Embarrasses the Signaler

Young J. Han, University of Southern California, USA
Joseph C. Nunes, University of Southern California, USA

Satisfying Identity-Signaling and Uniqueness Motives through Consumer Choice

Cindy Chan, Cornell University, USA
Jonah Berger, Wharton School of Business, USA
Leaf Van Boven, University of Colorado–Boulder, USA

Why Do Products Become Unpopular? Adoption Velocity and the Death of Cultural Tastes

Jonah Berger, Wharton School of Business, USA
Gaël Le Mens, Stanford University, USA

SPECIAL SESSION SUMMARY

Choices, Judgments, and Temperature: From Visceral States to Metaphors 85
Hee-Kyung Ahn, University of Toronto, Canada

The Influence of Visceral States on Forecasts of Future Events

Clayton R. Critcher, Cornell University, USA
Jane L. Risen, University of Chicago, USA

Being Hot or Being Cold: The Influence of Temperature on Judgment and Choice

Hee-Kyung Ahn, University of Toronto, Canada
Nina Mazar, University of Toronto, Canada
Dilip Soman, University of Toronto, Canada

Hot Wheels, Warm Hearts: The Effect of Temperature Metaphors on Product Replacement Intentions

Jesse Chandler, University of Michigan, USA
Lauren Szczurek, Stanford University, USA
Norbert Schwarz, University of Michigan, USA

SPECIAL SESSION SUMMARY

Having It All: Marketplace Negotiations of Feminism and Women's Roles 89
Leah Carter, York University, Canada

Discourses of Femininity in Advertising among Gen X Women
Linda Tuncay, Loyola University of Chicago, USA

Critically Romantic: Negotiating Feminist and Romantic Discourses in the Marketplace
Leah Carter, York University, Canada

Between and Between: Liminality and Feminism in the Twilight Brand Community
Hope Jensen Schau, University of Arizona, USA
Kate Thompson, University of Arizona, USA

SPECIAL SESSION SUMMARY

Are Crowds Always Wiser? 94
Andrew Stephen, INSEAD, France
Leonard Lee, Columbia University, USA

Are Crowds Wise When Predicting Against Point Spreads? It Depends on How You Ask
Joseph Simmons, Yale University, USA
Leif Nelson, University of California at Berkeley, USA
Jeff Galak, Carnegie Mellon University, USA
Shane Frederick, Yale University, USA

When it Comes to Wisdom, Smaller Crowds are Wiser
Jack Soll, Duke University, USA
Richard Larrick, Duke University, USA
Al Mannes, Duke University, USA

The Emotional Oracle: Predicting Crowd Behavior with Feelings
Leonard Lee, Columbia University, USA
Michel Tuan Pham, Columbia University, USA
Andrew Stephen, INSEAD, France

SPECIAL SESSION SUMMARY

The Other Side of the Story: New Perspectives on Word of Mouth 98
Sarah G. Moore, University of Alberta, Canada

Some Things Are Better Left Unsaid: How Word of Mouth Influences the Speaker
Sarah G. Moore, University of Alberta, Canada
Gavan J. Fitzsimons, Duke University, USA
James R. Bettman, Duke University, USA

Selecting Snapshots from Episodic Memory's Photo Album: Sharing Experiences and Retrospective Evaluations
Elizabeth Cowley, University of Sydney, Australia

Language Use in Word of Mouth
Gaby Schellekens, Erasmus University, The Netherlands
Peeter Verlegh, Erasmus University, The Netherlands
Ale Smidts, Erasmus University, The Netherlands

SPECIAL SESSION SUMMARY

Beyond Functionality: Aesthetic Considerations in Consumer Behavior 102
Joann Peck, University of Wisconsin-Madison, USA

Please Touch: Aesthetic Features that Invite Touch
Joann Peck, University of Wisconsin-Madison, USA
Roberta Klatzky, Carnegie Mellon University, USA

The Power of Aesthetic Design in Consumer Financial Decisions
Claudia Townsend, University California, Los Angeles, USA
Suzanne Shu, University California, Los Angeles, USA

Assisted Aesthetic Self-Design: Application to Nike Shoe Configurator
Xiaoyan Deng, University of Pennsylvania, USA
Sam K. Hui, New York University, USA
Wes Hutchinson, University of Pennsylvania, USA

SPECIAL SESSION SUMMARY

Deep Determinants of Value: New Perspectives on the Endowment Effect 107
Rama Ganesan, University of Arizona, USA

Defending Against Loss: Temperamental Fear Predicts Endowment Effect
Rama Ganesan, University of Arizona, USA
Najam Saqib, Ryerson University, USA

Wanting More but Liking Less: Counter-Driving Motivational and Appraisal Elements of Value
Ab Litt, Stanford University, USA
Uzma Khan, Stanford University, USA
Baba Shiv, Stanford University, USA

The Impact of Temporal Focus on the Endowment Effect
Promothes Chatterjee, University of South Carolina, USA
Caglar Irmak, University of South Carolina, USA

SPECIAL SESSION SUMMARY

What is the Intelligent Choice? Performance on the CRT and Preferences 111
Claudia Townsend, UCLA Anderson School of Management, USA

Getting Past that First, Compelling Response: Three Behavioral Studies and an fMRI Investigation of Performance and Overconfidence on the Cognitive Reflection Test
Robert Spunt, UCLA, USA
Matthew Lieberman, UCLA, USA

Should Einstein Manage your Money? Lay Theories and Normative Force of the Relation Between Cognitive Ability and Preferences
Shane Frederick, Yale University, USA
Nathan Fong, Sloan School of Management, USA
Eric Tsytlylin, Yale School of Management, USA

The Intelligence of Judging Products Based on Looks
Claudia Townsend, UCLA, USA
Dan Ariely, Duke University, USA
Sanjay Sood, UCLA, USA

SPECIAL SESSION SUMMARY

The Constructive Role of Effort in Consumer Choice 115
Rom Schrift, Columbia University, USA

The Tradeoff Heuristic: The Settling Effect of Conflict
Wendy Liu, UCLA, USA
Itamar Simonson, Stanford University, USA

Complicating Choice
Rom Schrift, Columbia University, USA
Oded Netzer, Columbia University, USA
Ran Kivetz, Columbia University, USA

Does Distance make your Heart Fonder or your Mind Wonder? An “Attainability-Efficacy” Framework of Preference Construction

Sara Kim, University of Chicago, USA
Aparna Labroo, University of Chicago, USA

SPECIAL SESSION SUMMARY

The Buzz about Buzz: Drivers and Consequences of Word-of-Mouth 118

Jonah Berger, University of Pennsylvania, USA
Andrew Stephen, INSEAD, France

Virality: What Gets Shared and Why

Jonah Berger, University of Pennsylvania, USA
Katy Milkman, University of Pennsylvania, USA

Why Do Consumers Talk, Does Anyone Listen, and What Happens?

Andrew Stephen, INSEAD, France
Donald Lehmann, Columbia University, USA
Olivier Toubia, Columbia University, USA

The Impact of Consumer Reviews on Consumer Search and Firm Profits

Dina Mayzlin, Yale University, USA
Wendy Moe, University of Maryland, USA

SPECIAL SESSION SUMMARY

The Role of Emotions in Self-control Dilemmas 122

Anastasiya Pocheptsova, University of Maryland, USA

The Motivation-Emotion Matching Hypothesis

Ayelet Fishbach, University of Chicago, USA
Tal Eyal, Ben Gurion University, Israel

What Movie Would You Watch with Your Salad? The Implicit Emotional Consequences of Exerting Self Control

David Gal, Northwestern University, USA
Wendy Liu, UCLA, USA

The Effect of Goal Setting on Consumption & Consumer Well-Being

Maura Scott, University of Kentucky, USA
Stephen M. Nowlis, Arizona State University, USA

SPECIAL SESSION SUMMARY

It's a Two-Way Street: The Influence of Communicators and Recipients in Word-of-Mouth Contexts 126

Andrew Kaikati, University of Minnesota, USA

Negative Word-of-Mouth: Self-Construal and Image Impairment Concern

Yinlong Zhang, University of Texas at San Antonio, USA
Lawrence Feick, University of Pittsburgh, USA
Vikas Mittal, Rice University, USA

Word-of-Mouth Communication as Helping Behavior

Andrew M. Kaikati, University of Minnesota, USA
Rohini Ahluwalia, University of Minnesota, USA

The Dynamic Effect of Source Certainty on Consumer Involvement and Persuasion

Uma R. Karmarkar, Stanford University, USA
Zakary L. Tormala, Stanford University, USA

SPECIAL SESSION SUMMARY

From Ear to Brain, From Heart to Pocket: Branding Challenges and Possibilities in the Music Industry 130
Chia-Jung Tsay, Harvard Business School, USA

Hearing, Remembering, and Branding: Guidelines For Creating Sonic Logos
Vijaykumar Krishnan, University of Cincinnati, USA
James J. Kellaris, University of Cincinnati, USA

“She’s a Natural!” : From Mere Label to Actualized Consumer Preference
Chia-Jung Tsay, Harvard Business School, USA
Mahzarin R. Banaji, Harvard University, USA

“I Want You Back” : Branding Classical Music For The New Generation
Lalin Anik, Harvard Business School, USA
Chia-Jung Tsay, Harvard Business School, USA

SPECIAL SESSION SUMMARY

Time is More Precious than Money 134
Stephen A. Spiller, Duke University, USA

Consumers Exhibit the Planning Fallacy for Time but not Money
Stephen A. Spiller, Duke University, USA
John G. Lynch Jr., University of Colorado, Boulder, USA

How and When the Moral Self Motivates Donations of Time versus Money
Americus Reed II, University of Pennsylvania, USA
Karl Aquino, University of British Columbia, Canada
Eric Levy, University of Washington, USA
Stephanie Finnel, University of Pennsylvania, USA

The Role of Time versus Money in the Pursuit of Happiness
Cassie Mogilner, University of Pennsylvania, USA

The Stability of Time versus Money Valuations
Leonard Lee, Columbia University, USA
Michelle Lee, Singapore Management University, Singapore
Gal Zauberman, University of Pennsylvania, USA

SPECIAL SESSION SUMMARY

Underpinnings of Risky Behavior: Non-health Motives for Health-related Behaviors 138
Merrie Brucks, University of Arizona, USA
Paul M. Connell, Stony Brook University, USA

The Use of Hypocrisy to Motivate Health Attitude and Behavior Change
Jeff Stone, University of Arizona, USA
Nicholas C. Fernandez, University of Arizona, USA

Children’s Ascribed Motivations for Smoking Elicited by Projective Questioning
Merrie Brucks, University of Arizona, USA
Paul M. Connell, Stony Brook University, USA
Dan Freeman, University of Delaware, USA

Symbolic Interactionism and Adolescent Reactions to Cigarette Advertisements
Connie Pechmann, University of California at Irvine, USA
Dante Pirouz, University of California at Irvine, USA
Todd Pezzuti, University of California at Irvine, USA

SPECIAL SESSION SUMMARY

Continuing to Sin or a Reformed Sinner: Examining Sequential Self-Regulation Choices 143
Yael Zemack-Rugar, Virginia Tech, USA

Seeking, Giving, and Responding to Negative Feedback in Self-Regulation

Stacey Finkelstein, University of Chicago, USA
Ayelet Fishbach, University of Chicago, USA

Sequential Influences on Dishonest Behavior

Nina Mazar, University of Toronto, Canada
Dan Ariely, Duke University, USA

The “What The Hell Effect” Scale: Measuring Post-Failure Sequential Self-Control Choice Tendencies

Yael Zemack-Rugar, Virginia Tech, USA
Canan Corus, St. John’s University, USA
David Brinberg, Virginia Tech, USA

SPECIAL SESSION SUMMARY

I’m Afraid, But Am I Persuaded? How to Make Fear Appeals More Effective 146
Eugenia Wu, Duke University, USA

That’s So Disgusting—I’ll Take Two!: How Disgust Enhances the Effectiveness of Fear Appeals

Andrea C. Morales, Arizona State University, USA
Gavan J. Fitzsimons, Duke University, USA
Eugenia C. Wu, Duke University, USA

Roundtable Summaries

ROUNDTABLE

Advancing the Production/Consumption Dialectic in Consumer Culture Theory 737

Chairs:

Ahir Gopaldas, York University, Canada
Sarah J. S. Wilner, York University, Canada

Participants:

Lisa Peñaloza, EDHEC Business School, France
David Crockett, University of South Carolina, USA
Kent Grayson, Northwestern University, USA
Bernard Cova, Euromed Management Marseilles, France
Hope Jensen Schau, University of Arizona, USA
Jean-Sébastien Marcoux, HEC Montréal, Canada
Fuat Firat, University of Texas-Pan American, USA
Julie Ozanne, Virginia Tech, USA
Clinton Lanier, University of St. Thomas, USA
Robert Kozinets, Schulich School of Business, York University, Canada
Richard Kedzior, Hanken School of Economics, Finland
Jill Avery, Simmons School of Management, USA
Aron Darmody, Schulich School of Business, York University, Canada
Gokcen Coskuner-Balli, Chapman University, USA
Ashlee Humphreys, Northwestern University, USA

ROUNDTABLE

Towards a Theoretical Vocabulary for Consumer Research on Sustainability 739

Chairs:

Melea Press, University of Wyoming, USA
Eric J. Arnould, University of Wyoming, USA

Participants:

David Crockett, University of South Carolina, USA
Diane Martin, University of Portland, USA
Guliz Ger, Bilkent University, Turkey
Pierre McDonagh, Dublin City University, Ireland, UK
Krittinee Nuttavuthisit, Chulalongkorn University, Thailand
Alice Grønhøj, Aarhus University, Denmark
Robert Fisher, University of Alberta, Canada
Benet DeBerry-Spence, University of Illinois at Chicago, USA
Julie Ozanne, Virginia Tech, USA
John Schouten, University of Portland, USA
Stacey Baker, University of Wyoming, USA
Jenny Mish, University of Notre Dame, USA
Susan Dobscha, Bentley College, USA
Vladas Griskevicius, University of Minnesota, USA
Robert Caruana, University of Manchester, UK
Gokcen Coskuner-Balli, Chapman University, USA

Chair:

Donna Hoffman, University of California at Riverside, USA

Participants:

Robert Kozinets, Schulich School of Business, York University, Canada

Nicholas Lurie, Georgia Institute of Technology, USA

Wendy Moe, University of Maryland, USA

Albert Muniz, DePaul University, USA

Thomas Novak, University of California at Riverside, USA

Thomas O'Guinn, University of Wisconsin-Madison, USA

Hope Jensen Schau, University of Arizona, USA

Ann Schlosser, University of Washington, USA

Allan Weiss, University of Southern California, USA

Tiffany White, University of Illinois, USA

Jill Avery, Simmons School of Management, USA

Kristine De Valck, HEC Paris, France

Uptal (Paul) Dholakia, Rice University, USA

Markus Geisler, York University, Canada

Andrew Gershoff, University of Michigan, USA

Ashlee Humphreys, Northwestern University, USA

Charla Mathwick, Portland State University, USA

Constance Porter, University of Notre Dame, USA

PRESIDENTIAL ADDRESS

The Consumer Experience

Chris Janiszewski, University of Florida, USA

Over the years, I have participated in a number of consortia, symposia, and meetings with graduate students. One of the most common questions has been, “What is hot?” My stock answer has always been, “Whatever is ‘hot’ today will be cold by the time you complete a research project in the area, so don’t chase current trends.” I then follow up with, “Find something interesting and make it ‘hot’.” This advice often results in a glazed look that I used to interpret as appreciation. Now that I am older, and less vain, I understand my advice contained little information. The graduate students could have gained as much information from a conversation with Sarah Palin.

My uninformative answer to the question, “What is hot?” was a consequence of my failure to understand the intent of the question. The real question was, “Can you explain the market place of academic ideas?” The graduate students knew they were entering a business where their job was to market ideas, but their current marketing plan lacked a customer and a competitive analysis. The students knew that if they could understand the needs of the target market, and the strengths and weaknesses of their competition, they could identify marketable projects. They could then make personal tradeoffs between pursuing these marketable projects versus projects that might be less marketable, but more intrinsically interesting.

Over the next twenty minutes, I hope to provide some insight into this issue. I will organize my comments around the broader issue of how academics typically identify interesting ideas, the competition you will face as you attempt to market ideas, and the types of research that are likely to allow you, and by extension the discipline of consumer behavior, to experience success. I will provide examples of promising areas of research, with the understanding that I intend to illustrate as opposed to advocate.

MAKING A CONTRIBUTION

There are two common approaches to identifying potentially interesting consumer research ideas. The first is to be an active participant in a basic social science discipline. Whether one is a disciple of anthropology, economics, psychology, or sociology, the prescription is the same. Try to reach a level of excellence and insight that allows you to understand and apply state-of-the-art theory. Use this knowledge to (1) extend theory and make a contribution to the core discipline, (2) gain insight into how and why consumers behave the way they do, or (3) both. This is an effective strategy that has been executed by consumer behavior researchers over the past 40 years. Yet, I perceive two problems with the core discipline approach. First, many of us do not have the resources to compete. For example, a successful psychology professor has post-docs, many Ph.D. students, and a cadre of undergraduate research assistants in his or her lab.

Academic progress is quicker in this environment. Second, consumer behavior research is by definition, an interdisciplinary endeavor. We make progress through shared interdisciplinary insights. Thus, as a consumer researcher becomes more expert in a core area, the person’s ideas are likely to become less interesting to the consumer research community as a whole. To put it plainly, enhancing discipline-specific expertise leads to an increased appreciation for one’s ideas in the core area, but less appreciation for one’s ideas among the consumer research audience.

The second approach to identifying potentially interesting research ideas is to focus on a substantive domain. There is a long

history of this type of research in consumer behavior. For example, advertising response, branding, collecting, gift giving, health behavior, impulsive buying, new product adoption, and nutritional labeling are some of the substantive areas that have received research attention over the past four decades. Again, a subset of consumer behavior researchers have executed this strategy successfully. Yet, a substantive focus does not guarantee that research is marketable. A substantive focus often involves an application of an existing theory that has been “borrowed” from a base social science discipline. When insight into a substantive domain is based on “borrowed” theory, there is always the danger that the insight will be perceived as redundant. This makes the publication of the idea more difficult.

So, we are faced with two approaches to making a contribution: (1) make a theoretical advance in a core discipline, using a consumer behavior context as a setting for the research, or (2) provide insight into a substantive domain. And, as I have argued, each of these approaches has potential disadvantages. The question is how to mitigate these disadvantages. The answer is not simple. My solution? I propose that you select substantive domains where existing social science theory is not easily applied or where social scientists from the core disciplines are reluctant to go. To put it another way, we need to work in areas where there is limited competition from the core social sciences, but where our insights are likely to capture market share somewhere down the road.

CAN AN APPLIED DISCIPLINE LEAD?

My advice that our discipline should focus on research topics that are somewhat removed from the mainstream of social science research implies isolationism and the potential of irrelevance. To allay these criticisms, I would like you to consider three areas in which consumer researchers were the driving force behind theory development.

1. 1970’s: Consumer satisfaction/dissatisfaction. Consumer satisfaction and dissatisfaction are consequences of consumption or service experiences. Consumer satisfaction and dissatisfaction research began during the 1970’s as a response to the concerns of government regulators and consumer advocates. The initial research focused on the measurement of consumer satisfaction (Pfaff 1972) and the role of expectation disconfirmation in dissatisfaction (Anderson 1973; Olshavsky and Miller 1972). Subsequently, research identified the antecedents and consequences of consumer satisfaction and dissatisfaction. Antecedents include performance expectations and the pleasantness of prior consumption experiences. Consequences include changes in price sensitivity, brand loyalty, and changes in the frequency of purchase. These findings led to expectation-confirmation theory of customer satisfaction (Oliver 1980) and to a discussion of the role satisfaction plays in a consumer’s life (Fournier and Mick 1999). To date, there have been over 3000 publications on consumer satisfaction, many of them motivated by the original research conducted in the consumer behavior domain.
2. 1980’s: Attitude toward the Advertisement. Attitude toward the advertisement refers to the “pleasant or unpleasant feelings evoked by advertising” (MacKenzie, Lutz,

and Belch 1986, p. 131). Although the Aad concept has a long history (see Lutz 1985; Silk and Vavra 1974), research began in earnest in the 1980's. The initial research focused on documenting that the feelings evoked by an advertisement could influence feelings toward the advertised product (Mitchell and Olson 1981), brand consideration (Moore and Hutchinson 1983), brand choice (Shimp 1981; Shimp and Yokum 1982), and the rate at which an advertisement lost its effectiveness owing to repeated use (Calder and Sternthal 1980). Subsequently, Aad research focused on the factors that influenced the attitude toward the ad and the likelihood that these feelings would impact relevant downstream behaviors including choice and purchase execution (MacKenzie and Lutz 1989). The Aad construct is interesting because it encouraged consumer behavior researchers to focus on how the feelings evoked by an advertisement interacted with the more cognitively-based beliefs the ad was designed to communicate (e.g., Brown and Stayman 1992; Madden, Allen, and Twible 1988).

3. 1990's: Brand relationships. In her 1998 JCR article, Susan Fournier proposed that consumers form relationships with their brands. Her analysis was based on relationship theory. Her insights were threefold. First, brand relationships come in many forms, including buddies, friendships, committed partnerships, and marriages of convenience. Second, these relationships evolve over time. Third, marketing actions can influence the quality and stability of these consumer-brand relationships. The key insight was that product usage not only provides a benefit experience, but also an experience related to the brand and the meanings it has come to represent. To my knowledge, this is the most cited piece of research in consumer behavior over the past ten years.

What is common across these three examples? These are examples of substantive domains that were initially of special interest to consumer researchers and of lesser interest to social scientists that seek to generate knowledge in their core areas. As a consequence, our discipline took a leadership position among social scientists in developing these areas of thought. In fact, I would argue that there was a collective recognition, by the intellectual producers and the gatekeepers of consumer behavior research, that these topics were interesting consumer behavior experiences that were worthy of investigation.

OUR OPPORTUNITY: CONSUMER EXPERIENCE

So, what is our opportunity? In what substantive areas do we, as a discipline have a special interest and a competitive advantage? The answer is "consumer experience." CCT researchers have a long history of calling for, and focusing on, consumer experiences (Arnould and Thompson 2005; Holbrook and Hirschman 1982; Hirschman and Holbrook 1982; cf. Holt 1995). There has also been growing interest in consumer experience among information processing and decision science researchers. In the past few years, I have seen papers on aesthetic experience (Joy and Sherry 2003; Veryzer and Hutchinson 1998), authenticity (e.g., Rose and Wood 2005), consumer socialization (John 1999), emotional responses (e.g., Andrade and Cohen 1997; Ramanathan and Williams 2007), excitement (Ding et al. 2005), extraordinary experiences (Arnould and Price 1993), hedonic experience (e.g., Nelson and Meyvis 2008; Ratner, Kahn, and Kahneman 1999), prestige and status (e.g., Ivanic and Nunes 2009; Ordabayeva and Chandon 2009), process-

ing fluency (e.g., Allen 2002), retail experience (Verhoef et al. 2009), self-identity (e.g., Wood, Chaplin, and Solomon 2009), tactile experience (e.g., Peck and Wiggins 2006), taste experience (e.g., Elder and Krishna 2009; Hoegg and Alba 2007), and visceral experience (e.g., Celsi, Rose, and Leigh 1993; Chang and Pham 2009).

Although consumer researchers may not have been the initiators of many of these research streams, our discipline certainly has the potential to develop innovative insights into these consumption experiences. Yet, in order to do this, we will have to focus on the richness of the consumer experience and the consumer's role in the management of this experience (e.g., Fournier and Mick 1999). In doing this, we must focus on the mental and physiological states that accompany information acquisition, product choice, consumption, and post-consumption activities. In the next part of my talk, I would like to illustrate what a discipline wide program on consumer experience might entail. I will focus on consumption utility because it is a concept that is relevant to researchers that represent the breadth of approaches to consumer research.

CONSUMPTION UTILITY

The utility of any object . . . pleases the master by perpetually suggesting to him the pleasure or conveniency which it is fitted to promote.

Adam Smith

Two foundational social sciences have informed the study of utility in consumer behavior (cf. Hsee and Tsai 2008). The economic approach to utility assumes that consumers have an underlying set of preference functions that allow them to anticipate the value of any product or experience. These preference functions are assumed to be relatively stable and enduring. Psychologists and decision making theorists accept that some portion of utility is stable, but add that context can alter the relative preferences for choice options. The literatures on preference reversals, constructed preferences, and local and global context effects all provide testimony to the malleability of utility. Economists and psychologists have shown that preferences are not time consistent, frame consistent, or context consistent. More importantly, we are not the dominant players in these literatures. We certainly have superstars that contribute to the research on utility, but I would argue that utility is studied in economics first, psychology second, and consumer behavior third.

So the question becomes, "What utility-based research could we own?" Where do we have a differential advantage with respect to our interest, our expertise, and our areas of application? I contend that it is not in the "utility of choice" (expected utility), but the "utility of consumption" (experienced utility or *subjective value*) (see Holbrook and Hirschman 1982). Although this change in emphasis sounds subtle, it is not. Our current focus in the "utility of choice" makes choice the seminal event. The antecedent and consequences of choice all must be understood through the investigative frame we have adopted. If our focus were to shift to the utility of consumption, then we would worry more about how people experience utility than how they anticipate utility. We would put less emphasis on the events that are external to the individual, such as product features and contextual events, and more emphasis on the consumption experiences and, by extension, events that are internal to the individual such as a consumer's mood (e.g., happiness, eagerness, calmness, relief, anger, sadness, embarrassment, anxiety) or mental state (e.g., pleasure, pain, confidence, uncertainty, desire, contentment). Even more importantly, we would look at how the external and internal factors interact to determine

the consumer's experienced utility (e.g., Chen 2009). This leads to the following research issues:

This leads to the following research issues:

1. Where does experienced utility come from? A typical approach to answering this question comes from the information processing perspective. Utility is a function of the features of a product. This viewpoint is predicated on the assumption that there is a one-to-one mapping between the level of a product's features and the benefits of consumption. Yet, we know this is not true. Benefits are not in the products. Benefits are in the consumer experience. Experienced benefits not only vary significantly across consumers, but across time for the same consumer, because internal factors such as emotional states, psychological states, and physiological states vary over time. Give the same person the same food or beverage on five different occasions and the experienced utility will vary by occasion. In fact, it can vary quite dramatically. A similar claim about the inconsistency of experience has been made with respect to time perception, pain perception, hedonic experiences, etc. Thus, internal states matter for experienced utility.
2. What events are responsible for experienced utility? One could posit that experienced utility is a consequence of direct and indirect sources. For example, baseball fans are prone to say that hot dogs taste better at the ball park. Many people also believe that beer taste better when it is consumed with friends. These examples are meant to illustrate that utility is derived from the consumption of the product itself (a direct source) and the social situations in which it is consumed (an indirect source). More interesting is what happens the next time the person consumes a hot dog or beer. Does the indirect utility from the prior social consumption episode influence the utility derived in the next consumption episode, even though the social cues are absent? If this is so, one might wonder about the conditions that are favorable to this form of utility expansion and/or contraction?
3. What are consumers trying to achieve with experienced utility? Do consumers simply seek to maintain a mood or are there other objectives? To illustrate, consider the consumption of a meal that consists of a single course with multiple food items. We could assess the utility associated with each individual bite, with a series of bites, with a series of bites interspersed with beverage consumption, or with bites, beverages, and conversation. Does the consumer manage this sequence of utility? This is not an issue of expectations (e.g., von Neumann and Morgenstern) or retrospective evaluations (e.g., Ratner, Kahn, and Kahneman 1999), but an issue of managed experiences. Rather than thinking about utility experiences as temporally distinct, we can of them as inter-temporally managed. Thus, if we were to extrapolate from the food example to a day's worth of events, we could research how consumers manage experienced utility throughout the day. We might even discover that there are different types of experienced utility that are being managed.
4. If consumers are trying to string together a set of experiences that provide utility, how does this process work? An obvious starting point for this conversation is the literature on adaptation. The literature on adaptation shows that an experience becomes less intense with repetition (Nelson

and Meyvis 2008). Yet, at some level, this process explanation is much too simplistic. Most adaptation level findings are local, not global. For example, I can quickly adapt to repeatedly listening to my favorite song, but not to repeated listening to a favorite collection of songs and even less to a mix of songs, conversation, and food (e.g., a party). The interesting question is why people satiate to a series of hedonic experiences when they come from the same source but not when they come from different sources? After all, utility is utility, right? Similarly, how do different types of intervening experiences influence adaptation and experienced utility? In effect, this is a question of variety seeking on a grand level, but with the emphasis on experience as opposed to prospective evaluation or retrospection assessment.

5. Has the focus on expectations about product performance led us ignore experiences that accompany the act of purchasing? The traditional focus on the "utility of choice", as opposed to the "utility of consumption", leads to the implicit assumption that expectations are focal and experiences are secondary. It's all about the choice. Yet, we could argue the opposite. Purchases do nothing more that create opportunities for experiences. In fact, it could be argued that the act of purchasing is sufficient to create the desired experience. To illustrate, consider food acquisition and consumption. In the U.S., 13% of income is spent on food. The average American consumer eats 1750 pounds of food per year and discards about 250 pounds of it. What is even crazier is that 20 percent of the food U.S. consumers discard food that hasn't even been removed from the package! This fact can lead to two very different research questions. First, we could adopt a traditional expected utility choice paradigm and wonder why consumers are being suboptimal. Why can't consumers learn to purchase and consume food properly? Alternatively we could adopt an experience perspective and seek to understand how utility is derived from the purchase, storage, and failure to consume the food. Maybe wilting one's lettuce in the refrigerator creates more utility than consuming it. This example illustrates the importance of understanding how consumers derive utility from a wide range of consumption-related experiences.

I have just made a case for investigating utility as an experience. If we can unlock the door into consideration, acquisition, and consumption experiences, we can gain insight into what people buy, when they buy, how much they buy, and why all of this buying influences, or fails to influence, their happiness. This is an area of inquiry that is closely aligned with consumer researcher interests, provides an opportunity for theory development, and can benefit from interdisciplinary study.

NARRATIVES, BELIEFS, AND UTILITY

Thus far, I have argued that consumers derive utility from experience. Yet, I have failed to discuss what makes an experience pleasurable or painful. For the marketing faculty in the audience, this is akin to asking, "Where do benefit segments come from?" Why do some people derive utility from a product whereas others do not? My contention is that utility is a function of an individual's beliefs, and by extension, the meanings that support these beliefs. Beliefs create utility during the acquisition of a product, the consumption of a product, and the communication about these experiences. Thus, insight can be gained by understanding the

events that lead to belief structures that allow a person to extract utility from an experience.

The idea that belief structures support utility extraction from experiences should sound like Marketing 101 because, in many ways, it is. Yet, what is interesting is the variability in the effectiveness of belief structures. For example, consider the belief structure that supports the use of dental floss. Everyone knows that flossing is important. It promotes healthy teeth and gums. In the U.S., we are taught this from our very first visit to the dentist. Yet, the American Dental Association reports that only 12% of American floss daily. Contrast this with another health behavior. Over the past 30 years, the U.S. market share of world pharmaceutical consumption has increased from 20% to 50%. A significant portion of this increased consumption is non-essential drug use. One could use observations about drug consumption and the use of dental floss to conclude that pharmaceutical manufacturers are much better marketers than dental hygiene product manufacturers. Alternatively, one could conclude that marketers are generally effective and that there must be something about how beliefs are organized or supported that creates differences in the utility for these two types of behavior.

There are two potential solutions to this problem of belief-behavior inconsistency. First it may be that consumption beliefs have to be supported by the appropriate foundational beliefs or values in order for utility to accrue from an experience. For example, Western cultures believe that man can control nature, that science can solve problems, and that life is sacred. Given these core beliefs, the promise of a pill is more believable and valuable than the promise of a piece of waxed string. Second, the narratives that accompany or organize beliefs lead to utility (Thompson and Haytko 1997; Thompson and Troester 2002). Certainly, the magic potion narrative associated with pill popping is more valuable than the manual labor narrative associated with plaque removal. This view of how belief structures contribute to utility lends itself to an interdisciplinary research effort. Relevant research questions include:

1. First, is there an optimal procedure for communicating information to consumers so that beliefs are perceived as consistent with an existing consumption utility narrative? Alternatively, why do certain people resist adopting certain beliefs about consumption experiences? In other words, to what extent do the characteristics of an existing utility narrative, the characteristics of proposed beliefs, or a combination of the two contribute to the formation of a belief structure that supports the creation of utility in a consumption experience?
2. Second, if consumption utility narratives are organizational schemes that structure beliefs and determine their influence on consumption utility, then there must be a process by which these narratives are adopted, used, and updated. I say this because narratives are largely culturally determined. We need research that identifies how a specific consumption utility narrative is chosen for a particular situation and the extent to which the narrative or the accompanying beliefs are updated as a consequence of the experience. Insight into this issue will help us understand the intensity, frequency, and persistence of consuming specific types of products.
3. Third, how are consumption utility narratives diffused (e.g., Sirsi, Ward, and Reingen 1995)? One possibility is that narrative acceptance happens in accordance with economic market principles (Glaeser 2004; 2005). If this is so, three conditions should support acceptance of the

consumption utility narrative. First, business or government must be able to extract value when consumers accept a consumption narrative. This encourages a supply of narratives that can be “marketed” to the public. Second, the consumer must experience value from adopting the narrative. Third, there must be limited negative personal consequences to adopting the narrative. In effect, this third condition limits the cost of adoption for the individual. If these conditions are met, businesses can peddle consumption utility narratives, consumers can adopt them, and social networks can reinforce them (e.g., Moore, Wilkie, and Lutz 2002).

Thus far, I have treated consumption utility narratives and their accompanying belief systems as a frame that influences the utility derived from a product acquisition or consumption experience. This is an appropriate framework given our field’s focus on consumerism. Yet, my remarks would not be complete if we did not consider two other major sources of utility: thought and social interaction (Ariely and Norton 2009). Thought clearly creates utility (e.g., Zauberger, Ratner, and Kim 2009). One simply has to think of one’s parents, spouse, or children to appreciate the power of thought. Relationships also have utility (Saffer 2008). We would not interact with others if there was no utility associated with the experience. What intrigues me is how consumers coordinate thought utility and social interaction utility with utility from consumption. If thought itself can generate utility, why do we acquire and consume so many products? And if John Lennon was right, isn’t the world filled with enough love to put some limits on excessive consumption?

Insight into how consumers might coordinate alternative sources of utility over time may be traced to the relative availability of utility producing narratives. The truth is that consumption utility narratives are much more available than narratives that allow us to derive utility from interpersonal interaction or thought (e.g., anticipation, recollection, creative ideas, etc.). To appreciate this fact, consider the consumption maturation of most children (cf. Chaplin and Roedder John 2007). Babies derive the most utility from interactions with their family. Toddlers derive utility from play and the thoughts that accompany it. Yet, as children mature, consumption utility narratives are learned and practiced. Growing up in Western culture teaches children many more consumption utility narratives than interpersonal interaction or thought utility narratives. Moreover, advertising and culture makes the consumption utility narratives much more salient than the competing narratives. Thus, altering the way humans consume the earth will never be accomplished by telling people to conserve, to be less superficial, or to live within their means. Instead, the mix of narratives must be changed. Someone has to market interpersonal interaction or thought narratives that can generate utility. Unfortunately, this is not something that capitalist cultures have been designed to do.

In the end, maybe insight can be gained by understanding how to increase the utility associated with any one narrative or how to create variations of interpersonal or thought utility narratives so that they can become more prevalent. Alternatively, we need to understand how to squeeze more utility out of an experience, or to create more utility experiences, per unit of consumption. Increasing the amount of utility derived from savoring, remembering, and interacting should allow people to live more satisfying lives. Of course, understanding how people coordinate these experiences, adapt to these experiences, and come to appreciate new experiences is one of the great mysteries of consumption (Hsee et al. 2009; Wilson and Gilbert 2008).

CONCLUSION

In summary, I have tried to make the case that we have a competitive advantage when it comes to the study of consumer experience. I expect we have competitive advantages in other substantive domains as well. I hope you will consider a research strategy that focuses on developing theory in these areas. Who knows, this research strategy might help you become famous.

SPECIAL SESSION SUMMARY

Planning to Save Money Seems to be a Good Thing: But is it Always?

Julia Belyavsky Bayuk, University of Delaware, USA

EXTENDED ABSTRACTS

“Framing Goals to Increase or Decrease Personal Savings: The Effect of Specific Goals and Construal Level”

Amar Cheema, University of Virginia, USA

Gülden Ülkümen, University of Southern California, USA

Although the importance of saving is indisputable, left to themselves, consumers don't save enough (e.g., Shefrin and Thaler 1988). Therefore, consumers are prone to deviate from their optimal saving levels. Thaler and Bernartzi (2004) suggest that these deviations may be due to errors in calculation or due to lapses in self-control, and consumers could benefit from mechanisms that help overcome these deviations.

Is it possible to influence consumers' saving behavior simply by changing the way they think about their savings? In the present research, we explore whether and how goal framing influences saving success. Imagine a consumer who wants to save money for an upcoming trip. There are several different ways to think about this saving goal. For example, when thinking about how much to save, consumers can be more or less specific. Consumers can decide to save some money without specifying an amount (e.g., “I need to save as much as I can”), therefore setting a non-specific goal. Alternatively, consumers can choose to specify the amount they need to save (e.g., “I need to save \$500”), thereby setting a specific goal. A second factor that influences how a consumers think about saving goals is the level at which this goal is represented. In particular, consumers can either focus on why to save (high level construal), or how to save (low level construal; Trope and Liberman 2003).

We study the how these two factors, namely, goal specificity, and the level of construal together influence several saving-related outcomes, such as anticipated success, commitment, and most importantly, goal achievement. We examine the conditions under which specific (vs. non specific goals) goals facilitate and impede goal attainment, by exploring how the effect of specificity varies across low versus high levels of construal (Vallacher and Wegner 1987).

The Effects of Goal Specificity

Previous literature has conflicting findings on the effectiveness of goal specificity. Numerous studies demonstrate the beneficial effects of goal specificity. For example, specific (vs. non-specific) goals increase goal commitment, are associated with lower performance variability, allow children to better resist temptation, and can increase persistence (e.g., Wright and Kacmar 1994).

In contrast, some literature suggests that goal specificity can have detrimental effects on goal pursuit. Kirschenbaum, Humphrey, and Malett (1981) find that people perform better with less (vs. more) specific goals, and speculate that specific goals may lead to “disengagement in self-regulation when the task at hand is difficult or perceived as difficult.” These results suggest that specific goals may be more discouraging than non-specific goals in some instances.

Moderating Role of Construal Level

According to the theory of action identification (Vallacher and Wegner 1987), construing a goal-directed action at a high level allows attention to be focused on why the goal is important. In

contrast, when the same action is construed at a low level, a consumer focuses more on how to do a task (Trope and Liberman 2003).

We propose that construal level influences how consumers interpret the meaning of the specificity of a saving goal. Since at high level of construal the individual is focused on why a goal is important, specificity of a saving goal can be interpreted as a signal of its importance. Consequently, among high-level construers, specific (vs. non-specific) goals may engender greater anticipation of success, commitment, and lead to higher amount of savings. In contrast, specific goals may be perceived as more difficult when the act is construed at a low level. As low-level construers are focused more on how to achieve a goal, specific (vs. non-specific) goals may appear rigid and discouraging, leading to lower commitment and disengagement, and consequently, lower amount of actual savings.

Overview of Results

Across four studies, to manipulate goal specificity we first ask participants to consider a saving occasion, and then to either indicate the dollar amount they would like to save for this occasion (specific), or we don't prompt them to specify the amount (non-specific). We either manipulate construal level via elaboration instructions (studies 1 and 2), or we measure chronic individual differences in construal (studies 3 and 4).

In study 1 we find that consumers who specify how much to save (vs. those who do not specify an amount) anticipate higher saving success if they construe this saving goal at a high level. In contrast, consumers who do not specify an amount anticipate higher success (vs. those who specify how much to save) if the saving goal is construed at a low level. Illustrating the process, study 2 reveals that high-level construers (who focus on why to save) perceive specific goals to be more important than non-specific goals, and therefore anticipate higher success. In contrast, low-level construers (who focus on how to save) perceive specific goals to be more difficult than non-specific goals, and therefore anticipate lower success. Moreover, we find that the level at which a saving goal is construed, and its specificity influence not only anticipated success, but also goal commitment, and actual success in saving. Study 3 demonstrates that anticipated success mediates the effect of specificity and construal level on goal-commitment. Importantly, study 4 explores extend these findings to actual savings, by examining consumers' actual savings over one month. Chronic high (low) level construers save more when they have specific (non-specific) goals.

"Letting Good Opportunities Pass Us By: Examining the Role of Mindset during Goal Pursuit"

Julia Belyavsky Bayuk, *University of Delaware, USA*

Chris Janiszewski, *University of Florida, USA*

Robyn LeBoeuf, *University of Florida, USA*

Consider the following scenario: your bank account is quickly approaching empty, and you acknowledge that dining out at restaurants, especially upscale ones, adds up quickly. Thus, you create a plan to increase your savings account that involves dining out less at restaurants and cooking more at home. You follow this plan religiously. Now imagine that the price of gas has skyrocketed, so carpooling to work and combining errands might also help you save a lot of money. How will the fact that you already have a plan to save money influence your propensity to adjust your lifestyle to drive less? In comparison to someone who has not yet formed a money-saving plan, are you more or less likely to take advantage of the public transportation and carpool options?

Although planning, or forming an implementation intention, is generally thought to promote goal achievement (Gollwitzer 1999), it is not yet known how forming an implementation intention (e.g., dining out less) might alter a consumer's evaluation of goal consistent, out-of-plan behaviors (e.g., driving less). On the one hand, an implementation intention makes a goal more salient (Gollwitzer 1999). Salient goals are more likely to be pursued (Bargh et al. 2001), and means associated with these goals are more likely to be valued (Chartrand et al. 2008). Thus, implementation intentions could enhance the value of all means (in- or out-of-plan) that are relevant to goal pursuit. On the other hand, an implementation intention involves mentally simulating the steps that must be taken to achieve a goal (Gollwitzer 1993, 1996, 1999). Specifying when, where, and how one will achieve a goal creates a readiness to respond to specific behavioral opportunities (Gollwitzer 1999). Yet, this readiness to respond to specific behavioral opportunities may encourage a narrow-mindedness that leads to a devaluation of out-of-plan opportunities to achieve a goal. Thus, there is reason to think that implementation intentions may increase or decrease the evaluation of goal consistent, out-of-plan behaviors.

We show that the influence of an implementation intention is moderated by the concreteness/abstractness of thought at the time a person evaluates goal consistent, out-of-plan behaviors. If a person is likely to be thinking concretely when exposed to goal-consistent, out-of-plan behaviors, then the person should not be encouraged to form an implementation intention: Forming an implementation intention will encourage the person to develop a specific plan, and a concrete mindset will reinforce thinking at a specific level. Thus, a concrete mindset following the formation of an implementation intention seems to simply reinforce commitment to a specific means, making goal consistent, out-of-plan behaviors seem less valuable. If, however, a person is likely to be thinking abstractly when exposed to goal-consistent, out-of-plan behaviors, then an implementation intention should be encouraged: Forming an implementation intention encourages a person to develop a specific plan, but an abstract mindset refocuses thinking at the goal level, as opposed to the plan level. Thus, an abstract mindset following the formation of an implementation intention

should reinforce commitment to the goal, making goal consistent, out-of-plan behaviors seem more valuable.

These hypotheses are investigated in a set of four studies using the important consumer goal of saving money. Study 1 investigates the influence of forming an implementation intention to save money on a consumer's willingness to resist an impulse purchase when in a concrete or abstract mindset. Studies 2a and 2b investigate the influence of forming an implementation intention on a consumer's willingness to take advantage of a wide variety of money-saving opportunities when in a concrete or abstract mindset. Study 3 extends this research by altering the time frame in which money-saving, out-of-plan behaviors can be pursued, using the insight that people will think more concretely (abstractly) when contemplating events that are in the near future (distant future) (e.g., Trope and Liberman 2000). Study 4 further extends this research by encouraging a prevention focus (i.e., a concrete mindset) or promotion focus (i.e., an abstract mindset) while people assess the appeal of money-saving, out-of-plan behaviors. Combined, these studies show that forming an implementation intention can have detrimental consequences for taking advantage of out-of-plan opportunities and for goal achievement if individuals consider these opportunities while in a concrete mindset.

To conclude, although implementation intentions are generally thought to be beneficial, we show that forming an implementation intention can lead individuals to be less likely to take advantage of goal-consistent, out-of-plan opportunities. These results suggest that even when a goal such as saving money is extremely important, as it is in today's economy, specifying a plan to achieve it can negatively affect open-mindedness to consider goal-consistent out-of-plan means, and thus, can negatively affect goal achievement.

"When Seeing is Believing: Visualization Effects on Regulating Savings Behavior"

Eunice Kim, *Yale University, USA*

Ravi Dhar, *Yale University, USA*

A major challenge facing many American households is how to save and plan for the future. Many people express the desire to save but find that they lack the needed self-control. Not surprisingly, the question of how to encourage consumers to exercise self-control and save for the future is an important one from both a theoretical and real-world perspective. Thus, one key to increasing savings may be in addressing the psychological variables that might

make it easier to self-regulate behaviors for future outcomes and benefits.

Prior research has focused mainly on showing how visualizing the pursuit of a goal (e.g. goal to study for an exam) or engaging in a specific goal-related behavior (e.g. going to the library) can increase the performance of that behavior and the eventual successful attainment of goals (Bator and Bryan 2008; Gregory et al. 1982). While visualization in prior research has been limited to circumstances in which individuals are visualizing the specific steps needed to reach a particular goal, our research examines how the simple task of visualizing the performance of everyday activities at an old age in the future, unrelated to the specific goal, can lead to the attainment of that same goal. We propose that the mere visualization of the self at an old age in the future can increase self-regulation and help individuals save today.

We posit that those who visualize routine activities at an old age will demonstrate an increased willingness to save because they feel less anxiety and more peacefulness than when they do not. Zeelenberg and Pieters (2006) proposed that one of the primary motivators of goal-directed behavior is emotions. Prior research suggests that emotions such as anxiety and stress hinder goal pursuit (Pham and Taylor, 1999; Taylor and Schneider, 1989), whereas an increase in emotions of peacefulness, which is the opposite of anxiety, can encourage goal pursuit. Therefore, decreasing emotions related to anxiety and increasing emotions related to peacefulness will allow individuals to feel as though the pursuit of long-term goals, whose consequences are attained in the distant future, (e.g. savings) is manageable. It follows, then, that the extent to which these relevant emotions can be felt via visualization of the self at an old age, is the key driving factor in affecting savings attitudes and decisions today.

We further show that the effect of visualization of old age is not based solely on priming any goal related to age. We compare the effects of visualization with those due to the semantic priming of concepts related to the elderly. While semantic primes of the elderly activate stereotypical associations of the elderly (e.g. walking slower; Bargh, Chen and Burrows, 1996), they do not facilitate the experience of emotional states as visualization does. Thus, the semantic priming of old age will not have the same impact on savings when it is not accompanied by instructions to visualize the future. We test these hypotheses in a series of three experiments.

Study 1 shows that visualization of the self at an old age leads to greater self-regulation and motivation to engage in savings behavior as evidenced by increased importance of attitudes towards a savings goal. Participants in the visualization condition visualized themselves engaging in various activities such as attending a family reunion at the age of 70 and wrote a few sentences describing thoughts, feelings, and details of each scenario. Those in the control condition completed simple mathematical calculations whose answers were close to the number "70". Then all participants completed various measures indicating the importance of long-term financial planning and saving money for retirement. As predicted, participants who had visualized themselves at age 70 reported significantly greater importance of future financial planning than those in the control condition.

Study 2 extends the influence of visualization to behaviors that reflect an increase in self-regulation toward the pursuit of long-term goals, and further demonstrates that visualization results in greater self-regulation compared to the semantic priming of old age or the elderly. Participants first either visualized themselves at the age of 70 engaging in various scenarios as in Study 1, or were semantically primed with old age by answering questions such as "At what age does the average person retire?" or "Is someone who is 70, too old

to be president of the US?" Then all participants were told to allocate \$5,000 into either a checking account for immediate use, or a savings account for a future purchase. As predicted, participants who had visualized themselves at the age of 70 were more inclined to spend less now and put aside more money for future use compared to those primed with the concept of the elderly.

Study 3 tests the mechanism underlying the effect of visualization by demonstrating how visualization, compared to non-visualization, increases the desire to save because it not only decreases feelings of anxiety but also increases feelings of peacefulness. Participants first visualized themselves in everyday activities at an older age or at their current age. Then, in what they believed to be a separate and unrelated task, they reported their attitudes regarding savings for the future, as well as various emotions that they were feeling at the time. Consistent with our hypothesis, participants visualizing themselves at an older age were more likely to report having a greater desire to save than those visualizing themselves at their current age. Furthermore, a mediation analysis indicated that an increase in feelings of peacefulness and a decrease in feelings of anxiety mediated the effects of visualization of the self at an old age on savings attitudes.

These findings contribute to the existing literature on visualization by demonstrating that merely visualizing about engaging in non-goal activities at an old age can increase the motivation for long-term goals with distant future consequences, such as saving. Furthermore, the visualization of everyday activities can be a more effective means of encouraging goal pursuit because this occurs naturally without external prompting.

Søren Askegaard, University of Southern Denmark, Odense, Denmark

SESSION OVERVIEW

The theme of this year's ACR conference is "A World of Knowledge At the Point of Confluence." In congruence with this theme, this session explores various angles of consumer acculturation as they relate to their heterogeneous identity constructs. Identity is seen as a confluence of cultural, social, temporal and contextual influences. The social and cultural aspects of consumption and consumption's relation to identity construction have been well documented in consumer culture theory (Arnould and Thompson, 2005). What has not been sufficiently considered so far was their relation to consumer acculturation of immigrants in combination with other variables, such as gender, temporal evolution, in-group differences or generational factors. In this session, we focus on the mechanisms with which these factors operate in the formation of identity for immigrants and their descendants. The four presentations together attempt to explore the immigrant consumer acculturation and examine it in contexts and from perspectives that have been understudied.

The first paper examines the relationship between the immigrant women's gender roles and the power discourse in the society. Romanian female immigrants in Italy were interviewed and observed in relation to their food consumption practices. The researchers identify two identity positionings of these female migrants that correspond to two spatial contexts and temporal reference points. They identify four contextual situations that imply different power relations that move between a traditional woman and a modern one. The second paper also takes Italy as the context of study and questions the application of the interpretative model of cultural adaptation—originally elaborated for first generations—to the children of migrants (Portes 1996, p. x). The author discusses the different levels of cultural consciousness that second generations show according to ethnic, local and global consumption, and describes four ways to deploy such consumption to navigate the borders between families and the group of peers. In the next presentation, Peñaloza elaborates additional differences between first generation immigrants and their descendants, documenting changes in consumers' identity over time. Based on oral history interviews with a heterogeneous group of Mexican Americans, her cultural genealogy dissects these identity inflections across a realm of social situations and market conditions. The final paper combines the themes of immigrant consumer acculturation, temporal changes, consumption differences within an immigrant community in relation to identity positionings from the previous papers and analyzes a group of immigrants' changing consumption practices in an attempt to differentiate themselves from the rest of the immigrant community and integrate into the host society. Turkish immigrants in Denmark are chosen as the context of the study.

All the session papers are completed projects and combined offer differing theoretical perspectives. Methodologically, they all adhere to the interpretivist approach and provide empirical knowledge based on ethnographic data. This session thus provides a platform for scholars who are interested in different aspects of immigrant consumer research and would like to familiarize themselves with the latest theory and empirical work in the field.

EXTENDED ABSTRACTS

"She, Who Has the Spoon, Has the Power: Immigrant Women's Use of Food to Negotiate Power Relations"

Zuzana Chytkova, University of Pisa, Italy

Nil Özçaglar-Toulouse, Université de Lille 2, France

Immigration has been in the centre of scholarly attention for some time now and several studies have investigated consumer acculturation of immigrants. Recently, in the consumer culture tradition (Arnould and Thompson, 2005), the postassimilationist theory has made an important contribution to our understanding of immigrants' use of marketplace in their movement between home, host and transnational consumer culture (Askegaard et al., 2005). However, it does not consider the effect of hegemonic discourses in the home and host society, as well as the singular power relations the immigrants encounter in their everyday experience. Yet, these elements also play a significant role in their use of marketplace offerings in the everyday pursuit of a satisfying identity. The focus of this research is the intersection of these areas, a lens that would see consumer acculturation as a network of power relations in the immigrants' lived experience. In accordance with the goal of the research, we concentrate on gender roles as a part of a power discourse in society. This is particularly apparent in societies based on patriarchal values. The women migrating from such a society had been socialized to a traditional gender role. Upon their arrival to the country of destination, they are faced with another concept of womanhood, which, in the case of immigration to an "advanced capitalist country" (Holt, 1997) is based on the host society's construction of gender roles, but also on the transnational "modern woman" discourse featured in the marketplace as the desirable ideal of womanhood. We argue that such power relations can be studied through the analysis of female immigrants' everyday food consumption choices. Food is known to act as a key element in power relations (Lupton, 1996) and the responsible for food preparation are usually women. Women also tend to figure more clearly as the dominated part in heterogeneous power relations.

Fourteen in-depth interviews (from one and a half to three and a half hours) have been carried out with Romanian women in Italy by the first author. These interviews have been complemented by observation at multiple sites of community gathering, such as parks, the Romanian Adventist Church and the Romanian Orthodox Church in Florence, which were either video registered or written up in field notes. The field work also comprised four cooking sessions with the respondents, all video registered. The interviews were integrally transcribed. We analyzed the interviews by alternating between the specific case of each interview and the interviews taken as a whole, and by making use of observation and literature.

The analysis reveals two distinct discourses corresponding to the two spatial and temporal references of the migration experience: the country of origin and of destination and the temporal setting before and after emigration. Such discourses emerged from the respondents' narratives of migration, which presented a common structure: the emergency situation (economical crisis or the experience of the unknown upon arrival) felt as disempowering, is

solved with great efforts and suffering resulting in an inner peace of the respondent, enlightened state of mind and sense of power achieved through the suffering/self-transformation. The narrative involves general understanding of womanhood in the culture of origin, which is based on a hegemonic patriarchal discourse of the traditional woman's role. This results in a disempowering relationship network and the consequent loss of the women's control over their bodies and lives. The central host culture discourse is that of a modern woman, mostly based on a marketplace myth and its liberatory power (Firat and Venkatesh, 1995), within a frame of which the woman is depicted as independent, powerful, seizing-the-day. This discourse allows the women to resist their ascribed identity as a traditional woman, providing them with concepts to redefine their understanding of womanhood and to regain the control over their body and life.

These two discourses on womanhood point out the two extreme positions in the power relations of an immigrant's everyday life. However the resistant acts are performed within heterogeneous power relations that situate the women at neither of the two extremes. The resistance must be played out in accordance with the various contextual relations that exist alongside a continuum between the two extreme situations, each one of them implying a different structure of power between its actors.

In the proposed model, four contextual situations implying different power relations were identified. Such contexts move along the imagined line of control over the self, that we call "regime of control" to illustrate its different structure in the relationship. On the one extreme of the continuum, we collocate situations, in which the actor is in relative control over his/her self. Such situations imply a relative autonomy in the decisions regarding one's body and life, including those concerning food choices. The contexts positioned on the opposite extreme are characterized by the presence of hegemonic discourses defining the role ascribed to the actor, and implicitly shaping his/her decisions concerning his/her body and life, including the food consumption decisions. The movement between these contextual situations implies a movement closer to or further from the ideal of modern or traditional woman, as well as closer or further from the symbols of these two discourses: the ideal of fast, easy, light cuisine or time-consuming, heavy, and elaborated cuisine. The proposed model permits to uncover a layer in the understanding of immigrants' consumer behavior that has not yet been explored. It demonstrates that their food preferences are not based solely on their level of acculturation from one culture to another, but are also functional to the heterogeneous power relations formed in their everyday lives and vice versa that these power relations can be studied through the analysis of food practices.

"Cross Generation: Cultural (In)visibility in the Consumption of Second Generations"

Luca Massimiliano Visconti, Bocconi University, Italy

Defining the "children of migration" (Portes, 1996, p. x) is not easy task. Subjectively, second generations (2Gs, in short) are characterized by different strategies of self identification (Rumbault, 1997) and patterns of segmented assimilation that vary with personal and family conditions (Portes and Rumbault, 2001). The arduousness of 2Gs' self definition is due to the inapplicability of the interpretative categories that first generations and others deploy to categorize them. On the one hand, human beings are prone to use the "linear bipolar model" of ethnic identity (Schaninger, Bourgeois, and Buss, 1985). The postulated zero sum game thus implies that what is gained in one culture is symmetrically lost in the rival one. On the other hand, the social context imposes ethnic categories

from the outside instead of looking for more germane, subjective definitions of the self (the so-called self-designated ethnicity, Stayman and Deshpande, 1989). It is no wonder, that consumer identity projects of 2Gs reflect the complexity, the social and psychological pressures, and the variety of personal and shared narratives originated by the aforementioned scenario.

From an epistemological viewpoint, ethnic studies—both in their traditional and postassimilationist elaboration (Askegaard, Arnould and Kjeldgaard, 2005)—have grounded a model of cultural adaptation dealing with first generation immigrants (Berry 1980), yet it is not clear that this applies to 2Gs. The constructs of original and host culture are not strictly applicable to 2Gs and also modify according to the age of arrival in the host country (Rumbault, 1994). 2Gs are often grown up and identify with the culture of destination of their parents and mostly maintain an imagined connection with the culture of origin of the parents. Frequently, their ethnic culture becomes an ethnoscape constructed by the stereotypical social and market discourse about the origins incorporated in the dominating mediascape (Appadurai 1990, 9).

As such, the adaptation processes characterizing 2Gs not only include ethnic and local cultures—however defined—but also the global and transnational culture (Glick Schiller, Basch, and Szanton Blanc, 1992). In making daily reconnection between the local and the global, 2Gs break the boundaries of the national state, and thus constitute a transnational basis where multiple systems of meanings live together regardless of their territorial rooting.

The paper is based on a three year field investigation of the 2Gs residing in the North of Italy. Data include 412 questionnaires and 32 depth interviews run afterwards to better investigate 2Gs' symbolic consumption and religious ties. Questionnaire data were elaborated in terms of descriptive statistics for quantitative information and content analyzed for the qualitative answers. Depth-interviews were fully transcribed and analyzed according to the criteria of interpretative ethnography.

First, findings illustrate the different level of cultural (in)visibility (i.e., salience) in the consumption of 2Gs when moving back and forth ethnic and local consumption. 2Gs tend to alternate higher and lower levels of awareness about the cultural basis of their consumption. When consuming global (e.g., jeans, English music, etc.) or local (e.g., pasta, television, etc.) artifacts, these teens are less conscious about the cultural rooting of their consumption but easily acknowledge the cultural loading of ethnic consumptions. Four main explanations about the alternating level of cultural (in)visibility are offered: i) cultural embeddedness; ii) iterated ethnocentrism; iii) unquestioned dominating culture; and iv) cultural appropriability.

Second, when visible to the eyes of the consumer, cultural meanings embedded in consumer goods can be manipulated and deployed to "navigate the border crossings between household and societal contexts" (Lindridge, Hogg, and Shah, 2004, p. 211). Field investigation confirms the intentional, transactional, and dialogic use of 2Gs' consumption when facing the requirements expressed by family members and the group of peers. Further, four main uses of consumption for 2Gs are detailed: i) consumption as trade; ii) consumption as gift; iii) consumption as opposition; and, iv) consumption as mediation.

By questioning the applicability of the traditional models of cultural adaptation, the paper identifies local, ethnic, global and transnational culture impacting 2Gs' identity structures. Findings unpack the motivations of cultural (in)visibility and show the use of consumption to cope with the double structural violence (Farmer, 2006) exerted by families and peers.

“Deciphering the Socio-Temporal Dimensions of Consumer Identity Development: A Cultural Genealogy”

Lisa Peñaloza, EDHEC Business School, France

Identity is one of the most basic constructs in consumer behavior. The existential question, “who one is” finds noteworthy expression in contemporary consumer behavior as a key domain of activity in which people continually reinscribe and constitute their identity in relation to others (Arnould and Thompson, 2005). Previous work has documented how persons alter their consumption to commune with particular groups (Deshpandé, Hoyer and Donthu, 1986) and diverge from them (Berger and Heath, 2007) in expressing important aspects of their identity. Notably, this previous work points to the importance of in-out group relations in consumption. Yet because it is based on rather static, snap shot glimpses, it leaves open a number of important questions such as the changing nature of identity over the course of consumers’ lives, how identity is expressed in consumption in relation to others over time, and the long term impacts on identity of selectively displaying consumption in relation to majority/minority groups and of target marketing and segmenting efforts. Such socio-temporal dimensions of identity development are particularly important for immigrants (Oswald, 1999; Peñaloza, 1994; Visconti, 2006), ethnic minorities (Askegaard, Arnould, and Kjeldgaard, 2005) and migrants (Ustuner and Holt, 2007), although they are also relevant to the growing body of work on mainstream consumers (Burton, forthcoming; Peñaloza and Barnhart, 2009)

This research extends previous work on the sociology of consumption by adding temporality to the study of identity projects. Of particular interest is dissecting changes in consumers’ identities over time, as impacted by minority and majority group relations and marketing practices targeting group members. The research design features oral history interviews with 15 Mexican Americans who vary by generation in the U.S., age, gender, social class, color, residential area, language, and political sentiments. Findings trace a cultural genealogy of consumption identity across first cultural experiences; identity terminology; day to day consumption of specific products/services/brands at home, work, in neighborhoods, stores, and tourist areas; leisure/holiday activity; language development and utilization; interactions with family and friends, both subcultural group members and members of other subcultural groups; thoughts and reactions to the segmenting and target marketing efforts of firms, community development concerns, and personal hopes and dreams. Analysis proceeds to identify economic, social, and cultural dimensions of capital (Bourdieu, 1984) in the genealogy and map disjunctions and overlaps between these various types of capital. These disjunctions and overlaps are useful in highlighting the dynamic and highly charged nature of in-out group relations and tracking their impacts on consumption and identity over time, as this cultural consumption genealogy focuses on the subcultural group rather than a specific brand (Holt, 2004). Specific changes over time feature the “hostile,” “welcoming,” and “neutral” zones where informants have been blocked by others in their expression of their culture or received neutral treatment versus those where they have nurtured their identity in consumption and interacted favorably with members of other cultural groups. Finally, I draw attention to the transformation of these various dimensions of capital from cultural to social and economic in making sense of observed changes in identity, consumption, social relations, and marketing activities over time. Notably, the negative stigma older informants experienced decreased over time, in contrast to the more positive valuation of younger informants. The more positive valuation of both cohorts corresponded temporally with the advent of cultural tourism in the area and the segmenting

and target marketing efforts by firms. Yet despite some increasing power in the ownership, representation, and exchange of cultural artifacts, a paradoxical social valuation for their subculture is juxtaposed with the economic deterioration of their neighborhoods, pointing to important limitations of consumption in identity maintenance and negotiation of social relations. Theoretical contributions provide a more comprehensive, dynamic, and nuanced account of identity development that expands understandings of consumption as an important domain through which individuals and groups negotiate cultural difference over time and elaborates the social legitimizing role of market targeting.

“From Resistance to Integration: Changing Consumer Acculturation Practices of Immigrants”

Mine Üçok Hughes, Woodbury University, USA

Consumer acculturation and identity have been two of the most popular topics studied by immigrant consumer researchers. Berry (1980), a highly referenced source on the topic of acculturation, classifies the varieties of acculturation as assimilation, integration, rejection and deculturation. Berry’s classification has provided a schema for many researchers (e.g. Peñaloza, 1989 & 1994) who studied immigrant consumer acculturation. Peñaloza (1989) adapts the acculturation concept to consumer behavior in which consumer acculturation is described as “the acquisition of skills and knowledge relevant to engaging in consumer behavior in one culture by members of another culture” (p. 110). The study of consumer acculturation primarily focuses on cultural adaptation as manifest in the marketplace and examines the cultural bases of consumption behavior and the processes of consumer learning that are affected by the interactions of two or more cultures (ibid.). Peñaloza (1994) acknowledges that “immigrants may have two conflicting sets of consumer acculturation agents: one corresponding to their culture of origin and one corresponding to the existing culture” (p. 35). Reminiscent of Berry’s (1980) modes of acculturation she suggests the following possible acculturation outcomes: assimilation, maintenance, resistance, and segregation. Subsequently, other post-assimilationist researchers (Askegaard et al., 2005) have argued that immigrant consumer acculturation is a more complex phenomenon which rather than lying on a linear continuum, embraces elements from both the home and host cultures, as well as a transnational consumer culture.

The main research question that is addressed in this presentation is what happens when the resistance takes place within the cultural group? More specifically, what are the factors that trigger a sub-group within the greater immigrant community to differentiate itself from that community, what are the practices that lead to this differentiation and how is this achieved?

The findings presented in this paper are part of a bigger study that investigates the Turkish (trans)migrants in Denmark (Üçok, 2007) based on data collected from 13 Turkish immigrant families. This research can be described as a multi-sited ethnography (Marcus, 1995), which included in-depth interviews and in situ observations in multiple locations. Historically the Turkish immigrants arrived in Europe as guest workers, hired to work in factories as blue-collar laborers. Their integration into their host societies were minimal as their main intention was to save money and return to their homelands wealthier and with higher social status. The size of this population rapidly grew due to family reunification. Today, there are 54,000 Turkish immigrants in Denmark. However, they do not constitute a homogeneous group.

The focus of this paper is a subgroup within this community that tries to differentiate itself from the above-mentioned type of Turkish immigrants and attempts to integrate into the host society

by consciously adopting differentiating consumption practices. Some examples of these practices are: moving out of the immigrant neighborhoods into neighborhoods populated by the host society, giving importance to higher education and encouraging their children to further their education, buying a brand new car as opposed to a second-hand one, decorating their homes in a style less reminiscent of the other Turkish immigrants' style, adopting consumption practices like wine drinking which is not typical of the Turkish immigrant community, going to vacation to places other than the home country.

The point in which this study departs from previous research on immigrant consumers is that the focus of study here moves away from the identity positionings between the home and host cultures to the one that is acquired in relation to the greater immigrant community. The resistance becomes not to the culture of origin or to the host culture but to the other members of the immigrant community. Integration becomes the desired immigrant consumer acculturation outcome. These immigrants strive to improve their social status and in relation to that their social and cultural capital in their host societies by means of their consumption practices (Üçok & Kjeldgaard, 2006).

This research contributes to the field of immigrant consumer research by providing empirical data on the in-group differences. Furthermore, I argue that these in-group differences stem from a desire to integrate better into the host culture and improve one's social status within this society. This is achieved through the transfer of various types of capital from one type to another (Bourdieu, 1984). The results extend the findings of previous research on immigrant consumer acculturation patterns by accentuating the in-group differences through fleshing out the identity positionings and the factors that influence the consumption decisions that shape these identity positionings.

SPECIAL SESSION SUMMARY

Attitude Strength and Consistency Between Attitude and Behavior

Kalpesh Kaushik Desai, State University of New York at Binghamton, USA

SESSION OVERVIEW

Social psychologists and marketers have long been interested in understanding the conditions under which attitudes influence behaviors, decisions, and information processing (Fabrigar, Petty, Smith, and Crites (2006). According to Crano (1997), "The current position in social psychology is that strong attitudes do affect behavior, although social, contextual, and intrapsychic sources of variation can affect the strength of such relationships (Krosnick 1990; Krosnick et al. 1993; Petty & Krosnick, 1995)." In marketing, Sengupta and Fitzsimons (2002, 2004) and others (e.g., Dholakia and Morwitz 2002; Sengupta and Johar 2002; Simonson and Nowlis 2000) have examined the issue of attitude-behavior consistency when respondents are asked to analyze reasons underlying their attitude before reporting their evaluations. Competing explanations of weakening of attitude strength vs. greater distraction have been proposed for the disruption in the attitude-behavior consistency in the condition of analyzing reasons.

The objective of this special session is to introduce four current lines of research that offer new perspectives for improving our understanding of the link between consumers' attitudes and behaviors. Together, they focus upon attitude strength, its antecedents, and uncover new factors that moderate the attitude-behavior consistency (e.g., internal vs. external source of information underlying attitude certainty; brand ambivalence). We believe that these papers shall stimulate interesting discussion which will raise new questions and suggest new directions for future research on the topic. *The data collection for all four papers is complete and they all are either in the manuscript preparation or working paper stage.*

Of the four papers, paper # 2 and 4 adopt a managerial bent to the topic of attitude-behavior consistency whereas paper # 1 & 3 have more of a theoretical orientation. Given this mixed orientation, the likely audience of this special session will be practitioners and researchers in attitude strength, resistance, attitude-behavior consistency, brand equity, and consideration sets. The specific topics that will be covered in the special session pertain to attitude certainty/attitude strength and consistency between attitude and behavior.

Paper # 1, 2, and 4 focus upon attitude strength/attitude certainty and its influence on attitude-behavior consistency. Specifically, paper # 1 by Dubois, Rucker, and Petty argues that consumers with sensitivity to external (internal) factors display greater attitude-behavior consistency when the sources of their certainty were external (internal). Paper # 2 by Desai, Hariharan, Inman, and Talukdar argues that the attitude-behavior consistency is moderated by (other factors along with) attitude strength such that greater commitment to the target brand accentuates the relationship between brand equity and brand loyalty. Paper # 4 by Nayakankuppam, Priester, and Sinha shows that strength of attitude towards an alternative influences its choice and inclusion in the consideration set. In contrast, paper # 3 by Litt and Tormala focuses upon the fragility of liking the chosen alternative from a difficult choice task i.e., behavior-attitude consistency.

The four papers make the following important contributions: i) examine the antecedents and behavioral consequences of adopting an external vs. internal attitude certainty focus; ii) identify important caveats to the presumed durability and strength of thoughtful and involving attitude formation; iii) propose an empirically tested parsimonious measure of brand equity based on comprehen-

sive search of prior literature and identify moderators of brand equity-brand loyalty relationship; iv) reveal the influence of attitude strength on inclusion in a consideration set and choice by impacting consideration set size.

EXTENDED ABSTRACTS

"Internal versus External Informational Sources: Causes and Consequences for Attitude Certainty and Attitude-Behavior Consistency"

David Dubois, Northwestern University, USA

Derek D. Rucker, Northwestern University, USA

Richard E. Petty, Ohio State University, USA

A key factor that has become of increasing importance in understanding attitude-behavior correspondence is the certainty individuals place in their attitudes. In this work we examine how people's sensitivity to external vs. internal information affects attitude certainty. While past research provides ample evidence that individuals rely on multiple informational sources when forming their certainty (Tormala and Rucker 2007), surprisingly little is known about the role of internal (i.e., information from oneself) vs. external (i.e., information from one's environment) factors on its formation. This work proposes and finds that consumers' sensitivity to external vs. internal informational cues leads to two types of certainty foci: while "external" certainty stems from information associated with environmental factors, "internal" certainty results from individuals' focus on personal, experience-based factors.

We first hypothesized that these two certainty foci have distinct psychological antecedents depending on individuals' sensitivity to external vs. internal information. Drawing on past research documenting chronic (Snyder 1974) and momentary (Trafimow et al., 1991) differences in individuals' sensitivity to external vs. internal information, we examined the effects of such differences on the formation of certainty based on information from external versus internal sources.

Second, we hypothesized that the adoption of a specific certainty focus would generate distinct behavioral consequences depending on people's intentions. Specifically, based on past work suggesting that realizing a goal entails consecutively going through different mindsets (e.g., Gollwitzer, 1990), we proposed that an external certainty focus would mostly impact the behavior of individuals deliberating about a goal, while an internal focus would mostly impact the behavior of individuals implementing this same goal.

Three experiments tested these hypotheses. Results were analyzed using ANOVAs and t-tests, when appropriate. In all experiments, attitudes are stable across conditions ($F < 1$).

Experiment 1: Examining consumers' self monitoring orientation on the formation of external and internal certainty. Using a 2-cells design (informational cue: external, internal and control; $N=82$), we tested the hypothesis that one's propensity to rely on external or internal factors when forming certainty is driven by one's self-monitoring orientation. After completing the self-monitoring scale (Snyder 1974), participants were invited to participate in an ostensibly unrelated purchasing scenario that either contained internal (e.g., perceived knowledge, repeated purchase), external (e.g., social consensus, source credibility) informational cues about a product, or unrelated information (control). Finally, participants'

certainty and attitudes toward the product was assessed. Results showed that high (low) self-monitors' certainty was significantly greater after they encountered an external (internal) informational cue than an internal (external) one ($p < .01$), suggesting that certainty formation is differentially sensitive to external or internal information, as a function of individuals' chronic self-monitoring orientation.

Experiment 2: Examining consumers' self orientation on the formation of external and internal certainty. A 2 (self-orientation: self vs. others) \times 2 (certainty focus: internal vs. external; $N=73$) examined whether a momentary shift in one's sensitivity to external vs. internal information, rather than a chronic orientation, could similarly affect certainty formation. After completing a self-orientation manipulation (Trafimow et al., 1991), participants read a newspaper excerpt about college students' knowledge of cameras, which was either high, or low (Internal focus) and subsequently received a WOM communication from either an expert or a novice (External focus) about a camera. Last, participants' attitudes, certainty and purchase intentions were assessed. Individuals with a self (other) orientation tended to rely on internal (external) sources of certainty when judging a product ($p < .01$). In addition, the type of certainty formed (external vs. internal) mediated individuals' behavioral intentions, suggesting the dual nature of certainty is consequential for attitude-behavior consistency.

Experiment 3: Examining consumers' mindset on the formation of external and internal certainty. A 2 (mindset: implemental vs. deliberative) \times 2 (certainty focus: internal vs. external) ($N=112$) aimed at suggesting that individuals rely on a particular type of certainty—external or internal—as a function of their mindset. After being presented with a purchasing scenario in which their mindset was manipulated, participants encountered an external or internal informational cue. Results suggested that individuals in a deliberative (implemental) mindset were more certain after being presented with an external (internal) cue than with an internal (external) one ($p < .01$).

Conclusion and Contributions. These findings suggest distinct antecedents and consequences of external and internal certainty. From a theoretical standpoint, the present research sheds light on our understanding of how certainty can emanate from different sources, and provides further evidence that each type of certainty foci investigated generates unique consequences for behavior. Given the governing role of certainty in attitude-behavior consistency, these experiments further enrich our understanding of attitude-behavior correspondence.

"A Field Examination of the Influence of Brand Equity on Behavioral Loyalty and Factors that Moderate this Relationship"

Kalpesh Kaushik Desai, SUNY-Binghamton, USA

Vijay Hariharan, SUNY-Buffalo, USA

Jeffrey Inman, University of Pittsburgh, USA

Debabrata Talukdar, SUNY-Buffalo, USA

Prior research in brand equity (or BE) has primarily focused upon its leveraging influence on brand and line extensions and feedback effects (e.g., Aaker and Keller 1990; Park, Milberg, and Lawson 1991). However, the relationship between brand equity and brand loyalty (or BE-BL) has been less than perfect (Keller and Lehmann 2004). Specifically, brands encounter four possible scenarios: i and ii) positive BE-BL relationship could see brands with high (low) equity correspondingly enjoy high (poor) loyalty; iii) brands enjoying high equity experience poor loyalty; and iv) brands with low equity could enjoy high brand loyalty.

Research Questions, Motivation, and Contribution

Managers, especially for brands in groups (ii)-(iv) above, would like to know how to enhance brand attitude-choice behavior consistency i.e., how to get more consumers on the high BE-high BL track. Which factors mitigate versus accentuate the BE-BL relationship? Based on prior work in several research streams, we identify 12 "contextual" factors relating to the target brand, product category, and consumers as important moderators. For example, we hypothesize that while target brand commitment and importance of brand decision accentuate the BE-BL relationship, brand ambivalence and perceived equity of other brands mitigate that linkage. We similarly hypothesize, for example, that BE-BL linkage will be accentuated for private (vs. national) label brands and for households with higher (vs. lower) income but the relationship will be mitigated by education of the primary shopper of the household and by category differentiation. By empirically showing the influence of BE on BL to be limited in several contexts, we argue that strengthening BE cannot be a solution to branding problems in all situations, contrary to the assumption of prior BE research and practitioners.

A related question that prior research has not examined is if there are distinct segments of consumers whose profile differences (e.g., maximizer vs. satisficers) make them more likely to engage in high attitude-choice consistency behavior. Dominance of the high equity-high loyalty customers (vs. high BE-low BL or low BE-high BL) among the target segment requires no change in the target marketing strategy of the brand. In addition, by focusing on profile differences, brand managers can devise appropriate marketing strategies to move "inconsistent" consumers to become high BE-high BL consumers.

A major challenge in the BE research is that prior research has proposed distinct measures of BE (e.g., Aaker 1996; Keller 1993; Yoo and Donthu 2001). Just being advised to strengthen BE without being told which variables to focus upon is not very helpful. Researchers and managers will benefit from a comprehensive but parsimonious measure of BE. Finally, we also investigate if the relative importance of the different variables that constitute the composite BE construct is stable to changes in the context engendered by moderators listed above (e.g., private label or age of consumers)? Answers to these questions for example, can help managers of private label vs. national brands to focus on distinct BE variables to strengthen BE-BL relationship and emphasize distinct BE variables in their marketing if they were targeting their brands to younger vs. older consumers.

Method and Findings

After comprehensive investigation of prior research, we identified the following nine variables as measures of brand equity: brand personality, perceived value, brand differentiation, brand trust, strength of brand's favorable associations, brand quality, brand satisfaction, brand justifiability, and in-store presence. Factor analysis using principal component extraction method revealed that all nine variables (measured by 18 items) fall into a single construct of brand equity (amount of variance explained=44.7%).

To test our hypotheses, we mailed surveys in February 2007 to 5000 bonus card shoppers of a leading grocery chain operating in the northeastern US. As incentive, participants were offered the opportunity to participate in a lottery drawing. The response rate was 75%. To ensure that we account for bulk of the grocery purchases of the participants, the 5000 bonus card holders were randomly selected from more than a million panel members such that the target grocery chain was the primary shopping outlet for these consumers accounting for more than 80% of their grocery purchases. Using established scales developed by prior research, the survey measured all the variables listed above and the hypotheses were tested using various multivariate regressions on the choice data of 52-weeks prior to the receipt of the survey i.e., April 2006-April 2007. The results were consistent across both categories (toothpaste and tortilla chips) and all our hypotheses except for the ones on age, income, annual category purchase, category differentiation, and maximizing vs. satisficing moderators were supported.

"Fragile Enhancement of Attitudes and Intentions Following Difficult Choices"

Ab Litt, Stanford University, USA

Zakary L. Tormala, Stanford University, USA

It is well-documented that, following difficult choices from sets of similarly attractive options, consumers show increased post-choice liking of chosen items, relative to choices between more easily differentiated options (e.g., Brehm 1956). Although others have been proposed, a prevailing explanation is that such choice-enhancement is driven by motivated rationalization, whereby consumers seek to reduce dissonance aroused by selecting one option while rejecting similarly attractive others. This entails an active and high-involvement process of changing attitudes and behavioral intentions post-hoc to align them with one's choice.

Despite considerable attention paid to understanding post-choice attitudinal enhancement, little has focused on examining its

stability. For example, once changed to support a choice, how do difficulty-enhanced attitudes and intentions withstand subsequent attack? If dissonance-driven attitude shifting is indeed an active and thoughtful (though biased) process, then from past research showing strong attitudes fostered by increased thought (Petty, Haugtvedt, & Smith 1995), it could be surmised that post-choice attitudinal enhancement would be quite durable in the face of persuasive attack. Across three purchase scenario free-choice studies, however, we find such enhancement to be fragile, yielding to even minor and superficial attacks. Moreover, rather than bolstering attitude durability and resistance to persuasion (e.g., Petty et al. 1995), we find that heightened involvement augments this fragile enhancement and vulnerability to attack.

Study 1: Difficulty and Fragile Enhancement. In a hypothetical product-purchasing scenario, participants ranked six digital cameras (based on pictures and image-quality, weight, and price information), and were then presented with a subset from which to choose. In line with the free-choice paradigm, choice-difficulty was manipulated by presenting either the 2nd and 5th ranked options ("Easy-Choice" condition) or the 2nd and 3rd ranked options ("Difficult-Choice" condition). Following this decision, all participants reported attitudes towards their chosen camera and behavioral intentions such as product recommendation, purchase deferral, and re-purchase likelihood. Finally, participants read a single negative customer review of their chosen camera criticizing only peripheral dimensions (e.g., strap-thickness, technical support), and were again asked about their attitudes and behavioral intentions regarding their chosen camera.

Consistent with past research, in the initial post-choice/pre-attack stage we observed more favorable attitudes and intentions towards products chosen in the Difficult-Choice condition. Compared to the Easy-Choice condition, these participants were more satisfied with their camera, more likely to recommend it to others, more inclined towards future re-purchase of the same camera, and less inclined to defer purchase. However, this enhancement did not afford Difficult-Choice participants any additional resistance to the negative customer review. After the attack, participants across choice conditions did not differ in attitudes and intentions, and within-participant comparisons showed greater collapse on these dimensions by Difficult-Choice participants, though both groups were affected. Moreover, whereas pre-attack positivity in attitudes and intentions strongly predicted post-attack resilience in the Easy-Choice condition, this was not true in the Difficult-Choice condition. In short, we observed a fragile enhancement effect in the Difficult-Choice condition: participants enhanced attitudes and intentions post-choice, but in a manner proving highly vulnerable to even minor attack. Choice rationalization may thus create the appearance of strong choice-consistent attitudes, but those attitudes can be quite susceptible to change when tested.

Studies 2-3: The Role of Choice Involvement. Two additional studies replicated fragile enhancement with different stimuli (Study 2: car-stereos; Study 3: customer review attacking central rather than peripheral product-dimensions). They also provided insight into mediation (by choice-discomfort, consistent with a dissonance-based motivated rationalization account) and moderation. Most notably, we observed increased fragile enhancement as a function of increased choice-involvement. In Study 2, attitudes and intentions showed significant interactions between choice-difficulty and measured choice-involvement: both initial enhancement and later collapse in the Difficult-Choice condition were greater among participants reporting high rather than low involvement. Study 3's replication manipulated choice-involvement by varying the perceived importance of the choice itself. Thus, following

difficult and important decisions, for which it would be most desirable to have a strong and defensible position, attitudes and intentions showed both greater post-choice enhancement and greater vulnerability to later persuasion.

Conclusions. Results support an involved rationalization process underlying difficulty-driven choice enhancement. In contrast to both implicit and explicit assumptions in past research, however, these motivated post-choice enhancements of attitudes and behavioral intentions turn out to be exceptionally fragile, collapsing in the face of even minor persuasive attack. Moreover, choice-involvement appears to amplify both initial post-choice enhancement and subsequent post-attack deflation. Thus, factors traditionally believed to foster increased resistance to attack by inducing thoughtful attitude change may foster increased susceptibility to attack in the free-choice paradigm. Overall, it appears that at least some forms of dissonance-based attitude change can be easily undone, and that involvement might have a more dynamic role in conferring attitude strength than is apparent from past research.

"The Influence of Attitude Strength on Consideration Set Size: Strong Liking Results in Smaller Consideration Sets"

Dhananjay Nayakankuppam, University of Iowa, USA
Joseph R. Priester, University of Southern California, USA
Jayati Sinha, University of Iowa, USA

Introduction

How individuals come to choose one alternative over another has lain at the heart of consumer psychology, indeed the entire field of marketing, since its very inception. This paper follows in this tradition, exploring a hypothesis that both builds upon past research and helps to understand prior findings. To do so, we adopt theory from both the literatures of attitudes (e.g., Petty and Cacioppo, 1986) and choice (e.g., Roberts and Latin, 1997): From attitudes we use the construct of attitude strength and from choice we use the construct of a consideration set.

Consideration set formation has proved to be important in consumer choice processes—much variance in choice is attributable to inclusion in a consideration set (Hauser and Wernerfelt, 1990). Prior research has shown that inclusion in a consideration set is influenced by attitudes but is moderated by attitude strength in that it is particularly true for strong, rather than weak attitudes (Priester et al., 2004). This research examines how attitude strength might moderate attitudinal influence on consideration.

Hypothesis Development

Why is it that attitude strength plays such a role in consideration? Recall that attitude strength confers greater accessibility, such that strongly held attitudes come to mind faster than weakly held attitudes (see Priester and Petty, 2003; Priester et al., 2004). If a strongly liked attitude comes to mind quickly in the formation of a consideration set, it is possible that its earlier arrival will truncate search and result in a smaller consideration set. We base this hypothesis on two distinct streams of research. First, Feldman and

Lynch (1988) find that the more accessible and diagnostic an alternative is, the more likely that it will be used, and subsequent search will be terminated. Second, Alba and Chattopadhyay (1986) find that brand salience inhibits recall of other brands. Together, these results suggest that the extent to which an alternative is held with greater strength, the more likely that other alternatives will not be brought into consideration. We propose a simple, yet potentially powerful hypothesis: This hypothesis is both consistent with, and may well help to understand the psychological processes underlying, prior literature. We test the hypothesis in two Experiments.

Experiment 1

Mitra and Lynch (1995) found that differentiating ads led to smaller consideration sets than reminder ads. Our interpretation of this finding is that it may have emerged because of differences in attitude strength resulting from the different ad types. Experiment 1 was designed to examine whether attitude strength can account for the Mitra and Lynch (1995) findings.

Specifically, experiment 1 examines whether differentiating ads led to smaller consideration sets than reminder ads because the differentiating ads set up conditions under which participants could elaborate, and thus form strong attitudes, whereas the reminder conditions did not foster such elaboration, and thus led to weak attitudes.

Participants were provided with mock advertisements for three brands (in three different product categories—burgers, granola bars and pizza). They processed these advertisements under conditions of either high or low elaboration, in order to form strong and weak attitudes respectively. Elaboration was manipulated between participants in a manner similar to Priester et al. (2004)—that is, participants were asked to pay attention to their thoughts and feelings as they read the ads (HiEl) or we imposed a secondary cognitive load on them by asking them to count the number of polysyllabic words in the ad as a way to reduce the resources that could be allocated to elaboration (thus LoEl). After exposure to the brands, we assessed attitudes and attitude strength, in addition to collecting their impressions of the ads.

The participants in the HiEl likelihood conditions report smaller consideration set sizes than those in the LoEl likelihood condition.

Experiment 2

The second study re-analyzes the results of two previously published studies that investigated the influence of attitude strength on consideration and choice. Participants provided attitude and attitude strength data towards a variety of soda and toothpaste brands (familiar brands). They also provided consideration sets and choice decisions in the two product categories.

This reanalysis provides further evidence that the greater the extent to which a chosen alternative is more strongly liked than the others in the consideration set, the more likely that the consideration set is smaller.

Experiment 3

In experiment three we tested the idea of search truncation i.e., the attitude strength associated with a retrieved alternative serves as a signal for search truncation. Participants were exposed to an ad for a target brand (unfamiliar brand) under conditions of high or low elaboration (same as experiment 1). After performing unrelated filler tasks, they were shown a sequence of brands with some information about each brand—one of the brands they encountered was the target brand. The position of the target brand was varied—they appeared at second, fourth or sixth position for different

participants. After viewing each brand, participants made two judgments—first, whether they would like to set this brand aside for further consideration and second, whether they would like to proceed to view more brands or make a choice from the brands set aside for consideration.

Results show that participants in the high elaboration condition were more likely to truncate search earlier compared to participants in the low elaboration condition. Also results show that the position of the target brand had no impact on the low elaboration participants. However, the target brand had a significant impact on the high elaboration participants. Encountering the target brand earlier resulted in smaller set sizes as compared to encountering it later.

Discussion

This paper advances and provides support for a rather simple, but potentially powerful, hypothesis: Choices associated with strong attitudes result in smaller consideration sets than choices associated with weak attitudes. At the most basic, this research contributes to our understanding of the determinants of consideration set size. In addition, this research provides a possibly more parsimonious explanation for previous research.

SPECIAL SESSION SUMMARY
On Being Better (or Worse) Than Others: Illuminating and Eliminating Biases in Social Comparison

Ellie Kyung, New York University, USA

SESSION OVERVIEW

Consumers make sense of their place in the world by comparing themselves to those around them. But as research in social comparison illustrates, these comparisons are typically rife with systematic biases—biases with documented effects on consumers' product choices (Burson 2007), health risk perception (Raghubir and Menon 1998), and shopping behavior (Moorman et al. 2004). In the vast majority of documented cases, people believe they are better than others (summarized in Dunning, Heath, and Suls 2004), and on some rarer occasions, they believe they are worse than others (Kruger 1999; Moore 2007). In general, people tend to believe they are better than average on easy tasks and worse than average on difficult tasks (Kruger 1999; Moore and Healy 2008).

Each of the papers in this special session examines better-than-average and worse-than-average effects in consumer judgments to collectively (a) further clarify the mechanism behind these biases, (b) illustrate ways of overcoming them, and (c) demonstrate the impact of such biases on real decisions.

The first paper by Menon, Kyung, and Agrawal examines how perceived similarity between self and others in an unrelated domain can influence social comparison judgments. The studies illustrate the role that perceived controllability over outcomes can play in determining whether people believe they are better or worse than average, and how increasing perceived similarity between self and other—versus changing the target of comparison as in previous work—attenuates both biases. However, when motivating people to act, attenuating these biases is not always desirable.

Building on this theme of considering similarities between self and others, the second paper by Gershoff and Burson examines the flawed assumptions about the distribution of reference groups. The studies demonstrate that people consider the characteristics of others when making judgments, but that people tend to overestimate the dispersion of that distribution of others. This error can result in both better-than-average and worse-than-average effects, which have been shown to influence consumption decisions. Furthermore, simple manipulations of scale granularity or exemplar availability can influence the construction of these distributions, serving to magnify or attenuate these biases when making judgments.

The third paper by Cain, Moore, and Chen investigates the generalizability of some of these effects and examines why we tend to see a prevalence of overconfidence in the real world when underconfidence is also demonstrated in laboratory studies. Focusing on self-selection, they find that people tend to choose to participate in tasks where they believe they are better than others. When choosing to participate in tournaments involving real money, people were more likely to opt to participate when the task was easy versus difficult, even though their odds of winning were the same for tasks of both types. Imperfect information about self and others drives this effect.

Thus this special session examines different antecedents and consequences of better-than-average and worse-than-average effects in consumer contexts. The first paper examines consumer motivation to act while the second investigates performance and usage estimates and the third evaluates market entry decisions. These papers and the discussion that following can raise interesting theoretical questions such as: What is the underlying mechanism

behind these biases? When and why do they occur in the “real world”? How can they be attenuated? Is it always desirable to do so? In short, we aim to discuss both theoretical insights and practical applications that stem from social comparison and related theories to deepen our understanding of when and why these biases occur and how to improve consumer decision making.

EXTENDED ABSTRACTS

“Biases in Social Comparisons: Optimism or Pessimism?”

Geeta Menon, University of Pennsylvania, USA

Ellie Kyung, New York University, USA

Nidhi Agrawal, Northwestern University, USA

The tendency for people to be comparatively optimistic or pessimistic about themselves, to the point of being unrealistic, has been well-documented. But under what circumstances do these better-than-average and worse-than-average biases occur? Recent work suggests that for easy tasks, people believe they are better than average and for difficult tasks they believe they are worse than average (Moore and Healy 2008.) We delve further into understanding this dichotomous bias by examining specifically how beliefs about one's own perceived control over an outcome and inferences about an other's can influence whether a better versus worse than average bias manifests. We also illustrate that merely increasing perceived similarity between self and others in an unrelated domain can attenuate both of these biases and when it might (or might not) be desirable to do so.

In a series of four studies, we show the following: (a) Better than average effects are likely to occur when one perceives more control over the outcome and worse than average effects are likely to occur when one perceives less control over the outcome; (b) Both these biases can be attenuated by increasing perceptions of similarity between oneself and a comparison target person (e.g., the average undergraduate) in an unrelated domain; (c) The mechanism for these effects is a change in perception of one's own control in a domain and not a change in perception of another person's control; (d) Under specific conditions, people are motivated to work harder in order to attain a positive outcome, thus helping managers and educators to provide the right work environment and means to do better and succeed. We illustrate these effects while controlling for outcome valence (positive outcomes), comparison target (average undergraduate at the school), as well as event domain (kept constant in each study) unlike previous research that varies these constructs to demonstrate these biases.

In Study 1, participants were asked to think of a course important to them and presented them with two grading scheme scenarios—one in which the outcome was highly controllable (e.g. final exam based primarily on class lectures) and one in which it was less so (e.g. final exam based primarily on ability to apply material to real world situations). They then rated the likelihood that they and the average undergraduate at the school were likely to get a good grade in the course (employing indirect comparative measures) and the extent to which getting a good grade in the course was in their control. The results revealed that in situations of high control, a better-than-average bias manifests while in situations of low control, a worse-than-average bias manifests. Additionally, percep-

tions of one's own control vary by situational context while those of the average undergraduate do not.

In Studies 2a and 2b, we examined the attenuating effect of perceived similarity between the self and the target other on these two biases. Rather than varying the target to be more or less similar to the self as in many previous studies, participants were all asked to think about the average undergraduate and consider either ways in which they were similar or different. Similar to Study 1, results indicate that better-than-average biases manifest in situations of higher control (Study 2a: trivia contest on pop culture) and worse-than-average biases manifest in situations of lower control (Study 2b: raffle). More importantly, we find that an increased in perceived similarity, even when the comparison target is kept constant, attenuates both biases.

In Study 3, we employed an experimental design similar to Study 1, but included a series of dependent measures related to motivation in the context of preparing for the course (hours spent preparing for class, likelihood of visiting professor during office hours, effort and motivation to work hard.) In lower control situations, where worse-than-average biases pervade, highlighting similarities leads to greater motivation to act while in higher control situations, where better-than-average biases pervade, highlighting differences leads to greater motivation to act. Mediation analysis revealed that perceptions of one's own control over these situations, and not the other's, drive this result.

Thus our studies integrate a variety of findings in extent literature by identifying outcome controllability as a variable that determines whether a better-than-average versus worse-than-average bias manifests, illustrating that in the face of uncertain information about others, highlighting perceived similarity can attenuate these biases. Furthermore, information about similarity or differences with others leads to changes in the perception of one's own control rather than that of the other person—people appear to use information by others to update information about themselves. Clarifying the roles of outcome controllability and perceived similarity in these comparative biases allows us to specify how situations can be framed to motivate desired behavioral action, such as in domains of education, employee incentive schemes, and beneficial public behaviors.

“It's Not Just Me: The Role of Inferences about Reference Distributions on Estimates of One's Own Comparative Performance”

Andrew Gershoff, University of Texas at Austin, USA

Katherine A. Burson, University of Michigan, USA

Research exploring how people make estimates about themselves compared to others has found systematic biases. For instance, easy tasks produce better-than-average (BTA) effects while difficult tasks produce worse-than-average (WTA) effects. Researchers have generally argued that these biases are due to participants' errors in combining the information about themselves and others into percentile estimates: People focus primarily on information about themselves and fail to incorporate information about the reference group (i.e. Kruger and Burrus 2004).

In three studies, we show that judges do attend to others when evaluating their relative standing, but that they tend to believe that others are distributed dispersly across the possible outcomes. Especially for easy or difficult tasks, the true distributions of performance are actually skewed. The first study illustrates how this simple misestimation can explain BTA and WTA effects. We then demonstrate that participants do indeed incorporate these beliefs about others into their comparative assessments. In studies 2-3, we are also able to show that participants' perceptions of the

reference group are labile. We demonstrate that simple availability or response scale manipulations can change the perceived dispersion of others and subsequently change estimates of relative standing.

In study 1, we gave participants one difficult, one moderate, and one easy quiz about everyday knowledge. Participants estimated their own score, provided us with their perception of distribution of others' performances on each quiz, and estimated their own relative standing. As predicted, participants believed they were WTA on the difficult quiz, were unbiased on the moderate quiz, and BTA on the easy quiz. However, inspection of the estimated distributions revealed that they were significantly more disperse than the actual distributions of performance. To examine whether participants showed BTA and WTA biases because they ignored others' when forming their relative perceptions, we created a new variable we call “should standing”: Given each participant's estimated score and estimated distribution of others, we calculated the percentile that each participant should have estimated. This variable contained both information about the participant's expected score and the distribution of performance in which that score lay. As predicted, regressions showed that BTA and WTA effects were explained by both participants' beliefs about their own scores and the distribution of scores. Specifically, this information fully mediated the relationship between estimated score and estimated percentile.

The next two studies also show that participants incorporate beliefs about others into their relative assessments. However, these studies also extend the results of the previous study to show how trivial manipulations can influence perceptions of the reference group and hence whether people believe they are better or worse than others.

In study 2, we asked participants how far they could putt in golf, how many Trivial Pursuit questions out of 20 they could answer correctly, and how many cell phone minutes they used per month. This time, the perception of the distribution of others for each of the three domains was manipulated. We varied the granularity of the scales. For instance, for trivial pursuit, one condition estimated the scores of the reference group on a scale that highlighted poor performance (0 correct, 1 correct, 2 correct, ...,6-10 correct, 11-15, etc.) while the other condition estimated others' performances on a scale that highlighted good performance (0-5 correct, 6-10 correct, 11-15 correct, 16 correct, 17 correct, 18 correct, etc.). Similar scale-granularity manipulations were used in the other two domains. As predicted, percentile estimates were significantly shifted by the scale manipulation. When low numbers on the scale were highlighted, participants tended to estimate that more of their reference group fell in this area of the scale than when the high numbers were highlighted. Furthermore, it was participants' incorporation of these distributional beliefs that explained the occurrence of both BTA and WTA effects.

Study 3 manipulated perceptions of the distribution by manipulating the availability of distributional extremes. We showed participants a website for products for short or tall consumers. Participants examining the “short” website believed they were taller than those viewing the “tall” website. Once again, inspection of the perceived distributions of others showed that the manipulations produced a significant shift in these perceptions and it was these perceptions that explained relative estimates.

These experiments show that participants can incorporate beliefs about others into their percentile estimates and strongly suggest that inaccurate estimated distributions are to blame for relative miscalibration. If these perceptions of relative standing are inaccurate, so may be purchases. But, if marketers anticipate that

people are likely to imagine referent distributions as normal, they may be able help them make better decisions.

“Overconfidence and Entry into Competitions: Reconciling Discrepant Results”

Daylian M. Cain, Yale University, USA

Don A. Moore, Carnegie Mellon University, USA

M. Keith Chen, Yale University, USA

Numerous research results attest to the robustness of people's belief that they are better than others. The strength of this evidence was sufficient for the most popular social psychology text in the United States to claim that “for nearly any subjective and socially desirable dimension...most people see themselves as better than average” (Myers 1998). Griffin and Varey (1996) went further, claiming that “Overconfidence is not only marked but nearly universal.” So it is noteworthy that recent studies have found strong evidence of instances in which people, on average, believe that they are worse than others (Kruger 1999; Moore 2007). We attempt to reconcile these discrepant findings.

Our reconciliation focuses on self-selection and argues that people naturally choose tasks on which they believe they are better than others. Therefore, wherever people can choose whether to take part, we should expect to find that competitors generally think they are better than others, even when they are not. We introduce a lab experiment—a market-entry game of skill—with both hard and easy tasks and allow participants to choose where to compete. We expected that people would be more likely to believe that they had performed better than others on the easy task than the hard one.

Hypotheses. We devised a market-entry game in which participants had to choose which of two tournaments they would enter. We randomly varied both the size of the prize associated with each tournament and the difficulty of the quiz, where scores determined entrants' chances of winning the prize. Each entrant's probability of winning the prize for a given tournament was proportional his or her relative quiz performance. For half of our participants, the hard quiz was associated with a \$90 prize and the easy quiz was associated with a \$45 prize. For the other half of our participants, the prize sizes were reversed.

Given prior experimental findings (Rapoport, Lo, and Zwick 2002), we predicted our experimental participants would respond to increased prizes with increased entry. The Nash equilibrium would predict that two-thirds of participants in each condition would choose the prize with the larger size. This implies the expected value of entry in each tournament would be equal.

These predictions stand in contrast to prior findings that people believe they are better than average on easy tasks and worse than average on hard tasks, which led us to predict excess entry in tournaments of easy tasks and insufficient entry in tournaments of hard tasks. Finally, we also predicted that those who most overestimate their performances on any particular task relative to others would disproportionately choose to compete in it. Consequently, we predicted that, subjects would, on average, believe that they were better than average at that task where chose to compete.

Method. The 160 participants in our experiment took two ten-item tests, one easy and one hard. Each test was associated with a cash prize. Participants had to choose which prize to compete for.

Results. On average, participants were more likely to believe that they were better than others on the easy quiz ($M=0.30$, $SD=1.76$) and worse than others on the hard quiz ($M=-0.12$, $SD=2.14$), $t(159)=2.41$, $p<0.02$. The majority of participants (67 percent) chose to compete for the prize associated with the easy quiz. This difference overwhelmed the effect of our manipulation of prize size. Similar proportions of participants chose to compete for the

easy prize, regardless of whether it was the \$90 prize (70 percent) or the \$45 prize (64 percent). However, looking only at the contests where participants chose to compete, they reported themselves to be, on average, above average ($M=.36$, $SD=1.92$), $t(159)=2.35$, $p=.02$.

Discussion. Most of our participants chose to compete in the easy tournament. Of those, 68% would have been better off individually competing in the hard tournament; and all but one would have been better off switching when the hard tournament held the large prize. So, participants correctly anticipated more competition in the easy tournament, yet flooded into the easy test tournament. No doubt this is because the easy test is where participants tended to underestimate others and therefore tended to believe that they were better than others.

This paper also illustrates how it is that self-selection produces a situation in which people systematically believe that they are better than others at the tasks in which they have chosen to engage. When people are free to choose where to compete, they self-select into domains where they think they have relative advantage. It is also interesting that this effect can result from individuals making rational choices with imperfect information. In other words, people make errors because they have imperfect information regarding their own and others' performances. However, many of these errors are consistent with Bayesian logic (which underlies differential regression). The final result, however, is that sensible people making sensible choices can produce an outcome that appears irrationally myopic, biased, and is collectively inefficient.

SPECIAL SESSION SUMMARY

Positive Emotions Are Like a Box of Chocolates: Without Identifying the Different Flavors You Never Know What Behavior You're Going to Get

Lisa Cavanaugh, University of Southern California, USA

Barbara Fredrickson, University of North Carolina, USA

SESSION OVERVIEW

How might different types (flavors) of positive emotions differentially influence consumption behavior? Many consumption decisions are driven primarily by a desire to cultivate positive emotional experiences for ourselves and for others. Despite the importance of positive emotions to marketing, researchers know relatively little about how or why specific positive emotions may influence behavior in different ways. For example, previous research shows that positive emotions can influence consumers in both favorable ways (e.g., increased helping and improved problem-solving; see Isen 2001; Isen 2008 for reviews) and unfavorable ways (e.g., increased stereotyping and shallow processing; see Cohen, Pham, and Andrade 2008 for a review). But to date little attention has been given to whether these effects may vary systematically across different positive emotions. The papers presented in this symposium investigate how and why different positive emotions influence consumer behavior in distinct ways.

This symposium bridges theoretical perspectives on positive emotions (i.e., appraisal, broaden-and-build, and evolutionary) to argue that positive emotions are more complex than consumer researchers have assumed to date. Together they present evidence and develop theory to explore why specific positive emotions uniquely impact consumers' judgments and behaviors across a range of consumption contexts important to marketing researchers.

Cavanaugh, Bettman, and Luce demonstrate that dimensions of positive emotional appraisal help to explain how specific positive emotions broaden consumers' thought-action repertoires in unique ways. They demonstrate dissociations among positive emotions characterized by problem-solving (e.g., hope), social connection (e.g., love and gratitude), and control (e.g., pride) appraisals using both manipulated and measured emotions. These specific types of positive emotions differentially influence effortful behaviors (e.g., considering more choice options and engaging in environmental actions) as well as socially conscious behaviors (e.g., behaviors benefiting distant others and donations to international relief).

Building on this theme, Algoe, Haidt and Gable examine other-praising positive emotions (e.g., gratitude, elevation, admiration). The authors present new data on the distinct situational appraisals and cognitive consequences of other-praising emotions. Across lab and field studies, this research demonstrates the importance of eliciting appropriate positive emotions for particular consumer contexts (e.g., gift-giving) and for producing desired effects for firms and service providers (i.e., promoting lasting relationships with both new and established consumers).

Griskevicius, Shiota, and Neufeld draw on an evolutionary approach to examine discrete positive emotions. They examine how specific positive emotions influence cognitive processing in the context of advertising and persuasion. In particular, they predict and find that certain positive emotions (e.g., amusement) lead to more heuristic processing while other positive emotions (e.g., awe) lead to more systematic processing of messages. This research helps to elucidate discrepancies in the literature regarding the relationship between positive emotion and consumer processing.

In keeping with the conference theme "A World of Knowledge At the Point of Confluence," the papers in this session bring

together distinct theoretical perspectives on emotion (i.e., appraisal, broaden-and-build, and evolutionary theories), which are likely to inspire much interest and debate. A rich discussion of these findings on the differential effects of positive emotions will be led by Barbara Fredrickson. As the Principal Investigator of the Positive Emotions and Psychophysiology Lab at the University of North Carolina and author of a 2009 book entitled *Positivity*, Dr. Fredrickson is a leading expert on positive emotions. Fredrickson has suggested that positive emotions serve a unique function—broadening thought and action tendencies and building enduring resources (Fredrickson 1998; 2001; 2009). In this symposium, she will share her expertise and unique insights on the role of positive emotions in consumer behavior research and facilitate discussion in a twenty-minute segment. This symposium is likely to appeal to researchers interested in emotion and decision-making as well as transformative consumer research. The research presented contributes to our understanding of how and why consumers behave the way they do in the domains of brand relationships, gift-giving, donation behavior, socially conscious consumption, advertising and persuasion. These findings have important implications for marketers, individual consumers, and society.

EXTENDED ABSTRACTS

"Feeling Good and Doing Better: How Specific Positive Emotions Differentially Influence Consumer Behavior"

Lisa A. Cavanaugh, University of Southern California, USA

James R. Bettman, Duke University, USA

Mary Frances Luce, Duke University, USA

Many consumption decisions are driven by a desire to cultivate positive emotional experiences for ourselves and others. Marketers, likewise, go to great lengths to engineer positive emotional experiences for consumers. However, researchers lack a clear understanding of the distinct behavioral consequences of different positive emotions.

We build on appraisal theory (Lerner and Keltner 2000, 2001; Raghunathan and Pham 1999; Smith and Ellsworth 1985) and the broaden-and-build theory of positive emotions (Fredrickson 1998, 2001) to understand the influence of different positive emotions on consumption behaviors. The broaden-and-build theory suggests that all positive emotions function similarly to broaden momentary thought-action repertoires. Instead, we argue that specific positive emotions broaden in distinct ways based on differences in appraisals. In particular, we use both manipulated and measured (dispositional) emotions to show that certain positive emotions may broaden a consumer's sense of self while others may broaden a consumer's efforts or consideration set.

In study 1, we characterize positive emotions in terms of new appraisal dimensions. The results show that positive emotions can be reliably distinguished along multiple appraisal dimensions, including two new dimensions: social connection (sense of connection to others) and temporal focus (focus on past, present, future). Notably, the dimensions that explain the greatest amount of variance among these positive emotions are different from the dimensions used previously to understand important differences in negative emotions. Specifically, we find that problem-solving (sense of

needing to expend energy or effort) and social connection (sense of connectedness to others) best distinguish among the positive emotions considered.

Studies 2–5 were designed to test whether the patterns of appraisals established in Study 1 enable prediction of differential effects of positive emotional experience, using specific emotions that are manipulated (studies 2 and 3) and positive emotional blends that are both measured (study 4) and manipulated through television commercials (study 5). We hypothesize that two different forms of broadening—broadened sense of self versus broadened consideration—will be triggered by different positive emotions, namely emotions high in social connection (e.g., love and gratitude) for broadened sense of self and emotions high in problem-solving (e.g., hope and interest) for consideration and effortful actions. We also introduce a new methodology accounting for the extent to which a consumer regularly experiences an array of positive emotions to develop appraisal dispositions characterizing the chronically active appraisal dimensions for that consumer. Thus, the appraisals underlying specific positive emotions can be used not only to predict consumers' momentary emotional states but also to predict patterns of behavior linked to the specific emotions that a consumer experiences regularly.

In study 2, we test our hypothesis that a high social connection positive emotion (love) but not a low social connection positive emotion (hope) will lead to a broadened sense of self and hence more socially conscious consumption behaviors benefiting distant others, with this difference dampened or eliminated for behaviors benefiting close others. As predicted, we find an emotion by social distance interaction on likelihood of engaging in socially conscious consumption behaviors. Specifically, momentary love increases intentions to engage in socially conscious behaviors benefiting distant others significantly more than hope. In contrast, love and hope have identical effects on behavior benefiting close others, i.e. above those in the neutral emotion condition. Significant moderated mediation demonstrates that appraisals of social connection mediate the relationship between emotion and behavior for distant but not close others.

In study 3, we test our hypothesis that specific positive emotions can lead to opposite effects within the same consumption context, i.e. in response to a fundraising appeal. We predict and find that a high perceived control emotion (e.g., pride) will lead donors to prioritize restricted (vs. unrestricted) monetary gifts more than a social connection emotion (e.g., love) and that a high social connection emotion (e.g., love) will lead donors to prioritize international (vs. domestic) relief more than a high perceived control emotion (e.g., pride).

Since emotional blending (i.e., experiencing multiple positive emotions concurrently) is particularly common among positive emotions, studies 4 and 5 examine positive emotional blends based on dimensions of appraisal. In study 4, we examine how combinations of dispositional positive emotions form appraisal dispositions which chronically influence consumption behavior and lead to distinct forms of broadening. In study 4, we predict and find evidence of a double dissociation such that positive emotions characterized by problem-solving (but not social connection) lead to broadened consideration (considering more options and more information seeking) and those characterized by social connection (but not problem-solving) lead to more socially conscious consumption behaviors benefiting distant others—two distinct forms of broadening. Simultaneous regression models based on the social connection and problem-solving appraisal disposition scores showed that different appraisal dispositions lead, as hypothesized, to these different types of broadening.

Study 5 predicts and finds that momentary positive emotional blends (based on positive emotional appraisal types) can similarly influence behavior. Participants who viewed a television commercial characterized by a problem-solving emotional blend (hope and interest) subsequently committed to more effortful environmental actions (e.g., bringing canvas bags to the grocery store; unplugging appliances not in use) than those who viewed a commercial depicting a social connection blend (love and gratitude). Mediation analysis shows that appraisals of problem-solving explain the relationship between positive emotional blend type and engagement in such actions.

In sum, five studies show that different positive emotions broaden in different ways and that different types of broadening foster different types of consumption behaviors. These results are among the first to characterize the different effects of distinct positive emotions. They provide the first empirical demonstration of differential broadening. We also introduce new appraisal dimensions useful for distinguishing among positive emotions and the new concept of appraisal dispositions as a means for characterizing chronic patterns of emotion and appraisal tendencies that influence consumption.

“Opportunity Knocks: Other-Praising Positive Emotions in Action”

Sara B. Algoe, University of North Carolina, USA

Jonathan Haidt, University of Virginia, USA

Shelly Gable, UC Santa Barbara, USA

Emotions mark moments and reliably coordinate humans' adaptive responses to common environmental situations that have arisen across millennia. New research and theory suggests that this characterization of emotions applies equally well to positive and negative emotions (e.g., Fredrickson & Branigan 2005). However, whereas scientists have a robust understanding of the form and function of distinct negative emotions like fear, anger, and disgust, relatively little is known about the form and functions of distinct positive emotions. This is despite the fact that positive emotions are experienced more frequently than negative emotions in daily life (e.g., Fredrickson 2009; Fredrickson and Losada 2005), and despite the fact that consumers crave, seek, and shape their lives to find positive emotional experiences.

A critical environmental factor in the experience of human emotion involves our social nature. Humans are often inspired and touched by the actions of others, triggering a range of positive emotional responses that have implications for behavior (Algoe and Haidt 2009). Drawing on theory from emotion and relationship science, we present data to document the distinct form and function of three positive emotions from the “other-praising” family: elevation, admiration, and gratitude. We then focus on specific positive emotions (e.g., gratitude) to illustrate the importance of eliciting the right appraisals (i.e., in gift-giving) to produce the desired effects promoting relationships with new and established consumers.

We first provide data to highlight key theoretical differences between moral elevation, admiration, and gratitude. These data document spontaneously-generated behavioral intentions that make each other-praising emotion distinct from joy, and each distinct from the other. As “other-praising” emotions, each emotion may help to enhance the reputation of the target (i.e., the praiseworthy other), but each appears to have unique form and function (Algoe and Haidt 2009).

Next, we present data from two experiments (studies 1 and 2) designed to demonstrate the distinct appraisal and motivational patterns of two other-praising emotions: moral elevation and admiration. Participants were randomly assigned and exposed to the

emotion manipulation (elevation/ admiration/ amusement) in each of two ways: a standardized video clip viewed in the lab, and then for a three-week period they completed reports each time they experienced the type of situation to which they were assigned. As predicted, results from each study showed distinct appraisals for each other-praising emotion, distinct patterns of emotional response, and distinct patterns of motivation.

In Studies 3 and 4, we hone in on a specific other-praising emotion particularly relevant to firms and service providers (e.g., relationship marketing) and consumer choice (i.e., gift-giving): gratitude. In these studies, we illustrate how understanding the situational appraisals that produce a given emotion help us better understand subsequent consumer beliefs and behavior. Simply receiving a gift is not enough to produce the emotion of gratitude. The actual emotional response is what matters in the coordination of the desired behavior.

In study 3, we present a field study suggesting that experienced gratitude has important and long-term implications for building loyalty and lasting relationships between new consumers and firm employees (Algoe, Haidt, Gable 2008). In this study, we explore the dynamics and implications of gift-giving among new brand initiates (i.e., sorority sisters) during an annual tradition on college campuses. In this study, new members of a sorority, who received a variety of benefits (i.e., a series of gifts) from a specific benefactor over the course of four days, reported their appraisals and emotional response to receiving each benefit (i.e., gift). The results show that beyond liking for and cost of the benefit, the perception that the benefactor was responsive to the needs and wishes of the recipient in the provision of the benefit robustly predicted gratitude. For the first time, these data show that, beyond cost/benefit analyses, gratitude entails perceptions of a benefactor's understanding, validation, and caring. Mostly notably, these findings have remarkable long-term implications for the relationship with the benefactor. In fact, follow-up measures show that the recipient's gratitude experienced during gift-giving predicted the benefactor's feelings about the relationship one month later regardless of time spent together.

In study 4, we provide evidence that effective expression of gratitude predicts consumers' feelings of relationship satisfaction and connection in long-term relationships as well (Algoe, Gable, and Maisel in press). To illustrate how essential other-praising emotions are to meaningful real-world outcomes, we examine their role in long-term relationships as well. Study 4 measured emotions and change in relationship quality in people with already established relationships. Specifically, we wanted to see what experienced gratitude could add in an already established relationship. Members of couples independently reported their emotional responses to interactions with their partners that day and then provided daily ratings of relationship quality for two weeks. Using multilevel modeling to pair couple-members' responses and assess change over time, a participant's gratitude predicted a partner's increased feelings of satisfaction with and connection to the relationship from the previous day. These findings held for men and for women, and controlled for several alternative explanations. As a contrast, the emotion of indebtedness, which is also associated with repayment behavior and so theoretically could build a relationship, was not associated with increased relationship quality when included in the same models. Thus, everyday gratitude appears to work as a booster shot for these relationships. In sum, a costly benefit is not enough; you need to get the appraisals and the specific positive emotion right to produce desirable relationship effects.

In just the past few years, evidence has accumulated that all positive emotions are not "happiness." Instead, emotions like admiration, gratitude, and elevation have distinct forms and func-

tions. These studies demonstrate that these emotions are differentiated in everyday life, and that they work in specific ways to change beliefs about the praiseworthy characteristics of the target, shape motivations to interact with the target and the world, and can have lasting impact on relationships, with implications for building customer loyalty and mutually beneficial relationships. Understanding the basic functions of specific positive emotions and specific types of positive emotions is important to unlocking their potential.

"Why Different Positive Emotions Have Different Effects: An Evolutionary Approach to Discrete Positive Emotions and Processing of Persuasive Messages"

Vladas Griskevicius, University of Minnesota, USA

Michelle N. Shiota, Arizona State University, USA

Samantha Neufeld, Arizona State University, USA

Imagine you're watching a pleasant television program. The program may be a travel show featuring awe-inspiring natural wonders, or an animal program about baby animals; it may be a sitcom that makes you laugh, or a highly anticipated sporting event. At some point during the program, you're likely to encounter a commercial message intended to persuade you. Given that any of these programs will elicit positive feelings, are you likely to process the persuasive message more carefully or more carelessly than if you felt no emotion at all?

The answer to this question might initially appear simple: Much research already shows that positive affect leads people to process messages in a more heuristic or careless manner. In the present series of experiments, we examine the complexity layered upon this general effect and address some of the mechanisms behind this complexity. Whereas traditional approaches have examined the influence of affective valence on cognition, our approach emphasizes differences among the likely evolutionary, fitness-enhancing functions of discrete emotions of the same valence, and suggests that emotions of the same valence can have quite different consequences.

Although positive emotion was long considered a single construct, researchers have begun to offer functional definitions of specific varieties of positive emotion, whereby different positive emotions facilitate fitness-enhancing responses to distinct types of opportunities (e.g., Keltner et al. 2006; Kenrick and Shiota 2007; Fredrickson 1998; Griskevicius et al. 2009). In the current research, we assessed the impact on processing of persuasive messages of four functionally distinct positive emotions described in previous literature (e.g., Keltner et al. 2006): amusement, enthusiasm, nurturant love (i.e., compassion), and awe.

Amusement is the positive emotion experienced during social or cognitive play, including humor. Play behavior and the experience of humor are both associated with a distinctive "drop-jaw" smile and/or laughter, expressions that promote social bonding by letting down one's guard and signaling social support. Enthusiasm serves primarily to facilitate the acquisition of material resources and rewards such as food. For example, consider the feeling experienced when smelling the preparation of a delicious dinner, or the feeling of excitement after overhearing that you might be getting a raise. Enthusiasm draws attention to predictable associations among cues of reward, the experience of reward, and behavioral strategies for acquiring rewards.

Nurturant love (sometimes referred to as compassion) is the feeling of love and concern for another's well-being, typified by one's emotions when seeing an infant, small child, or baby animal. This positive emotion serves to motivate nurturant and care giving behavior, such as attending closely to the target's needs and

protecting the target from possible harm. Awe is the feeling of wonder and astonishment experienced in the presence of something novel and difficult to grasp. Prototypical elicitors of awe include panoramic views, works of great art, and others' remarkable accomplishments. This positive emotion serves to facilitate new schema formation in unexpected, information-rich environments. Accordingly, awe leads people to shift their awareness away from day-to-day concerns and toward current incoming information.

The first goal of the current research was to investigate the effects of these four positive emotions on the processing of persuasive messages. This question was addressed by developing and validating two different methods to elicit the positive emotions, and by assessing the emotions' influence on persuasive message processing using two well-established paradigms. In Study 1, emotions were elicited by having participants write about a personal emotional experience with a prototypical elicitor of a specific positive emotion and processing was assessed via the classic "comprehensive exams" paradigm. In Study 2, emotions were elicited by reading a short story depicting prototypical elicitors of a specific positive emotion, and processing was assessed via another method involving a different type of attitude topic and heuristic cue (see Tiedens and Linton 2001).

In both experiments, we found that the positive emotions of enthusiasm and amusement enhanced heuristic processing, consistent with traditional findings on the influence of positive affect. Participants induced to feel either of these two emotions were more easily persuaded by a weak argument that had persuasive heuristic cues than those in a neutral control condition. In fact, a closer look at previous studies indicates that researchers have generally used "positive affect" manipulations targeting one or more of these emotions: watching a funny video clip, which elicits amusement; receiving a gift of candy, which likely elicits enthusiasm.

In contrast, when individuals were in the positive emotional state of awe (e.g., seeing a breathtaking panorama for the first time) or nurturant love (e.g., seeing a cute, vulnerable child), they were significantly less persuaded by weak arguments than people in an emotionally neutral state—an effect that suggests systematic processing (e.g., Tiedens and Linton 2001). Overall, we found that positive affect can produce more heuristic or more systematic processing than an emotionally neutral state, depending on the specific positive emotion that is elicited in the person.

We additionally examined whether the effects of different positive emotions were accounted for by a common mediator or by different mediators. To address this goal, we investigated whether several of the positive emotions were associated with different cognitive appraisals (Tiedens and Linton 2001), or with different patterns of thoughts about the persuasive message. We did not find that certainty—or any other single appraisal dimension—adequately explained our pattern of findings. Also, no single aspect of thoughts about the persuasive message adequately explained the pattern of positive emotion effects. Instead, meditational analyses suggest that enthusiasm, amusement, nurturant love, and awe each affect persuasion through a somewhat different mechanism, some of which are yet to be established empirically. This is consistent with the evolutionary perspective driving our research, which defines each emotion as a fitness-enhancing package of cognitive, physiological, and behavioral responses to a prototypical eliciting situation. Different emotion packages may include some overlapping elements, but no single element (such as an appraisal dimension) is expected to account for the effects of all emotions.

SPECIAL SESSION SUMMARY

Exploring the Links between Stigma and Consumption

Elizabeth Crosby, University of Illinois at Urbana-Champaign, USA

Cele C. Otnes, University of Illinois at Urbana-Champaign, USA

SESSION OVERVIEW

Goffman (1963) describes stigma as the possession of an attribute that has a negative connotation, and that deviates from what is considered normal in a specific category of people. Whether a particular attribute is considered a stigma varies depending largely on environmental and situational factors. Furthermore, what may be regarded as a stigma in one situation may be considered normal in another. Nevertheless, people cope with perceived stigmas in a variety of ways. Stigma management consists of the strategies employed by the stigmatized consumer or some other person on his or her behalf to cope with the stigma (Goffman 1963). Stigma is a well-researched phenomenon in sociology and psychology. Scholars have examined stigma management strategies such as resignation, confrontation, concealment, and enclave withdrawal (Miller and Kaiser 2001). Researchers have also explored the psychological effects of stigmatization, which include despondency and helplessness (Abramson et al. 1989). However, some stigmatized individuals view their stigmas as “blessings in disguise,” which can reap positive effects such as increased self-esteem (Ainlay et al. 1986).

Stigma and stigma management have emerged as important constructs within consumer research. Stigma has been examined in relation to senior citizen discounts (Tepper 1994), subcultures (Kozinets 2001), low-literate consumers (Adkins and Ozanne 2005, Viswanathan, Rosa, and Harris 2005), and coupon redemption (Argo and Main 2008). Unfortunately, however, these constructs are often relegated to the background as other constructs take center stage or are context-specific. Yet stigma and stigma management deserve study in their own right, because of their implications for consumer behavior and consumer welfare. This special session places the study of stigma front and center, by exploring the complex relationships among stigma, stigma management, and consumption. Elizabeth Crosby and Cele C. Otnes (University of Illinois at Urbana-Champaign) explore how consumers use consumption to manage stigma in a wide variety of contexts. Bige Saatcioglu (HEC Paris) and Julie Ozanne (Virginia Tech) examine stigma within the context of poverty. Daiane Scaraboto (York University) and Eileen Fischer (York University) examine how groups of stigmatized consumers collectively manage their stigma online. Madhu Viswanathan (University of Illinois at Urbana-Champaign) compares the stigmas and coping strategies for low-literate and poor consumers across two different cultures.

EXTENDED ABSTRACTS

“Consumption as a Strategy for Stigma Management”

Elizabeth Crosby, University of Illinois, Urbana-Champaign, USA

Cele C. Otnes, University of Illinois, Urbana-Champaign, USA

In his seminal book on stigma and stigma management, Goffman (1963) argues that consumers can be stigmatized because of their social class. A stigma “refers to an attribute that is deeply discrediting” (Goffman 1963, 3). There are many different sources of stigmas in society, from age to a physical handicap. A consumer’s stigma “makes him different from others in the category of persons available for him to be, and of a less desirable kind” (Goffman 1963,

3). Stigmatization affects not only how people perceive themselves, but also how they feel others perceive them (or will perceive them if others know about their stigmatized attribute) (Crocker, Major, and Steele 1998). Research finds that stigmatization can result in positive and negative psychological effects. Stigmatized individuals may also suffer from low self worth and depression (Abramson et al. 1989) while others may experience increased self-esteem (Ainlay et al. 1986). Much of the psychological effects of stigma depend on how the individual manages the stigmatization (Ainlay et al. 1986). As such, it is important to understand how individuals cope with stigma. Numerous studies have looked at how individuals cope with a particular stigma, such as social class (Granfield 1991), racially stigmatized individuals (Crandall, Tsang, Harvey, and Britt 2000), and HIV stigmatized consumers (Emlet 2007). Furthermore, consumer researchers also have explored the concept of stigma in particular contexts including senior citizen discounts (Tepper 1994), subcultures (Kozinets 2001), low-literate consumers (Adkins and Ozanne 2005, Viswanathan, Rosa, and Harris 2005), and coupon redemption (Argo and Main 2008).

This study explores how individuals use consumption to manage stigma across contexts. For this study, I collected 102 consumer narratives from young adult informants who detailed their experiences with being stigmatized. The narratives describe many different stigmas based on such characteristics as gender, race, religion, and social class. In analyzing the text, I sought out emergent themes while also engaging in dialectical tacking (Strauss and Corbin 1998). I read all narratives multiple times to identify salient and emergent themes (McCracken 1988).

The preliminary analysis reveals that informants employ four consumption-related strategies to manage stigma: (1) concealment, (2) reduction, (3) redirection, and (4) disclosure. With Concealment, individuals consume certain products that will hide their stigma. Consumers deliberately choose products that conceal their stigma. For example, one informant, William, felt stigmatized by his social class, and bought clothing accessories that he believed would conceal his lower social class. Consumers may feel pressured to make these consumption choices, fearing if they do not, their stigma will be revealed. This strategy has consumer welfare implications, because consumers may be pressured to spend beyond their means or consume products that are harmful to their health.

With Reducing, people attempt to decrease their stigma by limiting the consumption of products that might exacerbate their stigma. Informant Molly is often stigmatized because of her multiple tattoos. Others have told her that “tattoos make you look like a criminal.” Even though she would like to have more, Molly has limited her tattoos to four so that the effects of her stigmatization are within certain boundaries.

With Redirection, consumers manage their stigma by shifting attention away from it. They consume products that highlight some other attribute they have to make their stigma less noticeable. Consumers thus shift others’ attention away from the stigmatized attribute to some other attribute that better represents how they want others to view them. Another informant Mark was stigmatized for not being an athlete. In order to combat this characterization, he carried his drumsticks “prominently” on the outside of his back-

pack, directing people's attention away from his lack of athleticism to his musical talents.

Finally, with Disclosure, individuals can also manage their stigma by making consumption choices that intentionally draw attention to it. In doing this, consumers make the statement that they are not ashamed of whatever attribute for which they are stigmatized. Furthermore, consumers may also seek out consumption opportunities where they can meet with other individuals who are stigmatized by the same attribute (Kozinets 2001, Muniz and Schau 2005). Informant Michael notes that he enjoyed skateboarding, but felt that others stigmatized him for it, considering him to be a juvenile delinquent because of it. He dealt with the stigma by immersing himself more fully in the activity. Michael started spending considerable time at the skate park with other skateboarders. He also changed his style of dress to match the other skateboarders, so that he could easily be identified as a skateboarder. This paper will fully unpack each of these strategies, as well as their implications for consumer welfare and consumer research.

“The Voices of Trailer Park Residents: Towards a Multidimensional Understanding of Stigma”

Bige Saatcioglu, HEC Paris, France

Julie L. Ozanne, Virginia Tech, USA

Since Goffman's (1963) seminal work on stigma theory, a profusion of research has explored the sources, nature, and consequences of stigma. However, much consumer research on stigma focuses on stigma management strategies from a psychological perspective investigating micro-level interactions within marketplace encounters (see, for exceptions, Hill 2001; Hill and Gaines 2007). Fewer studies take into account the deeply embedded socio-cultural stigmas that permeate particular contexts. Thus, a need exists for more research involving socio-cultural accounts that explore the development of stigmas through not only marketplace behaviors but also consumers' dialectical relationships with the macro social structure (Link and Phelan 2001). Furthermore, the relationships between stigma and its related components (e.g., different forms of deprivation and exclusion) need to be taken into account in order to arrive at a richer understanding of the social construction of stigma.

Poverty is one such state through which multiple co-existing social, cultural, motivational, and material dynamics emerge. Poverty is not only about economic and material shortage but it also involves a lack of socio culturally perceived necessities (Sen 2000) and social exclusion from meaningful interactions and exchanges (Bauman 2000). However, traditionally, poverty is treated as merely an economic problem; the poor suffer from material deprivation. Implicit in this approach known as the 'absolute poverty' is a one-dimensional deprivation in which individuals lack economic capital to meet their primary material and physical needs (Lister 2004). Consistent with this tradition, much consumer research on poverty focuses on the economic aspects of resource-constrained consumers' lives while overlooking social, cultural, and motivational dynamics (see, for exceptions, Hill and Stamey 1990; Chakravarti 2006). Alternatively, a more multidimensional perspective takes into consideration different types of deprivations and stigmatizations experienced by poor consumers. Here, poverty is not merely economic and material shortage of resources; rather, it is a multidimensional, relational, dynamic, and complex phenomenon that encompasses many different realities of the poor. It is the lack of "consumer adequacy," defined as "the continuous availability of a bundle of goods and services that are necessary for survival as well as the attainment of basic human dignity and self-determination" (Hill 2002, p. 20).

The present research builds on these nuanced relationships that exist between the impoverished consumers and multiple social constituents. We demonstrate five distinct social constructions of poverty deriving from five fragmented social identities adopted by the poor to manage and cope with multiple social stigmas. Our research shows that, even within the same bounded geographical setting, there exist various meanings and flavors of stigma. For example, within the institutionalized and cultural norms, poor people are assigned multiple labels and, as consumers, they are categorized as "flawed, blemished, and defective consumer manqués" (Bauman 2005, p. 38). Poverty is also seen as a "manifestation of moral defect"; that is, a blemish of the individual character since it is assumed that the poor are generally responsible for their socio-economic status (Lewis 1970). Moreover, poor people are stigmatized as groups or communities, indicating a tribal-like social stigma as advanced by Goffman (1963). Taking an ethnographic approach within the context of a mobile home park, we investigate how the poor negotiate their social identity and manage multiple stigmas in everyday life. Consistent with a multi-dimensional approach to poverty, we first untangle different types of stigmatizations experienced by mobile home residents. We then explore a wide range of stigma management strategies they employ.

Mobile homes, once a low-cost opportunity for blue-collar workers to realize the middle-class American dream of home ownership and upward social mobility, have turned into degraded forms of housing since the 1960s. Their unusual appearance and potential mobility represent a threat to conventional American housing ideals and norms. Moreover, the negative social stereotyping of mobile home residents as dirty, lazy, and criminal-minded individuals further contributes to the stigmatization of mobile home parks as "white trash icons" (Bérubé and Bérubé 1997). Consequently, our findings suggest that mobile home residents are stigmatized on various dimensions and experience different forms of social devaluation. Within such proliferation of co-existing stigmas, our informants employ a variety of stigma management strategies to either manage or transform those cultural representations and practices that stigmatize. For example, many informants fight back against the stigma of 'trailer park trash' by expressing their pride in their homes through artistic and creative home projects. Others take a more consumption-oriented approach to poverty management and reject the label of poor and inadequate consumers through middle-class consumption aspirations. Those park residents with a stronger sense of belonging and affiliation to the mobile home park engage in collective community revitalization projects. At times, this active civic engagement extends beyond the confines of the trailer park and includes wider social settings such as the town council and religious communities. Such participation into meaningful social interactions and civic activities help park residents cope with feelings of isolation, exclusion, and alienation from mainstream consumer society. In contrast with these active stigma managers, some mobile home residents take a more subtle approach to stigma management. They emotionally distance themselves from similar others, engage in downward social comparison, and become outsiders within the "ghetto of similarly deficient consumers" (Bauman 2005, p. 41). Finally, other poor consumers who actually own the stigma of poverty reconstruct the meaning of stigmatization through horizontal social comparison and bonding capital (Putnam 2003).

Thus, this research approaches social stigma of poverty as a relational, multi-faceted, and dynamic process whereby individuals with different levels of agency and aspirations and multiple social constituents interact in an intertwined web of power relations (Waxman 1983). Combining individual-psychological and macro-

social research traditions on stigma and exploring multiple co-existing social stigmas within a mobile home park community, this research extends our understanding of stigma creation and management.

“From Individual Coping to Collective Action: Stigma Management in Online Communities”

Daiane Scaraboto, York University, Canada

Eileen Fischer, York University, Canada

Current perspectives on stigma define it as a persistent predicament with widespread consequences for stigmatized individuals (Henry and Caldwell 2006). This conception of stigma implies that to promote effective change, a multifaceted and multilevel approach is necessary. To combat stigma, it is necessary to address issues related to the many mechanisms that can emerge in the context of disadvantaged outcomes. Consumer researchers have mainly focused on understanding the consequences of stigmatization for consumers and on identifying individual passive strategies of stigma coping, as opposed to active strategies to change stigma. Similarly, other social science research has paid limited attention to active responses to stigma (Miller 2006). Despite a recent move towards a more contextualized, less pathological view of stigmatization (Dovidio, Major, and Crocker 2000, Miller and Major 2000), active responses to stigma have received limited consideration. In particular, collective responses have yet to be considered.

We propose that because they tend to challenge the legitimacy of an existing status situation and involve the elaboration of alternative meanings for individual and collective behavior while fighting the economic and social aspects that underlie the stigma, collectives fighting a stigma can be studied as a form of social movement. On the macro level, the focus is on the role of culture in giving rise to challenges to entrenched features of social structures, such as those that support particular stigma. On the micro level, the focus is on how individual identities and behaviors lead them to challenges to specific features of such structures (Pichardo 1997). The new social movement perspective and consumer culture literature lend support to our investigation of a collective of stigmatized consumers. We are interested in identifying and explaining how collectives attempt to deal with marketing practices that they view as reinforcing aspects of a particular stigma. We are also interested in how these collectives attempt to influence marketers to mitigate stigma in society more broadly. Our research is conducted in an online context by a qualitative investigation of the “Fat Acceptance Movement” (FAM) which fights the stigma associated with fat. This choice of context also contributes to extend our understanding of stigma in consumption domains. Prior studies on stigmatized consumers exclusively address domains where the stigma is concealable or not readily apparent, as for low literacy (Adkins and Ozanne 2005, Wallendorf 2001), subculture membership (Henry and Caldwell 2006, Kozinets 2001), and senior age (Tepper 1994). In face-to-face encounters, fat people cannot easily pass for “normal” (Goffman 1974) or conceal their stigma. Besides, heavy-weight individuals are generally considered blameworthy, unlike other physically stigmatized people, like the handicapped (Page 1984). Weight bias has existed for a long time, but only recently it has received the attention of researchers, legislators, and advocates (Brownell 2005).

The FAM is mostly an online phenomenon. Offline activities associated with the movement are infrequent, while the online group spreads globally over a net of interconnected blogs and social networking websites (Samuel 2007). This online community denounces the “weight loss industry,” questions the notion of an obesity epidemic, advocates “Health at Every Size,” and fights

weight-based discrimination (Rabin 2008). It constitutes a site of documented interactions that can provide insight into key aspects of how a community manages the stigma. Consistent with the nature of the phenomenon, we employ “netnography” (Kozinets 2002) to orient data collection and analysis. The study also involves interviewing individuals associated with the FAM movement and includes participant observation in offline settings. This methodological approach takes us closer to the meanings attributed by members to their actions, and provides an understanding of issues related to intersectionality (Gopaldas et al. 2008) and representativeness within the community.

A primary contribution of this investigation will be to explore how the actions of collectives fighting a stigma impact on cultural and marketplace practices, and, conversely, will illuminate the evaluation of market practices’ impact on stigma-related issues. In addition, this study will shift significantly our theoretical understanding of stigma management from an individual, passive, to a collective, active perspective. This study will also have significant implications for social scientists engaged in stigma related research by addressing the stigma associated with fat, an important source of debate and concern to public policy makers and to legions of consumers who struggle with the embodied experience of being fat in a society that reveres thinness. Our preliminary findings indicate that, as a consequence of taking part in collective advocacy against their stigma, these individuals become more critical of the social scene, and highly conscious of human relations. In this sense, they are more inclined to notice and discuss market practices that represent their group in a positive or biased way. Furthermore, we find support to prior research (e.g. Henry and Caldwell 2006, 1035) suggesting that “in contrast to withdrawing into an enclave, the stigmatized individual may respond by challenging the stigma label by attempting to participate in the mainstream domains.” Our study offers empirical evidence that endorses this assumption and also identifies how a collective of stigmatized individuals interact with the market to develop workable ways to fight the stigma and achieve mainstream insertion.

“Understanding Stigma and Coping Strategies across Resource and Literacy Barriers: A Cross-Cultural Comparison”

Madhu Viswanathan, University of Illinois at Urbana-Champaign, USA

This presentation will examine stigma and stigma management among low-literate, low-income consumers in the US and subsistence consumers and entrepreneurs in South India. Our research has focused on understanding marketplace behaviors of individuals living across literacy and resource barriers in the US and in South India. We draw from 15 shopping observations and 35 in-depth interviews of students at adult education centers in the US and from 75 in-depth interviews of low-income, low to moderately literate buyers and sellers in South India.

Research on low-literate consumers in the US has highlighted stigma and related coping strategies (Adkins and Ozanne 2005, Viswanathan, Rosa, and Harris 2005). Adkins and Ozanne (2005) employ dimensions of identity management strategies and acceptance or rejection of stigma arising from low literacy to identify types of low-literate consumers. Researchers have noted that seemingly straightforward events such as having insufficient money at the checkout counter can be cause for despair for low-literate consumers, attributed to not something as mundane as forgetfulness but to the state of low literacy and the stigma attached to it (Gau and Viswanathan 2008). Viswanathan et al. (2005) report a number of coping strategies including avoidance, dependence on others, and

social deception. The contrast with even poor but literate consumers who are not stigmatized by their literacy level is striking, in terms of the willingness of such consumers to complain and seek redress in the marketplace when compared to the relatively passive reactions of low-literate consumers (Gau and Viswanathan 2008).

On the other hand, the nature of stigma associated with being poor in an advanced country needs to be disentangled from the stigma associated with low literacy. The social stigma of being barely literate may heavily influence purchase decision-making, such as giving up on functional attributes to avoid embarrassment. In shopping contexts in the US where a certain level of literacy is assumed, the presentation will examine the nature of stigma attached to low literacy and low income as well as associated coping strategies. Large retail settings, with advanced technology for computation and symbolic package information assume certain levels of literacy. Low-literate consumers negotiate shopping encounters apprehensive about being “caught” or “exposed” for their lack of literacy. A sharp contrast is provided by a different setting across the world where poverty and low literacy are both more widespread. Our research on subsistence consumers and entrepreneurs in South India provides comparative insights on stigma and its management. This intensely relational marketplace is characterized by 1-1 interactions and oral communications, with consumers sharing adversity with small entrepreneurs. Much of the marketplace for the large population of poor, low-literate consumers is relatively distinct from those for the middle and upper strata of society. Subsistence consumers and entrepreneurs learn to evaluate generic products, bargain, count money, and develop related marketplace skills despite their lack of literacy and low income. As a result, we have described these marketplaces as being resource-poor but network rich (Viswanathan 2007), and a stepping stone for developing consumer skills.

With widespread poverty and low literacy, there is almost camaraderie in an otherwise extremely harsh world among the poor and social networks that provide support. The nature of stigma in these settings may be quite different, arising to a lesser extent from poverty or low literacy, but nevertheless existing at more extreme levels of these dimensions. For example, with extreme poverty, households have no choice but to renege on family traditions and associated expenses relating to weddings, birth or death, often leading to stigmatization and being ostracized from family circles. Similarly, public humiliation, the method through which non-collateral loans of astronomic interest are enforced, works by stigmatizing the family for being unable to pay back money they owe. Thus, the very same rich social networks that play a facilitating role can also amplify stigma and the need for its management. Compared to poverty, low literacy leads appears to lead to distinctly different and arguably more acute stigma, an issue that will be explored in the presentation. Despite subsistence marketplaces that do not rely on or assume a high level of literacy, low-literate individuals view themselves as possessing an attribute with a negative connotation, i.e., as a stigma, often an explanation for their being in the state of poverty. Low literacy can lead to fear of conversation and enquiry in a shopping context, feelings of futility even when cheated, and an acceptance of conditions as they are—often justified by the stigma of low literacy. Significant events such as learning a specific trade can act to lessen the stigma of lacking formal education. In summary, this presentation will take a cross-cultural journey toward understanding the nature of stigma in strikingly different marketplaces with distinctly different levels of poverty and low literacy, while emphasizing the interplay between low income and low literacy.

SPECIAL SESSION SUMMARY

Talk the Green Talk, Shop the Green Walk?

Gary Bamossy, Georgetown University, USA
Basil Englis, Berry College, USA

SESSION OVERVIEW

While the environmental movement in the United States is not new, its history is characterized by a series of stops and starts. Many view Carson's *Silent Spring* as the beginning of the modern environmental movement. In exposing the toxic hazards many widely-used pesticides and herbicides posed for non-targeted organisms, Carson's work raised awareness and prompted a new public discourse. American consumers began to re-conceptualize everyday decisions as affecting the interconnecting environmental web. Disturb the web in one area and the entire web trembles from the impact (Carson 1962). In their growing concern about pollution, suburbanization, and pesticides, American consumers began to understand, or at least to develop incipient awareness that their consumption choices have a broader, sometimes far-reaching impact on the environment. Yet this begs the question of how much has changed since the 1960s.

In 1989, just months prior to the 20th anniversary of Earth Day, a nationally representative survey of 1000 American consumers found that 89% of shoppers claimed to be concerned about the environmental impact of the products and services they purchased. Nearly as many (78%) said they would be willing to pay a premium for a product packaged with recyclable or biodegradable materials (Makower, 2009). And the beat goes on...Numerous commercial market research efforts provide consistent evidence that American consumers are aware of and concerned about environmental issues (MINTeL, 2008; American Environics, 2008; Bonini and Oppenheim/McKinsey, 2008; Karel and Neufeld/Yankelovich, 2007; Pike et.al./Earth Justice, 2008; LOHAS, 2009). While all these surveys report high levels of awareness and concern for issues that are variously described as "Environmentalism," "Sustainable Consumption," "The Environment," or in its simplest and most generic term, "Green," these studies also consistently report that few consumers translate their concerns into action. Most American consumers will not go out of their way to find "green" products and about one-half say that price premiums prevent them from buying "green." American consumers "Talk the Green Talk," but do not "Shop the Green Walk." This chronically weak relationship between Green Awareness/Attitudes and Green Behavior provides both the rationale and the focus of this Special Session proposal.

For decades, scholars have studied the relationships between attitudes, social norms, cultural context(s), rational decision making processes, and behaviors. With respect to Green in particular, a key challenge becomes applying such research. Thus, the challenge is to create a paradigm shift in how consumers' think about and act with respect to the environment. How can consumer behavior research play a role in moving "green behaviors" (however broadly defined) from being a set of values and behaviors that is present in only small segments of American society to one of green(er) values and behaviors that are part of the mainstream marketplace?

This special session offers theoretical perspectives and empirical support that challenge us to take up and apply our discipline's talents for transformative research on an issue that has meaning, and does matter on the ground, in the market, right now (Mick, 2006; 2007). The likely audiences for this session includes researchers with an interest in transformative consumer research as a general domain, those with specific interests in green marketing and consumption, consumer reactivity, consumer resistance and practice

theory, as well as colleagues with interests in applying theoretical perspectives in the public interest.

Our focus is on proposing research perspectives to better understand the multitude of reasons as to why consumers have been so reluctant to move from high levels of awareness and concern for the environment towards behaviors of sustainable consumption. We argue that green consumption behaviors must be understood within the context of a process of increasing individualization, where consumers can find ways to feel both responsible and empowered in dealing with environmental risks to both the wider global planet and themselves. The papers in this session recognize that Green is multi-layered and complex; that "Green-Washing" makes consumers feel cynical and confused; that Green is imbued with social status and is seen by many as divisive as opposed to uniting; and that consumer's feelings are accompanied by reactivity, resistance, doubts and insecurities about the consumer choices we all face (Dolan, 2002; Connolly and Prothero, 2008; Kilbourne and Carlson, 2008; Englis and Bamossy, 2009; Lorenzen, 2009; LOHAS 2009).

EXTENDED ABSTRACTS

"Green Dilemma: Libertarian Values Trump Communal Values"

Basil G. Englis, Berry College, USA

Gary Bamossy, Georgetown University, USA

We report the results of a large scale survey of American consumers which segments the market on the basis of consumers' attitudes toward the environment and how these different consumer segments engage (or, more often, don't engage) in pro-environmental consumer behaviors. As noted earlier, various industry studies estimate that 80-90% of American consumers are aware of and concerned about environmental issues, but far fewer translate their concerns into action. However, most consumers will not go out of their way to find "green" products and about one-half say that price premiums prevent them from buying "green" (Mintel 2008). A key question that consumer researchers should address is how (or perhaps, "can"?) we create a paradigm shift in how consumers' think about and act with respect to the environment. To contextualize this research within the framework of Transformative Consumer Research, how can we re-position sustainable consumption from being a niche behavior to become a more widespread behavior adopted in a more consistent manner by the majority of consumers?

There is some industry research which gives us insights on segments of green consumers. One study found that approximately 12% of the U.S. population (about 35 million people) were "True Green" consumers (Mintel 2008)—consumers who not only regularly buy green products, but also incorporate green behaviors such as reducing consumption, re-using products when possible, and recycling. Another study identifies a population segment characterized by a "Lifestyle Of Health And Sustainability" (French and Rogers 2008), and there is even a website devoted to the LOHAS lifestyle (www.lohas.com). With a few exceptions (e.g., Diekmann and Preisendorfer 2003; Ger 1999; Thorson, Thomas and Moore 1995; Meijer and Schuyt 2005), we find far less emphasis in the current consumer research or marketing literatures on studying consumers attitudes toward environmental issues and how these

attitudes do (or do not) impact consumers' behavior. Our research explores how the U.S. population is segmented according to their attitudes toward environmental issues and how these attitudes map onto pro-environmental behaviors.

We conducted a large-scale survey using a sample of 4,082 adults drawn from a commercially maintained online consumer panel and matched to the demographic profile of the U.S. population (income, gender, age, geography, and ethnicity). We asked participants to fill out the New Ecological Paradigm Scale, an instrument designed to capture respondents' general orientations toward the environment (see Dunlap et al. 2000 for a review of this scale's development). We also asked respondents to complete an extensive battery of items about their pro-environment behaviors (adapted from Barr 2006; Cordano, Welcomer and Scherer 2003; McDonald and Oates 2006).

Using factor, cluster, and discriminant analyses to identify consumer segments and provide various forms of evidence regarding validity of the results, our analyses of this extensive attitudinal and behavioral data reveal several interesting findings: consistent with prior research (Mintel 2008) we found that nearly 70% of consumers hold pro-environmental attitudes, although the correlations between environmental attitudes and environmental behaviors vary greatly across segments, and for many types of behaviors, within segments. Further, more than 30% of the population is largely indifferent to environmental issues despite the large amount of recent media coverage concerning global warming (e.g., *An Inconvenient Truth*) and pollution (e.g., prior to the Beijing Olympics). In addition to reporting on the underlying attitudinal and behavioral differences between segments, we also have strong empirical support regarding fundamental differences in beliefs about our basic role as consumers, and the impact of our consumption on the environment. One large segment of consumers believes that there are basic limits to human growth, while another large segment believes that growth can be achieved without harming the environment. A third relatively small group (11%) expresses environmental concerns but also believes that humans should "rule over nature." This segment of consumers tends to hold a more optimistic view (e.g., that human ingenuity can overcome negative environmental consequences), while also exhibiting just modest levels of pro-environmental behavior overall.

The descriptive contribution of identifying different segments of consumers based on their attitudes and beliefs regarding the environment, and examining their (lack of) green behavior is a first step. The important second step is to recognize that within each of these existing segments which vary in their attitudes and behaviors, there is a need for new understanding into how to further cultivate and increase green behaviors. This goal is at the heart of Transformative Consumer Research, and is the key focus of this paper, and presentation.

"Change Is In the Air?"

Steven French, Natural Marketing Institute¹, USA

This paper discusses key findings taken from NMI's 2007 and 2008 Lifestyles of Health and Sustainability (LOHAS) Consumer Trends Database® (LCTD), an annual quantitative study which measures and describes the marketplace for LOHAS products, the

consumers who use them, consumers' expectations of corporate behavior, and attitudes toward environmental and social issues. In this presentation, particular attention is paid to evolving consumers' attitudes, behaviors, and product/service usage patterns. Based on nationally representative surveys of 4,033 and 2,074 consumers conducted in July 2008 and July of 2007 respectively, the data clearly suggests that despite the economic crisis currently facing consumers, there continues to be high levels of concern about environmental issues and that consumers want to "act green." But at the same time, the findings point to a marketplace of consumers who are overwhelmed with green information and green dilemmas, tensions surrounding "green-washing," and confusion about just what is the best and most "green" course of action.

In just the past year, concern and discussion about environmental issues has soared by 30% (from 2007 to 2008), with more consumers reporting that "everywhere they turn people are talking about the environment" (LOHAS, 2009). At the same time, consumers increasingly do not want to make a sacrifice when buying environmentally-friendly products. Rather, consumers report feeling that manufacturers have had enough time to successfully integrate green benefits into products and that the purchase of "green" products should come without sacrifice in performance or inconvenience in acquisition. Furthermore, there is evidence that consumers are moving away from eco-friendly products that do not deliver on traditional attributes and benefits of performance. Consistent with this finding, the data also show that while consumer concern about the environment is increasing, their purchasing decisions continue to be determined mainly by price (a factor for the acquisition of almost all goods and services).

Consumers are also more likely to report feeling overwhelmed, saying that it is too difficult to consider all of the impacts of their actions. For example, upgrading old appliances to energy-efficient models means that old appliances will be sent to a landfill since appliance recycling can be inconvenient and costly. Buying Fair Trade fruit from Chile means foregoing local options that require fewer greenhouse gas emissions in transit. An issue in developing more mainstream adoption of sustainable consumption behaviors is that consumers feel it takes too much effort to consider all of the implications of their decisions, let alone make the "right" one.

Within the context of this "eco-information overload", this study also reports on the beginnings of consumer efforts to become more organized as well as consumer efforts at marketplace resistance by using a variety of tools to express their sentiments and to affect change. Increasing numbers of consumers are using social networking tools such as Al Gore's "We Can Solve It" (www.wecansolveit.org) network to influence political agendas, and websites such as EnviroMedia's Greenwashing Index (www.greenwashingindex.com), which allows consumers to score the credibility of sustainability-related advertising.

NMI's research findings suggest that sustainability clearly remains on consumers' radar screen despite the economic downturn, while at the same time, their expectations about green products and information has changed. They are expecting all of the traditional and green benefits in a product/service at the right price, with no sacrifice in convenience. They also want companies to cut through the confusion and clearly spell out the environmental benefits. Confusion over divergent marketplace signals and the tensions among the myriad of "seemingly" green choices represent key areas for consumer research. This presentation offers cutting edge empirical findings that the green "rules of the game" have changed markedly in just the past few years with respect to consumer expectations—results which offer new perspectives on developing relevant, transformative consumer research efforts.

¹Natural Marketing Institute (NMI) is a strategic consulting, market research, and business development company specializing in the health, wellness, and sustainable marketplace. NMI is the parent firm for LOHAS, with validated data from 35,000 consumers across 10 countries. “Dispersed Practices and Cultural Models: Implications for More Sustainable Electricity Consumption”

Eric J. Arnould, University of Wyoming, USA

Melea Press, University of Wyoming, USA

Our research aims to cast light on strategies of intervention to induce more sustainable household electrical energy consumption. Electrical energy consumption is crucial to the discussion of sustainability because it is foundational to so many other consumption practices that negatively impact the biosphere. We pay special attention to consumer tendencies for evasion and participation in the market system.

Based upon the limited research so far conducted on energy consumption and sustainable consumption generally, our argument is that classic approaches to mass behavioral change, such as pricing and public information linked to social marketing, are not likely to be effective in inducing more sustainable consumption. The reason is that electrical energy consumption is embedded in taken-for-granted dispersed behavioral practices. Practices are normative behavioral predispositions, something like the notion of habitus in Bourdieuan theory. They are comprised of discursive how-to knowledge, tacit know-how, and affective commitments and typically interact with rhetorical practices of representation. In contrast, specialized or “integrative” practices, for example, those associated with brand community participation are constitutive of particular domains or fields of social life and entail specialized behavioral expertise and jargon (Schau, Muniz and Arnould, forthcoming). In sum, practices are performative predispositions in which consumption behaviors are embedded (Schatzki, Cetina and von Savigny 2001; Warde 2005).

Dispersed practices, unlike integrative practices, are inherently more resistant to change because of their deeply tacit, rather than discursive nature. The appropriate performance of gender or composing a “proper” meal are other examples of deeply rooted, distributed practices. However, when distributed practices are challenged by market signals, powerful cultural models may be enlisted to defend them. For example, in North America, distinctive beliefs about Americans rights in nature, as well as the ideology of American exceptionalism may drive both resource intensive and luxurious “green” lifestyles that are cloaked in an ideology of frugality (Ludicke, Thompson and Giesler, n.d.). Furthermore, consumers’ experience of macro-social phenomena associated with the global risk society also provides a constraint to behavioral change. Finally, misunderstandings about electric energy and a lack of household level tools for managing energy interact to inhibit the emergence of more sustainable practices. Thus, approaches to behavioral change based on a grasp of macro level social forces, including general sociological drivers of consumer behavior such as postmodern authority, consumer reactivity, social strain, and Commons tragedies, midrange cultural models like American exceptionalism, and dispersed practices associated with conforming, innovative, ritualized, and retreatist, and rebellious responses to innovation in electricity markets, are more likely to provide actionable insight.

Our findings about energy consumption are based on ongoing research conducted in energy markets in the Rocky Mountain west in collaboration with electric energy providers. Data collection and analysis will proceed during the spring and summer. Our research aims to account for 1) the range in response to price and technology innovations that cannot be explained by demographic characteristics alone; 2) to identify the cultural and social drivers of resistance to, and innovation in, demand for innovative energy solutions; and 3) to identify the informational and other tools firms may need to move market segments to more active pro-innovative practices. Our results have implications for so-called green marketing and

sustainable consumption generally (Bartiaux 2008; Beck 2006; Maruyama, Nishikido and Iida 2007; Nash 1982; Owens and Drifill 2008; Shove 2003; Warde 2005; Wilhite 2005; Wüstenhagen and Bilharz 2006).

SPECIAL SESSION SUMMARY
Money and People Make Strange Bedfellows
Deborah Small, University of Pennsylvania, USA

SESSION OVERVIEW

Money often has peculiar effects on social relationships. Technically-speaking, money serves as a medium of exchange and a measure of wealth. Yet the ways that consumers feel about and behave with respect to money has implications that extend beyond money's economic purposes. Depending on the situation, money can either draw people closer together or isolate them, it can make them behave selfishly or altruistically, and it can engender relationship satisfaction or relationship conflict. The objective of this session is to discuss emerging research linking thoughts and feelings about money to social behavior. It also seeks to explore how such patterns ultimately influence relationship satisfaction and happiness more generally.

The four papers included in this session represent different perspectives on the role of money in interpersonal behavior. All papers are in late stages of completion (working paper, under review, and in press). The first two papers focus on relationships with strangers and friends, and the latter two papers focus on romantic relationships and marriage. Vohs will begin by examining the reciprocal link between thoughts of money and social exclusion. Then Norton will present research examining when spending money on others is most likely to promote happiness for both those on the spending and receiving end. Mead will move the focus to communal relationships in presenting research showing that money reduces felt moral obligations and trust in interdependent contexts. Finally, Rick will present research examining how emotional reactions toward spending money influence romantic attraction and marital satisfaction. We expect these papers will provoke productive discussions about the multifaceted impact of money in relationships. This session will appeal to a wide range of consumer behavior scholars and especially among those focused on money and other valued resources, interpersonal interactions, romantic relationships, emotions, and well-being.

ABSTRACTS

“Social Rejection and Desire for Money”

Kathleen Vohs, University of Minnesota
Xinyue Zhou, Sun Yat-Sen University
Roy Baumeister, Florida State University

Prior work showed that reminders of money led people to put more physical distance between themselves and another as well as choose activities to be enjoyed alone rather than with friends and family. These findings suggest that money reminders decrease social needs. Does this extend to being rejected by others too? Three studies tested the relationship between money reminders and social exclusion. Interpersonal rejection caused an increase in the desire for money. Counting slips of currency (compared to paper) reduced feelings of distress after social exclusion. Being reminded of having spent money, however, intensified the pain of social exclusion.

“Putting the “Social” in Prosocial Spending: Interpersonal Giving Promotes Happiness”

Michael I. Norton, Harvard Business School
Lara Aknin, University of British Columbia
Elizabeth Dunn, University of British Columbia

Recent research has demonstrated the positive impact on well-being of spending money on others. We explore the impact of

increasing the “social” in prosocial spending, hypothesizing that the benefits of such spending are amplified when giving takes place in an interpersonal context. In a field study in which we gave participants Starbucks gift cards, the benefits of having coffee with a friend were particularly pronounced when participants treated their friend to that coffee. In a dictator game, the amount of money given to receivers was associated with happiness for both givers and receivers only when offers were made face-to-face.

“Reminders of Money Weaken Sociomoral Responses”

Nicole Mead, Tilburg University
Kathleen Vohs, University of Minnesota
Krishna Savini, Stanford University
Tyler Stillman, Florida State University
Roy Baumeister, Florida State University

Money reminders evoke a self-sufficient state that implies that each person take care of him/herself (Vohs, Mead, and Goode 2006). The present work tested whether money reminders produce self-sufficient behavior even within communal domains, which endorse of a code of caring for and respecting others (i.e., opposite of self-sufficiency). Even within communal contexts, money reminders reduced sociomoral responses. In India, money reminders diminished perceived moral obligations (experiment 1). In romantic relationships, money reminders reduced willingness to help (experiment 2). Experiment 3 showed that money reminders heightened perceptions that other people act in their own self-interest, which in turn reduced trust.

“Fatal (Fiscal) Attraction: Tightwads and Spendthrifts in Marriage”

Scott I. Rick, University of Michigan
Deborah A. Small, University of Pennsylvania
Eli J.Finkel, Northwestern University

Although most attraction research suggests that “birds of a feather flock together,” surveys of married adults reveal that opposites attract when it comes to emotional reactions toward spending money. That is, “tightwads,” who find the prospect of spending money painful and thus tend to spend less than they would like, tend to marry “spendthrifts,” who find spending painless and thus spend more than they would like, consistent with the notion that people are attracted to mates who possess characteristics dissimilar to those they deplore in themselves (Klohn and Mendelsohn 1998). Unfortunately, spendthrift/tightwad differences stimulate conflict over money, diminishing marital satisfaction.

SPECIAL SESSION SUMMARY

The Pitfalls of Fame: Insights from Human Brands

Marie-Agnès Parmentier, HEC Montréal, Canada

SESSION OVERVIEW

Consumers relate to brands of many types, but none more than human brands, “one of several operationalizations of the broader concept of a brand” (Thomson 2006: 104). Human brands (sometimes equated with celebrities) are a vital part of both contemporary culture and the contemporary market economy. Given the centrality of human brands to consumers’ lives, it is surprising that research that touches directly on the topic is extremely limited within our literature. The purpose of this symposium was to offer a forum for scholars interested in how consumers relate to and co-create human brands. Our aim was to provide insights on how human brands come to have the meanings they do, the implications of having powerful human brands, and the role consumers play in human brand development. In the first presentation, Hope Jensen Schau (University of Arizona) and Cristel Antonia Russell (University of Auckland) examined how the human brands developed by actors in television series matter to the relationships consumers form with these actors and the characters they portray. Next, Marie-Agnès Parmentier (HEC Montréal) and Eileen Fischer (York University), using case studies of David Beckham and Ryan Giggs, provided insights into the factors at play in the emergence and evolution of human brands with which consumers form relationships, and the practices that help maintain and restore human brand equity in the eyes of both fans and industry insiders when equity erodes. In the third presentation, Susan Fournier (Boston University) discussed the approach that has driven Martha Stewart’s brand building effort while revealing the flaws of this approach, highlighting how it falls short because of its failure to take into account the full range of processes that feed the creation of human brands. Finally, Matt Thomson (University of Western Ontario), discussed the papers and offered some concluding remarks on the issues raised as well as avenues for future research.

EXTENDED ABSTRACTS

“The Ties that Bind: Consumer Engagement and Transference with a Human Brand”

Cristel Antonia Russell, University of Auckland, New Zealand
Hope Jensen Schau, University of Arizona, USA

Beginning with Fournier (1998), research on consumer-brand relationships has assumed a level of anthropomorphism and is guided by the extant literature on interpersonal human relationships, asserting that brands can be active relationship partners. Research shows that consumers develop relationships with celebrities (Thomson 2006), TV characters (Russell, Norman and Heckler 2004), and service providers (Price and Arnould 1999) because the human brand is capable of a wider range of attribute evolution than an inanimate consumption object and has an enhanced reciprocity potential. Human brands provide a vivid context to examine consumer-brand relationships because they mature and adapt to changing circumstances; or put simply they more closely mimic relationships between and among people.

This research investigates another parallel with human relationships: transference, the tendency to carry over attachment patterns from one relationship to the next. We focus on consumers’ experience of the cessation of a brand’s production, to identify whether and to what degree transference occurs with subsequent offerings of the human brand. The literature on human loss, and the

processes of grief, mourning, and recovery, provides a conceptual basis for investigating the emotions and behaviors associated with the departure of a favored brand and the process of transference whereby new relationships are impacted by previous relationships.

According to adult attachment theory, previous relationship patterns can reemerge when people form new relationships (Andersen and Cole 1990). Past experiences and interpersonal patterns learned are superimposed onto the new relationship, including memories and affective responses. Transference is most likely triggered when previous relationships are salient (Andersen et al. 1995). In psychiatry, Freud (1917) proposed that the period following a loss is used for decathexis, the incremental divestment of libido from memories of the lost object, and that it eventually leads to recathexis, the redirection of libido from the memory of the lost person to available survivors which removes the cause of the pain and renews opportunities for pleasure. Research shows that the process of transference applies to a greater degree when there is more resemblance between the old and the new relationship objects (Brumbaugh and Fraley 2006). This process has clear implications in the domain of human brands, but, as in the brand extension area (Aaker and Keller 1990; Boush and Loken 1991), the process of transference might apply best when consumers perceive coherence between original and the extension.

The extant transference literature suggests that a brand’s withdrawal might prompt the development of new consumer-brand relationships where the previous relationship pattern resurfaces. We test this proposition in the context of relationships formed with a human brand within television programs. TV programs are consumed in the intimate, domestic space, where the strongest interpersonal relationships take place, and they promote the formation and development of deep and intense attachments with characters (Russell and Puto 1999). We analyze the process consumers go through when TV programs with which they presume an active relationship are discontinued, and assess the processes of transference to subsequent programs featuring the same actor and role.

Observational and survey data were collected before, during and following the final season of one of television’s most popular and long-lived programs (Friends: 10 years, 238 episodes) and at the onset of a spin-off program (Joey: 2 years, 47 episodes) that features the same actor in the same role (Matt LeBlanc as Joey Tribbiani). These data provide insights into how consumers cope with the loss of their relationship partner and whether transference occurs with the new program. Joey launched its first season with a respectable audience of 11million; however, it ended with audiences only slightly above 4 million. While Friends features an ensemble cast, this is a fragment of the Friends finale audience (52.5 million) and Joey’s following decreased over time.

We examine observational data collected on three online forums centered on Matt LeBlanc and Joey (271,318 posts). Fans “forced to live without Friends” expressed loss at its end and excitement about Joey returning. Using the language of transference, fans explicitly claim to be “shifting their alliance” to Joey and “moving over with Joey” indicating that the main impetus for watching the show is to transfer their bonds to the new program and experience the continuation. Fan complaints about the show revolve around changes in continuity (Joey’s family, absence of other “friends”) creating impediments such that they state their transference is “less than seamless,” “jarring,” and “unfulfilling;” further-

more, Joey is perceived, even by his most ardent fans, as “a shadow of himself.” Interestingly, prior to the cessation of *Friends*, these fans expressed extreme allegiance to Joey and Matt LeBlanc posting homage websites dedicated to following LeBlanc’s professional and personal life. These fan tributes are often referenced in fans’ signature files that follow every post on a forum.

Survey data (N=262) were collected five months after the withdrawal of *Friends* from a sample of viewers, ranging from occasional to avid, and including 30% who had watched *Friends* from the beginning. Along with participants’ histories of viewing the original and spin-off series, the survey collected measures of attitude and connectedness to both series, attachment to the Joey character, as well as measures of the counteracting processes of transference and counter-transference. The results indicate that viewers maintain continuing bonds by watching re-runs and that the intensity of their bond (in this context, connectedness) is a key predictor of these continuing bonds. Connectedness is also a key predictor of the process of transference and it affects transference to viewing the spin-off series through the experience of grief. Consumers experiencing strong bonds with the original series are not only more likely to seek out the characters in their spin-off afterlife but also to develop strong bonds with the characters in the afterlife, in line with the transference process in adult attachment theory (Andersen and Cole 1990; Brumbaugh and Fraley 2006). In a manner typical of that observed in bereavement research, the newly formed bonds provide liberation from the loss and grief caused by the withdrawal of the original series.

We find that when a given program is discontinued, consumers do experience transference when they have strong bonds with human brands and when these human brands migrate from one program to another. However countertransference is also present where pre-existing strong bonds can inhibit the transference of previous bonds because the expectations for the relationship are so high they cannot be met and because the similarities with the previous experience provide a hurtful reminder of the previous relationship.

“Branded Like Beckham? An Examination of Dynamic Processes in Human Branding”

Marie- Agnès Parmentier, *HEC Montréal, Canada*
Eileen Fischer, *York University, Canada*

Given recent work on consumers’ attachments to celebrity brands (Thomson 2006), we are beginning to understand that human brands are important to end consumers, to people building their brands, to the industries in which the brands emerge, and to economies as a whole. However, we have yet to develop systematic insights into how such brands emerge and evolve as people’s careers progress, as they engage with distinctive target audiences, and as unforeseen or uncontrollable events occur that can challenge a person’s brand equity.

In order to address this gap, our paper develops case studies of soccer stars David Beckham and Ryan Giggs as human brands. Drawing on definitions that emphasize consumers’ understandings as the basis of brands (e.g., Keller 1993) we define a human brand for a person engaged in a field of practice as the sets of associations that audiences within and beyond the field identify with the individual. Drawing on our two cases, we develop theory that helps answer the following questions: What factors, including consumer fans’ evolving relationships, contribute to the emergence of a powerful human brand? What challenges can undermine equity for such a human brand among consumers? And how can equity be maintained or restored?

The data used to develop our case study is archival. For each player, we collected: published biographies or autobiographies

(e.g., Beckham and Freeman 2001; Beckham 2005; Milligan 2004); postings from websites (www.davidbeckham.com; www.ryangiggs.cc); and websites maintained by and for fans (e.g., davidbeckham.fans-online.com; www.start.at/giggisy). Further, we collected all articles that mentioned either Giggs or Beckham in: *Sports Illustrated*; *World Soccer*; *ESPN the Magazine*; *Vogue UK*; and *People*. We also examined each player’s Facebook, MySpace, and Twitter postings as well as media coverage describing fan reactions to both Giggs and Beckham (e.g. <http://www.helium.com/debates/73611-does-ryan-giggs-have-david-beckham-to-thank-for-his-career>). Our analytic focus has been on identifying factors that lead to equity, on categorizing challenges to equity, and on discerning practices that have helped to maintain or to re-establish equity with audiences.

In answering the first question regarding factors that contribute to the emergence of a powerful brand, the paper identifies two distinct elements of human brand equity: professional equity and celebrity equity. Our analysis suggests that while Giggs and Beckham both have the former, Giggs lacks the latter. Professional equity is earned among audiences within the field practice (e.g., professional soccer). It is earned in part through demonstrating the ability to perform well specialized activities valued within the field, but also by forming upward reaching social networks with more powerful actors in the field and by taking opportunities to achieve visibility within the field (e.g., by choosing to play for the most storied Manchester United club). Celebrity equity is earned outside the field of origin among consumers (who in this case may well not be soccer fans). And while professional equity can serve as a basis for forming celebrity equity, celebrity requires the individual to cultivate an authentic persona (cf. Thomson 2006) that is of interest to consumers relatively unfamiliar with the field (as Beckham has done through his combination of dedication to a ‘manly’ sport coupled with a high fashion sensibility), to develop field-spanning networks (as Beckham has done by hiring Simon Fuller, a celebrity impresario rather than a soccer agent), and to take opportunities to achieve visibility beyond the field of origin (for example by cultivating affiliations with celebrities in other fields, e.g., Tom Cruise).

In answering our second question we identified challenges to professional equity as distinct from threats to celebrity equity. Factors that promote one type of equity can challenge the other. For example, threats to professional equity can arise from publicly visible performances that are interpreted (often with critical assistance by fans and the media) as failures to demonstrate those abilities most valued in the profession (as when Beckham was sent off against Argentina in the 1998 FIFA world cup). These challenges can be compounded when it is perceived that opportunity-seeking beyond the field of practice (such as the pursuit of endorsements) is impeding performance within the profession. Celebrity equity, in contrast, is threatened when visibility beyond the field declines as may happen when individuals re-invest in their profession and withdraw from activities that attract media attention (as Giggs has done).

In addressing our third question, we identify “balancing” practices that simultaneously demonstrate the individual’s ability to perform well within the standards of the profession while providing opportunities to reinforce a persona that engages fans attention and attracts media attention. Beckham’s move in 2007 to the LA Galaxy team in the America, and his recent efforts to be “transferred” to AC Milan can be interpreted as (unevenly effective) efforts to rebalance his brand equity. In the conclusions of our paper, we discuss the implications of our insights for understanding both consumers’ relationships to human brands, and the roles that consumers may play in shaping the evolution of human brands.

“Taking Stock in Martha Stewart: A Cultural Critique of the Marketing Practice of Building Person-Brands”

Susan Fournier, Boston University, USA

This inquiry concerns the phenomenon of the celebrity person-brand: a productized, branded entity that derives its equity from association with a celebrity that serves as creator, muse, and steward of the brand. Celebrity person-brands are at once celebrities (persons) and products (brands). They are a sub-class of celebrity brands as both are marked by recognizability, visibility, and attractiveness within the society (Gamson 1994; Turner 2004), but not all celebrity brands have been productized (e.g., Sheryl Crow, Barack Obama). In our hyper consumer culture, motivations to commercialize celebrity to capture branded product value are great (Lieb 2007).

Although recent research explores consumers’ relationships with celebrity brands (Thomson 2006), insight into supply-side mechanisms through which equity is developed in person brands is lacking (for exception, see Lieb 2007). As paradigms for marketing and entertainment increasingly collide (Donaton 2004), the need for insights into celebrity brand-building grows. This research imparts a deeper appreciation of the complex workings of the process of celebrity brand creation, and the principles that guide equity development of such brands over time.

Our research focuses on one person-brand exemplar: Martha Stewart, as owned and managed under the entity Martha Stewart Living Omnimedia (MSO). Our case selection follows the logic of inquiries that inform their phenomena by focusing on that phenomenon in its extreme. While other celebrity person-brands exist—e.g., Wolfgang Puck and Emeril Lagassi—these brands are narrower in their productization, and weaker in markers of celebrity overall. It is also significant for theory development purposes that Martha Stewart experienced a lengthy, highly-visible crisis. In 2001, after thirty years in the making, the Martha Stewart brand stood as one of the world’s strongest (Khermouch 2001). This situation changed entirely in 2002 when word broke of an investigation that eventually landed Stewart in jail. Though business improved with Stewart’s return to MSLO as Chief Creative Officer in Fall 2006, signs of recovery are mixed. Lost equity has yet to be recovered, and analysts remain split in their forecasts. MSO’s crisis serves as a critical inflection point in the trajectory of our phenomenon; the system in stress provides diagnostic learning opportunities by exposing the processes in play (Reis and Kneee 1996).

This research advances the cultural branding paradigm (Holt 2004, Schroeder and Salzer-Morling 2005) by providing insight into the fallible habits of mind that brought the Martha Stewart brand to the brink of extinction. By popular accounts, MSO operated as best-in-class marketers and yet this acknowledged excellence did not prevent them from jeopardizing their brand. We argue that MSO’s predicament signals fundamental shortcomings in the classic marketing principles managers apply to build, leverage, and sustain their brands.

Data for our investigation include: four MSO business case studies spanning from IPO to post-jail recovery (Fournier et al. 2001; Fournier 2001; Fournier 2006; Glynn and Mihoubi 2000); biographies of Stewart and histories of MSO (Byron 2002); company SEC filings, releases, and annual reports; MSO marketing campaigns; media coverage of MSO. Using grounded theory, we first induct a five-stage person-brand development model from the historical archives of activities at MSO. The model reflects classic brand leverage logic (Farquhar et al. 1992), whereby resources are first devoted to establishing strength in the master brand (Martha Stewart the Person) such that it can sponsor powerful extensions downstream. The model adopts a financial markets’ perspective, striving

toward a self-sustaining, risk-tolerant multi-brand portfolio that transitions from the parent brand. Intermediate stages in the model differ with respect to the reflexive relationships existing between the person and brand components, and the relative marketing emphasis placed on person versus brand. Second, we critique MSO’s strategy from the perspective of cultural branding theory, highlighting three blind spots that compromised development of the person-brand: (a) Failure to consider multivocality of the person and brand; (b) Denial of the reciprocating, non-linear system of person-brand meaning making; and (c) Illusions of control over the collaborative cultural process of person-brand meaning making. Lastly we offer a revised framework for person-brand building that contrasts with psychologically-oriented association models that treat person-branding as a leveraging process (Keller 2003). In our model the process is one of collaborative meaning making that enables co-creation of the brand.

SPECIAL SESSION SUMMARY

On Being the Same and Different: The Dynamics of Interpretation and Comparison in Consumer Judgment

Femke van Horen, Tilburg University, The Netherlands

SESSION OVERVIEW

Symposium Objective. To comprehend an ambiguous product, person or brand (is the product of high quality?, will she be a good salesperson?) accessible information is used to guide evaluation which may lead to assimilation or contrast. In the past, research on accessible knowledge effects, both in social psychology and consumer behavior, has focused on the various factors that determine the direction of these effects, resulting in a host of moderators predicting either assimilation or contrast. Recently however, social cognition research has demonstrated how different types of processing may produce assimilation and contrast effects (Förster, Liberman and Kuschel 2008; Stapel 2007) and has shown that the same accessible information may lead to assimilation or contrast depending on the processing style, i.e. whether this information is used as an interpretation frame or as a comparison standard. The purpose of this symposium is to present research that builds on these recent developments in social cognition research, which are bound to have implications for our understanding of consumer behavior.

Overview. Traditionally, research on assimilation and contrast effects in social psychology and marketing has focused on the identification of moderating factors determining the direction of the effect (assimilation or contrast). Such factors include the distinctness of information (Stapel and Koomen 2000), extremity of information (Herr 1989; Smeesters and Mandel 2006) and categorical overlap (Mussweiler and Bodenhausen 2002). Instead of taking this indirect route to investigate context effects, a more direct approach has recently been taken through identification of the specific processes that determine the effects. Fresh dual process models in social cognition research, like the Interpretation Comparison Model (ICM, Stapel 2007) or the global/local processing style model (GLOMO, Förster, Liberman and Kuschel 2008), postulate a process distinction between assimilation and contrast. The ICM for instance posits that when people use information as an interpretation frame, assimilation is a likely outcome. However, when people use information as a comparison standard, then contrast is more likely to occur. GLOMO extends the inclusion/exclusion model (Bless and Schwarz 1992) and demonstrates that activating a global processing style results in assimilation, whereas activating a local processing style results in contrast. This symposium is positioned at the forefront of these new developments by showing how consumers use information (as a comparison standard or interpretative frame) in product judgment. The symposium builds on and extends the recent developments with a focus on important issues for consumer behavior, i.e. when and how feature characteristics of products and the consumer's self-concept activate specific processing mindsets, which in turn guide product evaluation and judgment.

Papers. The three papers in this set demonstrate how the type of processing may influence the direction of context effects. The first presentation focuses on the importance of interpretation processes. Specifically, Reed, Forehand and Perkins reveal that consumers who are high self-monitors, instead of low self-monitors, tend to use an interpretative frame when accessible contextual information is social but not when it is individual in nature. The second presentation of Van Horen, Pieters and Stapel addresses the evaluation of look-alike products. They show how a specific type of product imitation activates comparative mindsets in consumers,

and that as a consequence the imitation of highly similar, distinct features (e.g. the color purple of the Milka chocolate brand) is liked less than the imitation of subtly similar, diffuse themes (e.g. the Alps with grazing cows of the Milka chocolate brand). The third presentation of Meyers-Levy, Zhu and Liang integrates both of the processing modes and examines the effect of distance on bodily sensations affecting product evaluation. They find that bodily sensations, elicited through floor tiling (comfort of carpet versus discomfort of tiles) are used as a comparative standard when distance is close, resulting in a contrast effect, but as an interpretative frame when distance is moderate, resulting in assimilation. In all, this symposium presents the findings of various novel research streams that both connects to the extant literature, and highlights fruitful avenues for further research on the impact of context effects on consumer behavior.

Contribution. Recent developments in social cognition theories on accessibility effects on judgment focus on the processing styles, foci or mindsets behind these effects, instead of exploring the specific factors that determine the effect. In this symposium we build on this new development and address how different types of processes (interpretation versus comparison) influence product evaluation (assimilation or contrast). Each of the three papers in this symposium presents novel and interesting results on this issue. Taken together, they constitute a new perspective on how context or priming effects determine the direction of product judgments, which can stimulate a host of research ideas. All three papers include multiple completed studies, are new and have not been submitted. None of the papers has ever been presented at ACR.

Discussion Host. The symposium's discussion host, Diederik A. Stapel (TIBER, Tilburg University, The Netherlands), is a thought leader in judgment theories in social cognition. He will introduce the symposium by shortly presenting the new developments in dual processing models on comparison and interpretation (5 minutes), and will introduce each of the speakers.

Likely Audience. We believe that this symposium will draw a large audience of researchers and PhD students interested in fundamental social cognition theories that provide new insights into consumer behavior. The presenters are at the forefront of research on the impact of interpretative or comparative effects on product judgment. We expect lively discussions that inspire new research ideas on the impact of dual processes in product evaluation.

EXTENDED ABSTRACTS

"The Color of the Chameleon Depends on the Prime Type"

Americus Reed II, University of Pennsylvania, USA

Mark Forehand, University of Washington, USA

Andrew Perkins, Rice University, USA

One of the most robust findings in psychology and consumer behavior is that priming constructs can have an impact on attitudes, judgments and behavior. For some time, a prime was just a prime. Research was silent on the extent to which these primes were actually relevant to a participant's self-concept or not. For example, in Bargh, Chen and Burrows's (1996) classic study, it would be hard to argue that their college student participants "had" an "elderly identity" in walking slower in response to exposure to their subtle cognitive primes (e.g., bingo, wrinkle).

Recent research however, has begun to more actively account for prime to behavior effects by more explicitly considering the self. DeMarree, Wheeler and Petty's "Active Self Account" (2005) argues that primes are more likely to affect behavior when the prime temporarily alters self-perceptions. Their evidence for this relies on the moderating role of "self monitoring" (Snyder 1974) where they find that low-self monitors—consumers who tend to rely on their internal stable beliefs, are more likely to assimilate to primed constructs. They argue that this is due not to a need to "fit in" but rather in the service of "being oneself" (DeMarree et. al 2005, page 659)—a kind of "informational influence" that drives the assimilation effect.

It seems at first glance odd that low self monitors would exhibit greater shifting of behavior as compared to high self-monitors in reaction to a cognitive prime. It is however not the case that low self monitors self-concepts exhibits no stability, rather, the stability lies in whatever internal self-representation is on top of mind. Hence, cognitive primes may be more likely to affect low self-monitors because they are more likely to react to information referring to the internal nature of the self. If primes subtly activate constructs that are perceived to be "diagnostic self-information", then one would expect these cognitive primes to have a greater effect on low-self monitors rather than high self-monitors (Wheeler and Petty 2001). However, some primes are more "social" in nature. In other words, they emanate from situational cues that have direct relevance to linking the self-concept to its connectedness to others in the immediate social environment (Forehand and Deshpande 1999). These kinds of social primes should be much less likely to be "misconstrued" as internal cues to the self. Hence, we argue that these primes will have a different effect than the work done by Wheeler and colleagues—and our research expands the view of the Active Self account—by demonstrating this empirically.

In three experiments we test whether the role of self monitoring in response to contextual triggers depends on the nature of the trigger. Although traditional stimulus primes are more influential on low self-monitors, situational or social triggers appear to me more influential on high self monitors. We demonstrate this by assessing response to social distinctiveness within low and high

self-monitoring populations. In the first experiment, we used a subtle but "social" prime—the relative distinctiveness of the participants' ethnicity and gender on self-reported identification with the primed concept. Students who are members of an ethnic minority were more likely to mention ethnicity in a self-description than those who were members of an ethnic majority (19% vs. 6%)—replicating previous work (Forehand and Deshpande 2001; Deshpande and Stayman, 1994). However, as predicted, High Self-Monitors were more sensitive to the gender composition of the room in which they completed the survey. Based on a median split on the Self-Monitoring variable: when in "gender majority," 12% of high self-monitors reported their gender in self-descriptions, whereas when in "gender minority" 30% of high self-monitors reported their gender in self-descriptions. Low self-monitors demonstrated the opposite reaction to gender-minority status (22% mentioned when in majority, 13% when in minority). In the second experiment, we manipulated minority/majority standing on racial and gender dimensions and assessed activation of these components in the self-concept using an implicit measure of self-concept activation. The results showed that those exposed to the social prime of highlighting their minority status on gender were more likely to shift their working self-concepts—especially if they were high self-monitors. In the third experiment, we extend the basic moderation effect into work-group situations and assessed whether cooperative/competitive mindsets influence both self-concept activation and whether that activation mediates other outcome measures.

The totality of our research elaborates on previous work. Our analysis shows that it is important to understand the nature of the prime under consideration. Primes that are cognitive like the ones used in prior work may trigger an assimilation effect along the lines explained by the Active Self account. However, social primes have a completely opposite effect. This finding is important because marketers will attempt to prime self-identities in different ways, and the precise effects of primes under strategic consideration must be considered to understand the likely success of using such tactics. Moreover, our findings attest to the power of identity and its flexibility in driving self-expression in response to self-concept activation that may ultimately drive consumption.

“On Subtle Themes and Blatant Features: The Effect of Imitation-Type on Evaluation and Choice of Copycats”

Femke van Horen, Tilburg University, The Netherlands

Rik Pieters, Tilburg University, The Netherlands

Diederik A. Stapel, Tilburg University, The Netherlands

Suppose you are in Safeway for your grocery shopping. In the potato chips section you encounter Safeway’s private label chips, packaged in a bright red, rectangular tube with plastic, see-through cap; features that are also used by the Pringles brand. You walk further, into the aisle with spreads, and see that the package of Safeway’s spreadable butter with olive oil displays a Tuscan farm on a hill with olive- and pine trees; a theme that is used by the Bertolli brand as well. Which of the two types of imitation (imitation of the more blatant features versus imitation of the more subtle theme) would you evaluate more positively? Previous literature would predict that imitation of more blatant, distinct features would be evaluated more positively, as similarity with the leader brand is higher when blatant features, as compared to when subtle themes, are copied (Kapferer 1996). We argue, instead, that blatant imitation of distinct features may backfire and reduce the evaluation of copycats, whereas copying subtle themes can increase the evaluation of the copycat. To date little is known about how type of imitation (what is copied as compared to how much is copied) affects copycat evaluation. Further, because the focus has traditionally been on highly similar copycats, the effects of more subtle degrees of copycatting are still largely unknown.

Copycats imitate aspects of the trade-dress of leading brands to free-ride on the positive associations attached to these brands (Zaichkowsky 2006). When copycats imitate leading brands, they often choose to imitate the distinct, prototypical features (the specific colors, lettering and shapes), instead of the more subtle themes (referents to the country of origin, benefits and values). Copying the distinct features that are uniquely associated with the leading brand, will increase similarity more than imitating subtle themes, which would result in a more positive evaluation (Loken, Ross, and Hinkle 1996; Warlop and Alba 2004).

We posit however that attaining high similarity through copying the prototypical features results in contrast, as a distinct representation of the leader brand will become accessible (Stapel and Koomen 2000) which, in turn, will make consumers more aware of the practices employed by the copycat (Campbell and Kirmani 2000). Copying more subtle themes on the other hand will result in assimilation as more generic, diffuse associations will be activated, which are more likely transferred to the representation of the copycat. Support for these ideas would show that the type of imitation importantly determines copycat evaluation. Further, it would reveal that copying subtle themes is sometimes more beneficial than copying blatant features. This would point out that more subtle copycatting practices are in need of greater attention from brand management and trademark legislation, and worthy of more consumer behavior research.

Four studies were conducted to test the hypothesis if type of imitation (theme versus feature-based) affects the evaluation and choice rate of copycats. Study 1a and 1b tested the prediction that theme-based copycats are evaluated more positively than both feature-based copycats and products that show no similarity with the leader brand. Participants were asked to evaluate either a feature-based copycat in which the specific features of the Milka brand was copied (e.g. the lilac color, a Milka-like cow), or the theme-based copycat in which the theme communicated by the Milka brand was imitated (cows grazing in the Alp-mountains), or a visually differentiated product. In Study 1b a different product category was used (“Margarine with olive oil”), in order to prove

the robustness of the effects. The results of Study 1a and 1b showed, as predicted that theme-based copycats were evaluated more positively than feature-based copycats and visually differentiated products. Study 2 tested whether the feature-based copycat increased awareness of insincere tactics of marketers more than the theme-based copycat. In support of the predictions, participants rated the feature-based copycat as less trustworthy, less sincere and less fair than the theme-based copycat. In Study 3 we posited and showed that the negative evaluation of the feature-based copycat as compared to the theme-based copycat is mediated by persuasion knowledge. It further showed that the effects on evaluation transferred to willingness to buy and choice. These results show the positive effects of subtle imitations of themes as compared to blatant imitation of features. The present findings show that copycat evaluation is not just determined by how much is copied, but also by what is copied, which may contribute to a better understanding of the effectiveness of copycatting.

“When Bodily Sensations Elicit Context Effects: The Moderating Role of Physical Distance”

Joan Meyers-Levy, University of Minnesota, USA

Rui (Juliet) Zhu, University of British Columbia, Canada

Extending on existing research which indicates that people’s incidental affective feelings are often assimilated with their assessments of unrelated items, we demonstrate that more localized bodily sensations, which emerge when people’s sensory receptors come in contact with external sensory stimuli (e.g., textures), can produce either assimilation, contrast, or no effects on assessments of target products. Specifically, we show that the physical distance from which a person views a product when standing on an (un)comfortable hard tile or softly carpeted store floor can moderate the direction of the resulting context effects on people’s product assessments.

Our theorizing anticipating such outcomes draws on the context effect literature. Such work indicates that the direction of context effects critically depends on how people use contextually activated data (e.g., a concept, sensation) during two stages: when encoding or interpreting the target product, and when rendering a formal judgment of it by comparing it with a standard. Further, some research shows that the clarity of the mental representation

people form of a target product can influence how contextually activated data will be used at each stage, thereby determining whether assimilation or contrast effects obtain. Specifically, when one's mental representation of a product is poorly (clearly) defined, assimilation (contrast) effects should occur.

We reasoned that in most instances, the clarity of the mental representation that one forms of a product should increase as the distance between the person and the product decreases. Thus, if the texture of the flooring on which a consumer stands during product examination (i.e., the hardness of the tile or softness of the carpeting) prompts the consumer to experience bodily sensations of discomfort or comfort, the influence of these sensations on viewers' product assessments should vary as a function of the distance that separates the consumer from the product. Specifically, because a product displayed at a moderate distance is apt to prompt a somewhat ill-defined product representation, viewers should assimilate their bodily sensations with target product assessments. However, because a product displayed at a close distance should yield a clear product representation, these viewers' bodily sensations may be used as a comparison standard and prompt a contrast effect on their assessments. Finally, a product that is displayed at an extremely far distance may render its product features so blatantly ambiguous that viewers may recognize that their bodily sensation of (dis)comfort could not have emerged from the barely visible product. Thus, in this instance, we reasoned that individuals may discount their sensations, resulting in no context effects.

In Study 1 each participant stood in a specific location on either carpeted or hard tile flooring and viewed a target vase placed on the floor at a close (6 inches), moderate (5 feet), or extremely far (10 feet) distance from them. Then, participants assessed how comforting the target vase's appearance was. The results supported our predictions. When individuals viewed the product from a moderate distance, they assimilated their bodily sensations with their product assessments, but when the product was viewed from a close distance a contrast effect emerged. When individuals viewed the target product from an extreme distance no context effects emerged. Study 2 theoretically replicated these findings by using a different dependent variable, namely the firmness of the product, and demonstrated that when people are made aware of the source of their bodily sensation, these effects go away.

While these findings are encouraging, questions could arise about whether the outcomes were truly attributable to people's bodily sensations per se. It is possible that they actually reflect people's use of semantic concepts that were primed by the contextual flooring. In turn, these primed semantic concepts—not people's bodily sensations of (dis)comfort—could have served as contextual cues that shaped people's product assessments. Study 3 sought to distinguish whether our findings reflect such cognitive priming, or, as we propose, the influence of bodily sensations. It also explored whether bodily sensations elicit context effects that are confined to assessments that relate to the relevant sense, versus, overall affective assessments of the target product. To test whether our results were driven by people's internally experienced bodily sensations versus widely shared semantic concepts associated with the flooring, we examined whether differences in participants' self-monitoring would moderate our context effects. Hence, if our findings reflect people's reliance on people's internal sensations, the effects should emerge primarily among low, not high, self-monitors, as prior research has shown that they base their responses by attending to their own internal states or bodily sensations. Results from this study supported our notion that the context effects occurred because of how people used their bodily sensations (not cognitive concepts) aroused by the flooring. Further, no context effects emerged on

participants' overall affect toward the target product, indicating that context effects spawned by bodily sensations may be more limited in scope. Study 4 provided further support for our theorizing by experimentally focusing people's attention on either their bodily sensations or cognitions. As anticipated, the context effects observed before only emerged when people were primed to focus on their inner sensations.

SPECIAL SESSION SUMMARY

How Environmental Cues Impact Consumer Judgments

Leonard Lee, Columbia University, USA
Michel Tuan Pham, Columbia University, USA

SESSION OVERVIEW

A substantial body of research has established the critical effects that a consumer's encompassing environment has on his or her judgments and decisions. A cohesive framework that can be used to conceptualize the different ways in which environmental cues can impact how consumers think, feel, and behave is illustrated in Figure 1.

Moving from the more concrete to the more abstract, our environment can not only increase our awareness of our available choices and influence the specific goals we pursue, it can also alter how we process external stimuli as well as affect our attributions of outcomes.

This session brings together an integrated set of four recent papers that document these four dimensions. Berger, Sorensen, and Rasmussen show that, contrary to lay beliefs, negative environmental publicity (e.g. rumors and reviews) can have an unexpected upside—creating greater awareness and boosting consumption of available options (e.g. books), particularly if these options come from relatively unknown producers. Environmental cues also change the goals we pursue and influence how we evaluate brands, even brands that are irrelevant to our goals, e.g. Dalton, Fitzsimmons, Fitzsimmons, and Chartrand found that priming a creativity goal not only improved evaluations of goal-relevant options (e.g. Apple laptops) but also hurt evaluations of goal-irrelevant options (e.g. Dell or IBM laptops). More generally, adopting a dual-system model, cues in our environment can also influence whether we rely on intuitive experiential processing or deliberative cognitive processing in responding to external stimuli. For example, Lee and Thomas show that environmental music can induce greater experiential processing, which in turn, increases consumers' penchant for hedonic products and innate retrieved preferences. Finally, Pham, Goukens, Stuart, and Lehmann demonstrate the surprising power of seemingly trivial environmental artifacts (e.g. mirrors, video cameras)—heightening consumers' self-awareness and increasing their own-attributions of both positive and negative outcomes; in a retail context, for instance, these cues can increase customer satisfaction for an unfavorable service interaction but decrease satisfaction for a favorable service interaction.

Interestingly, many of these effects occur outside of consumers' conscious awareness, whether it's the potentially positive effect of negative publicity on product evaluation, or the consumption goals or processing style that external cues activate, further highlighting the counter-intuitiveness of these findings. Overall, given the fundamental relevance of these effects to consumers' daily lives, this session should be of substantial interest not only to marketing researchers and psychologists, but also to anyone who is fascinated by how environmental factors can affect consumer judgments and behavior, be it consciously or unconsciously.

EXTENDED ABSTRACTS

“Positive Effects of Negative Publicity”

Jonah Berger, University of Pennsylvania, USA

Alan Sorensen, Stanford University, USA

Scott Rasmussen, Stanford University, USA

Negative publicity often hurts. Negative rumors (e.g., a company uses worm meat in their hamburgers) decrease brand evalua-

tions (Tybout, Calder, and Sternthal 1981) and negative reviews hurt purchase likelihood and sales (Basuroy, Chatterjee, and Ravid 2003; Huang and Chen 2006). At the same time, however, some intriguing examples seem to contradict these findings. A wine reviewed as being “redolent of stinky socks,” for example, saw its sales increase by 5%, and after a popular movie made relentless fun of Kazakhstan, there was a 300% increase in requests for information about the country. Can negative publicity actually have a positive effect? And if so, when?

We argue that negative publicity can positively affect consumer choice by cueing, or priming people to think of the product. Just as environmental cues, such as advertising, can make people more aware, even negative cues can be useful by making products more top of mind. Accordingly, we suggest that whether negative publicity has positive or negative effects will depend on existing product awareness. When product awareness is already high, negative publicity should have little ability to boost awareness (see Nedungadi 1990), but should lower product evaluation, and consequently, decrease consumer choice. When product awareness is low, however, negative publicity should increase awareness and may boost choice if awareness and publicity valence become dissociated in memory. Similar to the sleeper effect (Hannah and Sternthal 1984), people may have a feeling of awareness, or remember they heard something about the product, but the valence may be forgotten. Due to decreased processing and encoding in memory of unknown product information, this dissociation should be particularly likely when product awareness is low. Three studies test these hypotheses using a combination of experimental methods and econometric analysis.

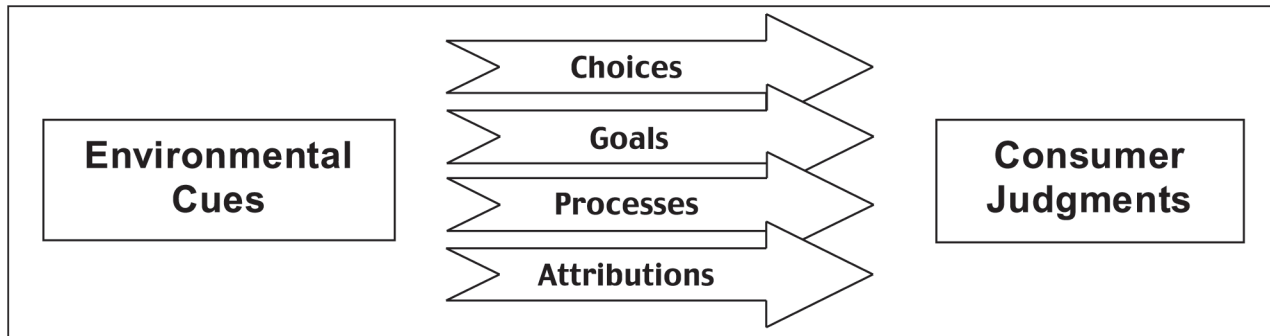

Study 1 investigates the effect of publicity valence and product awareness on actual book sales. We estimate the impact of New York Times book reviews on sales of over 200 hardcover fiction titles. To avoid potential endogeneity bias, our analysis focuses solely on reviewed books, and we examine whether positive and negative reviews have different effects on post-review sales patterns. We systematically classified reviews as positive or negative using a textual search algorithm. We then examine the post-review sales patterns among new and well established authors (i.e., those that have published more than 10 books).

As predicted, analyses revealed a review valence by product awareness interaction. While a positive review increased sales of both new and established authors (between 32% and 52%), the effect of negative publicity depended on whether the author was well known. Negative publicity decreased (-15%) sales of established authors, but it had the opposite effect on relatively unknown (new) authors, increasing sales by 45%.

Study 2 investigates these effects in a more controlled laboratory setting. We suggested that positive effects of negative publicity might be caused by the dissociation of valence in memory over time for unknown products, so to test this possibility, we manipulated whether people reported purchase likelihood either right after reading a product review, or after a delay. We also manipulated review valence and product awareness (i.e., whether an unknown or well-known product was reviewed).

As expected, analyses revealed a 3-way interaction. For well known products, there was only a main effect of review valence: Participants reported they would be more likely to purchase well

FIGURE 1

known products that were positively (vs. negatively) reviewed, regardless of whether they reported purchase likelihood right away, or after a delay. In contrast, for unknown products, delay moderated the effect of review valence on purchase likelihood: Review valence had an effect when participants reported purchase likelihood right away, but this dissipated such that after delay, purchase likelihood was similar after a positive or negative review.

Study 3 directly examined the mediating role of increased awareness. First, participants reported their awareness of a number of books. They were then exposed to either a positive or negative review about either a well known or unknown book from the set. Finally, after a long delay, participants again reported product awareness (which allowed us to calculate whether publicity affected awareness) as well as product evaluation and purchase likelihood.

Results support the expected pattern. For well-known products, being reviewed did not affect awareness. But while positive reviews increased purchase likelihood, negative reviews decreased it, and these outcomes were mediated by product evaluations (which were driven by review valence). For relatively unknown products, in contrast, review valence had little effect on product evaluations. Both positive and negative reviews boosted purchase likelihood, however, and this was mediated increased product awareness.

Overall we demonstrate that even negative cues can sometimes have positive effects. Our findings delineate conditions under which negative publicity will have positive versus negative effects on purchase likelihood and actual sales, while also shedding light on the mechanism behind these effects.

“When does Priming Cause Us to Value or Devalue a Brand?”

Amy Dalton, *Hong Kong University of Science and Technology, China*

Gráinne Fitzsimons, *University of Waterloo, Canada*

Gavan Fitzsimons, *Duke University, USA*

Tanya Chartrand, *Duke University, USA*

Activating (or priming) a mental construct can produce wide-ranging effects on choices, behaviors, and evaluations. In terms of evaluations, priming nonconsciously boosts evaluations of prime-relevant stimuli relative to prime-irrelevant stimuli. Although several studies have documented this effect, few studies have decomposed it to address whether priming is boosting evaluations of stimuli associated with a primed construct (valuation), and/or hurting evaluations of stimuli that are irrelevant to a primed construct (devaluation). Moreover, the few studies that have separated valuation and devaluation effects have not reliably yielded evidence for each, nor have they revealed when priming causes one

effect or the other. It is possible that prior research has not reliably obtained both valuation and devaluation effects because these effects are associated with the priming of different types of mental constructs, i.e., priming of semantic associations versus goal associations. Along these lines, we propose that both goal priming and semantic priming can unobtrusively boost evaluations of prime-relevant stimuli (valuation), but only goal priming can reduce evaluations of prime-irrelevant stimuli (devaluation).

The purpose of Experiment 1 was to demonstrate nonconscious valuation and devaluation of consumer products as a function of brands and goals. Experiment 1 used a 2 (creativity prime vs. neutral prime) X 2 (evaluate Apple vs. IBM brand) between-subjects design. First, a scrambled sentence task was administered to supraliminally prime a creativity goal (or no goal). Participants then read a description of a new laptop that was supposedly designed by Apple or by IBM and were asked to evaluate it. We predicted that the Apple laptop would be more attractive following creativity goal priming because the Apple brand image is one of innovativeness and uniqueness. We further predicted that the IBM laptop would be less attractive following creativity goal priming because the IBM brand image is irrelevant to creativity. This pattern is precisely what we found. Thus, experiment 1 demonstrated the basic effect: that priming can simultaneously boost evaluations of a prime-relevant brand and hurt evaluations of a prime-irrelevant brand.

Experiment 2’s purpose was to replicate and extend the basic valuation and devaluation effects in two ways. First, we manipulated product features in addition to brands and second, we used an entirely different product domain, automobiles. Thus, experiment 2 used a 2 (morality prime vs. neutral prime) X 2 (Prius vs. Echo brand) X 2 (fuel efficient vs. inefficient car) between-subjects design

In experiment 2, after being supraliminally primed with a morality goal (or no goal), participants evaluated one of four vehicles. Two vehicles were the brand Prius, which is associated with morality via fuel efficiency and environmental consciousness. The other two vehicles were the brand Echo, which is not associated with morality. Within each brand category, one vehicle was described as having a low environmental impact, while the other excelled on other dimensions, including performance. We predicted and found that morality goal priming caused valuation of fuel-efficient vehicles and devaluation of fuel-inefficient vehicles. But this effect was qualified by an interaction. The Prius brand gave a fuel-efficient vehicle an extra evaluative boost and buffered a blatantly fuel-inefficient vehicle against evaluative costs. These findings suggest that products are valued and devalued based on brand and features, and as a function of consumers’ goals. But do valuation and devaluation occur independently?

We posit that semantic activation can produce valuation through a non-motivational process of spreading activation, but only goal activation leads to both valuation and devaluation. Experiment 3 tested this hypothesis using a satiation paradigm. Satiation should eliminate goal-based but not semantic priming effects—devaluation, but not valuation, according to our hypothesis.

Experiment 3 used a 2 (creativity prime vs. neutral prime) X 2 (evaluate Apple vs. Dell brand) X 2 (satiation vs. no satiation) between-subjects design. The methods were identical to experiment 2 except that the brand Dell was used (not IBM) and satiation was manipulated such that half the participants satisfied their creativity goal before evaluating a laptop. As we would expect, the results of the no satiation condition replicated experiment 1. Moreover, as predicted, satiation reduced devaluation but not valuation. Thus, experiment 3 showed valuation for goals and semantically-activated constructs, but devaluation only for goals.

Taken together, these studies show that product evaluations can be colored by 2 independent evaluative biases—valuation and devaluation. These effects occur nonconsciously and can be based on tangible product attributes and brand names. Moreover, valuation occurs following either goal or semantic priming, while devaluation is unique to goal priming. Devaluation, therefore, is one way to disentangle goal-based from semantic priming.

“The Effect of Music on Retrieved and Constructed Preferences”

Leonard Lee, Columbia University, USA

Manoj Thomas, Cornell University, USA

The effects of music on diverse facets of human emotion and cognition have been well documented (Kellaris 2008). As the number of headphones-wearing iPod owners sauntering through the streets continues to skyrocket, it is important to understand how music can influence how we think, feel and behave. Building upon extant research on music and preference, we examine the effects of music on retrieved and constructed preferences.

In Experiment 1 we examine the effect of music on preferences for books. Based on a pre-test, we gathered that men are more likely to prefer books on power/politics relative to those on pain/suffering. We hypothesized that listening to music will increase the propensity to retrieve these pre-existing genre-based preferences rather than constructing preferences based on the details of the book. One hundred and fifty two undergraduate and graduate students participated in this study. They were randomly assigned to one of the two conditions: music or control. Pairs of books were used as stimuli in this experiment. In each pair, one book was on power and politics while the other book was on the pain and suffering in life. In one of the pairs, participants chose between “The Federalist,” a series of essays on the constitution of America, and “Candide,” the adventures of a youth forced into the army, flogged, shipwrecked, and separated from his beloved. In the other pair, they chose between “An American Slave,” an autobiographical account of slavery in the United States, and “Lost Illusions,” on the disastrous journey of a naïve young poet who left his home to seek fortune in Parisian society. The experiment was titled “Book Evaluations” and was conducted on computers. The music was introduced subtly such that it would appear as a natural element of the study. After the audio instructions, participants saw an hour-glass-wait icon, requesting them to wait for a minute as the computer sorted the books to be tested in a random order for each participant. Participants assigned to the music condition heard background music as they waited for the book evaluation task to begin. After a minute of waiting, they saw the pairs of books on the screen, one pair at a time. On each screen, they saw descriptions and

posters of two books, and indicated their relative preference for these two books by clicking a button on an 11-point scale shown below the two books. Consistent with our hypothesis, we found that under conditions of music, men were more likely to prefer books on power and politics than women. Further analyses revealed that gender had a significant effect on preferences in the music condition ($p < .01$) but not in the control condition ($F < 1$).

In Experiment 2, we wanted to replicate and extend these results to a different context. Further, we wanted to examine the effects of different types of music. A total of 211 participants were recruited for a study on “Foreign Movie Evaluation” and randomly assigned to one of three conditions: control, slow music, and fast music—we included two music conditions to rule out the possibility that any observed effects were caused by idiosyncratic effects (e.g. tempo or fit) due to any particular piece of music. Participants in both music conditions listened to background music on headphones during the primary task while those in the control condition did not. Participants were shown eight pairs of movies and asked to rate (on a 11-point scale) their relative rental preference between each pair. For four of the movie pairs, one movie belonged to the action/crime genre, whereas the other, the romance/comedy genre; the remaining four pairs were designed as control movies and were all documentaries. Consistent with our hypothesis, we found that in the music conditions (compared to the control condition), males and females were more likely to rent action/crime and romance/comedy movies respectively, suggesting a stronger preference for retrieved preferences when listening to music. This effect was mediated by participants’ self-reported movie genre preferences and did not apply to the documentary movies.

Experiment 3 is a field study conducted in a mid-size convenience store selling a variety of common grocery products. Ninety-three customers entering the store received a \$2-off coupon each and were randomly assigned to one of two conditions—approximately half of the customers were handed an iPod pre-loaded with instrumental music and asked to listen to the music while shopping (music condition), whereas the other half were not handed an iPod (control condition). Subsequently, we collected these customers’ receipts when they redeemed their coupons after shopping and asked them to complete a short post-shopping survey. Consistent with our prediction, we found that participants in the music condition bought significantly more items from hedonic categories ($p = .04$) based on product ratings from two independent coders (inter-rater reliability = 80%); however, customers across both conditions did not perceive any difference in changes to the amount they had spent compared to previous visits ($p = .3$), suggesting that customers in the music condition were not consciously aware of the effect that the music had on their shopping.

Together, these experiments demonstrate how music-induced experiential processing can influence consumers’ preferences and shopping behavior.

“Shaping Customer Satisfaction through Self-Awareness Cues”

Michel Tuan Pham, Columbia University, USA

Caroline Goukens, University of Maastricht, The Netherlands

Jennifer Ames Stuart, Bayer Healthcare, USA

Donald Lehmann, Columbia University, USA

Improving customer satisfaction is obviously of great importance to marketers. Although satisfaction is obviously a function of the level of product/service performance vis-à-vis customers’ expectations, it also depends on the outcome attributions that are made. Studies generally find that, in case of delivery failure, dissatisfaction with the provider is stronger if the failure is attrib-

uted to the provider than if it is attributed to the customer or to an external cause. On the other hand, in case of delivery success, satisfaction with the provider tends to be greater if the success is attributed to the provider than if it is attributed to the customer or to an external factor.

Findings from the social psychology literature suggest a person's state of self-awareness can influence people's attributions. In particular, high self-awareness prompts people to make more internal attributions, and does so independently of the outcome to be attributed. If customer satisfaction is a function of the perceived locus of responsibility for product/service performance, and if the perceived locus of responsibility can be shifted by states of self-awareness, it should be possible to influence customers' satisfaction by varying the customers' level of self-awareness while holding objective product/service performance constant. This prediction was tested in a series of six studies (including one field experiment) involving four different types of service interactions and four different manipulations of self-awareness.

In each study, participants whose self-awareness was manipulated were exposed to information about different service interactions and asked to rate their satisfaction with the service. The first two experiments tested the basic prediction that mere exposure to innocuous cues that heighten self-awareness can influence customers' satisfaction with a service provider. It was found, across two different service interactions and across two different self-awareness manipulations, that heightened self-awareness increased satisfaction when the outcome of the interaction was unfavorable, but lowered satisfaction when the outcome was favorable. These effects were mediated by an increased perceived responsibility of the self for the outcome under high self-awareness.

The third experiment tested whether the effects of self-awareness on customer satisfaction are driven by changes in the encoding of the service interaction or by changes in the summary interpretation of the interactions. The results favor the latter explanation. Given these results, the next experiment examined whether the same effect would hold if the service interaction occurred much earlier (e.g., several months ago). College students whose self-awareness was manipulated were asked to assess their satisfactions with college courses they were currently taking versus courses they had taken earlier. The results showed the self-awareness on satisfaction extends to current satisfaction with real service interactions that occurred much earlier. This latter finding reinforced Study 3's interpretation that the source of self-awareness effects on satisfaction lies at the moment of impression formation rather than at the encoding of the service interaction. From a substantive standpoint, the finding suggests that marketers may be able to shape not only satisfaction with recent service interactions but also satisfaction with past ones.

The fifth experiment identified a boundary condition for the above-found effects. That is, the results of this study showed that while raising self-awareness may increase the overall satisfaction with service interactions with an unfavorable outcome, it will only do so when there is mixed responsibility for the outcome. If responsibility for the outcome rests entirely with the provider, raising the customer's self-awareness may backfire and further decrease his or her satisfaction. This backfiring effect seems to be due to the triggering of ego-defense mechanisms under high self-awareness when the customer bears no responsibility for the outcome.

A sixth, field experiment, shows that the key effect—the increase in satisfaction after negative outcome interactions—also holds in a real retail setting. The study was conducted in a clothing retail store in New York City. The results show that customers who

were about to return or exchange merchandise at the store's customer service desk were more satisfied (less dissatisfied) with the merchandise they were about to return when mirrors were placed in the customer service desk area than when they were no mirrors.

In sum, these six studies provide strong evidence that subtle cues that raise self-awareness can influence satisfaction with service providers, even if the objective service performance remains constant. This effect has obvious managerial implications for marketers looking for ways to improve their customers' satisfaction following delivery failures. Satisfaction-through-self-awareness tactics can be implemented relatively inexpensively (e.g., mirrors at customer service desk, addressing customers by their names, etc.), especially compared to the cost of true product/service delivery improvements.

SPECIAL SESSION SUMMARY

Plates, Smiley Faces and Price Tags: How Contextual Factors Bias Consumption

Meng Zhu, Carnegie Mellon University, USA

SESSION OVERVIEW

Decades of research in judgment and decision making (e.g., Tversky & Kahneman 1974; Chaiken, Liberman & Eagly 1989; Sloman 1996) has established the view that everyday behaviors are often guided by simple heuristics instead of deliberative reasoning. Although relatively effortless, simple heuristics can lead to systematic biases. While a great deal of research has focused on investigating heuristics and biases in judgments (e.g., Tversky & Kahneman 1974; Kahneman, Slovic & Tversky 1982) and choices (e.g., Huber, Payne & Puto 1982; Simonson 1989; Simonson & Tversky 1992), little attention has been given to how heuristic cues can bias consumption decisions. In a few notable exceptions, consumption behaviors have been shown to be influenced by package size (Wansink 1996), container shapes (e.g., Wansink & Ittersum 2003), and serving units (e.g., Cheema & Soman 2008).

Given the crucial role consumption plays in today's economy, health care, and its impact on the natural environment, it is critical to understand how people's consumption decisions can be swayed by different contextual factors. In this session, we present three papers that add to the emerging view that consumption behaviors are largely constructive and context-specific. The papers demonstrate how different subtle contextual cues (e.g., the plating and presentation of a food, the image of a smiling face, and prices of weight loss pills) can produce systematic impact on people's consumption behaviors across different domains (e.g., food, personal care products, and dieting and exercising programs), thus providing an opportunity to establish linkages between various research streams.

In the first paper, Payne and Wansink show that visual cues can induce a generalized "halo effect" and bias the consumption experience of food products. In particular, they show that the plating and presentation (e.g., presenting a brownie on a china plate, a napkin or a paper plate) significantly influence ratings of a food's taste and how much someone is willing to pay. Their results suggest that the heuristic-based "what is beautiful tastes good" association provides a better explanation of how favorable food-related visual cues (e.g., a china plate) bias post-consumption evaluations than does the conventionally used "confirmation bias" perspective.

The second paper by Zhu, Billeter and Inman illustrates how visual cues bias consumption in an advertising context. Their findings suggest that consumers rely on pictures rather than product descriptions in advertisements to infer product effectiveness and accordingly decide how much to consume. They demonstrate that pictures (e.g., a smiling face with great teeth) can increase perceived effectiveness of the advertised products (e.g., a whitening rinse) and concomitantly reduce usage amount of the featured products. They provide evidence that this negative impact of pictures on consumption mainly arises from heuristic processing and is attenuated by cognitive deliberation.

Finally, Bagchi and Cheema look at how contextual factors affect consumption of goal-relevant alternatives in consumer consumption context. They demonstrate that rather subtle cues (e.g., paid price for weight loss pills) can induce different efficacy perceptions about whether the goal is easy or hard and hence systematically impact consumption of goal-consistent (e.g., exercising to lose weight) vs. goal-inconsistent (e.g., avoiding rich foods) alternatives. Their results suggest that efficacy increases motivation to pursue goals when individuals focus on engaging in

goal-consistent consumption alternatives (e.g., exercising), but hurts when the focus is on avoiding goal-inconsistent consumption alternatives (e.g., dieting).

Taken together, the three papers (all in advanced stages) in this session examine the largely underexplored relationship between contextual factors and consumption and present a consistent picture suggesting that consumption decisions are largely constructive, context-specific, and are often determined by heuristic cues rather than deliberate thoughts and stable preferences. As the session integrates diverse research, it is expected to appeal to a broad audience, including those interested in consumption, decision-making, information processing, judgment biases, advertising and goals.

EXTENDED ABSTRACTS

"What is Beautiful Tastes Good: Visual Cues, Taste, and Willingness to Pay"

Collin Payne, New Mexico State University, USA
Brian Wansink, Cornell University, USA

The plating and presentation of a food, much like the attractiveness of a person, could induce a generalized halo for it. For example, if a food is presented on an attractive plate with an attractive presentation, one might assume this food to have other related positive characteristics. Once this assumption is made, favorable assessments of the food may be generated before it is even consumed (Mela, 1999). The assumption of a direct association between favorable food-related visual cues (plating and presentation), perceived taste, and "willingness to pay" is the basis for a proposed "what is beautiful tastes good" perspective of food ratings.

In contrast to the "what is beautiful tastes good" perspective, it may be that the plating and presentation of a food may create a belief about how much one is willing to pay for it that typically would be confirmed (rather than disconfirmed) through its perceived taste ("confirmation bias" perspective) (Wason, 1960). For example, if a food is presented on an attractive plate with an attractive presentation, a restaurant patron may assume that the food is "good" or high quality and initially believe that they would be willing to pay more for it. Once this belief is made, patrons will be biased in their search for positive taste evidence that confirms, rather than disconfirms, their initial belief of their willingness to pay more for it.

Where these two perspectives differ is the importance given to such taste evaluations. The confirmation bias perspective assumes the taste of a food must first be confirmed before one will be willing to pay more for it. In contrast, the "What is beautiful tastes good" perspective assumes that "there is enough information" in the plating and presentation of the food to affect not only perceived taste, but also how much one is willing to pay for it. We suggest that visual cues of plating and presentation provide enough information to influence one's willingness to pay, which is minimally influenced by an actual taste experience.

Study 1 involved 119 students (68.1% female; 19.1 years old) who were regular diners in a cafeteria. While still seated, each participant was shown a salad, sandwich, and brownie, which were all presented in one of three presentation styles (on a paper plate, on a glass plate, or on a glass plate with a garnish of parsley). Both the

presentation order of the foods and its presentation style were systematically rotated. After seeing each food, participants were asked to fill out a brief questionnaire which included the question, "If this was a new menu addition in the cafeteria, what is the most you would pay for this food?"

There was a notable increase in how much people would pay for a food item based on its presentation for the sandwich [$F(2, 226)=28.81, p<.001$], the brownie [$F(2, 225)=6.69, p=.002$], and to a lesser extent, the salad [$F(2, 223)=2.86, p=.059$]. All possible post-hoc contrasts for sandwich were significant (all $p's<.01$) while—for the brownie—significant differences were found between the presentation of it on a paper plate versus glass plate with garnish ($p=.001$) and between its presentation on a glass plate and a glass plate with garnish ($p=.029$). No significant differences were found for the salad. No explicit measures were taken to check for the participants' evaluation of the appearance of the food in Study 1. The subsequent study evaluates the appearance of food as a function of its presentation and also includes an actual consumption experience.

One hundred seventy-five cafeteria diners (72% female; 26.2 years old) participated in this study. They were asked if they would like to sample a free brownie. A brownie was then presented to the seated participants in one of three ways: on a napkin, on a paper plate, or on a china plate. After consuming the brownie, participants were given a questionnaire, which assessed their perception of the brownie's taste and how much they were willing to pay for it.

A manipulation check showed plating and presentation improved appearance ratings of the brownie, $F(2, 172)=39.87, p<.001$. All possible post-hoc contrasts for appearance were significant and in the anticipated direction (all $p's<.01$). An increase in the perceived taste of the brownie as a function of plating and presentation was also found [$5.22, 5.61, \text{ and } 6.16; F(2, 172)=13.9, p<.001$]. This result supports the idea that the plating and presentation of a food can influence subsequent taste. Post-hoc analyses indicated that the significant differences were found for "taste" between presentation of a brownie on a napkin and glass plate ($p<.001$) and also between a brownie presented on a paper plate and glass plate ($p<.01$).

To test whether plating and presentation significantly affected "willingness to pay" after controlling for taste, we conducted a Sobel test (see Baron & Kenny, 1986). This test specifically assesses whether the relationship between plating and presentation and "willingness to pay" can be accounted for by perceived taste. If the relationship is significantly reduced, the relationship is said to be accounted for by taste. The Sobel test resulted in nonsignificance (Sobel Test=1.6, $p=.11$). Improvements in plating and presentation influenced how much a person indicated they would be willing to pay. Improving plating and presentation in Study 1 led participants to indicate they would pay the equivalent of 22.6% more for a brownie, 14.5% more for a salad, and 60.6% more for a sandwich. In Study 2, participants given the attractively presented plate after eating their lunch were willing to pay 139.6% more for it (\$0.53 vs. \$1.27). It appears that a person's evaluation of willingness to pay for a food can be better explained by a person's initial impression of the appearance of the food than by their subsequent taste of it.

"Can Pictures in Advertisements Curb Consumption?"

Meng Zhu, Carnegie Mellon University, USA

Darron Billeter, Brigham Young University, USA

J. Jeffrey Inman, University of Pittsburgh, USA

Marketers often use pictures in advertisements with the hope and conviction that they would produce a positive impact on consumer preferences. Accordingly, the effect of pictures on adver-

tising has been studied extensively by marketing researchers. Pictures have been shown to have a positive impact on advertising effectiveness, by enhancing consumer's recall of brand name (e.g., Lutz and Lutz 1977), facilitating retrieval of attribute information (e.g., Houston et al. 1987) and forming favorable attitudes towards the brand and advertisement (e.g., Mitchell 1986). However, whether the positive effect of pictures on advertising effectiveness leads to higher consumption volume remains an uninvestigated and intriguing question that has both theoretical and practical marketing implications.

The purpose of this paper is to systematically investigate the impact of pictures in advertisements on consumption. Building on an emerging stream of research showing that consumption behaviors are often guided by simple heuristics rather than deliberative thinking (e.g., Wansink 1996; Wansink and Ittersum 2003; Cheema and Soman 2008), we suggest that consumers use pictures in advertisements to simplify their consumption decision. Particularly, we suggest that the impact of pictures on consumption is mediated by perceived product effectiveness. That is, consumers infer effectiveness of the advertised product from pictures presented in the advertisement. In deciding how much of a product to consume, people rely on their perceptions of product effectiveness as an indicator for what amount is required. Because a more effective product often requires a smaller amount to accomplish the same objective, we propose that pictures that increase perceived effectiveness of the advertised products will reduce usage amount at a single occasion. As this effect mainly arises from heuristic processing, we predict that cognitive deliberation will attenuate the negative impact of pictures on consumption. Further, we predict that other marketing variables, such as brand names, can also serve as heuristic cues for inferring product effectiveness and consequently generate a similar systematic impact on consumption.

Study 1 is designed to demonstrate the proposed main effect. In particular, we study whether adding the picture of a smiling face with great teeth to an otherwise text-only rinse advertisement reduces consumption volume at a single occasion. Subjects were shown an ad for a new teeth whitening rinse, either with or without a smiling face, and then asked to estimate how much rinse they would use at one time. We found that adding the image of a smiling face with great teeth reduced the estimated consumption rate of the advertised rinse by 42.35%.

Study 2 investigates whether the negative impact of pictures on consumption occurs primarily due to heuristic processing and is attenuated by cognitive deliberation. We directly manipulate cognitive deliberation by asking half of the subjects to rate the importance of each product description presented in the advertisement (Wilson & Schooler, 1991), before estimating the consumption volume. As expected, without rationalization manipulation, subjects indicated less rinse needed for a single occasion when the image of a smiling face was added to the otherwise text-only rinse ad; in support of the proposed heuristic account, we find that the negative impact of the picture on consumption decreased in the rationalization conditions.

Study 3 demonstrates the proposed main effect in an actual consumption scenario. We presented subjects with the actual teeth whitening rinse featured in the advertisement and asked them to pour the amount of rinse they would use into a plastic cup provided by the experimenter. Our results indicate that adding the image of a smiling face reduced actual usage amount of the advertised new teeth whitening rinse by 26.54%. The results of Study 3 also provide further support for the proposed heuristic processing account by showing that pictures mainly influenced the consumption rate of

individuals whose need for cognitive thinking was low, rather than individuals who had a higher natural tendency to engage in deliberative processing.

Study 4 investigates the boundaries for the proposed negative impact of pictures on consumption. We choose three different pictures found in actual advertisements of existing insect repellents, that is, a plant, a live bug and a crossed-out bug, to create advertisements for a new herbal insect repellent. Consistent with previous findings, the addition of a picture that enhanced judgment of product effectiveness (a crossed-out bug) led subjects to use less of the advertised product (insect repellent). Additionally, we find that pictures that generated worse effectiveness judgment (a live bug) and did not directly influence perceived effectiveness (a plant), led an increase and no difference respectively in consumption. The data confirmed the significant mediating role of perceived product effectiveness in the relationship between pictures and consumption. Study 5 extends the impact of pictures on consumption to brand names in another product category, toilet bowl cleaner. We find that the brand name "BalanceClean" as compared "BalanceGreen" led to increased effectiveness judgment about the featured toilet bowl cleaner and consequently decreased consumption volume.

The present research offers implications for marketing practitioners. Contrary to the common belief that pictures in advertisements generate positive influences on consumer demand, we show that pictures, particularly those images that increase perceived effectiveness of the advertised products, can inadvertently decrease sales volume due to reduced usage amount at a single occasion and lengthened repurchase cycle. Our results also indicate that pictures that decrease perceived product effectiveness can in fact increase consumption, implying that choosing pictures or brand names that do not enhance perceived effectiveness for new products and brand extensions may be a viable marketing strategy.

"The Ironic Effect of Efficacy on Consumer Consumption"

Rajesh Bagchi, Virginia Tech, USA

Amar Cheema, Washington University/University of Virginia, USA

Literature on goal-pursuit reveals that self-efficacy perceptions enhance effort and persistence of individuals pursuing a goal (Bandura 1977). Individuals also exert more effort when pursuing easy-to-achieve (vs. hard-to-achieve) goals and when the likelihood of reaching the goal is higher (Naylor and Ilgen 1984). However, other research suggests that when goals conflict (Shiv and Fedorikhin 1999), individuals sometimes decrease their effort towards one goal and focus on a competing goal. Koo and Fishbach (2008) label this as balancing and suggest that, when provided with information on how much effort remains to achieve a goal, individuals who are uncertain about their commitment towards the focal goal shift efforts to a competing goal, while those who are certain highlight the focal goal. Related research suggests that remedial products, such as a patch to quit smoking, increases incidence of smoking among existing smokers (Bolton, Cohen, and Bloom 2006). Thus, it is not evident how increased efficacy (effectiveness) influences goal-pursuit in the presence of competing goals.

We focus on situations where multiple competing goals exist, specifically in the context of losing weight. In this context, individuals try to manage goals of eating tasty (and often unhealthy) foods with a weight-loss goal, which requires exercising and dieting (avoiding rich foods). We argue that the type of action considered (engaging in goal-consistent action vs. avoiding goal-inconsistent action) will moderate the effect of efficacy on goal-

pursuit. Specifically, when considering engaging in goal-consistent actions (exercising), increased efficacy will enhance goal-pursuit. However, when considering avoiding goal-inconsistent actions (dieting), increased efficacy will decrease goal-pursuit.

We expect that elaborating on goal-consistent actions will increase goal commitment. Higher efficacy will make the desirable goal easier to achieve and will enhance goal-pursuit. In contrast, elaborating on goal-inconsistent actions will decrease commitment towards the focal goal. In this context, making the focal goal easier to achieve (through increased efficacy) may encourage balancing. We demonstrate these effects in two studies.

In study 1, participants learn that they are trying to lose weight by exercising and by dieting. We measured participants' willingness to persist in actions to achieve this goal. We manipulated the type of action between subjects. Half the participants were asked how likely they were to continue working out, while the rest indicated how likely they were to continue on a diet. Participants also responded to a seven-item efficacy scale. We classified each participant as being low, medium, or high in efficacy related to the action asked. Thus, the study was a 2 (action: avoiding goal-inconsistent actions versus persisting in goal-consistent option) x 3 (efficacy: low, medium, high) mixed between-subjects design.

An ANOVA with likelihood of goal-pursuit as the dependent measure and type of action and efficacy as the predictors elicited a significant action x efficacy interaction, $F(2, 146)=3.82, p<.05$. Among participants considering the goal-consistent action (exercise), high- (vs. low-) efficacy led to greater likelihood of goal-pursuit ($M_{high-ef} = 6.55$ vs. $M_{low-ef} = 5.38$). Moderate-efficacy people were also more likely to pursue their goal ($M_{moderate-ef} = 6.21$) than low-efficacy people. There was no significant difference between moderate and high-efficacy participants considering the goal-consistent action.

In contrast, among participants considering avoidance of the goal-inconsistent option (diet), high-efficacy participants were significantly less likely to pursue the goal than moderate-efficacy participants ($M_{high-ef} = 5.36$ vs. $M_{moderate-ef} = 6.28$). However, consistent with a beneficial effect of efficacy, moderate-efficacy participants were more likely to pursue their goal than were the low-efficacy participants, ($M_{moderate-ef} = 6.28$ vs. $M_{low-ef} = 5.00$). While high-efficacy participants were directionally more likely to pursue their goal than low-efficacy participants, this difference was not significant. Thus, moderate levels of efficacy increase goal pursuit, while high levels of efficacy decrease goal-pursuit when the individual focuses on goal-inconsistent options. Using a continuous measure of efficacy, with a squared term for the non-linear effect, also led to similar results. In study 2, we replicate these results by manipulating perceptions of efficacy.

The scenario indicated that participants were trying to lose weight and that the university was providing free weight loss pills to help. We manipulate perceived efficacy by indicating whether the university paid full price for these pills or not. Research suggests that full-priced drugs are perceived to be more efficacious (Shiv, Carmon, and Ariely 2005). Participants then responded to likelihood of pursuing their weight-loss goal. We also manipulated type of action between subjects as in study 1. Thus, the study was a 2 (action: avoiding goal-inconsistent actions versus persisting in goal-consistent option) x 2 (efficacy: low, high) full factorial between-subjects design.

An ANOVA with likelihood of goal-pursuit as the dependent measure and type of action and efficacy as the predictors elicited the predicted action x efficacy interaction, $F(1, 136)=17.52, p<.0001$. Among people considering the goal-consistent action, those in the

high-efficacy condition are more likely to pursue the goal (M high-efficacy=6.23 vs. M low-efficacy=5.40). In contrast, among people considering the goal-inconsistent action, increased efficacy decreased likelihood of goal-pursuit (M high-efficacy=5.11 vs. M low-efficacy=5.80). These results were consistent with those from study 1.

Thus, efficacy increases goal-pursuit when individuals elaborate on goal-consistent actions, but hinders goal-pursuit when individuals focus on goal-inconsistent actions. We believe this process occurs because elaboration of goal-inconsistent actions decreases individuals' commitment towards the goal and licenses the individual to focus on goal-inconsistent actions (Fishbach and Dhar 2005). We also discuss theoretical and managerial implications and suggest future extensions.

SPECIAL SESSION SUMMARY

Constraints and Consequences: Psychological Reactance in Consumption Contexts

Amit Bhattacharjee, The Wharton School, University of Pennsylvania, USA

SESSION OVERVIEW

The purpose of this special session is to explore the importance of psychological freedom and reactance in consumer contexts. The marketplace is replete with promotional and social influences, persuasion attempts, advertisements perceived to be manipulative, firm and government regulations, and product unavailability or other barriers (Clee and Wicklund 1980). All of these factors may threaten the ability of consumers to make free and unconstrained choices. Psychological reactance concerns a motivation to restore a threatened freedom (Brehm 1966), and has unique and specific implications for behavior. Though researchers have suggested that psychological reactance is an important construct to study in the field of consumer behavior (e.g. Clee and Wicklund 1980), the topic has received scant empirical attention. The three papers in the proposed session illustrate the versatility and universality of reactance processes, demonstrating the influence of this understudied construct in various novel contexts.

Bertini and Dholakia investigate how common marketing promotions may undermine intrinsic motivations and arouse reactance, inducing more price-sensitive, cautious decision-making by consumers and leading to less favorable managerial outcomes. These findings provide an important counterpoint to the notion that consumers respond favorably to incentives. The second presentation, by *Bhattacharjee and Berger*, examines how identity marketing messages that are positioned too strongly, though unwittingly favored by managers, may provoke reactance in consumers. Identity marketing reactance not only results in worse managerial outcomes, but may impact the way consumers see themselves, influencing downstream identity-relevant decisions. The final presentation, by *Leander, Chartrand, Shah, and Fitzsimons*, explores how differences in chronic reactance may alter the effects of social influences, giving rise to either assimilation or contrast effects. Highly reactant individuals are likely to act in opposition to social pressures, with important implications for consequential behaviors such as underage drinking.

Together, these papers highlight some of the ways in which consumers strive to assert control over their decisions and choices by countering external influences that are perceived to diminish their freedom. Specifically, the symposium demonstrates that both firm-generated promotions and peer and social influences can threaten perceived freedom and arouse reactance. Furthermore, reactance may potentially influence managerial and purchase outcomes, consequential health behaviors, and the way in which consumers see themselves. Given the widespread applicability of the issues discussed, it is expected that the session will be attended by researchers with interests in decision-making, communication and persuasion, promotions, identity, social influence, and consumer welfare and well-being. Following Kivetz (2005), we hold that psychological reactance is a mechanism critical to consumer functioning within the marketplace. As such, we believe that psychological reactance is a crucial avenue for future consumer behavior research. We hope that the diverse approaches to consumer freedom and reactance represented in this session will generate a lively and fruitful discussion.

EXTENDED ABSTRACTS

“Financial Incentives and Consumer Product Choices”

Marco Bertini, London Business School, UK

Utpal (Paul) Dholakia, Rice University, USA

A cardinal argument in managerial economics is that individuals respond to financial incentives. This intuition follows from the assumption that money affects effort and performance such that rewards reinforce desired behaviors while penalties mitigate undesired ones. Social and cognitive psychologists, on the other hand, often claim the opposite is true. For example, they argue that behavior is primarily driven by intrinsic motivations (e.g., altruism), and that compensation, an extrinsic motivation, can crowd out the first to the point that the activity becomes less appealing (Deci, Koestner, and Ryan 1999). Similarly, researchers have also suggested that financial incentives undermine performance because they violate social norms of approval (Fehr and Falk 2002) and reciprocity (Fehr, Gächter, and Kirchsteiger 1997), or because they induce behavioral justifications that damage interpersonal judgments (Bem 1967; Kelley 1971).

The ongoing debate on the merits and shortcomings of economic concessions has important implications in the field of marketing, where consumers are constantly offered discounts in exchange for buying certain products or quantities. As recently as 2004, for example, approximately 30% of marketing mix budgets in the United States (US) was spent on promotional activities.¹ In the United Kingdom (UK), £19 billion was spent in 2007 alone, with up to 60% of the population responding to one or more campaigns in any given month (Mullin and Cummins 2008).

Building on the notion that providing incentives undermines an individual's intrinsic motivation and arouses reactance and suspicion, we propose that the mere presence of promotional instruments (all involving a lower purchase price) induces more price-sensitive, cautious consumer decision-making among existing (but not new) customers of a firm. This proposition was supported in six studies, four laboratory experiments and two field studies, conducted using a variety of different incentives in different contexts. Specifically, we studied the effects of five common marketing tactics: (1) bundling products at a lower aggregate price, (2) offering a quantity discount on larger purchases, (3) providing an initial payment to consumers that switch suppliers and become customers, (4) giving a price reduction for transactions made through a low-cost channel (e.g., the Internet), and (5) giving a referral discount to customers for signing up their family, friends, or coworkers. In each of these cases we found that the monetary incentive “backfired.”

In study 1, the addition of bundled offers to a line of individual products decreased the likelihood that participants elected to purchase from this store. Moreover, participants spent significantly less money per transaction when bundles were made available. In study 2, selling two different sizes (small and large) of the same branded products led to an increase in the proportion of respondents preferring the lower priced, lower quality option. We also observed a shift in attention from quality attributes (quality ratings) to price

¹Promotion Marketing Association (2005), 7th Annual State-of-the-Promotion Industry–2005 Report.

during decision-making. In study 3, cellular phone services with either a short (3 months) or long (2 years) contract term were offered to new customers who contacted the firm on their own initiative or were given \$75 to switch providers. In the latter case, participants were more likely to choose a less expensive plan and spend less on add-on services, but only for the contract of longer duration. Finally, in study 4 we examined the effect of offering a discount for using an online channel to sign up for cable TV and Internet service. In this experiment, participants that were offered an incentive were less likely to pick a premium (more expensive) channel package and also more likely to select a lower-speed Internet connection.

Study 4 included two different tests of referral discounts. The first was conducted with 98 patrons at a café. Participants were given a screenshot of an eBay CD auction, with a picture of the CD cover, a description, a starting price of \$0.99, and shipping costs of \$5. The seller's feedback rating was displayed on the top right-hand corner. We manipulated whether the seller offered a referral discount or not. Specifically, only participants in the Incentive condition read the following additional message: "I offer a referral discount. Get your friend to bid and win one of my other auctions within seven days of yours and receive 10% off your winning bid." After reading their respective version of the stimulus, respondents noted the maximum amount they would be willing to bid for this CD. Participants that were offered a financial incentive (the referral discount) from the seller entered a lower maximum bid (\$5.89) than those in the Control condition ($M=\$8.25$, $p<.05$). A second test, involving evaluation of a pre-approved credit card offer from a bank, showed that participants in the Incentive condition were less likely to apply for the credit card ($M=4.06$) and liked the offer less ($M=4.94$) than those in the Control condition (likely to apply: $M=5.16$; $p<.02$; liking of offer: $M=6.03$; $p<.02$).

These laboratory results provide initial evidence that firms may in fact be better off not offering monetary incentives to consumers. In an effort to provide real-life evidence to support this claim, we then conducted two longitudinal field studies and found consistent results. One was conducted in cooperation with an automotive services firm and revealed that the detrimental effects of being given a coupon were limited to the firm's existing customers. In contrast, its new customers did not show any adverse effects. The last field study was conducted in cooperation with a major bank and showed that the preferences of its existing customers for incentive-based promotions foreshadowed their relational behaviors towards the firm over the course of a year afterward. Taken together, the results of these varied tests provide convergent evidence for our proposition and provide new insights into the role of reactance in customer decision making. In our presentation at the conference, we plan to present the results for a selection of these studies and discuss the theoretical and practical implications of our research.

"Escaping the Crosshairs: Reactance to Identity Marketing"

Amit Bhattacharjee, University of Pennsylvania, USA

Jonah Berger, University of Pennsylvania, USA

Researchers and practitioners alike have long acknowledged the importance and potential of marketing appeals based on identity. For decades, academics have looked beyond the functional aspects of products to examine the symbolic nature of consumption (e.g., Levy 1959). A sizeable literature has established that the identities consumers hold drive them to select constellations of products and services that maintain and strengthen those identities (e.g., Forehand Deshpande and Reed 2002).

Given that consumers are attracted to brands and products that reflect the identities that they possess (Forehand et al. 2002), brand

managers and marketers presumably are smart to attempt to position brands and products in order to reflect particular social identities: fostering this sense of connection may lead to a deeper, more persistent sense of consumer loyalty (Reed 2004). Achieving a sense of congruence or fit between the product, marketing appeal, and the consumer is thus seen as mutually beneficial, helping both the company and the consumer (Sirgy 1982).

But can targeted identity marketing messages have a dark side? Research suggests that consumers are inherently motivated to avoid biasing factors such as marketing influence (Wegener and Petty 1997). Similarly, Friestad and Wright (1994) have argued that the marketplace is fraught with situations in which consumers must interpret and react to persuasion attempts and marketing messages. As such, consumers develop a store of personal knowledge of persuasion tactics, and are constantly employing these skills in negotiating the social environment (Wright 1986).

The current research examines when identity marketing may backfire. In particular, we suggest that if messages are too strongly targeted, consumers may react against them, leading to decreased evaluation and choice. Consumers often choose products and cultural tastes in order to construct their identities and communicate information to others (e.g., Berger and Heath 2007; Douglas and Isherwood 1978; Shavitt 1990), and they are motivated to protect their sense of individual agency, such that they can ensure that their expressions of identity are intrinsically motivated and not influenced by external factors (Kivetz 2005; Lepper 1981). The theory of psychological reactance concerns freedom of choice (Brehm 1966). Reactance itself is defined as "the motivational state that is hypothesized to occur when a freedom is eliminated or threatened with elimination" (Brehm and Brehm 1981 p. 37). In other words, the theory contends that when an existing freedom is threatened, people are motivated to reassert the freedom. Thus, the present research proposes that identity marketing messages that are too strongly targeted—that is, messages that infringe on the consumer's ownership of the identity, or that threaten the intrinsic nature of the expression of that identity—may threaten the freedom of consumers to freely express the targeted identity, resulting in consumer reactance. As a result, consumers may turn on the brand, leading to lower evaluation and purchase likelihood.

Three experiments begin to test this theorizing. The first study tested managerial intuition about potential reactance in identity marketing. Undergraduate business majors were shown three marketing messages (one strongly targeted: "You're not green unless you clean with Charlie's!", one moderately targeted: "Two green thumbs up for Charlie's!", and one with no targeting: "Two thumbs up for Charlie's!") for a biodegradable cleaning product identity-relevant to "green", environmentally friendly consumers, and told to choose the most effective one to reach this segment. Results revealed that the strongly targeted message was favored over the nontargeted message and the moderately targeted message, and was predicted to result in the highest consumer evaluation and purchase likelihood.

But while these results are consistent with the thrust of the identity literature, study 2 demonstrates that stronger is not always better. Participants were primed with green versus neutral identities, and viewed the advertisement for a biodegradable cleaning product from the study 1, accompanied by one of the three identity marketing messages. Results indicated that participants with activated green identities felt significantly less freedom to express their identities, and indicated lower product evaluations and purchase likelihood when they had viewed the strongly targeted advertisement, relative to participants who viewed the other messages. Furthermore, a meditational analysis showed that freedom to ex-

press identity mediated the relations between message targeting and the outcome measures of product attitude and purchase likelihood. Together, study 1 and study 2 suggest that managers may not anticipate reactance, and may unwittingly prefer those messages most likely to provoke this response in consumers.

In addition to these managerial consequences, study 2 provides initial evidence that identity marketing reactance alters the way in which consumers see themselves: consumers targeted with strong identity marketing appeals may experience a threat to the identity, subsequently de-emphasizing it and reducing its centrality. Study 3 extends these findings, demonstrating an impact on downstream identity-relevant decisions: participants who had viewed a strongly targeted message for the biodegradable cleaner indicated significantly less willingness-to-pay for an unrelated green identity-relevant item, relative to moderately targeted and nontargeted messages. This result did not hold for a neutral, non-identity-relevant item.

Taken together, the current results indicate that targeted identity marketing appeals may have a dark side. Strongly targeted messages can restrict consumer freedom, provoking consumer reactance and resulting in unfavorable outcomes for both the brand and the consumer. Consistent with research suggesting that individuals shift identities strategically in response to threat (Mussweiler, Gabriel, and Bodenhausen 2000), identity marketing reactance may have important downstream consequences. The current research underscores the importance of crafting promotions and advertisements that maintain a sense of consumer agency, particularly for products and domains relevant to the way in which consumers see themselves.

“Feeling the Pressures: Considering the Context-Dependencies of Reactance Motivation in Underage Alcohol Consumption”

N. Pontus Leander, Duke University, USA

Tanya Chartrand, Duke University, USA

James Shah, Duke University, USA

Gavan Fitzsimons, Duke University, USA

Every parent of a teenage son or daughter has struggled with how best to introduce and manage the subject of alcohol consumption with their child. Should a parent offer their sixteen year old son a beer while out fishing in the hopes of demystifying alcohol? Or should that parent suggest to their son that he not have his first beer until he turns 21, the legal drinking age, and turn a blind eye to the social realities of teenage life? In our paper, we examine the influence of the social environments in which underage potential drinkers find themselves on their drinking related attitudes. We introduce into this research domain an important psychological moderator of peer influence, namely chronic reactance (Brehm 1966).

Psychological reactance was defined by Brehm as a motivational state in which an individual seeks to restore a restricted freedom. In other words, when someone feels that you are taking away one of their choice freedoms, they will experience a desire to reassert that freedom. A typical example of such a restriction would be a parent, teacher or authority figure telling a teenager that they are forbidden from engaging in a certain activity (e.g., using drugs, drinking, unsafe sex, etc.). A reactant response to such a restriction would be a desire to be able to choose for themselves whether or not perform such a behavior. Such reactance is typically manifested in two ways. First, the restricted freedom (e.g., drinking, drugs, etc) becomes much more attractive. Second, the source of the restriction (e.g., the parent or teacher) becomes derogated.

More recently, researchers have argued that not all individuals experience reactance in similar magnitudes, but rather that some individuals are likely to experience reactance more intensely than others (Hong and Faedda 1996). In our work, we build on this basic notion and argue that the individual tendency to experience reactance is a critical moderator in determining the alcohol related attitudes and behaviors of consumers under 21 years of age. This group is particularly likely to experience reactance in this domain as prior research has found that younger consumers are more reactant than older consumers, and more importantly, that prior to 21, the law explicitly prohibits the consumption of alcohol in the United States, serving as a major restriction of a young person’s freedom to consume alcohol. Across three studies, we explore situations in which trait reactance moderates underage consumers’ reactions to social cues that could be perceived as restrictions to their alcohol related freedoms.

In study 1, we explore whether the choices a friend makes concerning underage drinking will impact participants. Specifically, we ask participants to imagine that a friend either made a choice to go drinking that night, or has a choice to go drinking, with the premise that a friend who has made a choice will be more of a social threat to freedom than one who simply has a choice. We later measure time spent considering alcohol related advertisements by our participants as an indirect measure of their inclination towards alcohol consumption (i.e., the more time they spend examining an alcohol related ad the more they are predisposed towards alcohol consumption). Our results show that for consumers low in trait reactance, the made/has a choice manipulation did not affect alcohol ad reading time. But as anticipated, for consumers high in trait reactance, when a friend had made a choice to go drinking (thus threatening the participants ability to choose not to go) alcohol ad reading time is significantly lower than when a friend simply has an option to go drinking, but has yet to make the choice. In other words, for reactant individuals, a choice by their friends to go drinking actually reduces the attractiveness of drinking for the participant.

In study 2, we examine an additional moderator of the effect observed in study 1, namely closeness of the other person making the drinking decision. In essence we argue that a choice by a close other should be substantially more threatening to a reactant individual than should a choice by a more distant other. This is precisely what we observe. When a close other chooses to pursue a drinking goal (i.e., to go to a party) those low in reactance also want to drink much more than if a distant other makes the same choice. However, this effect is reversed for those high in trait reactance. These consumers express more pro-drinking implicit behavior when those distant from them choose to drink than when those close to them do (as the close others choice to drink serves to threaten the high reactance consumers freedom to choose to drink, or not to drink). Study 3 extends these basic results by examining whether the context interacts with the choices of social others to influence reactant response to alcohol related choices. We find, for example, that a choice by another to have a non-alcoholic beverage in a bar serves as a highly threatening choice to consumers high (but not low) in trait reactance, and leads to more pro-alcohol related attitudes and behavior.

In summary, we find that trait reactance is a very important moderator of underage consumers’ reactions to the alcohol-related choices of social others. We hope our research serves to stimulate research in the domain of teen drinking behavior, and its interaction with the desire to maintain one’s freedom to choose. To date, campaigns such as “Just Say No,” a famous/infamous advertising campaign against drugs that targeted a highly reactant population,

suggest a deeper understanding could be highly beneficial from a public policy perspective.

SPECIAL SESSION SUMMARY

The Effects of Process and Outcome Simulations on Decision Making

Michal Herzenstein, University of Delaware, USA

SESSION OVERVIEW

Process and outcome mental simulations have been researched in psychology for over two decades; however, the marketing literature has only recently begun exploring their effects on consumer behavior. Process simulation focuses on the process of reaching a goal (or using a product) while outcome simulation focuses on the benefits of reaching a goal (or the benefits that are derived from product usage.) Which simulation is better for consumers, and under which conditions? The research presented in this session addresses these questions by examining the positive and negative effects of these simulations on effort, choice, product evaluations, and decision making.

Three papers, each with multiple studies, were presented. The first paper shows that when a product is instrumental to goal pursuit then process simulation increases its appeal, but when it is not instrumental then outcome simulation increases its appeal. The second paper shows that process-focused simulation can enhance the judgments of consumer segments that resist effortful processing, because the beneficial effects of process-focused thought can be obtained without increases in cognitive effort. Finally, the third paper examines the effect of these simulations on the evaluation of really new products (RNPs) and finds that outcome simulation under a cognitive information processing mode or process simulation under an affective information processing mode is more effective in increasing the evaluation of RNPs. The reverse is found for a distant future time frame.

EXTENDED ABSTRACTS

“The Journey to Goal Attainment: When Process Focus is Engaging”

Michal Herzenstein, University of Delaware, USA

Aparna Labroo, University of Chicago, USA

Prior research distinguishes between two types of mental simulations, outcome and process (Taylor et al. 1998). Process simulation focuses on the process of reaching a goal while outcome simulation focuses on the benefits of reaching a goal. Which simulation encourages proactivity? The literature provides mixed findings. On one hand, outcome simulation increases effort and choice. For example, Thompson, Hamilton, and Petrova (2009) show that in the face of a tradeoff between a desirable option (e.g., a camera with many features that is difficult to use) and a feasible option (e.g., a camera with less features that is easy to use), process-oriented thinking increases decision difficulty because individuals focus on the tradeoff attributes. As a result, choice was delayed and task performance was degraded. Similar results were obtained in the context of consumer saving (Baumeister 2002)—consumers perceive saving money as important when its benefits are mentioned, but find it less important when the process of savings is mentioned. This is because the process of saving money highlights its difficulty and as a result consumers yield to temptations (spending now rather than in the future.)

On the other hand, process simulation increases effort and choice. For example, Pham and Taylor (1999) show that students who simulated the process for doing well on an exam (good study habits) studied more and received better grades compared with those who simulated the desired outcome (getting a good grade). Escalas and Luce (2003, 2004) show that when advertising argu-

ments are strong, process (vs. outcome) oriented thinking increases behavioral intentions because it delineates the path consumers should take.

The distinction between the above two streams seems to be that in the latter (process simulation is better) participants pursued a goal while in former (outcome simulation is better) they did not. Is goal pursuit the explanation for these differences? Specifically we ask: when consumers encounter a product, under which conditions process simulation (how to use the product) increases its appeal and under which conditions outcome simulation (the benefits of using the product) increases its appeal? The answer, we suggest, largely depends on the extent to which one considers the product to be relevant and instrumental to goal attainment. When a product is perceived as relevant then process simulation will increase its appeal, because it maps the path to goal attainment (the necessary steps required to use the product and achieve the goal.) However, when the product is not relevant then outcome simulation will increase its appeal because it focuses on the benefits which are important even to those who do not pursue a goal.

We support our claims in three experiments using different manipulations, products (hedonic or utilitarian), and behavioral measures, including actual behavior. In all experiments we manipulate focus by creating two ads for the same product, one highlights the process of using the product and the other, the outcome (benefits) of using it.

In experiment 1 we measured the individual inclination toward success vs. enjoyment goals, and manipulated outcome vs. process focus using two ads for a new business magazine. The process ad focused on what needs to be done in order to find a good job (with the help of the magazine), while the outcome ad focused on the benefits of finding a good job (again, with the help of the magazine.) As predicted, the magazine was more appealing to participants who saw the process focused ad and have a success (vs. an enjoyment) orientation, and to participants who saw the outcome focused ad and have an enjoyment (vs. a success) orientation. Next we explore the important role of instrumentality of the product as means to goal attainment in driving this result.

In experiment 2 participants adopted either an enjoyment or self control goal, and read one of two ads for new imported chocolate truffles. The ads either focused on the outcome of eating the chocolate (sensual, delightful, luxurious taste) or the process of eating the chocolate (opening the box, smelling the chocolate, unwrapping it while making sure not to drop even the minutest chocolate dusting). We note that the ads did not alter the importance participants assigned to their adopted goal. Results show that the chocolate was perceived as more instrumental to feeling good and more appealing to participants who saw the process focused ad and adopted an enjoyment (vs. self control) goal and to participants who saw the outcome focused ad and adopted a self control (vs. enjoyment) goal. Regression analyses show that increased instrumentality of the chocolate as means to feeling good mediated the effect of process vs. outcome focus on the chocolate's appeal.

Finally, we tested our predictions with real choice behavior in experiment 3. Participants adopted either a health or enjoyment goal, saw an ad for a health drink based on vinegar that is “really good for you but not so tasty”, and rated its instrumentality to becoming healthier. Our main dependent variable is the amount participants drank from the “health drink” (they were given a mix

of water and vinegar). Consistent with our previous results, those who saw the process focused ad and adopted a health goal and those who saw the outcome focused ad and adopted an enjoyment goal found the health drink more instrumental to becoming healthier and actually drank more. Regression analyses show that increased instrumentality of the health drink as means to becoming healthier mediated the effect of focus on the amount of participants drank.

The literature is inconclusive regarding the effects of process and outcome simulation on effort and choice. In goal pursuit, Pham and Taylor (1999) show that process simulation is better, but when people do not pursue a goal, Thompson et al. (2009) show that outcome simulation is better. Our research contributes by explaining why we see this difference. Instrumentality of the means (e.g., to what extent chocolate truffles are considered a means to a feel-good outcome) is the driver of this difference.

“Using Process-Focused vs. Outcome-Focused Thought to Enhance Consumer Judgment”

Jennifer Escalas, Vanderbilt University, USA

Mary Frances Luce, Duke University, USA

One of the most important goals of the marketing discipline is to assess and increase consumer decision quality. However, increasing the quality of many everyday consumer judgments is complicated by the fact that a clear cut behavioral rule is not feasible. That is, consumers cannot (and should not) be told to stop purchasing food, to avoid all use of over-the-counter drugs, or to avoid going outdoors during daylight to reduce the risk of skin cancer. However, these everyday decisions often lead to negative outcomes and the standard, normative advice to work harder or think more carefully, is often resisted in practice. In this paper, we argue that encouraging process-focused mental simulation is a creative option that will lead to more appropriate choices for consumer segments with low motivation to engage in decision effort.

Traditional consumer research approaches suggest increasing cognitive effort as the primary pathway for improving the quality of consumer decisions. However, our research suggests that decision quality can sometimes be improved through the form rather than the amount or effortfulness of decision-related thought. Specifically, process-focused (versus outcome-focused) thought can improve decision making without increasing the cognitive effort required in decision making. In two experiments, we show that process-focused thought can improve decision quality for low-motivation consumers. We believe that this is particularly important because low-motivation consumers seem particularly unlikely to respond to interventions designed to increase the amount of processing. We also show that the beneficial effects of process-focused thought do not extend to high motivation segments.

Escalas and Luce (2003, 2004) demonstrated that focusing on the process of using fictitious vitamin and shampoo products show enhanced sensitivity to argument strength, such that process-focused instructions enhance the favorable effect of strong arguments and the unfavorable effect of weak arguments. However, these beneficial effects of process-focused thought occurred only under conditions when consumers do not engage in systematic processing. Escalas and Luce (2004)'s results are consistent with the argument that relatively spontaneous planning processes are evoked by process-focused thought. When consumers engage in process-focused thought, they naturally attempt to link actions and outcomes to each other in the context of forming a plan. Thus, process-focused participants accept (or reject) the link between advertised behavior and outcomes as they spontaneously formulate (or veto) such a plan. There is also some evidence that higher elaboration

actually dilutes or undermines these beneficial effects (Escalas and Luce 2004).

Given these prior findings, we predict that the advantages of process-focused thought in increasing sensitivity to argument strength will be greatest under low- to moderate-elaboration conditions. We expect that process-focused types of thought have the potential to increase decision accuracy holding constant the amount of thought; process-focused thought is naturally occurring and does not require significant amounts of cognitive elaboration. On the other hand, high levels of elaboration are necessary for outcome-focused thought to elicit sensitivity to argument strength, consistent with traditional findings of dual process models such as the elaboration-likelihood model. Thus, we expect “accuracy without effort” effects for process-focused mental simulation specifically, and not for outcome-focused thought. Process-focused thought should be a relatively easy way to improve judgment quality, particularly for those segments that are resistant to increased cognitive effort. In this research, we focus on segments that are resistant to engage in effortful thought processes due to low motivation

In our first experiment, we tested the effect of mental simulation in a college exam setting to test whether the beneficial effect of process-focused thought on study behavior is moderated by both motivation to elaborate and the appropriateness of that behavior in the student's particular context (a corollary of strong vs. weak arguments in an advertising context). We found a three-way action appropriateness by thought-focus by motivation to elaborate interaction for our plan to study dependent variable ($F(1, 194)=5.74, p<.05$). High motivation participants differentiated between strong versus weak action appropriateness under both conditions of outcome- and process-focused thought. On the other hand, low motivation participants differentiated between strong versus weak action appropriateness only under conditions of process-focused thought. Thus, our results support our assertion that under conditions of low to moderate levels of elaboration motivation, students are more sensitive to action appropriateness when given process-focused (vs. outcome-focused) instructions. In this way, process-focused thought led to more discerning consumer judgments.

In our second study, we examined the interactive effect of process versus outcome thought-focus and argument strength on behavioral intentions (BI), in the context of print advertisements for a fictitious vitamin and a healthy bread product. Our results again supported our expectation that argument strength will differentially affect BI under process-focused thought for participants who are low in need for cognition (NFC) and thus not motivated to elaborate. We found a significant three-way argument strength by thought-focus by NFC interaction for BI ($F(1, 205)=3.87, p=.05$). There was a differential effect of argument strength in the process condition for participants who are low in NFC, but in the case of the outcome condition, the differential effect of argument strength only existed for participants who are high in NFC.

Our research shows that focusing on the process of using a product can improve consumer decision quality in common, low-motivation to elaborate settings. Encouraging consumers to focus on the process of using a product may be a good method for improving consumer decision-making in low motivation segments, without the perhaps unattainable goal of convincing consumers to engage in effortful elaboration. This seems to be particularly promising for those consumers likely to resist the call to increase the amount of their elaboration or the complexity of their decision processes, because process-focused thought can do so without relying on appeals that consumers “think” or “work” harder. Thus, we believe it will be easier to motivate low-involvement consumers to “think better” (by encouraging them to think about the process

involved, which is a relatively natural and easy thing to do) than to motivate them to “think more.”

“Process- versus Outcome-focused Simulation and the Evaluation of New Products: The Temporal Effects on the Affective and Cognitive Dimensions”

Min Zhao, *University of Toronto, Canada*

Steve Hoeffler, *Vanderbilt University, USA*

Gal Zauberan, *University of Pennsylvania, USA*

In this research, we examine the role of process- versus outcome-focused mental simulation in the learning of really new products (RNPs). Research in psychology has identified two distinct types of mental simulation: process simulation that is focused on the process of reaching a goal versus outcome simulation that is focused on the desirable outcome of achieving the goal (Taylor et al. 1998). Process simulation has been found to be generally more effective than outcome simulation in facilitating goal attainment (e.g., Taylor et al. 1998) or behavioral intentions (Escalas and Luce 2003, 2004). However, we believe that when applied to the new product domain, process simulation is only more effective for INPs, for which people are able to figure out how to use the product (Hoeffler 2003), whereas for RNPs which evoke high learning cost association (Mukherjee and Hoyer 2001), process and outcome simulation with a traditional approach does not lead to enhanced product evaluation.

We demonstrate how manipulating the type of information processing mode (cognitive vs. affective) with a different temporal perspective elicits the unique effects within process and outcome simulation on the evaluation of RNPs. Much previous research on mental simulation has either confounded process and outcome simulation with cognitive and affective components (i.e. process simulation with a cognitive focus vs. outcome simulation with an affective focus (Taylor et al. 1998), or has incorporated both cognitive and affective components into process and outcome simulation (Escalas and Luce 2003, 2004). We attempted to tease apart the cognitive and affective processing focus and to investigate the unique effect of process and outcome simulation on the evaluation of RNPs under each type of processing when a different temporal perspective is involved. We predict that in an instant evaluation scenario where the learning cost is salient, when evaluating the RNP with a cognitive focus, outcome simulation will lead to higher product evaluations than will process simulation, whereas the reversal is true when these products are evaluated with an affective focus. However, when we introduce a distant future perspective for the product evaluation such that consumers’ natural focus of the RNPs is shifted to the product benefits, we hypothesize that outcome simulation under an affective mode or process simulation under a cognitive mode will be more effective in increasing the evaluation of RNPs.

In Experiment 1, we first examined the role of traditional process and outcome simulation (i.e. combined focus on both the cognitive and affective components) on the evaluation of RNP (i.e., AudioPC) compared with INP (i.e., ThinkPad). We asked participants to practice either a process-oriented (i.e. visualizing the steps of using the product) or outcome-oriented (i.e. visualizing the benefits of using the product) simulation task after they read the ad. The results showed that the positive effect of process simulation was only replicated for the INP, whereas for the RNP, which naturally evoked high learning cost association, the effect of process and outcome simulation on product evaluation did not differ.

Experiment 2 investigated the specific effects of process and outcome simulation on the evaluation of RNPs (i.e., AudioPC) by teasing apart the effect of cognitive vs. affective processing mode in an instant evaluation scenario where consumers’ natural focus of

RNP is on the learning cost. Participants performed either a process-focused or outcome focused visualization task that emphasized either the cognitive or affective components. The results indicated that under a cognitive processing mode, outcome simulation increased product evaluation more than process simulation, whereas under an affective mode, process simulation was more effective than the opposite type of simulation. In addition, we found a partial mediating role of product uncertainty on this pattern.

In Experiment 3, we explicitly introduced different temporal frames by asking the participants to evaluate a RNP (a new video-editing software in this study) in a distant future scenario which enhanced participants’ construal level and evoked benefit-related considerations, or in a near future scenario which evoked default usage process consideration and served as our control conditions. The results showed that when the usage process information was more salient (i.e. in the near future conditions which were similar to the settings in experiment 2), we replicated the findings of experiment 2. However, when the novel benefits became more salient, the effect of mental simulation was reversed such that process simulation led to higher product evaluation under a cognitive processing mode, and outcome simulation led to higher evaluation under an affective processing mode. In addition, product uncertainty mediated this interactive effect between time, simulation type and processing mode.

Our research centers on the role of process- and outcome simulation in the evaluation of RNPs. Our findings showed the role of affective and cognitive considerations in the different effectiveness of these two types of simulations under a different temporal perspective. We further identified performance uncertainty as a mediator. We believe that our research provides some answers to the open questions about new product preference development, and well as the open questions about the exact nature of different types of mental simulations and their effectiveness.

SPECIAL SESSION SUMMARY

Multiple Systems for Choice and Valuation: New Perspectives from Decision Neuroscience

Ab Litt, Stanford University, USA

SESSION OVERVIEW

Typical consumer decisions involve the consideration and integration of a diverse range of information about the appeal of available options, decision context and situational history, and the importance and implications of making the 'right' choice. While behavioral studies have illuminated much about the nature of consumer decision making, teasing apart differences in how contributing underlying processes operate is a difficult problem for these approaches alone. Neuroscientific investigations of decision making offer direct and real-time access to these component processes, and so can crucially augment and enrich our current understanding of consumer decision making.

The objective of this session is to present an interlocking set of such insights into the multi-dimensional bases of decisions. The common thread is exploring precisely how different aspects of decision making marshal common versus dissociable underlying processing systems, and the predictive and explanatory implications thereof for central issues in consumer psychology and behavioral decision research. Bolstered by pertinent behavioral results, we employ functional magnetic resonance imaging (fMRI) to develop a more complete picture of the nature of decisions in scenarios akin to many typically faced by consumers. These findings in turn may inspire and shape further neural and behavioral investigations into how dissociable underlying choice and valuation systems may be divergently affected under specific conditions.

Hytönen, Baltussen, van den Assem, Klucharev, Smidts and Post present strong evidence for distinct neural networks active during and after experiencing gains and losses, and for how these distinguishable circuits drive path dependence in risky decision behaviors. From such prior-history effects on choices we move to future-reward discounting, where Figner, Johnson, Krosch, Steffener, Chu and Weber reveal distinguishable neural systems underlying asymmetric expressions of relative impatience across differently framed decisions regarding immediate versus future rewards. Neural circuits for affect, valuation, and action-impulse that these papers identify obtain converging support from the findings of Litt, Plassmann, Shiv and Rangel dissociating computations of motivational salience from valuation at the time of decision making. The striking divergences they observe support growing interest by behavioral decision researchers in teasing apart these components of value, and are consistent with our overarching theme of illuminating the importance of disentangling multiple distinct systems underlying valuation and decision making.

The papers in this special session feature data collected using both behavioral and neuroimaging measures. Our discussion leader, Carolyn Yoon, has conducted important behavioral studies of valuation, memory, and decision making, and is at the forefront of decision neuroscience research in consumer contexts and broader domains. While our techniques will appeal directly to those interested in (or who appreciate the growing importance of) neuroscientific and physiologically informed consumer research, our results are of broader significance to an audience interested in the nature of consumer decision making. Taken together, the findings described in this special session help to pry open the 'black-box' of the act of deciding, by revealing precise mechanisms for how dissociated and shared contributing sub-systems are engaged, interact, and lead to specific patterns of overt behavior.

EXTENDED ABSTRACTS

“Brain Processes Underlying the Influence of Prior Gains and Losses on Decisions under Risk”

A large body of behavioral experiments has convincingly shown that the risk attitudes of consumer decision makers for a given risky choice problem generally depend on the outcomes of previous choice problems (i.e., path dependence). Most notably, Thaler and Johnson (1990) showed that the average decision-maker tends to take more risk if she has a chance to gain back a previously experienced loss, the “break even effect”. Moreover, after experiencing a gain which cannot be lost, she also has a greater risk appetite, the “house money effect”. These effects are pervasive outside the laboratory (Post et al., 2008), and they are expected to be common in, for example, sequential choice behavior by private investors.

In this fMRI experiment we study the behavioral changes and brain activations related to prior experiences in decision making under risk. First, we test whether removal of options from a set of possible outcomes is interpreted as a positive or negative event in the brain, relative to the overall composition of an outcome set. Second, we explore how affective neural reactions to gains and losses influence and drive future choices.

Task. Subjects (N=22) undergoing fMRI made decisions between risky lotteries and sure amounts of money (offers). Each choice problem consisted of either one or two sequential stages, depending on a subject's behavior. In the first stage, subjects selected between a lottery with three outcome options and an offer. If a subject chose the offer, they proceeded to the next choice problem. If a subject took the risk of choosing the three-outcome lottery, one outcome option was randomly removed from the lottery (outcome phase). The subject then proceeded to the second stage of the choice problem, where they chose between a lottery with the remaining two outcome options and an updated offer. The choice problems were designed so that subjects faced a fixed set of 24 lotteries and offers following a previously experienced relative gain (smallest outcome option removed), neutral outcome (middle outcome option removed), and a relative loss (highest outcome option removed). The 24 lotteries were thus replicated three times, with the same second-stage lottery evaluated after a loss, gain and neutral outcome. This within-subjects design enabled us to isolate the effects of previous relative gains and losses on future choices between lotteries and offers.

Analysis. To test the nature of subjects' risk-seeking attitudes after relative gains and losses, we compared the percentage of lottery choices for identical sets of second-stage choices across the three conditions, i.e., following a previous relative gain, neutral, or relative loss outcome. In the analysis of the brain data we concen-

trated on two time windows: the outcome phase, where one outcome option was removed from the lottery, and when making the second-stage choice. For both time windows we located brain areas that were sensitive to relative gains and losses in the choice problem. Using regression analyses we examined which neural regions activated during the second-stage correlated with changes in the percentages of lottery choices between the conditions.

Behavioral Results. Participants showed decreased risk aversion (i.e., an increased percentage of lottery choices), relative to following a prior neutral outcome, following both a prior relative gain ($p < 0.05$) and a prior relative loss outcome ($p = 0.06$). These results indicate that prior experiences influence future choices under risk in accordance with the house money and break even effects, even in a within-participants design.

Neural Results. In the outcome phase, where one of the three lottery prizes was randomly removed, we found activity in the ventral striatum and medial prefrontal cortex. These areas were most active when participants experienced a relative gain and least active when a relative loss occurred. These brain areas have been previously related to the processing of unexpected rewards (O'Doherty, 2004; Delgado, 2007). Furthermore, these regions deactivate for losses even more strongly than they activate for gains, reflecting loss aversion (Tom et al., 2007). The present findings thus indicate that the brain does indeed process lottery prize removals as relative gains and losses, even before the actual lottery win or loss is revealed. This is an important extension of existing results on reference dependence of lottery outcomes (Breiter et al., 2001).

The effects of previous outcomes during the second-stage choice were reflected by activity in the operculo-insular cortex and anterior cingulate cortex, regions known to be related to cognitive control, emotions, and pain processing (Carter et al., 1999; Frot & Mauguière, 2003). Activity was higher in these regions in the loss condition than in the gain condition. In an additional regression analysis, we found that the insular cortex activity correlated with decreased risk aversion in the loss condition as compared to the neutral condition ($b = 0.5$, $p < 0.05$), which is consistent with prior findings linking insular activity to choosing high-risk options (Platt & Huettel, 2008). Another region showing increased activity after loss outcomes during the second-stage choice was the right inferior frontal gyrus, which has previously been related to suppression of responses, and linking emotional reactions and motor actions (Garavan et al., 2006; Schulz, 2009). Here we found that the smaller the difference in right inferior frontal gyrus activity between the gain and neutral conditions, the more lottery choices increased relatively after a gain ($b = -0.43$, $p < 0.05$). These results suggest that prior events can lead to an increase in affect-related neural activity and a decrease in control in subjects vulnerable to biases.

In sum, these results demonstrate that removal of an option from a set of possible outcomes is processed in the brain as a positive or negative event relatively to the original outcome set, and that activity involved in processing emotions and control distinguishably drives path dependence in risky decision behaviors.

"Impatient No More! Impulsivity in Choice Depends on How you Frame the Question"

Bernd Figner, Columbia University, USA

Eric Johnson, Columbia University, USA

Amy Krosch, Columbia University, USA

Jason Steffener, Columbia University, USA

Eustace Hsu, Columbia University, USA

Elke Weber, Columbia University, USA

One of the most important consumer decisions is whether to consume now, or wait until later. This willingness to trade immediate rewards for later benefits determines how much we save for retirement and whether we have that extra drink at a party (Mischel et al., 1969; Weber et al., 2007). While classical economics assumes exponential (constant per-period) discounting, people in fact discount future outcomes more steeply when they have the opportunity for immediate gratification than when all outcomes occur in the future, that is, they exhibit hyperbolic discounting (Frederick et al., 2002).

Many different explanations exist for hyperbolic discounting. A prominent example is the beta-delta model (Laibson, 1997), in which total discounting is the (quasi-hyperbolic) sum of two exponential discounting components, one (delta) that is present in all intertemporal choices, the other (beta) that is present only when immediate rewards are one of the choice options. Imaging evidence for this form of discounting decomposition was provided by McClure and colleagues (2004).

However, this approach and many other analyses ignore a robust empirical fact: people are much more impatient when delaying consumption (e.g., demanded price reduction for a downgrade from express to regular shipping) than when given the opportunity to accelerate consumption (e.g., willingness-to-pay for

an upgrade from regular to express shipping; see Loewenstein, 1988). Loss aversion, as formalized by prospect theory (Kahneman & Tversky, 1979), has been used to explain such asymmetric discounting. People are assumed to encode delay of consumption as a loss and acceleration as a gain, and delays are thereby proposed to be more painful than accelerations are pleasurable. This account is silent, however, regarding the precise psychological mechanisms giving rise to any such loss aversion and consequent asymmetric discounting. Moreover, it predicts a non-existent relation between an individual's degree of loss aversion and the degree of impatience asymmetry.

An alternative, more process-specific class of explanations suggests that different kinds of valuations (acceleration vs. delay; buying vs. selling prices) shift the decision-maker's focus of attention, consistent with differences in implicit goals (Fischer et al., 1999; Weber & Kirsner, 1997). Query Theory (Johnson et al., 2007) hypothesizes that decision defaults influence the sequence of retrieval of evidence, with the expected option (immediate consumption in delay decisions, larger but later consumption in acceleration decisions) being considered first, and with initial queries generating output interference that reduces the output of subsequent queries.

Task. To explore these questions regarding the basic processes underlying asymmetric discounting and impatience, we ran an online investigation of choices made by 20 participants undergoing fMRI. Participants made binary choices between gift certificates, using stimuli based on those used by McClure et al. (2004). In each of approximately 120 trials, participants made a delay or accelerate decision between a smaller/sooner (SS) and a larger/later (LL) reward. Amounts (ranging from \$15 to \$85), times of delivery (either immediately, i.e., day-of-participation, 4 weeks later, or 6 weeks later), and relative time difference between SS and LL (either 2 or 4 weeks) varied across trials. After finishing the scanning portion of the experiment, one of the participant's choices was randomly selected and paid out for real, and at the designated time of delivery for that prize on that trial, participants received the gift certificate they had chosen in the selected trial. This design enabled us to investigate neural activation differences underlying observed impatience asymmetries between delay decisions and accelerate decisions, further contrasting (a) choices between an immediate and a future reward; with (b) choices between two future rewards. This allowed investigation of relative differences in hyperbolic discounting between delay and accelerate decisions.

Behavioral Results. We observed significant effects (all $p < .001$) of the length-of-delay-time difference (with participants being more patient for shorter wait periods), the magnitude of the earlier reward, and the relative difference between SS and LL (indicating a trade-off between the cost of waiting and the increased reward of the LL). Moreover, and as predicted a priori based on Query Theory, we found hyperbolic discounting only in the delay condition, and not in the accelerate condition, with more impatient choices if a reward was immediately available as opposed to when both rewards were only available in the future.

Neural Results. The fMRI data revealed important differences in the two ways of measuring preference that were consistent with Query Theory. Contrasts comparing delay and accelerate decisions confirmed three hypotheses. First, as consistent with the Direction Hypothesis, greater activation in delay decisions was observed in key valuation-related brain regions: ventral striatum, medial prefrontal cortex, and orbitofrontal cortex. This suggested the distinguishable involvement of valuation circuits for each direction, delay or accelerate. Since Query Theory suggests that these judg-

ments are constructed from recollection, our observation (particularly with immediate rewards) of activation of bilateral hippocampus and an additional network involved in prospective judgment confirmed the Memory Hypothesis. Finally, we predicted and indeed observed increased activation of anterior cingulate cortex in delay decisions, a region crucial to the monitoring of response conflict and online performance (e.g., Carter et al., 1998; Botvinick, Cohen, & Carter, 2004), and so consistent with our Conflict Hypothesis.

In ongoing additional analyses, we are relating individual differences observed in this study to (1) results of Diffusion Tensor Imaging (DTI) measurement of white matter neural-tract connectivity between key regions of interest, (2) observed activations in target regions, and (3) eye movement recordings done during imaging. These approaches provide further evidence for specific relationships between our results and similar phenomena and neural activation patterns studied in extant research on memory, choice, and valuation.

“Distinguishable Neural Circuits for Motivation and Valuation Underlying Decision Making”

Ab Litt, Stanford University, USA

Hilke Plassmann, INSEAD, France

Baba Shiv, Stanford University, USA

Antonio Rangel, California Institute of Technology, USA

Many common consumer decisions involve considerations of value, to determine the type or nature of appropriate response; and motivational salience, influencing strength of engagement in both decision context and response implementation. Mounting research indicates important ways in which valuation and motivational components of decisions are dissociable in terms of underlying psychological processes and behavioral outcomes (e.g., Higgins, 2006). While conceptualizations of this disjunction vary—from “hedonic states” versus “hedonic stakes” (Lyubomirsky & Ross, 1999) to wanting versus liking (Winkielman & Berridge, 2003)—the notion that valuation and motivation may act in different ways and through distinct means seems of express importance to understanding the bases of consumer decision making.

Neuroscientific investigations of motivation and valuation have proven very effective in establishing the extent and limits of disjunctions between these psychological constructs, by revealing how their respective biological substrates differ, overlap, and interact (Berridge, 1996; Zink et al., 2004). This in turn sheds light on the basic psychological mechanisms influencing observed patterns of overt behavior. We conducted an fMRI study that explores dissociations in humans between specific valuation and motivational processes active and involved at the time of decision making, using an explicit and clear conceptualization of such a disjunction.

Task. During scanning, subjects (N=20) made a series of 240 choices involving different appetitive and aversive foods (60 distinct items, randomized and repeated once per session, for two sessions). Subjects were instructed, for each trial, to indicate (within a 2s interval) their willingness to eat the displayed food-item at the end of the experiment, using one of four response keys: “Strong No”, “No”, “Yes”, or “Strong Yes”. Subjects were told that at the end of the experiment, a random trial would be selected: they would actually receive that trial’s food item to eat if they responded “Yes” or “Strong Yes” on the trial, but would not if they responded “No” or “Strong No”. It was reiterated to subjects that “the response you gave on that [randomly chosen] trial will determine whether or not you will be asked to eat that food item at the end of the experiment.” Thus, subjects faced response decisions involving valuations of food items under motivation to respond accurately in line with those valuations. Subjects were asked not to eat immediately prior to the experiment, and were pre-screened for at least occasionally eating the food stimuli generally classifiable as appealing (snack foods, chocolate, etc.).

Analysis. Valuation was captured by observing the specific response given on any trial, and taken to be increasing from “Strong No” to “No” to “Yes” to “Strong Yes”. In contrast, we conceptualized motivation as the cross-valence strength of the response given on a trial: i.e., “Strong” responses were considered to be of greater motivational engagement than non-“Strong” responses. We thus coded the four possible trial responses as RESP {“Strong No”=-2, “No”=-1, “Yes”=+1, “Strong Yes”=+2}, and included RESP (valuation) and IRESP (motivation) as modulators of food item presentation in the AR(1) GLM estimated to analyze trial events in the experiment. Single-subject and group-level contrasts were calculated to determine brain regions in which activation during decision trials was 1) modulated by valuation, but not motivation; 2) modulated by motivation, but not valuation; and 3) modulated by both motivation and valuation.

Behavioral Results. In line with our conceptualization of motivation as response strength, subjects responded significantly faster for Strong Yes/No than non-strong Yes/No ($t(77)=4.22$, $p<.00005$, computed across subjects using means pooled within-subject). Additionally, subjects’ responses were correlated to a pre-scanning task in which they rated their overall liking of each food item used in the experiment, in order to test whether scanning-trial responses accurately matched valuations in both valence and intensity/strength. This correlation yielded $R^2=.9514$, supporting this contention.

Neural Results. Increased activity modulated by valuation was observed bilaterally in medial orbitofrontal and rostral anterior cingulate cortices, consistent with a wide range of findings in the cognitive neuroscience of decision making (e.g., Plassmann, O’Doherty, Shiv, & Rangel, 2008). Activity observed in dorsal posterior cingulate is consistent with work on reward-related signals in monkeys (McCoy et al., 2003). Additional valuation-modulated activity in precuneus and parahippocampal gyrus may be related to memory retrieval-related functionality previously observed for each of these regions: foods valued more highly by subjects are likely to be more familiar than the foods chosen to be generally unappealing (e.g., squash baby food, clam juice).

Increased activity modulated by motivational salience was observed bilaterally in posterior insula, dorsal anterior cingulate, supplementary motor areas, and primary motor cortex. This network of brain regions suggests several important conclusions regarding how motivational salience is represented in the brain and directs overt behavior. Insula activity correlated with cross-valence motivational salience is in contrast to a preponderance of work showing insula encoding primarily negative responses, such as disgust. These previous findings might be re-interpreted as indicative of the relatively greater motivational salience of those strong negative feelings, in a manner analogous to what has been argued for the amygdala (Anderson et al., 2003). In line with findings showing addiction and craving disruption with insula damage (Naqvi, Rudrauf, Damasio, & Bechara, 2007), our findings suggest that increased (cross-valence) motivation engages the insula, and that this representation of a high motivational state activates the planning and selection of an appropriate response action in dorsal anterior cingulate and downstream motor regions (similar to an account of ADHD by Bush et al., 1999).

Finally, different sub-regions of the nucleus accumbens (NAcc) were either distinctly or overlappingly modulated by valuation and motivation. This suggests a potential resolution to an ongoing debate over whether activity in NAcc is involved in encoding actual levels of reward or valuation, or rather representations related to the incentive salience or behavioral relevance of stimuli (Rodriguez, Aron, & Poldrack, 2006; Cooper & Knutson, 2009). Our results suggest that these divergent functionalities may be implemented in distinct but partially overlapping sub-regions of NAcc. Thus, consumer decision making seems grounded in dissociable but not disjoint sub-systems computing choice value and motivational salience.

SPECIAL SESSION SUMMARY

Other People's Things: Perspectives on Ownership Transfer and Sharing

Zeynep Arsel, Concordia University, Canada

SESSION OVERVIEW

Ownership and possession practices have historically been a central interest to Consumer Culture Theory (Arnould and Thompson 2005). While there is an increased interest in boundary conditions of ownership, such as the disposal of possessions (Lastovicka and Fernandez 2005; Price, Arnould, and Curasi 2000), access in contrast to possession (Chen 2009) and sharing of possessions (Belk forthcoming), these boundary conditions still remain an under-explored territory. This session threads three empirical studies that examine boundary conditions of ownership, more specifically ownership transfer and shared ownership. We seek to address the following issues:

1. Exploring how attachment to and appropriation of objects are performed in these boundary conditions.
2. Demonstrating how emerging marketplace structures mediate these hybrid and transient forms of ownership.
3. Investigating the ways individuals manage symbolic and physical contamination of goods that are shared with or transferred from others.
4. And lastly, highlighting the ecological and political issues that arise in the context of these transient and alternative forms of ownership models.

These three papers provide a focused, but multifaceted and multi-method treatment of the topic. The specific contexts that the presenters ground their theories in are also novel: second hand clothing users, online bartering communities and shared car ownership. These marketplace contexts promise many discussion opportunities and further theory development.

This session is likely to attract three groups of ACR members: (1) researchers that are interested in ownership and identity (2) those who study emerging marketplace structures that mediate new forms of exchange, consumption and divestment (3) a broader audience that consists of Consumer Culture Theory researchers and students. We anticipate a lively dialogue facilitated by John Deighton, who will tie the session together, highlight theoretical and practical implications of the papers and offer insights for further inquiry.

EXTENDED ABSTRACTS

"Identity and Self-Territory in Second Hand Clothing Transfers"

Dominique Roux, IRG-Université Paris-Est, France

Previous studies have highlighted the emotion of disgust and the negative representations associated with possible reuse of other people's possessions (Gregson and Crewe 2003). Anthropologists and psychologists attribute this taboo to the principle of sympathetic magic and its two laws (Frazer 1950; Mauss 1902/1972; Rozin et al. 1993). The law of contagion recognizes the offensive effect that slight or incidental contact with a polluted object may have, even long after the pollution, whereas the law of similarity assumes that things that resemble each other are from the same essence. Because clothing intimately links with the body, negative contagion both through similarity and contact, may impede the reappropriation of unknown people's possessions (Gregson and Crewe 2003; O'Reilly et al. 1984). However, these principles sharply contrast with the development of second hand markets, in

which clothing is an important if not central category among the wide range of goods for sale. The volume of commerce in second-hand clothes seems to contradict prevailing theories about contamination and disgust, especially when the social distance from previous owners increases.

The gap between theory and consumer practices originates in the assumptions that unfamiliarity inevitably triggers a fear of contagion but is also supported by experimental methods that tend to emphasize specific contamination cues. For example, Rozin and Fallon (1987) gather reactions to different disgust elicitors, which represent artificial situations that consumers seldom face in reality (e.g., wearing a laundered sweater that belonged to Adolf Hitler). Similarly, recent investigations of consumers' reactions to products touched by others in retail contexts (Argo et al. 2006) manipulate explicit contamination cues that might not be as salient in natural settings. When patronizing second-hand channels, consumers are perfectly aware that clothes have been previously worn. This research thus aims to understand how people, in anonymous but normal contexts of exchange, manage to reappropriate clothing from unknown owners and what distinguish them from those who reject pre-used garments.

In the literature devoted to second hand markets and exchanges, very few studies have examined appropriation or rejection processes of previously worn clothes. What they bring to light are the specific conditions that increase or reduce the perceived risks and facilitate or limit the transfers of garments. For example, O'Reilly et al. (1984) indicate that the newness and the quality of the merchandise strongly affect their resale. Gregson and Crewe (2003) confirm that specific conditions such as the absence of signs of wear, temporal distance from the former wearer, cleansing rituals and exclusion of certain types of garments are preconditions for a possible reuse of second hand clothes. As a consequence, underwear is considered as never reusable, even if washed or laundered (O'Reilly et al. 1984). The continuity of links within, and beyond, transmission has also been stressed by Lastovicka and Fernandez (2005) who emphasize the "common-identity shared self" that underlies transmission processes, even in non-family contexts.

In this study, I examine the meanings and representations that second hand buyers attached to other's possessions and contrast them with those of people who refuse to wear used clothes. More precisely, I try to uncover the reasons that are put forward to support their appropriation versus rejection processes and the underlying mechanisms that are at stake. The data come from a three-year survey conducted between 2003 and 2005 in Paris, France, that followed three steps: a first sample of eighteen second hand shoppers was recruited in different second hand outlets and settings to ensure a diversity of motives, profiles and types of clothes purchased; a second data set of 212 second hand consumers and non-consumers was built in order to get a broader knowledge of general behaviors toward previously worn clothes and to offer alternative insights; a third data set of twenty-two informants consisted in selecting respondents who could complete less common profiles such as male or older informants, enlighten unusual standpoints and provide negative cases.

The findings show that the appropriation/rejection processes of pre-used garments are both grounded in the categorization of the previous owner and in a possible or impossible negotiation of his/her territory. First, while for non-consumers the law of similarity is

confirmed along the lines of “the garment makes the man”, the fact that the former owner could be socially distant, totally unknown or morally unacceptable is not the only cause triggering rejection. This phenomenon is also linked to the feelings of deterritorialization and depersonalization that derive from the difficulty of re-inscribing the self into objects that remain first and foremost “inhabited”. From this standpoint, reusing second hand clothing prevents these respondents from extricating themselves from a confusion of identity with the other. Second, although the law of contagion states “once in contact, always in contact” (Mauss 1902/1972), the results seem also to contradict this assertion, as several respondents testify to the possibility of wearing used clothes under particular conditions, such as a second hand evening dress or suit for a fancy dress ball or a special event. Third, a large number of respondents occasionally (20%) or regularly (2%) purchase and/or wear second-hand clothes, even of unknown origin. The appropriation mechanism is based on a process of categorization of the seller as another oneself, someone who could be the buyer in his/her role of buyer, thus freeing the objects of their history and provenance. Clothes can thus be “emptied” of the presence of a prior owner and become re-appropriable by virtue of the exchange process. This neutral, depersonalized view of the object does not support the existence of a shared self in the sense intended by Lastovicka and Fernandez (2005), but of a shopping role community experienced in second hand buying.

“Exploring the Social Dynamics of Online Bartering”¹

Zeynep Arsel, Concordia University, USA

Informal exchange of used commodities has been an ongoing interest of consumer culture researchers. In their influential methodological piece that introduced the naturalistic inquiry to consumer researchers, Belk, Sherry and Wallendorf (1998) depict a swap meet as an anachronistic but alternative medium of exchange. Other studies of ownership transfer (Lastovicka and Fernandez 2005; Arnould and Curasi 2000; Herrmann and Soiffer 1984; Nelson, Rademacher and Paek 2007) explore similar angles and depict socio-cultural aspects of transferring personal goods to others. While previous researchers have exemplified many ritualistic, meaning-making and identity effects of ownership transfer, the social dynamics of the process and the way emerging marketplace structures function in these dynamics is an understudied territory.

This research explores how informal marketplace structures, more specifically bartering communities, mediate ownership transfer. While bartering might be perceived as an outdated form of exchange, quite a number of online bartering communities were formed in the last few years. Through online messaging and matching systems, individuals could participate in non-monetary transactions of a gamut of consumer goods such as video games, craft supplies, clothes, books, diapers, plant seeds and even used cosmetics. In the case of cosmetics, bartering sites provide a secondary market for goods that are otherwise disproportionately depreciated, contaminated, or even deemed illegal to sell in the formal economic markets. The system theoretically provides better efficiency in trade by reducing waste and establishing exchanges that account for the use value of commodities rather than their depreciated market values.

However, the system also introduces numerous consumer vulnerabilities. For example the ability to exchange previously unmarketable goods encourage some participants to act impulsively,

increase their perceptions of disposability, perpetuate compulsive variety seeking and foster the over-glorification of the treasure-hunt aspect of the medium. Furthermore, a great proportion of the products that are bartered with complete strangers are previously used cosmetics items that potentially pose health risks to their new owners. Likewise, these grassroots marketplace systems are also structurally vulnerable, in the sense that the usual safeguards of formal economy, such as consumer protection institutions, do not support them. Lastly, the social stigma of seeking returns from goods by violating the alienability and hygiene norms of the formal marketplace creates anxieties in the participants.

Drawing from multi-sited netnographic fieldwork and in-depth interviews, I explore the social dynamics of this complex marketplace system. My presentation aims to highlight four processes that sustain this otherwise risky and stigmatizing exchange behavior: humanizing (de-commercializing and de-stigmatizing), hedging (risk reducing), circulating (alienability) and vigilantism (policing). Humanizing is performed by socializing throughout the exchange and ritualizing the process akin to reciprocal gift giving. Furthermore, the participants challenge the apprehensions of using potentially contaminated products through apothecizing the previous owners and differentiating them from the *hoi polloi* in terms of personal ethics and hygiene. Hedging is maintained by a complex status hierarchy where the majority of the risk is transferred to newer members of the community until they are proven reliable. Furthermore, members of swapping communities protect themselves by establishing idiosyncratic principles of exchange and shipping. Circulating corresponds to perpetual re-bartering items after a period of use, which is subjectively experienced as borrowing or sampling, rather than owning. This serves as a preventative strategy to hoarding, while satisfying variety-seeking impulses. Lastly, since there are almost no consequences of fraud within these communities, members seek justice through vigilantism, more specifically by publicizing and slandering the names of those who act dishonestly through third party web sites they establish.

Through these four processes, the participants of this online community create a self-sustaining, self-regulating and interactive marketplace system, which facilitates exchanges that customarily violate the legal, economic and hygiene norms of the formal marketplace. My findings not only theoretically advance our understanding of ownership transfer, alienability, risk and consumer communities, but also highlight issues that are of interest to marketing practitioners and policymakers and provide them with directions to make better informed decisions and policies regarding secondary markets.

“Market-Mediated Collaborative Consumption in the context of Car Sharing”

Fleura Bardhi, Northeastern University, USA

Giana M. Eckhardt, Suffolk University, USA

Rifkin (2000) suggests that in today’s hypercapitalist economy, buying and owning things are outmoded ideas. Rather, consumers want access to goods, and prefer to pay for the experience of using a consumption object rather than buying it. Indeed, during the last decade, we have seen the development and popularity of alternative consumption models which involve sharing or pooling of resources/products/services (Belk 1997, forthcoming). Examples of such collective consumption models vary from time-share real-estate, to more recent developments in car-sharing programs (e.g. Zipcar.com), bag sharing programs (e.g. Bagborroworsteal.com), and jewelry renting programs (e.g. Adornbrides.com and Borrowedbling.com). While sharing has been and continues to be the norm in some cultures and social contexts, such as within the family (Belk forthcoming; Epp and Price 2008), observers argue

¹The author thanks ACR Transformative Research Grants and Social Sciences and Humanities Research Council of Canada for their financial support for this project.

that models of collaborative consumption mediated by the marketplace, such as Zipcar, are and will continue to gain popularity fueled by the internet, as well as by a capitalist marketplace trading in cultural resources rather than material objects (Belk forthcoming, Rifkin 2000). The goal of this research is to examine this model of collective consumption when it is mediated by the marketplace.

Shared consumption has received little attention in the marketing literature. Recently Belk (2007, forthcoming) conceptualizes sharing in consumption as an alternative to the private ownership emphasized in both marketplace exchange and gift-giving. In sharing, two or more people may enjoy the benefits and costs that flow from possessing a thing. "Rather than distinguish what is mine and yours, sharing defines something as ours" (Belk 2007, p. 127). Sharing includes joint ownership, voluntary lending and borrowing, pooling and allocation of resources, and authorized use of public property. There are two types of sharing: sharing in and sharing out (Belk forthcoming), which correspond to altruistic sharing and what we call collaborative consumption. Sharing in is altruistic, involves gift-giving, and expands the extended self by expanding the domain of common property. Examples of this are the consumption of shared property or shared meals within the family by family members. Within the sharing-in consumption model, Belk (forthcoming) finds that shared consumption enables family members to create bonds/feel part of a collective, extend the self to the family, and is guided by norms of generalized reciprocity (Sahlins 1972). However, the marketplace mediated shared consumption models such as Zipcar, or collaborative consumption (Felson and Spaeth 1978), divides a resource among discrete economic interests, preserves the self/other boundary and does not involve expanding the sphere of aggregate expended self beyond the family. In this sharing out model of consumption, consumers do not own or possess the product/services, but share its consumption, which is motivated by non-altruistic concerns. While altruistic sharing is beginning to be investigated in the literature (Belk forthcoming), collaborative consumption has not been examined.

As such, in this study we examine the role of the marketplace in collaborative consumption. Belk (2007) suggests that commoditization of shared possessions doesn't change or eliminate its value. We examine this claim empirically in the context of car sharing. More specifically, we examine consumer motivations for participating in car sharing, compare and contrast the model with car ownership, and investigate the role of the company in mediating the model. The data for the study is based on 45 semi-structured interviews with Zipcar customers. Zipcar is currently the market leader in car-sharing in the US. Zipcar has 180,000 members, who pay at least \$50 a year to access cars in 50 cities in US and the UK and its business hit \$100 million in revenue in 2008 (Frankel 2008; Naughton 2008). For about \$10 per hour, which includes gas and insurance, Zipcar customers can use any car located conveniently near them. Our results highlight the lack of brand community, the paradox of freedom within car sharing, and the lack of responsibility present in the model. We discuss the implications of our findings for theories of brand building, brand community, and gift giving/sharing.

SPECIAL SESSION SUMMARY

Customization and Consumer Choice

Aner Sela, Stanford University, USA

SESSION OVERVIEW

Marketing is increasingly seen as an interactive process in which sellers and buyers rely on each other to co-create value (Alba et al. 1997). One of the most prominent strategies reflecting this development is offer customization, the process by which individual components of an offer are selected and modified to provide consumers with offers that match their individually stated preferences (e.g., Ansari and Mela 2003; Pine, Peppers and Rogers 1995). The assumptions underlying customization are that if consumers' preferences can only be revealed, customized offers will provide them with superior fit and satisfaction, reduce information overload, and ultimately increase perceived value, purchase likelihood, and loyalty (Simonson 2005).

However, despite the importance of customization, we still know relatively little about the conditions under which these fundamental assumptions actually hold. The present session seeks to address this topic and provide new insights into the factors that determine consumers' choices under different customization modes, their evaluation and likelihood of acceptance of the customized offer, and their ensuing satisfaction.

One of the central variables in every implementation of customization is the procedure by which preferences are elicited. This is especially true in the case of self-customization, the process by which consumers customize offerings to their own preferences. The paper by Ana Valenzuela, Ravi Dhar, and Florian Zettelmeyer examines whether and how the self-customization procedure (by-attribute versus by-alternative) influences the subjective experience of making the decision and, consequently, the construction of preferences. This research suggests that because customization by-attribute is associated with a smaller choice conflict, it tends to increase the willingness to purchase the customized option as well as the satisfaction consumers derive from it.

Another important question relates to the consequences of customization in different contexts. Providing consumers with individually customized offers is an effective strategy in general, but are there conditions under which customization can actually undermine, rather than enhance, the attractiveness of offers? The paper by Aner Sela, Itamar Simonson, and Ran Kivetz suggests that explicit customization by the marketer can undermine the perceived value of seeming "opportunities", such as offers presented as special bargains. This is because customized offers tend to be perceived as reflecting the marketer's self-interested intentions, thereby reaping any above-normal gain from the transaction. Thus, although customization is a positive signal by itself, indicating a better fit to the consumer's preferences, this research suggests that its effect on value perceptions may depend on other characteristics of the transaction.

Finally, self-customization typically involves either sequential or simultaneous evaluation of the offer's individual components. The paper by Alexander Chernev examines the impact of the evaluation mode on consumers' perceptions of the customized offer's overall value. The investigation is conducted in the important context of selecting food items from a menu to form a customized meal. Specifically, when evaluating vice and virtue combinations simultaneously, consumers tend to underestimate overall calorie content such that the combined meal can be perceived as having fewer calories than the unhealthy item alone. When a virtue item is evaluated before a vice item, however, consumers tend to overestimate the overall calorie content of the customized meal.

This session highlights the importance of understanding how specific procedures (e.g., presentation order and evaluation mode) and contexts (e.g., bargain offers) can affect consumers' perceptions and acceptance of customized offers. The session would be of interest to researchers and marketers interested in consumer judgment and decision making and choice theory.

EXTENDED ABSTRACTS

"Contingent Consumer Response to Self-Customization Procedures: Implications for Decision Satisfaction and Choice"

Ana Valenzuela, Baruch College, USA

Ravi Dhar, Yale University, USA

Florian Zettelmeyer, University of California-Berkeley, USA

The opportunity to self-customize products and services tailored to individual preferences is viewed as an important way to enhance customer relationships and reduce competitive threats. An implicit assumption for the superior value of self-customization is the notion that consumers have inherent preferences (Simonson 2008) and are able to construct the customized offer that best fits their preferences compared to a non-customized offer. This paper focuses on comparing two formats designed to help consumers self-customize a product among a large set of feasible options. We demonstrate that the two most common methods for self-customization can result in a different consumer construction processes as well as different options being chosen as most preferred.

Furthermore, consistent with the established notion that consumers have limited insight into their preferences (Simonson 2005), the construction process of self-customization may also determine consumers' post-hoc evaluations of the customized option. In particular, customers' assessment of the customized option is likely to be affected by the ease or difficulty experienced in the process of customizing (e.g. Novemsky, Dhar, Schwarz and Simonson 2007). In this paper, we differentiate between two sources of difficulty associated with the constructed choice. One source arises from choice complexity due to the sheer amount of information that requires processing as the number of available options increases (Huffman and Kahn 1998). A second source is based on an explicit consideration of between-attribute tradeoffs (Dhar 1997), that is, the extent to which the customization format makes trade-offs between competing characteristics (or quality attributes) more or

less explicit. Regardless of the source of difficulty (i.e., whether it is based on processing large amount of information or based on making fewer effortful competing tradeoffs), we show that the subjective feeling of difficulty during self-customization may affect choice processes and outcomes.

Specifically, the studies in this paper highlight the effect of the two most often used self-customization procedures on consumer choice processes and preferred outcomes: i) the by-alternative customization method, which allows consumers to customize by identifying their most preferred option from a set of fully specified products; ii) the by-attribute customization method, which lets consumers decide one-by-one the desired level of each product attribute. Studies 1a and 1b show that consumers tend to choose intermediate options significantly more often when they customize a product by-attribute than when they customize by-alternative. This implies that when consumers have to make price-quality tradeoffs for each attribute in isolation, they base their choices on the ordinal position of options in the choice set. As a consequence, they perform a series of two-dimensional "compromises" between price and the particular (quality) attribute being customized. On the other hand, respondents in the by-alternative customization procedure have to perform multiple-way tradeoffs between different attributes, which makes it much harder for them to identify these "2-dimensional compromises" and, therefore, the compromise option itself.

Two additional studies support that self-customization procedures influence the construction of preferences and the subjective experience of making the decision. In particular, Study 2 shows that by-attribute customization reduces choice difficulty, enhances satisfaction and increases the probability that the customized option will actually be purchased. However, the decrease in experience difficulty in by-attribute customization is not solely due to the reduced choice complexity and information overload but is also driven by the fact that tradeoffs among competing characteristics are less explicit. By-attribute self-customization reduces emotional trade-off difficulty because of framing choice as a decision between each individual (quality) attribute level and price. In contrast, by-alternative self-customization makes consumers explicitly give up one specific (quality) attribute for another. Accordingly, if consumers were to encounter a by-attribute self-customization task which made competing (quality) attribute tradeoffs explicit, they should experience the same negative effects found in Study 2 for by-alternative self-customization. In line with this, Study 3 shows that when tradeoffs among attributes are made salient, decision conflict, satisfaction, and willingness to purchase are at a similar level to that associated with by-alternative customization.

Our findings contribute to the literature in several different ways. Customization allows consumers to exert control over shopping decisions. Our findings empirically show that differences in the experience of decision difficulty in the two self-customization modes affect consumers' decision satisfaction and their willingness to purchase the customized option. Results also support that the decrease in experienced difficulty in by-attribute customization is not solely due to the reduced choice complexity and information load but rather to less explicit tradeoffs among competing characteristics.

- Marketing researchers and practitioners alike have long emphasized the benefits of customizing offers to match consumers' individual needs and preferences (e.g., Ansari and Mela 2003; Pine et al. 1995). Customization can reduce information overload, provide consumers with superior fit and satisfaction, and increase loyalty and purchase likelihood. Moreover, because consumers often do not have well-defined preferences, a "customized" label, by itself, can increase the perceived fit of the offer, thereby increasing its attractiveness (Simonson 2005).
- However, are there conditions under which customization can undermine, rather than enhance, the attractiveness of offers? The present research suggests that under certain conditions, marketing offers that are presented as tailored to the consumer's individual circumstances or preferences may be perceived as less attractive than self-discovered opportunities that consumers perceive as valuable to them by coincidence.
- Specifically, it is proposed that consumers seek opportunities to "beat the market" by taking advantage of offers they believe happen to be more valuable to them, due to favorable personal circumstances, than what was intended by the marketer. Thus, the allure of such perceived opportunities is based on the implicit assumption that the consumer's distinctive circumstances indeed have not been taken into account by the marketer when the parameters of the offer (e.g., price) were designed. It is suggested that consumers tend to place a large weight on whether the fact that the offer has above-normal value for them is "transparent" to the marketer. Consequently, opportunities that are self-discovered and appear to the consumer as "unforeseen" by the marketer tend to be perceived as more attractive. In contrast, when consumers believe that the circumstances that make a certain option particularly advantageous for them have been "factored-in" by the marketer, they may perceive the deal as "fairly priced" for them rather than as representing above-normal value. Over-relying on such a cue can lead consumers to prefer a dominated, non-tailored option over a superior option which has been specifically tailored for them.
- Four studies, involving both real and hypothetical choices, support these propositions. Study 1 suggests that explicitly customizing a bargain offer, based on the stated preferences of the consumer, can undermine the attractiveness of the offer among people who believe they value the product more than the average person. Participants were offered to buy a subscription for *The Economist* magazine at 30% off the regular price. Half of them were told that the offer they received was selected randomly. The other half were told that the offer had been customized for them, based on their previously stated preferences. The results suggest that people who had indicated they were more interested in economic magazines than the average person were more likely to take advantage of the

offer when they believed it matched their preferences by coincidence (23%) than when it was said to be tailored for them based on the questionnaire (3%). Importantly, the effect of customization on choice was not affected by the chronic tendency to experience psychological reactance, casting doubt on the possibility that reactance was driving the effect.

Study 2 suggests that consumers who believe they value a particular option more than the average person may find a bargain offer more attractive when it is framed as designed to attract average consumers than when it is framed as designed for people "like them". Half of the participants were offered a subscription for *The Economist* at 25% off the regular price, framed as "intended to get the average person excited about *The Economist*". The other half were offered a subscription at 30% off the regular price, framed as "intended for the classic reader of *The Economist*: a special offer for people who would naturally find it interesting". Participants who had indicated that they were more interested in economic magazines than the average person were subsequently more likely to take advantage of the offer when it was framed as intended for average (27%) rather than for "classic" readers (4%).

Study 3 extends these findings to a situation where the offer is tailored to consumers' distinctive circumstances rather than their preferences. Participants received an offer to join a frequent flyer program. Half of them were required to accumulate 14,000 miles to receive a free ticket. The other half were required to accumulate 15,000 miles but were told that the 700 miles just traveled on their incoming flight would qualify toward their reward. Participants who received a 700 miles head-start were willing to pay more in order to join the program (\$9.5) than those who did not (\$3.6). However, the effect disappeared when the offer was said to be tailored for the particular flight people came with (\$5.3 vs. \$7, respectively). The effect of offer customization was mediated by the extent to which consumers believed it would be easier for them to accumulate the required mileage than would normally be the case.

Study 4 examines the role of accessible concepts and norms related to competition and self-interestedness in these effects. Participants were primed with either business-related or neutral stimuli (Kay et al. 2004). They then considered a bargain offer which either seemed particularly valuable to them by coincidence or was targeted at them by a marketer who was informed about their circumstances. Participants found the offer less attractive when it had been tailored for them ($M=4.2$) than when it matched their preferences by coincidence ($M=5.2$). However, this effect was significantly stronger among participants primed with business-related stimuli ($M=3.3$ vs. $M=5.3$). This result is consistent with the notion that the effect of customization on choice is driven by consumers' lay theories about marketers' self-interested behaviors (Friestad and Wright 1994; Wright 2002).

Taken together, the studies suggest that consumers tend to associate offers with above-normal value more when they perceive them as self-discovered and "unforeseen" by the marketer, rather than as tailored especially for the consumer's individual circumstances. These findings have theoretical implications for understanding consumers' perceptions of marketing offers, as well as important practical implications for designing customized offers and targeted promotions.

- "Menu Customization and Calorie Estimation Biases in Consumer Choice"**
Alexander Chernev, Northwestern University, USA
- Customization of offers typically involves deciding on which components to combine, as well as deciding on the sequence in which these items are presented to consumers. This research explores the impact of these decisions on consumer value judgments in the context of food consumption, where value is reflected in consumers' evaluations of the calorie content of the available items. For example, assembling a full meal from an a la carte menu might involve evaluating the caloric content of individual dishes in different categories. In particular, this research examines consumer evaluations of combinations of items classified as vices and virtues. From a conceptual standpoint, the issue of how consumers estimate the calorie content of vice/virtue combinations raises the more general question of how individuals derive numeric estimates of categorically opposite items. The goal of this research, therefore, is to investigate the decision processes leading to the formation of caloric estimates of vice/virtue combinations in a customized bundle and identify potential biases that are likely to occur in deriving such estimates.
- Conventional wisdom suggests that deriving calorie estimates of combinations of food items should be fairly trivial, such that the calorie content of a meal comprising several items should be equal to the sum of the calorie estimates of the individual items. This research argues, however, that this is not always the case and that people display systematic biases in evaluating the calorie content of combinations of items. Specifically, when evaluating vice/virtue combinations, consumers tend to underestimate their calorie content, such that the combined meal can be perceived not only as having fewer calories than the sum of its individual components, but also as having fewer calories than the unhealthy item alone. This leads to the paradoxical finding that adding a virtue to a vice can lower the perceived calorie content of the combined meal.
- This research further documents that the underestimation effect in evaluating vice/virtue combinations is contingent on the mode in which information is presented, and that it occurs only in scenarios in which options are presented simultaneously. When items are presented sequentially, however, the nature of the estimation bias is a function of the sequence in which options are presented, such that a virtue followed by a vice leads to an overestimation (rather than an underestimation) of their combined calorie content.

These underestimation/overestimation biases are attributed to the qualitative nature of people's information processing, stemming from categorizing food items into virtues and vices. It is argued that when evaluating combinations of vices and virtues, people use an averaging heuristic, which leads them to believe that the combination of a vice and a virtue has fewer calories than the vice alone. In contrast, when options are presented in a sequential manner, consumers tend to anchor on the virtue and overestimate the calorie content of the vice—a contrast effect resulting from the semantically opposite nature of virtues and vices. These decision biases are examined in a series of six empirical studies, which investigate their underlying mechanisms and identify boundary conditions.

The first set of three experiments examines the underestimation bias in simultaneous evaluations of vice/virtue combinations. In particular, Experiment 1 documents the existence of the bias and shows that adding a virtue to a vice can lead to an underestimation bias, whereby the vice/virtue combination is perceived to have fewer calories than the vice alone. Experiment 2 further investigates the underestimation bias by documenting that it is likely to be a function of the extremity of the virtue added to the vice and is more pronounced in the presence of more extreme virtues. Building on these findings, Experiment 3 examines the availability of alternative means for inferring calorie content, showing that the underestimation bias can be attenuated and even reversed when option size is made salient and individuals use it to infer options' calorie content.

The second set of experiments examines the overestimation bias in sequential evaluations of vice/virtue combinations. Experiment 4 documents the presence of contrast effects in sequential evaluations, showing that consumers tend to overestimate the calorie content of a vice preceded by a virtue. Experiment 5 further tests the theory by illustrating that contrast effects are a function of the type of categorization and that they are more pronounced when the vice/virtue categorization is made more salient and attenuated when an alternative (price-based) categorization is made salient. Finally, Experiment 6 lends support to the categorization theory by providing evidence that the observed contrast in numeric estimates is a function of individuals' awareness of the magnitude of the differences between the available options, such that it is attenuated in cases when the sequential evaluation is preceded by an initial overall evaluation of the options in the choice set.

SPECIAL SESSION SUMMARY

Nudging Consumers Towards Healthier Food Choices

Pierre Chandon, INSEAD, France

EXTENDED ABSTRACTS

“Vicarious Goal Fulfillment: When the Mere Presence of a Healthy Option Leads to an Ironically Indulgent Decision”

Keith Wilcox, Babson College, USA

Beth Vallen, Loyola College, USA

Lauren G. Block, Baruch College, CUNY, USA

Gavan Fitzsimons, Duke University, USA

In response to mounting criticism that their offerings contribute to rising obesity rates, many fast food chains have added healthier options to their menus. While this menu expansion has been beneficial for consumers who tend to make healthier meal choices, its effect is far from ubiquitous. In fact, much of McDonald's recent financial success is not attributed to new healthy menu additions, but rather to increased sales of more indulgent options like burgers and fries (Case 2006). With the increased availability of nutritious menu options, why have more consumers not swapped their french fries for salad? In this paper, we present evidence that for many consumers, the mere presence of such alternatives can, ironically, increase the consumption of the unhealthiest item on the menu.

Recent research suggests that individuals license themselves to indulge in temptations when they have previously acted in line with a long-term goal. This research suggests that when individuals focus on their progress towards a focal goal, it allows them to temporarily disengage from that goal to pursue indulgent alternatives (Fishbach and Dhar 2005). Related research on the licensing effect shows that prior virtuous behavior—or even intentions to act in such a manner—provides individuals with the rationale for activities and choices that are not in line with long-term goals (Khan and Dhar 2007). We extend this reasoning to suggest that when individuals have the opportunity to engage in a course of action that is consistent with healthy eating goals, the consideration of this option will satisfy the goal—at least temporarily—and, in turn, license them to indulge. Moreover, we suggest that this licensing effect does not merely result in the selection of a less healthy option, but rather the most indulgent option available.

Interestingly, the goal activation processes that underlie this behavior suggests an ironic effect of sorts at the individual level; namely that the effect will be accentuated for individuals who are high in self-control. Previous research has shown that individuals high in self-control have more accessible cognitions associated with the achievement of long-term goals compared to those low in self-control, thus demonstrating a greater focus on achieving important long-term objectives (Giner-Sorolla 2001). In addition, high self-control individuals are also likely to rely more heavily on cues that justify indulgent choices (Kivetz and Zheng 2006). Thus, we predict that the mere presence of a healthy item in a choice set of less healthy food alternatives will result in a greater likelihood of choosing the least healthy item for individuals with high self-control.

In study 1, we presented respondents with side dish menus consisting of either relatively unhealthy food items (i.e., french fries, chicken nuggets and baked potato) or the same items in addition to a relatively healthy item (i.e., salad). We found that, ironically, when the healthy alternative was added to a menu, it increased the likelihood of selecting the most indulgent option for people with high self-control.

Our second study replicated the findings of study 1 in two different, food-related contexts, specifically the selection of an entrée and the choice of a within-category packaged snack food.

Study 3 provided direct evidence of goal activation/fulfillment as the underlying process. When the choice set did not include a healthy option, higher levels of self-control corresponded to faster response times to health-related words, indicating greater activation of these goals relative to lower levels of self-control. Interestingly, when the choice set did include a healthy option, the response times to health-related words for high self-control individuals were slower, demonstrating less accessibility when the choice set includes a healthy option, compared to when the healthy option was not included. In other words, while high self-control individuals are better equipped to activate self-control in response to tempting stimuli, they are also highly susceptible to cues that reduce the threat imposed by tempting stimuli and, as such, are likely to fail in self-control efforts under some conditions.

Our final study provided additional support for our proposed goal activation process using a categorization approach to demonstrate vicarious goal fulfillment. Prior research (Ratneshwar et al. 2001) shows that accessible health goals lead individuals to rate food items with different levels of healthfulness as less similar to one another, while individuals with less accessible health goals rate such items as more similar to one another. In study 4, we show that the presence of the healthy item increases the perceived similarity of the items for individuals with high self-control compared to when the healthy item is not present. Importantly, we show that once healthy eating goals are fulfilled and perceived similarity among items in the choice set is high, high self-control individuals pay more attention to the most indulgent option in the choice set. Thus, we demonstrate that high self-control individuals increase the amount of attention paid to the most indulgent option in the choice set, explaining why the most indulgent option, rather than any indulgent option, is chosen.

The most obvious implication of these findings is that, despite the rush to offer healthier food alternatives, this trend may be doing little to alleviate the deeper societal issue of rising waistlines. Interestingly, while the waistlines of many consumers might be suffering as a result of the inclusion of healthier menu options, food retailers appear to be reaping substantial benefits. For instance, a recent consumer loyalty study ranks McDonald's as the front-runner in the fast food category (Hein 2008). Typically low in the rankings, McDonald's turnaround performance this year has been attributed, in part, to the inclusion of healthier alternatives that increase menu variety. Therefore, while the inclusion of healthy items is driving some consumers to make less optimal food choices, it appears to be increasing their satisfaction with food retailers and, perhaps, the choices themselves. Thus, an understanding of goal fulfillment processes is of substantial importance for understanding consumer behaviour at the individual level, as well as broader issues like the U.S. obesity epidemic.

"Rejection is Good for Your Health: The Influence of Decision Strategy on Food and Drink Choices"

Jane Machin, Virginia Polytechnic Institute and State University, USA

Yong Wan Park, Virginia Polytechnic Institute and State University, USA

A hungry woman stands at a breakfast buffet deciding whether to consume an apple or a donut. Can she be nudged towards the apple simply by thinking about which option to reject, rather than which option to select? Laboratory studies provide support for this idea.

Decision strategy is the process used to make a choice: a rejection-based decision strategy occurs when the primary focus of the decision is on rejecting the undesired option(s) whereas a selection-based decision strategy occurs when the primary focus of the decision is on selecting the desired option. Prior research suggests that selection and rejection are not complementary strategies (e.g. Shafir, 1999). Of importance here is the finding that using a different decision strategy can lead to preference reversal in choice sets where one option has stronger positive attributes but also stronger negative attributes relative to another more neutral option. The positive information is weighted more heavily when using a selection-based decision strategy, but the negative information is given more attention when using a rejection-based decision strategy, resulting in the enriched option being both selected and rejected more frequently than the impoverished option.¹

We extend findings in this literature to the area of food decisions, improving our knowledge of the food and drink decision making process and providing a simple intervention to improve dietary choices. Specifically, we propose that unhealthy foods are often spontaneously construed as enriched options. A donut, for example, is very high in calories (a strong negative attribute) but tastes great (a strong positive attribute). An apple, on the other hand is, relatively, more neutral. In support of this idea, Raghunathan, Naylor & Hoyer (2006) find that consumers rate unhealthy foods as better tasting than healthy foods. Combining these two research streams leads to the proposition that, compared to selectors, rejecters will spontaneously focus more attention on the negative attributes of the enriched option (e.g. the relatively high calorie content), leading them to reject this option and consume the alternative,

relatively healthier option. Selectors, on the other hand, will focus more attention on the positive attributes of the enriched option (e.g. the superior taste), leading them to consume it.

Shafir (1993) provides some early support for this proposition in his Problem 6 (p 551). Our research extends Shafir's finding in numerous ways. First, in Shafir's vignette, rejecters received supplementary information and were also artificially endowed with both options. To demonstrate that the results replicate in more natural situations, information about the choice options was held constant between selectors and rejecters in all our studies and only decision strategy differed. For example, Study 1a presented identical information about the healthiness and taste of two types of frozen dessert to all participants. Half the participants were then asked "which do you want to eat" while the other half were simply asked "which do you not want to eat?" Consistent with the hypothesis, participants who chose by rejecting the dessert they did not want were significantly more likely to choose the healthier option. Study 1b replicated this result in a drink choice situation. Rejecters were significantly more likely to select the healthy option (mineral water) compared to selectors.

More importantly, Shafir's participants were given explicit information about both health and taste attributes. In the real world, however, such overt information is often not readily available. Building on the "unhealthy=tasty intuition" (Raghunathan, Naylor & Hoyer 2006) we expect that participants, spontaneously inferring that unhealthy options will taste better, will both select and reject the unhealthy options more frequently. Results confirm this hypothesis. Study 2 demonstrates that using a rejection-based decision strategy leads to healthier food choices when only health information is provided. Participants were given a real choice between three types of cracker, varying in the degree of fat they contained. Compared to participants who chose by selection, participants who chose by rejection were significantly more likely to choose the healthiest cracker. Study 3 removed all explicit information about the options. Participants were shown a mock drink vending machine where the brand names of various drink options were visible, but no explicit health or taste information was presented. Once again, participants who chose by rejection were significantly more likely to choose the healthier option (bottled water) compared to participants who chose by selection. Additional analyses in studies 2 and 3 demonstrate that differences in beliefs about the relative taste of the options mediate the relationship between decision strategy and choice.

Study 4 extends the findings to a situation where actual dietary information could be analyzed to provide an objective reference point regarding the healthiness of the choice. Participants were presented with a take-out menu from Arby's and asked to choose a meal for lunch that day by either selecting the items they wanted or rejecting the items they did not want. Rejecters made objectively healthier meal choices. For example, the total carbohydrate count in the meals chosen by selectors was significantly higher than that of the meals chosen by rejecters and the total grams of fat in the meals chosen by selectors was significantly higher than that in the meals chosen by rejecters.

In all the above studies, decision strategy was manipulated. While these demonstrate that consumers can be encouraged to adopt a rejection based decision strategy, leading to healthier choices, there is little understanding whether rejection-based decision making ever occurs spontaneously. Study 5 presented participants with a variety of choice situations and, using language meant to be as neutral as possible, asked participants to "indicate their decision". Compared to those who used a selection-based decision strategy, participants who spontaneously reported using a rejection-based decision strategy were significantly more likely to

¹The term "enriched" has a specific meaning within research on nutrition (i.e. vitamins have been added to the food; Doyon and Labrecque 2008) that is not relevant here. Enriched is used only as Shafir (1999) defines it, to refer to the option with more positive as well as more negative dimensions.

choose frozen yogurt over ice cream, an apple over a donut and a medium size fast food meal over a large size.

Marketers of healthy food products could easily encourage the use of a rejection-based decision strategy through, for example, comparative advertising techniques and in-store decision aids, helping to nudge consumers to “have it their way—more healthily”—more apples, less donuts.

“Linearize This! Why Consumers Underestimate Food Portion Changes and How to Help Them”

Pierre Chandon, INSEAD, France

Nailya Ordabayeva, INSEAD, France

Because large packages and portions lead to greater consumption, the trends towards supersized food portions and packages is considered one of the prime drivers of the obesity epidemic (Cutler et al. 2003; Nielsen and Popkin 2003). Supersizing leads to overeating because people do not realize just how big these portions are. Therefore, improving people’s size estimations is essential to help consumers choose smaller, and healthier, portions sizes (Chandon and Wansink 2007). In this research, we examine how consumers estimate changes in package and portion size and what can be done to improve their estimations.

Research in psychophysics has shown that people’s estimations of object size follow an inelastic power function of its actual size (Estimated size = $a \times (\text{Actual size})^b$, where $b < 1$), which means that people underestimate the magnitude of size changes (Stevens 1986). In previous research (Chandon and Ordabayeva 2009), we showed that size estimations are even less elastic when a package increases or decreases along all three dimensions (height, length, and width) rather than a single dimension in space (e.g., only in height). However, we still do not know why this happens.

As suggested by prior research (Raghubir 2007), we examine two potential causes of these psychophysical biases—information integration (i.e., incorrectly integrating dimensions) and information attention (i.e., ignoring some dimensions). We further hypothesize that the key problem is biased information integration caused by the reliance on an additive model of size change (vs. the correct multiplicative one). Specifically, we hypothesize that consumers add the increases in package dimensions instead of multiplying them. As a result, people think that a 26% increase in height, width, and length increases volume by 78% ($26+26+26$) when, in reality, it increases volume by 100%.

Our model leads to several testable hypotheses. First, it predicts that consumers accurately estimate size changes when they occur along a single spatial dimension but underestimate size changes when they occur along two dimensions, and even more so when they occur along three dimensions. Second, linearizing size changes by decreasing the dimensionality of changes from 3D to 2D to 1D reduces the underestimation bias and increases the preference for large packages and portions (when people prefer more food to less). Third, because it is an information integration and not an

information attention bias, drawing attention to the fact that all three dimensions of a package change (i.e., by asking people to estimate the change in each of the three dimensions) does not reduce the underestimation bias or people’s size preferences. However, it is possible to improve people’s size change estimations by simply multiplying their (linear) estimations of the change in each of the three dimensions. We test these hypotheses in two studies.

In Study 1, we studied the effect of the two linearizing manipulations (dimensionality and decomposition estimation) on consumers’ size estimations for increasing packages. The participants saw pictures of four sizes of popcorn boxes which increased either in 1D, 2D or 3D (between-subjects). Participants were given the size and the price of the smallest box (A) and were asked to estimate the sizes and prices of the remaining three boxes. Participants in the decomposition estimation condition were also provided with the sizes of the dimensions of size A and were asked to estimate the dimensions of the remaining three boxes before providing their size estimations. As expected, we found that people underestimated the magnitude of supersizing ($b = .63$), and more so in 3D vs. 2D vs. 1D ($b = .48, .65, .73$, respectively). As expected, drawing attention to the fact that all three dimensions could be changing by asking people to estimate the size of each dimension did not improve their size estimations ($b = .62$) and did not reduce the effect of dimensionality ($b = .50, .54, .70$ in 3D, 2D and 1D conditions, respectively). All these results were also obtained when looking at willingness to pay, supporting our hypotheses. In addition, the additive model of information integration fit the data significantly better than the multiplicative model, suggesting that people do indeed add % changes instead of multiplying them.

In Study 2, we looked at increasing as well as decreasing package sizes, used real products (instead of pictures), and examined the effect of the two linearizing strategies on choice (and not just on size estimations and WTP). The participants saw four increasing or four decreasing sizes (between-subjects) of a rectangular candle and a cylindrical candy box displayed on the table. We manipulated the dimensionality of size change and decomposition between-subjects as in Study 1. In addition to size estimations and WTP, we asked the participants to indicate their preferred size for each product. We found that, for both supersizing and downsizing, decreasing the dimensionality of size change improved the accuracy of size estimations. Interestingly, we found that size estimations were steeper and more linear (and hence more accurate) for downsizing than for supersizing ($b = .75$ vs. $.85$ for supersizing vs. downsizing, respectively). As in Study 1, decomposition task did not improve size estimations or reduce the effect of dimensionality. Again, the additive model predicted size estimations better than the multiplicative model.

Study 2 also showed that decreasing the dimensionality of size change increased the preference for large sizes of both products (30% vs. 43% vs. 64% chose the largest two sizes in 3D, 2D, and 1D, respectively), as expected. However, the decomposition strategy increased the preference for large size of candles (from 30% to 46%) but decreased the preference for large sizes of candies (from 55% to 49%). This suggests that drawing attention to the three dimensions, although it did not improve people’s size estimations, activated more utilitarian goals and thus motivated people to choose larger (and cheaper) candle sizes but smaller (and healthier) candy sizes.

In a final study in progress, we are testing the conflicting predictions of the additive and multiplicative models when package dimensions change in opposite directions (e.g., the height of a cylinder increases, but its diameter decreases). This will allow us to test whether consumers can be fooled by downsized packages

which appear bigger than they actually are (because the strong % reduction in one dimension seems to be compensated by the % increase in two other dimensions).

Understanding what drives the underestimation of size changes should suggest effective strategies to improve consumers' perceptions of supersized and downsized packages and portions. Our findings suggest that packages that linearize the estimation problem (by reducing the dimensionality of size change) should nudge consumers toward healthier choices.

SPECIAL SESSION SUMMARY

The Interplay between Goal Categories and Effort

Antonios Stamatogiannakis, INSEAD, France

SESSION OVERVIEW

“Man is a goal seeking animal. His life only has meaning if he is reaching out and striving for his goals.” (Aristotle)

Dating back to the ancient Greeks, scholars have attempted to elucidate the motivational factors underlying human goals. The importance of understanding goals and their effects on effort has been recognized by consumer researchers as well. For instance, goals increase effort and do so more strongly for difficult and specific goals (Locke and Latham 1990). Further, as people move closer to their goal they are likely to invest more effort toward that goal (Kivetz, Urminsky and Zheng 2006), and goal progress interpretations influence whether people commit to or deviate from the goal (Fishbach and Dhar 2005). The three papers in this session integrate some of these perspectives in presenting a dynamic view of goals and effort.

The broad purpose of this session is to present work that adds to the growing body of research on the interplay of goals and effort. Specifically, this session examines 1) the effect of different goal types on effort and 2) the impact of effort investment on valuation of subsequent consumption items. While the first paper examines the impact of attainment versus maintenance goal on effort, the second paper extends the focus of the first paper by examining the impact of initial success in enhancing effort on a recurring goal. Finally, the third paper complements the first two papers by examining the impact of effort investment in a meaningful goal or task on the WTP for a subsequent consumption item. A twenty minute discussion led by Ayelet Fishbach will follow the three presentations.

Stamatogiannakis, Chattopadhyay and Chakravarti pit maintenance goals against attainment goals. They find that maintenance goals are judged as harder than objectively harder modest attainment goals. For example people think that it is easier to increase one's daily working out time by five minutes than to maintain its current level. This effect is driven by biased cognitive processing of goals. Finally, the authors show circumstances under which maintenance goals can be detrimental to performance, compared to attainment goals.

Nunes and Drèze investigate recurring goals, i.e., goals for which people strive again and again, like getting a reward from a loyalty program. They find that after initial success in such goals, consumers learn about their ability to succeed in the same goal again. This results in increased perceptions of self-efficacy and therefore increased motivation in future pursuits (Bandura 1982). Importantly, as successful completions increase, so does motivation.

Wadhwa and Trudel take a different approach and examine the moderating role of task and goal characteristics on the relationship between effort investment in and willingness to pay for a consumption item. First they demonstrate the “fruit of labor effect”, i.e., that investing effort in a meaningful task enhances the wanting for an associated consumption item. Further, they examine the role of meaningfulness of the task that requires effort, and the reward salience of the consumption item in moderating the proposed fruit of labor effects.

All three papers provide cutting edge counterintuitive insights into the goal processes that drive consumer behavior and decision

making. In addition to attracting researchers interested in the domains of goals and motivation, we expect further interest from those who work within the application areas represented.

EXTENDED ABSTRACT

“Maintenance versus Attainment Goals: Why People Think it Is Harder to Maintain their Weight than to Lose a Couple of Kilos”

Antonios Stamatogiannakis, INSEAD, France

Amitava Chattopadhyay, INSEAD, Singapore

Dipankar Chakravarti, Johns Hopkins University, USA

The goal setting literature posits that goal distance has a positive monotonic effect on subjective goal difficulty, after controlling for self-efficacy (Locke and Latham 1990). This literature usually assumes a discrepancy between an actual and a desired state (e.g., Kruglanski 1996), but fails to acknowledge maintenance goals, i.e., goals in which the actual and the desired states coincide, but there is a time difference between the present and the goal time horizon.

The violation of the state discrepancy assumption by maintenance goals, makes doubtful the extension of the relation between goal distance and subjective difficulty to this goal category, especially since several streams of research seem to suggest otherwise. First, based on Heath, Larrick, and Wu (1999), goals are reference points and people think that the same amount of progress gives more utility and leads to greater effort in the losses than in the gains domain. Maintenance goals actors are already on or beyond the goal-reference point-and thus in the gains domain-but attainment goals actors are in the losses domain. People then could infer more effort for attainment than for maintenance goals and thus believe that attainment goals are more likely to be achieved. Second, actions interpreted as progress towards a goal make people deviate from it, but actions interpreted as commitment to a goal make people highlight the achievement of that goal (Fishbach and Dhar 2005). People might feel that they have fully progressed towards a maintenance goal, but feel committed to a modest attainment goal, because with a little more effort they can achieve it. This would make people pursuing an attainment goal try harder than people pursuing a maintenance goal. If people have this lay theory, then subjective judgment of future success will be higher for attainment goals.

Finally, Gilovich, Kerr, and Medvec (1993) find that short temporal distance from goal results in the generation of more reasons for failure, but longer temporal distance results to the generation of more reasons for success. If we extrapolate this result to goal distance, we would predict that people facing maintenance (attainment) goals would generate more reasons for failure (success). Therefore, when making a difficulty judgment, they will view maintenance goals as more difficult.

In a series of five studies, where we manipulate goal type (maintenance vs. attainment) between participants, we document that maintenance goals are judged as more difficult to attain than modest attainment goals, we examine which of the mechanisms above account for this phenomenon, and we extend our results to effects on performance. The first three studies are scenario based. Scenarios about weight, GPA, daily working out time, money, and weekly sales goals are used. The first study documents that main-

tenance goals are judged as more difficult than modest attainment goals, and this effect can not be attributed to differences in expected motivation between the two goal types. This suggests that the differences are likely to be driven by differences in the cognitive processing of the two goal types.

The second study confirms this prediction. It replicates the main effect of study one, and further find that when people consider maintenance goals they tend to generate more reasons for failure but less reasons for success, compared to when they consider attainment goals. Differences in reason generation mediate differences in subjective difficulty, showing that the effect is driven by differences in cognitive processing.

The third study uses a 2 X 2 between participants factorial design. Some participants judged maintenance goals and some attainment goals. Further, some participants were given a cue which aimed to make success and failure equally salient, and therefore should attenuate the effect, while others received no cues. In the no cue condition, we replicate the result that people think maintenance goals are harder than attainment goals. However, in the cued condition, which made success and failure equally salient the effect disappeared, supporting the notion that biased cognitive processing is the source of the bias. Interestingly, the neutralizing cue had an impact only on attainment goals, and not on maintenance goals.

The fourth study replicates the above effect with a self-relevant goal. Specifically, participants had to solve two word-search puzzles. They indicated that it was harder to solve the second puzzle in at most the time they solved the first, compared to improve this time by a second. The results further demonstrate that difficulty judgments of attainment and maintenance goals are impacted differently when a high performance standard is active (Bargh et al. 2001). This is important given that such standards are often active in goal directed consumption cases.

Finally, study five extends the above results to a performance measure in a laboratory word search task. The results suggest that although the two goal types have similar effects on performance, maintenance goals can act as a cue that current state is good enough, and therefore hamper performance when a high performance standard is active (Bargh et al. 2001).

“Recurring Goals and Learning: The Impact of Successful Reward Attainment on Purchase Behavior”

Joseph Nunes, University of Southern California, USA

Xavier Drèze, University of Pennsylvania, USA

“If I did it once, I can do it again,” is a common mantra for those who have attained success. However, there is no indication regarding whether they will try as hard or harder the next time around. This research approaches the impact of loyalty programs and their rewards differently than previous research. Rather than model the impact of membership in a firm’s loyalty program or the nature of a program’s rewards on share-of-wallet, we look at the impact of successful reward redemption on future purchase behavior. More specifically, this research examines the long-term relationship between customers and the firm and whether successful reward redemption leads consumers to consolidate and/or accelerate their future purchases. While research has shown that progress toward a reward can lead consumers to accelerate their purchases, much less is known about how earning rewards can impact behavior. This research illustrates how success in a recurring goal framework allows consumers to learn something about themselves and leads them to amplify their effort in successive endeavors toward the same reward.

Kivetz et al. (2006) conducted a field study at a university café where participating customers were required to make 10 coffee

purchases in order to get one free. They found consumers who accelerated their purchases faster toward their first reward exhibited a greater probability of retention and faster reengagement in the program. Reengagement was assessed by comparing the time period between the last purchase toward earning the first reward and the first purchase toward earning the second reward. More relevant for our purposes is what happened with those who reengaged. Kivetz et al. (2006) found that for customers who earned the first reward, purchase rates slowed as they began working toward their second reward. Subsequently, purchase rates accelerated as cardholders neared the second reward, just as they had for the first reward. The authors dubbed this slowdown in the inter-purchase time between the first reward and first purchase toward the second reward as post-reward resetting. They argued resetting ruled out learning as an explanation for the acceleration in purchases observed as consumers approach a reward because this deceleration would imply what was learned had been suddenly forgotten.

We argue that the increase in effort brought on by successfully reaching a goal and earning a reward is due to learning-self-learning. Our interest is in thoroughly investigating consumers’ capacity to learn as a result of successful reward attainment. While post-reward resetting suggests the goal gradient phenomenon is not due to procedural learning, it does not preclude other forms of learning from taking place. We use the term self-learning to describe what Bandura (1982) called predictive learning; the reassessment of one’s self-efficacy. Self-efficacy refers to an individual’s perception of how well he or she can execute courses of actions to deal with prospective situations. Attaining a reward requires consumers to orchestrate their buying behavior in very specific ways. Consumers must schedule and steer purchases in a deliberate manner in order to earn rewards from select firms. Utility-maximizing individuals will modulate these efforts as a function of the perceived likelihood of success, which depends largely on judgments of how well they performed in the past.

In Study 1, we utilize real world frequent flier program data to show how success fosters reengagement; successful fliers begin the new year flying more frequently. In addition, reaching the goal of earning status impacts a flier’s likelihood of success in subsequent attempts of earning status. Study 2 reveals that only in cases where the reward is challenging enough, but not too challenging, does the impact of success affect forecasts of future effort. In Study 2, we use lab data based on scenarios to show that increasing divisibility or how frequently rewards are doled out (from \$1,000 to \$500), reframes a larger task as several smaller tasks and can boost people’s perceptions of self-efficacy. If they succeed once, albeit at reaching an easier goal, this tells them something about themselves. Conversely, too much divisibility or success arrived at too easily (rewards at every \$100) was shown to be de-motivating. Therefore, loyalty programs that offer people multiple redemption opportunities must balance the attractiveness of an award with an appropriate level of difficulty in attaining success. Finally, in Study 3, we explore the underlying process. The study was presented as a game whereby the respondent’s goal was to determine whether the experimenter was lying by judging his or her facial expressions. By partitioning a task differently (3 sets of 10 trials or one of 30 trials) and reframing the task as either complete or incomplete, we show how successfully reaching a pre-ordained goal enhances perceptions of self-efficacy while controlling for overall performance.

In all three studies, achieving more than one success is shown to matter. Hence, not only does goal attainment result in increased effort the second time around, but successive successes further elevate effort. We show how the successful attainment of a goal and the accompanying reward increases consumers’ motivation in

subsequent undertakings and that this increase in motivation can endure after more than one or two successes. From a practical perspective, all possible successes may not be entirely within the control of the firm. For example, frequent flier miles are becoming interchangeable with several other currencies and some can be redeemed at numerous second-party vendors. The result is myriad outside rewards that might qualify as successes. Earning 25,000 miles for a free roundtrip ticket is no longer the quintessential goal.

“The Fruit of Labor Effect”

Monica Wadhwa, *Stanford University, USA*

Remi Trudel, *University of Western Ontario, Canada*

Consumers often engage in experiences that require some level of effort from them. For instance, burgeoning hobby stores, such as “paint-your-own-pottery” or “make your own jewelry” stores, demonstrate consumers’ desire to invest effort. The aforementioned examples raise an interesting question—Could varying the effort required in an experience impact consumer’s evaluations for the associated consumption item? A pretest conducted with marketing experts indicates that the product associated with an experience that requires additional effort investment should be evaluated less favorably.

Interestingly, the implications of the findings from our pretest contradict those arising from an emerging body of research on the neurobiology of rewards. Recent research in this domain demonstrates that expending effort to earn a reward leads the ventral striatum (part of brain associated with motivational drive and reward processing) to be more intensely stimulated as compared to when no such effort is expended (Zink et al. 2004). Drawing upon this stream of research, we propose that investing a bit of effort in a task is likely to activate a motivational drive, and thereby enhance the wanting for the associated consumption item, a notion we term as the “fruit of labor” effect. Further, we argue that meaningfulness of the task that requires effort is essential for the fruit of labor effects to emerge. Specifically, when the meaningfulness of the task requiring effort is high (than when the meaningfulness is low), investing a bit of effort should enhance the wanting for the associated consumption item.

In order to examine the aforementioned propositions, in study 1, we employed a sampling task. Specifically, participants sampled a new brand of powdered energy drink purportedly meant to enhance mental acuity and intellectual performance. Effort required was manipulated by giving one group of participants premixed form of the drink (effort -absent). A second group of participants was asked to mix the drink and stir it for thirty seconds (effort -low), and a third group for three minutes (effort-high) so the crystals are properly dissolved. To manipulate the meaningfulness of the task (i.e., stirring the energy drink), prior to the sampling task, participants were either primed with an intellectual goal or were not primed with any goal. In line with the fruit of labor proposition, our results show that those primed with an intellectual goal stated higher WTP for the drink when they had invested a little bit of effort than when they had invested no effort. These participants also stated higher WTP than those not primed with the intellectual goal in the low-effort condition. Moreover, when the effort required was too high the impact of investing effort on WTP for the drink was attenuated. These results rule out alternative accounts related to cognitive dissonance and licensing, which would predict that participants in the high effort condition should have stated higher WTP than those in low effort condition.

Study 2 sought to achieve two main objectives. Besides providing further support for our fruit of labor proposition using a different manipulation for task meaningfulness, it also examines whether investing effort in one task can enhance wanting for a

subsequent reward that is not related to the task. We again employed an orange juice sampling task. Participants were told that as compensation for their participation in the study, \$1 would be donated to a charity. To do so, they would be provided with a coupon, which they would need to hand over to the experimenter at the sampling station. People in the high-effort condition cut out a coupon printed on a thick paper. Those in the low-effort condition were handed the same pre-cut coupon. To manipulate the task meaningfulness, we employed either a charity that participants could highly relate to—Ontario Cancer Foundation-(task-meaningfulness-high) or a charity that participants could not relate to as much—Canadian Landmine Eradication Awareness and Removal Project (CLEAR; task-meaningfulness-low). These charities were chosen based on a pretest. Subsequently, participants engaged in the orange juice sampling task and then indicated their WTP for it. As we predicted, effort investment positively impacted the WTP for the subsequently consumed orange juice, but only when task-meaningfulness was high (i.e., when participants cut the coupon for Cancer charity).

Study 3 examines the moderating role of reward salience of the consumption item. Extant motivation research suggests that when the salience of the reward is heightened prior to exerting effort in a task, the activated motivational drive is strengthened (Higgins 2006; Zink et al. 2004). Based on this logic, we argue when the reward salience of the subsequently sampled orange juice is heightened prior to investing effort in the task, the fruit of labor effect should get more pronounced. The procedure of this study closely paralleled that of study 2 with one major change. To manipulate the reward salience of the orange juice, the participants in incentive salience-high condition saw a color picture of a glass of orange juice along with the instructions for the sampling task, but those in the incentive salience-low condition saw only the instructions. In line with our predictions, we find that the participants in the effort - present condition were willing to pay more for the juice when the reward salience was high as compared to when it was low. However, when the effort investment was absent, there was no such difference in WTP between the reward salience high and the reward salience-low conditions.

In conclusion, while most of extant research on cost-benefit approach in the decision making literature considers effort as a cost (Russo and Doshier 1983), the present research suggests that the act of putting a little bit of effort in some consumption scenarios could in fact add value to the overall consumption experience. Implications for marketers are discussed.

SPECIAL SESSION SUMMARY

Is Identity Signaling so Great? Limitations and Negative Consequences

Rosellina Ferraro, University of Maryland, USA

SESSION OVERVIEW

People often buy products and brands for signaling who they are or who they want to be. Prior research has provided evidence for the phenomenon of identity signaling and shown how it affects choices. The four papers in this session expand the theory related to identity signaling by exploring boundary conditions, such as negative consequences and abandonment. Two of the papers propose that engaging in identity-signaling can backfire in its purpose. One of the papers explores the functioning of identity signaling when there is a competing goal. Finally, the fourth paper explores the abandonment of culturally created tastes as a form of identity signaling.

Ferraro, et al., argue that since identity-signaling serves an important communication function, it should be perceived positively by observers. Instead, it is perceived negatively as observers view identity signaling as extrinsically motivated and a reflection of an inauthentic self. Thus perceptions of authenticity mediate how much an observer likes the signaler. The authors also show that the signaler's perceived similarity to the observer moderates this effect. Han and Nunes also examine the response to identity signaling via the interactive dynamic between the signaler and the receiver. The authors propose that while the signaler expects to feel positive from engaging in signaling, she may instead feel embarrassment under certain conditions; specifically when the signal is more conspicuous and easy to recognize and when there is explicit acknowledgement of the signal by others. Chan and Van Boven examine the tension that exists between the conflicting motives of signaling group membership and expressing uniqueness. Research suggests that people express uniqueness by opting for products that are owned by fewer others, which contrasts with identity signaling research that indicates people signal social identity by behaving similarly to in-group members. The authors propose that the conflict may be reconciled via convergence at the brand level and divergence at the product level. Finally, Berger and Le Mens examine the abandonment of cultural tastes. They propose that the speed with which a taste is adopted (i.e., its popularity) determines how quickly that taste is abandoned. The speed reflects whether the taste is a fad and thus has symbolic value. The negative signal that would come from adopting a perceived fad leads to a greater likelihood that the taste is abandoned.

Each presenter (R. Ferraro, Y. Han, C. Chan, and G. Le Mens) has agreed to serve if the proposal is accepted. Questions will be taken at the end of the session. All data have been collected. This session will have wide appeal, including to scholars of self-identity, brand relationships, and product adoption.

EXTENDED ABSTRACTS

“Signaling Identity through Brands: The Role of Perceived Authenticity”

Rosellina Ferraro, University of Maryland, USA

Amna Kirmani, University of Maryland, USA

Ted Matherly, University of Maryland, USA

Consumers frequently purchase brands for the purpose of communicating information about the qualities they possess or the categories to which they belong. In other words, people use brands for identity signaling. Prior research suggests that identity signaling can satisfy consumers' association and communication goals. This

research, however, says little about how observers react to identity signaling. If identity signaling serves as an effective means of communication, recipients should interpret the signal as intended and should view the person favorably (assuming that the signaled trait is valued positively). We propose, instead, that identity signaling is perceived negatively by observers. This is because observers view identity signaling as an inauthentic means by which someone represents the self. Buying a brand for the sole purpose of conveying a particular identity may be seen to be motivated by extrinsic rewards, such as social approval, and thus a reflection of an inauthentic self. In contrast, buying a brand for intrinsic motives, such as for utilitarian benefits, is viewed as more authentic. Higher perceived authenticity is expected to translate into more favorable attitudes toward the signaler. We propose, however, that similarity to the signaler moderates the effects of purchase motives on perceived authenticity and attitude.

Study 1 examines perceptions of a target who uses a brand to signal identity compared to a target who uses the brand for utilitarian reasons or whose reason for using the brand is unspecified. Participants read about the motivation behind the target's purchase of a Toyota Prius. We expected that the target would be perceived as more authentic and likable when he bought the brand for utilitarian than for signaling reasons. The results indicate that a target engaged in identity signaling was perceived less favorably than the target whose brand usage was motivated by utilitarian reasons. Moreover, perceived authenticity appears to underlie these effects. The signaling motivation decreased perceptions of the target's authenticity, coolness, and intrinsic motivation, and increased perceptions that the target was extrinsically motivated.

Study 2 examines whether negative perceptions of identity signaling will be attenuated when the signaler is perceived to be similar to the observer. Research has found that people judge their own actions more positively than those of others, but that this asymmetry can be eliminated when the other person is perceived as similar. In our context, this is manifested in the belief that one behaves in a manner consistent with one's authentic self while others do not. We predict that this unfavorable perception of others' authenticity will be attenuated by perceptions of similarity to those others. Participants read a description of a target who recently bought an Apple computer. Motive was manipulated by varying the stated reason behind the target's purchase. Similarity was indicated via ownership of the brand. Brand users rated the target favorably regardless of his motive for buying the brand. Nonusers, however, liked the target less when he engaged in identity signaling. Authenticity, as measured by innovativeness, mediated the interactive effect of motivation and similarity on attitude.

The goal of study 3 was to test the predictions in a context in which the target's signaling motive is inferred rather than explicitly stated; specifically, in a public versus private setting. Because others can observe the target's behavior, the target is more likely to be actively managing the impression she is making when in public and as a consequence, an observer is more likely to infer an identity signaling motive. Participants read about the target, including details about the target's demographic information. This information was expected to serve as the basis for perceived similarity to the target. Motive was manipulated by varying whether the target read *The New York Times* in a public or private setting. Participants who felt highly similar to the target liked her equally across condition,

while participants who did not feel similar to the target liked her more when she was not engaged in identity-signaling than when she was engaged in identity-signaling. A similar pattern of results emerged for the perceived intelligence of the target. Authenticity mediated the interaction effect of motive and perceived similarity on liking and perceptions of intelligence.

In sum, observers respond negatively to identity signaling, and authenticity underlies this effect. However, the data also show that as the signaler is seen as more similar, the attitude becomes positive in nature.

“Read the Signal but Don’t Mention It: How Conspicuous Consumption Embarrasses the Signaler”

Young J. Han, University of Southern California, USA

Joseph C. Nunes, University of Southern California, USA

Research has shown consumers use products as communication devices when they express their desired self-identity and image to others. Among the most popular meanings consumers convey using products are wealth and status, what has been dubbed conspicuous consumption (Veblen 1899). Research on conspicuous consumption has focused on the intentions of the signaler, and has left the interaction between the signal provider and the recipient relatively unexplored. This research is a first step towards filling that gap.

When consumers engage in conspicuous consumption, they expect others to recognize and interpret their signals as they had intended. It is natural to expect that when an observer recognizes the sender’s signal and provides positive feedback, the sender should feel positive, both pleased and proud. However, across several studies we find when the targets of these signals acknowledge the signal, the sender is more likely to respond negatively, specifically by feeling embarrassed. Traditionally, embarrassment arises when a person believes their demeanor has been inappropriate and judged negatively by others (Edelman 1981). Or it can occur when someone feels his behavior, or some aspects of the self, needs to be carefully monitored, hidden, or changed (Goffman 1956). In other words, embarrassment can be elicited by sensitivity to social norms. Hence, if positive feedback on leads the signaler to worry about unexpressed and potentially negative judgments, the acknowledgement of a signal should lead to embarrassment.

This occurs in two ways. First, acknowledging a signal with a compliment may lead the signaler to believe their signal was too conspicuous because it encouraged an uncommon response. Compliments typically express goodwill toward the addressee and the primary response is affective. However, compliments can convey a referential meaning in that a particular aspect of the signaler was chosen for the speaker’s attention (Johnson and Roen 1992). In turn, the signaler may infer the speaker believes the signaler is being manipulative in attempting to make a particular impression. We hypothesize that the more conspicuous the signal, the more likely the signaler is to feel embarrassed when complimented by others. Second, if the signaler is communicating an inauthentic identity, explicit acknowledgement makes the false nature of the signal salient. When people are highly motivated to impress others and doubt their ability to do so, high social anxiety results, including the appearance of nervousness (Leary 1983). We explore how signalers respond to acknowledgement in four studies.

In Study 1, we test whether the false nature of signals influence a signaler’s level of embarrassment upon being complimented using a thought experiment. Respondents read a scenario that either described a woman who purchased a conspicuous designer handbag, or a bag that is far more subtle. We varied the extent to which the purchase was a financial stretch. Results reveal an interaction

such that respondents expected the woman to feel more embarrassed when the signal was loud and inauthentic and more proud and pleased when the signal was quiet and authentic. Study 2 is a field study focusing on the differential response by people identified and interviewed carrying either a conspicuous or an inconspicuous luxury handbag. During the interview the experimenter complimented the handbag. A recording of their emotional reaction was subsequently analyzed using Layered Voice Analysis (LVA) technology. Respondents also completed a survey designed to test the authenticity of the signal. Study 2 provides a real-world replication of Study 1—women carrying loud handbags were more embarrassed by the compliment and this effect was magnified if the signal was deemed inauthentic.

Study 3 examines the dynamic interaction between two signalers. Focusing on consumers utilizing a conspicuous signal, we focused on a signaler’s response to acknowledgement from someone also signaling, either conspicuously or inconspicuously. Upon being complimented, the signaler is less likely to become embarrassed or believe the recipient is being judgmental when the recipient is signaling conspicuously. Finally, study 4 examines the connection between conspicuousness and the authenticity perception of signaling behavior. In this study, we examine whether people possess inherent beliefs about the authenticity of a signal which depends on its relative conspicuousness. People were found to be more doubtful about the authenticity of a conspicuous signal. The results help explain why conspicuous signalers become anxious when their signal is acknowledged, even when it is legitimate.

Taken together, this research documents how consumers who deliberately signal more conspicuously, respond more negatively (i.e., are more embarrassed) when their signal is acknowledged. However, we find this embarrassment is attenuated when the recognition giver was also observed signaling loudly. Furthermore, the results reveal that even consumers who signal their true identity can feel embarrassed. The extent to which they feel this way is shown to depend on their beliefs about the interpretation of the signal and the authenticity of the signal.

“Satisfying Identity-Signaling and Uniqueness Motives through Consumer Choice”

Cindy Chan, Cornell University, USA

Jonah Berger, Wharton School of Business, USA

Leaf Van Boven, University of Colorado–Boulder, USA

Consumers concerned with conveying their social identity may often experience tension between communicating their group membership and communicating what makes them unique. Different research streams have separately examined different identity motives. Work on uniqueness suggests that people want to be (at least somewhat) unique (Snyder and Fromkin 1980). People with higher needs for differentiation, for example, prefer products owned by fewer others (Tian, Bearden, and Hunter 2001). Work on identity-signaling, in contrast, suggests that people behave similarly to in-group members to effectively communicate social identity. By converging on in-group preferences (and diverging on out-group preferences), people can signal group affiliation (Berger and Heath 2007).

Because uniqueness and identity-signaling are studied independently, however, little is known about how people integrate these motives through consumer choice. Are there systematic ways in which people signal identity while still differentiating themselves? Optimal Distinctiveness (Brewer 1991) suggests that by activating social identities, people simultaneously meet needs for assimilation (by identification with an in-group) and differentiation (by comparisons to out-groups). People do not behave identically to

in-group members, however, and thus we argue the need for distinctiveness continues at the intra-group level.

In particular, we focus on how choice at multiple product levels may allow consumers to satisfy both motives simultaneously. Consumers may select the same brand as their in-group, for example, but pick a slightly different product. Most research has taken a one-dimensional view of similarity and differentiation: people either select the same product as another person, or a different one. Real choice, however, is more nuanced and we explicitly allow for this. We argue that while consumers generally conform to in-group members on one level to effectively communicate social identity, they often simultaneously diverge at another level allowing them to also feel unique.

Experiments 1 and 2 provided a preliminary investigation of how consumers satisfy these different motives through choice. We asked people to identify an in-group and, across five consumer domains (e.g. shoes), to list two brands: one that was strongly associated with their in-group (Brand A), and one that was also liked by the group, but was a weaker signal of group identity (Brand B). They were next given information about the preferences of their in-group and asked to choose among four options. Specifically, they were told to imagine that out of 100 group members, 60 preferred Product 1 from Brand A, 17 preferred Product 2 from Brand A, 17 preferred Product 3 from Brand B, and 6 preferred Product 4 from Brand B. Thus, there was a majority (Product 1 and 3) and minority (Product 2 and 4) option from both a brand that would signal group identity, and a brand that would not. Participants also completed the Consumer Need for Uniqueness scale (CNFU; Tian et al. 2001).

As predicted, we found that people conformed on markers of group membership but differentiated within their group. At the brand level, people tended to choose brands that were more strongly associated with their in-group (i.e., Brand A). At the product level, however, people with higher CNFU strategically chose the less popular product from that brand (i.e., Product 2 from Brand A).

In Experiment 3, we varied the identity of the reference group by asking half of participants to list an in-group and half to list an out-group (the rest of the study was similar to Experiments 1 and 2). Consistent with an identity-signaling perspective, at the brand level, participants only tended to choose brands linked to their reference group when that group was their in-group, and this was mediated by their desire to signal that identity to others. People who had a greater desire to be associated with their reference group tended to choose options from brands linked to that group. At the product level, on the other hand, we again found that choice was driven by individual needs for differentiation. Participants with higher CNFU tended to select the minority option from the brand associated with their in-group.

Rather than measuring individual differences, Experiment 4 directly manipulated uniqueness-seeking with an image exposure task that primed half of participants with uniqueness (adapted from Maimaran and Wheeler 2008). They then completed the same choice task as in the prior studies. As predicted, uniqueness priming did not affect choices at the brand level—this was again driven by how much they wanted to be associated with that group. Instead, the uniqueness prime impacted product choice. Among participants who had conformed to the in-group at the brand level, those primed with uniqueness were more likely to select differentiating options at the product level.

Overall, these results provide insight into how people integrate identity-signaling and uniqueness motives through consumer choice. Importantly, these motives need not act in competition; by strategically conforming on one level while differentiating on another,

people can effectively communicate social identity while also being unique.

"Why Do Products Become Unpopular? Adoption Velocity and the Death of Cultural Tastes"

Jonah Berger, Wharton School of Business, USA
Gaël Le Mens, Stanford University, USA

Products become unpopular and styles fall out of favor. But while researchers have long been interested in why cultural tastes and practices catch on and become popular, much less attention has been given to why these items are abandoned. Why do particular music artists become unpopular or popular names drop out of the cultural repertoire? More broadly, when and why do cultural tastes and practices die out?

We suggest that tastes which quickly increase in popularity die faster. In addition to functional benefits, the decision to adopt a particular product or cultural taste often depends on symbolic meaning, or what consuming the item communicates about the user. People may avoid products that are too popular, for example, or linked to dissociative reference groups) because of what that consumption would signal about them. Similarly, we argue that potential adopters may avoid items that catch on quickly because of symbolic concerns. Things not only have a particular level of popularity, but vary in how quickly that popularity has changed over time. Two styles may have each been adopted by 1000 people last year, for example, but one may have slowly increased in popularity (900 adopters the prior year) while the other shot up in quickly (100 adopters the prior year). We argue that high rates of change may lead items to die out or drop out of the cultural repertoire. Fads are often perceived negatively, and if people think that sharply increasing items will be short lived, they may avoid such items to avoid doing something that may later be seen as a flash in the pan. We test this possibility using both experimental and historical data. In particular, we focus our analysis on first names. There relatively little influence of technology or commercial effort on name choice, making it easier to tease out the effect of social dynamics. Further, data is available on the popularity of names over time, making it possible to examine the effect of popularity dynamics on cultural abandonment.

Study 1 used over 100 years of data on the number of children born each year with different names (this includes over 10,000 names). We use survival analyses (hazard modeling) to examine how adoption velocity and various control factors (e.g., time or how long a name has been around, novelty, and popularity) influence the hazard of abandonment, or likelihood that the name will no longer be used. Results demonstrate a strong positive relationship between

adoption velocity and abandonment: even when controls are included, names that experience sharper increases in popularity tend to die faster. This result persists across a host of robustness checks. The effect is not simply driven by a few names that come and go very quickly (e.g., due to brief attention associated with passing celebrities). Rather, even non-extreme rates of adoption have a positive effect on the death rate. The result also holds using alternate strategies to control for time, various thresholds for defining abandonment, and data from both the United States and France, which speaks to the generalizability of the effect.

To strengthen our suggestion that adoption velocity is driving cultural abandonment, Study 2 examined this relationship at the individual level. Cultural abandonment is a collective outcome, but relies on the aggregation of individual behavior. If sharper increases in adoption really drive abandonment at the aggregate level, they should also have detrimental effects on attitudes at the individual level. To test this possibility, we gave expecting parents a sample of first names and asked them how likely they would be to give each to their child. We then computed the actual adoption velocity for each name, along with its popularity. As expected, expecting parents were more hesitant to adopt names that had sharply increased. (This persisted controlling for recent and cumulative popularity of the names).

We also investigated the mechanism behind the observed effects. We suggested that people avoid identity relevant items which spike in popularity because they do not want to adopt things that may be short lived fads. To test this possibility, we also had participants rate their perception of whether each name was a fad. As predicted, fad perceptions mediated the effect of adoption velocity on preferences. Names which were adopted more quickly were seen as more likely to be short lived fads, which decreased future parents' likelihood of adopting them.

Overall, these findings shed light on how identity and the meaning of consumption contribute to the abandonment of cultural tastes.

SPECIAL SESSION SUMMARY

Choices, Judgments, and Temperature: From Visceral States to Metaphors

Hee-Kyung Ahn, University of Toronto, Canada

SESSION OVERVIEW

Session Objective: Temperature and weather are all around us, quite literally. Furthermore, temperature and weather not only permeate our atmosphere, constantly affecting our visceral states of warmth and coldness, but they metaphorically permeate our language. People, products, and ideas can all be “hot” or “cold.” Given this ubiquity, it is perhaps surprising that relatively little research has systematically examined the influence of temperature on choice and judgment. This special session features current research programs that offer new perspectives on how temperature impacts judgment and choice, shed insight into new psychological processes that underlie these effects, and provide an integrative platform to discuss new research directions.

Overview: Past research on temperature in consumer behavior and social psychology demonstrated that ambient (physical) temperature can affect mood, which in turn can influence behavior (Anderson, 1989; Cunningham, 1979; Howarth & Hoffman, 1984; Parker & Tavassoli, 2000). However, recent research suggests that temperature can influence judgments and choices directly, without the person’s awareness or the mediational role of incidental mood (Williams & Bargh 2008; Zhong & Leonardelli 2008). Three papers in this session attempt to investigate how temperature and its metaphoric associates can affect consumer choices and judgments, thereby expanding on recent research in qualitatively distinct ways. The present papers show how temperature can shift the perceived likelihood of future events; change preferences for impulsive, emotionally-oriented (versus more cognitive or reasoned) products; and alter one’s product replacement intentions. In doing so, relevant psychological accounts are discussed.

Papers: Temperature permeates human experience, both by prompting visceral states (i.e., feeling hot or cold) and by providing useful metaphors (e.g., a “cold, calculated” decision vs. a “hot, impulsive” temper). All three papers propose that temperature—actually experienced or conceptually primed—can affect judgments and choices. Critcher and Risen suggest that temperature’s influence on one’s visceral states can influence the likelihood judgments of future events associated with that state (e.g., feeling hot and believing in global warming) due to visceral fit—a match between one’s present visceral state and a future state of the world that would cause that visceral state. Furthermore, they demonstrate that merely priming the concepts of “warmth” did not have analogous effects. In the second paper, Ahn, Soman, and Mazar examine how variations in both physical and primed temperature can lead to different decisions due to temperature’s metaphoric relation to two different psychological states (i.e., impulsive=hot, calculated=cold). Across a series of studies they show that people exposed to literal or conceptual (primed) heat are more likely to be impatient and impulsive in their judgments and decision making, whereas coldness elicits a relatively more distanced and rational approach. In the third paper, Chandler, Szczurek, and Schwarz demonstrate that when consumers are primed to think of products in anthropomorphic terms, temperature metaphors can heavily influence consumers’ product replacement intentions. People feel “warmth” for other humans, but do people feel similar “warmth” for inanimate products? When first led to anthropomorphize their cars, people primed to view their car’s appearance in “warm” (versus “cold”) terms stated their intention not to replace their cars, regardless of its current quality.

Contribution and Likely Audience: These papers apply novel perspectives in understanding the relationship between temperature and judgment and decision making. Critcher and Risen’s notion of visceral fit; Ahn et al.’s dual links between temperature concepts and mental states; and Chandler et al.’s anthropomorphic approach to consumer behavior, all reflect new approaches that both account for the findings presented here and can be used to generate a host of new hypotheses relevant to consumer behavior. Furthermore, differences between these papers also raise new questions of interest in themselves. For example, Critcher and Risen found that visceral states, but not related conceptual primes, influenced judgment. In contrast, Ahn et al. found their effects both by influencing actual visceral states and by merely priming related concepts. This discrepancy raises a heretofore underexplored topic in this literature that is crucial for predicting when these documented effects will emerge: Under what conditions can merely priming visceral states, as opposed to experiencing the visceral states, yield (dis)similar consequences on consumers’ judgments and choices? Finally, Chandler et al. show that how temperature metaphors influence product evaluations depends on how much consumer have anthropomorphized the target product. This suggests an important boundary condition on these effects. Researchers and practitioners must be sensitive to how consumers construe a target consumer product to understand whether and how temperature will influence judgments of it. All papers include multiple completed studies that have not been presented at ACR before. The session is structured in an interdisciplinary manner with behavioral decision research and social psychology as backgrounds, and should appeal to researchers interested in consumer information processing and judgment and decision making more broadly.

EXTENDED ABSTRACTS

“The Influence of Visceral States on Forecasts of Future Events”

Clayton R. Critcher, Cornell University, USA
Jane L. Risen, University of Chicago, USA

Should one stock up on water in order to weather a future water shortage? Is it wise to invest in a more efficient cooling system for one’s house in anticipation of global warming?

The answers to these and related questions require one to look into the future and make forecasts about the likelihood of different future states. Desertification is a growing problem, and residents of many communities must decide whether the trend is serious enough that they should take steps to preemptively avert disaster. The release and success of Al Gore’s *An Inconvenient Truth* made the public bluntly aware of the problems associated with global warming, but skepticism still abounds about whether global warming is a veritable concern, or “just a theory.”

In looking to the future to answer these questions, one would think (or hope) that people would look to experts to assess the likelihood that these consumer-impactful states would befall us. Although the dissemination of scientific knowledge no doubt informs some people, we propose that one’s current visceral states may play a surprising role in guiding belief in the likelihood of these future possibilities.

Past psychological research has found that visceral states (e.g., thirst, warmth, hunger) can influence judgments by one of three pathways. First, experiencing a visceral state can be an indirect means to prime related concepts (Williams & Bargh, 2008). Second, the experience of a visceral state can moderate the effect of a conceptual prime. For example, a thirst prime only leads people to drink more when they are experiencing the visceral state of thirst (Strahan, Spencer, & Zanna, 2002, 2005). Finally, the experience of a visceral state can help one appreciate the power of a visceral state. For example, Nordgren, van der Pligt, and van Harreveld (2007) found that people were more willing to excuse the offensive behavior of a fatigued parent when the participants were fatigued themselves, presumably because they could better understand how fatigue could lead one to behave uncharacteristically.

We propose a fourth possibility, that when there is a visceral match between one's current visceral state and the visceral state that one would experience if a future state occurred, people believe it is more likely that these future states will occur. Four studies examine this hypothesis by testing whether those who experience a visceral state—warmth or thirst—are more likely to predict that there is convincing evidence in support of related phenomena—global warming or future water shortages, respectively.

Study 1 was conducted outdoors. Participants expressed their attitudes on a number of political and policy-related issues. One of the items related to global warming. The question wording was adopted from a recent CNN poll. Participants indicated to what extent participants believed that global warming was “a proven fact” or “a theory that has yet to be proven.” While participants answered these questions, the experimenter recorded the outdoor temperature. Belief that global warming was a proven reality was significantly predicted by the outdoor temperature $\beta=.24, t(63)=2.04, p=.05$.

Of course, it is possible that the participants were simply inappropriately inferring a long-term weather pattern from the temperature at that specific moment, and that their experience of warmth was not important. To rule out this explanation, we moved Study 2 indoors, such that we could manipulate participants' experience of warmth without providing any information about the actual weather. We found that those participants randomly assigned to state their belief in global warming in a 27°C (81°F) room expressed greater belief in global warming than did those who stated their belief in a 23°C (73°F) room.

We do not claim that our effects emerge because visceral states merely conceptually activate a related visceral state concept (e.g., Williams & Bargh, 2008), which then influences one's judgments. In other words, we do not believe that our effects are mediated by the conceptual activation of the concept warmth. To more conclusively rule out conceptual activation as a mediator of our effects in Study 3, we primed some participants conceptually with “warmth”, using a sentence-unscrambling task. We found that this priming task did lead participants to complete incomplete letter strings with warmth-related words (confirming that the concept of warmth was indeed primed), but belief in global warming was unaffected.

In a final study, we moved to a new visceral state—thirst—and a new judgment—belief that the American Southwest would soon hit “peak water,” which would lead to water shortages in the region. Participants were randomly assigned to a condition in which they were made thirsty by eating pretzels (visceral condition), primed subliminally with the concept thirst (prime condition), or neither (control condition). Then participants watched a video explaining the debate over whether the American Southwest would soon reach “peak water.” A word-completion task found that those in the visceral and prime condition, compared to those in the control, had thirst-related concepts conceptually active. But only participants in

the visceral condition actually became more convinced after watching the video that peak water would soon be reached.

These studies reflect a theoretically novel pathway by which visceral states can influence judgment. Just as the conceptual accessibility of a statement may lead it to be processed with enhanced conceptual fluency, leading to an inference of validity (see Schwarz, Sanna, Skurnik, & Yoon, 2007), we believe that the visceral fit between one's experience and a considered state of the world may lead it to be simulated with enhanced “visceral fluency,” leading to a similar inference of validity (see Cesario & Higgins, 2008, for a similar “fit” argument).

Although many psychological biases are studied in contexts in which people are led astray, we have intentionally studied visceral fit in contexts in which these “biases” actually pushed people toward expert-endorsed opinions. Thus, although it is non-normative to rely on visceral states in the ways demonstrated here, these effects are not inherently helpful or harmful. Even though visceral fit may at times lead participants' judgments astray, the principle can also be harnessed to enhance the power of expert-endorsed communication.

“Being Hot or Being Cold: The Influence of Temperature on Judgment and Choice”

Hee-Kyung Ahn, University of Toronto, Canada

Nina Mazar, University of Toronto, Canada

Dilip Soman, University of Toronto, Canada

Temperature is a very familiar concept to most consumers. It not only describes our physiological degree of comfort, but it also metaphorically permeates our language. People, products, and ideas can all be “hot” or “cold.” For instance, temperature-related words such as “hot” and “cold” are often used to describe impulsive and calculated behaviors, respectively. In a similar vein, our languages are replete with expressions such as “he has a hot temper,” “what a cold, unfeeling person she was,” and “the media, meanwhile, has blown hot and cold on the affair.” In these expressions, “hot” and “cold” are interpreted through metaphoric meanings rather than as direct thermal concepts. Furthermore, even though relatively little research has systematically examined the influence of temperature on choice and judgment, psychologists as well as behavioral decision researchers often use the thermal concept “hot,” (vs. “cold”) to describe impulsive behaviors metaphorically (Loewenstein 1996; Metcalf and Mischel 1999; Peters et al. 2005). These metaphoric associations of thermal concepts raise the question as to whether temperature and psychological states are related to each other, and if so, how.

In this research, we examine three research questions: (1) what is the effect of temperature on choice and judgment, especially in the domain of impulsive behaviors? (2) Do these effects of temperature persist when the concept of temperature is primed rather than experienced? (3) What could be a theoretical approach that explains these effects?

To address these questions, we have conducted a series of field and laboratory experiments and have found support for a relationship between temperature and impulsivity. We operationalize impulsive behaviors by measuring a) willingness to pay [WTP] for products, b) preferences for a smaller-sooner [SS] reward over a larger-later [LL] one, c) preferences for a short term bank deposit over long term bank deposit, d) preferences for a risky gamble over a less risky gamble, and e) the errors made in answering a quiz where the intuitive answer is different from the calculated one. Across five studies, we demonstrate that the actual experiences of ambient temperature trigger decision outcomes in line with the metaphoric association between temperature and impulsivity. When people are hot, they become more impulsive than when they are

cold. Moreover, these temperature effects persist when the concept of temperature is primed by temperature-related words and pictures.

In the pilot (field) study, we find evidence that temperature can influence participants' WTP judgments. WTP measures for a number of product categories were significantly higher when measured in a hot spa room than in a cold spa room. To examine whether the effect of this metaphoric link persists in the extreme temperature condition, we conducted study 1 at a spa adding one more experimental condition (i.e., an extremely hot spa room). Study 1 supported the notion that the link between temperature and impulsivity may not persist in extremely hot temperatures. We also obtained evidence to support the influence of temperature on choices. In the subsequent studies, we replicated the effects of temperature on WTP judgments and choices by using temperature primes such as slideshows of seasonal pictures (study 2) and scrambled sentence tasks (study 3). In addition, we tested the metaphorical link between hotness and impulsivity using various concepts of impulsivity including impatience (study 1, 2, and 3), risk taking (study 2), and decision time (study 4). In sum, participants in the hot (vs. cold) condition indicated a higher WTP for target products and were more likely to choose relatively impulsive options such as a 1-year bank term deposit, a risky gamble, a smaller but sooner [SS] reward, and an incorrect answer to the target problem.

Finally, we manipulate temperature by using hot and cold therapeutic packs to examine whether the simultaneous experiences (activations) of hot and cold temperatures wipe out the temperature association effect. We developed four conditions including hot packs only, cold packs only, one hot/one cold pack, and no pack (control) conditions. The results of study 4 revealed that the simultaneous experiences of hot and cold temperatures result in a similar pattern of judgments and choices as the control condition, in which temperature was not manipulated. The findings rule out a couple of alternative explanations; studies show that mood and arousal do not explain the effects of temperature on WTP and choice.

We suggest that the theories of embodied cognition provide an explanation for these findings. This theory suggests that processing of abstract concepts involves embodiment; where embodiment refers both to actual bodily states and simulations of experience in the brain's modality-specific systems for perception, action, and introspection (Barsalou 1999; Lakoff and Johnson 1999; Neidenthal et al. 2005). For example, a recent study by Zhong and Leonardelli (2008) suggests that the linguistic coupling between social isolation and coldness may reflect a person's predisposition to use concepts that are based on bodily experience (e.g., coldness) to describe complex concepts such as social rejection. Consistent with this view, the current findings demonstrate that not only actual experiences of temperature, but also temperature primes which simulate experience can influence subsequent choice and judgment.

While recent work on the effect of temperature has focused on actual temperature and its direct consequences (mood, cognition, and behaviors), our findings take this insight a step further by demonstrating that the metaphoric link between temperature concepts (temperature primes as well as actual temperature) and impulsivity can influence judgments and choices. This work demonstrates the robustness of temperature effects on judgment and choice by examining the effect across various constructs of impulsivity, product categories, and dependent variables. This research implies that the activation of the hot-impulsivity link may influence various aspects of consumer behavior varying from risk taking to excessive reliance on intuition in addition to the delay of gratification (Ainslie 1975; Metcalfe and Mischel 1999). The results also

have practical implications for packaging, advertising, merchandising and pricing; as well as for public policy and awareness.

"Hot Wheels, Warm Hearts: The Effect of Temperature Metaphors on Product Replacement Intentions"

Jesse Chandler, University of Michigan, USA

Lauren Szczurek, Stanford University, USA

Norbert Schwarz, University of Michigan, USA

Judgments of interpersonal warmth produce striking and consistent differences in the perception of others. Information signaling warmth can come from many sources, including meaning laden personality descriptions (Asch, 1946), irrelevant semantic primes (Scholer & Higgins, 2008) and ambient temperature cues (Zhong & Leonardelli 2008). Despite the varied sources of temperature information, its influence is quite specific and theory-driven. Generally speaking, people described as "warm" are perceived more positively. However, the influence of temperature metaphors cannot be explained as a simple halo effect—connotations of warmth primarily influence evaluations of interpersonal characteristics and can even reduce the likelihood that some positive traits, such as strength and persistence, come to mind (Asch, 1946). Moreover, the evaluative consequences of temperature metaphors depend on other accessible information about the target such as co-occurring personality traits; under different circumstances "cold" can mean either aloof or ruthless (Asch, 1946). Together, these findings suggest that temperature is integrated with other social knowledge to make specific inferences about the target of judgment rather than simply promoting a diffuse positive feeling.

The meaning of metaphorical warmth may depend on the domain of judgment. Outside of the social realm, metaphorical connotations of warmth and cold may not matter, or may carry different meanings entirely: connotations of warmth differ when the target of judgment is a close friend or a refrigerator. However, what belongs within the social realm is itself ambiguous, and sometimes people treat objects as if they are alive (for a review see Epley, Waytz & Cacioppo, 2007). For example, people are less willing to replace anthropomorphized objects (Chandler & Schwarz, 2008), prefer anthropomorphized objects that display prosocial cues (smiling; Aggarwal & McGill, 2007) and spontaneously apply social knowledge structures when describing or interacting with objects (Heider & Simmel, 1944; Nass & Moon, 2000). The influence of temperature metaphors on the perception of products may likewise mirror the influence of temperature metaphors on person perception when people think about objects in anthropomorphic terms. To test this hypothesis, we examine whether i) connotations of warmth and cold influence people's intentions to replace their car and ii) whether this influence depends upon the accessibility of anthropomorphic beliefs.

Participants were recruited for an online experiment about their cars. To manipulate the warm or cold connotations of the car, participants selected the color that most closely resembled their car's color from a matrix of nine colored squares and remembered the color's label as a part of a "memory task". Depending on condition, the five most common car colors were labeled with "warm" (e.g. "summer blue") or "cold" (e.g. "blizzard blue") names. Thus, both warm and cold concepts were equally accessible to all, but only one was applicable to judgments about their car. All participants saw a mixture of "warm" and "cold" color names along with four less common colors given distracter labels (e.g. "canary yellow").

Next, participants were randomly assigned to rate their car along 5 scales anchored with adjectives that implied either *psychological* (e.g. "reserved" to "enthusiastic") or *physical* features (e.g. "quiet" to "loud"); a *control* group did not provide ratings. Partici-

pants then described their car in their own words, indicated their desire to replace their car, and reported the name assigned to the color of their car (thus completing the memory task). These manipulations resulted in a 2 (warm vs. cold color labels) x 3 (psychological vs. physical features vs. control)-factorial between-participants design in which the car's temperature was purely symbolic (stripped of the physical sensation of warmth/cold), arbitrary (not dependant on the actual color of the car), and randomly assigned.

Replicating previous research, we find that participants who described their car negatively were more willing to replace it, except when psychological features of the car were accessible (Chandler & Schwarz, 2008). Although participants were more willing to replace poor quality than high quality cars in the physical feature and control conditions, this relationship vanished in the psychological feature (anthropomorphization) condition: A desire to keep their current cars was uniformly high for this group. We further find that people were particularly unwilling to replace anthropomorphized cars when their color had been associated with warm rather than cold labels. In contrast, color labels did not influence participants' replacement willingness in the physical features and control conditions.

Other experiments extend this logic by examining other contexts in which metaphorical connotations of warmth and cold influenced preferences for products. For example, we find that consumers' preferences for metaphorically warm and cold objects depend upon such products' intended use. Consumers rated notebooks with warm color names (e.g. "summer sky") as more desirable after being asked about personal uses for notebooks, and notebooks with cold color names (e.g. "blizzard blue") as more desirable after being asked about school uses for notebooks.

Taken together, these findings indicate that warm and cold metaphorical connotations influence how consumers perceive objects, but that the consequences of these connotations on judgment differ depending on both the category to which the object is assigned and its function. This line of research identifies important boundary conditions of the effects of warm and cold connotations, and has implications for how we portray objects that are imbued with agentic qualities or have social uses.

SPECIAL SESSION SUMMARY

Having It All: Marketplace Negotiations of Feminism and Women's Roles

Leah Carter, York University, Canada

SESSION OVERVIEW

Traditional feminist discourse challenged social structures and cultural discourses associated with the patriarchal domination of women (cf. Hollows 2000). The marketplace was identified as a negative capitalistic structure and the media was perceived as a vehicle for disseminating stereotypical, sexist portrayals of women (Linder 2004). As a result, feminists and marketing scholars have been slow to bridge marketing and feminism (cf. Catterall, Maclaran and Stevens 2000). In recent years, researchers have begun to address the positive role of the market for feminism and to challenge traditional thought (e.g., Scott 2005, Catterall, Maclaran and Stevens 2000). However, researchers have not studied the marketplace interplay between feminist discourses, consumers' feminist perceptions, and the construction of feminine identities.

One popular feminist discourse of women's identity construction focuses on the myth of "having it all" (Bordo 1989, Haussegger 2005). This idealized discourse centers on the belief that women can successfully fulfill diverse roles simultaneously: mother, wife, professional, friend, consumer, and so on, and is often represented in the media. However, "having it all" juxtaposes diverse discourses and roles of women (i.e., professional role/capitalistic discourse; mother role/nurturer discourse), creating a tension-filled, multi-discursive environment for identity work. The proposed session frames the consumption of female-targeted media as a space for negotiating the complexities of modern feminist and cultural discourses through the characters or representations of women who embody various roles and identities. By so doing, the media acts as a mirror in which women reflexively analyze and incorporate or reject cultural material into their identity and beliefs (Schroeder and Zwick 2004).

The proposed session addresses the question of how women interact with the media to identify feminist discourses and construct modern feminist beliefs and identities. The objectives of the proposed session are therefore to: (1) demonstrate responses of women to female-targeted media, (2) discuss the salient discourses in female-targeted media and characters, (3) examine the relationship between market-mediated discourses and individual notions of feminism, and (4) analyze the effects of media incorporation in the behavior, attitudes, and lifestyles of women.

To address the session objectives, the researchers demonstrate how women analyze and incorporate elements of market-mediated discourses to create personalized, multi-dimensional feminist beliefs and identities. First, Linda Tuncay discusses the ideals of femininity women create in response to advertised depictions of women, interweaving authenticity and feminist discourses. Leah Carter then explores the relationship between feminism and romance, analyzing how women construct practical feminisms of romance through consumption of "chick flicks." Finally, Hope Jensen Schau and Kate Thompson show how the Twilight brand community is used as a marketplace tool for negotiating feminist ideas and roles based on the liminality of represented discourses. In each of these contexts, women encounter multiple discourses in the media representations of women and resolve the discursive and role tensions by active engagement with the material and identity construction.

We anticipate discussant Pauline Maclaran will encourage audience participation and direct the discussion of session themes utilizing her understanding of consumer culture and feminist litera-

tures. We also anticipate the broad appeal of this session among consumer culture researchers as we address the popularity of female-targeted media consumption, explore manifestations and consumption of market-mediated discourses to resolve role and discourse tensions from "having it all", and investigate the identity work of the marginalized female culture in marketing research (Bristor and Fischer 1993; Ozanne and Stern 1993).

EXTENDED ABSTRACTS

"Discourses of Femininity in Advertising among Gen X Women"

Linda Tuncay, Loyola University of Chicago, USA

Much of gender research in the past followed the feminist critique tradition and sought to highlight the prevalence of gender stereotypes and sexist portrayals of women in advertising, such as the homemaker or the sexualized woman (Linder 2004). This early research serves as an important foundation for subsequent scholarly research in this area. However, as Stern (1999) points out, it is important to explore the complexities of gender across individuals, not conceptualizing women as a homogeneous group that is innately different from men.

In this vein, this study explores Gen X women's conceptualizations of femininity within the context of advertising. Gender is an important factor in not only the way consumers construct meanings in their lives, but the way in which individuals interpret text such as advertising (Stern and Holbrook 1994). Due to the fact that individuals glean much information about gender from media, advertising serves as an important milieu in which to explore the complexities of femininity among women. Defining femininity can be difficult due to a number of factors which have altered the discourses of gender in today's American society. These include the increasing earning power of women as well as a greater variety of representations of women in the media. However, little past research actually explores what consumers, themselves, define as femininity and how these notions influence the way gendered ads are interpreted. Thus, the principal research questions for this study are, 1) What ideals of femininity are held by women? and 2) How do women interpret notions of femininity in advertising?

To explore these questions, a qualitative study of 19 Gen X women was conducted. Because notions of gender can be influenced by factors such as social class, education, race/ethnicity, age (e.g., see Beynon 2002), this study examines notions of femininity from the perspective of women falling into the Gen X cohort, who are largely college educated and living in the Midwest. In-depth, semi-structured interviews using ads as projective aids (McGrath, Sherry, Levy 1993) are employed to uncover meanings of femininity in advertising. A series of ads depicting various notions of femininity were selected from some of the top circulating lifestyle magazines for the Gen X female demographic, including Vogue, Glamour, Cosmopolitan, Oprah, and Parenting Magazine. Informants were asked open-ended "grand tour" questions (McCracken 1988), as well as questions specifically probing into their ideals of femininity and their interpretations' of the ads. This research mirrors a study conducted by Tuncay (2006) on men's conceptualizations of masculinity.

Three themes dominate women's ideals of femininity in this study: the Alpha Woman, the Classic Woman, and the Centered

Woman. The ideal of the Alpha Woman emerges when women discuss confidence, strength, independence, empowerment, and a “take charge” attitude as attributes which exemplify their ideal sense of femininity. The Classic Woman is another ideal that informants identify. Women often discuss the notion that elegance, class, sophistication, and grace go hand in hand with femininity. The third salient theme is that of the Centered Woman, who is happy, relaxed, and at peace with herself. Women often comment on the desire to be happy in one’s own skin, and to be drawn to women depicted in ads in a relaxed, positive atmosphere, where the models are laughing or smiling. This last theme illuminates the way women make comparisons to models in ads. When women engage in social comparison to ads, they often feel the most appealing ads are ones that they could identify with (similar to some of the informants in a study by Hirschman and Thompson, 1997) and ones that present attainable standards. Informants reveal that they feel women in advertising should be authentic and accessible and even “flawed,” “not perfect.” Decidedly absent from the narratives of the informants is an ideal related to domesticity, or an “other-oriented” perspective (Bordo 1989). This is surprising given this theme has been widely discussed by past scholars as central to predominant discourses of femininity.

While the themes of femininity discussed above can be seen in various forms in past research, what is most telling is that women continue to use moral judgments as a distinct lens through which they interpret feminine ideals. For instance, while having an attractive appearance or being in shape is valued, women maintain certain boundaries of what is acceptable, particularly when it comes to sexual depictions. Lamb (2001, p.43) states, “Ideals of femininity ensure that girls will not be too sexual or too aggressive...” and that it is taboo to be sexual if it is not within the context of romantic love. In fact, several informants displayed high agency negative emotions (Fisher and Dubé 2005) such as anger and disgust when they viewed an ad which depicted very thin women in scantily clad clothing (see Bower 2001). They found the ads objectifying, annoying and even calling them “disturbing” and “repulsive,” and rejecting any notion of comparison (e.g. Richins 1991). Thus, while being beautiful and sexy are discussed by women, the scantily clad models depicted in the ads are conceptualized as crossing the boundary of “normal” femininity by giving a performance that is not respectable. This notion of respectability (and morality) serves as a distinct lens through which many of the women interpret gender ideals (see discussion of respectability by Skeggs 1997). Images that cross these boundaries are met with extreme outward resistance.

One limitation of this study could be the subset of ads used in this study. Further research should seek to develop a more refined understanding of what gender means today among Gen X women, as well as how notions of gender are interpreted by consumers among other groups of women and using different methodologies.

“Critically Romantic: Negotiating Feminist and Romantic Discourses in the Marketplace”

Leah Carter, York University, Canada

Early feminist discourse centered on liberating women from oppressive patriarchal systems and discourses of power (Hollows 2000). The media, in particular, was criticized for shaping women into one-dimensional, passive consumers of “false consciousness” and hindering women from freeing their “true” and natural “wild woman within” (Embree 1970; Friedan 1963; Daly 1979). In order to liberate women and encourage “true” feminine identity construction, feminists advocated recognizing and resisting the influential power of patriarchal trappings disseminated in the marketplace (Embree 1970). Female identity construction was therefore placed

outside the realm of the market and in direct opposition to perceived masculine-oriented structures and discourses of power.

Romanticism was also cast as a cultural discursive villain that promoted the female surrender to male domination (Beauvoir 1953; Firestone 1970; Millet 1970; Faludi 1992). Romantic relationships, ideals, and goals were believed to constrain women to the subordinate, dependent role of the traditional “house wife” and limited the development of one’s “true” identity (Friedan 1963). Contemporary cultural critics and feminist writers frequently problematized the ubiquity of romantic discourses in modern entertainment television and cinematic outlets on the basis that the consumption of these story lines and narratives reinforces longstanding gender norms and power structures (Mulvey 1975; Mintz 2003). Alternative research suggested, however, that consumption of romantic novels provided a necessary, beneficial escape from women’s roles and the associated stresses of everyday life (Radway 1984). Thus, though traditional feminist discourse emphasized a dualistic worldview that reinforced binaries of romanticism/agency, market/consumer authenticity, masculine/feminine, and constraints/empowerment, consumption of romantic narratives in the media appears to create a space for active negotiation and deconstruction of feminist and romantic discourses.

In this research, I address how individual consumers integrate and enact feminism and romanticism by analyzing female consumption of mass market-mediated discourses in “chick flicks.” I argue that a more nuanced theorization of the traditional relationship between feminism, romanticism, and the representations of women in the media can be derived from investigating female identity politics at the intersection of practical feminisms (the discursive and practical ways in which women construct their feminist identities in their everyday social surroundings) and the consumption of contemporary media. By so doing, I aim to deconstruct the binary boundaries in feminist discourse between feminism and romanticism, romanticism and agency, and feminism and the marketplace.

The central research question is how women engage with market-mediated products to navigate feminist and romantic discourses and construct personal, modern feminist beliefs of romance. In order to address the research question, this research focuses on consumption of female-targeted movies and television shows (i.e., “chick flicks”). These media products are specifically created for and targeted to women and are thematically centered on romantic discourses from a female’s perspective. Further, they generally depict women’s struggles in contemporary romantic encounters as the protagonists navigate issues such as traditional versus modern gender roles in dating contexts, relationship discord, and personal identity within a relationship situation, with the goal of achieving the idealized “happy ending.” The data consist of: (1) in-depth interviews with 10 women, ages 18-30, (2) online message boards and communities connected to female-targeted media products, and (3) participant observation field notes.

From the data, the “Critically Romantic” process emerges in which women engage with and negotiate market-mediated discourses of romanticism and feminism. The media disseminates a combination of feminist and romantic discourses to the mass population in its portrayal of female stereotypes: the homemaker, the promiscuous woman, the career woman, and so on. Women identified and interacted with these market-mediated discourses as embodied and enacted by the female characters. Acting as creative agents, the respondents reflected on the symbolic meanings associated with the represented stereotypes through the lens of internalized personalized discourses (religion, ethnicity, and so on) and life experiences. For example, finding “Mr. Right” was often described as a desired fantasy ideal promoted by the media and yet tempered

by real-life romantic mishaps. Real life experiences acted as criteria for assessing the truth-value of the romantic and feminist discourses depicted. Respondents also highlighted the centrality of social interactions with other women during and after the media consumption experience in analyzing represented themes and representations. Women then constructed practical, modern romantic beliefs interweaving both romantic and feminist, fantasy and “reality” elements. These beliefs shaped feminine self-concepts, personal romantic ideals and goals, and consumption preferences. Based on their own practical feminism of romance, women selected and evaluated media products, indicating certain prototypes and romantic narratives as superior to, or more resonant than, other media offerings. Respondents often cited “Sex and the City” as an exemplar of the right mix of women’s roles portrayed, and of romance and feminism. Other similar shows (e.g., “Lipstick Jungle”), however, failed to portray a resonant mixture of characters, themes, and discourses, and as such, failed to connect with the respondents.

The “Critically Romantic” process develops key theoretical insights for feminist and consumer research: (1) the permeability between cultural discourses and the marketplace, (2) the intertwining of traditionally disparate romantic and feminist discourses when represented in the media and consumed by women, (3) the necessity of the market as a fluid site of discursive construction and deconstruction, (4) the agentic nature of consumers in consuming mediated discourses and constructing a practical, working concept of feministic romance, (5) the social component of discourse negotiation, and (6) the deconstruction of historically and discursively reinforced dualities in individual discourse construction. By detailing the “Critically Romantic” process, I demonstrate the necessity of the marketplace and media in the construction of practical feminisms and the interconnectedness of feminism and romanticism enacted on the consumption level.

“Betwixt and Between: Liminality and Feminism in the Twilight Brand Community”

Hope Jensen Schau, University of Arizona, USA

Kate Thompson, University of Arizona, USA

Our research revolves around representation of, and collective consumption by, females engaged in the Twilight brand community. The Twilight saga is a series of novels aimed primarily at young adult, female readers. The saga revolves around a human, Bella, and her romance with a vampire, Edward. The title Twilight captures the liminality of the heroine. Like twilight is the liminal space between day and night, Bella is riddled with liminality: child and adult, mortal and immortal, love and hate, good and evil, independence and dependence, lover and friend, present and past, mother and child, spiritual and corporeal, and offense and defense. Importantly, girls and women deeply and collectively engage with the brand. Empirically, the Twilight consumer collective offers a unique female-centered incarnation of brand community and feminine-driven consumer engagement which contrasts with previous studies favoring male-dominated brand communities, with two notable exceptions: Martin, Schouten and McAlexander (2006) who investigate modes of femininity within the Harley-Davidson brand community and Schau, Muniz and Arnould (2009) who examine value creating practices across a set of brand communities including those that skew male, are gender balanced and skew female. We reveal the manner in which feminist discourses are collectively negotiated, intertwined and reconstituted in a female-dominated brand community (Gill 2007).

Our data consist of: the Twilight saga (composed of four official novels and an unauthorized draft novel), a feature film (with another film in production and two other films planned), literary and film criticism of the Twilight media products, naturalistic and

participant observation in three online fan discussion forums, fan-created videos, email and chat interviews with forum participants and videographers, and face-to-face interviews with Twilight fans. Our data were iteratively collected and thematically coded and recoded following the hermeneutic tradition.

We find this brand community is, as anticipated, composed primarily of female members ranging in age from 8 to 65. Members use Twilight as a platform to negotiate feminism and socially prescribed female roles (Mulvey 1975): good girl, independent woman, lover, wife, and mother. Twilight offers fans a paradoxical interplay of feminist and anti-feminist discourses characteristic of post-feminist media culture (Friedberg 1993). Throughout the saga, the female self is deferred in favor of the primacy of good intentions toward humanity, highlighting the “problem of femininity” as a quintessential pathology when defined in patriarchal discourses (Moscucci 1990). As in previous research tackling the intersection and interaction of gender and the marketplace (cf., Catterall, Maclaran and Stevens 2000, Costa 2000, Dobscha and Ozanne 2000, Scott 2000), this paper explores gender expressions within a media brand and specifically within the realm of brand communities (Muniz and O’Guinn 2001). The brand community members are energized by Bella’s haphazard navigation of disparate role expectations and her perpetual liminality. The coven of vampires Bella (human/food) joins suppress their predatory instinct and dietary imperatives, favoring compassion, reason and defensive combat, over aggression, apathy, bloodlust and hunger. Similarly, Bella navigates her expressed ideal of eternal commitment, which is tempered by Bella’s reluctance to embrace marriage and the danger motherhood poses as a “newborn vampire.” In essence, we find that it is precisely Bella’s liminality and her quest for equality against almost insurmountable odds that make her a compelling heroine and rallying point for the community. At the conclusion of the saga, Bella is integral in conquering seemingly omnipotent foes through enacting a protective screen on the clan that, together with a clever plan put in place by her sister-in-law, proves a triumph of the feminine defensive over the masculine offensive tactics of the foes. Fans are quick to address this gendered strategy and use it toward negotiating their own social roles and toward understanding the post-feminist perspective (Johnson 2007).

The Twilight brand community walks the line of compromise and tradeoffs as the price of being a contemporary woman through collective discourse that focuses on maximizing complex social functions: maintaining familial loyalties while pursuing romantic love, asserting independence and reveling in dependence within romance and domesticity, asserting one’s self while advancing the collective good, and balancing motherhood and professional ambition. The Twilight brand community provides a media based platform to think through the complexities of femininity and of the different incarnations of feminism. Because the liminality is never fully resolved, there is ample opportunity for engagement and for continued engagement. The fan discourse is supported by the Twilight narrative, which leaves room for fans to write themselves into the story and to locate resonating themes (Derecho 2006) to extend their brand engagement. In short, our data reveal that the liminalities are key attributes of fan engagement. Furthermore, the primarily female members of the brand community grapple with fundamental issues surrounding femininity, expected roles and modes of feminist resistance (Whelehan 1995). Interestingly, the fans’ discussions map rather closely onto “third wave” feminism that recognizes and asserts multi-fold gender positions (Henry 2004).

While it would be easy to dismiss the Twilight phenomenon as yet another vampire tale or Harry Potter clone, our research demonstrates that Twilight is neither of these. The brand community

actively negotiates multi-fold liminality and feminism through the Twilight saga. The brand serves as a vehicle to contemplate women's potential and place in the world.

SPECIAL SESSION SUMMARY

Are Crowds Always Wiser?

Andrew Stephen, INSEAD, France
Leonard Lee, Columbia University, USA

SESSION OVERVIEW

Popularized by James Surowiecki's book of the same title (Surowiecki 2004), the "wisdom-of-crowds" hypothesis states that the aggregation of information in groups can result in better reasons than any single member of the group could make. Surowiecki argues that disorganized group decisions enjoy the advantages of being faster, more reliable, less subject to political forces that can adversely impact decision quality. The popularity of this hypothesis can be attested by the throngs of applications it has spurred and endorsed, ranging from online prediction markets (e.g. NewsFuture, BetFair) to education reform (e.g. Fullan 2004).

This session brings together three recent papers that propose critical boundary conditions for the validity of the "wisdom-of-crowds" hypothesis. Simmons, Nelson, Galak, and Frederick open the session by demonstrating that point spread betting markets, an important application of this hypothesis, lead to systematically biased predictions of NFL football winnings. Even with the opportunity to learn their prediction errors over time throughout the football season, bettors did not improve due to erroneous attributions. Using a longitudinal experiment, they systematically tested the validity of four competing hypotheses and found that the estimation of point differentials, rather than point spread betting, produced significantly improved predictions.

In the same vein of refining the "wisdom-of-crowds" hypothesis, Soll, Larrick, and Mannes posit that "crowds are wise, but well-chosen small crowds are even wiser." They distinguish between the two extremes of "aggregating the masses" and "chasing the expert" on the continuum of prediction strategies and propose the middle-ground solution of using smaller crowds (e.g. of five people) to improve predictions. Using a range of methodologies—empirical, behavioral, and analytical—they demonstrate convincingly that smaller crowds can indeed be wiser.

Finally, taking things to the other extreme of the continuum, Lee, Pham, and Stephen argue that even with the sole predictor, trusting one's feelings can significantly improve one's predictions of a wide variety of crowd behavior over popular prediction markets—from important political outcomes (i.e. the recent Democratic presidential nomination race between Senators Obama and Clinton), to results in the financial (i.e. Dow Jones Index) and entertainment industries (i.e. movie box-office success).

Together, these three papers present diverse perspectives that converge towards the same conclusion—that while crowds may be reasonably wise at times, there are certain interventions or approaches that can be taken to optimize their collective wisdom. Overall, given the fundamental relevance of these papers' topics to consumers' every day lives, this special topic session should be of great interest not only to marketing researchers and psychologists, but also to anyone who is interested in the factors and strategies that can improve our prediction making.

EXTENDED ABSTRACTS

"Are Crowds Wise When Predicting Against Point Spreads? It Depends on How You Ask"

Joseph Simmons, Yale University, USA
Leif Nelson, University of California at Berkeley, USA
Jeff Galak, Carnegie Mellon University, USA
Shane Frederick, Yale University, USA

The wisdom-of-crowds hypothesis predicts that the judgments of a crowd (as measured by any form of central tendency) will be relatively accurate, even when most of the individuals in the crowd are ignorant and error-prone (Surowiecki 2004). Point spreads are often cited as an important example of the wisdom of crowds, because they are very accurate and are widely believed to reflect the "crowd's" predictions of upcoming sporting events. However, other research (Simmons & Nelson 2006) shows that bettors are biased in their predictions against point spreads: They bet on "favorites" more than "underdogs" despite the empirical observation that the two bets are equally likely to obtain. This research challenges the notion that point spreads capture crowd sentiment, leaving the "wisdom" of the crowd in question.

To test the wisdom-of-crowds hypothesis, we conducted a season-long (17-week) experimental investigation, in which a geographically diverse sample of enthusiastic NFL football fans wagered more than \$20,000 on NFL football games against point spreads that were manipulated to favor the underdog (i.e., point spreads that were increased). We investigated four hypotheses. The first hypothesis constitutes the strong version of the wisdom-of-crowds hypothesis and it predicts that crowds will wisely choose against biased point spreads even when they are not told that the spreads are biased (Surowiecki 2004). Our investigation soundly rejected this hypothesis. When predicting against biased point spreads, the crowd predicted vastly more favorites than underdogs, lost more games (and money) than it won, and performed worse than the vast majority of its individual members.

The second hypothesis constitutes the weak version of the wisdom-of-crowds hypothesis, which predicts that crowds will wisely choose against biased point spreads when they are told that the spreads have been increased. Although this warning slightly increased the crowd's tendency to predict underdogs, the crowd nevertheless predicted more favorites than underdogs, lost more games (and money) than it won, and performed worse than most of its individual members. Thus, this more charitable version of the wisdom-of-crowds hypothesis was also rejected.

We investigated a third hypothesis, which asserted that even if crowds are unwise at the start of the study, they should improve over time, as the crowd's members accumulate evidence of the inferiority of favorites. This hypothesis was also rejected. Moreover, although crowds did not get more or less accurate over time, their predictions did worsen over time in the sense that they unwisely predicted more favorites as the study progressed. Analyses of participants' tendencies to attribute prediction outcomes to luck or to skill indicate that participants were more likely to attribute correct favorite (vs. underdog) predictions to skill and to attribute incorrect favorite (vs. underdog) predictions to luck. This attributional pattern may have caused people to "learn" that predict-

ing favorites is wiser than predicting underdogs as the study progressed, despite the fact that favorites lost more than underdogs against the spread.

Finally, despite our failure to find evidence for the wisdom-of-crowds when people were asked to predict against point spreads, we did find that a different method of eliciting the same judgment (asking participants to predict point differentials rather than make choices against point spreads) produced vastly different, and vastly wiser, predictions against the spread. In this case, the crowd predicted vastly more underdogs than favorites, won more games than it lost, and outperformed the majority of its individual members. Thus, the same “crowd” of bettors can appear wise or unwise, depending on how their predictions are elicited.

“When it Comes to Wisdom, Smaller Crowds are Wiser”

Jack Soll, Duke University, USA

Richard Larrick, Duke University, USA

Al Mannes, Duke University, USA

An aggregate opinion of the masses can be more accurate than the best experts. James Surowiecki popularized this idea in his best-seller *The Wisdom of Crowds*. The power of aggregation is surprising because it contradicts people’s intuition, when faced with a prediction task, to “chase the expert” by seeking out the one person who knows the most. One source of misapprehension is that many people incorrectly believe that an aggregate mirrors the accuracy of its average input (Larrick & Soll 2006). People also mistrust crowds because they fear being dragged down by the crowd’s worst members. This is a valid concern. Aggregation may entail mixing the opinions of skilled and unskilled judges. Chasing might be better and safer, assuming that true experts can be reliably identified.

If chasing means forgoing the statistical benefits of aggregation, and using the whole crowd leaves one vulnerable to incompetence, might there be a middle-ground that employs the best of each strategy? Therein lies the beauty of small crowds. Small crowds achieve most of the benefits of aggregation (Hogarth 1978), and if well-chosen avoid being dragged down by the worst judges.

We examine the wisdom of small crowds from empirical, behavioral, and analytical perspectives for quantitative judgments. First, we compared the small crowd strategy to chasing and averaging the whole crowd in 37 experimental datasets. The chasing and small crowd strategies involve rank-ordering the judges based on their accuracy in a small sample of observations (e.g., one to ten estimates for which the correct answer is known). In the vast majority of cases, the whole crowd beats the best expert, but the small crowd does just as well or better. We also analyzed a real-world dataset—data from an economic forecasting competition sponsored by the Wall Street Journal. The dataset included semi-annual forecasts of macro-economic variables from about fifty economists representing banks, government, and academia. We replicate the wisdom of crowds, but again show that the small crowd strategy outperforms the whole crowd, even when economists are rank ordered based on performance in just one prior forecasting period.

Next, we discuss two experiments that examine beliefs and behavior. In the first experiment, the WSJ panel of economists was described to participants, who then rank ordered five potential strategies for using the forecasts. Participants clearly preferred averaging the top five economists to both chasing the most accurate economist from the previous period and averaging all fifty forecasts. The second experiment used the forecasts of eleven economists from the WSJ survey as stimuli, and required participants to make forecasts over a series of rounds. In each round participants could review summary statistics of the performance of the eleven

economists on the preceding rounds. In the “All or One” condition, participants had to decide whether to go with a single expert on a given round or average all eleven forecasts. In the “Small Crowd” condition, participants could average the opinions of any subset of economists, which included the options of selecting one or averaging all. Participants in “All or One” chased a single expert on the vast majority of rounds, and their performance suffered compared to the alternative of averaging all. In contrast, the “Small Crowd” participants tended to include more than one economist in their subset. They typically averaged the forecasts of two chosen economists, which led them to perform better than the “All or One” participants, although not quite as well as they could have done with a somewhat larger small crowd (we recommend five).

Finally, we conducted simulations to investigate the generality and robustness of the small crowd strategy. To do this, we first categorized environments according to three dimensions, corresponding to dispersion in accuracy across judges, correlation in judges’ forecast errors, and the validity of cues to expertise. Averaging the whole crowd performs well when dispersion and correlation are low, and chasing a single expert is ideal when dispersion is high and the better experts can be reliably identified (Soll & Larrick, in press). We find that a small crowd strategy tends to perform closer to the better of these two pure strategies regardless of the environment, and beats them both in many intermediate environments. An interesting result is that small crowds of size five, when selected based on past performance, are robust in the sense that they tend to perform reasonably well across environments, regardless of the size of the crowd from which they are drawn (assuming crowds of size ten or larger).

The fact that a “top five” strategy consistently performs well is surprising, especially in light of the fact that either pure strategy can perform very poorly in the wrong environment. Equally surprising is the fact that the rank-ordering need not be based on a large sample of available data. We find that samples of two or three estimates lead to good results, and the benefits beyond ten are very small. There is a compelling intuition for this result. When there is high dispersion in expertise the better judges are readily apparent with just a few judgments. In contrast, when there is low dispersion in expertise one would require a large sample to obtain a good rank ordering, but in this case it does not matter much which judges are included. Either way, only a small sample is needed.

Crowds are wise, but well-chosen small crowds are even wiser. People do appreciate the wisdom of small crowds, although our research shows that people tend to select crowds that are too small. Our prescription is to rank-order the judges, and then average the top five. We also discuss extensions to consumer research. For example, in choosing hedonic goods such as movies or a vacation destination, consumers can rely on either crowd ratings (available at web sites such as tripadvisor.com and IMDb.com), or on the advice of an “expert” on one’s own preferences, such as a similar other. The small crowds strategy suggests that an aggregate opinion of a small group of similar others may outperform both these strategies.

“The Emotional Oracle: Predicting Crowd Behavior with Feelings”

Leonard Lee, Columbia University, USA

Michel Tuan Pham, Columbia University, USA

Andrew Stephen, INSEAD, France

On August 28, 2008, Barack Obama became the official Democratic candidate for President of the United States in the 2008 presidential election. While this might have seemed inevitable in hindsight, foreseeing it a few months earlier was difficult, especially considering the span and intensity of the contest between him

and Hillary Clinton. Election outcomes, as well as events such as the success of new products (e.g., movies) and stock market movements all depend on the collective actions of masses of people. In this research, we concentrate on the challenge of predicting how such crowds will behave.

Predictions of mass behavior can be made through two distinct processes: (1) a cognitive, scenario-building process, and (2) a feeling-based process that involves the monitoring of one's subjective feelings toward the options (Dunning 2007, Loewenstein and O'Donoghue 2004). Thus, in predicting crowd behavior, affect might play a role. Whereas the cognitive system of judgment is analytical and logical, the affective system is more holistic and associative (Epstein and Pacini 1999). Consequently, the affective system fosters a more comprehensive processing of available information, distilling the situation to its gist or essential elements (Stephen & Pham 2008). It may also help predictors better relate to—or put themselves in the shoes of—the people whose behaviors they are forecasting.

We examine how reliance on feelings affects the accuracy of peoples' predictions of crowd behavior across four studies and three diverse contexts. Each study uses the same subtle procedure to induce different degrees to which participants rely on their feelings in making their predictions (Avnet & Pham 2007, Lee, Amir, & Ariely, in press, Stephen & Pham 2008). Participants were randomly assigned to either a "high-trust-in-feelings" (high-TF) or a "low-trust-in-feelings" (low-TF) condition, and asked to describe either two (high-TF) or ten (low-TF) past situations in which they trusted their feelings to make a decision and it emerged as the right decision. Participants typically find it easy to recall two examples of successful reliance on feelings and difficult to recall ten. Thus, those asked to recall two (ten) examples tend to believe that such examples are common (uncommon), and increase (decrease) their reliance on feelings when making subsequent decisions (Avnet & Pham 2007).

In study 1 (N=68; undergraduates), after completing the manipulation, we gave participants information about five movies to be released nationally in early October 2008 (the study was conducted three days before these movies' release). The task involved ranking these movies in order of predicted success, measured by opening weekend box office revenues. Using the rank-order correlation between each participant's predicted order and the actual order as a measure of prediction accuracy, high-TF participants were more accurate than their low-TF counterparts. This result held after controlling for prior knowledge and liking of the movies.

Study 2 (N=41; undergraduates) used the same procedure as study 1 and replicated this result (although here we used a set of four movies that were released in mid-December 2008). Additionally, we had participants list all the things that they thought of when making their predictions. We counted the number of items listed that were about mass behavior (and what "other people" would do). As process evidence, we found that a greater percentage of the items listed by high-TF participants were other/crowd-focused and that this was positively correlated with their prediction accuracy. Mediation analysis suggested that the positive effect of reliance on feelings on prediction accuracy was mediated by a greater focus on projections of how "other people" would feel about the movies.

In the third study (N=52; undergraduates), we asked participants (who first completed the trust-in-feelings manipulation) to predict the closing values of the Dow Jones stock market index one week in the future (this study was conducted in February 2009). The same basic result from studies 1 and 2 was replicated in this different context: high-TF participants made more accurate predictions. The dependent variable here was the prediction error (actual

future value–predicted value); thus, the mean prediction error was lower for high-TF than for low-TF participants. However, we found that this effect only held for participants who possessed some expertise or knowledge of the prediction target (i.e., the economy and stock market): trust in feelings interacted with target knowledge (high for participants who were economics or finance majors, low otherwise) such that high-TF participants were only more accurate if they were knowledgeable.

Finally, in study 4 (N=229; national sample of registered voters, run in mid-February 2008), participants first completed the trust-in-feelings manipulation and then predicted the winner of the 2008 Democratic primary. We deliberately ran this study when the Democratic primary contest was far from being conclusive, with both candidates virtually tied in national opinion polls. The results revealed that six months before the Democratic National Convention, high-TF participants were more likely to correctly predict that Obama would win the nomination than low-TF participants. This result held in general, as well as separately among registered Democrats, registered Republicans, and even among participants who had already voted for Clinton.

Overall, we find that feeling-based predictions may lead to greater predictive accuracy of mass crowd behavior. This result holds across different contexts and for short- and long-range predictions. Further, regardless of one's inherent preference for the collective outcome (e.g., personally liking a particular movie or having already voted for Clinton) this result holds despite cases where the predictor's personal preference does not align with the crowd. Our results are consistent with the notion that reliance on feelings help people be less encumbered with their own personal preferences or tastes and thus better able to put themselves in the shoes of others—the crowd—to consider how others would feel and what they would do. Accordingly, this leads to more accurate predictions and the counterintuitive finding that focusing less on logic and reasoning and more on feelings enables people to better foresee the future.

SPECIAL SESSION SUMMARY

The Other Side of the Story: New Perspectives on Word of Mouth

Sarah G. Moore, University of Alberta, Canada

SESSION OVERVIEW

Consumers frequently engage in word of mouth (WOM) communication, where one individual shares information about a consumption experience with another. WOM can occur face-to-face, or via spoken or written communication through various technologies (e.g. the Internet) (Godes et al. 2005). WOM has long been recognized as an important process for firms and consumers, and it remains so today, with 60% of consumers consulting friends or family about purchases (Hampton 2006). Past work on WOM has focused on how it impacts the listener (Arndt 1967) and the firm (Chevalier and Mayzlin 2006), as well as on who shares WOM and why (Wojnicki and Godes 2008). However, this work has neglected some fundamental aspects of WOM. Most importantly, there has been little attention to the question of what consumers actually say, how they say it, and how these two factors influence not only the listeners, but the speakers themselves. In this session, we hope to tell the other side of the WOM story by introducing recent work that will broaden the field's perspective on this important topic.

Our papers highlight several new aspects of WOM. We examine the specific content of WOM (Moore, Fitzsimons, and Bettman 2009; Schellekens, Verlegh, and Smidts 2009), how and why this content influences speakers (Moore et al., 2009; Cowley 2009), and how speakers think strategically about WOM (Schellekens et al. 2009; Cowley 2009). These papers "zoom in" on WOM: instead of examining the consequences of WOM for listeners or firms, we focus on the language speakers use, on the determinants of language use, and on how this language influences speakers.

First, Moore et al. (2009) examine how characteristics of experiences influence WOM content as well as how specific WOM content influences speakers' evaluations of experiences through a process of sense-making. Cowley (2009) also investigates how WOM influences the speaker, focusing on how consumers' retrospective evaluations of experiences are influenced by conversational norms and by consumers' awareness of these norms (e.g. whether they are purposely exaggerating). Finally, Schellekens et al. (2009) examine how characteristics of experiences and consumers' communication goals influence WOM content; they also examine how listeners are persuaded by different WOM content. These papers demonstrate the value of a deeper focus on WOM content and its determinants, and on how this content influences individuals who share WOM. While these papers examine similar novel aspects of WOM, each has a unique contribution: Moore et al. (2009) and Schellekens et al. (2009) both examine WOM content, but focus on different types of content, while Moore et al. (2009) and Cowley (2009) examine two different processes through which speaking can influence the speaker.

In combination, these papers provide an exciting new perspective on WOM and a solid foundation from which to begin additional research in this domain. We hope that this symposium will attract a wide audience, from WOM researchers to those who examine the roles of memory, attitudes, metacognition, and language in consumer psychology. These papers are in advanced stages of completion, and we expect this symposium to stimulate much discussion on the current work and on areas for future research. Thus, we hope to save 15-20 minutes following the presentations for Larry Feick to discuss the presentations and to receive questions from the audience.

EXTENDED ABSTRACTS

"Some Things Are Better Left Unsaid: How Word of Mouth Influences the Speaker"

Sarah G. Moore, University of Alberta, Canada

Gavan J. Fitzsimons, Duke University, USA

James R. Bettman, Duke University, USA

WOM, where individuals share information about consumption experiences with others, is an everyday occurrence. WOM spreads through various media, both traditional (face-to-face) and non-traditional (online reviews). Past research has focused on how WOM influences those who hear it (Arndt, 1967) and how this influences the firm (Chevalier and Mayzlin 2006). However, a fundamental question remains unanswered: how does WOM influence the speaker?

To answer this question, we develop a comprehensive model of how speaking affects the speaker. We argue that it is not simply the act of speaking that influences individuals sharing WOM, but that it is story content or how things are said that strongly influences storytellers. We synthesize past research from psychology and linguistics to develop a model that incorporates: 1) the process by which language influences speakers; 2) antecedent variables that influence what speakers say; and 3) the consequences of speaking, including changes in speakers' evaluations of experiences, as well as changes in speakers' intentions to repeat, recommend, and tell others about experiences.

We focus on one important type of story content and how that influences speakers. Past work suggests that individuals can understand and recover from traumatic experiences by building narratives around them and figuring out why they occurred (Pennebaker 1997). Thus, we focus on whether storytellers explain why events occurred or explain why they feel the way they do about experiences, and examine how this explaining language influences speakers. We suggest that antecedent variables such as experience valence (positive or negative) will influence how much explaining language individuals use in their stories. The use of explaining language is then hypothesized to change evaluations through a process of sense-making, where individuals come to understand experiences and consequently find them less compelling (Gilbert, Wilson, and Centerbar 2003). In short, sense-making makes positive experiences less positive and negative experiences less negative. We contribute to this literature by focusing on how specific types of language influence sense-making. In four studies, we demonstrate that explaining language does facilitate sense-making and can thereby cause paradoxical effects of WOM. Specifically, explaining positive experiences decreases the speakers' evaluations of and their willingness to repeat and recommend experiences. Conversely, explaining negative experiences increases the speakers' evaluations of and their willingness to repeat and recommend experiences. Finally, making sense of an experience makes consumers less likely to spread future WOM by telling others about the experience.

In study 1, we showed individuals two positive or negative photographs and asked them to write a story about one of the photos. First, we found that writing had an overall dampening effect on participants' photo evaluations compared to not writing. We also found that participants used more explaining language when telling stories about negative compared to positive photos. Most impor-

tantly, we found that participants who used more explaining language in their stories evaluated the positive photos less positively and the negative photos less negatively than participants who used less explaining language. These results were mediated by sense-making, where explaining language increased sense-making, and sense-making decreased evaluations of positive but increased evaluations of negative experiences. We also ruled out two alternative explanations for our findings: participants' evaluations were not altered because explaining language influenced metacognitive perceptions of difficulty in writing, nor were evaluations altered because explaining language encouraged individuals to include evaluation inconsistent information in their stories.

In study 2, we coded actual Amazon.com book reviews to ensure that our findings were not restricted to lab participants writing to an unspecified audience. We found that individuals rating books extremely, at one or five stars, used less explaining language than individuals rating books less extremely, at three stars; we observed these effects using both an across reviewer data set and a within-reviewer data set. As in study 1, then, explaining language was associated with less extreme evaluations of positive and negative experiences.

Studies 3 and 4 manipulated language use to provide experimental support for the idea that explaining language alters evaluations. In study 3, we gave individuals a Scrambled Sentence Task with explain, relive, or control prime words. We found that individuals in the explain prime conditions used more explaining language in their stories and had less extreme evaluations of positive and negative experiences than individuals in the relive prime conditions, who used less explaining language in their stories. The impact of prime on evaluations was mediated by sense-making, such that explaining language helped individuals make sense of their experiences, leading to decreased evaluations of positive but increased evaluations of negative experiences.

In study 4, we provided individuals with a constructed story for which they filled in the blanks. We had an explain, a relive, and a control condition, where the only difference between the relive and explain conditions was an explaining clause at the end of some sentences (e.g. "Dinner was _____." vs. "Dinner was _____ because _____."). Thus, this study controls for various potential differences between explaining and reliving language (e.g. evaluation inconsistent information, emotionality, detail) and varies only whether individuals provided explanations or not. This study replicated our previous findings: individuals in the explain condition had less extreme positive and negative evaluations than individuals in the relive or control conditions.

In sum, we proposed and tested a model for understanding a critical but understudied issue in WOM. While past research has indicated that WOM influences listeners (Arndt, 1967), in addition to understanding this outward ripple, it is vitally important to understand how WOM influences the speaker. We go beyond previous work to highlight WOM content and demonstrate how that content influences critical downstream consequences for the speaker. We show that some things are, indeed, better left unsaid: sharing positive stories can be bad for the speaker, while sharing negative stories can be good for the speaker, depending on their story-telling language. Explaining language dampens evaluations of positive experiences and improves evaluations of negative experiences, and these evaluative changes are linked to changes in intentions to repeat and recommend experiences.

"Selecting Snapshots from Episodic Memory's Photo Album: Sharing Experiences and Retrospective Evaluations"

Elizabeth Cowley, University of Sydney, Australia

Everyone loves a good story: hearing one is entertaining and telling one is satisfying. Stories give life to past experience and are an effective form of communication (Schank 1990). However, telling stories may adversely affect the storyteller's memory for how they felt during the event. Why? By following conversational norms such as keeping the story interesting to the listener, the storyteller may exaggerate the intensity of the most pleasant or painful moments of an experience. Since the most intense moments of an experience are used to construct a retrospective evaluation (RE) (Fredrickson and Kahneman 1993; Redelmeier and Kahneman 1996), storytelling may influence REs. Exaggeration may be particularly likely when consumers tell entertaining stories. In this case, consumers may attempt to correct for the distortions when they are subsequently remembering the experience. However, if consumers are unaware of the distortions introduced by exaggeration, then storytelling may result in biased REs (Wilson and Brekke 1994).

In two studies, we demonstrate that recounting an experience in a conversational format does polarize REs when storytellers are unaware that they may have included exaggerated affective reactions in their conversation. Study 1 also reveals that changes in REs are accompanied by changes in intentions to repeat the experience. In study 2, we find that changes to the pre-conversation peak moment of pain or pleasure do not cause shifts in REs, but that REs are influenced by a new moment which emerges as the most affectively intense as a result of the conversation.

In study 1, 94 students participated in a 2 x 2 x 2 between subject design with conversational goal (be entertaining vs. be informative), event valence (positive vs. negative), and goal instruction type (implicit vs. explicit) as independent factors. Participants thought of two recent experiences of the same valence that had occurred in two different restaurants. After providing a RE of the events, participants were provided with implicit or explicit instructions to be either entertaining or informative during an upcoming conversation. Participants then had a conversation about the least positive or negative of their two restaurant experiences, depending on condition. One day later, participants were asked to report their RE and to choose a restaurant to revisit.

In the explicit instruction conditions, REs were amplified after people recounted their experience with an informative goal, but not with an entertaining goal. The implicit instruction conditions revealed amplification of the RE in both goal conditions. The results are consistent with the assertion that it is awareness of the potentially distorting effect of the entertainment goal which eliminates the polarization of the RE. The results also provide evidence that behavioral changes accompany shifts in REs. Specifically, in the positive conditions, participants selected the restaurant they had told a story about to revisit, as opposed to the restaurant they had preferred prior to their conversation. In the negative conditions, participants selected to revisit the non-discussed restaurant, as opposed to the pre-conversation preferred (or least negative) restaurant. The only exceptions were participants in the explicit/entertaining conditions: these participants chose to revisit restaurants consistent with their pre-conversation REs and were not influenced by storytelling.

Although study 1 shows that telling someone about an experience may result in more extreme REs, the findings do not provide insight into how the shift occurs. At least three mechanisms could facilitate the adjustment: 1) Telling the story could increase the intensity of the pre-conversation peak moment. If this is the case,

then information regarding the cause of the peak intensity remains intact; 2) A new, more intense, peak could be introduced during the conversation. If this is the case, then the relationship between peak intensities and moments within the experience is altered by the conversation. The moments which are inconsistent with the pre-conversation peak could be assimilated in the direction of the peak; 3) The speaker simplifies the story and makes the explanation for the events more definite by altering affectively inconsistent moments to be consistent with the affective reaction to the peak moment.

In a second study examining these mechanisms, 80 students participated in a 2 x 2 between subject design with two levels of conversational goal (be entertaining, be informative) and two levels of event valence (positive, negative). Participants thought of a positive or negative restaurant experience and provided a RE of the event. Then, they listed the moments or snapshots of the experience and rated the importance of each moment and the degree to which the moment was enjoyable. Participants were then given an explicit goal (informative vs. entertaining) to accomplish while telling a story about their experience to a conversation partner. One day later, participants were asked to report their remembered RE and to rate the importance and enjoyment of each of the moments listed before the conversation and added during the conversation. Study 2 results indicated that shifts in RE occurred because a new experience peak emerged after the conversation. The new peak was either a new moment included during the conversation which had not been identified before the conversation or was a pre-conversational non-peak moment which intensified in terms of its utility. It is interesting to note that the pre-conversation peak did not become more intense, nor was there was a general increase in the degree of pain or pleasure associated with all of the moments.

In sum, we provide evidence that REs are amplified after recounting an experience in conversation, unless the storyteller is being purposely entertaining. What difference between pre- and post-conversation REs leads to this amplification? Study 2 revealed that the post-conversation RE was constructed using a new peak. The new peak was either a pre-conversational moment which became more intense, or was a new peak, included in the conversation, but not reported before the conversation. This is an important finding because previous research has implicitly assumed that there is a peak moment from the experience which continues to be a critical determinant of REs; these studies demonstrate that storytelling can change this peak moment.

“Language Use in Word of Mouth”

Gaby Schellekens, Erasmus University, The Netherlands

Peeter Verlegh, Erasmus University, The Netherlands

Ale Smidts, Erasmus University, The Netherlands

Consumers like to share their experiences with products and services with each other. But what do consumers say during WOM conversations? For example, when your bright new “brand X” shirt has lost its color after you have washed it once or twice, you could say to your friend, “My brand X shirt has faded,” or you could say, “My brand X shirt was of poor quality.” In the former case, you provide a very concrete description of what actually happened. In the latter, you use more abstract wording which generalizes your experience with the shirt fading to the overall quality of the shirt. These differences in language use can also have an effect on the receiver of the WOM message. In spite of the substantial amount of prior research on WOM, there has been little attention to the question of how consumers talk about products and brands, and whether and how this influences the extent to which they persuade other consumers.

Previous research has found that abstract versus concrete descriptions of experiences influence the processing of and the inferred meaning drawn from such descriptions. To understand and study these implications, particularly in the area of person perception, Semin and Fiedler (1988) developed the Linguistic Category Model. According to the model, event descriptions that use more abstract terms (implicitly) convey that an actor’s displayed behavior is more typical of the actor and is more likely to be repeated. Thus, the description is viewed as more informative of the actor and is less focused on the specific circumstances under which the behavior was performed. More concrete descriptions, on the other hand, are objective descriptions of the specific observable behavior, and are therefore verifiable and lead to less dispute (Semin and Fiedler 1988; Wigboldus et al. 2000).

The present paper first demonstrates that consumers systematically use more concrete or abstract language in descriptions of product experiences. The studies presented here are the first to examine language abstraction outside the interpersonal domain and to evaluate language use in descriptions of products. In line with earlier research (Wigboldus et al. 2000), we argue and show that consumers’ a priori expectations about a brand or product determine whether they describe their experiences in abstract or concrete terms. More specifically, product experiences that are congruent with a consumer’s product attitude are communicated more abstractly than incongruent experiences. We also show that consumers can use language abstraction strategically in word of mouth. Although people generally are unaware of the level of abstraction that they use to describe an event, some studies suggest that language abstraction can be used in a strategic manner (Douglas and Sutton 2003). We extend these findings by showing that consumers vary language abstraction based on a communication goal, such as the goal to persuade someone of the quality of a product. More specifically, if consumers want to persuade someone of a product, they will use a more abstract message for a favorable experience and a more concrete message for an unfavorable event.

The strategic use of language abstraction suggests that consumers consciously or unconsciously assume that there are differences in the persuasiveness of language abstraction (see Hamilton 2003 for a similar argument). To our surprise, there has been no research examining whether abstract descriptions of favorable experiences (and concrete description of unfavorable experiences) are indeed more persuasive and lead to more favorable evaluations of the actor (or, in this case, the product). In the last study of our paper, we show that the language abstraction of a message affects the purchase intentions of the receiver. Positive messages about a product are shown to be more persuasive when they are presented in more abstract language. However, the opposite effect is found for negative messages: an increase in language abstraction for a negative product referral leads to a decrease in receivers’ intentions to purchase the product.

Our research extends previous work on language abstraction while providing important insights into the nature of WOM communication, which may be of use for marketers who are seeking to manage and optimize WOM marketing (Ryu and Feick 2007).

SPECIAL SESSION SUMMARY

Beyond Functionality: Aesthetic Considerations in Consumer Behavior

Joann Peck, University of Wisconsin-Madison, USA

SESSION OVERVIEW

“Beauty is a harmonious relation between something in our nature and the quality of the object which delights us.” Blaise Pascal

The objective of this session is to highlight the role of aesthetics in consumer behavior. This session has a diversity of topics that will interest individuals interested in sensory perception, product design, web based shopping and product customization. What is especially appealing about this session is the breath of the papers included.

Peck and Klatzky investigate the attributes that invite people to reach out and touch. While we know that touch can increase impulse purchase, the feeling of ownership and other measures, we do not know anything about the visual attributes of an object that make touch irresistible

A natural paper to follow is the Townsend and Shu paper which examines the visual appeal of documents. This research uses the buying and selling of stocks to investigate the aesthetics of document design and the effects on stock valuation and investment behavior. Three studies are completed and reported in this research.

The final two papers (Deng, Hui and Hutchinson and Moreau and Herd) both address the aesthetic choices consumers make in product design. Deng, Hui and Hutchinson, in the context of designing a Nike shoe, are interested in whether assisting consumers in their self design choices is superior than providing no assistance. These researchers have completed a preliminary study with almost three hundred participants in order to determine the point at which they should offer design assistance to consumers. They expect that the assisted self-design group will be more satisfied with their aesthetic design experience than those that are unassisted.

Finally, Moreau and Herd delve into the question of *why* consumers are willing to pay a premium for self-designed products. The authors have three completed studies that examine a consumer's social comparison to the professional designers of products. Their third study uses a real online design task in which designs are created, orders are placed and product are produced and delivered to the participants. Aesthetic design is an emerging area in our field. The breath of this special session will likely have great appeal and will stimulate interesting discussion. Each paper will be presented for 15 minutes and the last 15 minutes will be a general discussion.

EXTENDED ABSTRACTS

“Please Touch: Aesthetic Features that Invite Touch”

Joann Peck, University of Wisconsin-Madison, USA

Roberta Klatzky, Carnegie Mellon University, USA

The sense of touch is important in consumer behavior for both instrumental and hedonic purposes. Instrumentally, touch can be thought of as a way to obtain specific product information in order to make a more informed purchase decision. Touch excels at obtaining texture, hardness, temperature and weight information (Klatzky and Lederman 1992, 1993). If a product category varies in a diagnostic way on one of or more of these attributes, also termed material properties, consumers will be more motivated to touch the product prior to purchase (Grohmann, Spangenberg and Sprout 2007; McCabe and Nowlis 2003; Peck and Childers 2003a). For

example, books do not vary in a diagnostic manner on one these attributes so touch is relatively unimportant for purchases in this category. However, cell phones likely vary in a diagnostic way on weight which makes this category more likely to encourage touch. More recently in consumer behavior, touch that provides no diagnostic attribute information has also been found to be persuasive (Peck and Shu 2009; Peck and Wiggins 2006). Consumers may be motivated to touch solely for the sensory experience that touch provides. In summary, previous shows that consumers may be motivated to touch an object for both instrumental and/or hedonic reasons.

Being able to touch an object has been shown to increase impulse purchasing (Peck and Childers 2006) and to increase the feelings of ownership of an object (Peck and Barger working paper; Peck and Shu) and also to increase the amount an individual is willing to pay for an object (Peck and Shu). But how do we encourage consumers to reach out and touch an object? More specifically, what aesthetic features of an object encourage touch?

Evidence has been found for a “visual preview model” which states that vision provides a quick “glance” which results in coarse information about the haptic properties of an object, information that is useful in directing further processing (Klatzky, Lederman and Matula 1993). When encoding properties of some objects, vision may be sufficient because it triggers the retrieval of information about the object's properties stored in memory, eliminating the need for direct perceptual encoding by touch. However, vision may reveal that more detailed information is desired. For example, a visual glance at a sweater may encourage a consumer to touch for both instrumental reasons (to ascertain how comfortable the material would be to wear) and/or for hedonic reasons (it looks like it would feel good to touch). The goal of our research was to begin to explore which attributes encourage a consumer to reach out and touch.

We also include the individual difference in the preference for touch information (Peck and Childers 2003b) termed the Need for Touch scale (NFT). We expect that aesthetic touch judgments will be greater for those high, as compared to those low in their NFT.

Study 1 Procedure

To examine aesthetic touch, our first study uses a methodology where we show experimental participants various objects on a screen. They then rate whether the objects invite touch. The design is a 3 (shape variations) by 3 (visual texture variations) by 2 (size or graspability of an object) by 2 (object material). After the participant judges the “touchability” of each object, we also measure the individual difference need for touch.

Independent Variables: The objects used are adapted from Cooke, Kannengiesser, Wallraven, and Bulthoff (2006) and are objects in which both the macro geometry (the number of protrusions, or shape) and the micro geometry (the visual texture) of the object are varied systematically. More specifically we use three levels of macro-geometry and three levels of micro-geometry.

We also manipulate the size of the object with two levels either graspable (the size of a ping pong ball or less graspable (the size of a cantaloupe). Finally, the material is manipulated with participants being told the object is made out of either a smoother material (marble) or a rougher material (concrete). In total each participant makes 36 judgments.

Dependent Measures

Aesthetic touch—For each object viewed, a participant completes four seven point scales with endpoints “strong agree” to “strongly disagree” including “this object invites touch,” “this object would feel pleasant,” “this object is aesthetically pleasing,” “I want to touch this object” and, “I wouldn’t be able to resist touching this object.” Need for Touch—The 12 item need for touch (Peck and Childers 2003) scale will also be administered.

Thus far, it appears that the more graspable, smoother material objects are more aesthetically pleasing, especially for individuals higher in their need for touch. Fewer protrusions (macro-geometry) seem to encourage touch and a moderate amount of visual texture (micro-geometry) seem to be most attractive to touch. The study will be completed in June and results will be available for the conference.

Study 2

A second study will follow in which physical objects will be constructed for participants to evaluate. The objects will vary in size and material. Participants will evaluate the aesthetic touch appeal of the objects. The objects will be constructed in the summer/fall of 2009 and preliminary results will be available for the conference.

“The Power of Aesthetic Design in Consumer Financial Decisions”

Claudia Townsend, University California, Los Angeles, USA

Suzanne Shu, University California, Los Angeles, USA

While there has certainly always been an inherent understanding that aesthetics impacts product success in the marketplace, lately the business community’s appreciation for product design and its impact on the bottom line has grown (e.g. Gibney and Luscombe 2005; Postrel 2003; Schmitt and Simonson 1997). And yet our knowledge of the impact of aesthetic design on decision-making behavior is minimal. In an attempt to understand the possible limits of the impact of design, we examine it in an extreme context; we observe the influence of aesthetics on behavior involving financial products—an area where, presumably, design’s impact on decision-making is at its limit as it has absolutely no rational role. In a series of three studies we find that, indeed, in hypothetical investment decisions, such as the buying and selling of stocks, the overall look of a document—even one not associated with the company’s product and for a company that does not do anything design-related—impacts valuation and behavior. Our results suggest that this occurs both through an increased sense of ownership as well as through self-affirmation and, moreover, that the effects spill over into subsequent financial decisions with high design association leading to riskier investment behavior.

Our first study establishes that design does, indeed, impact hypothetical financial decisions. We find that the aesthetics of a symbolic document given at the time of purchase of company stock (e.g., a stock certificate) impacts respondents’ selling price for the stock. In particular, respondents assign a higher selling price to the stock when the stock certificate is highly aesthetic versus when the stock certificate is not highly aesthetic ($M_{\text{high aesthetics}} = \38.95 , $M_{\text{low aesthetics}} = \33.22 , $t = -2.06$, $p = .04$). Moreover, this effect exists regardless of whether or not the decision-maker actually is to keep the stock certificate in his/her possession, thus, ruling out a “rational” explanation for this behavior based on higher utility from being able to display the aesthetically appealing certificate.

Our second study shows consistent findings but with a different document, a company’s annual report which, while related to the company, is not related to its product. Again we find that respondents both rate and evaluate a company higher when the annual report is highly aesthetic versus when the annual report is not highly aesthetic. This occurs both in a context where aesthetics is evidently intrinsic to company success (e.g. for a vase manufacturer) and where aesthetics is not evidently essential to success (e.g. for a bubble wrap manufacturer). We find that a sense of ownership partially mediates the impact of aesthetics on company judgment; high aesthetics leads to a greater sense of ownership of the company than low aesthetics and this, in turn, leads to higher company valuation. This confirms the more emotion-based and less rational explanation for this impact of design.

In our third and final study we look more closely at the psychological impact of design on decision-makers and how this affects investment-related behavior. Previous research (Townsend Sood working paper) suggests that the choice of a high design option is self-affirming; in particular, they find that the choice of a high design option has the same impact on subsequent behavior (in particular, openness to counter-attitudinal arguments) as does a self-affirmation manipulation. Given that the authors found these results using a hypothetical choice context, we hypothesized that similar effects might be found by simply creating a strong association between the decision-maker and high design, even without actual choice. Using the prior literature as a starting point, in this

study test whether providing the consumer with a simple personal association with high design (versus high function) impacts financial decision-making. If association with high design is self-affirming, and impacts subsequent openness to arguments, it might also impact openness to investment in a risky opportunity. Indeed, we find that association with high design (hypothetical ownership in a design-related company) leads to subsequent riskier investment activity and less risk aversion as measured through willingness to accept a risky gamble. No such effect occurs after association with high function.

Thus, the learnings from this research are two-fold. First, that aesthetic attributes impact behavior in the context of financial decisions reveals just how robust the role of aesthetics is in evaluation and decision-making. Second, we understand more about how this occurs—both through sense of ownership’s partial mediation as well as through self-affirmation. Further research is needed to understand how and why respondents feel a greater sense of ownership for something that is better looking. This effect seems to imply an inherent personal connection to good looks and may be related to the illusory superiority effect (Alicke 1985, Kruger Dunning 1999, Sedikides Gregg 2003). The finding that mere association with high design leads to riskier investment activity, again, speaks to the power of aesthetics and merits further investigation and likely has implications in both consumer behavior and finance.

“Assisted Aesthetic Self-Design: Application to Nike Shoe Configurator”

Xiaoyan Deng, University of Pennsylvania, USA

Sam K. Hui, New York University, USA

Wes Hutchinson, University of Pennsylvania, USA

Self-design is a form of mass customization in which consumers partly design a product by specifying certain product attributes in the product configurator provided by manufacturers.¹ For mass customization to create real value, those attributes should be ones

on which consumers’ preferences differ sharply and that consumers can easily manipulate and evaluate with the configurator (Zipkin 2001). *Aesthetic self-design*, a particular form of self-design in which consumers choose only the product’s aesthetic specifications, meets these two conditions. “Beauty is in the eyes of the beholder.” While inferring functional benefits from technical specifications often requires a high level of consumer expertise (e.g., Randall, Terwiesch, and Ulrich 2007), aesthetics is in most cases subjective, making consumers into de facto experts about what they personally find attractive. A brief examination of over 500 web-based configurators (www.configurator-database.com) reveals that about 50% are from fashion industries (e.g., apparel, footwear).

The configurators offered by manufacturers in these industries (e.g., Adidas, Converse, Lands’ End, Nike, Ralph Lauren, Reebok, Timberland) are characterized by providing different color palettes for different product components and a variety of color options in each palette. For example, a consumer can use Nike’s shoe configurator (www.nikeID.com) to design a Nike shoe by selecting a color from a platter of 6-12 colors for each of the 7 shoe components (e.g., base, secondary, swoosh, accent, lace, lining, and shox). Presumably the consumer wants to create an aesthetically pleasing color combination for the shoe.

Given that a consumer can select any color combinations for the 7 components, the choice space from which she can pick her most-favorite shoe is huge; a consumer can pick from more than 5 million different shoe designs (Deng and Hutchinson 2009). From a theoretical perspective, the consumer is faced with a high-dimensional optimization problem that involves numerous alternatives, which is made even more difficult because colors “interact” with each other (e.g., Matsuda 1995); for example, red may look great with green, but not with purple, and so on. We expect that consumers may become cognitively overloaded due to the huge number of possible choices (e.g., Schwartz 2004), and thus may not be able to optimally select the shoe that she likes best.

Our main goal in this research is to improve consumers’ aesthetic self-design experience. Our proposed solution to the “choice overload” problem is an “assisted aesthetic self-design” paradigm. Instead of only allowing consumers free and unrestricted choice, we assist them by providing recommendations during their design processes. That is, using an algorithm similar to collaborative filtering (Bodapati 2008), we recommend completed shoes to the consumer while she is still designing her own shoes. For instance, after the consumer selects a “red” base color, we offer a few recommendations (based on how other consumers design their shoes), which also has a red base color and other colors already configured. At any time, the consumer is allowed to switch to any of the recommended design and continue her design process from there. Our hypothesis is that this assisted mode of self-design is superior to the free mode of self-design (which is used by Nike and other manufacturers) in terms of both design outcome and process.

We first conducted a pretest to determine the optimal level of prior information that we should elicit from a consumer before offering her recommendations. That is, should we recommend shoe designs after the consumer makes the 1st, 2nd ... or 7th color decision? 294 participants were asked to self-design a Nike shoe (in phase 1) and later evaluate their self-designed shoe along with recommended shoes (in phase 2). The recommendations shown in phase 2 were drawn from the self-designed shoes collected in phase 1. For each participant, around 20 recommendations were made using 1-6 component colors in her self-designed shoe as anchor(s). For example, recommended shoes anchoring on the 1st color choice would have the same base color as the self-designed shoe; recommended shoes anchoring on the 1st and 2nd color choices would have the same base and secondary colors as the self-designed shoe,

¹Self-design is also called “adaptive customization,” “co-design,” and “user design” and configurator is also called “co-design platform,” “toolkit,” and “choiceboard” in the mass customization literature.

and so on. During the study, participants were unaware of the fact that their self-designed shoe was embedded in the set of recommended shoes. The result indicates an inverted-U relationship between preference and the number of anchor (p -value for the quadratic contrast $<.05$). Recommendations anchoring on 3-5 component colors of a self-designed shoe were rated higher in preference than were the self-designed shoe and other recommended shoes (p 's $<.05$). This pattern suggests that recommendations should be made using the moderate level of color preference information from consumers.

To test our hypothesis that assisted self-design via the recommendation system is better than free self-design, in our main study we will ask participants to self-design a Nike shoe using either the NIKEiD configurator (free mode) or the configurator providing recommendations (assisted mode). The later configurator has been developed by us specifically for this study. Based on the pretest result, our configurator is designed to automatically generate a few recommendations after a consumer makes the first 3, 4, and 5 color choices, respectively. Our goal is to demonstrate that the assisted self-design group has higher satisfaction, a more positive experience, and a higher purchase probability than the free self-design group.

"To Each His Own? How Comparisons to Others Influence Consumer Self-Design"

C. Page Moreau, University of Colorado, Boulder
Kelly Herd, University of Colorado, Boulder

In product categories ranging from running shoes, to pet beds, to ceiling fans, consumers are becoming the designers of their own products, picking aesthetic components such as colors and images, creating designs that reflect their unique preferences. Research shows that consumers are willing to pay a substantial premium for these self-designed products compared to comparable manufacturer-designed alternatives (Franke and Piller 2004), yet limited research explores *why* they are willing to pay this premium.

In this paper, three studies demonstrate that consumers' social comparisons to the designers of comparable products influence evaluations of their own creations, their behavior following the self-design experience, and their product satisfaction. Since professionally-designed, "off-the-rack" alternatives often serve as a basis of comparison for one's own designs, the first two experiments examine how social comparisons with the designers of these products influence consumers' self-evaluations. These experiments also identify two key moderators useful in overcoming the negative effects of an upward comparison to a professional designer. A third study examines how social comparisons to other self-designers influence evaluations and behavior during and after a self-design experience. This study does so by using a real online design task in which designs are created, orders are placed, and products produced and delivered to the participants.

In the first two studies, we examine the influence of social comparison by holding constant the default reference product (an LL Bean backpack) but varying whom the participants thought was its designer (a professional at LL Bean vs. an amateur who won an LL Bean-sponsored design contest). Process measures and preferences for the customized backpack were the dependent measures in all studies.

In Study 1, we manipulated both the designer of the default backpack (professional vs. amateur) and the amount of guidance provided in the self-design task (present vs. absent). The results showed that attitudes toward the *self-designed* product were higher when participants thought that the default backpack was designed by another consumer rather than by a professional ($M_{\text{Professional}}=36.2$ vs. $M_{\text{Amateur}}=39.5$, $p<.05$). In addition, the factors interacted such that when no guidance was provided, participants rated the self-designed backpack significantly higher when the default was designed by another amateur ($M_{\text{No Guidance, Amateur}}=40.0$ vs. $M_{\text{No Guidance, Professional}}=34.3$, $p<.01$); no such differences emerged in the presence of guidance. Participants appeared to process upward social comparison information non-defensively.

Study 2 provides further evidence that social comparison processing occurs in self-design situations by testing for derogation. In this study, we manipulate the order in which participants are told they will be allowed to customize their backpack (before vs. after they evaluate the default backpack). Participants who knew about the customization opportunity before they evaluated the default backpack rated it lower when the designer was a professional as compared to an amateur ($M_{\text{Professional}}=24.1$ vs. $M_{\text{Amateur}}=27.6$, $(F(1, 145)=4.58, p<.05)$). Participants who had no knowledge of the customization opportunity when they rated the default showed no difference in their evaluations ($M_{\text{Professional}}=27.2$ vs. $M_{\text{Amateur}}=24.7$, $(F(1, 145)=2.04, p>.10)$). Evaluations of the self-designed backpacks are also consistent with the social comparison account. For participants who had the chance to derogate the default, no differences emerged in their self-evaluations ($M_{\text{Professional}}=35.2$ vs. $M_{\text{Amateur}}=34.8$, $(F(1, 119)=.29, \text{NS})$). However, of the participants who did not have the chance to derogate the default, those facing an upward comparison incorporated the negative comparison information into their self-evaluations in a manner consistent with non-defensive processing ($M_{\text{Professional}}=31.8$ vs. $M_{\text{Amateur}}=38.1$, $(F(1, 119)=6.88, p<.01)$).

In study 3, we introduce a design contest as another means for repairing threatened self-regard, manipulating the timing of the contest announcement. In this study, all participants designed customize skins for an electronic device. The results show that when a contest provides a means for repairing threatened self-regard (i.e., is announced prior to a design task), upward comparison targets (i.e., professional designers) yield higher contest participation rates than comparisons to more equivalent targets (i.e., amateur designers). When a contest does not provide a means for repairing threatened self-regard (i.e., is announced after a design task), participation rates were unaffected by type of comparison target. This decision to enter the contest lead to differences in evaluations of the self-designed skins, evaluations of perceived fit of the design, willingness to pay, time spent on design, product satisfaction, and ratings from independent judges.

The first two studies indicate that upward comparisons to professionals tend to be processed non-defensively, resulting in lower evaluations of self-designed products. Providing guidance and prompting defensive processing are both effective ways to diminish the influence of the negative information generated by these upward comparisons. The third study demonstrates that when defensive processing is prompted (e.g., by an explicit competition),

the upward comparison can enhance evaluations of self-designed products when accompanied by an opportunity to repair self-regard. It does so by increasing participation in the repair opportunity, which subsequently leads to higher evaluations of self-designed products, greater willingness to pay, and higher long-run satisfaction. Ratings from independent judges confirmed these effects.

SPECIAL SESSION SUMMARY

Deep Determinants of Value: New Perspectives on the Endowment Effect

Rama Ganesan, University of Arizona, USA

SESSION OVERVIEW

Decision makers exhibit a number of systematic biases both in the lab and in the field. The endowment effect demonstrates two such biases, reference dependence and loss aversion, in the framework of economic transaction. Although the endowment effect has been applied to explaining a wide variety of small and large scale economic phenomena, its underlying mechanisms still remain obscure. Illuminating these deep *determinants of value* shaping the endowment effect and related phenomena can inform novel predictions, identify the potential scope of observed effects, and reveal the degree to which various market incentives will mitigate or enhance effects (Chen, Lakshminarayanan and Santos 2006). For instance, is the endowment effect driven by universal processes arising from evolved biological features? Emerging evidence for loss aversion in animals suggests that this may be the case (Chen et al. 2006; Marsh and Kacelnick 2002). On the other hand, loss aversion is known to be limited and influenced by complex higher-level cultural and contextual factors (Novemsky and Kahneman 2005). The papers in this session explore the endowment effect and the specific processes and systems of valuation from which it arises, employing diverse levels of analysis and taking disparate points of view.

The first two papers address the phenomenon as more fundamentally driven, respectively examining emotional reactions to anticipated losses, and anticipated (but unrealized) gain or reward. Emphasizing the loss aversion that forms the basis of the endowment effect, Ganesan and Saqib examine the temperamental variables that might predispose one to be more or less sensitive to loss. Specifically, they show that prices elicited in the endowment paradigm are dependent upon inherent differences in temperamental fear. Conversely, Litt, Khan and Shiv focus on how gain-anticipation may differentially influence distinct components of value determining the endowment effect. Drawing upon recent neuroscientific research, they examine circumstances that cause the decoupling of *wanting* (as determining prices offered by buyers) and *liking* (driving prices and sufficient-substitutions demanded by sellers). The third paper gives more emphasis to contextual factors, such as the *temporal frame* that embeds the transaction. Chatterjee and Irmak show that when pre-owned objects are presented in the past (vs. future) temporal frame (e.g., “three years of the car’s lifetime have passed” vs. “nine years of the car’s lifetime remain”), they are not susceptible to differential valuation by buyers and sellers.

Although the three papers apply different and complementary approaches to studying the bases of the endowment effect, they are united in their measurement and relation of the phenomenon to important individual differences in traits and tendencies. A key unifying goal of discussion will be to explore the compatibility of these approaches and results, and how each paper may illuminate different facets of the deeper processes of valuation driving the endowment effect. Guiding this discussion and audience-inspired debate will be Joel Huber, a leading researcher on the endowment effect and broader conceptualizations of choice and value.

This session will appeal both to researchers interested in the endowment effect itself, as well as those studying the underlying components and mechanisms of valuation probed by the session’s papers in order to provide new insights into the effect and related phenomena. This audience includes behavioral decision researchers, those interested in emotional and motivational influences on

valuation and decision making, and those employing methods ranging from behavioral study to neuroscientific investigation.

EXTENDED ABSTRACTS

“Defending Against Loss: Temperamental Fear Predicts Endowment Effect”

Rama Ganesan, University of Arizona, USA
Najam Saqib, Ryerson University, USA

The endowment effect demonstrates one of the essential properties of Tversky and Kahneman’s (1991) reference-dependent model in that the psychological effect of a loss is greater than a gain of the same magnitude. What causes this endowment effect? To answer this question, we investigate the fundamental psychological mechanism that might conceivably determine this loss aversion. We posit that the mechanism for loss aversion is *fear*. Fear is our reaction to anticipated loss, whether it is the loss of life itself at one extreme, or the loss of a consumer good in our possession at the other end. Camerer (2005) has previously suggested that the endowment effect may be a short-term fear reaction to anticipated losses and gains.

However, because the behaviors and self-reports of participants in the typical endowment paradigm do not evince fear, one needs to look for alternative methods to determine its effect. We reasoned that, if the endowment effect is essentially determined by fear, then it must be related to the inherent fearfulness of the individual. We suggest that loss aversion is related to one particular *trait variable* that relates to the threat of loss, *temperamental fear* or *trait fear*. In our first study, we show that in the standard endowment paradigm, prices elicited are highly dependent upon temperamental fear, particularly among the sellers. We find further correlational evidence in that a manipulation that reduces the endowment effect (Novemsky and Kahneman 2005) also reduces the relationship between temperamental fear and prices offered or demanded. In the second study we support our argument by manipulating fear and we find that inducing fear increases the magnitude of the endowment effect.

In the first study, we related the participant’s inherent fearfulness to the price offered for buying the focal object and the price demanded for selling the focal object (set of highlighters). Participants were 228 undergraduate students who were randomly assigned to play the role of buyers or sellers. Temperament scales were administered, followed by filler tasks prior to the endowment procedure. Temperamental fear was measured by the Fear Survey Schedule II (FSS, Bernstein and Allen 1969). For FSS ($\alpha=0.83$), the subjects reported their fear for fourteen individual objects or situations (such as *getting hurt*, *snakes*, and *public speaking*) on 7-

point scale of *none, very little, a little, some, much, very much* and *terror*. As it is important to distinguish temperamental fear from other related trait constructs, we also included other well-known and popular scales for anxiety, depression and prevention and promotion focus (NEO-PI-R, Costa and McCrae, 1992; Lockwood et al. 2002). Prior to price elicitation in either condition, current affect was measured by the PANAS scale (Positive and Negative Affect Scale, Watson et al. 1988).

The typical endowment effect was confirmed as sellers demanded twice the amount for the endowed object relative to buyers (\$4.08 vs. \$1.79, $F(1,224)=140.7, p<0.001$). Subsequent analyses indicated a significant relationship between the measure of temperamental fear and price demanded by sellers and price offered by buyers. Specifically, we find a strong positive relationship for sellers ($r=0.74$) and a more moderate negative relationship for buyers ($r=-0.36$). This indicates that temperamental fear is related predominantly to the increased valuation of the focal object by sellers, but also to some extent to a decreased valuation by buyers. A median split of the subjects based on the FSS score showed that the extent of the endowment effect is significantly greater among the high fear group relative to the low fear group (significant interaction between role and fear group, $F(1,144)=53.78, p<0.001$).

Other variables (NEO-PI-R anxiety and depression, PANAS current positive and negative affect) had no relationship to price in either condition. A small positive relationship found for promotion and prevention focus became nonsignificant in the follow up regression where temperamental fear score was added to the equation (control factors include age and gender). In the additional condition where subjects experienced a prior loss (losing out in a random drawing for a cup) the endowment effect was eliminated (2.77 vs. 3.08 in buyers and sellers respectively, *ns*). Here there was no correlation between FSS score and price demanded or offered. This is an important result in relation to the standard endowment condition, as it shows that the effect can be eliminated by quite simple interventions.

In the second study, we induced fear among our participants ($n=84$) by requiring them to prepare for a public presentation (a modified Trier Social Stress procedure, Childs et al. 2006). Subjects in the neutral condition ($n=84$) were required to prepare to evaluate a public presentation. Affect scores indicate an increase in current fear (relevant terms include *afraid, scared* and *nervous*) in subjects in the fear condition relative to the neutral condition, (2.03 and 1.54, $t(1,172)=3.08, p<0.001$). Price was then elicited among buyers and sellers in both affect conditions. Price demanded by fearful sellers was increased relative to neutral sellers, \$4.26 vs. \$3.45, $t(1,87)=2.62, p<0.01$. The endowment effect was enhanced in the fear condition relative to the neutral condition, $F(1,164)=3.38, p<0.07$. This result further supports the argument that fear is the mechanism underlying loss aversion, and the endowment effect (Camerer, 2005).

Taken together our findings have implications for the current global recessionary climate. As fear leads to both an increased valuation for owned objects, and a decreased valuation for objects not owned, the net effect could be a reduction in all types of buyer-seller transactions. Consumers and markets are now focused on defending against further loss than on pursuing new opportunities. In addition, our paper has implications for the resolution and management of the recessionary paralysis. Under laboratory conditions, certain interventions can eliminate the effect of fear and return participants to a more rational valuation.

“Wanting More but Liking Less: Counter-Driving Motivational and Appraisal Elements of Value”

Ab Litt, Stanford University, USA

Uzma Khan, Stanford University, USA

Baba Shiv, Stanford University, USA

Underlying many instances of the endowment effect may be qualitative differences in valuation formation processes in the presence versus absence of ownership. Value judgments in the absence of ownership may be most reflective of individuals' desire or *wanting* for a target. In contrast, valuation of owned targets may reflect actual, perceived, or forecasted *liking* of the target; that is, appraisal of its overall appeal and the pleasure it brings one. Growing work in psychology and neuroscience is establishing that wanting and liking are underserved by distinct and dissociable subsystems (Berridge, 1996; Winkielman & Berridge, 2003). This dissociability may not only underlie the valuation disparity characteristic of the endowment effect, but raise the potential for differentially influencing these systems to mitigate or reverse that disparity.

We propose that frustrating failure to obtain desired outcomes can induce such parallel counter-driving. Responses to such unpleasant “jilting” have significant implications for both peoples' subsequent desire for denied objectives (wanting), and how they feel about the targets themselves (liking). In particular, we propose that failure to achieve a desired end-state can simultaneously *increase* desire to obtain the outcome, but *decrease* its overall appeal due to tainting by the unpleasantness of failing to obtain it. Perversely, a target becomes more desired as it becomes less desirable. Thus, after experiencing initial denial, people can come to want something more and like it less, a valuation disparity opposite to that most consistent with the endowment effect.

Primary-Effect Study

Experiment. Sixty subjects were provided an allotment of ‘virtual tokens’, and told they would be used to purchase or play games for real prizes. They then made a series of willingness-to-pay (in tokens) judgments for various potential prize products. For half of the subjects (the “non-jilted” group), this initial series included a prize, P , that they subsequently won in a rigged game. The other half (the “jilted” group) were instead told that they lost this same game with the same possible prize P , and only after were queried

regarding willingness-to-pay for *P*. These willingness-to-pay judgments were our dependent measures of “wanting” for prize *P*.

All subjects then played a second rigged game, in which the jilted group finally won prize *P* (and non-jilted subjects won tokens). All were then offered the chance to trade *P* for an alternative, *Q*, with willingness-to-switch taken to conceptualize “liking” for prize *P*, in terms of satisfaction (higher willingness-to-switch being akin to lower liking, and lower willingness-to-accept in typical endowment effect studies). Subjects also completed an Affect Intensity Measure (AIM) of individual differences in strength of emotional experience and responsiveness (Larsen & Diener, 1987), to explore the centrality of affective reactions to our proposed effects.

Results. For wanting, jilted subjects reported significantly amplified willingness-to-pay for prize *P*, both compared to non-jilted subjects (mean 7.56 vs. 5.29 tokens; $t(53)=2.289$, $p=.026$), and in within-subject comparison to a highly similar prize, *P'* (paired $t(26)=3.276$, $p=.003$) pre-tested to be similarly attractive. Importantly, this effect was driven by individuals scoring low in affect-intensity, based on an AIM median-split (interaction $\beta=-1.602$, $p=.043$); high-AIM jilted subjects did not show significant mean difference from non-jilted subjects in willingness-to-pay for *P*. In contrast, for liking, jilted subjects reported significantly higher willingness-to-switch away from prize *P* to alternative prize *Q* (78%) than did non-jilted subjects (43%; $p=.013$, Fisher’s exact test).

A second study provided converging evidence by employing alternative wanting-liking operationalizations; tested robustness to changing product-denial attribution from a subject’s own failure to a stock-out; and explored generalizability of jilting effects to based on brand-overlap alone.

Generalized-Effect Study

Experiment. Using a nested between-subjects design ($n=159$), in Part 1, half of subjects faced an “out of stock” denial of putative potential to obtain a pair of Guess-branded sunglasses following task completion. The other half performed the same task and were exposed to the same sunglasses, but did not expect to receive them (or anything else).

Part 2 measured wanting and liking between-subjects across Part 1 conditions. Rather than the Guess sunglasses, a pair of his-and-her Guess watches (the “jilt-proxy”) was introduced. For wanting measurement, subjects chose one of two prize packages for a lottery draw-entry, either the Guess watches or similar Calvin Klein-branded watches. In contrast, our liking measure queried attractiveness evaluations, detached from wanting-influenced choice inclinations. We adapted the distortion paradigm (e.g., Russo et al., 1996), in which favoring/disfavoring of alternatives is captured by individuals’ judgments of serially presented equivocal information as actually favoring one alternative over another. In particular, we measured distortions between the Guess and CK watches in evaluating equivocal and non-diagnostic attribute information (movement, watch-band, etc.). Finally, all subjects completed the AIM used in the primary-effect study.

Results. As before, we observed AIM-moderation for wanting: jilted low-AIM subjects significantly over-chose the jilt-proxy (83%; $B(24,0.5)$, $p=0.0015$), whereas high-AIM subjects trended marginally towards under-choosing the jilt-proxy (30%; $B(23,0.5)$, $p=0.093$) in favor of the alternative ($p<0.0005$, Fisher’s exact test).

For liking, distortion computed across nine attributes as per Russo et al. yielded near-zero distortion in favor of either Guess (jilt-proxy) or CK by non-jilted subjects, versus $+0.40$ units against the Guess item by jilted subjects ($t(582)=2.7592$, one-sided $p<0.005$,

and cumulative distortion after all nine stages of 3.83 units against Guess. Paneling by AIM did not yield significant differences in anti-Guess liking-distortion ($t(286)=1.1637$, $p=0.2455$).

Implications

These findings support the notion that wanting and liking can be counter-driven by denial of desired targets; in particular, in a direction contrary to that most consistent with the endowment effect. This may aid in understanding how consumer experiences such as stock-outs could differentially affect valuation metrics that are more wanting-driven (e.g., demand, WTP) versus those more related to liking (e.g., return rate, repeat-purchase propensity, WTA). Affect-intensity interaction results may suggest tighter coupling of wanting and liking sub-systems in high-AIM individuals, leading to greater inter-regulation and reduced disparity. Such “hot-headed” individuals actually exhibit more hedonically normative desires, that is, desires and desire-driven behaviors more consistent with the ultimate evaluative feelings that would govern happiness.

“The Impact of Temporal Focus on the Endowment Effect”

Promothesh Chatterjee, University of South Carolina, USA
Caglar Irmak, University of South Carolina, USA

Imagine a consumer interested in buying a three-year-old, pre-owned car. The seller claims that the car is good for nine more years (future focus). On the other hand, the buyer can think of the car as one that has been used for three years (past focus). Do sellers and buyers approach such exchange occasions with pre-determined temporal foci, which diverge from each other? If so, does this variation in the temporal focus affect selling and buying prices? Given the large body of research on the endowment effect (Thaler 1980), demonstrating selling prices of objects to be considerably higher than buying prices, answers to these questions are of considerable theoretical and practical importance.

While the endowment effect has mostly been explained as a manifestation of loss aversion (Kahneman, Knetsch and Thaler 1990), some recent research investigated how sellers’ and buyers’ foci diverge, which sheds more light into the underlying process of this phenomenon. For example, Carmon and Ariely (2000) show that buyers and sellers focus on what they forgo in the exchange. While buyers focus on the money, sellers focus on the benefits of possessing the product and, as a result, buying prices are more affected by the change in expenditure-related aspects of the object; whereas selling prices are more influenced by the change in aspects that are related to the benefits of the object. Nayankuppam and Mishra (2005) indicate that sellers and buyers focus on features of differing valence. Sellers’ evaluations of the products are more influenced by the positive (vs. negative) features of the products,

while buyers' evaluations are more affected by the negative (vs. positive) features of the products.

In the present research, we build on this body of research by investigating how temporal focus affects selling and buying prices of objects. Since time is an inherent factor in the evaluation of pre-owned products, we focus on such products in our research. Focusing on pre-owned products is not only theoretically interesting and perhaps necessary in our context, but also it is practically important given the market size of some pre-owned products (e.g., books, cars) in the U.S. is actually larger than that of the new counterparts. For example, Bureau of Transportation Statistics (2007) reports a trade volume of \$339 billion for pre-owned cars and substantially greater number of old automobiles being traded than new ones.

Research on time perspective literature suggests that future-orientation entails a focus on future goals and a tendency to relate immediate choices to distant objectives (Lewin 1948). Past-orientation, on the other hand, involves a focus on similar previous situations with their accompanying positives and negatives. Importantly, Zimbardo, Keough and Boyd (1997) contend that though time perspective tends to be a functional cognitive style, it can vary as a function of situational, structural, and task demands. Based on this, and the aforementioned research on the endowment effect, we predict that, when a pre-owned product is presented in the future temporal frame, sellers, with ownership as their point of reference, will view the sale as a loss of the future benefits, while buyers will incorporate both past and future aspects of the product in their evaluation. Consequently, selling prices will be higher than buying prices. When the product is presented in the past temporal frame, however, sellers will not be able to focus solely on future benefits of the product, resulting in no significant difference between selling and buying prices, i.e., mitigation of the well-established endowment effect. We tested these predictions across three studies, summaries of these studies are described next.

In study 1 we explored how chronic temporal focus (i.e., temporal orientation) affects selling and buying prices of an object. We reasoned that sellers who are high on past-orientation would focus on the past of the product (a 3 year old car) and thus lower their valuation mitigating the endowment effect. Consistent with this, we find that endowment effect is mitigated for high past oriented people but not low past oriented people. In study 2a, 2b we manipulate the foci of buyers and sellers by a temporal framing (e.g., 3 years life used vs. 9 years life remaining) across two different domains—used cars and partly used football season tickets. Consistent with our hypothesizing we find endowment effect only in the future frame but not in the past. Study 3 again used a temporal framing but used a real stimulus of Netflix coupon instead of hypothetical scenarios as in previous studies. We also focus on the process underlying the effect. Our findings suggest that it is sellers' heightened focus on future that results in the disparity of selling and buying prices. These findings not only provide insight to the underlying process of the endowment effect by demonstrating a key moderator (e.g., temporal focus), but also have important implications for marketers of used goods (e.g., eBay, Amazon.com, car dealers).

SPECIAL SESSION SUMMARY

What is the Intelligent Choice? Performance on the CRT and Preferences

Claudia Townsend, UCLA Anderson School of Management, USA

SESSION OVERVIEW

Typically in consumer behavior and decision-making research we examine the general trend of responses—what the majority is doing or choosing. However, it is also informative to look at the differences between individuals. The papers presented in this session examine intelligence, as measured by the Cognitive Reflection Test (CRT; Frederick, 2005), its correlates, and how this individual difference impacts various behaviors. The CRT primarily measures respondents' propensity to resist reporting the first response that comes to mind. However, its correlation with intelligence measurements allows it to substitute for such a tool as well. The works presented here utilize the CRT in both of these capacities to provide new insights both about correlates of this tendency to resist (or not) the first heuristic response, as well as the relationship between intelligence and preferences for risk, time, and aesthetically pleasing products.

In the first presentation Spunt and Lieberman examine the CRT in its primary role to discriminate “gut” first responses from slower more methodological responses. They propose that the propensity to go with one's initial response is the result of overconfidence. In three behavioral studies they find that reducing confidence in first responses, either through indirect inductions of self-doubt or by directly invalidating initial responses, can make individuals behave in what seems to be a more intelligent manner. Moreover, the results of a fourth fMRI brain imaging study corroborates this notion. Thus, this work is able to explain something further about the CRT and, subsequently, about response behavior.

The other two projects build upon this work and use the CRT as an intelligence indicator—by itself in the work by Frederick Fong, and Tsytsylin and along with vocabulary questions (Mill Hill Vocabulary Scale) in the work by Townsend, Ariely, and Sood. Both these works examine the differences in preferences between less and more intelligent individuals. Frederick, Fong, and Tsytsylin not only examine preferences, but also lay-theories about these preferences—how people expect more intelligent and less intelligent people to differ. They find that providing the less intelligent with information on the preferences of the more intelligent impacted actual choice behavior in only some domains e.g. risk preferences and not in others e.g. time preferences. Thus, as with the first work presented, Frederic, Fong, and Tsytsylin suggest one way in which to engender more intelligent choice behavior, though only in some realms. And, indeed, as the authors point out, a relation between intelligence and preference, by itself, does not necessarily identify the correct choice in all cases.

Townsend, Ariely, and Sood also examine the relationship between lay-theories about intelligent choice versus actual choice. Testing the old adage that one ought not to “judge a book by its cover,” the authors examine respondents' propensity to choose good looking products—even when the choice of good looks means giving up higher functionality or a well-known brand. Contrary to popular wisdom, they find that highly aesthetic choices are more popular among the highly intelligent than the less intelligent suggesting something consequential about product design.

By looking at individual differences on the CRT, these three studies provide insights on both personal preferences as well as general trends. Specifically this research offers learnings on the propensity to respond heuristically, the role of overconfidence, and the relationship between lay-theories about intelligence and actual

behavior. Moreover, these studies both suggest and find limits on interventions to encourage intelligent choice.

Therefore, the proposed session would be of interest to a broad swath of consumer researchers and anyone interested in promoting normative choice behavior. This session would be of special interest to those interested in individual differences, risk or time preferences, aesthetics and brand preferences, and/or fMRI research. We hope that a session on these essential topics will incite debate and ideas for further research.

EXTENDED ABSTRACTS

“Getting Past that First, Compelling Response: Three Behavioral Studies and an fMRI Investigation of Performance and Overconfidence on the Cognitive Reflection Test”

Robert Spunt, UCLA, USA

Matthew Lieberman, UCLA, USA

This research offers theoretical and empirical perspectives on the constructs of cognitive reflection and overconfidence as measured using the Cognitive Reflection Test (CRT; Frederick, 2005). The various forms of the CRT feature quantitative reasoning word problems, each of which tends to induce a single incorrect response which is typically reported with high confidence. The following item is illustrative: “A bat and a ball cost \$1.10 in total. If the bat cost \$1.00 more than the ball, how much does the ball cost?” In scores of studies, over 90% of individuals who answered this item incorrectly did so by reporting the same response—10 cents. Frederick (2005) thus defined cognitive reflection as the tendency to resist reporting the first response that comes to mind when making a judgment or decision. Moreover, this tendency was explained using a two system model (Stanovich & West, 2000), which states that judgments and decisions often induce a first response that is the product of a fast and automatic computation system (System 1), but that these responses can be overridden by a relatively slower control system (System 2), which can implement the rule-based sequential operations that permit judges and decision makers to carefully consider alternatives. It was assumed, then, that individuals who are low on cognitive reflection rely too heavily on System 1, while individuals who are high on cognitive reflection tend to spontaneously activate System 2 before committing to a response. Additionally, the tendency to cognitively reflect on the CRT is associated with measures of intelligence as well as normative preferences in the face of risk and delay.

The first three studies expand on this two system account by additionally taking an attribution substitution approach to performance and overconfidence on the CRT (Kahneman & Frederick, 2002). The framing of each problem (e.g., the bat and ball problem above) suggests an easy, heuristic operation (e.g., subtracting) on the given quantities (e.g., \$1.10 and \$1.00) that becomes substituted for the relatively more effort- and time-costly target operations (e.g., the algebraic relationship among the bat, ball, \$1.10, and \$1.10). The resulting answer is then subjectively experienced as correct because it is the correct output, but to the wrong operation. Thus, attribute substitution explains not only errors on the CRT, but also overconfidence in those errors (referred to elsewhere as intuitive confidence; Simmons & Nelson, 2006).

The two system, attribute substitution account generates the simple hypothesis that reducing confidence in or invalidating the heuristic operation should boost performance and reduce overconfidence in errors on the CRT. In three studies, we show that both of these are true. Compared to a control condition where participants complete the CRT with no special instructions, participants for whom the heuristic response (e.g., 10 cents) was indirectly invalidated performed better and exhibited realistic levels of confidence in their errors. In a third condition, participants who were explicitly cautioned against reporting the first response showed a similar improvement in performance, but those who continue to commit heuristic errors continued to exhibit overconfidence. These effects of invalidation were specific to the heuristic responses and did not occur when alternative, nonheuristic responses were directly invalidated (e.g., 20 cents). In another study, we show that describing the CRT as a confirmation of gender differences in mathematical ability (which in women is known to induce a state known as ‘stereotype threat’; cf. Shapiro & Neuberg, 2007), improves performance for women but actually impairs performance for men. Given that stereotype threat is thought to induce self-doubt in women and confidence in men, this suggests that contextual variables that modulate confidence can incidentally modulate the likelihood that a given individual will seek out alternatives to their first response when making a judgment or decision. Altogether, these studies suggest that reducing confidence in first responses, either through indirect inductions of self-doubt or by directly invalidating responses known beforehand to be prepotent, can make individuals behave in what seems to be a more intelligent, self-conscious manner.

In addition to these behavioral studies, we investigated the neural correlates of performance on the CRT using functional magnetic resonance imaging (fMRI). Given that the networks for deliberative quantitative reasoning have already been mapped in the brain, comparing brain activity during the computation of correct and heuristic responses enables a novel test of the two system characterization of judgment and decision making. For this study, we developed a 48-item adapted version of the CRT that participants completed while being scanned. Preliminary results show that solving the CRT items correctly compared to heuristically is associated with regions of the lateral frontoparietal cortices believed to be involved in deliberate logical and mathematical computation. Analyses are currently underway to determine brain regions selectively associated with the computation of heuristic responses.

Taken together, these findings shed light on the psychology of naively going with one’s first response versus carefully considering alternatives when making a judgment or decision. Additionally, they suggest that in addition to its utility as a brief individual differences measure of the tendency to resist reporting first responses, the CRT items present useful tools for studying the two system account of the process of attribute substitution.

“Should Einstein Manage your Money? Lay Theories and Normative Force of the Relation Between Cognitive Ability and Preferences”

Shane Frederick, Yale University, USA

Nathan Fong, Sloan School of Management, USA

Eric Tsytlylin, Yale School of Management, USA

Attitudes towards time and risk affect everything from how early a person leaves to catch a 10:00 flight, to the perceived urgency of regulating carbon emissions to combat global climate change. Much evidence now suggests that smarter people both discount future rewards less and have greater risk tolerance (see, e.g., Frederick, 2005). Such results could be interpreted as support for philosophical or theoretical arguments against excessive discounting or risk aversion (Rawls, 1971; Rabin & Thaler, 2001). Some do, in fact, draw this conclusion (Stanovich & West, 2000; Frederick, 2005), while others resist this inference (Sternberg, 2000).

In this research, we study whether people are aware of the relations between cognitive ability, such preferences, and the significance they attach to these facts. Koriat and Nisan (1977) examined both of these issues with young children. Kindergarten students drew pictures for the experimenters, and were rewarded with a choice between one candy immediately and two candies the next day. While 54% chose the larger delayed reward, 86% predicted that a “smart kid” would choose the later larger reward. Surprisingly, children who were first asked what a smart kid would do did not increase their patience—although 79% predicted that the smart kid chose the delayed larger reward, only 36% did so themselves. Thus, Nisan and Koriat demonstrated that children as young as five years old anticipate the relationship between intelligence and time preferences, but gave no weight to this fact even when their attention was directed towards it.

We used a similar design with adult respondents. Respondents were told (truthfully) that previous studies had found a relation between cognitive ability and some types of preferences. Respondents then attempted to predict the direction and strength of these relations by estimating the proportion of low-scoring and high-scoring respondents who preferred the various options.

Most subjects, for example, correctly predicted that smarter people would be more inclined to choose The New Yorker magazine over People magazine, and a larger later reward (\$3800 next month) over a smaller sooner reward (\$3400 this month). However, for items involving choices between a sure thing (e.g., \$100) and a risky option (a coin flip for \$300), respondents either failed to predict the observed difference, or generally predicted the opposite effect. For instance, although high scoring respondents were much more likely to prefer the gamble (63% vs. 21%), only 29% of respondents asked to predict the difference managed to correctly predict even the direction of this effect.

When respondents were told of the true relation between cognitive ability and various preferences, the impact depended on domain. In the domain of time preference discovering (or being reminded of) the correlation between intellect and time preferences (since most predicted it correctly) did not influence respondents' time preferences, replicating Nisan and Koriat's findings with children. By contrast, for decisions involving risk, while most respondents did not anticipate the greater risk tolerance among high scorers, learning about the true correlation did influence respondents' choices, increasing the proportion of respondents choosing the gamble from 15% to 26%. In other words, the news that "Johnny chose the gamble" may have provided justification (if not the compulsion) to choose it themselves.

The relevance of a correlation between some ability and some preference clearly depends on the type of ability and the type of preference in question. It is obvious that one should imitate Gary Kasparov if deciding which chess piece to move, but equally obvious that Einstein's preference for apples over oranges has no special significance to which you should prefer. Thus, a relation between cognitive ability and preference, by itself, surely does not identify the correct choice in all cases. But such information does, apparently, have significance, in at least some domains.

"The Intelligence of Judging Products Based on Looks"

Claudia Townsend, UCLA, USA

Dan Ariely, Duke University, USA

Sanjay Sood, UCLA, USA

There is a common belief that making decisions based on the way something looks is not an intelligent way to think. There is the familiar adage that one ought not to "judge a book by its cover" and this bias against evaluation based on appearance is likely considered, either consciously or unconsciously, by people in a variety of situations—from meeting new people to selecting a new household appliance. Moreover, recent work indicates that respondents consistently under-value the importance of product aesthetics in choice and also look to other, more functional, attributes to justify the choice of more attractive products (Townsend Sood working paper A). Indeed, there seems to be some common understanding that performance and functionality ought to play a greater role in evaluation than looks. And yet, in a series of studies we find that more intelligent individuals are more likely to choose better looking options—even when selecting good looks means selecting poorer functionality or a worse brand. Along with functionality, we examine the trade-off made with brand as this is another attribute that, even more so than design, may be considered an indicator of overall quality. Moreover, in the realm of fashion-related products it functions similarly to design as a source of value and as a signal to

others. And yet, the preference for good design over a well-known brand persists, despite intelligent individuals having greater overall brand knowledge. That intelligent people are more likely to allow design to drive their choices, suggests there is some value in good design that ought to be further recognized.

The Cognitive Reflect Task (CRT) was introduced to measure one specific type of cognitive ability—the propensity to question one's initial response and correct it if there is a better one (Frederick 2005). Yet, it is positively correlated (with medium correlation) with self-reports on various intelligence and performance measures including the Scholastic Aptitude Test (SAT, .44) and the Wonderlic Personnel Test (WPT, .43). Thus, we used the three question CRT, as well as ten questions from the Mill Hill vocabulary test, as an indicator of overall intelligence. Using the CRT as part of our intelligence test, in fact, worked against our hypothesis that more intelligent people would choose based on design. Previous research (Townsend Sood working paper B) provides evidence for a more system 1-based processing of design relative to the more system 2-like processing of functional attributes, finding that cognitive load increases the choice share of the more aesthetic option. Based on this finding, one would expect those who are more prone to cognitive reflection and who are less likely to give the initial or more system 1-based response are also less likely to base a decision on design and more likely to take into account the functional attributes which are, presumably, processed with more reflective system 2 thinking. Therefore, our findings that intelligence, as partially measured by CRT, and preference for good design are correlated is particularly intriguing.

In Study 1 we found that when faced with a hypothetical choice between two options where one performs better on a functional attribute and the other is better looking, those who score better on the CRT as well as our overall intelligence indicator (combination of CRT and Mill Hill vocabulary score) were more likely to select the better looking, though functionally inferior option, than less intelligent respondents. One possible explanation for these results is that, despite asking respondents to assume the products were the same on all other attributes, because we provided information on only one functional feature along with design, perhaps the selection of good looks was driven by a notion that good looks implies better performance in other domains.

In Study 2 we examined design versus brand. Moreover, we examined fashion-related goods (e.g. clothing, accessories) where functionalities are less relevant. Thus in Study 2 respondents chose between two options where one was good looking and from an unknown brand while the other was less good looking and from a well-known brand—e.g. attractive Sun Song-branded dress versus unattractive Donna Karan-branded dress. Again, we found that more intelligent respondents were more likely to select the better designed options, despite the unknown brand name.

In our third study we examined this same issue using a different probing mechanism and asked respondents to give a price at which they would be equally likely to purchase two options. Respondents were shown a branded fashion item with a price and asked at what price they would be as likely to purchase a counterfeit version. Thus, in this study we were examining more specifically the value of an authentic brand-name to consumers. Consistent with our previous results, intelligent respondents valued the authentic brand-name less, pricing the counterfeit version higher, on average, than less intelligent respondents and, again, indicating that the overall look of the product is more important to highly intelligent individuals than those less intelligent.

The research presented here reveals that, at least in consumer products, valuing looks is associated with higher intelligence. These results are counterintuitive with respect to both our lay-

114 / *What is the Intelligent Choice? Performance on the CRT and Preferences*

theories about not “judging a book by its cover” as well as research on CRT, system 1 versus System 2 processing, and design. But also, these findings build on other work on both CRT and intelligence—some of which is also presented in this session.

SPECIAL SESSION SUMMARY

The Constructive Role of Effort in Consumer Choice

Rom Schrift, Columbia University, USA

SESSION OVERVIEW

Different streams of literature suggest that experienced effort in choice plays an important role in consumer choice and judgment. Although the sources for effort in choice are numerous and diverse (e.g. type and amount of conflict, similarity among alternatives, perceptual fluency, amount of information, etc.) the literature supports the notion that consumers are averse to effort and often engage in behaviors intended to reduce it. Such demonstrations of effort and conflict reduction behaviors can be seen in different streams of literature such as pre-decisional distortion of information (e.g., Russo, Medvec, and Meloy 1996, 1998), motivated reasoning and judgment (e.g. Kunda, 1990; Kruglanski 1990), confirmation bias (Lord, Ross, and Lepper, 1979), and also in the effort-accuracy paradigm (Payne, Bettman and Johnson 1993).

In accordance with the aforementioned effort reduction behaviors, most research has explored and reported the negative impact that effort may have on different aspects of choice. For example, research in behavioral decision theory has shown that the likelihood to defer choice is positively correlated with the intensity of conflict in choice (Tversky & Shafir 1992; Dhar 1997). In addition, research on meta-cognition has repeatedly demonstrated that effortful processing of visual stimuli (visual disfluency) decreases the evaluations of the target object (e.g. Schwarz, 2004; see Labroo and Kim, 2009 for exception).

In contrast to existing literature, the papers in this session explore the positive aspects of effort in choice and investigate consumers' tendency to prefer and even create effortful decisions. When and why will people value more effortful decision processes? When and why will feelings of effort versus ease motivate people to work harder or make them value products more? Do we complicate our decisions? The papers in the session answer these and other related questions. Specifically, the first paper demonstrates that increased conflict in choice can actually increase the likelihood of purchase. The second paper demonstrates that consumers are not only attracted to difficult decision processes, but also endogenously seek to enhance their decision effort in order to feel that they are making an adequate choice. The third paper explores the hypothesis that feelings of effort can increase people's tendency to work harder and value products more when such effort signals higher efficacy of the particular outcome. All three papers, which are to be submitted soon for publication, include multiple studies with data that has already been fully analyzed. However, none of the three papers has ever been presented at ACR.

The proposed special session is designed to present emerging work in decision research and its implication for consumer choice. The papers in the session should help in highlighting some of the promising avenues that are emerging in this area of research. Moreover, the session's discussion leader, Drazen Prelec, will engage the audience and the authors in an analysis of the session's content as well as a discussion of the potential for future research in this area.

EXTENDED ABSTRACTS

"The Tradeoff Heuristic: The Settling Effect of Conflict"

Wendy Liu, UCLA, USA

Itamar Simonson, Stanford University, USA

Conflict is one of the most fundamental phenomena in decision making. Decisions often involve options that each has pros and

cons relative to each other, creating the need to reconcile such conflicts if only (or at most) one of the options can be adopted. Generally, the consideration of conflict has been found to negatively impact people's propensity to take decisive action. For example, high conflict between competing options has been shown to lead to inaction or deferral of choice (Tversky & Shafir 1992; Dhar 1997). When people have difficulty deciding between current options, they often choose not to choose any of the options—even though each option in itself might be quite attractive. Further, in existing theory of decision making, the negative effect of conflict is assumed to be additive to the attractiveness of the options. That is, generally the perceived attractiveness of the best option within a choice set positively correlates with whether people will buy from the current set—on top of that, if there is high conflict among the options, this adds a negative effect on the probability of purchase.

In this research, we propose a more nuanced view of the role of conflict in purchase decisions by focusing on a contradiction to the two general assumptions above. First, we show that sometimes conflict can have a positive effect on purchase likelihood. Second, we show that the relationship between option attractiveness and option conflict is not additive, but rather, interactive, in determining purchase likelihood. Specifically, we propose that while conflict indeed has a negative effect on purchase likelihood when options are relatively attractive, conflict can have a positive effect on purchase when options are relatively unattractive. That is, when given two options that may not successfully exceed the threshold for purchase based on their absolute attractiveness, people can be more likely to purchase one of them (rather than search further for a better option) when the current options contain a mild conflict than when one option dominates the other option. We propose the mechanism behind this positive effect of conflict on purchase is a process we call "the tradeoff heuristic"—when people see that they have to give up some unit of one attribute in order to gain on another attribute, they are more willing to accept the current attribute levels. In other words, by considering a tradeoff, people become less optimistic about finding an absolute best option in the future, effectively lowering their sufficiency threshold for commitment. Consequently, people will be more likely to stop their search with the current choice set. We test the settling effect of conflict in 4 studies.

Study 1 establishes the basic effect that conflict (compared to dominance) can lead to greater purchase likelihood. Participants are asked to imagine themselves looking for an apartment for rent in a new city. They are randomly assigned to two conditions: in the dominance condition, one apartment is larger in size, as well as being closer to work; in the conflict condition, apartment sizes are the same as condition one, but distance to work is flipped between the two options. In both conditions, apartment size is relatively small in absolute terms. Participants are asked whether to rent one of them, or look at the next option. Results show that indeed, people are more likely to take a current option in the conflict condition (37% vs. 20%).

Study 2 demonstrates the interaction between conflict and absolute valuation using a context of shopping for a vacuum cleaner. Participants are told they are considering two vacuum cleaners at Costco, but they could also decide to go to Sears to look further. When all options are relatively attractive, dominance (69%) leads to greater purchase likelihood than conflict (58%), consistent with prior research on the attraction effect (Huber et al.

1992). However, replicating study 1 results, when both options have low attractiveness, people are more likely to purchase when there is conflict (54%) rather than dominance (35%). Of note, the tradeoff heuristic is different from merely focusing on relative rather than absolute values (Hsee 1998). Specifically, the option's relative value (compared to the other option) is worse in the condition of conflict than in dominance. Hence, if the effect is simply directing attention to relative values, purchase likelihood should be higher in the dominance condition.

In study 3, we test a boundary condition to this effect, namely, the conflict between options needs to be relatively easy to reconcile. When the conflict is large, rather than small, purchase likelihood will indeed decrease, due to choice difficulty. In study 4, we extend this effect to evaluation procedures that involve more than two options. We find that a procedure such as ranking that creates more conflict can lead to greater likelihood of purchase, compared to a procedure that involves less conflict, such as rating.

In summary, this research focuses on the question: When do people accept a current opportunity, rather than search for better opportunities? Our findings contribute to our understanding of the decision by highlighting the role of subjective sufficiency in such decisions.

“Complicating Choice”

Rom Schrift, Columbia University, USA

Oded Netzer, Columbia University, USA

Ran Kivetz, Columbia University, USA

It has been well documented that, in the pre-decisional stage, consumers often simplify their decisions by bolstering one of the alternatives and/or denigrating others (Brownstein, 2003; Janis and Mann, 1977; Mills, 1968; Montgomery, 1983; Russo Medvec and Melloy 1996, 1998; Tyszka, 1985). Such reduction of choice conflict enables consumers to make easier, more confident choices. In this research, we provide a theoretical analysis of, and empirical evidence for, the opposite behavior. We discuss conditions under which consumers complicate choices in order to feel that they invested enough effort to make the right choice. Specifically, we postulate that when faced with important decisions, such as choices between primary physicians or between career paths, consumers are motivated to engage in a diligent decision process or due diligence. When an important choice feels too easy, consumers artificially increase the choice conflict and effort by reconstructing the choice context. Consumers are shown to bolster unimportant attributes and reverse the ordinal valence of attributes (e.g., more is better becomes less is better) in a direction that counteracts the virtually-dominant alternative, which they initially prefer and eventually “choose.”

We propose a unifying “effort-compatibility” principle that accounts for both simplifying and complicating decision processes. The effort compatibility principle asserts that consumers value and strive for compatibility between the degree of effort they anticipate, or think is adequate to reach a certain decision, and the level of effort they actually exert. Accordingly, when a certain decision seems harder than initially anticipated, a simplifying process ensues. However, when the decision feels easier to resolve than anticipated (e.g., important, yet easy choices), consumers artificially increase the effort they invest in making the decision. We demonstrate that the latter, complicating process is characterized by an enhancement of the conflict in choice. Such conflict enhancement, through bolstering unimportant attributes, or reversing the valence of ordinal attributes, enables consumers to attain effort-compatibility and perceive themselves as engaging in a diligent decision.

Five studies examine consumers' choice complicating processes and the effort-compatibility principle. We first demonstrate

the existence of the effort enhancement behavior and its impact on consumer choice (Studies 1-3). We show that for important decisions, such as choices of primary physicians or career paths, choice sets that invoked low levels of conflict (mismatch between actual and expected effort), gave rise to pre-decisional effort enhancement behavior. Specifically, in Study 1, participants distorted the importance of different information components in a manner that facilitated greater conflict in choice. In accordance with the effort-compatibility principle, this complicating behavior was significantly attenuated after the choice was made (post-decisional stage) and in conditions where no choice was required. In Study 2, participants enhanced their pre-decisional effort by constructing positive preferences towards attributes that opposed their preferred, and ultimately chosen alternative. Study 3 demonstrated that in sequential decision process, once a complicating process is triggered, it can alter the ultimate outcome of the decision.

In Studies 4 and 5, we further investigated the underlying psychological mechanism, namely the effort-compatibility principle. We manipulated the expected and experienced effort, as well as the importance of the choice. In Study 4, we offered respondents an alternative source of experienced effort using a preference fluency manipulation. We found that the introduction of an external source of difficulty drastically reduced the need for internal effort enhancement behaviors. In Study 5, we manipulated the level of anticipated effort by cueing subjects how long the task typically lasts. Although they faced identical tasks, those participants that anticipated low effort employed simplifying processes, while those anticipating high effort increased their conflict in choice.

In summary, we hypothesize and empirically demonstrate that, in certain situations, consumers complicate their choices. Such behavior may first appear contradictory to well-documented simplifying processes, such as pre-decisional distortion of information and post-choice cognitive dissonance. However, we test and support an effort-compatibility principle that accounts for both simplifying and complicating processes, sometimes observed in the context of the same decision. Thus, consumers not only simplify and bolster the difficult choices they make, but also make harder and less appealing the obvious (or illusory) choices they fake. We discuss how this could lead to an “illusion of choice,” whereby consumers agonize over (non) decisions.

“Does Distance make your Heart Fonder or your Mind Wonder? An “Attainability-Efficacy” Framework of Preference Construction”

Sara Kim, University of Chicago, USA

Aparna Labroo, University of Chicago, USA

It is not surprising that consumers put maximum effort into obtaining products or doing things they like, however, do they also prefer products or things associated with effort (to get/ do)? For example, consider this situation. It is the holiday season, you are on your way to the grocery store, and you have been thinking about donating some money to charity. In one scenario, imagine that as you enter the store, you notice a volunteer from the Salvation Army right next to the entrance asking for a donation. In a second scenario, imagine that as you enter the store, you see a volunteer from the Salvation Army a few steps away from you at the opposite entrance asking for a donation. When are you more likely to make a donation, and why? You have been thinking about making a donation, and in the first scenario, the volunteer is close to you and it is easy to make a donation. In the second case, you will have to exert some token effort to make the donation. It appears normative that if you have been thinking about making a donation, and if you consider the Salvation Army a good cause to support, you should be more willing to make a donation when it is easy rather than effortful to do

so. But are there situations when you might prefer to engage in the token effort? Further consider this situation. As you proceed inside the store, looking to purchase cookies, you find one box on the shelf right up front and another a little way behind it. Both boxes are fresh, so why exert effort to reach for the one at the back? In the current article, we examine this issue—do when and why do feelings of effort versus ease motivate people to work harder or make them value products more?

Whether it is deciding to make a donation or to buy a product, most existing research will argue that ease is good and people like to do activities or get products that are easy to do or get. A recent set of intriguing findings have additionally suggested that even when feelings of ease arise from subjective characteristics of the target and are independent of its descriptive features (Schwarz 2004), for instance, the volunteer is next to you and have your glasses on (vs. you forgot them at home) and s/he looks clear (vs. blurry), they increase value of the outcome and motivation to act. Ease is associated with positive feelings which are usually attributed to the outcome being considered and as a consequence they increase preference towards the outcome. In this paper, however, we discuss when feelings of effort, rather than ease, can motivate people to work harder and can make people value products more.

We argue that evaluating products, consumers focus either on how attainable the outcome is or if it is the best one available. When people experience illusory high control, their focus turns to product efficacy rather than product attainability. As people usually infer value from their actions (e.g., Bem 1972), and as they put most effort to pursue only the best outcomes, they mistakenly reverse this correlation when assessing efficacy of the outcome. Thus, feelings of effort also make them value the outcome more (Labroo and Kim 2009; Pochepsova et al. 2009). Only when perceived control is low, peoples focus is on successful outcome attainability. In such situations, effort signals infeasibility of attaining the outcome and they prefer outcomes associated with ease, not effort.

Across three experiments, we provide evidence for our premise. We show that people with high control (illusory or real) prefer products that are psychologically or physically effortful rather than easy to attain and they donate more to a charity when donation is effortful rather than easy. In contrast, people with illusory low control prefer products and are more likely to act if things feel easy rather than effortful. Process measures show that illusory low control results in concerns about product attainability, and ease increases perceived attainability of a successful outcome. In contrast, illusory high control increases the desire to get the best option (attainability is no longer a concern), but interestingly things that are effortful are better than things that are easy. Of additional interest are the subtle manipulations of illusory control. For example, simply writing ones own lucky number on a raffle ticket rather than being assigned one, for a box of cookies, creates illusory control, and can make us evaluate the cookies more favorably, but only when they are physically (or psychologically) distant rather than close. Or, being the first (rather than last) to make a difference to the lives of poor children, also creates illusory control, resulting in people making larger donations, but only when they have to reach out a couple of feet to the donation box (vs. it is next to them). Rolling a dice by oneself rather than having the experimenter roll it also results in preferences for products that are psychologically far rather than close. We additionally rule out mood, construal level, attention, overall goal engagement as possible alternative explanations.

In the end, all control might just be an illusion; therefore, it is particularly powerful that such subtle manipulations of controllability can alter preferences to this degree. The surprising inference is that people with high control (real or illusory) like complicated

lives, and when people feel control they complicate rather than simplify their lives. Theoretical implications pertaining to the role of feelings in judgment and preference construction and managerial implications regarding what managers might be able to do to improve consumer satisfaction with products will be discussed.

SPECIAL SESSION SUMMARY

The Buzz about Buzz: Drivers and Consequences of Word-of-Mouth

Jonah Berger, University of Pennsylvania, USA

Andrew Stephen, INSEAD, France

SESSION OVERVIEW

Talking and sharing are some of the most fundamental consumer motives. People tell friends about new restaurants, email relatives interesting articles, and post online reviews about books they like (or hate). But while it is clear that such behavior is frequent, and important, we know less about the causes and consequences of such behaviors.

A great deal of research in both consumer behavior and marketing science recognizes that word-of-mouth (WOM) is important, but less work has drilled more deeply to examine the psychological factors driving transmission. Research has shown that WOM can impact sales (Chevalier and Mayzlin 2006), and diffusion (Goldenberg, Libai, and Muller 2001), but what motivates consumers to spread WOM and how do aspects of conversation partners influence what people talk about? Similarly, while we know that people like to share, what types of things tend to be shared? Certain YouTube videos, ads, or New York Times articles end up being viral, but why? How do content characteristics influence what spreads? Finally, what are the consequences of transmission for consumer attitudes, choice, search, and willingness to pay?

This session addresses these, and related questions, as it integrates various research perspectives to examine drivers and consequences of WOM. Berger and Milkman use six months of data from the New York Times most emailed list to examine characteristics of content that make them more likely to be shared. Moldovan and Lehmann investigate how aspects of advertisements, such as their creativity and informational content, generate WOM and affect purchase intent. Stephen, Lehmann, and Toubia look at both sharing and listening, and consider what drives people to share WOM as well as how transmitter and item characteristics drive the decision to listen. Mayzlin and Moe focus on the impact of WOM, and investigate how customer reviews influence consumer search, willingness to pay, and outcomes for the firm.

Taken together, these talks blend psychological factors that drive transmission and reception, as well as the consequences of these processes for consumer behavior. Distinguished ACR Fellow, and renowned scholar, Donald Lehmann will integrate the papers and lead a discussion about important directions for future research. It is hoped that the discussion will generate some interesting possibilities for future work in this exciting area.

Given how fundamental transmission and sharing is to our everyday lives, we expect this session will be of substantial interest to a host of contingencies. Not only should it appeal to researchers working on social influence, attitude change, and new product adoption, but also to those who study advertising, social networks, and decision making more broadly.

EXTENDED ABSTRACTS

“Virality: What Gets Shared and Why”

Jonah Berger, University of Pennsylvania, USA

Katy Milkman, University of Pennsylvania, USA

What makes certain things more viral? Word-of-Mouth and interpersonal transmission drive social influence, purchase behavior (Godes and Mayzlin 2008), diffusion (Rogers 2003), and

product success (Godes and Mayzlin 2004), but what types of things are more likely to be shared and why?

Some perspectives have argued that cultural prominence is driven by random copying, advertising, or social influence dynamics (Bentley and Shennan 2005; Salganik, Dodds, and Watts 2006). An alternate explanation of cultural selection, built on notions from the biological realm, suggests that due to shared human psychology, characteristics of items themselves can drive transmission (Schaller and Crandall 2004). Unfortunately, however, empirical tests of these predictions have been limited by the ability to examine actual transmission in the field across a host of cultural items measured on various characteristics.

We study virality and cultural transmission by examining six months of data (over 7,000 articles) on which New York Times articles make the most emailed list. The data includes everything from world news and politics to sports and travel, and its breadth and reader base makes this an ideal domain to study virality. Further, by controlling for the amount of time spent on the homepage, and where articles appeared in the print edition, we can test whether above and beyond such “advertising,” item characteristics drive success.

Many theories paint transmission as an economic, value-based exchange. Linguists often assume that the function of language is to share factual information which will have immediate value (e.g., where good food is readily available or the location of predators). Similarly, social exchange theory (Homans 1958) suggests that transmission is an economic exchange of useful resources. To test such informational selection (things spread based on their utility), we examined whether content that is more broadly relevant (i.e., provides information that is relevant to more people) or provides advice (i.e., information on how to do things) is more viral.

We also take a broader theoretical perspective and argue that people also transmit information to deepen social relationships. Language can be seen as a form of social grooming (Dunbar 1996) and people may be more likely to share emotional content because it deepens social bonds (Peters and Kashima 2007). Along these lines, people may be more likely to share surprising content because it breaks existing schemas, and encourages people to confer with others to resolve the discrepancies. Consequently, we examine whether these aspects, above and beyond informational utility, increase transmission

Using a webcrawler, we collected every article that appeared on the New York Times website from August 30th, 2008 to February 15th, 2009. For each article, we collected the title, text, length, author name, publication date, section and page where it appeared, and the one sentence summary provided by the paper. We also collected snapshots every 15 minutes of where articles appeared on the New York Times website and which articles appeared on most emailed list (emailed the most in the last 24 hours). We used name lists to determine author gender, and used Google hits as a rough measure of author fame.

We used both automated and manual coding to score articles on our key independent variables. Standard word lists (General Inquirer) were used to measure the number of positive and negative words in each article and from this we computed valence and emotionality. In cases where it was not possible to use automated

coding, we trained coders to rate articles of some key measures. We selected a random sample of 1,446 articles, and two independent raters coded each of the three remaining measures (surprise, broad relevance, and advice). Inter-rater reliability was high and codes were averaged to form a measure of each dimension.

Before turning to our variables of interest, we first consider controls and other factors that might drive virality. Not surprisingly, articles which should have received more attention (i.e., appeared on earlier pages of the physical paper or spent longer on more visible places on the newspapers homepage) were more likely to make the most emailed list. Articles were also more viral if they appeared in particular sections (e.g., Opinion), and were written by women or more famous authors.

Even controlling for these factors, however, our results demonstrate that content characteristics also drive transmission. Content that was more broadly relevant or contained advice was more likely to be viral. Further, even beyond more economic value, emotional selection also played a role. While more positive and surprising articles had a higher propensity to make the most emailed list, content that was more emotional, regardless of valence, was also more likely to be viral.

Overall, these results illustrate the important role that cultural selection, and shared psychology, play in cultural transmission.

“The Effect of Advertising on Word-of-Mouth”

Sarit Moldovan, Technion, Israel Institute of Technology, Israel
Donald Lehmann, Columbia University, USA

When considering the purchase of a new product, consumers often rely on word of mouth (WOM). While WOM can be important to new product success, it is not always clear how WOM can be initiated and managed. In this paper we claim that advertising can trigger WOM about the product and about the ad. Further, the spread of WOM about the ad (and not the product) may have additional effects on sales.

Previous research that explored advertising effectiveness has usually tested how different ad characteristics affect attitudes toward the ad, the brand, purchase intent, and ad recall (Brown and Stayman 1992). Although these factors may affect WOM, the common marketing models do not take into account the effect of marketing efforts on WOM (Bayus 1985). While some studies showed initial evidence that WOM can be stimulated by marketing efforts (Bayus 1985; Gelb and Johnson 1995; King and Tinkham 1990), these studies hardly discuss the valence of WOM (positive or negative), or the content of WOM (about the product or about the ad).

Based on previous findings our main hypotheses are that creative ads will have a small effect on purchase intent. However, these ads will lead to WOM about the ad. Informative ads, on the other hand, are expected to lead to greater purchase intent and positive WOM about the product, but not to WOM about the ad. While WOM about the product is expected to lead to further purchase intent, WOM about the ad is expected to increase involvement in the ad, and increase the purchase intent of the product as a result of watching the ad.

In Study 1 we asked 424 participants to rate 21 print ads (between subjects). The dependent variables were: WOM about the product (including WOM amount, positive and negative WOM, and information search), Ad WOM (intentions to talk about the ad or forward it to friends), and purchase intent. The independent variables (after factor analysis) were: creative, informative, sex appeal, status appeal, and negative. Regression results supported our hypotheses: Creativity is the main ad characteristic that leads to WOM about the ad and about the product. However, it does not lead

to purchase intent. In addition, as we expected, informative ads lead to more positive WOM and increase purchase intent, but have no effect on Ad WOM.

In Study 2 we collected data of actual forwarding of 53 TV commercials in an online site. We tested how the ad characteristics (as rated by judges) affected the number of times an ad was forwarded per view, a proxy for actual spread of the ad. Ad characteristics explained 51% of the variance in actual forwarding behavior, and the results were very similar to those of Study 1.

Since creative ads were found to lead to WOM about the ad, but had little effect on purchase intent, Study 3 explores whether exposure to ad WOM prior to the ad can moderate the effect of a creative ad on purchase intent. In this study, 87 students were exposed to either a creative ad or to WOM about the ad (the WOM did not mention the product, only the ad). Later, half of all participants were then exposed (or re-exposed) to the creative ad. The dependent variable was purchase intent of the product (1-7 scale).

The results showed that the purchase intent of the product was significantly higher in the condition in which participants were exposed to the ad WOM and after that to the ad, compared with the other three conditions, indicating that exposure to WOM about the ad can moderate the effect of creative ads on purchase intent. Results confirm our hypothesis that while a creative ad had a small effect on purchase intent, exposure to WOM about the ad, prior to watching the ad, led to higher purchase intent.

Results of the three studies indicate that advertising can trigger WOM about the product and about the ad. Different characteristics of the ad lead to different types of behaviors, such as WOM and purchase intent. Although ad creativity hardly leads to purchase intent by itself, it may lead to WOM about the ad, which may in turn have an effect on purchase intent of the consumers exposed to this WOM.

“Why Do Consumers Talk, Does Anyone Listen, and What Happens?”

Andrew Stephen, INSEAD, France
Donald Lehmann, Columbia University, USA
Olivier Toubia, Columbia University, USA

Despite the large amount of research on word-of-mouth (WOM) and social contagion in marketing, sociology, physics and elsewhere, surprisingly little is known about the individual-level talking, listening, and impact processes. We know little about the underlying individual-level processes that drive WOM. Why do consumers transmit WOM about products to their peers? When do they listen to these messages? And when and in what ways are they impacted by WOM? In this research we study transmission, reception and impact. We address the following questions: (1) what are consumers' motivations or reasons for transmitting information to others, (2) what factors related to recipients affect transmitters' likelihoods of talking, (3) what factors related to transmitters affect recipients' likelihoods of listening, and (4) what types of WOM are likely to be more impactful on recipients' brand/product-related attitudes and subsequent consumption behaviors?

For transmission, in the first study (N=110) we asked participants to recall times when they actually transmitted WOM, asked them “why?” and asked them to give information on the characteristics of the people who they talked to (recipients). We found that transmission motives were predominantly self-focused and centered on needs to either express opinions or to in fact solicit (not give) information. When participants were sharing their own experiences with products the former was the only motive. However when they were passing-on information about others' experiences

(retransmitting) they not only wanted to express this opinion but also sought information from the recipient (possibly to validate or verify the previously-received information).

In study 2 (N=200), participants were in a hypothetical situation where they had to select recipients who they would transmit WOM to, given knowledge of recipients' characteristics (interest in topic, track-history of being receptive, tie strength, and social connectivity). We found that transmitters preferred recipients who were likely to listen (e.g., strong topic interest, past receptivity, strong friendship tie). This was all that mattered when transmitting own information, and is consistent with just wanting to express one's opinion to people who would actually listen. However, when retransmitting information from others the social connectivity (many versus few friends) of the recipient also mattered. Well-connected people have access to more sources of information and, all else equal, should themselves be better sources. Indeed, in study 3 (N=28) we found that transmitters expected well-connected people to be sources of high quality information. Based on these studies, transmission is associated more with using the social capital embedded in one's social ties than it is for building social capital (e.g., by transmitting in order to give advice). However, transmitters use social capital in different ways: when sharing own information recipients are used as a receptive audience for one's opinions, and when passing-on others' information recipients are used for validating, verifying or elaborating the existing information.

In a fourth transmission-related study (N=920,770) we examined a different type of transmission—sharing information in an online social network—using data from a popular Facebook “app.” App users can share the app itself with “friends” and can share results from quizzes that they take within the app (they take personality and psychological tests). We find the probability of sharing the app or of sharing various quiz results decreases exponentially as a person's number of friends (social connectivity) increases. Also, as a person's social connectivity (and hence their stock of social capital) increases, people become more strongly focused on using their network connections for seeking information. Related to the previous three studies, having more social capital means a stronger desire to use it for self-focused purposes.

We then consider reception/impact with three studies (participants are recipients). In the first study (N=127) we examine listening decisions as functions of transmitter characteristics (expertise, social tie strength, connectivity) and message characteristics (valence) in a hypothetical situation where participants imagined themselves exposed to WOM from certain people. Participants indicated who they would listen to. Although transmitters who are perceived to be “experts” are more likely to be listened to, we found high reception probabilities under various other combinations of transmitter and message characteristics, including cases where transmitters lack any objective credibility or expertise. In the two other studies (Ns=276 and 272; also hypothetical), participants were given uninformative product information and exposed to WOM about that product. We measured attitudes toward the product and purchase intentions pre- and post-WOM. The message varied on valence and tone (factual versus emotional), and the transmitter varied on objective credibility (category expertise) and tie strength (friend, acquaintance, or stranger). Instead of measuring only dispositional attitude, we also measured certainty (i.e., confidence in disposition toward the product). Capturing certainty changes were important: e.g., in 45% of the cases where dispositions did not change post-WOM, certainties did change (indicating that WOM had an impact, just not on disposition). Disposition and certainty changes (individual or combined) affected purchase in-

tentions. Moreover, although objectively-credible transmitters are influential, low-credibility transmitters (e.g., strangers, novices) sometimes impact attitudes and purchasing, provided the message makes recipients feel more certain about their existing opinion. Thus, under the right conditions almost any transmitter has a good chance of being influential.

“The Impact of Consumer Reviews on Consumer Search and Firm Profits”

Dina Mayzlin, Yale University, USA

Wendy Moe, University of Maryland, USA

A number of studies have demonstrated that customer reviews affect product sales (see, for example, Chevalier and Mayzlin (2006) and Dellarocas, Zhang and Awad (forthcoming)). In particular, both the valence and the quantity of reviews influence sales on a product level. But how do customer reviews impact consumer search and what they choose, as well as company profits and category-level performance? This is the focus of the current study.

In particular, consider a retailer with multiple products that implements a review tool that allows customers to post feedback on its site. The reviews can serve as a matching tool that reduces consumer uncertainty about the products. This could have two possible effects: 1) Re-allocate sales across products within a category which may result in higher utility for the consumer but not in higher profits for the retailer in the short run, and/or 2) Raise the firm's profits by increasing the probability that the consumer purchases within a category and increasing her willingness to pay for the product. Here we look at the effect of consumer reviews on category sales and traffic within a site.

To test our hypotheses, we have obtained a data set from a retailer that sells products across a large number of categories. A unique aspect of our study is that we have sales and search data before and after the review tool is introduced. This allows us to determine the effect of the introduction of the ratings tool on sales and search, as well as measuring how the volume of reviews affects search and sales within the category. Another interesting aspect of the data is a measure of search behavior: the number of times that a product is viewed within a course of the week. We argue later that the data on search behavior allows us to identify the mechanism through which reviews influence sales.

To determine the effect of the introduction of reviews onto a site, we estimate an aggregate model, where the dependent variable is category sales. First, we show that the over-all category sales increase in the period after the ratings tool was introduced. This is true even once we control for cross-category heterogeneity. Some of the increase in dollar sales seems to be due to the increase in search. That is, the total number of category page views increases in the period after the ratings are introduced. However, increase in search alone is not sufficient to explain the increase in dollar sales: even after we control for the number of page views of the category's products per week, the dollar sales per week are still significantly higher in the period after ratings were introduced. On the other hand, once we control for the number of page views of the category's products per week, the unit sales are not significantly higher in the second period. This seems to suggest that ratings increase search and make it more likely that consumers buy relatively more expensive products. This last finding leads us to investigate the effect of reviews on the relative distribution of product sales.

Next, we consider the impact of the introduction of review on the distribution of search and sales across products within a category. In particular, we investigate how the impact of reviews is moderated by the initial market share of a product as well as its

price. Since reviews reduce uncertainty in consumer's expected valuation of the product, we would expect that the introduction of reviews would lead consumers to be willing to buy more expensive products. Of course, another reason why demand may shift towards more expensive products is that in the presence of correlation between price and quality, more expensive products will obtain better reviews and hence will have more sales.

We analyze the review-generating process as a function of the product's own characteristics as well as the characteristics of other products sold within a category. Our analysis also sheds light on the debate whether additional information creates a bigger marginal impact for the already successful products or for the less successful products (see Salganik et al (2006) and Tucker and Zhang (2008)). The findings in the previous literature have been mixed: Salganik et al (2006) find that previous download information helps the already successful products more, while Tucker and Zhang (2008) find that previous clicks information is especially useful for the niche products. We find that sales within a category become more concentrated after the introduction of the review tool. Hence, we find that reviews seem to drive consumers to more expensive, successful products.

SPECIAL SESSION SUMMARY
The Role of Emotions in Self-control Dilemmas
Anastasiya Pocheptsova, University of Maryland, USA

SESSION OVERVIEW

Consumer choices often involve self-control conflict between options that are immediately tempting and options that serve long-term goals. Though prior research has examined how consumers deal with such conflict, the current session expands our understanding of this topic by examining the role of emotions evoked by self-control dilemmas that consumers face when pursuing health goals. By looking at the role of emotions in self-control conflicts, the four papers in the session raise several interesting questions that have been under-researched in the literature. Do people experience different type of emotions when they monitor pursuit of high-level goals vs. low-level temptations? Do people experience negative or positive emotions after resolving self-control conflict in favor of a higher order goal? Do people experience different levels of guilt when violating health goals during group vs. alone consumption? Finally, is there a difference in experienced affect and subsequent behavior when consumers strive to reach specific vs. abstract self-control health goals. Taken together the questions examined in this session bridge research on health consumption and emerging research in the domain of the role of the emotions in self-control conflicts to better understand consumer decision making.

The papers in this session study three important research questions. First, Fishbach & Tal show that facing a self-control conflict consumers experience abstract emotions (e.g. pride) when monitoring a pursuit of high-order goals, but concrete emotions (e.g. happiness) when monitoring the pursuit of low-order temptations. The authors further show that emotions associated with higher-order goals are more prolonged, whereas affect experienced following the pursuit of temptations is short-lived. Expanding on this theme, Gal & Liu further examine feelings that people experience as a result of resisting temptation and following long-term goals. In contrast to previous research that emphasizes positive consequences of resisting temptation, the authors show that people experience negative emotions (anger) and look at its effect on consumption choices. Next, Pocheptsova et al. examine how mere presence of others during self-control conflict affects the emotions and choices people make. They find that due to heightened feeling of guilt people tend to overestimate the calories they consume while eating in a group setting (vs. alone) which results in more health goal consistent choices later. Finally, Scott & Nowlis examine difference in consumers' health-goal pursuit based on the level of specificity of the goals. The authors find that setting more specific goals may lead to feelings of regret, guilt and over-consumption.

All papers in this session include multiple empirical studies that test both the main propositions and the underlying mechanisms of the proposed effects. Taken together, the papers examine emotions evoked by self-control conflicts and explore the consequences of such emotions on consumer choice. By looking at these issues from four different angles, the session provides a more comprehensive look at the role of emotions in self-control dilemmas. Further, all papers in the session primarily focus the attention of empirical studies in the domain of food consumption. It is well established that despite the popularity of weight-loss programs, the public focus placed on health, and the implementation of mandatory nutrition labels of packaged foods, consumers continue to make poor diet and lifestyle choices. Current session contributes to the growing body of research that examines this issue and is expected to attract audience interest at the conference for both researchers

that are interested in conceptual understanding of the role of emotions in self-control dilemmas as well as researchers interested in affecting consumers' well-being in the domain of health consumption.

EXTENDED ABSTRACTS

“The Motivation-Emotion Matching Hypothesis”

Ayelet Fishbach, University of Chicago, USA

Tal Eyal, Ben Gurion University, Israel

Positive emotions signal successful goal pursuit, and the quality of the emotional experience depends on the type of goal a person pursues (Dweck and Leggett 1988; Higgins 1997). Accordingly, our research focuses on how distinct positive emotions signal the successful pursuit of conflicting motivations in a self-control dilemma. We argue that a self-control dilemma poses a conflict between two goals that vary hierarchically: high- versus low-order goals. In addition, emotions vary from abstract to concrete. These two hierarchies correspond to each other, leading to what we term as “the motivation-emotion matching hypothesis.” According to this hypothesis, people associate high-order goals with abstract emotions and low-order goals (or temptations) with concrete emotions.

In support of our hypothesis, we find that individuals form implicit between high- (vs. low-) order goals and abstract (vs. concrete) emotions (study 1). Specifically, using an IAT (Nosek, Greenwald and Banaji 2005), we find faster response times for sorting affective and motivational concepts when participants use one response key for either goals or pride stimuli and the other key for either temptations or happiness stimuli, than in the incongruent pairing condition, mapping one response key for goals or happiness stimuli and the other key for either temptations or pride stimuli

Three predictions further follow from this hypothesis and received support in our studies. The first pertains to the emotional consequences of goal-pursuit. We find that regardless of the content of the self-control dilemma, abstract emotions follow from carrying out high-order goal-related behaviors, whereas concrete emotions follow from carrying out low-order goal-related behaviors. For example, consumers experience abstract emotions (e.g., pride, self-worth) after choosing to eat healthy or choosing a highbrow news magazine, and they experience concrete emotions (e.g., happiness, joy) after eating unhealthy or choosing a lowbrow news magazine (study 2). The second prediction pertains to the duration of the emotional experience. We find that abstract and concrete emotions vary in their duration. Although the elicitation of both types of emotions is an immediate response to pursuing the corresponding goal, abstract emotions are experienced for an extended period of time, whereas concrete emotions are experienced for a brief period of time. Specifically, participants who made a choice from a healthy set of options felt proud for at least 20 minutes, whereas those who made a choice from an unhealthy set felt happy for about five minutes (study 3).

The third prediction states that the activation of emotional terms cues the pursuit of the corresponding goal. We find that priming abstract emotional terms (e.g., pride, self-worth) helps people control indulgence compared with priming concrete emotional terms (e.g., happiness, joy; study 4). In addition, priming abstract emotional terms helps people persist on difficult academic

tasks more than priming concrete emotional terms (study 5). Together, the results of these five studies provide evidence that distinct affective experiences monitor the pursuit of high-order goals versus low-order temptations in a self-control conflict.

We discuss the implications of the motivation-emotion matching hypothesis for self-control theory. Some previous research attests that in a self-control conflict, low-order goals are more “emotional;” that is, they involve representations that are more arousing and consummatory than high-order goals (Loewenstein, 1996; Metcalfe and Mischel 1999). In contrast with that alternative, we propose that low-order temptations are a source of concrete emotions and high-order goals are a source of another type of feeling-based experience that nonetheless “feels.” Our hypothesis modifies self-control theory; it suggests the self-control conflict is a conflict between motivations that are experienced differently rather than a conflict between temptations that “feel” and goals that do not. It implies that self-control success is not tied to putting emotions aside but rather to tuning in to different emotional cues.

“What Movie Would You Watch with Your Salad? The Implicit Emotional Consequences of Exerting Self Control”

David Gal, Northwestern University, USA

Wendy Liu, UCLA, USA

A great deal of research on consumer self-control shows that yielding to temptation can lead to aversive emotions, such as feelings of guilt and regret (e.g., Baumeister 2002; Giner-Sorolla 2001; Hoch and Loewenstein 1991). Conversely, research highlights that exerting self-control by resisting temptation results in positive psychological consequences, such as an improved sense of self-worth and a heightened self-concept (Dhar and Wertenbroch 2007; Khan and Dhar 2006). In the present research, we argue that resisting temptation may also lead to aversive emotions. In particular, we argue that when individuals’ freedom to fulfill their desires is thwarted by their need to act responsibly, the natural emotional response is anger. Along with happiness, sadness, fear, and disgust, anger is identified as one of the basic emotions (Ekman, Friesen, and Ellsworth 1972). In general, anger can be defined as the emotion that ensues due to a “conspicuous slight or frustration” of the individual by another (Zajonc 1998). Previous research shows that when the individual feels that his/her freedom is being restricted, reactance and hostility ensues (Brehm 1966; Wicklund 1974). Building on this conceptual framework of anger, in this research we propose that although anger manifest as psychological reactance is typically assumed to arise from the restriction of an individual’s freedom by others, it can also arise from the restriction of an individual’s desires by their own sense of responsibility. However, unlike when freedom of desire is restricted by another person, in the case of yielding to one’s own sense of responsibility, people may not readily identify the situation as anger-inducing. Consequently, a person may not be able to consciously articulate one’s emotional state as feeling angry; nonetheless, the affect of anger will be displaced to and manifest itself in the person’s subsequent actions. Further, to the extent the next contexts are more readily recognized as anger-inducing, people may be able to report their displaced feelings of anger and irritation.

Based on prior research showing that angry individuals tend to evaluate anger-framed appeals particularly favorably (DeSteno et al. 2004), our first experiment examined whether anger-framed appeals would be evaluated more favorably by individuals that resisted temptation. Moreover, we examined whether this effect would apply to sadness-framed appeals and whether the effect would be more pronounced among restrained eaters. Restrained eaters are defined by their heightened sense of responsibility to delay the immediate gratification of food in order to maintain or

lose weight. That is, restrained eaters have a particularly heightened sense of responsibility to constrain their desires.

We found that restrained eaters became more favorably disposed towards anger-framed messages after resisting temptation, consistent with an anger emotional state. In contrast, unrestrained eaters, for whom eating does not involve a conflict between one’s desires versus sense of responsibility, did not become angry when resisting temptation. This result provided insight into the process by which anger is produced—specifically, the effect only occurs when the tempting option is construed as a “vice,” and not being able to have it is construed as a restriction on one’s free desire. Moreover, we did not observe similar effects for sadness-framed appeals, suggesting that the effect was specific to anger, rather than to a generalized negative mood state.

Our second experiment examined how resisting temptation affected participants irritation (a mild form of anger) at a persuasive appeal that used controlling language. Further, experiment 2 examined whether expressing anger can attenuate displaced anger evoked by resisting temptation as suggested by prior research showing that explicit anger-expression tends to attenuate suppressed anger (Gross 2006). We found that participants given the opportunity to express anger in an unrelated task after resisting temptation expressed less irritation at the persuasive appeal than those not given such an opportunity. No such difference was found among participants that yielded to temptation, suggesting that anger was evoked by resisting temptation and attenuated by the anger expression task.

Our third experiment extended the findings of the first two experiments to a consumer context where the task following the self-control task was not itself anger-provoking. In particular, experiment 3 found that participants that resisted temptation (chose an apple over a candy bar) before rather than after choosing movies, were more likely to choose anger-themed movies. A similar effect was not observed for individuals yielding to temptation, suggesting that the act of resisting temptation led to the increased choice share of anger-themed movies.

“Food Consumption in the Presence of Others”

Anastasiya Pocheptsova, University of Maryland, USA

Sara Freiberg, Yale University, USA

Ravi Dhar, Yale University, USA

Consumers frequently face self-control dilemmas when making food consumption choices: should I order a fruit salad or a chocolate cake for dessert? should I cook a healthy meal at home or go out for dinner? Oftentimes a resolution of such self-control conflicts towards temptations results in experienced feelings of guilt which affect subsequent consumption choices. Though previous research has identified a number of factors that affect consumers’ resolution of self-conflict dilemmas and consequent experienced emotions, in this paper we propose a novel factor affecting such decisions: presence of others during food consumption. While the presence of others has been shown to directly contribute to consumption volume due to an increase in meal duration (de Castro & Brewer 1992, de Castro 1994, 2000) and variety-seeking (Levav & Ariely 2000), we propose that it can have an indirect effect by influencing one’s consumption monitoring accuracy due to increased levels of experienced guilt.

We argue that the presence of others during food consumption prompts increased feelings of guilt due to lay belief that associates eating in groups with unhealthier food choices. This in turn leads to higher calorie consumption reports as compared to situations where individuals are dining alone. We further propose that people would rely on their lay beliefs and believe that they consumed more calories in a group setting than in individual setting even when they objectively consumed the same meal. In support of this hypothesis,

across four studies we find that individuals eating alone give significantly lower calorie estimates than those eating in a group for the same meal. In Study 1, we asked participants to imagine one of three conditions: that they were eating ice cream alone, that they were eating ice cream with their family, or that they were eating ice cream with their friends. Participants were then presented with a description of an ice cream. Consistent with our proposition, participant in the group conditions reported higher consumption amounts than those in the alone condition.

We test the generalizability of our findings in Study 2, by showing that similar effects exist when people are making estimates about others' rather than their own consumption. The participants were presented with either an image of a woman eating alone or an image of a woman eating in a group. Participants were then asked to estimate the calories in this individual's entrée. Consistent with our earlier findings, participants in the group condition gave significantly more exaggerated calorie estimates than those in the alone condition. We next tested our hypothesis in a real food consumption setting (Study 3), asking participants to estimate the number of calories in the bowl of M&Ms which they consumed either alone or in the presence of other. Participants in the group condition estimated more calories in their bowl of M&Ms than those in the alone condition.

In our final study we investigate the implications of such exaggerated calorie reports in a group setting on subsequent choices. Since consumer choices are rarely made in isolation, but are frequently made in sequence (Khan and Dhar 2008) systematic errors in caloric estimation of one meal could have large consequences not only for immediate consumption but for future consumer choices. To test this proposition we first asked participants to imagine one of the two scenarios: that they consumed an ice cream cone alone or that they consumed the same ice cream cone with their friends. Participants were later asked to imagine that they would be dining alone and were asked to choose either pizza or salad as their entrée. Consistent with our predictions, participants in the group condition were far less likely to choose pizza following the ice cream scenario (25.0%) than those in the alone condition (57.9%). Further the results of this study support our argument that individuals dining in groups experience increased guilt and imply that such guilt affects subsequent consumption choices. Due to increased feelings of guilt, participants dining in groups attempt to compensate for their perceived overconsumption by subsequently selecting a more healthy option.

“The Effect of Goal Setting on Consumption & Consumer Well-Being”

Maura Scott, University of Kentucky, USA

Stephen M. Nowlis, Arizona State University, USA

Many consumers set goals such as counting calories, carbohydrates, or fat grams to manage health concerns (Parker-Pope 2003), and 1 in 4 Americans is on a diet at any given time (Crossen 2003, Fetto 2002). For example, an individual may pursue a more specific (consume 1500 calories per day) or less specific goal (consume between 1400 and 1600 calories per day). In light of these issues, we examine the following research questions: Do consumers more effectively establish and reach consumption goals when the goals are more or less specific? What is impact of varying goal strategies on emotional responses, performance, success rates, and self-perception? How do consumers' goal strategies and processes differ depending on their level of dietary restraint?

Goals that are both specific and difficult lead to higher performance levels, relative to vague, non-quantitative goals such as “do your best” and more demanding goals lead to lower levels of

performance satisfaction (Locke and Latham 1990). The ‘Performance-Success Dilemma’ predicts that as goals increase in specificity, at the more difficult end of the goal continuum, as performance increases, satisfaction decreases (Locke and Latham 1990).

Consumers vary in their ability to predict future successful self-regulation attempts (Chandon, Morwitz, and Reinartz 2005). Our experiments demonstrate that restrained eaters, those consumers who are chronically focused on managing their weight and food consumption (Herman and Polivy 1975, 1980), based on their highly emotional relationship with food (Fletcher et al. 2007, King, Herman, and Polivy 1987), experience a more difficult process to reach their objectives, and while they reach their immediate objectives (Ward and Mann 2000), they may be less successful in sustaining their efforts over the longer term.

In study 1, during the process of pursuing their stated consumption objective, restrained eaters felt more regret, guilt, embarrassment, and feelings of over-consumption about the food. In particular, restrained eaters found the process of pursuing less specific goals to be significantly more stressful. However, despite these difficulties during the consumption process and differences in choice of goal strategy relative to unrestrained eaters, the restrained consumers' performance outcomes were not significantly different than those of unrestrained consumers.

In study 2, as specificity of consumption goals increases (e.g., consume 25 of 100 M&Ms versus consume 20-30 of 100 M&Ms), consumption levels decrease (performance increases) and goal attainment decreases (success rates decrease). Hence, more specific goals result in lower levels of enjoyment, feelings of guilt, regret, and failure. Consistently experiencing lower success rates over time may be demoralizing for consumers and make it more difficult for them to sustain goal pursuit over the longer term.

These effects influence consumers' well-being two-fold. First, those consumers achieving very low levels of consumption tend to set stringent goals, so they are reaching their goals less often. These consumers tend to feel relatively less successful and do not enjoy the process of eating even pleasant products such as chocolate. Consumers taking this approach may have a more difficult time sustaining such a performance level over time, and may also tend to be less happy. Second, restrained eaters experience a significantly more stressful process relative to unrestrained eaters. Although they experience comparable levels of performance and success relative to unrestrained eaters, the strain and difficulty restrained eaters experience during the process may negatively impact their ability to sustain their performance over the long-term, which may result in those consumers being relatively more unhappy.

Our research contributes to the goal theory literature and the literature on consumption behaviors. This research predicts which approaches (specific or non-specific) yield successful short-term and sustainable outcomes. This research explains how goals and consumption behavior impact consumer well-being; we demonstrate that unrestrained consumers are generally unhappy during the process of striving to reach goals and estimates, and tend to experience guilt and regret through the goal striving process, and in general, consumers pursuing relatively more specific goals generally experience feelings of failure and lack of enjoyment.

SPECIAL SESSION SUMMARY

It's a Two-Way Street: The Influence of Communicators and Recipients in Word-of-Mouth Contexts

Andrew Kaikati, University of Minnesota, USA

SESSION OVERVIEW

Word of mouth (WOM) is defined as person-to-person communication concerning a brand, product, or service in the marketplace (Dichter 1966). It is a key source of information for consumers, and its importance is growing due to increases in product complexity and quantity of information, as well as increased avenues for interpersonal communications such as the internet (Godes et al. 2005). Consequently, companies are increasingly relying on WOM to promote their products (Kaikati and Kaikati 2004).

This session takes a unique and broad perspective on the topic of interpersonal WOM communication by presenting WOM research from the vantage point of message recipients, as well as from the perspective of the communicators of the message. Specifically, the first two papers attempt to understand different characteristics of the communicator (self-construal, altruism) which are likely to influence the extent as well as conditions under which WOM is likely to be generated (cf. Cheema and Kaikati 2009). These papers identify conditions under which potential communicators are likely (vs. not likely) to consider the potential message recipient, and how consideration of the potential message recipient influences their decision to talk. The third paper focuses on the recipient perspective in attempting to examine factors that are likely to influence the persuasiveness of WOM (message content and source characteristics). The three papers together provide insights relating to how individual characteristics of (potential) communicators affect both the decision to share information and also the influence of information that is shared. Across studies, these effects are examined in both face-to-face offline and also online WOM contexts.

The Zhang, Feick and Mittal paper (presented by Lawrence Feick) attempts to understand which people share negative WOM experiences, and with whom, as a function of their level of self-construal. These issues are examined in a face-to-face interpersonal setting, to various relationship ties. Their theorizing suggests that image concerns are likely to deter negative WOM transmission to weak ties (but not to strong ties) by individuals for whom an independent construal is activated. Thus, independent-construal individuals are more likely to consider the identity of the potential recipient (e.g., whether the person is a strong or a weak tie) in their decision to talk.

The Kaikati and Ahluwalia paper (presented by Andrew Kaikati) proposes a cost-benefit framework to test how people decide to share information with others, as a function of their individual differences in altruism, or their internal motivation to help others, in both online and offline settings. Their theorizing suggests that high altruists' WOM decisions are driven more by the perceived diagnostic value of information, while low altruists' WOM decisions are driven more by the perceived costs to the communicator (resource costs, social costs) of sharing the information. Thus, high (vs. low) altruists are more likely to consider the potential recipient in their decision to talk.

The Karmarkar and Tormala paper (presented by Uma Karmarkar) uses an online setting to understand when consumers are likely to be persuaded by others, as a function of source credibility and expressed certainty. Persuasion is greater for low credibility communicators who express certainty, and for high credibility sources who express uncertainty. The authors propose an incongru-

ity hypothesis, and identify involvement of the recipient as the underlying mechanism. Thus, the effect of source credibility on information recipients' acceptance of a message is dependent upon expressed certainty.

J. Peter Reingen will serve as the discussion leader. He is a well-accomplished researcher in the area of the word of mouth — in particular, as it relates to social ties, referral networks, and interpersonal influence. He will bring to bear his breadth of knowledge in this area by providing an integrative perspective on the role of communicators and recipients in WOM, and discussing future research directions.

EXTENDED ABSTRACTS

"Negative Word-of-Mouth: Self-Construal and Image Impairment Concern"

Yinlong Zhang, University of Texas at San Antonio, USA
Lawrence Feick, University of Pittsburgh, USA
Vikas Mittal, Rice University, USA

After a negative consumption experience, are people more likely to transmit word-of-mouth (WOM) to strong rather than weak ties? The literature includes conflicting empirical results. For example, on the one hand, some research has found that consumers have a higher propensity to spread negative WOM to their strong ties than weak ties (e.g., Weenig, Groenenboom, and Wilke 2001). On the other hand, Wangenheim (2004) found that consumers are more likely to spread negative WOM to weak than to strong ties.

In this paper we articulate and test conditions that may explain at least part of this inconsistency. Specifically, we argue that after a negative purchase experience, consumers can experience two conflicting motives that affect their likelihood of transmitting WOM. On the one hand, they may feel the need to warn individuals about the product or service, but also, they may be concerned about maintaining a positive image (i.e., not revealing that they made a bad choice). The former of these motives is other-focused and the latter self-focused, and either can be more important for a given consumer in a given situation. We show in three studies that the effect of tie strength is related to the presence of either self-focused or other-focused motives.

We take a social-identity perspective that leads us to examine the role of self-construal and image-impairment concern in moderating the relationship between tie strength and (negative) WOM

transmission. Study 1 focused on self-construal. The self can be seen as being more connected to others (an interdependent self-construal) or being more distinct from others (an independent self-construal) (Markus and Kitayama 1991; 1996). According to Markus and Kitayama (1991), those with activated independent self-construals are likely to be affected most by self-focused motivations. In contrast, those with activated interdependent self-construals are likely to be affected most by other-focused motivations. In our context then, consumers who are focused on the needs of others are likely to engage in negative WOM regardless of whether the ties are strong or weak. Thus, we expect that individuals with an interdependent self-construal will view weak ties altruistically and share information with them. In contrast, those with an independent self-construal will adopt this perspective only when interacting with strong ties. These arguments suggest that after a negative experience, self-construal will moderate the effect of tie strength on the likelihood of WOM transmission: we expect that under an independent self-construal, consumers are more likely to transmit negative WOM to strong ties than weak ties. In contrast, under an interdependent self-construal, consumers are equally likely to transmit negative WOM to strong ties and weak ties.

Study 1 employed a 2 (Self-Construal Priming: Independent vs. Interdependent) X 2 (Tie Strength: Weak vs. Strong) in which 78 student participants reacted to a negative consumption scenario. The results support our hypothesis: differences in WOM transmission likelihood between strong and weak ties only emerge when the independent self-construal is primed. With an interdependent self-construal, WOM is equally likely to strong and weak ties.

Study 1 results are consistent with our hypothesis, but do not address the question of how more or less self-focused thinking affects WOM transmission likelihood. We theorize that the process underlying the results involves the differential salience of image-impairment concern under independent versus interdependent self-construal. More specifically, we expect that under an independent self-construal, individuals' focus on the self allows image impairment concerns to become salient, while it is not made salient under an interdependent self-construal.

For individuals with an independent self-construal, we argued and demonstrated that a self-focused perspective dominates decision making. For such individuals, image concerns are salient (whether or not there is an additional effort to make them salient). Thus, we should expect that for such individuals we obtain results similar to those in Study 1, that is, greater WOM transmission likelihood to strong than to weak ties. On the other hand, for an interdependent self-construal, we have demonstrated that other-focused concerns are salient because an interdependent self identity motivates people to think about others and pursue relational goals. Consequently, for interdependent self-construal there was no difference between strong and weak ties in WOM transmission likelihood. However, if image impairment concerns are made salient for this group, we should see a reversal in the pattern of results. Specifically, individuals with either an interdependent or independent self-construal should be concerned with their image and should be likely to withhold negative WOM to both strong and weak ties. In summary then, we expect a three way interaction among these variables.

In Studies 2 and 3, we examine this hypothesis. Study 2 and 3 tested the same set of three variables: self-construal, tie strength, and image impairment concern. Study 2 was an experiment in which a sample of 195 students reacted to a negative consumption scenario. Study 2 used manipulated variables in a 2 (Image Impairment Concern: High salience vs. Low salience) X 2 (Self-Construal Priming: Independent vs. Interdependent) X 2 (Tie Strength: Weak

vs. Strong) between-subjects design. In contrast, Study 3 was a survey of 401 adult consumers in which image impairment concern and self-construal were measured and tie strength was manipulated between subjects. A marketing research company used probability sampling from its online panel of U.S. adult consumers to obtain participants.

Results from Studies 2 and 3 support the hypothesis. Image impairment concern moderates the interactive effect of self-construal and tie strength on the likelihood of negative WOM transmission. When image impairment concern is made salient, WOM transmission is similar between self-construals. When image impairment concern is not made salient, we find greater WOM transmission for strong than weak ties for an independent self-construal and no effect of tie strength for an interdependent self-construal.

In combination, the results of our studies show that the process of managing one's image is integral to understanding the likelihood of WOM transmission. Further, our results reinforce the importance of understanding the motives—structural and psychological—that drive WOM decisions and also provide insight into the mechanisms underlying the effect of self-construal on information processing.

"Word-of-Mouth Communication as Helping Behavior"

Andrew M. Kaikati, University of Minnesota, USA

Rohini Ahluwalia, University of Minnesota, USA

A person who acquires marketplace information must decide whether to share that information. WOM occurs only if a person is motivated to talk after weighing the associated costs and benefits (Cheema and Kaikati 2009; Frenzen and Nakamoto 1993). One potential benefit of sharing product-related information could be facilitating recipients' future decisions by helping them to make informed decisions and to avoid costly pitfalls. At the same time, sharing this information could result in potential costs to the communicator. There are social costs; for instance, information conveyed may reflect poorly on the communicator if others act on that information and disagree with it, or if others perceive the communicator to be a complainer. There are also resource costs. For instance, information involves a certain amount of time and effort to transmit.

We suggest that the effect of these costs and benefits on WOM behavior may differ as a function of the person's underlying values. Values are abstract representations about desired end states that are hierarchically organized in terms of their importance to the self (Bardi and Schwartz 2003). High-priority values are central to

one's self concept, and serve as motivational constructs that may define a situation, elicit goals, and guide action (Torelli and Kaikati 2009; Verplanken and Holland 2002). Actions become subjectively more attractive to the extent that they lead to attainment of valued goals; thus, each person defines a situation, and weighs its associated opportunities and constraints, in terms of his or her own important values.

Specifically, the current research develops a cost-benefit framework to systematically test the effect of individual differences in altruism, which is the internal motivation to help others that is based on one's personal values, on WOM. One of the primary motivations suggested in the WOM literature is the desire to help other consumers (Price, Feick, and Guskey 1995); however, there has been little systematic experimental research examining when this motivation is relevant and what its effects are on the likelihood of sharing information.

It is expected that individuals who score high (vs. low) in altruism are more focused on the needs of others, and that their behavior will be proportional to the magnitude of the perceived informational benefit (Bendapudi, Singh, and Bendapudi 1996). In a WOM context, this means that these individuals' WOM likelihood increases with information diagnosticity. Furthermore, they should be less sensitive to other factors, such as their own level of expended resources and the potential social costs of sharing information. Individuals who score low (vs. high) in altruism, on the other hand, focus less on the needs of others, and are thus less likely to be affected by the diagnosticity of information. However, they should be sensitive to the expended resources and potential costs of a situation.

Three studies were designed to test these propositions. Across three studies, participants either read a hypothetical consumer scenario or reported on a prior product experience. In each study, the relative benefits and/or costs associated with WOM were manipulated (based on pretests of these costs and benefits). After reading the study materials, participants reported their likelihood of sharing information about the product or service with others in either a face-to-face (study 1 and 2) or an online (study 3) context. They also completed a series of measures, including altruism.

In study 1, the benefits and costs of WOM communication were manipulated simultaneously via characteristics of the information (negative versus positive restaurant experience) to test the likelihood of information sharing. Pretests confirmed that compared with positive information, negative information is more useful to recipients (Feldman and Lynch 1988), but it also carries more social costs for the communicator because others may perceive him or her as a complainer (Laczniak, DeCarlo, and Ramaswami 2001). Results confirmed that high altruists were more likely to communicate negative as compared to positive information, since it offered more benefits to others, even at greater social costs to oneself. In contrast, low altruists exhibited the opposite pattern of WOM behavior—they were more likely to communicate positive versus negative experiences to others, since the latter tended to carry more social costs to the self.

In study 2, only the information value was manipulated (costs were held constant), using the context of information about an in-store special for a popular consumer product (digital cameras). The informational value (benefit) was manipulated as either moderate (store located further away) or high (store located closeby). Consistent with expectations, high altruists were more likely to talk to someone about the digital camera sale when the store was closer, due to greater information value. Low altruists, however, were unaffected by the information value of WOM, and were equally likely to engage in WOM in both conditions.

Study 3 was a computer-based study that tested the implications of the framework in an online context. In this study, only the resource cost of sharing information was manipulated (information value was held constant). Participants first reported on the most recent new movie they had seen. On the next screen, the number of existing online movie reviews for that movie was manipulated to be either very low (two reviews) or moderate (35 reviews). Pretests confirmed that WOM may take more time and effort (higher costs) when there are fewer reviews, but that the information is perceived as equally beneficial to recipients in the two conditions. Results indicated that low altruists were less likely to post a review when there were fewer existing reviews, because of the additional time and effort required. High altruists' WOM, however, was not affected by the number of reviews.

In total, three studies suggest that level of altruism, which is based on one's personal values, is an important driver of WOM motivation. Specifically, findings indicate that high altruists' WOM behavior is driven by the perceived diagnostic value of information, whereas low altruists' WOM behavior is driven by perceived communicator costs.

"The Dynamic Effect of Source Certainty on Consumer Involvement and Persuasion"

Uma R. Karmarkar, Stanford University, USA

Zakary L. Tormala, Stanford University, USA

Suppose a traveler is planning a vacation through a popular travel website and reads a reviewer's recommendation for a particular beachside resort, containing several strong arguments in its favor. It seems reasonable to surmise that the more certainty the reviewer expresses about this recommendation, the more likely the traveler will be to take his or her advice. However, is it possible that by voicing certainty the reviewer will undermine his or her persuasiveness? Are there conditions under which the reviewer could gain influence by expressing uncertainty about his or her attitude? In this research, we explore the possibility that the effect of expressed

certainty on persuasion can vary dependent on the expertise of the message source.

While an extensive literature speaks to the important consequences of attitude certainty for a consumer's own attitudes and behavior (see Tormala and Rucker 2007 for a review), far less attention has been devoted to exploring the impact of expressed attitude certainty on other consumers. In terms of word of mouth communications, one straightforward prediction would be that expressing certainty generally increases persuasion. Consistent with this hypothesis, research in other domains suggests that individuals who express high levels of confidence tend to be perceived as more credible than those who express lower level of confidence (e.g., Price and Stone 2004; Tenney, MacCoun, Spellman, and Hastie 2007). Thus, source certainty might have a positive effect on persuasion that is mediated by perceived source expertise.

In contrast to this main effect hypothesis, we propose that in subjective consumer contexts source certainty can have a dynamic effect on persuasion that is moderated by perceived source expertise. Under low expertise conditions (e.g., when a consumer receives a message from a nonexpert source), we predict that source certainty will have a positive effect on persuasion such that consumers are more persuaded when the source of a message expresses high compared to low certainty. Under high expertise conditions (e.g., when a consumer receives a message from an expert source), however, we predict that source certainty will have a negative effect on persuasion, such that consumers are more persuaded when the source expresses low compared to high certainty.

This interaction hypothesis is based on past research exploring the effects of informational incongruity on message processing. Most germane to our concerns, mismatches between various source attributes have been shown to increase message processing, which can boost persuasion when message arguments are strong (e.g., Ziegler, Diehl, and Ruther 2002). Thus we posit that consumers will feel greater involvement with a message when source expertise and source certainty are incongruent (low expertise/high certainty or high expertise/low certainty) rather than congruent (high expertise/high certainty or low expertise/low certainty). Furthermore, to the extent that the message itself is reasonably strong, or compelling, greater involvement should foster greater persuasion (Petty and Cacioppo 1986). In essence, we hypothesize that incongruity between perceived expertise and certainty should violate expectancies, which feels surprising and motivates involvement. Increased involvement, in turn, can enhance persuasion in response to strong arguments. However, in a situation with weak arguments, incongruities leading to greater involvement should have no appreciable benefit for persuasion and may even cause reactance against it.

In Experiment 1, we tested the impact of source certainty and source expertise on expectancy violations. A favorable restaurant review was presented from a source who varied in expertise and level of expressed certainty. Following the message, we assessed participants' perceptions of how unexpected and surprising the content of the material was. Although source expertise and certainty did not interact to influence the perceived similarity, likeability or trustworthiness of the source, they did interact to affect expectancy violations. We found that expressions of certainty induced greater surprise and unexpectedness when the source was low in expertise, whereas the converse was true for high expertise sources.

Experiment 2 examined the implications for persuasion. In this experiment, all participants received a strong and favorable restaurant review ostensibly taken from a consumer website. As in Experiment 1, the source of this review was described as either an expert or nonexpert on food and dining, and he expressed either high or low certainty about his recommendation. Following the

review, we measured participants' willingness to pay (WTP) for a meal at the restaurant. Results indicated that participants who received a recommendation from a nonexpert source reported greater WTP when that source expressed certainty rather than uncertainty. Conversely, participants who received a recommendation from an expert source reported greater WTP when that source expressed uncertainty rather than certainty.

Finally, Experiment 3 sought to establish the mediating role of involvement, as measured by cognitive elaboration, in the persuasion effect revealed by the second experiment. Replicating the restaurant review paradigm with strong arguments, we found that participants generated more positive thoughts and reported more favorable attitudes and intentions when a high (low) expertise source expressed uncertainty (certainty). However, when a review with weak arguments was presented, these effects disappeared (and tended to reverse). Furthermore, the three-way interaction between source expertise, source certainty, and argument strength on attitudes and intentions was mediated by thought favorability. In short, then, incongruity between source expertise and source certainty fostered increased elaboration, which enhanced persuasion under strong but not weak argument conditions.

Discussion. Previous research exploring the effects of source certainty generally supports the existence of a confidence heuristic, whereby expressed confidence, or certainty, is interpreted as a marker of expertise (e.g., Price and Stone 2004). In the current experiments, we found that source certainty and source expertise were distinct constructs that could be manipulated without impacting other types of source perceptions. Furthermore, the current studies suggest that the effects of source certainty are dynamic, being completely contingent upon the source's level of underlying expertise. In particular, nonexperts (e.g., other consumers) can gain interest and influence by expressing certainty regarding their opinions and recommendations. In contrast, experts appear to gain interest and influence when they express uncertainty about their opinions and recommendations. Implications for interpersonal influence in word of mouth marketing contexts are discussed.

SPECIAL SESSION SUMMARY

From Ear to Brain, From Heart to Pocket: Branding Challenges and Possibilities in the Music Industry

Chia-Jung Tsay, Harvard Business School, USA

SESSION OVERVIEW

The music industry faces new challenges as its nature is altered by the changing tastes of its consumers and the values of the creative industries in general. As the internet and various other mediums dominate the production, access to, and consumption of music, the perception of product quality and the objective measures of the assets are less definable and even less predictable. In three different papers, we examine the creation, development, evaluation, and communication of products through the branding perspective. Even though the three projects are grounded in an investigation of music and the music industry. The findings hold relevant insights for other, creative industries and with other important implications for businesses beyond the creative industries as well.

This Special Session on music aims to tackle the branding of music at multiple levels. The series of presentations start with a look at auditory branding, focusing on how sound may be used to create an authentic auditory identity for a brand. The experimental approach of the first paper captures the cognitive processing of the individual and offers new directions for the better use of music for higher consumer recognition and involvement. The second paper expands branding from an individual level to the product and transitions from the consumer to the organization. The experiments explore the creation of achievement as the product and the consumers' perceptions and reactions to the product, operationalized as the judgments of achievement. The third paper completes the loop by analyzing the branding of organizations as means to attract new customers. The final presentation explores how a major symphony orchestra can be re-branded via the development of their products to satisfy the varied tastes and preferences of consumers from different age groups and levels of expertise.

In order to focus on a narrower set of industries within the creative genres to develop deeper understanding of the challenges and potential solutions, we have limited this set of studies to the music industry. However, our results are very applicable to other creative industries where the strategic branding of products and organizations directly and significantly impacts consumer behavior. We foresee the issues and topics to be covered to be of interest to both academics and practitioners. We believe that by triangulating through multiple methods, including experimental methods and survey analyses, and through multiple levels of analyses, our findings will provide various opportunities for rich discussions of new directions in research and practice throughout a range of important industries that traditionally have been overlooked.

EXTENDED ABSTRACTS

“Hearing, Remembering, and Branding: Guidelines For Creating Sonic Logos”

Vijaykumar Krishnan, University of Cincinnati, USA

James J. Kellaris, University of Cincinnati, USA

A Sonic Logo, “sogo,” the auditory analog of a visual logo, is a typical sonic branding device. Some interesting examples are the 5-tone Intel sogo, windows vista's 4-tone start-up chime and NBC's 3-tone sogo. Sogos vary in their design characteristics. They may have an ascending pattern (Windows Vista), descending pattern (windows XP) or a zigzagging contour (Intel). A sogo may

be easier to remember because it repeats a pattern or ‘chunks’ (Baddeley and Hitch 1974) groups of similar tones. Thus, number of tones they comprise, their contour and their chunkability may characterize Sogos.

Per logo literature (Henderson and Cote 1998), good sogos should engender favorable consumer responses on recognition, affect, and familiarity dimensions. For instance, sogos with fewer tones should be easier to remember; thus obtain high true recognition on a subsequent encounter. On the other hand, because they are easier to process, they may engender illusions of familiarity (Whittlesea 1993) leading to high false recognition. Sogos with a zigzagging contour may be more difficult to recall but may be perceived novel and so liked more. In other words, consumers experience differing levels of ease in processing sogos based on the design characteristics.

This subjective experience of ease of processing incoming auditory information (Reber, Wurtz and Zimmerman 2004; Whittlesea 1993; Janiszewski and Meyvis 2000; Winkielman et al 2003) is misattributed to judgment at hand-Familiarity (Whittlesea 1993); Positive affect (Reber et al 1998; Winkielman and Cacioppo 2001); Judgments of truth (Reber and Schwarz 1999); Brand Evaluation (Lee and Labroo 2004). This research explores the systematic influence of three design characteristics of sogos—number of tones, contour, and chunkability across five studies on response dimensions. Study finds evidence of processing fluency mediation of these influences.

In study 1, participants were blocked into three groups. All participants heard a commercial for a hypothetical brand of bread. The commercial was identical across the three groups but for the accompanying sogo which comprised 3-tone, 6-tone or 9-tone. At test, participants rated willingness to pay for this hypothetical brand of bread. Results show that the number of tones influences the willingness to pay and this influence was fully mediated by the processing fluency of the sogo. Processing fluency was operationalized as an assessment of the ease with which an average person can hum this sogo on a seven-point scale.

In Study 2, participants heard three target sogos varying in number of tones interspersed with distraction tasks. At test, participants heard six sogos—three targets and three foils and rated recognition on a six-point scale (This sogo was in the first set too). Results show that number of tones influence false recognition. Sogos with fewer tones reveal greater perceptual fluency and a higher false recognition. A multilevel mediational analysis reveals significant fluency mediation of false recognition.

Study 3 was similar in structure to study2 except that the sogos varies only on ease of chunking—a pattern such as ABC-ABC-ABC is easy to chunk which A-B-C-D-E-F-G-H-I is not—although both have exactly same number of tones. Results show that chunking influences fluency.

Study 4 varied the contour—ascending, descending or zigzagging. Results show that contour influences affect. A multilevel mediational analysis reveals significant fluency mediation of affect—fluency is affectively positive. Contour also influences both true and false recognition.

Study 5 shows interesting interaction effects between contour and number of tones on recognition and familiarity. False recogni-

tion is for zigzag sogos is lower than that for linear sogos when the number of tones is four; this pattern flips when the number of tones in the sogo is .seven

Taken together, these results show that several response dimensions vary systematically with the sogo design characteristics, thus providing for guidelines. Leader brands would want a high true recognition and a low false recognition; brands in a low involvement product segment (e.g., bread) could profit from high false recognition and illusions of familiarity.

Huge investments are made for creation and airing of auditory branding stimuli; rights for popular songs for use in commercial jingles may top \$500,000 such as for “stand by me,” deployed by Citibank, (Krasilovsky and Shemel 2007). Microsoft commissioned the services of the famous musician Robert Fripe to create the 4-second Windows Vista start-up sogo, who took eighteen months to create the final version. That must surely have been a lot of investment. In conclusion, given that sogos are branding devices, guidelines from this research should reduce the precarious dependence of marketers on musicians, and provide for greater control over sonic branding.

“She’s a Natural!’: From Mere Label to Actualized Consumer Preference”

Chia-Jung Tsay, Harvard Business School, USA
Mahzarin R. Banaji, Harvard University, USA

Industry leaders in marketing and public relations know well the importance of image management and branding. When the product involves an individual or an individual’s output, and when assessments of such products are likely to entail much subjectivity, it often becomes important to build a narrative to best allow consumers to relate to the core attributes of the individual and products associated with such an individual. In sports, for example, several cycles of the Olympics have exemplified the success of the massive campaigns to humanize the champions whose feats defy imagination. Media pick up quickly on such human interest stories, stories of great sacrifice, of perseverance against all odds—stories where the cliché of blood, sweat, and tears is but an understatement. We see quite a different approach when it comes to the marketing and branding of classical musicians, a field that is littered with “prodigies.” It is the natural talent that captures our intrigue—the youthful looks of a Joshua Bell; the nearly everyday occurrence of yet the next wunderkind; the ingénue who is featured prominently on a CD cover, her age and diminutive stature made only more striking by the elderly and robust conductor pictured standing at her side. Industry intuition would suggest that society rewards the natural, and here, we test this theory empirically.

In any domain of expertise, be it art, sports, or academia, achievement is assumed to derive from both natural and acquired sources. Of all those who undergo extensive training in any sphere of achievement, there are those who seem to shine in ways that cannot be explained by practice. On the other hand, there are those with talent, but unless that talent is put to rigorous training, nothing much can result from it. It is hardly controversial to claim that achievement in any sphere is a function of both. Our beliefs about the relative contributions of these two sources are important because they can shape our behavior toward our own talents and toward the talents of others we judge, such as with consumers’ preferences towards performers and artistic products. We are interested in testing whether the evaluation of achievement, such as the assessment of performance quality, is shaped by the belief about the natural versus acquired basis of achievement. We suggest that our preferences for both early talent and the hard-working hero may co-occur, but in dissociated fashion, such that abstract, propositionally

represented values about accomplishment may genuinely favor a strong work ethic, but that specific choices will reveal a preference for the natural. In other words, a dissociation between expressed values favoring hard work, or the “Striver,” and actual preference for innate talent, or the “Natural,” may in fact be the reality. We may say we respect and admire hard workers, but when it comes to selecting a recording or buying a concert ticket, our dollars may instead go to the natural prodigy.

In the first two experiments, we explored whether knowledge about the source of achievement influences the evaluations of target musicians (Study 1), and whether professionals differ from amateurs in vulnerability to the bias (Study 2). Our strategy was to familiarize participants with two musicians, using background descriptions that were matched for level of performance and degree of achievement described, but which differed in whether the musicians’ talent appeared to be either naturally acquired, the “Natural,” or rather developed primarily through hard work and training, the “Striver.” Then, participants heard brief performances attributed to each musician, but which in reality were performed by the same anonymous musician, thus controlling for actual level of ability or accomplishment. After hearing each performance, participants evaluated the target musician on several dimensions intended to gauge their perceptions of the performers’ musical achievement.

We observed a dissociation between reports of what mattered in the creation of achievement (hard work and training) and judgments of achievement (inborn qualities) in the field of music performance. After hearing performances that were controlled so as to be equal in quality, experts—heavy consumers of music—in Study 1 rated a musician described as having inborn ability, the “Natural,” as more talented than a musician described as having worked hard to develop her ability, or the “Striver.” In spite of the way they evaluated the target performers, when asked directly about their general beliefs, participants regarded effortful training as a more influential determinant of musical achievement than innate ability. Thus, the expression of the naturalness may be an implicit bias, because its manifestation in specific judgments contradicted the implications of participants’ explicit general beliefs. We replicated these results in Study 2, with experts again rating effortful training as the superior determinant of musical achievement, and this difference was more pronounced for these experts than for novices, who showed a slight reversal.

As little research has thus far tackled the effect of apparent basis of achievement on our evaluations of artistic products, and since our findings in the first two studies suggest that the naturalness bias may be operating at an implicit level, we sought to triangulate through different methodologies to determine whether the naturalness bias would still be elicited. In Study 3 and Study 4, we replicated the result of a naturalness bias in the domain of music using a conjoint analysis design. Through the presentation of a set of alternatives that allowed the deduction of preferences from the tradeoffs made when choosing between sets of attributes, we tested whether the naturalness bias would emerge on a new measure of direct choice.

Much work remains to be done to clarify the processes producing the naturalness bias, and the conditions under which it is and is not likely to occur. Given the rather consequential implications of the bias for decisions involving the assessment of individual performers and their output of artistic products, a substantial investment in that mission would be well justified. Hopefully, this research will inform efforts to best allow consumers to appreciate the culmination of what is usually the combination of natural talent and hard work.

“I Want You Back’: Branding Classical Music For The New Generation”*Lalin Anik, Harvard Business School, USA**Chia-Jung Tsay, Harvard Business School, USA*

Beyond the many challenges inherent in the creative industries, such as the level of subjectivity that fosters huge unpredictability in reception to products and talents and the dependence on the blockbuster hits that offset the negative revenues accrued to the large majority of products, the classical music industry poses several additional unique issues worthy of examination. While defining success and popularity for talents and brands is shaped by objective measures in many creative industries, this is far more elusive in the music industry. And although many arts organizations exist as non-profits, they still do need to keep in consideration the long-term financial sustainability of their very existence. Indeed, even the top opera houses make major artistic and strategic decisions with their donors as a priority—for example, in 2006, 41% of the revenues for the Metropolitan Opera were from contributions.

Perhaps most importantly, unlike other genres in which the target core audience can be quite large, one of the key issues for the classical industry is the aging and increasingly limited core demographic. In this paper, we collaborate with industry leaders to focus on honing a better understanding of how to best balance the varied tastes and preferences of consumers of a range of age and expertise is paramount to. Our goal has been to use the music industry as a proxy for many other creative industries that face the risk of changing demographics of customers and we make higher level suggestions for how to brand a creative organization to capture new consumers.

In the film industry, 72% of the public over 12 years old are consumers and the 12-29 age group makes up 30% of the population and half of theater admissions—while the National Endowment for the Arts reports that the average age of those attending a classical music performance in 2002 was 49. In the soccer industry, Spain’s Santiago Bernabeu Stadium opened with a capacity of 75,000 back in 1947, now with further revenues from audiences through pay-per-view and internet streams—while in the classical industry, the most famous concert hall in the world, Carnegie Hall, seats a mere 2,804. The need to capture and maintain segments of the population is still important in other industries, but we note a host of additional factors that contribute to such difficulties in the classical music industry. Here, the consumption of products and the assessment of talents often involve greater levels of investment in special training or knowledge. Given that consumption of products from creative industries can often be experienced as a social activity, as social consumption of products, this again limits the range of the population that may be naturally drawn to classical music. Comparing to other genres of music, the classical segment lags far behind in sales, occupying only 2.4% of music buyer purchases in 2005.

In this paper, we worked with a major symphony orchestra to examine the outcomes of various initiatives (such as innovative uses of digital technology and social media) to attract new consumers, along with their impact on the core audience. We also explored how consumers’ choices are affected by the organization’s programming, including the consideration of both economic and artistic influences, such as the stature and appeal of guest artists, the inclusion of new music in repertoire, and the brand of the institution.

We also targeted strategies on both short and long term horizons. Considering the short term, we focused on issues in balancing the core missions of the organization as it develops its multiple sub-brands, with the demands of the aging core demo-

graphic. Through data from over 6,000 audience members provided by the symphony orchestra, the findings add to our understanding of the barriers to and motivators of repeat visitation, through the identification of factors that stimulate repurchase, increase frequency, and reduce churn. First of all, the data allowed us to segment the types of customers into 6 distinct groups: “unconverted trailists,” who were first-timers who attended one concert and did not come back; “special occasions” who attended one concert per year for multiple years; “non-committed” who attended a couple of concerts per year but still churned at high rates; “snackers” who attended smaller concert packages and were very loyal; “high potentials” who attended a lot of concerts and were likely to purchase a subscription; “core audience” who were all subscribers. One of the most striking results was the big gap between the churn rates of the different groups. The “unconverted trialists” attended one concert per year and churned at a rate of 91%, while the “special occasions” also attended one concert in a given year but had a much lower churn rate at 67%. On the other end of the spectrum was the “core audience” with only 8% churn rate. Our analysis indicated that the frequency of annual concert attendance and the years of ‘tenure’ at the symphony were the two best predictors of the churn and sub rates. Our results also revealed large gaps between the number of customers who fell into each category.

For the long term, we focused on how best to expand the core demographic given the constraints of the products in the genre, which may affect decisions to encourage the development of group rather than solo talents, and also greater versatility through crossover acts. The issue of maintaining the core audience while drawing in new audiences has been one of the greatest needs and challenges in the classical industry, perhaps best captured by the example of *bond*, the British string quartet that has its roots in classical training but marketing efforts towards wider, pop appeal—efforts that propelled the group to its status as the best-selling string quartet of all time, but at the same time, much controversy in classical circles and even removal from the UK classical chart. We found that for this symphony orchestra, the use of strategies typical of other organizations in the classical industry may have unintended effects. For example, programming decisions that include crossover repertoire actually dilute the brand of the organization and its products, such that major segments of the core demographic— young musicians and conservatory students, as well as those in the donor population who are accustomed to the inclusion of famous works and performers more traditionally associated with the classical genre—question the legitimacy of such programs.

However, the development of multiple sub-brands to which separate segments of the demographic may identify holds promise. With 5,678 valid respondents, each making twelve offer choices and yielding over 68,000 purchase decisions, we also included a conjoint analysis on the various offers, where key elements varied across the terms of package and times, the type of program, the repertoire, seating, parking as well as the availability of different pricing and ticketing options. The revealed preferences through consumers’ choices and behaviors allowed us to assess the attributes that maximize utility for each cluster/group of the demographic, through the presentation of various combinations of alternatives.

These analyses were supplemented by an examination of two recent initiatives that target different segments and preferences, which have significantly increased revenues, decreased the mean age of the audience members, and even attracted a significant fraction of those who were first-time attendees. The development of individual sub-brands may also lead to greater awareness of the other alternatives. In the survey data, we find that there exists

approximately a 20% crossover rate between sub-brands, despite the disparate programming and marketing between each. Another finding from analyses of survey data on another sub-brand holds implications regarding the importance of valued partners. Given the increasingly competitive landscape of not only the music industry but the entertainment industry as a whole, associations with relevant partners may provide value-added for segments of the population that may be less attracted to the music, and music alone.

SPECIAL SESSION SUMMARY
Time is More Precious than Money
Stephen A. Spiller, Duke University, USA

SESSION OVERVIEW

The allocation of time and money is fundamental to consumer behavior. Previous research comparing time and money has focused on identifying systematic differences in consumers' perceptions and has found that time and money differ in their value ambiguity (Okada and Hoch, 2004), perceived future availability (Zauberman and Lynch, 2005), and degree of personal connection (Mogilner and Aaker, 2009). The four papers in this session advance this research by considering antecedents and implications of the underlying differences between time and money and focusing on time's unique role in decision making as a particularly precious resource. We examine its unanticipated scarcity (Spiller and Lynch), its self-expressive value (Reed, Aquino, Levy, and Finnel), its implications for the pursuit of happiness (Mogilner), and its role in promoting preference stability (Lee, Lee, and Zauberman).

First, Spiller and Lynch consider why consumers have less time than expected, but not less money. They find that consumers exhibit a greater planning fallacy for time than for money because they plan more for their use of time than money. Next, Reed and colleagues examine why an active moral identity leads to a preference to donate time rather than money and find that donating time is more self-expressive than donating money. Moreover, they consider how this preference for time versus money differs depending on whether the donation is real or hypothetical. The final two papers build on the finding that the mere concept of time increases the weight consumers put on personal connection (Mogilner and Aaker, 2009). First, Mogilner shows that when time rather than money is activated, individuals are more likely to pursue consumption that leads to greater happiness. Finally, Lee and colleagues find that although time's value may be more ambiguous than money's, preferences are more stable when time (rather than money) is the resource of exchange, due to its emotional tags.

EXTENDED ABSTRACTS

“Consumers Exhibit the Planning Fallacy for Time but not Money”

Stephen A. Spiller, Duke University, USA

John G. Lynch Jr., University of Colorado, Boulder, USA

The planning fallacy has been defined as “the fact that people invariably underestimate the resources, such as time and money, that will be required to finish a project” (Taylor, Pham, Rivkin, and Armor, 1998, p. 434). Although a planning fallacy for money has been referenced by other researchers (e.g., Kahneman and Tversky, 1979; Kruger and Evans, 2004), empirical research at the personal level has focused exclusively on time plans. Given important differences in perceptions of time and money (e.g., Mogilner and Aaker, 2009; Okada and Hoch, 2004; Zauberman and Lynch, 2005), we pose the question: Does the personal planning fallacy apply to money as it does to time?

Some existing evidence suggests it does not. If individuals expect to spend less time and less money on projects than they actually spend, they will overestimate the amount of “time slack” and “money slack” they have left. Zauberman and Lynch (2005) find that although people overestimate their future time slack, they do not overestimate their future money slack, suggesting the absence of a planning fallacy for money. More direct evidence

comes from Kruger and Evans (2004, Study 1), who found that decomposing a project (e.g., holiday gift shopping) into its component parts (e.g., each person on the list) increased predictions of the amount of time to be spent by more than 30% but only increased predictions of the amount of money to be spent by less than 10%. These findings lead us to hypothesize that individuals exhibit the planning fallacy for time but not for money (H1). We test H1 in Studies 1, 2, and 3.

In Study 1, 2078 members of an online panel reported how much and how frequently they exhibit the planning fallacy for time or money. In support of H1, participants reported exhibiting a greater and more frequent planning fallacy for time than for money.

In Study 2, 93 undergraduates listed short-run and long-run plans for their uses of time and money and reported when they would finish their time plans and how much money they would spend on their money plans. They later reported when they completed their time plans and how much money they spent on their money plans. In support of H1, participants completed their time plans later than planned, but spent less money than planned on their money plans.

The generally accepted explanation for the planning fallacy is that planners focus too much on how they will successfully execute their plan (they take the “inside perspective”), and neglect distributional information of past planning failures and future potential obstacles (they ignore the “outside perspective”; Kahneman and Tversky, 1979; Buehler, Griffin, and Ross, 1994). As a result, planning more leads to a greater planning fallacy. Although this inside versus outside distinction applies equally to time and money plans, people may be more likely to take the inside perspective for time than for money. Lynch, Netemeyer, Spiller, and Zammit (2009) develop and validate a measure of propensity to plan with parallel versions for time and money planning in the short-run and long-run. They find that individuals have a greater propensity to plan for time than for money, suggesting that individuals are more likely to take the inside perspective for time than for money. These findings lead us to hypothesize that individuals with a greater propensity to plan exhibit a greater planning fallacy (H2) and propensity to plan mediates the cross-resource difference in the planning fallacy (H3). We test H2 and H3 in Study 3.

In Study 3, 90 MBA students were asked when they planned to finish their holiday gift shopping, how much money they would spend on their holiday gift shopping, or both. Every day, they reported whether they went shopping the previous day and if they did go shopping, how much money they spent. In support of H1, participants exhibited the planning fallacy for time but not for money. In support of H2, participants with a greater propensity to plan exhibited a greater planning fallacy than those with a lesser propensity to plan. In support of H3, the cross-resource difference in the planning fallacy was mediated by propensity to plan; controlling for propensity to plan, there was no difference in the planning fallacy for time versus money.

This work provides the first systematic comparison of the degree to which consumers exhibit the planning fallacy for time and money and links it to existing work on the “inside perspective.” Due to differences in propensity to plan, consumers exhibit a greater planning fallacy for time than for money, leaving them with less time than expected but not less money and thus making their limited

remaining time all the more precious. This research also reveals a “dark-side” to the propensity to plan, which might otherwise be viewed a priori as a primarily positive trait.

“How and When the Moral Self Motivates Donations of Time versus Money”

Americus Reed II, University of Pennsylvania, USA

Karl Aquino, University of British Columbia, Canada

Eric Levy, University of Washington, USA

Stephanie Finnel, University of Pennsylvania, USA

Donating time and donating money appear equivalent, but consumers treat them differently (Liu and Aaker 2008). Consumers prefer giving time versus an equivalent amount of money when their moral identity is either consistently central to their self-concept or temporarily primed (Reed, Aquino, and Levy 2007). Reed et al. (2007) hypothesized that this effect occurs because emphasizing moral identity makes consumers choose behaviors that express that identity. Giving time (vs. money) should be seen as more expressive of the moral self because it entails greater contact with needy others and hence greater willingness to sacrifice for them. This concern for others characterizes the moral self (Aquino and Reed 2002).

However, Reed et al. (2007) did not directly test their reasoning for why consumers with an activated moral identity prefer giving time versus money; something unrelated to self-expressiveness could be driving their results. We propose the following self-expressiveness hypothesis: activating moral identity strengthens consumers’ belief that giving to charity expresses who they are, and this belief makes them prefer giving time, an act more consistent with the moral identity they want to express than giving money.

But do these self-expressive benefits mean moral identity will always make consumers prefer giving time versus money in real donations? Past research cannot address this question because it considered hypothetical preferences, but we suspect the answer is no. Unlike money, time cannot be replenished through work. Thus consumers may perceive time as scarcer than money and may view giving time as costlier than giving money. They may report a hypothetical preference to give time to express their moral self but be unwilling to bear the costs of giving real time (cf. Batson and Thompson 2001). Both internal (moral identity centrality) and external (temporary moral identity priming) sources of moral motivation, rather than just one as in previous work, may be necessary to induce giving real time versus money. We call this the real donation hypothesis.

Study 1 tested the self-expressiveness hypothesis. The study was a 2 (moral identity prime: high versus low) x 2 (effort: moral versus non-moral) between-subjects design. University participants (N=183) completed two tasks. In the first task, moral identity was primed (Reed et al. 2007). Participants copied words and used them to write a story. In the high (low) moral identity prime condition, the words were traits related (unrelated) to being moral such as compassionate (carefree) (Aquino and Reed 2002). In the second task, participants imagined contributing to an organizational effort. They indicated how self-expressive contributing would be and chose from three hypothetical options: giving \$5, giving \$5 worth of time, or giving nothing. Following Reed et al. (2007), we manipulated the effort’s perceived morality because the identity prime was expected to affect time versus money preferences for a moral but not a non-moral cause. In the moral (non-moral) effort condition, the effort’s objective was to promote volunteering (sell advertising services). Manipulation checks confirmed both manipulations’ effectiveness. Analyses on both dependent measures (self-expressiveness and donation preferences) revealed a moral

identity prime x effort interaction such that priming moral identity led participants to view contributing as more self-expressive and to prefer giving time versus money for moral effort but not non-moral effort. Importantly, self-expressiveness mediated the relationship between the moral identity prime x effort interaction and donation preferences, supporting the self-expressiveness hypothesis.

Study 2 tested the real donation hypothesis. The study was a two-group (moral identity prime: high versus low) between-subjects design with moral identity centrality measured. University participants (N=105) completed three tasks. The first task contained Aquino and Reed’s (2002) moral identity centrality scale. The second task primed moral identity using slide shows. The high moral prime show contained photographs of historical figures acknowledged to be moral (e.g., Gandhi) and of ordinary people expressing concern for each other. The low moral prime show contained photographs of flowers. Manipulation checks confirmed the primes’ effectiveness. In the third task, all participants read the moral effort description from study 1 and received a real donation opportunity. They chose from three options: give part of their \$10 participation payment to the effort, spend time after the experiment aiding the effort, or do nothing. Participants were debriefed afterward and did not really donate. Our analyses of the donation decision revealed a centrality x prime interaction such that higher moral identity centrality increased preference to give time versus money in the high but not low moral prime condition. In support of the real donation hypothesis, both sources of moral motivation were needed to elicit preferences to give real time versus money.

“The Role of Time versus Money in the Pursuit of Happiness”

Cassie Mogilner, University of Pennsylvania, USA

Money is assumed to be critical for pursuit of the American Dream and our unalienable right to be happy. Indeed, when a sample of 127 American university students were asked to share their feelings related to money, “happiness” was the most frequently cited emotion. However, psychology research reveals there to be a weak relationship between money and happiness (e.g., Kahneman et al. 2006), and economists have found Americans’ happiness levels to have remained constant over the past several decades despite an increase in financial wealth (Easterlin 1995). How can we reconcile the assumed association between money and happiness with empirical demonstrations suggesting the two to be largely unrelated?

Exploring the role of our other principle resource, time, may shed some light. An investigation into national allocations of time reveals that while wealth in the U.S. has increased over the last quarter of a century, so too has the number of hours Americans have spent working. In contrast, Europeans have decreased the number of hours spent at work in response to gains in economic wealth, and their happiness levels have increased (Layard 2005). This highlights the possibility that Americans’ extant focus on money as the resource most critical to attaining happiness has been misdirected, and we should instead shift our focus towards time.

To explore this possibility, I conducted four lab and field experiments testing whether directing attention to time (rather than money) can improve Americans’ pursuit of happiness by driving individuals to behave in ways that prior research indicates increase experienced happiness.

Prior research has found that individuals feel greater happiness having spent money to acquire an experience than having spent money to acquire a material possession (Van Boven and Gilovich 2003). Experiments 1A and 1B were conducted to test the hypothesis that increasing the relative salience of time (vs. money) would

increase individuals' tendencies to choose purchases associated with greater happiness.

In experiment 1A, participants were primed with either time or money through incidental exposure to time- or money-related advertisements, and then they were presented with a series of choices between experiential and material purchases. In line with greater happiness, participants who were primed with time (vs. money) were more likely to choose experiential purchases over material purchases. Experiment 1B then demonstrated the robustness of the finding, showing that the effect occurs with an even more subtle prime of time (vs. money) and extends from tradeoffs that participants thought they would make to a choice with real consequence.

With evidence suggesting that activating time (vs. money) can lead people to spend their money in ways associated with greater happiness, experiments 2A and 2B were conducted to test whether priming time (vs. money) would also lead individuals to choose to spend their time in ways associated with greater happiness.

Prior research tracked how a national sample of Americans spent their days, as well as how they felt over the course of their days, and found people to be most happy when socializing and during intimate relations, and to be least happy when working and commuting (Kahneman et al. 2004). Participants in experiment 2A were nonconsciously primed with either time or money using a sentence scramble task, and then asked them to report the extent to which they planned to engage in various activities during the next 24 hours. The results revealed that participants primed with time (vs. money) planned to spend more time engaging in intimate relations and socializing (daily activities associated with greater happiness) and less time working and commuting (daily activities associated with less happiness).

Experiment 2B was a field experiment conducted to test whether such a subtle activation of time (vs. money) could not only impact how individuals plan to spend their time, but also how they actually spend their time. Upon entering a campus café, students were implicitly primed with either time or money while volunteering to complete a sentence scramble task. Those primed with time subsequently spent more time at the café socializing than doing schoolwork, whereas students primed with money spent more time doing schoolwork than socializing.

Together, these findings demonstrate that drawing individuals' attention to time, rather than money, increases their tendencies to spend both their money and their time in ways that are associated with greater happiness. This work contributes to the growing streams of research on time, money, and happiness.

“The Stability of Time versus Money Valuations”

Leonard Lee, Columbia University, USA

Michelle Lee, Singapore Management University, Singapore

Gal Zauberman, University of Pennsylvania, USA

Consumers make decisions about the expenditure of time and money on a daily basis. In this work, we examine the stability of consumer valuations of time versus money across different choice occasions. By stability, we specifically refer to whether there is consistency (or transitivity) in expressed valuations of time versus money—transitivity is lacking when, for instance, one prefers A to B, and B to C, but then contradictorily prefers C to A.

In two experiments, we tested two competing hypotheses. On the one hand, prior research that has examined time-money differences (e.g. Okada and Hoch 2004, Zauberman and Lynch 2005) points toward relatively greater ambiguity in time valuation versus money valuation, which may in turn translate to less stability in expressed valuations of time. On the other hand, a separate stream

of research suggests that there could be less stability in expressed valuations of money, given that (1) affective processing of choice options has been found to generate greater preference consistency than more deliberate cognitive processing (Lee, Amir, and Ariely 2009); (2) money (vs. time) is likely to invoke more analytical as opposed to holistic thinking; and (3) time considerations naturally evokes more emotional responses than money considerations (Mogilner and Aaker 2009).

In experiment 1, 166 US student participants studied a set of nine different flight options for an upcoming international trip they had to make. They were subsequently shown all pair-wise combinations of these nine flight options (36 pairs) and asked to choose their preferred option within each pair. Participants were randomly assigned to one of three conditions: time, money, control. Across conditions, they were given different information about these flight options: in the control condition, each option was represented by both a service rating and an in-flight entertainment rating; additionally, the air fare of each option was also given in the money condition whereas the average one-way flight time was given in the time condition instead. The results revealed that participants in the money condition made significantly more intransitivity errors than both participants in the time condition and the control condition. Participants in the time condition, however, were equally consistent in their choices as those in the control condition. The results also indicated that the different degrees of choice consistency across conditions could not be sufficiently explained by any real or perceived differential difficulty of the choice task.

Experiment 2 conceptually replicated this basic result using a different experimental design and a different set of choice stimuli. Seventy-eight participants were asked to suppose that they had to purchase a photo essay software package for an important project. They were first shown a set of nine different software options represented by four attributes (software features, software quality, set-up time, and price) and then given all binary combinations of these nine software options (36 pairs) and asked to choose their preferred option within each pair. Participants were randomly assigned to one of three conditions: time, money, or control. Unlike experiment 1, participants were shown all four attributes, but which attribute values differed across the product options depended on the condition to which they were assigned: in the control condition, only features rating (1-5) and quality rating (1-5) differed across options while the set-up time and the price of the options were held constant; in the money condition, features rating, quality rating, and price varied across options while set-up time was held constant; in the time condition, features rating, quality rating, and set-up time varied across options while price was held constant. As such, different attributes were made relatively more salient to participants across conditions, hence inducing different degrees of consideration across attributes. To ensure similar magnitudes of attribute values for time and price, we used an implied conversion rate of 1 additional minute of set-up time for \$1 of price reduction.

Again, the results demonstrated that participants in the money condition made significantly more transitivity violations than those in the control condition and those in the time condition. Additional data indicated that participants did not perceive any differences in the variability of the given product options across conditions.

Together, these results provide convergent evidence that preferences based on time are more consistent than preferences based on money. We believe that our research provides a unique test of two competing processes underlying time versus money considerations. Furthermore, it furthers our understanding of the relationship between mental representation of outcomes and type of information processing (affective versus deliberative), as well as how

consumers form preferences based on two fundamental economic resources.

SPECIAL SESSION SUMMARY

Underpinnings of Risky Behavior: Non-health Motives for Health-related Behaviors

Merrie Brucks, University of Arizona, USA
Paul M. Connell, Stony Brook University, USA

SESSION OVERVIEW

Consumers often know of risks to themselves, but fail to act in ways to reduce these risks (Verplanken and Wood 2006; Thaler and Sunstein 2008). In their comprehensive review of the literature on health risk perceptions literature published in the Handbook of Consumer Psychology, Menon, Raghurir, and Nidhi Agrawal (2008) persuasively argue that there is a need to identify “antecedents other than cognitive belief-based ones.” They identify a wealth of motivational, affective, individual, contextual, and disease factors that have been studied and how they relate these to consumer outcomes. Within the specific category of motivation, they discuss theoretical work on self-control, self-positivity, and social desirability. The papers in this proposed session share a focus on motivational antecedents for behaviors, but are guided by theoretical frameworks that have been under-explored in the health context: hypocrisy theory, associative processing of others’ motivations, and symbolic interactionism.

This session brings together rigorous research relevant to understanding consumers’ motivations for engaging in desirable and non-desirable social outcomes. More broadly, the authors in these studies take novel theoretical and methodological approaches within the context of motivation, persuasion, and consumer attitudes and behavior. Bundling these papers together is intended to stimulate discussion and to explore ideas for future research, perhaps beyond the health context. We will build in time to discuss each paper immediately after it has been presented. The audience for this session would likely include researchers interested in the self, motivation, persuasion, transformative consumer research, and public policy topics.

The first paper is co-authored by Jeff Stone (Associate Professor of Social Psychology at the University of Arizona), who has published numerous studies on cognitive dissonance in high-impact journals such as *Journal of Personality and Social Psychology* and *Journal of Experimental Social Psychology*, and his doctoral student Nicholas Fernandez, also at the University of Arizona. Their work examines the use of inducing cognitive dissonance via hypocrisy to achieve desirable health outcomes. The second paper is co-authored by Merrie Brucks (Professor of Marketing at the University of Arizona), Paul Connell (Assistant Professor of Marketing at Stony Brook University) and Dan Freeman (Associate Professor of Marketing at University of Delaware). In this paper, the authors find that children ascribe motivations to smoke or not to smoke at a very early age, even though they cannot articulate the reasoning behind these motivations. The final paper is co-authored by Connie Pechmann (Professor of Marketing at the University of California, Irvine), Dante Pirouz (Doctoral Student at the University of California, Irvine), and Todd Pezzuti (Doctoral Student at the University of California, Irvine). Across three experiments, the authors find that when teens are exposed to advertisements featuring young adult models, they actually have higher intentions to smoke than when exposed to advertisements featuring other teens, as teens see cigarettes as a means of communicating an adult identity.

EXTENDED ABSTRACTS

“The Use of Hypocrisy to Motivate Health Attitude and Behavior Change”

Jeff Stone, University of Arizona, USA
Nicholas C. Fernandez, University of Arizona, USA

This presentation examines the use of the hypocrisy strategy as a social-marketing tool for changing consumer health behaviors. Feelings of hypocrisy occur when people make a public statement about the importance of a target health behavior, such as using condoms to prevent sexually transmitted diseases like AIDS (Stone et al. 1994, 1997), quitting smoking (Peterson et al 2008), or using sunscreen to reduce the risk for skin cancer (Fernandez et al 2009). By itself, the advocacy is consistent with prevailing attitudes beliefs about the issue, and does not cause discomfort. However, when people are then made mindful that they themselves have not performed the behavior regularly in the past, the discrepancy between their advocacy and past behavior causes the discomfort associated with cognitive dissonance. To reduce their discomfort, hypocrites become motivated to “practice what they preach” and take the necessary steps toward bringing their own health behavior into line with their “preaching” about the importance of the standards for good health.

A recent review of the hypocrisy literature (Stone and Fernandez 2008) shows that there are over 20 studies of the effect of hypocrisy on motivating consumer behavior change in the domains of health, the environment and the community. The results of these studies indicate that following hypocrisy, people are most motivated to perform the target behavior when they publically advocate the target behavior and then are privately made mindful of past recent failures to perform the behavior. Studies also indicate that the hypocrisy strategy operates effectively to modify behavior in non-Western cultures (Takaku 2001, 2006).

Recent empirical research focuses on changing behaviors related to the risk for cancer (Fernandez et al 2009). A new line of study examines how much “mindfulness” of past failures is necessary to motivate behavioral change following hypocrisy. According to Festinger (1957), the magnitude of dissonance is highest when more inconsistent than consistent cognitions are present in memory. In the case of hypocrisy, this implies that after advocating the target health behavior, recalling many past failures will cause more dissonance and more behavior change. However, recent research on the role of self-validation in ease-of-retrieval processes (Tormala et al 2007) suggests that when advocates are asked to recall past instances of when they failed to perform the behavior, they may also recruit examples of when they successfully performed the behavior, especially when they are motivated and have the ability to think carefully about the past (i.e., high elaboration). The “self-validation” process predicts that if advocates carefully recall both failures and successes, it could balance the ratio of inconsistent to consistent cognitions, which would reduce the level of dissonance and need to change behavior following hypocrisy. This leads to the counter-intuitive prediction that when advocates think carefully as they recall past failures to perform the target health behavior, recalling fewer past failures may reduce the number of successes that are also recalled, such that recalling fewer

past failures will cause more dissonance and more behavior change. Thus, it was predicted that under high elaboration conditions, when advocates were asked to recall many past failures to perform a health behavior, the self-validation process would reduce the magnitude of dissonance and the motivation to change behavior. However, carefully recalling few past failures would reduce the self-validation process and cause more dissonance and behavioral change following hypocrisy.

In contrast, it was hypothesized that when they are not highly motivated to think about past failures (i.e., low elaboration), advocates will focus primarily on the number of failures recalled without recruiting other relevant information (e.g., successes). As a result, under low elaboration, recalling many past failures will induce more dissonance and behavioral change following hypocrisy than recalling few past failures. In summary, we predicted that under high elaboration, advocates who think about few past failures will exhibit more behavior change, but under low elaboration, advocates who think about many past failures will exhibit more behavior change.

In a 2 (Elaboration: High vs. low) X 2 (Past failures: 2 vs. 8) experimental design, 90 female college students wrote a brief persuasive message for other college students about the importance of using sunscreen to reduce the risk for skin cancer. All were then asked to report past failures to use sunscreen. To manipulate high elaboration (Tormala, Brinol, and Petty 2007), half were told that only a few people were being asked to report information about past failures to use sunscreen; those in the low elaboration condition were told that thousands of people were reporting information about past failures to use sunscreen. Then half were asked to recall 2 past failures to use sunscreen whereas the other half were asked to recall 8 past failures to use sunscreen. All were then provided an opportunity to order a sample of sunscreen from an independent national organization, with the percentage that acquired sunscreen as the primary dependent measure.

The results revealed the predicted elaboration X past recall interaction. As hypothesized, under conditions of high elaboration, significantly more participants (82%) acquired a sample of sunscreen when they were asked to recall 2 past failures compared to those asked to recall 8 past failures. In contrast, under low elaboration, significantly more participants (68%) acquired a sample of sunscreen when asked to recall 8 past failures compared to those asked to recall 2 past failures (39%). Overall, the pattern supports the hypothesis that in hypocrisy, the effect of recalling many past failures on behavior change is a function of how carefully advocates think about their past behavior. Potential mediators of this finding and other future directions for research will be discussed.

"Children's Ascribed Motivations for Smoking Elicited by Projective Questioning"

Merrie Brucks, University of Arizona, USA

Paul M. Connell, Stony Brook University, USA

Dan Freeman, University of Delaware, USA

Critics of increased regulation on tobacco advertising and promotion seen by children argue that such regulation would result in small, if any, effects in reducing initiation of tobacco use among minors. After all, the argument goes, eight year olds do not smoke, so cigarette advertising is personally irrelevant to them. But this perspective assumes that advertisements must be actively processed to be effective. In contrast, we note that considerable research has documented advertising effects on attitude, even under very low involvement conditions (e.g., peripheral processing, mere familiarity, evaluative conditioning). Taking this perspective, we argue that exposure to cigarette advertisements and media images are likely to be processed and encoded into memory despite the lack of individual salience of tobacco promotional activity in childhood.

Our reasoning is consistent with the associative processing model of memory, which is one of the two memory systems proposed by Smith and DeCoster (2000). Associative processing operates preconsciously and automatically (Bargh 1994) and is learned over many experiences. Hence, individuals are typically not aware of the processing itself, but only the results of it. Because tobacco advertising and media images are not likely to be self-relevant to children, we argue that they are processed through such an associative mode.

Furthermore, such associative processing of smoking imagery may produce effects that extend beyond childhood. This is because bias correction is best facilitated when individuals possess both the ability and motivation to reconsider their attitudes). If positive psychosocial associations are learned at a nonconscious and automatic level, then the individual will not likely recognize his or her own biases held in memory, thereby inhibiting the ability to metacognitively reconsider attitudes (Petty and Briñol 2008).

The goal of this study was to aid in generating a theoretical model for the psychological processes involved in children's learning of lifestyle associations with adult-themed products. Given this objective, we pursued our empirical research in the spirit of discovery-oriented research (Wells 1993). Because we suspected that children's lifestyle associations might have been learned implicitly, and because social desirability biases are a threat to validity in

substance use research, we employed projective interviewing techniques.

We conducted 271 projective interviews with second and fifth grade children from three different elementary schools. Two varieties of projective stimuli were used to elicit participant responses: print advertisements and pictures of people who have various personal and lifestyle characteristics. Each child saw two ads for cigarettes, which were embedded in a series of five ads (including three unrelated products). For each ad, children were asked to choose select pictures of specific people who might be likely or unlikely to use that product. Each child was probed with follow up questions to reveal the motivations he or she attributed to these people.

In the presentation, we will show: (1) the three images that were most strongly associated with smoking, as these images were attributed with multiple motives for smoking; (2) the four images that were also associated with smoking, and were attributed with one or two motives for smoking; (3) the six images that were strongly associated with non-smoking, and were attributed with motives for non-smoking; and (4) four images that were inconsistently associated with smoking, and were attributed with motives for both smoking and non-smoking. Typically, the second graders had difficulty in articulating these motives, often with responses such as "s/he just looks like s/he would smoke." Therefore, the emergent themes were drawn largely from the fifth grade interview dataset. Nevertheless, the second graders often made many of the same lifestyle associations as the fifth graders. Chi-square analysis of the pattern of picture selections indicated that they associated the same images with smoking and non-smoking as the fifth graders did.

Qualitative data analysis revealed three broad areas of motives attributed to the characters in the images: social motives, esteem motives, and relaxation motives. Themes within the social motive included smoking for fun in social situations and smoking to impress others, whereas themes within the esteem motive primarily included issues with weight and thinness. Themes within the relaxation motive primarily included needing to escape one's troubles or smoking for leisure. Finally, for one of the images, general inactivity or lack of motivation in general was associated with smoking.

We argue that the similarity of lifestyle picture selections and attributed motivations between the second and fifth graders, in combination with the non-verbal nature of the second graders' associations, suggests that children did not purposefully and thoughtfully develop them. This pattern of data is consistent with the associative processing model of memory, in which advertisements, media images, and personal observations are encoded into memory preconsciously through associative processing.

- "Symbolic Interactionism and Adolescent Reactions to Cigarette Advertisements"**
Connie Pechmann, University of California at Irvine, USA
Dante Pirouz, University of California at Irvine, USA
Todd Pezzuti, University of California at Irvine, USA
- Does restricting the age of models in cigarette advertising to 25 years or older really work in deterring adolescents from smoking? Health researchers and advocates have stressed the importance of using only adult models in cigarette ads because younger models might entice adolescents to believe that smoking is for them. As a result, there have been a number of regulatory attempts to specify the minimum age of models in cigarette ads (Richards, Tye, and Fischer 1996). For example, the Voluntary Cigarette Advertising and Promotion Code, which tobacco manufacturers claim to use as a guideline, states that "any models used in advertising be and appear to be older than 25" (The Tobacco Institute 1990, p. 1). Previous academic literature has focused on the perception of model age in cigarette advertising and has shown that people perceive many cigarette ad models to be younger than 25 (Arnett 2005; Barbeau et al. 1998; Mazis et al. 1992). However, these studies have not linked model age to persuasion nor have they studied the effect of manipulating model age.
- Similarity-based theories, such as social comparison (Festinger 1954) and social identity (Tajfel and Turner 1986), predict that consumers are more influenced by similar others (White and Dahl 2006). A major implication is that ad models should mirror the target audience and teens are more likely to be persuaded by models their own age than by older or younger ones. However, these theories have focused on normative influence and have not addressed aspirational or symbolic factors. On the other hand, symbolic interactionism focuses on how people interpret, act towards, and give meaning to symbolic objects, events and situations around them (Blumer 1969; Sandstrom, Martin, and Fine 2003; Solomon 1983; Stryker 1980). Symbols acquire meaning through socialization and products that function as symbols can carry potent information about an individual's social role and status (Reynolds and Herman-Kinney 2003).
- Age is a powerful indicator of social role and status (Holstein and Gubrium 2003). Across life stages, products are used as symbols to signify to the self and others the transition to a new developmental level (Peterson and Peters 1983; Piacentini and Mailer 2004). Many adolescents have a fragile and unstable self-concept which leads them to aspire to look and act older (Barker and Galambos 2005; Galambos, Turner, and Tilton-Weaver 2005). Thus, products with specific social meaning can be used to facilitate the transition but the imagery and symbolism surrounding the product must appropriately signal adulthood (Berger and Rand 2008; Solomon 1983).
- Cigarettes belong to a unique class of products that are a key identity signal of adulthood (Eckert 1983). Unlike other publicly consumed products, such as music and clothing, smoking symbolizes the adult world and is taboo for adolescents and children in most cultures (Rugkasa et al. 2001). Thus many adolescents seek out conspicuous symbols of adulthood, such as cigarettes, to reinforce their pseudomature identity and help them bridge the gap to adulthood (Eckert 2007; Galambos and Tilton-Weaver 2000; Noble and Walker 1997). For adolescents, this may have an unexpected influence on their response to cigarette advertising featuring models their own age.
- Our theoretical framework predicts that for an adult-signaling product category like cigarettes, young adult models would influence adolescents more positively than same age models. It also predicts that teenage or same age models might, in fact, boomerang. However, for other product categories such as clothing, teen models

would be more influential than young adults. These effects would be mediated by what the model's age communicates about the product, for example, age appropriateness. Theory would also predict that because adolescence is a period of transition, only teens would be susceptible to the teenage model boomerang effect but young adults would not be.

In a series of experiments, we investigated how altering the age of models used in cigarette advertising affects whether adolescents are drawn to—or deterred from—smoking. We pretested over 1000 model images to choose a set of 16 advertising models that were equally attractive but varied on gender (2 levels), ethnicity (2 levels) and age (4 levels: child, teen, young adult and middle age). We then conducted the first study with 221 ninth grade students who rated the model images. We manipulated whether the models held cigarettes or not. As hypothesized, we found that adolescent participants identified most with teen and young adult models, suggesting that they are most likely to be influenced by these age groups.

A second study investigated how cigarette model age might affect persuasion. Participants were 479 ninth grade students who viewed a mock-up magazine containing cigarette ads or matched control ads. The ad models' age was manipulated. The teenage cigarette models boomeranged, lowering intent to smoke. The young adult cigarette models increased intent to smoke, while child and middle-aged cigarette models had no effect on intent. We repeated this experiment using 284 college students who were 18-21 years old. As predicted, the cigarette models had null effects because young adults do not need cigarettes to signal an adult identity.

A third study examined whether the age effects were moderated by product category and also explored the underlying process by identifying mediators. Participants were 278 ninth graders who were shown a magazine with cigarette ads or designer t-shirt ads. The ad models' age was manipulated. As posited, participants perceived cigarettes (vs. designer t-shirts) as more for public display, more reflective of "who the person is," and more "for adults." The cigarette ads also affected both product category (primary) and brand specific (secondary) demand. Specifically, teen versus young adult cigarette ad models lowered cigarette product and brand intent, as hypothesized. The effect of ad model age on intent to use the cigarette product and brand was at least partially mediated by age appropriateness perceptions. Teen (versus young adult) cigarette models decreased perceptions that cigarettes were an appropriate teenage product, which then lowered intent to use cigarettes.

SPECIAL SESSION SUMMARY

Continuing to Sin or a Reformed Sinner: Examining Sequential Self-Regulation Choices

Yael Zemack-Rugar, Virginia Tech, USA

SESSION OVERVIEW

In the recent decade consumer research has seen a burgeoning interest in self-regulation. A host of situational antecedents to self-regulation failures have been identified, including resource availability, emotion, regulatory focus, and justification to name just a few. Several individual difference measures have also been developed including the self-control scale, impulsivity scale, hyperopia scale, frugality scale and others. These research streams identify a wide range of individual/situational antecedents to self-regulation failure and if they teach us one thing—they teach us that such failure is bound to happen.

However, a singular self-regulation failure does not lead to the problems often cited in this research stream; having the occasional slice of cake does not an obese person make. Instead, one needs to make sequential self-regulation failures to encounter undesirable end states such as obesity and debt. This session examines sequential self control choices. We accept the widely held notion that self-regulation is no easy feat; some of us can succeed at it some of the time, but all of us cannot succeed at it all of the time. As a result, initial failures of self-regulation are bound to happen, and what determines their long-term effects is how we respond to them.

This session investigates these responses. We propose that there are essentially two response options: recommit to the goal and become a “reformed sinner”, or abandon the goal and “continue to sin”. In three papers we examine what might lead people to do one or the other, what actions are effective in “reforming”, what actions consumers themselves might take to protect themselves against “continued sinning”, and whether these responses can be related to an underlying individual difference.

In the first paper, Finkelstein and Fishbach examine the effects of feedback regarding initial failure on subsequent self-regulation. In five studies they find that experienced consumers are more sensitive to negative feedback about their lack of accomplishments. This feedback allows them to monitor their progress towards a goal and therefore supports “reform”, that is, subsequent goal-congruent behavior. Experienced consumers therefore seek negative feedback as well as provide negative feedback to experienced others. These findings suggest that communication with experienced consumers should focus on past failures and “misses” to encourage future goal-congruent actions, whereas communication with inexperienced consumers should focus on prior success.

In the second paper, Mazar and Ariely examine ethical decision making and the “What-The-Hell Effect” (WTHE henceforth). The WTHE is directly related to sequential self-regulation. This effect occurs when an individual who has failed at an initial self-regulation goal (e.g., a dieter having one cookie from the jar), then completely foregoes the goal and subsequently engages in goal-incongruent behavior (e.g., eating the contents of the entire cookie jar). Mazar and Ariely show that there is a WTHE in ethical decision making, such that people who have cheated on previous tasks and pass a certain threshold, appear to forgo their moral self-regulation, and keep on cheating. The authors identify conditions that moderate these effects such as positive reinforcers (against subsequent “sinning”) and environmental control. However, this paper shows that other methods, such as confessing, do not help sinners reform.

In the third paper, Zemack-Rugar, Corus, and Brinberg develop a scale that measures individuals’ propensity to enact “WTHE”. The authors argue that like many other self-regulation behaviors,

the tendency to respond to initial failure with reform vs. continued sinning is an individual difference factor. Moreover, this construct is distinct from the tendency to enact initial failures. The authors discuss the scale development process, identifying two cognitive/emotional factors (“sin as motivation” and “sin as permission”) that differentiate between those who tend to enact WTHE and those who do not. The authors also provide three studies in which the WTHE predicts post-failure self-regulation behavior above and beyond existing measures.

We believe this session will appeal to a wide audience at ACR. The session focuses on a topic of great interest, self-regulation, but with a much needed twist—sequential choice. There is relatively little research on sequential choice, and in particular—on sequential self-regulation. In three papers we offer several different points of view on this issue, examining a variety of consumer domains (from friendship to cheating to eating) across 14 studies. We also have a discussant, Jonathan Levav, with great experience and knowledge in the domain of sequential choice. His comments are sure to add insight to the discussion during this session.

EXTENDED ABSTRACTS

“Seeking, Giving, and Responding to Negative Feedback in Self-Regulation”

Stacey Finkelstein, University of Chicago, USA

Ayelet Fishbach, University of Chicago, USA

Research on the Dynamics of Self-Regulation attests that in the course of pursuing multiple goals (e.g., the desire to enjoy one’s food and be a healthy person), whether a consumer experiences commitment to or progress towards a goal influences the consumer’s course of self-regulation over time. While an experience of commitment encourages goal-congruent actions due to an increased sense that one can perform the goal, the experience of not making progress towards the goal encourages goal-congruent actions when it signals that one is not doing as much as one should.

The present research applies this framework to understanding feedback seeking, feedback giving, and response to feedback with respect to goals that involve a sequence of choices that unfold over time. We propose that the emphasis on assessing commitment or monitoring progress changes as consumers become more experienced with a task. Specifically, as consumers become more experienced at pursuing a goal, they are more sensitive to negative feedback about their lack of accomplishments as this feedback allows them to monitor their progress towards a goal. Thus, experienced consumers are more likely to seek negative feedback about their lack of accomplishments, give negative feedback to experienced others, and will be more likely to subsequently perform goal-congruent actions when they consider negative feedback about their “misses.”

We report five studies that tested these hypotheses. In study 1, students in a dancing class were made to feel that they are either novices or experienced, before they sought feedback about their mistakes and how they can improve. We found that compared with students who felt they have been dancing a short while (“inexperienced”), students who felt that they have been dancing a long time, sought more negative feedback about their dancing.

Study 2 extends these results to a foreign language class, where we measured how the level of experience influences stu-

dents' preference for an instructor who gives them positive feedback about their performance versus an instructor who gives them negative feedback about their mistakes. Inexperienced students who were enrolled in a beginner's class preferred the instructor who provides positive feedback more than students enrolled in the advanced class. Conversely, advanced students preferred the instructor who provides negative feedback about how they could improve compared to inexperienced students enrolled in the beginner class.

Next, in study 3, we tested the hypothesis that as one becomes more experienced with a task, one moves from seeking positive feedback to seeking negative feedback. We had participants engage in an unfamiliar task where they had a chance to get feedback on their performance. Participants were told they could only get one piece of feedback and were asked to choose whether they would like to receive positive feedback about what they do well or if they would like to receive negative feedback on how they could improve. We find that as people become more experienced with the task, they seek more negative feedback about how they can improve and less positive feedback on what they do well.

In study 4, we tested for feedback giving. We hypothesized that people who infer they have been pursuing a shared friendship goal with someone for a long time will give their experienced friend negative feedback about their weaknesses. To test this hypothesis, we had participants write a toast to a friend and we analyzed the amount of positive versus negative feedback they incorporated in their toast. We found that those who thought they knew the other person for a long time gave more negative feedback to their friend than those who thought they knew their friend a short while (inexperienced) but there was no difference in positive feedback giving depending on perceived experience in the relationship.

Finally, in study 5 we explored the hypothesis that after gaining some experience in a domain of goal pursuit, individuals respond more to negative feedback by increasing their efforts in that domain and making subsequent goal-congruent choices. To test this prediction, we manipulated perceived experience in the friendship using social comparison information so that friends were made to feel as if they had known each other a short while or a long time. After this experience manipulation, we asked participants to consider a time they received positive feedback about their "hits" or negative feedback about their "misses." We found that participants who were made to feel as if they had known their friend a long time and who considered negative feedback were more likely to make goal-congruent choices (e.g., indicate they wanted to spend time with their friend or contact their friend) than participants who were made to feel experienced but considered positive feedback.

These findings have important implications for how marketers can increase the motivation to adhere to different consumer goals, in particular those that involve a sequence of actions that evolves over time. For example, we suggest that a persuasive appeal for inexperienced gym users should emphasize their successes in maintaining good health in the past, whereas a message that is directed toward experienced gym users should emphasize their lack of actions toward successfully maintaining good health.

"Sequential Influences on Dishonest Behavior"

Nina Mazar, University of Toronto, Canada

Dan Ariely, Duke University, USA

In our daily lives we find ourselves continuously tempted to behave dishonestly: overstating expense reports or tax exemptions, taking credit for other people's work, picking up a zip car earlier than what we have booked it for, or copying a song. It's easy to deviate from the path of honesty from time to time, even if most of

us value honesty and have very high beliefs in our own morality. But is there a tipping point? An unwelcome moment when our dishonest behavior "crosses a threshold, tips, and spreads like wildfire" (Gladwell 2002)? This paper investigates dishonesty in an episodic rather than singular context and explores mechanisms to return to the path of honesty.

People's escalation of behavior has been studied among others in the context of addiction. For example, a dieter, who, in a moment of weakness, succumbs to the temptation and has a bite of chocolate, is more likely to give up any self-control induced restriction and eat the entire bar—after all, if one's daily dieting goal has been already violated, the day is lost. This type of behavior typical for dieters has been coined the "What-the-hell" effect (Polivy and Herman 1985). One popular strategy to prevent oneself from falling into such a trap is to eliminate tempting foods from the immediate environment altogether, which requires not only to admit that indulging is unwanted, but also to foresee future self-control problems (Fishbach and Trope 2007).

When it comes, however, to ethical decision making it has been criticized that most theories and empirical evidences focus on singular events, neglecting the influence of recent behavioral histories (Zhong, Liljenquist, and Cain 2009). For example, it has been shown that when tempted to benefit financially from cheating on a test, a vast amount of people will cheat, but only by a small amount, in order to maintain their moral self-worth (Mazar, Amir, and Ariely 2008). Such research is important to understand the basic mechanism underlying the decision to be dishonest, but falls short off considering that not only current situational factors and individuals traits can influence subsequent behaviors but also past situational factors and behaviors.

Given that continuous temptations play an important role in the context of unwanted behaviors such as binge eating, we set out to explore (1) whether there exists something like the "what-the-hell" effect in the domain of dishonesty and (2) what are the measures to break a vicious cycle of dishonesty. We report three studies that document people's vulnerability to continuous temptations, which can result in unwanted escalations of dishonesty, and ways to get out of them. Study 1 shows that over 100 trials of a task, in which each trial offers a choice between being honest and dishonest, at some point 67% of participants show behavior in line with "what the hell" effect: they reach a point at which they cheat all the time. Mark Twain contemplated "there are several good protections against temptations but the surest is cowardice." In line with this notion, we find in study 2 that if given an explicit choice about the environment to which people want to be exposed to (continuing with the same tempting task as before or moving to a less tempting task), a considerable amount is willing and able to avoid subsequent temptations—even if costly. Finally, study 3 investigates the effectiveness of various measures to reform a "sinner". For this purpose we introduced a break in the middle of a tempting task and either gave no instructions, asked participants to think about their past good deeds, or to confess their regrettable actions. The good news is that we find that positive reinforcers can be effective. However, confessing one's sins to strengthen one's resolutions, and regain a pure soul appears rather harmful.

The implications of this research may be substantial for policy and education. Future studies that investigate the psychological mechanisms underlying positive reinforcers and confessions, their potential connection to moral self-regulation, and the long-term effectiveness of these approaches particularly in light of adaptation can provide valuable insights needed to design better measures to curb dishonesty.

“The ‘What The Hell Effect’ Scale: Measuring Post-Failure Sequential Self-Control Choice Tendencies”

Yael Zemack-Rugar, Virginia Tech, USA

Canan Corus, St. John's University, USA

David Brinberg, Virginia Tech, USA

Self-control failures lead to a variety of individual and social malaise including obesity and debt. However, one could argue that such long term outcomes require repeated consumption episodes, and repeated self-control failures. The present research examines one aspect of such sequential self-control choices.

In particular, we examine how individuals respond to initial self-control failure in subsequent choices. This question is interesting because occasional self-control failures are bound to happen; it is how we respond to these failures that determines long term implications.

Literature suggests individuals can respond in one of two ways: self correct by increasing self control or continue to indulge. The latter behavior, continued indulgence, has been dubbed the “What The Hell Effect” (WTHE henceforth). We argue that much like other self-control characteristics, the tendency to enact the WTHE is based on an individual difference; we develop a measure capturing this difference.

What limited research exists about WTHE focuses on situational antecedents such as goal framing, including short/long and gain/loss frames. However, limited attention is paid to cognitions/emotions experienced in response to goal-failure, individual differences on these factors, and their effects on subsequent behavior.

We address this gap by focusing on the thoughts/feelings that consumers have in response to initial failure, and how these help predict their responses. To this end, we developed the WTHE scale, focusing on two central consumer self-control domains, eating and spending. We briefly describe below the scale development process and 3 predictive validity studies.

Given the limited literature to support item generation, we allowed for an organic development of WTHE questionnaire through consumer experiences. In study 1, 11 scenarios describing WTHE situations were created and presented to 73 participants. Each participant saw 3 random scenarios, and was asked what they would feel/think/do in response (each separately). Participants were then asked to make a choice related to the scenario and were finally asked to evaluate how realistic each scenario was.

We created a 25-item coding scheme designed to capture the different thoughts, feelings, and actions. The diaries were then coded by two independent coders (agreement: 95%). A high correlation of responses to each item was observed across all scenarios (Cronbach's $\alpha > .7$ for all), lending credibility to the selected thought/feeling themes.

The 7 (3 budget, 4 food) most realistic scenarios were selected, and 25 items (corresponding to the themes) were created for each. In study 2, 163 undergraduate students completed this 175-item questionnaire. Exploratory and confirmatory factor analyses were conducted leading to the identification of two factors. Factor one had six items and was consistent with an adaptive, corrective, response to goal-failure (failure as motivation). Factor 2 had three items and was consistent with a WTHE type response (failure as permission). The WTHE score was designed to be the difference between the first factor and second factor average, with lower scores indicating a higher tendency to enact the WTHE.

In study 3, this 63-item questionnaire was administered to 124 participants along with twelve other scales (e.g., self control, impulsivity, causality, perfectionism, locus of control, dieting). The scale was significantly correlated with five scales (TOSCA, dieting, two causality subscales, and impulsivity) in the expected

direction, but only to a moderate degree (highest correlation 0.35), suggesting the scale was unique.

Having developed the questionnaire, we turned to examine its predictive validity. In studies 4 and 5 we provided participants with an eating/spending scenario similar to that provided in Soman and Cheema (2004), where participants had the opportunity to buy a ticket to a concert (have dessert) after either having already exceeded their budget (calorie) goal/having enough money (calories) to afford the ticket (cake).

In a separate session participants completed the WTHE scale, the four scales previously found to correlate with our scale, and several other new scales (e.g., Elaboration on Potential Outcomes, Frugality). Analysis revealed that our scale uniquely predicted whether participants indulged/not when they had already exceeded their budget (calorie) goal. The only other significant measure was the self-control scale, which predicted behavior only for those participants who had not exceeded their budget (calorie) goal. Thus, whereas the self-control scale predicts the likelihood of initial goal-failure, the WTHE scale uniquely predicts post-failure behavior, a separate construct.

Study 6 is ongoing and is a longitudinal study involving diary recording. We seek to examine in this study whether the real-life behavior of consumers following goal failure (recorded in diaries) is uniquely predicted by the WTHE scale.

In sum, the WTHE scale is extremely important and should be of interest to researchers examining self control. It not only identifies an individual difference in responding to failure, it provides insight as to the underlying cognitions/feelings (failure as permission/failure as motivation) that may underlie this difference. As sequential self-control failures are what truly underlie the long-term negative effects on consumers, it is important to identify those consumers most vulnerable to those effects as well as the reasons for this vulnerability.

SPECIAL SESSION SUMMARY

I'm Afraid, But Am I Persuaded? How to Make Fear Appeals More Effective

Eugenia Wu, Duke University, USA

SESSION OVERVIEW

Though appealing to fear is a commonly used persuasive tactic, both practitioners and academic researchers remain divided on whether fear appeals are an effective means of conveying a message or not. While the success of some real world fear appeal campaigns suggests that fear has a positive influence on persuasion, the results of other ad campaigns indicate that fear may actually hamper message acceptance (e.g., Prevention First, 2008; Rhodes, Wolitski and Arguelles, 1989). Similarly, over fifty years of academic research on fear appeals yields mixed evidence as to how persuasive fear appeals really are, with the results of some studies showing a positive relationship between fear and persuasion and others indicating a lack of or even a negative relationship (Janis and Terwillinger, 1962; Witte and Allen, 2000). The three papers in this session all focus on exploring when fear appeals are effective and why. More specifically, each of the three papers examines a different type of factor that may influence whether consumers are persuaded by a given fear appeal or not. Broadly construed, this symposium aims to shed some light on the debate surrounding a classic persuasion technique.

To offer a fuller understanding of when fear appeals are effective and why, each paper examines a distinct factor that may influence fear appeal persuasion and offers a unique perspective. First, Morales, Fitzsimons and Wu (2009) examine how features of the appeal itself, specifically the presence or absence of a disgust-eliciting element, might influence how persuasive consumers find a given fear appeal to be. Second, Agrawal and Menon (2009) explore how factors incidental to the appeal might carry over to influence message acceptance. In particular, they investigate how incidental discrete emotions differentially determine fear appeal effectiveness. Finally, Lau, Williams and Drolet (2009) focus on how individual difference factors can moderate fear appeal persuasion. Specifically, they examine how differences in empathy neglect might impact consumer responsiveness to ads that evoke their fear of embarrassment. Together, these papers suggest that appealing to fear can be an effective persuasive technique but that there are limits and boundary conditions that may hinder persuasion.

Fear appeals have been commonly used to address a wide range of the most urgent social and public health issues ranging from domestic violence and driving while under the influence to AIDS prevention and teenage pregnancy. Given the frequency with which fear appeals are used and the significance of the messages they are attempting to convey, it becomes that much more important for marketers to understand how these appeals work, when they will get the message across and when they will backfire. This symposium aims to contribute to consumer research by providing a nuanced and detailed view of some of the factors that determine whether fear appeals will be persuasive or not.

We hope that this symposium will attract a wide ACR audience, from researchers interested in fear appeals specifically to the broad range of researchers who examine the role of emotion in consumer psychology. This symposium is also relevant for marketers interested in persuasion and emotional coping. Of note, these papers are all in advanced stages of completion. As such, we expect this symposium to stimulate much discussion. For this reason, we hope to save 20 minutes following the presentations for Lauren Block to discuss the presentations and to receive questions from the audience.

EXTENDED ABSTRACTS

“That’s So Disgusting—I’ll Take Two!: How Disgust Enhances the Effectiveness of Fear Appeals”

Andrea C. Morales, Arizona State University, USA

Gavan J. Fitzsimons, Duke University, USA

Eugenia C. Wu, Duke University, USA

Fear appeals have been used to promote a wide variety of consumer products and services and to address a broad range of pressing public health issues including AIDS prevention and drug use (e.g., Freimuth, Hammond, Edgar and Monahan, 1990). Despite the frequency with which fear appeals are used, practitioners and academics remain divided over whether fear appeals are an effective means of persuasion or not (e.g., National Institute on Drug Abuse, 1997; Prevention First, 2008; Beck, 1984; Rogers and Mewborn, 1976).

Research has identified a number of message features and individual difference variables that influence the effectiveness of fear appeals (e.g., Keller and Block, 1996; Rogers, 1983). We propose a previously unexamined factor that may affect fear appeal persuasiveness: the presence or absence of a disgust-eliciting element. Studies have suggested that fear appeals may evoke other emotions in addition to fear (e.g., Dabbs and Leventhal, 1966) and that these emotions may affect persuasion (Passyn and Sujana, 2006). In the current work, we focus on the role of disgust in increasing the persuasiveness of fear appeals. We focus on disgust because its role in persuasion is little understood and because many existing fear appeals seem to also include a disgusting element.

Though both fear and disgust are negative emotions, the distinct properties of each emotion should lead to divergent effects on persuasion. In terms of appraisal pattern differences, fear is characterized by maximal uncertainty whereas disgust is described by a relatively high degree of certainty. When individuals are threatened, feelings of certainty or uncertainty help determine how they will respond. Feelings of uncertainty cause individuals to question their ability to avoid an unpleasant outcome whereas feelings of certainty lead individuals to feel that they can deal with the problem. This suggests that when individuals experience fear in response to a fear (without disgust) appeal, their sense of uncertainty should make message compliance less likely, as they will be unsure whether they can actually do anything to avoid the unpleasant outcome. When individuals experience both disgust and fear in response to a disgust-eliciting fear appeal however, the sense of certainty associated with disgust (that is absent in the case of a fear-without disgust-appeal) should lead to increased message persuasion and a higher likelihood of compliance with the message's recommendations.

Similarly, the unique action tendencies that describe fear and disgust should also lead to disparate effects on persuasion. Most fear appeals are future-oriented (e.g., you will develop skin cancer if you do not use sunscreen) rather than present-oriented (e.g., you are developing skin cancer right now) so that the threat is not imminent. This characteristic of fear appeals should interact with the action tendencies of fear and disgust to influence persuasion. The action tendency in fear is avoidance or escape (Lazarus, 1991) but interestingly, fear often results in freezing or “deer in headlights” behavior. Rosen and Schulkin (1998) suggest that the fear reaction occur in two stages: threat causes individuals to freeze up

initially and then to actively avoid or escape only when the danger becomes imminent. Consistent with this, consumers have been found to “seize and freeze” in response to health-related or threatening messages in fear appeals, thereby hindering persuasion (Block and Williams 2002). In contrast, disgust is characterized by a strong and pronounced impulse to move away from disgust-eliciting object in an immediate and certain manner (Lazarus, 1991). Given that fear causes individuals to freeze if the danger is not looming and that disgust causes individuals to act immediately, we expect that individuals should respond more strongly to fear appeals that also co-activate disgust relative to fear appeals that do not.

In study 1, we first explore the distinct effect that disgust has on persuasion. Though disgust’s expelling properties suggest that disgusting ads may repel consumers away from the suggested behavior and advertised brand, we propose that disgust can lead to increases in persuasion if the frame of the ad fits with disgust’s expelling action tendency. We test this idea in a 2 (disgust level: low vs. high) by 2 (frame: approach vs. avoid) experiment. Results reveal that participants in the high disgust/avoidance frame condition were the most persuaded relative to participants in all other conditions.

In study 2, we begin to examine how disgust might affect fear appeal effectiveness. To tease out disgust’s influence on fear appeals, we pit a fear appeal that does not elicit disgust, a neutral appeal and an appeal in which disgust and fear are co-activated against each other and measure their respective effects on persuasion. Specifically, we use advertisements that attempt to persuade consumers not to use drugs. Study results show that participants were the least likely to use illegal drugs in the disgust and fear co-activation condition.

Studies 3 through 5 build on the results of study 2 and continue to examine how disgust might influence fear appeal persuasiveness. In study 3, we demonstrate that the persuasive effects of disgust-inducing fear appeals generalize across appeals that elicit disgust both through images and through ad copy. In study 4, we would like to draw on our study 1 findings and show that disgust-inducing fear appeals should be particularly effective in the context of an avoidance frame, given the fit between avoidance and how consumers naturally respond to disgust. This is exactly what we find. In study 5, we turn to the appraisal differences between disgust and fear to further examine the distinctions between disgust-inducing fear appeals and fear appeals that do not elicit disgust. Results reveal that the presence or absence of a disgust-eliciting element has a significant effect on persuasion but only for individuals who are motivated to seek a sense of certainty. For individuals who are not motivated to seek certainty, the presence or absence of disgust has little effect on persuasion.

In sum, we find that including disgust-eliciting elements in fear appeals can augment persuasion. An examination of some of the most highly cited fear appeals articles and of real world advertising campaigns suggests that many of these appeals inadvertently elicited disgust in addition to fear. Thus, disgust may be a key moderator of fear appeal effectiveness and may be able to resolve some of the controversy over them. More generally, our findings suggest that future research should examine the role of specific emotions in persuasion appeals, as discrete emotions can have unique effects on persuasion.

“Harboring Hope and Avoiding Anxiety: The Role of Emotions in Determining the Effectiveness of Fear Appeals”

Nidhi Agrawal, Northwestern University, USA
Geeta Menon, University of Pennsylvania, USA

Health messages frequently try to convince consumers that they are at high risk of contracting a disease by presenting an array of risk factors and consequences that resonate with the consumers. Such messages intended to promote safe, precautionary and preventative behaviors in the context of health by creating a fear of having a disease. Such fear appeals that highlight risk factors and consequences are inherently threatening. A growing stream of research on health seeks to understand the factors that affect how people respond to fear appeals. The question that this research has

asked is: When, why and how are such fear appeals effective in convincing people of their vulnerability?

Existing research has suggested that people have two responses to fear appeals: fear control or danger control. Fear control encourages people to cope with the emotion itself and process information in a way that reduces their fear. Fear control hurts the processing of fear appeals and renders them ineffective. The other response of danger control encourages people to manage the threat that lead to fear. This response encourages them to process health information and focus on actions that might help control the source of the fear (Leventhal 1971; Witte 1994). Health research has examined conditions that encourage a fear control or danger control response. Most of this past work has examined the role of message factors in determining the effectiveness of fear appeals. In this paper, we focus on role of the broader emotional context in which the appeal is presented in determining the effectiveness of the appeal. Specifically, we suggest that participants' incidental emotions, specifically those varying on valence and uncertainty (e.g., happiness, sadness, hopefulness, anxiety) will determine whether they respond to fear appeal by trying to control the fear or the danger.

To understand how incidental emotions might affect responses to fear appeals, we draw on a significant stream of research that has examined the role of specific emotions (e.g., anger, sadness, peacefulness) in processing information and forming judgments (Lerner and Keltner 2000). This literature argues that individuals' responses to given emotions are directed by the underlying appraisals (e.g., valence, uncertainty) associated with that emotions. For example, anxiety is a negatively valenced emotion with a high uncertainty appraisal whereas sadness is a negatively valenced emotion with a low uncertainty appraisal. In another contrast, hope has a high uncertainty appraisal like anxiety but is positively valenced. These distinctions in valence and uncertainty are likely to drive the systematic variations in responses across these emotions. We propose that primed emotions would only influence responses to fear appeals when they are seen as applicable or relevant to the appeal (Agrawal, Menon, and Aaker 2007). Uncertain emotions would be more applicable and hence more likely to influence the processing of uncertainty-inducing fear appeals. Certain emotions would be less applicable and hence less likely to influence the processing of fear appeals. Then, to understand how two uncertain emotions varying in valence might influence individuals' response to fear appeals, we draw on the literature on valenced affective states. We propose that positively valenced emotions would lead to a danger control response that would enhance the effectiveness of fear appeals. In contrast, negative valence would lead to an emotion-repair focused fear control response which would hinder the effectiveness of fear appeals (Raghunathan and Trope 2002). Hence, we predict that valence and uncertainty appraisals will interactively determine individual's response to fear appeals.

In all three experiments, participants are primed with one of four emotional states (i.e., happiness, hopefulness, anxiety, or sadness). Then they are exposed to a fear appeal and measures of risk perception (study 1), message processing (study 1), and health behaviors (study 2) are collected. In Experiment 1, participants experiencing anxiety exhibited a fear control response, manifesting as lower risk estimates and defensive processing of the message relative to those experiencing sadness. Those experiencing hopefulness showed a danger control response manifesting in greater risk perceptions and objective processing of the message relative to happy individuals. These findings supported our predicted interaction between valence and uncertainty. Experiment 2 followed the same paradigm but collected measures of subsequent processing of health related information. In experiment three, participants primed

with one of the four emotions were shown either a high or low fear appeal. Our effects held only for high fear appeal. The processing of the low fear appeal did not vary by valence and uncertainty of the incidental emotion.

These findings add to the literature on the processing of fear appeals as well as advance our understanding of how primed emotional states might affect the processing of emotionally aversive information. These findings have implications for designing health communications as well as broader contexts in which health communications are offered.

"Why People Fear Embarrassment: The Role of Empathy Neglect"

Loraine Lau, University of California at Irvine, USA

Patti Williams, University of Pennsylvania, USA

Aimee Drolet, University of California at Los Angeles, USA

People will go to great lengths to avoid feeling embarrassed. They will sacrifice their own health (Helwig-Larsen and Collins 1994) and financial gain (Corley and Rinker 1990) to evade embarrassment. They will not help others in need if such acts prove too embarrassing (Foss and Crenshaw 1978). They will behave in many ways indicative of an underlying deep fear of embarrassment. Embarrassment is indeed a strong motivating force affecting many decisions in life. This research examines factors that determine consumers' underlying fear of embarrassment and identifies ways to manage embarrassment-avoidant behavior through persuasive ads.

The threat to the self due to embarrassing mishaps in front of others appears more imaginary than real. Recent research reveals that embarrassing pratfalls often go unnoticed and are not judged as harshly by others as expected (Gilovich, Medvec and Savitsky 2000). This suggests that actual or expected feelings of embarrassment typically prove unwarranted, for people tend to overestimate the impressions they make upon others and believe the impressions formed will be negative. Moreover, the inaccuracy of others' judgments can be attributed at least in part to empathy neglect, the tendency to not consider others' empathic orientation (Epley, Savitsky and Gilovich 2002).

The present research explores the possibility that empathy neglect may underlie embarrassment-avoidant behavior. People may steer clear from potentially embarrassing activities because of their misjudgments about others' judgments of their own actions; they assume others not only will take note of their embarrassing missteps but also will evaluate them negatively as a result of it. We

examine the nuances of empathy neglect by investigating how it corresponds to people's chronic levels of public self consciousness (PUBSC). People characterized by increased levels of PUBSC tend to believe they are being noticed and negatively evaluated by others more so than people with decreased levels of PUBSC (Fenigstein, Scheier and Buss 1975). Lau-Gesk and Drolet (2008) recently showed that heightened levels of PUBSC led to increased purchase intentions for embarrassing-to-buy products designed to help fend off greater future embarrassment once consumed. This is because the more elevated in PUBSC, the more people expect to be embarrassed. However, once convinced that future embarrassment is likely for them, purchase intentions for embarrassment-prevention products tend to be elevated regardless of PUBSC levels.

The present research builds on this initial work by investigating more closely which of the two components of empathy neglect underlie these differences in expectations to feel and motivation to prevent embarrassment among people who vary in PUBSC. In sum, we test whether people's failure to realize that others do not necessarily notice them, and more crucially, if others do happen to take notice, these others tend to make less harsh judgments when empathic to the embarrassing episode can explain embarrassment-avoidant behavior.

In the first two experiments, we test our theory by examining the role of PUBSC in people's responses to real ads for an embarrassing research assistantship. The job is advertised as requiring them to walk around campus with toilet paper stuck in the zipper of their pants and count number of people who inform them of it. In experiment 1, the ads for the embarrassing research assistantship job either reminds potential applicants of the possible scrutiny of others or does not. We expected and found the latter ad to produce embarrassment-avoidant behavior as evidenced through lower intentions to apply for the job regardless of PUBSC. The control ad also generated the expected pattern of results. Increased PUBSC led to lower job application intentions. Results from the first experiment help to establish the basic idea that higher levels of PUBSC correspond to higher expectations for negative social evaluations of others.

Experiment 2 attempts to disentangle whether the effects are due to a failure to realize others do not take much notice of embarrassing outcomes versus due to the failure to realize others have empathy and won't judge embarrassing outcomes harshly. Though the control ad remained the same, two new ads were created. Specifically, one ad cautioned potential applicants that people definitely would notice and remember seeing the toilet paper person walking around campus. Note that, unlike in the first experiment, this ad did not explicitly state that onlookers would cast unfavorable judgments. The other new ad reminded potential applicants that observers would have empathy and thus not judge as harshly as they expect. Findings indicate that people with increased PUBSC automatically assume others will notice their embarrassing pratfalls. They believe themselves the focus of attention. People with lower levels of PUBSC do not appear to assume this. However, once they believe others will take notice of embarrassing social blunders, they also tend to suffer from empathy neglect as well by not taking into account others' empathic nature. Regardless of PUBSC levels, people assume others judge embarrassing outcomes harshly. The final experiment explores the possible ways to undo empathy neglect.

Experiment 3 explores whether perspective-taking can help undo empathy neglect among individuals with heightened PUBSC. These individuals should correspondently have greater empathy towards others who suffer from embarrassment. Results support this proposition. Heightened PUBSC is associated with greater

empathy displayed towards an individual featured in an ad who committed an embarrassing pratfall (i.e., accidental flatulence in front of his crush), thereby producing more favorable attitudes toward him and lowering purchasing intent for a gas prevention product designed to help people avoid future embarrassment. Findings across these three experiments are discussed in light of the emerging view about the importance of understanding the interaction between individual difference and situational variables as well as that among multiple emotions including fear, embarrassment and empathy.

SPECIAL SESSION SUMMARY

Metacognitive Experiences in Number Processing

Keri Kettle, University of Alberta, Canada

SESSION OVERVIEW

Numbers are central in many decisions: consumers evaluate quantitative product attributes (Payne, Bettman, & Johnson, 1993), investors examine financial data (Slovic, 2001), and brands often include numeric values (Pavia & Costa, 1993). The objective of this symposium is to challenge the prevailing assumption that number processing is inherently cognitive. Metacognitive experiences are shown to influence people's evaluations of, and preference for, alpha-numeric brands (Paper 1) and risky gambles (Paper 2), and subjective confidence in the evaluation of precise numeric attributes (Paper 3).

Although research suggests that metacognitive experiences in information processing affect evaluations and preference in a wide range of domains (e.g., Janiszewski & Meyvis 2003; Schwarz 2004), it has been assumed that number processing is exclusively deliberative and not affected by metacognitions. The research covered in this symposium suggests that, in fact, some numbers are more fluent than others. The characteristics of particular numbers generate more or less favorable metacognitive experiences that, in turn, affect judgments and choices.

Janiszewski and King (Paper #1) show that people prefer numbers that are the sums of common addition problems (sum-numbers) and the products of common multiplication problems (product-numbers), and that this preference influences liking of alpha-numeric brand names (e.g., Resorcinol 25). The second paper, by Kettle and Häubl, demonstrates that people prefer numbers that are products of 25 and 10 (e.g., 50%, \$125). People rate risky prospects comprised of those numbers as more attractive, and choose those prospects over similar prospects comprised of non-fluent numbers. Critically, each paper shows that consumers who indicate that they like a particular fluent number or gamble respond more quickly, which supports the hypothesis that processing fluency may drive this preference. The third paper, Manoj Thomas et al., suggests that precision or roundness of prices affect magnitude judgments because precise prices are less fluent than round prices. When asked to categorize products according to price, people were less confident in their response when the offer price had no zeroes (precise number) than when it had two zeroes (round number).

Aparna Labroo (University of Chicago), the discussant, will provide her own insights, and address directions for future research. Taken together, the research presented in this symposium provides additional insight into how consumers process information and form preferences, and offers the exciting potential for marketers to build more appealing numeric brand names and quantitative attributes. This research offers the exciting potential to enhance consumer decision-making in personal and business finances, budgeting and mental accounting, and product evaluation and choice.

EXTENDED ABSTRACTS

“The Affective Consequences of Alpha-Numeric Branding”

Chris Janiszewski, University of Florida, USA

Dan King, University of Florida, USA

The selection of a specific number (henceforth brand number) to be part of a brand name (henceforth alpha-numeric brand name) does not appear to be guided by a single strategy (Boyd 1985; Pavia and Costa 1993). Instead, it appears that brand numbers are selected

for a variety of reasons (Boyd 1985; Pavia and Costa 1993; Robertson 1989). For example, a brand number may be phonetically consistent with other parts of the brand name (e.g., Core 2 Duo), semantically consistent with the desired brand image (e.g., 5th Avenue), semantically consistent with the product function (e.g., XBOX 360, 2000 Flushes), or highly associable (e.g., 0, 1, 7, 13, and 100) (Battig and Spera 1962; Boyd 1985; Cochran and Wickens 1963; Pavia and Costa 1993). We contend there may be an additional reason for managers to use certain brand numbers. People may like some numbers more than others (Heywood 1972; Schimmel 1993; Simon 1972). If marketers can take advantage of this fact, without violating guidelines that typically guide brand number selection, then they should be able to build more appealing alpha-numeric brand names.

We posit that one source of liking for a number is the fluency experienced when processing the number. In study 1, we have people view a randomly ordered presentation of the numbers 1 through 100 and indicate, as quickly as they can, whether they like, dislike, or are indifferent about each number. We find that people like the sum-numbers two through 20 (e.g., $1 + 1 = 2$ through $10 + 10 = 20$) and product-numbers (e.g., $2 \times 2 = 4$ through $10 \times 10 = 100$) more than the other numbers. In addition, when a person likes a number, the person responds to the number more quickly. This implies that fluent processing may be responsible for the number liking.

In study 2, we illustrate the importance of this finding. A choice-based-conjoint task is used to show that people prefer a brand named using a product number (e.g., Resorcinol 25) more than a brand named using a non-product number (e.g., Resorcinol 29) or no number at all (e.g., Resorcinol). Comparing the size of the brand name trade-off to the average size of a price tradeoff suggests the favorable product-number adds \$ 0.43 of value to the brand name.

Study 3 is used to investigate the representation of numbers. Ashcraft (1982; 1987) proposes that declarative knowledge about arithmetic problems (e.g., $3 \times 4 = __$) and correct responses to these problems (e.g., 12) are represented in a semantic network. The strength of association between these nodes increases with practice so that the response node (e.g., 12) is more active after encountering an arithmetic problem involving that response node (e.g., $6 + 6$, 3×4). Campbell and Graham (1985) extend Ashcraft's ideas by arguing that the representation of arithmetic facts also includes associations from operands (e.g., 3, 4) to results (e.g., 12). The implication is that commonly practiced problems (e.g., $6 + 6 = __$, $3 \times 4 = __$) are more likely to prime a product-number than uncommon problems (e.g., $67 - 55 = __$) or unrelated problems (e.g., $77 + 4$). Study 3 illustrates this priming effect using addition and multiplication problems. Common problems made sum-numbers and product-numbers more accessible and more liked.

Study 4 illustrates how operand priming can operate in an advertising context. Ads are created for a product-number (e.g., 12) or a non-product number (e.g., 29). These ads include operands that can prime the product-number or not (e.g., 6, 2) (see below). Participants are asked to view one of the four ads and then report their attitude toward the ad, attitude toward the brand, and purchase intention. The ad liking, brand liking, and purchase intention measures were combined to create an affect toward the brand measure (Cronbach's $\alpha = .85$). The type of number by priming

interaction was significant ($F(1, 181)=3.93, p<.05$). Operand priming led to more positive affect toward the brand when the product-number was in the brand name ($M_{No\ prime}=5.70, M_{Prime}=6.30; F(1, 181)=6.15, p<.01$), but not when a non-product/non-sum number was in the brand name ($M_{No\ prime}=5.19, M_{Prime}=5.12; F(1, 181)=.10, p>.05$). Two other ad replicates showed similar results.

“Numeric Fluency and Preference”

Keri Kettle, University of Alberta, Canada
Gerald Häubl, University of Alberta, Canada

Consumers often evaluate numbers in a decision context; they choose among products described by quantitative attributes (Payne et al., 1993), set budgets (Ülkümen et al., 2008), make investment decisions (Slovic, 2001), and decide how much to tip a waiter (Lynn et al., 1993). Although research has primarily examined the deliberate, cognitive evaluation of quantitative information (e.g., Dehaene, 1997), a growing body of literature suggests that people actually like some numbers more than others. For example, people spontaneously round off estimates of time and money (Kandel et al., 2001; Schindler & Kirby, 1997), and both stock prices and IPO offers disproportionately congregate at prices ending in “.00”, “.00”, “.50” and “.25” (Huttenlocher et al., 1990; Sonneman, 2005). We propose that these numeric biases can be explained by the fluency experienced when processing the number.

Our key premise is that multiples of twenty-five and powers of ten (e.g., 10, 75, 125, 200), commonly referred to as “round numbers”, are more fluent than sharp numbers of similar magnitude. According to the processing fluency model, exposure to a stimulus creates a feature- and/or meaning-based representation of that stimulus in memory that, in turn, enhances the ease with which one processes the stimulus in subsequent exposures (Lee & Labroo, 2004). Fluency is enhanced by incidental exposure and increases monotonically with repeated exposure (Janiszewski & Meyvis, 2001; Zajonc, 1968). Prior research has shown that round numbers are used in written and spoken language with greater frequency than sharp numbers (Dehaene & Mehler, 1992). We posit that the repeated use of, and exposure to, round numbers enhances their processing fluency (Lee & Labroo, 2004; Schwarz, 2004; Zajonc, 1968).

We examined numeric fluency in the context of choices between risky prospects (Kahneman & Tversky, 1979). Each prospect is described in terms of two numeric properties—a monetary payoff and the probability of attaining that payoff (as opposed to receiving nothing)—that jointly determine the expected value. Because round numbers are also easier to use in arithmetic, this context enables us to disentangle our processing fluency account from an alternative, cognitive account of the preference: effort minimization (Payne & Bettman, 2001). An effort minimization account suggests that, because people have limited cognitive capacity, they may strategically choose to exert the minimal amount of cognitive effort required to attain a satisfactory outcome. By this account, a preference for alternatives involving round numbers would reflect one’s desire to avoid difficult calculations or comparisons.

To disentangle the metacognitive (fluency) and cognitive (effort minimization) explanations, we independently manipulated whether a prospect was comprised of round or sharp numbers, and the number of steps necessary to calculate the expected value. To illustrate, imagine the following choice between a prospect comprised of round numbers (Prospect A: 50% chance of \$400) and a prospect comprised of sharp numbers (Prospect B: 53% chance of \$378). In addition, we created prospects for which participants

needed to make three additional calculations (two products and a sum) in order to estimate the expected value (e.g., Prospect B: 53% chance of $0.43 \times \$376 + 0.56 \times \387). We refer to such prospects as being of high arithmetic complexity. The fluency and effort accounts predict contrasting effects of arithmetic complexity on preference and decision time (the time required to process the information, form a preference, and indicate that preference). First, an effort minimization account predicts that increasing the arithmetic complexity of a prospect should decrease preference for that prospect. Second, the effort account suggests that increasing the arithmetic complexity of a prospect should not lead to longer decision times (beyond an incremental increase to process the additional stimuli). That is, if the preference for round numbers reflects the desire to minimize cognitive effort, then people should not exert additional effort to estimate the expected value of a more complex prospect.

In study 1, each participant made 8 choices between pairs of prospects. Choice sets were designed such that the two prospects had nearly identical expected values, with any small discrepancies favoring the prospect comprised of sharp numbers. As predicted, participants chose the prospect comprised of round numbers 63% of the time. Participants took twice as much time to decide between two complex prospects (19.6 seconds) as they did to choose between two simple prospects (8.9 seconds), but increasing the arithmetic complexity of a prospect did not decrease preference for that prospect. Critically, decision times were significantly shorter when the fluent prospect was chosen irrespective of whether participants were choosing between two simple prospects, ($M_{RoundChosen}=8.0$ seconds, $M_{SharpChosen}=11.0$ seconds), one simple and one complex prospect ($M_{RoundChosen}=14.7$ seconds, $M_{SharpChosen}=16.1$ seconds), or two complex prospects ($M_{RoundChosen}=18.4$ seconds, $M_{SharpChosen}=21.9$ seconds), which demonstrates that processing fluency drives the preference for round numbers. In study 2, we show that these results generalize to all sharp numbers by randomly generating the sharp numbers for each choice. The key results of study 1 were replicated. In study 3, prospects consisted either of all sharp numbers or of one sharp and one round number. The results demonstrate that the presence of even a single round number is sufficient to enhance preference by approximately 10 percentage points.

In study 4, participants were provided with the expected value of each prospect, in addition to its payoff and probability. They were first asked to choose between the same prospect pairs as in study 1. Then, they were presented with prospects one at a time, asked their willingness to pay for the prospect, and then asked to rate the attractiveness of the prospect. Numeric fluency did not affect willingness to pay. However, people rated round prospects as more attractive than sharp prospects, and they took less time to rate the sharp prospects, even though they were provided with the expected value of, and had already processed, each prospect. This pattern of results provides compelling evidence for our processing fluency account.

“The Precision Effect in Numbers: How Processing Fluency of Numbers Influence Response Confidence”

Manoj Thomas, Cornell University, USA
Vicki Morwitz, New York University, USA
Jin Seok Pyone, Cornell University, USA

Previous research has shown that precision or roundness of a price can influence magnitude judgments. For example, Janiszewski and Uy (2008) have shown that participants are willing to pay more when sellers ask for a precise list price (e.g., 799,800 or 800,200) instead of a round price (e.g., 800,000). Thomas, Kadiyali and

Simon (forthcoming) suggest that this precision effect occurs because precision or roundedness influences the magnitude perceptions of prices. They suggest that precise prices are judged to be smaller than round prices of comparable magnitudes.

This research further explores the mechanisms that underlie the precision effect. Specifically, we hypothesize that precision or roundness of prices affect magnitude judgments because precise prices are less fluent than round prices. The disfluency evoked by precise prices induces a feeling of uncertainty. This occurs because people consider the subjective experience as a metacognitive cue to assess the effectiveness of the mental processes. They try to reduce this feeling of uncertainty by heuristically attributing it to the most salient cause. The heuristic beliefs used for the attribution could be based on practices observed in the market place (e.g., sellers are more likely to round-up than to round-down prices) or the distribution of precise and round numbers in daily written and oral communication (e.g., large numbers such as the price of a car are rounded, while small numbers such as the price of gasoline are precise). The conceptual model is schematically summarized below:

Precision→Disfluency→Lower Confidence→Heuristic Attribution→Magnitude Judgment

Fundamental to this conceptualization is the premise that precision-induced processing fluency influences response confidence. Two studies that test this hypothesis are presented in this conference.

The first study shows that precision can reduce response confidence. The second study shows that direct manipulations of response confidence can moderate the effect of precision on magnitude judgments. In study 1, participants were asked to categorize various prices as high or low relative to an internal standard. They were shown a stapler and asked to guess the regular price of this stapler at a store. For each participant, the computer generated 12 offer prices, of which 6 were above the articulated internal standard and 6 were below the articulated internal standard. Participants' task was to categorize the offer prices as "HIGH" or "LOW" by clicking on one of the two response buttons. For each categorization response, we measured their confidence in the response. Participants were less confident in their response when the three digit offer price had no zeroes (78% confidence on a 50% to 100% scale), more confident when the prices had two zeroes (80% confidence), and most confident when the offer price had two zeroes (84% confidence, $p < .01$). Similar pattern manifested for response time. In study 2 we manipulated response-confidence and price-precision in a magnitude judgment task using between-subjects design. Participants were shown six prices of a house listed for sale. For each round price (e.g., 365000), we created a precise price that was comparable in magnitude (e.g., 365,583). It was observed that nominally larger precise prices were incorrectly judged to be smaller than round prices. However, precision affected magnitude judgments only when participants were uncertain about their ability to make magnitude judgments. Together, these results support the hypothesis that precision-induced processing fluency influences response confidence.

SPECIAL SESSION SUMMARY

Finding the Uncompromising Consumer: A Deeper Understanding of Context Effects on Choice

Jeffrey Parker, Columbia University, USA

SESSION OVERVIEW

Time and time again, choice context has been found to dramatically affect consumer preferences (see, e.g., Huber, Payne & Puto 1982; Shafir, Simonson & Tversky 1993; Simonson 1989; Simonson & Tversky 1992). For example, choice reversals resulting from the introduction of compromise options or asymmetrically dominated alternatives are particularly robust. However, little attention has been given to how the manner in which consumers process the choices might affect their susceptibility to such biases. The question is important as different processing styles have been shown to significantly influence judgment and behavior by altering attention to and processing of information. For example, more comparative (vs. evaluative) judgments have been shown to focus consumers on more comparable (vs. enriched) attributes (Nowlis & Simonson 1997).

The current session includes three papers that examine how different processing styles influence common context effects. While all three papers explore information processing or decision strategies that influence context effects, each paper approaches this topic from a unique perspective, identifying specific influences of different evaluative processes. Specifically, the effects of non-conscious processing, affective evaluations, and abstract mindsets are investigated. This session takes the viewpoint that not only does the context surrounding the options affect consumer preference, but so too does the manner in which consumers think about those options and that context. Accordingly, the first paper, by Goldsmith, Dijksterhuis and Dhar, investigates if non-conscious processing prior to choice can attenuate the compromise effect due to an enhanced ability to resolve tradeoffs. These authors find support for this, showing that non-conscious processing reduces the compromise effect (vis-à-vis conscious elaboration or mere distraction). Correspondingly, in the second paper, Pham and Parker test the hypothesis that engaging in feelings-based processing will reduce consumer preference for compromise options. These authors find significant moderation, demonstrating that feelings-based choices shift preferences towards extreme alternatives. Finally, in the third and final paper, Khan, Zhu, and Kalra test how a consumer's level of abstraction affects their likelihood of falling prey to three classic context effects: the compromise effect, the attraction effect, and the background contrast effect. By manipulating consumer mindsets (abstract vs. concrete) the authors demonstrate that abstract mindset reduces the compromise effect, reduces background contrasts and enhances the attraction effect. All of the papers in this proposal are in their final stages of preparation.

Using multiple, yet related, theoretical perspectives these three papers extend what is currently known about when and how consumer choice may be affected by context. While some moderators of context effects have been identified (see, e.g., Dhar and Simonson 2003; Murali, et al. 2007), no research to date has investigated how the manner in which a consumer processes their choices might affect their susceptibility to such biases. By investigating this topic, we can not only advance our theoretical understanding of the origins of these effects but can also offer practical insights for consumers and practitioners seeking to mitigate the effects of context on their choices.

We anticipate that this session will be attended by consumer researchers in general and by members of ACR who have a

particular interest in context effects, consumer choice, and processing styles. Each paper in the session includes multiple completed studies with supporting results. Further, our discussant, Joel Huber, who is an expert on context effects, is expected to lead a stimulating discussion.

EXTENDED ABSTRACTS

"Non-Conscious Processing and Choice in Context"

Kelly Goldsmith, Northwestern University, USA
Ap Dijksterhuis, Radboud University Nijmegen, The Netherlands
Ravi Dhar, Yale University, USA

Most consumer choice requires making tradeoffs among the available options (e.g., should I pay \$50 more for the iPod with more memory?). A major finding in choice research has been that when faced with decisions that involve making tradeoffs, consumers' choices can be inconsistent and susceptible to influence, for example, from the choice task or the decision context. This occurs as such factors can highlight different considerations, leading to different choice outcomes. These context effects have been shown to be robust across a wide variety of stimuli, and arise even when consumers are instructed to carefully process their decisions (Pocheptsova et al. 2009).

Recent research has debated whether conscious elaboration or non-conscious processing leads to better decisions (Dijksterhuis and van Olden 2005, Payne et al. 2008). We extend this research by examining how conscious vs. non-conscious processing affects a bias relevant to making tradeoffs; specifically, we examine how these different modes of processing affect consumers' propensity to demonstrate the compromise effect (Simonson 1989). The compromise effect is observed when choice of an option increases when the option is made the middle option (e.g., b in set abc) as opposed to

an extreme option (e.g., b in set bc). This effect occurs due to consumers' inability to resolve tradeoffs across attributes (Dhar and Simonson 2003). Research in the domain of social psychology has demonstrated that conscious elaboration impedes our natural ability to weigh decision criteria, showing that non-conscious processing allows for superior integration and evaluation of choice attributes (Dijksterhuis and van Olden 2005, Wilson 2003). Drawing from both of these research streams, we propose that consumers who non-consciously process their options prior to making a choice will be less likely to demonstrate the compromise effect than those who consciously elaborate on the alternatives prior to choice, due to their superior ability to resolve tradeoffs.

We test our main proposition in two studies. The first study is designed to test if non-conscious processing will decrease the compromise effect as compared to conscious elaboration. For this study, participants were presented with a choice set (either ab or abc) and instructed that they would later make a choice. Following Dijksterhuis et al (2006), participants were then randomly assigned to complete either a conscious elaboration or a non-conscious processing task. Participants assigned to the conscious elaboration task were instructed to "think very carefully" about their choice and to write out their thoughts for two minutes. Participants assigned to the non-conscious processing task were instructed to "think very carefully" as they completed a two minute distraction task. This resulted in a 2 (choice set: ab vs. abc) x 2 (conscious elaboration vs. non-conscious processing) design. Finally, all participants made a choice from the set they had been shown initially. Consistent with our predictions, we observe the compromise effect only among participants who engaged in conscious elaboration. Respondents who engaged in non-conscious processing showed no evidence of the compromise effect. The interaction between processing style and the choice set was significant.

While the results of Study 1 support our hypothesis that non-conscious processing reduces the magnitude of the compromise effect, it is important to note that we do not predict this pattern of results will hold when consumers are merely distracted prior to choice. Prior research has demonstrated non-conscious elaboration is necessarily a goal directed process: the goal to make a decision is vital for the operation of non-conscious processing during an intervening task (Bos et al. 2007). Thus we argue we will observe a reduction in the compromise effect only among participants who are initially given the goal of making a choice prior to the intervening distraction.

Study 2 was intended to test this directly while providing a conceptual replication of Study 1. Half of the participants were randomly assigned to the non-conscious processing condition and asked to form an impression of a set of products, for a choice at a later stage. Remaining participants were assigned to the mere distraction condition and instructed to simply review the set of products (no mention of future choice). All participants were then shown a set of options (ab vs. abc). This resulted in a 2 (non-conscious processing vs. mere distraction) x 2 (choice set: ab vs. abc) design. All participants then completed the intervening task from the non-conscious processing condition in Study 1, then made a choice. Consistent with our predictions, we observe the compromise effect among participants who were merely distracted. In contrast, respondents who engaged in non-conscious processing showed no evidence of the compromise effect. The interaction between processing style and the choice set was significant, meaning that non-conscious processing decreased the share of the compromise option relative to the share of the extreme option. These results rule out mere distraction as an alternate explanation for the results of Study 1.

In summary, our findings demonstrate that non-conscious processing can reduce compromise effect. We believe these findings offer both theoretical and practical insights. Not only do they extend what is currently known about potential benefits of non-conscious processing for the weighing of decision criteria, they suggest that for choices involving effortful trade-offs, a decision strategy requiring non-conscious processing may be optimal.

"The Uncompromising Heart: How the Reliance on Feelings in Decisions Reduces the Preference for Compromise Options"

Michel Tuan Pham, Columbia University, USA

Jeffrey R. Parker, Columbia University, USA

While the study of human judgment and decision making has historically emphasized the role of computational, "cognitive" processes, more recent research from various disciplines has highlighted the importance of noncomputational, affective processes in judgments and decisions (Pham 1998). This research has shown that affective evaluative judgments exhibit distinct properties, when compared to cognitive evaluative judgments (see Pham 2007 for a review). For example, in addition to being produced generally faster (Pham et al. 2001), affective evaluations have repeatedly been found to be less sensitive to the quantitative magnitude of the target (Hsee and Rottenstreich 2004), and more reference-dependent in that they tend to respond not to the focal object or outcome in isolation but in relation to other objects or outcomes (Pham 2007). The purpose of this research is to examine how reliance on feelings in decision making moderates the preference for compromise options.

Consumers tend to prefer compromise options when their preferences are uncertain and when they expect their choice to be evaluated (Simonson 1989). While this effect has been found to be robust across many product categories, it has also been found to be

moderated by factors such as consumers' regulatory focuses (Mourali, et al. 2007) and the availability of a no-choice option (Dhar and Simonson 2003). Less attention, however, has been paid to the effect of different decision processes (e.g., cognitive vs. affective) on this phenomenon. Accordingly, we examine how choices based on feelings (vs. objective evaluations) affect the preference for compromise options. We propose that consumers making feelings-based choices will prefer compromise options less than consumers making choices based on objective evaluations. It is argued that extreme alternatives provide a "clear picture," leading to clear feelings towards the alternatives, facilitating a feelings-based choice, whereas compromise alternatives, which are more ambiguous, lead to more ambivalent feelings, impeding feelings-based choices. We present three studies in support of our propositions.

Study 1 investigated the strength of the compromise effect across two product categories (printers and restaurants) when choices were based on feelings versus objective evaluations. The differences between choices made using feelings and choices made using objective evaluations were fully explained to the participants. Each participant was then directly encouraged to either rely on their feelings or objective evaluations when making their upcoming choices. The participants then viewed one choice set from each product category containing alternatives described on four attributes. Two of the attributes were held constant across all alternatives while the other two varied across the alternatives. Each "extreme" option was the best on one of these attributes and the worst on the other. The "compromise" option was neither the best, nor the worst on either of the attributes. To examine the compromise effect, participants were randomly assigned to receive either two or three alternatives in each category. It was predicted and found that participants encouraged to use their feelings while choosing did not exhibit the compromise effect, while participants encouraged to use their objective evaluations demonstrated a strong compromise effect. Involvement was found not to vary across conditions.

Study 2 extended Study 1 by using a more subtle manipulation. Previous research has shown consumers are more likely to rely on their feelings to make decisions guided by consummatory motives than equivalent decisions guided by instrumental motives (Pham 1998). Building on this, participants were asked to list either ten items that were purchased "purely for pleasure" or 10 items that were purchased "purely for function." It was expected that these tasks would activate the participants' consummatory or instrumental motivations, respectively. The second task of the study asked participants to choose from the same restaurant choice sets used in Study 1. The results from Study 1 were replicated. Participants whose consummatory motivations were activated did not shift their preferences toward the compromise option, while those whose instrumental motivations were activated did. Again, involvement was found to be equivalent across conditions.

Study 3 was designed to tease apart two competing explanations for the results of the first two studies. While we propose that the reduced preference for compromise options found with feelings-based choices is caused by a desire for a "clear picture" of each alternative, it is also possible that the use of feelings to make choices inhibits the ability to make quantitative tradeoffs of the attributes (Pham 2007). We suggest that extreme options present a clear picture (e.g., the "best price alternative" or "highest quality alternative") which will result in more valenced feelings towards the alternatives, thereby facilitating feelings-based choices. Conversely, it is expected that compromise options are more ambiguous (e.g., "it's not the best or worst on anything"), which results more ambivalent feelings that do not facilitate feelings-based judgments.

To test this, we examined participants' preference for the compromise option when all attributes for all alternatives were described with point data (e.g., quality="5") versus when the extreme alternatives' attributes were described with range data (e.g., quality="between 4 and 6"). Reliance on feelings was manipulated as in Study 1. Replicating Study 1's findings, when point data was used, participants making choices based on objective evaluations preferred compromise options more than participants making feelings-based choices. Importantly, it was found that among participants making feelings-based choices the compromise option was preferred more when the extreme options were described by range data. In other words, when the "clear picture" associated with extreme options was muddied by range data, the compromise option described with point data became more attractive. Thus, the evidence suggests that the need for a "clear picture" of the alternatives may be driving the reduced preference of compromise options found when choices are made using feelings.

"Minding the Mindsets in Context Effects"

Uzma Khan, Stanford University USA

Meng Zhu, C.M.U., USA

Ajay Kalra, Rice University, USA

Past research has shown that individuals process information differently and form different representations of the same stimuli depending on whether it is construed at an abstract de-contextualized level or at a concrete contextualized level (Trope & Liberman 2003; Fujita et al., 2006). For example, as consumers take on a more abstract rather than concrete mindset they tend to give more weight to central and global features rather than peripheral and local features of events. In other instances individuals in abstract mindsets have been shown to categorize objects in fewer and broader categories (Liberman, Sagristano & Trope 2002), classify others using traits and stereotypes (Nussbaum et al. 2003), and perform better on creative tasks but worse on analytical problem solving (Forster et al. 2004).

Despite extant research on the impact of construal levels on information processing and judgment, no research to date has

examined how different mindsets impact judgment biases arising from the context in which a decision is made (Huber, Payne & Puto 1982; Simonson 1989; Simonson & Tversky 1992). In the current research we bridge this gap and investigate the effect of abstract versus concrete mindsets on three commonly reported biases in consumer decision-making – 1) a bias to choose the middle option in a choice-set (compromise effect); 2) a tendency to choose an asymmetrically dominating option (attraction effect) and 3) a tendency to be influenced not only by the tradeoffs presented in the choice-set under consideration but also by a contrast generated due to the background tradeoffs.

Construal Level Theory (CLT) proposes that in abstract mindsets individuals give more weight to central and global features of events, whereas in concrete mindsets individuals center their attention on comparative and detailed features (Trope & Liberman 2003). To the extent that a compromise effect results from a focus on the relational properties of alternatives and the accompanying choice difficulty of making compensatory comparisons (Dhar, Nowlis & Sherman 2000), we propose that in comparison to a concrete mindset, an abstract mindset will reduce the compromise effect by shifting attention to global aspects of the decision and reducing the number of trade-offs and the resulting difficulty. Similarly, we predict that an abstract mindset will decrease the background contrast effect. Since the background contrast effect is driven by the influences of relevant past alternatives, diverting attention away from detailed comparative attributes across choice sets should reduce the impact of the background set on the target set. The attraction effect, however, is largely perceptual. Since an abstract mindset draws attention to global characteristics, we predict that it will further highlight the perceptually salient asymmetric-dominant relationship and hence magnifies the attraction effect.

Five experiments show support for our propositions. Study 1 demonstrates that an abstract versus a concrete mindset induced through a temporal distance manipulation (Liberman & Trope 1998) systematically impacts share of a compromise option in a subsequent choice task. Participants were asked in between-subjects conditions to either think of a goal they wanted to achieve in a week (concrete mindset) or in a year (abstract mindset). Next, they were asked to make a choice from a three-option choice-set featuring a compromise option in the middle. As predicted, we find that compared to a concrete mindset (which was similar to the control where participants did not indicate any goal prior to making the choice) an abstract mindset leads to significantly decreased choice share of the middle option. Using a different manipulation of the construal level, Study 2 found that participants were more (less) likely to choose an asymmetrically dominating option from a choice set when they were in an abstract (concrete) mindset. Consistent with our theorizing, Study 3 shows that background contrast effects have less (more) impact on participants' judgments in an abstract (concrete) mindset.

To show support for a mechanism based on difference in local tradeoffs in abstract versus concrete mindsets, Study 4 examined participants reasons for their choice and found that participants in abstract mindsets (as compared to those in a concrete mindset) indeed made fewer direct trade-offs between attributes of the different options and were more likely to base their decision on generalized preferences. Finally, we examined participants' response latencies in abstract and concrete mindsets. The results indicate that participants in an abstract mindset not only showed decreased compromise effect they also took less time to decide. The findings are consistent with the notion that the compromise effect arises due to difficulty experienced in making hard trade-offs. We

propose that this difficulty can be significantly reduced in an abstract mindset that shifts consumers focus from local trade-offs to generalized global preferences.

SPECIAL SESSION SUMMARY

Examining Individual and Situational Drivers of Prosocial Behaviors

Andrew Kaikati, University of Minnesota, USA

SESSION OVERVIEW

Prosocial behavior is the label for a broad category of actions that are defined by society as generally beneficial to other people and to the ongoing political system. Past research in this area has sought to identify the characteristics of individuals who engage in prosocial actions, and has rightly noted that prosocial behavior is a joint product of the person and the characteristics of the situation. Despite 50 years of research on prosocial drivers, most of the findings regarding personality factors and prosocial actions are correlational in nature, and there is almost no empirical work on the relationship between important individual differences in personal values and prosocial tendencies (Dovidio et al. 2006). Gaining an understanding of individual and situational factors influencing prosocial behavior is important for charities such as United Way, for instance, which need to compete vigorously for donor dollars.

The proposed session includes three papers, each aiming to further understanding of the interplay between individual-level differences (moral identity; personal values; attachment style) and situational factors (congruity between ideology and cause; abstract/concrete mindset; relationship between donor and recipient), and their combined effects on prosocial behaviors. Taken together, the papers cover three major kinds of prosocial behavior (charitable donations, volunteering one's time to close and far others, and environmental concern) and draw upon a variety of theoretical perspectives (attachment theory, construal-level theory, action identification theory, and multiple identities), to unite under a common theme of providing insights on the effects of dispositional and situational factors driving prosocial behavior.

The Winterich, Zhang, and Mittal paper (presented by Karen Page Winterich) builds upon past research on multiple identities and donations intentions. Their research provides a new perspective for understand the roles of moral identity and moral obligation, the latter of which is influenced by political ideology. They suggest that in the case of those for whom moral identity is important, alignment between political ideology and charity (e.g., characteristics of the recipient, such as pro-life/pro-choice or privately/government managed) will affect intentions to donate, and is mediated by moral obligation towards the recipient organization. Interestingly, the authors conclude that both Democrats and Republicans can be generous, depending on their moral identity and the characteristics of the donation recipient.

The Kaikati and Torelli paper (presented by Andrew Kaikati), builds upon past value-behavior research that has exhibited mixed findings on the relationship between personal values of benevolence and universalism and helping behavior. They suggest construal-level mindset as a moderating factor, such that personal values of benevolence and universalism are more likely to influence helping behaviors toward in-group members (helping a friend move), out-group members (volunteering one's time), or the environment (recycling) when people are in an abstract (vs. concrete) mindset.

The Jeong and Liu paper (presented by Genevieve Jeong) builds on past research in the area of charitable giving. Their research focuses on the role of attachment or relationship style in influencing giving to charities that do or do not emphasize close relationships between donor and recipient. They suggest that consumers for whom attachment style is chronically (or primed as) insecure (vs. secure) are more sensitive to the nature of relationship with the receiver (e.g., ingroup; outgroup), and are more likely to

give in both hypothetical and real donation situations when this relationship or potential relationship is perceived to be close vs. far.

The goal of this symposium is to foster an engaging discussion on the role of individual and situational factors in prosocial behavior by bringing together researchers who are currently approaching different aspects of the topic, from different theoretical perspectives. In particular, discussion leader Mikael Strahilevitz, who is a well-accomplished researcher in this area, will attempt to involve the audience by tying these papers together and discussing future research directions.

EXTENDED ABSTRACTS

“Compassionate Conservatives AND Loving Liberals?: Political Ideology, Moral Identity, and Donation Intentions”

Karen Winterich, Texas A&M University, USA

Yinlong Zhang, University of Texas at San Antonio, USA

Vikas Mittal, Rice University, USA

Political ideology represents a person's beliefs related to the underlying goals and ideals of a political system (Grove, Remy, and Zeigler, 1974). Within the United States, the Republican party represents a more conservative political ideology and the Democratic party represents a more liberal ideology (Anderson et al. 2004; Cohrs et al. 2007; Farwell and Weiner 2000). There has been some debate as to which political ideology is the more giving and compassionate of the two (Brooks 2006; MacDonald 2004; Skitka and Tetlock 1993; Sidanius et al. 1996; Wilson and DiIulio 2004). When measured as the respondent's support for government spending on social programs, liberals are more generous (Anderson et al., 2004; Brooks, 2006; Wilson and DiIulio, 2004). In contrast, when measured as the average dollar amount donated (Brooks 2006) or as the percentage of income given to charity (MacDonald, 2004) households headed by a conservative individual are more generous. Furthermore, some experimental evidence suggests no significant differences in giving based on the respondent's political ideology (Anderson et al., 2004).

The goal of the current research is to examine factors underlying the donation intentions of both conservatives and liberals. We propose that charitable donation decisions by members of either political ideology are a function of two moral dimensions inherent in a specific decision situation—moral obligation and moral identity (Creyer et al. 2004; Dunfee et al. 1999). The first of these, moral obligation, is the extent to which a person feels he or she should or ought to act in a particular manner in a particular situation (e.g., donate to a specific cause; Schwartz 1970; Zimmerman, 1996). The level of moral obligation is likely to be higher when the donation recipient, or charity, is aligned with one's political ideology (e.g., pro-life charity for conservatives; pro-choice charity for liberals). However, we predict that this alignment alone is not sufficient to predict donation intentions. The second moral dimension we examine is a person's moral identity, defined as the extent to which moral notions, such as being fair, just, and good, are central, important,

and essential to one's self-understanding (Blasi 1984). Moral identity is a general "motivating force" such that placing a higher importance on moral identity results in moral actions such as greater donations (Aquino and Reed 2002). The higher the self-importance of moral identity, the more motivated one is to "do something" about a charity.

Thus, moral identity is expected to moderate the effect of political ideology on donation intentions. Amongst those for whom moral identity is important, the alignment between political ideology and charity will impact donation intentions. In contrast, among those for whom moral identity is less important, the alignment of political ideology and charity will not impact donation intentions. These ideas are tested in three studies.

Study 1 uses an experimental test to determine differences in donation intentions to victims of terrorist attacks in Iraq. In the current political milieu, we expect conservatives (Republicans) to have a higher moral obligation toward the Iraq war. However, we expect only those with high importance of moral identity to act on their moral obligation, resulting in donation intentions to terrorist victims in Iraq. Measuring moral identity (Aquino and Reed 2002) and political affiliation, we find that Republicans have significantly higher donation intentions than Democrats when moral identity is important. For those whom moral identity is less important, donation intentions do not differ between Democrats and Republicans.

Surveying a panel of U.S. adults in study 2, we expand results of study 1 by examining donation intentions to two charities with high levels of moral obligation for liberals (pro-choice charity) or for conservatives (pro-life charity; Langer 2001; Sussman 2003). Political ideology is measured with the 6-item scale by Mehrabian (1996). Supporting our theory, we find a significant three-way interaction of moral identity, political ideology, and charity type.

Specifically, among those for whom moral identity is important, conservatives have significantly higher donation intentions to pro-life than liberals, while liberals have higher donation intentions to pro-choice charities than conservatives. There is no effect of political ideology on donation intentions among those for whom moral identity is less important. Importantly, we find that amongst those high in moral identity, moral obligation toward pro-life and pro-choice organizations mediates the differential effect of political ideology on donation intentions. One alternative explanation thus far is that political ideology influenced perceptions of deservingness to the donation recipient (Farwell and Weiner 2000; Reyna et al. 2005). This is addressed in Study 3.

A third study manipulates the process by which a charity distributes its funds (i.e., privately or through government), holding perceptions of deservingness (i.e., feeding hungry children) constant across political ideology. Among those for whom moral identity is important, liberals have lower donation intentions than conservatives when the charity is privately managed whereas conservatives have lower donation intentions than liberals when the charity is managed by the government. For individuals to whom moral identity is less important, donation intentions do not differ between conservatives and liberals, regardless of how the charity is managed. Again, moral obligation fully mediated the effect of moral identity and political ideology on donation intentions.

While both public opinion surveys (Smiley 2004; Strom 2005) and academic studies (Farwell and Weiner 2000) show a widespread stereotype that liberals are more charitable than conservatives, our results take a situated perspective arguing that the question should no longer be who donates more, but rather under what conditions will one donate more to a specific charity. Examining donation intentions to various charities (terrorism victims in Iraq; pro-life/pro-choice; needy children), we find that the extent to

which conservatives and liberals are generous depends on their moral identity, the donation recipient, and even fund management. We also note that religion was measured in all studies, but did not influence the pattern of results. This research not only contributes to the theoretical understanding of the role of multiple identities on decisions such as charitable giving, but it also has substantive implications for fundraising and for public policies regarding the role of political affiliation in charitable behavior.

"When Do Personal Values Predict Helping Behaviors? It's All in the Mindset"

Andrew Kaikati, University of Minnesota, USA

Carlos Torelli, University of Minnesota, USA

Personal values are motivational constructs involving the beliefs that people hold about desirable goals that can be applied across contexts and time (Bardi and Schwartz 2003). For instance, benevolent values are associated with the abstract goal of enhancing the welfare of in-group members with whom one is in frequent personal contact, such as friends, and universalism values are associated with protecting the welfare of out-group members or protecting the environment.

There are inconsistencies in the current literature about whether and when values guide behaviors. The main objective of the current research is to try to identify a factor that affects in the strength of the value-behavior relationship. Building upon the tenets of action identification theory (Vallacher and Wegner 1987), we argue that mindsets that facilitate defining a situation in terms of one's relevant values will affect whether behavior reflects one's values. We predict that an abstract (vs. concrete) mindset should facilitate defining a subsequent, unrelated action in terms of one's relevant values, because values are high-level constructs that are associated with abstract goals. This will consequently affect whether intentions to engage in actions are a reflection of values. Thus, we expect that the level of abstraction at which events are construed is an important moderator of the value-behavior relationship.

Across three studies, we measured the importance of values (either benevolence or universalism) at the individual level (using Schwartz's Value Survey, Schwartz 1992), where participants rate the importance of values as guiding principles in their lives (-1=opposed to my principles; 7=of extreme importance). Then following several filler tasks, we primed either an abstract or concrete mindset using manipulations in which participants were instructed to think of the "why" (abstract) or the "how" (concrete)

aspects of a situation. Finally, we presented participants with real or hypothetical situations and collected measures of helping intentions or behaviors towards ingroups, outgroups, and the environment, to examine the effect of mindset on the strength of the value-behavior relation.

Study 1 tests the relationship between measured benevolence values (i.e., preservation and enhancement of the welfare of people with whom one is in frequent personal contact) and the intention to help an in-group member, a friend. Participants were instructed to imagine themselves in a situation commonly faced by students, helping a friend move to a new apartment, and then to report their intention to help the friend move. Results indicated that participants primed to think abstractly reported intentions to help a friend move that were consistent with their benevolence values, but participants primed to think concretely and those in a control condition did not.

In Study 2, we extend these findings to a different value type (universalism instead of benevolence) and measure actual behavior instead of behavioral intentions. Study 2 tests the relationship between measured universalism values (i.e., understanding, appreciation, tolerance, and protection for the welfare of all people and of nature) and signing-up to volunteer to help out-group members. At the end of the session, the experimenter introduced participants to an unrelated volunteer program involving assistance to refugee immigrants from East Africa with their reading and writing skills in English. The total number of minutes signed up to volunteer was the measure of behavior. Results confirmed our predictions that participants primed to think abstractly behaved in accordance with their universalism values in signing up to help the out-group, whereas participants primed to think concretely did not.

Study 3 explores the mechanism underlying the effect of mindset activation on the value-behavior relationship, in the context of the environmentally-friendly behavior of recycling a battery. We propose that a concrete mindset interferes with value expression by directing attention to contextual details and away from the relevant values in the situation. We expect that values will predict behavioral intentions regardless of the mindset prime when only a broad overview of the situation as related to relevant values is provided. Participants read a description of a hypothetical situation regarding the recycling of an old cell phone battery, which either included a lot of contextual information (e.g., contained several specific details) or simply described an overview of the situation as related to values. Participants rated their intention to perform the recycling behavior. Results indicate that participants primed to think abstractly reported recycling intentions that were consistent with their universalism values; however, participants in the concrete mindset condition reported intentions dissociated from their universalism values only when they were given the opportunity to construe the situation on factors other than relevant values (e.g., contextual details). These findings support our predictions that a concrete mindset interferes with defining a situation in terms of relevant values, and consequently with the expression of these values, by directing attention to contextual aspects of the situation.

In combination, results from the three experiments provide evidence for the moderating role of abstract and concrete mindsets on the strength of the value-behavior relationship. We find that personally important values predict helping behaviors and intentions after individuals are primed with an abstract (and not a concrete) mindset. We tested this in the context of multiple values and helping behaviors. These included benevolence values (context: helping a friend move) and universalism values (contexts: volunteering to help outgroup members; recycling).

"When to Give? Charitable Giving as Social Relationship"

Hyewook Genevieve Jeong, UCLA, USA

Wendy Liu, UCLA, USA

Charitable giving is one of the fastest growing industries in the United States. As a result of the growth of the giving industry, consumers are exposed to an ever wider variety of charitable giving opportunities and ways to give. Among the numerous ways of giving, one of the fastest-growing methods is a charity program that emphasizes close relationships between the donor and the recipient (e.g., sponsoring one particular child in need throughout his/her development, giving to one's alma matter or church). Such emphasis on closer relationships contrasts with the other end of the relationship spectrum whereby the donor has scant ties to the recipient, in effect giving to a complete stranger (who will remain a stranger). An interesting question thus arises: Does proposing a close relationship with the recipient help to raise money for a non-profit organization? This research sheds light on when people engage in charitable giving by examining the social motivation underlying giving. In particular, we focus on giving as a form of social relationship. Drawing on attachment theory, we find that people with secure (low avoidance and low anxiety) vs. insecure (high avoidance and anxiety) relationship styles engage in giving behavior differently. Specifically, insecure individuals give more when the relationship between them and the receiver of help is close, whereas secure individuals are less sensitive to the nature of relationship with the receiver. Three studies demonstrate this effect using both chronic measures of individual relationship style and situational priming of security, and with hypothetical as well as real dollar decisions.

Attachment theory (Mikulincer and Shaver 2005) suggests that people with insecure attachment styles (high anxiety and high avoidance) have a desire for intimate interpersonal relationship. However, they are chronically concerned about acceptance and rejection from others. Therefore, we propose that insecure people would see giving as a means to establish a secure social relationship, and the promise of such a relationship motivates giving. Thus insecure individuals are more likely to donate when they perceive an interpersonal relationship with the beneficiary, than when the donation does not imply a relationship. On the other hand, people with secure attachment styles are not motivated by relationships when deciding whether to give. Therefore, they give with equal likelihood whether they have close or aloof relationship ties to the receiver.

Among the variety of ways of giving to people in need, one of the fastest growing methods is a sponsorship program (Giving USA Foundation 2007) which links a sponsor with a specific person in need on a relatively long-term basis. In Study 1 and 2, we examine the implication of such a sponsorship relationship.

Study 1 studies the basic effect of attachment style on charitable donation. All participants read a charity request letter. In the relationship condition, the charity request describes the sponsorship program which provides the continuous interpersonal interaction between the sponsor and a beneficiary. In the control condition, there is no interpersonal interaction with the receiver of help. The results show that people with insecure attachment donate more when the charity included the interpersonal relationship compared to when it did not (40% vs. 8.7%, $p < .002$). However, those with secure attachment do not show this differentiation (19.2% vs. 24.1%, $p > .5$).

Study 2 primes attachment security vs. insecurity situationally. In the attachment security priming condition, participants are told to imagine the situation of being loved by their romantic partner. In the attachment insecurity priming condition, participants are asked to imagine being abandoned by their romantic partner. Female participants in the insecurity condition donate more when the charity involved interpersonal relationship, compared to when it did not (70% vs. 35%, $p < .04$). Female participants in the secure condition, and male participants, do not show this pattern. (Presumably males react differently to romantic abandonment; e.g., rather than insecurity, they may feel anger.)

Study 3 attempts to generalize the results to real donations, and to a different operationalization of relationship. UCLA undergraduate students receive \$2 as compensation for completing a survey. However, during the survey, they are also informed the opportunity to donate their compensation to a children's hospital. The key manipulation is whether there is a relationship tie with the beneficiary (in-group: UCLA Children's Hospital vs. out-group: University of Michigan Children's Hospital). It is found that insecure people donate to the ingroup but not the outgroup (56.3% vs. 28.2%, $p < .04$), whereas secure people make no distinction between ingroup and outgroup (54.8% vs. 48.6%, $p > .5$).

Although individual giving is always the largest single source of donation to charitable organizations (Giving USA Foundation 2007), previous studies have not extensively researched the individual differences in charitable giving behavior. Our findings contribute to the understanding of why different people donate to different causes, and have important implications for studies of charity decisions and helping behavior. The current study has also important practical implication which consumers like which types of donations. Charitable support by individual is critical to the functioning of many non-profit organizations. Thus, if marketers know certain types of consumers like specific types of donations, they can focus on target market. Our results suggest that insecure consumers donate more when there is a relationship between donor and beneficiary, while secure consumers do not care the relationship with beneficiary. Therefore, fundraising by charity organizations may be improved by allowing for a personal relationship between donor and beneficiary. Moreover, based on study 2 in which attachment security was primed, marketers may also apply relationship priming techniques to their advertisement or charity request letters in an effort to increase giving.

SPECIAL SESSION SUMMARY

Let the Games Begin: Evaluating Fun Experiences

Sayantani Mukherjee, California State University, Long Beach, USA

SESSION OVERVIEW

Consumers experience and seek fun in a variety of consumption situations, from playing videogames (Koster 2002) and sky diving (Celsi, Rose and Leigh 1993) to gambling (Hope and Havir 2002) and river rafting (Arnould and Price 1993). Fun is a key element of hedonic (Babin, Darden and Griffin 1994), playful (Grayson 1999; Kozinets et al. 2004) and experiential (Holbrook and Hirschman 1982) consumption. Consequently, fun has emerged as an important goal in product development (Norman 2004) and marketing communications (Morgan and Rao 2003).

Emerging research suggests that fun is a positive and complex experience (Celsi et al. 1993) that involves challenge (Celsi et al. 1993), goals (Draper 1999), and learning (Bandura 1997). However, very little is known about factors that influence consumer evaluations of fun consumption experiences. The three papers involved in this symposium reveal the complex nature of fun and examines how this complexity interplays with consumers' decisions regarding fun experiences.

The first paper by Mukherjee, Lau-Gesk, and Kramer investigates how consumers' episodic memories of fun experienced during a recent videogame play episode influence their global evaluations of the episode. Drawing upon research on episodic reports of past emotional experiences, they develop a relationship between moments of fun that consumers retrieve from a recent videogame play episode and their global evaluations of the episode. The second paper by Namkoong and Raghunathan examines consumers' risk seeking behavior in fun experiences. They argue that consumers' risk-seeking tendencies depend on the kind of goals that are salient in fun experiences. The third paper by Anthony and Cowley suggests that frequent (infrequent) gamblers focus on future (current) outcomes in a gambling experience. These gamblers generate mixed counterfactuals which fuels their pursuit of future better opportunities.

Two themes emerge from the current collection of works. First, the papers identify the implications of goals in fun experiences. Mukherjee, Lau-Gesk, and Kramer find that consumers' global evaluations of recent videogame episodes depend on the intensity of fun that consumers recall having experienced at the end moment of the episode. They show that final moments are memorable because they are not only accessible but also meaningful. Final moments in the current context, allow people to assess whether they have accomplished goals related to the videogame experience. These goals involve gaining levels, securing weapons, killing monsters and getting special skills and often usurp the goal of winning the game. Namkoong and Raghunathan illuminate the role of goals further, and argue that promotion (vs. prevention) oriented consumers are more risk-seeking in fun experiences. This is because, in fun contexts, consumers are more concerned about a maximal goal. When having fun, people want to enhance the chance of achieving an ideal- "hope to achieve"—goal. Relatedly, Anthony and Cowley demonstrate that when gamblers are focused on a promotion goal in the future (e.g. promoting a better situation later), they generate mixed counterfactuals (i.e. both upward and downward counterfactual) and are more willing to take increased risk in future gambles

The second theme that arises is the role of temporal focus in fun experiences. Mukherjee, Lau-Gesk, and Kramer demonstrate how consumers' episodic memories of "fun" moments in recent videogame episodes impact global evaluations of the episode.

Hence, the emphasis in their paper is on past or recalled fun experiences. Namkoong and Raghunathan's paper focus on consumers' decisions and risk-seeing tendencies in fun consumption experiences that are made in the context of possible future outcomes. Complementing this is Anthony and Cowley's paper, which demonstrates that temporal focus impacts consumers' emotional experiences in gambling situations. Frequent (infrequent) gamblers focus on future (current) outcomes which cause them to have a weakened emotional reaction to gambling outcomes.

Fun experiences are growing in importance among consumers and marketers. This symposium is expected to have significant theoretical and practical implications. It is also expected to generate discussion among a wide audience, including researchers in the areas of hedonic psychology, experiential, hedonic and playful consumption, judgment and decision making, temporal issues, affect and emotion, and consumer behavior in general. The symposium is comprised of papers that are well grounded in theory and each with several completed studies.

Rebecca Ratner will synthesize the three papers. Ratner's expertise in the area of consumer decision-making and hedonic experiences is particularly valuable in providing insights into this "fun" and exciting stream of research.

EXTENDED ABSTRACTS

"What Makes Videogame Experiences Fun?"

Sayantani Mukherjee, *California State University, Long Beach, USA*

Loraine Lau-Gesk, *University of California at Irvine, USA*

Thomas Kramer, *Baruch College, CUNY, USA*

This research seeks to understand how consumers' episodic memories of fun experienced during a recent consumption episode influence their global evaluations of the episode. Specifically, within the context of videogames, we examine how consumers construct global evaluations based on the specific moments of fun that they retrieve from a recent videogame play episode.

Previous research suggests that when people report on past emotional experiences, they rely on their episodic memory of specific moments of the episode for information (Aaker, Drolet and Griffin 2008; Robinson and Clore 2002). More memorable or distinct moments have a disproportionately greater influence on the recall of the associated affect because of their greater accessibility (Kahneman 1999). Therefore, when reconstructing the fun at various moments during the recent videogame episode, players' attention is likely to be drawn to particularly memorable moments, which will then be used to evaluate the overall experience. We expect that the most memorable moments during the videogame episode are the final ones—not just because of their relatively greater accessibility, but because of their greater personal meaningfulness and relevance (Fredrickson 2000). Specifically, people experience fun when working towards and achieving a specific goal (Draper 1999). Recent work suggests that the outcome of goal-driven experiences aligns well with end moments (Ariely and Carmon 2000) and carries personal meanings (Fredrickson 2000). End moments represent the culmination of the experience and coincide with the time at which one assesses whether goals are met (Fredrickson 2000). In videogames, goals can include gaining levels, securing weapons, killing monsters, acquiring special skills, and exploring difficult zones, which may often be more important than winning the game (Taylor 2006). Therefore, given that affect associated with memorable moments is more likely to be recalled, and that end moments tend to be the most memorable in the current context, fun associated with the end of the videogame experience may be more influential than other moments in players' retrospective evaluations. This explanation is aligned with Feldman and Lynch's (1988) accessibility-diagnostics framework, which would predict that the likelihood that end moments of fun are used as input into global evaluations of a consumption episode is a positive function of the accessibility of the end-moment fun, a positive function of the diagnosticity of end-moment fun, a negative function of the accessibility of alternate inputs, and a negative function of the diagnosticity of the accessible alternate inputs (Feldman and Lynch 1988). In the current context, this would suggest that accessible end moments of fun should be used as input into global evaluations only to the extent that they are diagnostic, that is, meaningful.

We start to explore these issues in the first field study using individual depth interviews (Moore and Lutz 2000) with videogame players in an arcade. Depth interviews involved engaging players in open-ended dialogs about the fun they experienced in a recent videogame episode. These dialogs reveal that players exclusively

recall the fun experienced at the end moment of the episode. Further, the dialogs suggest that end moments are memorable not because they are merely accessible or perceptually salient; rather end moments are memorable because these moments are personally meaningful.

Study 2 investigates the impact of recalled end moments of fun on global evaluations of a recent videogame episode through a field experiment. A confederate posing as an employee randomly approached patrons entering the arcade. Participants played a videogame of their choice. Participants were then asked to provide details associated with their recent videogame play and to report the fun they experienced during the episode. Participants also provided their global evaluations of the recent episode. Results indicate that players' global evaluations do not depend on the average of the recalled fun moments experienced during the entire game, the recalled peak moments of fun or on the outcome of the game (i.e., win-lose). Rather, it is the recalled end moment of fun that predicts consumers' global evaluations. Global evaluations were higher as the intensity of fun at the end of the videogame experience increased.

Study 3 seeks to tease apart the accessibility versus meaningfulness explanations by manipulating the meaningfulness of the end moments. If end moments are more memorable because they are meaningful, and hence used as input into global evaluations, then making them less meaningful should reduce or eliminate the impact of the end-moment fun, despite its accessibility. Similar to study 2, a field experiment was conducted in an arcade. All participants played videogames of their choice. However, in this study we included repetition of the game as a moderator, which constituted the meaningfulness manipulation. In particular, when players repeat a game, the end moment does not represent the culmination of the game and loses meaningfulness. Hence, under repetition, the impact of recalled end moments of fun on global evaluations should be lower. As predicted, the results of the third field experiment indicate that recalled end moments of fun impacts global evaluations only in the condition when players do not repeat a game.

This research contributes to the areas of affect and consumer decision-making, especially in the domain of episodic memories of emotional experiences. It also has implications for designing and advertising in "fun" videogames.

"Risk-Seeking in Utilitarian vs. Hedonic Domain: Implications for the Prospect Theory Value Function"

Jae-Eun Namkoong, University of Texas at Austin, USA

Raj Raghunathan, University of Texas at Austin, USA

How do people value monetary and other pay-offs in risky contexts, for example, how do they value a sure bet of \$10 versus a 50% chance of winning \$25 and a 50% chance of winning nothing? The Prospect Theory value function (cf. Kahneman and Tversky 1979) provides perhaps the most parsimonious and generalizable answer to this type of question. However, although this value function is capable of both predicting and explaining a multitude of phenomena (including mental accounting effects [Thaler 1985], loss aversion [Arkes and Blumer 1985], etc.), it actually runs contrary to some other robust real-world phenomena—like the popularity of insurance and lotteries. It is in attempting to explain these phenomena that Kahneman and Tversky (1979) proposed that people assign a subjectively higher probability to very low-probability events, like the probability that one's house will burn down, or the probability that they will win a lottery.

But what if—in addition to the (subjective) inflation of low-probabilities—there is another mechanism that boosts the popularity of insurance and lotteries? We examine such a possibility in this research. Specifically, we propose that people are more risk-averse in contexts where a utilitarian (vs. hedonic) goal is more salient and, conversely, they are more risk-seeking when a hedonic (vs. utilitarian) goal is more salient. Our proposition is based on the idea that utilitarian and hedonic contexts evoke "minimal" and "maximal" goals (Idson et al. 2000). Specifically, in contexts where a utilitarian (vs. hedonic) goal is more salient, we propose that people are more concerned about meeting a minimum "cut off" level (Chitturi et al. 2007; see also Idson et al. 2000), whereas they are more concerned about enhancing the chance of achieving an ideal—"hope to achieve"—goal in hedonic contexts. As a result, people spend on insurance to make sure that even the "worst-case scenario" (which is the occurrence of the negative event for which they are seeking insurance) is acceptable and, likewise, they spend on lotteries to increase their chances of experiencing the "best case scenario" (winning the lottery).

In order to test this hypothesis in a monetary context, we used decision making scenarios, all of which involved money—choosing between two different cell phone plans, restaurants, and lottery options—and framed them to be either hedonic or utilitarian (e.g. choosing a monthly cell phone plan either for entertainment or business use). The two options they could choose from varied in terms of both payoffs and risk (probabilities), but were identical across conditions. Specifically, participants chose between a risky (but more attractive) option and a safe (but less attractive) option. Results showed that people were more willing take the chance of obtaining a higher (vs. lower) payoff, when the situation-frame was hedonic (vs. utilitarian). We found a significant pattern consistent with our predictions in all three scenarios—cell phone plan ($F_{(1,158)}=5.314, p=.022$), restaurant ($F_{(1,159)}=18.948, p<.0005$), and lottery ($F_{(1,159)}=6.573, p=.011$). This is after we controlled for

affect in all scenarios and, in addition, for monthly cell phone usage in the cell phone scenario.

In our second study, we used one of the scenarios from study 1 (lottery), in an attempt to replicate our results, with a goal of providing evidence for the underlying mechanism for our effects. Since we hypothesized that the underlying mechanism is the activation of minimal vs. maximal goal, we measured participants' chronic level of regulatory focus (Lockwood, Jordan, and Kunda 2002) to examine its role in risk-seeking tendency¹. Our results confirmed that hedonic (vs. utilitarian) scenario renders more risk-seeking ($F_{(1,65)}=6.71, p=.012$), and also, that chronically promotion (vs. prevention) oriented participants sought more risky options ($F_{(1,65)}=4.644, p=.035$). Risk-aversion in the utilitarian scenario is expected to be prevalent, because people (regardless of their individual characteristics) tend to make sure that they meet a minimum level of functionality first, a tendency also referred to as the principle of precedence (see Chitturi et al. 2007). Hence, the difference between chronically promotion vs. prevention people is likely to be attenuated in the utilitarian (vs. hedonic) scenario, which is exactly what we found. Consistent with the idea that risk-aversion is more likely to be prevalent in utilitarian scenarios than risk-taking is in hedonic ones, a significant simple effect of chronic regulatory focus emerged in the hedonic scenario ($F_{(1,29)}=5.637, p=.024$), but not in the utilitarian scenario ($F_{(1,34)}=.434, p=.515$). In study 3 (proposed), we aim to examine the effect of framing an identical gamble as either insurance or lottery. We expect to find more risk-seeking tendency in the context of lottery vs. when the same "lottery" is used as for insurance. This is a meaningful step as it explains some of the behaviors that are not fully explained by existing behavioral decision theories (e.g. being risk-seeking or risk-averse over large gains or losses with extremely small probabilities).

Through a series of experiments, we demonstrate the effect of framing a situation as hedonic vs. utilitarian on risk-seeking tendency, and also show its relationship with one's chronic level of regulatory focus. Further, we attempt to make theoretical contributions by providing a better picture to some of the unresolved questions in decision making literature which is why people engage in gambling and purchase insurance.

"Chasing Rainbows: Strategies for Promoting Future Better Outcomes"

Christina I. Anthony, *University of Sydney, Australia*
Elizabeth Cowley, *University of Sydney, Australia*

Research on counterfactual thinking demonstrates that thinking about how an outcome "could have been better" (i.e. generating Upward Counterfactual Thoughts; UCTs) allows one to prepare for future better outcomes (Epstude and Roese 2008; Markman et al. 1993; Markman, McMullen, and Elizaga 2008; Roese 1994) whereas thinking about how an outcome "could have been worse" (i.e. generating Downward Counterfactual Thoughts; DCTs) allows one to savour a good outcome or mood repair one's feelings following a bad outcome (McMullen 1997; McMullen and Markman 2000; Medvec, Madey, and Gilovich 1995; Roese and Hur 1997; White and Lehman 2005). According to this view, contrastive UCTs and DCTs, by virtue of the affect they evoke (UCTs evoke negative affect, DCTs evoke positive affect) are believed to serve distinct and competing motivations (Gleicher et al. 1995; Markman et al. 1993; Markman et al. 2008); UCTs serve a preparatory function and DCTs serve an affect regulation function. However, we propose that under certain conditions, DCTs will support the preparatory function of UCTs, given the value of the positive affect they provide. Specifically, we argue that UCTs provide the necessary cognitive information that opportunities for better outcomes exist (Epstude and Roese 2008), and that contrastive DCTs, by virtue of the positive affect they evoke, may fuel the pursuit and acquisition of future better opportunities (Carroll and Shepperd 2009). We predict that frequent gamblers are motivated to promote a good outcome later and accordingly, will strategically generate mixed counterfactuals (both UCTs and DCTs). Whereas frequent gamblers are motivated by good outcomes in the future and the anticipation of future pleasure, we propose that infrequent gamblers are motivated to enjoy a good outcome now. Therefore the presence of a win should result in enjoyment (pure DCTs), and the absence of a win (a loss) should cause disappointment (pure UCTs). We investigated this phenomenon in three studies; one in the field and two in the lab.

In study 1, real gamblers played 300 gambles on a simulated slot machine and either won or lost the game. As predicted, we found that infrequent gamblers generate pure counterfactuals (disappointing UCTs following a loss, pleasurable DCTs following a win). Alternatively, frequent gamblers generate mixed counterfactual thoughts (both UCTs and DCTs).

In study 2, we test our contention that mixed counterfactuals are generated when anticipating future pleasurable outcomes. Undergraduate students played the game in the lab and either won or lost. We then manipulated participants temporal focus (now, future) and regulatory focus (promote good outcome; prevent bad

outcome) by asking participants to recall times in their life when they saved (spent) money to promote (prevent) a good (bad) situation now (later). As expected, when participants focused on promoting a better situation later they generated mixed counterfactuals. They were also more willing to take increased risk in a subsequent game. Further, we rule out the alternative explanation that mixed counterfactuals cause strategic emotional regulation. We do not find evidence of mixed counterfactuals when people were focused on preventing a bad situation later. This rules out the possibility that participants were attempting to mood repair or strategically numb their feelings in order to minimise the impact of affective interference on future goal pursuit. Thus, it appears that DCTs and the positive affect they provide are used to motivationally energise the pursuit of future better outcomes that UCTs have uncovered.

Finally, in study 3 we explore the emotion dilution found in studies 1 and 2. Again participants played the same simulated poker machine game and either won or lost credits. Counterfactual type (mixed vs. pure) and counterfactual order (better first, worst first) were then manipulated by instructing participants to consider the possibility that the outcome could have been; worse only, better only, better then worse or worse then better. As expected, mixed counterfactuals caused a weakened emotional reaction towards the outcome. Further we demonstrate that this phenomenon is not a case of emotional ambivalence.

Contrary to the common belief that frequent gamblers are addicted to the thrill of a win, it appears that they chase rainbows by imagining future wins at the expense of enjoying current wins. The frequent gamblers really are looking for the elusive pot of gold. Infrequent gamblers on the other hand are more susceptible to the highs and lows of gambling as they are more focused on the current outcome.

SPECIAL SESSION SUMMARY

Dynamic Influences on Investors' Decisions

Stephen Gould, Baruch College, CUNY, USA

Ana Valenzuela, Baruch College, CUNY, USA

SESSION OVERVIEW

Behavioral finance theory suggests that individual investment decisions will, to a certain extent, be affected by characteristics of one's personal psychology and what are said to be irrational biases (Thaler 1987). Furthermore, research on actual investment decisions shows that psychological variables do matter and actually cause individuals to make non-optimal decisions (e.g., Goldstein et al. 2008; Lee et al. 2008; Morrin et al. 2002). In that regard, investment behavior might be subject to influences and biases reflecting various cognitive traits (e.g., belief in luck), personal characteristics (e.g., gender), motivational stages (e.g. promotion or prevention focus), process responses (e.g., change in frame from gains or losses) and context characteristics (e.g., option assortment size).

Nonetheless, despite the importance of understanding the determinants of investors' decisions, and the growing interest in them in consumer research relatively little research has examined the effect of the decision maker's personal psychology, self-expressive needs and heuristic approaches on actual investment/trading decisions. The four papers in this special session are a step forward in such an investigation since they explore the theoretical intersection between product, investor characteristics, and behavioral tendencies in the determination of trading/ investment decisions.

In the first paper, Daniel Goldstein shows that in domains involving losses, prevention-oriented individuals behave differently than predicted by the regulatory focus theory framework and, surprisingly, take greater risks. In the second paper, Stephen Gould, Ana Valenzuela, Luke Kachersky and Richard Holowczak analyze biases in traders' strategies, behaviors, and performance that result from distal personality traits. In the third paper, Priya Raghubir and Meir Statman identify 8 self-expressive benefits of financial investing and key personality constructs that distinguish between different financial products so as to provide a multi-dimensional mapping of financial instruments. Finally, in the fourth paper, Maureen Morrin and Susan Broniarczyk explore how increasing investment fund assortment size causes individuals to choose more funds for their portfolios, which is cognitively depleting, and this process results in further use of heuristic approaches to allocating one's dollars across the chosen funds.

Gita Johar briefly summarized the overlapping points across the four papers. Taken together, these papers highlight the important influence of both product characteristics and individual differences in determining consumers' investment-related evaluations and choice. With well-developed frameworks and data, all four papers provide a roadmap for how the intersection between product and investor characteristics determines trading/ investment decisions. To finalize the session, the audience participated in a discussion of areas of future research on the topic of behavioral finance and the role that different psychological variables play in consumers' investment decisions.

EXTENDED ABSTRACTS

“When Prevention-Oriented Investors Take Greater Risks: Breaking a Confound”

Daniel Goldstein, London Business School, UK

Rongrong Zhou, Hong Kong University of Science and Technology, Hong Kong, China

Michel Tuan Pham, Columbia University, USA

For those who were overinvested in stocks (relative to their taste for risk), the unfortunate consequence of incorrectly-gauged investor risk preferences is all too clear in the current market downturn. Can marketers better predict consumers' propensity for taking financial risks? Since demographic variables including age and sex are broad, and of limited predictive value (Goldstein, Johnson & Sharpe, 2008; Bajtelsmit & Bernasek, 2001), the goal of offering more individualized predictions and advice has led marketers at investment firms to devise personality scales for recommending products to investors. Unfortunately, none of these scales have been validated in a peer-reviewed article to our knowledge, and the only published journal article on the topic finds that responses from different vendors' scales have only a modest inter-correlation, even when administered in direct succession (Yook & Everett, 2003).

A promising finding of recent years was that of Zhou and Pham (2004), who investigated financial risk taking as it connects with Regulatory Focus Theory (RFT; Higgins, 1987). Zhou and Pham showed that investments products mentally coded as promotion-oriented trigger more financial risk taking compared to investments products mentally coded as prevention-oriented (Study 2). They also showed that priming of promotion or prevention through an unrelated task framed in approach or avoidance-oriented manner steers investment toward more conservative options under prevention: mutual funds rather than individual stocks, and retirement accounts rather than trading accounts. A number of other researchers in Marketing and Psychology have found a connection between RFT and risk taking outside financial services, typically finding that promotion orientation is correlated with risk taking and prevention orientation is related to risk avoidance (Liberman, Idson, Camacho, & Higgins 1999; Crowe & Higgins, 1997; Chernev, 2004; Förster, Higgins, & Bianco, 2003; Friedman & Förster, 2001; Lee & Aaker, 2004).

In the present work, we suggest that the classical relationship between financial risk taking and regulatory focus may only tell half the story, due to a confound. Typically, taking more risk is associated with potentially greater gains and greater losses. In such situations, promotion-oriented individuals take greater risks. However, when risks are framed as losses instead of gains, greater risk taking may be necessary to avoid a certain loss. We predict that, relative to promotion-oriented individuals, prevention-oriented individuals will be more concerned with avoid loss altogether and thus more likely to take greater risks in the domain of losses.

We demonstrate this counterintuitive effect using simple gambles (Zhou, 2002). In addition, to gain deeper insight into cognitive processes, we employ the Distribution Builder methodology (Goldstein, Johnson & Sharpe, 2008). The Distribution Builder allows individuals to graphically manipulate cost-constrained prob-

ability distributions of investment wealth from which they will later draw. Its advantages over simple gamble choices are many, including the ability to: detect reference dependence in addition to risk aversion, measure reaction time, test RFT-specific hypotheses about maximum and minimum outcomes, and employ click-tracking to understand which outcome levels are attended to most. Results from the Distribution Builder studies show that in the domain of gains, promotion-oriented individuals assume more downside risk in order to obtain upside gains (relative to prevention-oriented individuals). However, in the domain of losses, the relationship reverses and it is the prevention-oriented people who take greater risks in order to escape certain losses of moderate magnitude.

This research aims to clarify the relationship between promotion/prevention orientation and financial risk taking, which has important practical applications for marketers who wish to provide responsible advice (and suitable products) to their customers.

“The Behavioral Dimensions of Trading: Proximal and Distal Influences on Performance”

Stephen Gould, Baruch College, CUNY, USA

Ana Valenzuela, Baruch College, CUNY, USA

Luke Kachersky, Fordham University, USA

Richard Holowczak, Baruch College, CUNY, USA

Behavioral finance theory suggests that stock market trading performance outcomes (e.g., making or losing money) might be subject to influences and biases reflecting various cognitive traits (e.g., belief in luck), personal characteristics (e.g., gender), process responses (e.g., change in focus on gains or losses) and behaviors (e.g., trading more or less frequently). Although the influence of some of these variables has already been studied, some of traders' cognitive traits have been overlooked perhaps because they appear more distal to the trading process, and there are still other, more proximal variables yet to be studied. To this end we implemented a trading simulation in which participants were endowed with shares of a hypothetical stock and cash, and traded with each other for a period of 10 minutes. Importantly, in addition to measuring distal and proximal character traits, we measured participants' cognitive and affective states before and after the trading session.

One hundred fourteen participants recruited from a large Northeastern university participated in exchange for a cash payment and the opportunity to win a larger cash prize for the top trading performer. Trading simulations were run in groups of about 25. Participants were seated at computer terminals and given an interactive demonstration of the Rotman Interactive Trader (RIT) software. The software allows participants to interact in real-time with a central limit order book by placing market orders and limit orders to buy and sell shares of a hypothetical stock. Participants were told that they would be trading a hypothetical security with each other, and would be given 100 shares of the security and \$1 million to start. As part of the simulation, participants were told that the security they were trading had five possible target prices of \$20, \$22, \$24, \$26 or \$28. During the course of the simulation participants received information in their “news” window about values that the security could not be. This was done so that the market would converge toward a single price by the end of the simulation. They then participated in the real trading simulation in which the trader with the highest final value (stocks plus cash) won a real cash prize. Participants finished with a post-simulation questionnaire pertaining to the simulation, demographics, and personality traits: non-cooperative tendencies; confidence in intellectual ability; self-esteem; fatalism; desirability of control; primary-secondary control; attitudes toward risk; belief in luck; competitiveness; and regulatory focus.

A number of behavioral variables were regressed on the personality variables. One such behavior, the number of “buy” transactions the trader engaged in, was significantly related to secondary control ($p=.009$). The number of “sell” transactions was significantly related to risk taking ($p=.045$) and marginally to primary control ($p=.081$) and negatively to belief in luck ($p=.078$). We created a performance variable to reflect traders' success in buying low and selling high. The volume weighted average price (VWAP) ratio compares the VWAP of shares sold to the VWAP of shares bought. Values over 1 indicate that, on average, a trader sold his shares for a higher price than he bought them. Trading behavior and personality traits explained variation in this performance metric. Primary control ($p=.019$) and belief in luck ($p=.056$) were significant in explaining the VWAP ratio, while the number of “sell” transactions exerted a negative influence ($p=.044$). Finally, traders' change in value from their starting \$1 million endowment was dependent on the VWAP Ratio ($p=.014$). Additionally, for those who made money, desirability of control ($p=.004$) and primary control ($p=.055$) were positively related with money made while belief in luck ($p=.038$) and regulatory focus ($p=.017$) were negatively related. For those who lost money, only desirability of control was significant ($p=.021$) and negatively related to money made.

Overall, the results indicate that personality variables can play an important role in determining trading behavior and performance along with proximal trading variables. The next study will test these traits in the same simulation by priming them in terms of opposing characterizations of traders as being lucky versus being able to control the results of their trading.

“Personalities of Financial Products”

Priya Raghubir, New York University, USA

Meir Statman, Santa Clara University, USA

Financial products, like most products, have utilitarian attributes and expressive attributes. The utilitarian attributes of financial products include their expected returns, risk, liquidity and fees. Self-expressive attributes are those that allow us to convey to ourselves and others our values, tastes and social class. Self-expressive attributes answer the question “What does the product say about me?” For example, one self-expressive attribute of a hedge fund is status. It says “I have arrived.” An insurance policy says “I am responsible.” A socially responsible fund says “I am a good person.” An active mutual fund says “I can be a winner.”

In this paper, we examine the perceptions of the utilitarian and self-expressive attributes of financial products and how these perceptions define the overall personalities of financial products. A personality is defined as a set of traits that distinguish one entity from another. We examine whether financial products have a “personality”—a set of defining characteristics and traits that are able to distinguish one financial product from the other. In doing so, we go beyond the utilitarian attributes of financial products, and examine how these affect usage benefits. Specifically, a benefit hierarchy model translates the functional attributes of a product or service into their usage benefits, laddering up to the feelings that these benefits invoke among customers, and triangulating to a set of key higher order self-expressive benefits.

In a benefit hierarchy framework, lower order functional attributes (such as fees charged, rates of return, variance around the returns, guarantee of capital remaining intact, tax advantages, presence of a market and its size, etc.) map onto a set of rational benefits. These rational benefits include utilitarian benefits such as risk, return, and liquidity. However, beyond rational benefits are emotional and self-expressive benefits that capture how a product makes people feel and what it says about them. Our approach is to

map rational benefits through to these higher order self-expressive benefits that are the apex of the benefit hierarchy.

Stage 1: In the initial stage of scale development, we identified 264 words including attributes of a financial product, investor goals, descriptors of a personality, demographic descriptions, self-expressive benefits and emotions, drawing from the literatures of finance, marketing, and psychology.

Face Validity: These 264 descriptors were reduced to a set of 107 that were categorized into a set of 70 adjectives that were personality descriptors of a financial instrument; and 35 feelings and emotions that were emotional and self-expressive benefits.

Construct Validity: Study participants (n=150) rated one of twelve (savings account, checking account, stocks, time deposits, mutual funds, retirement accounts, hedge funds, private equity, stock options, life insurance, real estate and lotteries and gambles) instruments using the 70 adjectives (1=Not at all, and 5=Very) and 35 emotions (1=Not at all, and 9=Very). Exploratory factor analysis with a varimax rotation using cutoffs of .60 for factor loadings was used to reduce the data to 11 factors using 37 descriptors, and six factors using the 35 emotions.

Stage 2: Stage 2 investigated six instruments: savings accounts, stocks, retirement accounts, mutual funds, hedge funds and real estate. All participants were asked to "Think that the ___ is a person," prior to being asked to rate it on the set of 37 adjectives, and 35 emotions, using a nine-point scale. All participants (n=56) rated all six instruments on the adjectives as well as rated the feelings these elicited with the order of the instruments fully counter balanced.

Results

Personality Constructs: The 37 items tapping personality constructs were subjected to exploratory factor analysis with a varimax rotation for each of the six different financial instruments to assess which items to retain. Items whose factor loading was low overall (i.e., lacks predictive validity); that load onto a marginal factor (e.g., indicating low reliability), load onto different factors for different financial instruments (i.e., is not generalizable), and/or loads less onto a factor than other items (i.e., is not distinctive) were dropped, leading to 27 of the items being retained:

Good: positive, good, valuable (alpha=.85)
 Bad: negative, bad worthless (alpha=.86)
 Aesthetic: Beautiful, aesthetic and pretty (alpha=.90)
 Intelligent: intelligent, up to date, latest (alpha=.77)
 Boring: sleepy, shy, lethargic, and old (alpha=.83)
 Fun: exciting, amusing, energetic, lively, young, entertaining, adventurous, fun, and playful (alpha=.95)
 Masculine: Masculine, extroverted (alpha=.74)

Self-expressive Benefits: A similar set of analyses on the 35 items in the self-expressive benefit inventory revealed (Scales for each factor were reliable ($\alpha > .70$):

Honest: Honest, free, and common
 Adventurous: fearful, reckless, adventurous, risk taker
 Smart: special, smart, A winner, A sense of achievement, and responsible
 Good: Intelligent, High Status, A Good person, optimistic
 Hip: Playful, young, cool, hip
 Connectedness: A sense of belonging, A part of a club, A member of a community
 Prestige: Elite, exclusive
 Power: A sense of control, A sense of dominance, A expert,

Unique
 Bad: Pessimistic, patriotic, and sinful.

Stage 3: To be conducted: Testing Predictive Validity: We will test this instrument with a group of adult experienced investors using a wide range of financial products and eliciting attitudinal and behavioral responses (e.g., attitude, experience, portfolio allocation, intentions). Robustness Checks: The survey will also collect information on the psychological, demographic and behavioral profiles of investors to examine differences in the perception of financial products across sub-groups of individuals and identify moderating variables.

"The Moderating Effect of Fund Assortment Size on the 1/N Heuristic"

Maureen Morrin, Rutgers University-Camden, USA

Susan Broniarczyk, University of Texas at Austin, USA

J. Jeffrey Inman, University of Pittsburgh, USA

Does offering more choices in retirement plans result in systematic decision biases? Prior research has shown that investors sometimes exhibit a naive diversification strategy whereby they evenly divide up their dollar contributions among all of the options offered, engaging in what Benartzi and Thaler (2001) term the "1/n heuristic." Interestingly, more recent research by Huberman and Jiang (2006), suggests that few investors engage in the strict definition of the 1/n heuristic. Notably, the work of Huberman and Jiang (2006) was based on a data set whose mean fund set size was about double that used by Benartzi and Thaler (2001); 13.7 versus 6.8 mean number of funds offered, respectively). Could the discrepancy in results reported by these two research teams be attributed to the different fund assortment sizes from which investors chose?

Our research explores the moderating effect of mutual fund assortment size on use of the 1/n heuristic by decomposing the heuristic into its two underlying behavioral dimensions: 1) choosing the funds from among those offered in which to invest, and 2) deciding how to allocate one's dollars across the set of chosen funds. Importantly, we argue that the two behavioral tendencies operate differently as a function of fund assortment size due to cognitive depletion. Recent investigations (Huberman and Jiang 2006) indicate that most retirement investors tend to invest in about three to five, or a handful, of funds. Thus a naive interpretation of portfolio diversification would seem to involve the sheer number of funds consumers want to include in their portfolios. If most investors feel they should be investing in a handful of funds to be sufficiently diversified, and only a few are offered for investment in a 401k plan, then many investors are likely to include all of the available options in their portfolios in order to arrive at the desired number of investment options—even if the set of options made available does not perfectly match their preferences. If this is the case, the 1/n heuristic should be less evident as fund assortment size increases. Because Benartzi and Thaler (2001) examined smaller assortment sizes, their findings may reflect, in part, a ceiling effect due to an inadequate fund assortment.

Although we posit that choosing from a larger assortment will reduce the tendency to invest in all available funds, we do expect that the average number of funds chosen will increase (Benartzi and Thaler 2001). Choosing from a larger fund assortment will encourage investors to choose more funds for their portfolios, because they use assortment size as a normative consumption cue regarding the sheer number of funds they should choose (Kahn and Wansink 2004). When consumers do not have well-defined preferences in a choice domain, they construct their preferences using strategies that are contingent on task demands (Bettman et al. 1998). A conse-

quence of this behavior is that investors become cognitively depleted (Pocheptsova, Amir, Dhar and Baumeister 2009), yet are faced with the daunting task of how to allocate their dollars among the large number of funds they have chosen for their portfolios. Simply dividing up one's dollars approximately evenly among the chosen alternatives represents one way to simplify this stage of the decision task. Thus, we expect that this aspect of the 1/n heuristic will be more evident as assortment size expands because of the tendency of investors to choose more funds when selecting from a larger assortment, which depletes their cognitive resources.

To date, two studies among adults have been completed, in which fund assortment size is manipulated (n=260, mail survey; n=363, online panel). In these studies mediation analyses are based on the number of funds invested in and thought listings. A third study, in which both fund assortment and cognitive load are manipulated, is in progress. As a whole, the results support our theoretical framework and help to reconcile discrepancies noted in previous research regarding asset allocation heuristics.

SPECIAL SESSION SUMMARY

The Role of Stereotypes in Changing Consumers' Attitudes and Behaviors

Linyun Yang, Duke University, USA

SESSION OVERVIEW

Given their broad applicability and rich content, it is important to understand how stereotypes influence consumer's attitudes. Because individuals use stereotypes to understand their social environment, stereotypes can be activated through a wide range of cues, and this can lead to attitudes and behaviors congruent with the stereotyped group. For example, the presence of an African American individual in a record store could increase preferences for rap music or the presence of an overweight individual in a restaurant could possibly prime consumers to order and eat more food. Individuals themselves are also often targets of stereotypes and must deal with being judged based on group membership. Though depicting stereotypes in the media is generally avoided, stereotypes, particularly positive ones, can be inadvertently portrayed. For example, the use of an African American athlete can be construed as stereotyping by African American consumers and lead to detrimental consequences for the advertised product.

This collection of research seeks to understand the various ways stereotypes can shape consumer's attitudes and also identify important factors that moderate these effects. Wheeler et al. and Campbell and Mohr's papers examine how stereotypes prime attitudes and behaviors consistent with the stereotype. Wheeler et al.'s paper focuses on how individuals view themselves on traits related to a stereotype affect their susceptibility to priming. They find that individuals with consistent self-concepts on stereotype relevant traits are the most resistant to priming and demonstrate the least amount of stereotype consistent attitudes. Campbell and Mohr's paper demonstrates that priming individuals with overweight people can lead to the stereotype consistent behavior of overeating. However, this effect can be attenuated by reminding individuals of their health goals and also by reminding them that overeating leads to weight gain. Yang et al.'s research takes the perspective of the stereotype target and focuses on how they view depictions of positive stereotypes in the media. They find that group identification moderates whether individuals respond negatively or positively to an advertisement portraying a positive stereotype. These papers also emphasize the importance of individual level factors (i.e. self-concept consistency and personal goals) in understanding the effect of stereotypes on behavior.

Despite their power to shape attitudes and behavior, stereotypes have received little attention in the consumer behavior literature. This special session seeks to highlight the importance of understanding their role in shaping consumer behavior and should appeal to a wide audience. These papers demonstrate the various perspectives one can take in examining stereotypes and how they may relate to important marketing variables such as preferences, eating behavior, and persuasion.

EXTENDED ABSTRACTS

“Self-concept Consistency Fosters Resistance to Prime-induced Attitude Shifts”

Christian Wheeler, Stanford University, USA

Kenneth G. DeMarree, Texas Tech University, USA

Kimberly R. Morrison, Ohio State University, USA

Richard Petty, Ohio State University, USA

Research on stereotype priming has shown that it can have a wide array of effects on behavior and judgment. One effect of

particular interest to marketers is that stereotype primes can lead to attitude shifts among prime recipients, both when they are targeted by the stereotype (Steele and Ambady 2006) and when they are not (Kawakami, Dovidio, and Dijksterhuis 2003). Specifically, following the activation of stereotypes, people report more stereotypical attitudes (e.g., racist attitudes following a skinhead stereotype prime).

There has been a great deal of recent research on the mechanism by which these types of effects occur. According to one account, the Active-Self account (Wheeler, DeMarree, & Petty, 2007), primes can have such effects via their effects on the active self-concept. A rapidly growing body of research shows that primed constructs can affect the active self-concept and lead to congruent subsequent behavior (see Wheeler, et al., 2007, for a review).

If primes affect behavior via the self-concept, factors that affect the resistance of the self-concept to change should lead to smaller priming effects. One factor associated with resistance is self-concept consistency. Paralleling research on attitude consistency, research on self-concept consistency has shown that those with consistent self-concept representations are more resistant to prime-induced self-concept shifts than are those with inconsistent self-concept representations (DeMarree, Morrison, Wheeler, and Petty 2009). We therefore predicted that people would be more resistant to priming effects on their attitude reports when there was consistency between prime-relevant aspects of their self-concepts.

In our first study, White participants were primed with either the African-American stereotype or no stereotype using a sentence unscrambling task. After the priming manipulation, participants indicated their level of agreement with four attitudinal statements that a pretest indicated were associated with the African American stereotype (e.g., “Policies aimed to reduce racial inequalities, such as affirmative action, are important to our society”). These items assessed attitudes toward affirmative action, welfare, rap music, and playing basketball and football. To minimize suspicion, these statements were interspersed with several others that were unrelated to the African American stereotype (e.g., “I like to eat apples and other fruit”).

At the end of the session, all participants completed six questions designed to assess self-concept consistency along three stereotype-relevant dimensions (e.g., lazy/athletic), and we computed self-concept consistency using a formula paralleling that used to compute attitude ambivalence. In this formula, conflict within the self-concept is higher to the extent that people simultaneously strongly endorse opposing traits.

Analyses revealed the predicted prime x stereotype trait inconsistency interaction. Participants with high levels of trait inconsistency assimilated to the prime (i.e., reported more stereotypical attitudes following the stereotype prime), whereas those with low levels of trait inconsistency showed no effect of the prime.

In our second study, we replicated these effects with a different stereotype and a different measure of self-concept consistency. Research on the self has suggested that people have multiple self-representations, including representations of themselves as they actually are and representations of themselves as they desire to be (Higgins, 1987; Markus & Nurius, 1986). Actual and desired self-representations can differ in the extent to which they lead to the same overall evaluation or belief, and as such, they represent

another possible measure of structural consistency. We predicted that, parallel to study 1, participants with large actual-desired self-discrepancies would exhibit larger priming effects on their attitudes.

In this study, participants first completed our actual-desired self-discrepancy measure. They indicated the extent to which each of three elderly stereotype traits—traditional, stubborn, and forgetful—characterized their actual, ideal, and ought selves. Later in the session, we primed college students with the elderly stereotype by asking them to write an essay about either an elderly woman or a young woman. Participants then indicated their level of agreement with three statements that reflected social conservatism, a component of the elderly stereotype (e.g., “There is too much violence in the media”). To minimize suspicion, these statements were interspersed with six others that were unrelated to the elderly stereotype (e.g., “I like to wear a watch”).

Analyses revealed the predicted two-way condition x stereotype discrepancy interaction, whereby participants with large discrepancies assimilated to the prime (i.e., reported more conservative attitudes following the elderly prime), whereas participants with small discrepancies were not influenced by the prime.

These studies advance our understanding of both the priming literature and the attitude change literature. These findings show that structurally consistent self-concept representations foster resistance to priming effects and provide additional support for the Active-Self account of priming to behavior effects. They also lend additional insight into how attitudes can be shifted by even very subtle factors such as the accessibility of social stereotypes.

“Effects of Priming on Instrumental Behaviors”

Margaret C. Campbell, University of Colorado at Boulder, USA
Gina S. Mohr, University of Colorado at Boulder, USA

Recent research proposes that there are person-to-person influences on weight gain such that the weight of others in individuals’ social networks influences the probability of gaining weight (Christakis and Fowler 2007). While this research indicates that social factors influence weight gain, the nature of the data set precludes examination of how this influence might occur. We draw from the literature on social stereotype priming to explain how exposure to an overweight person can give rise to an increase in food consumption. We propose that social factors can influence instrumental behavior, that is, behavior such as eating that is considered to be causally linked to weight gain. We develop the idea of how instrumental behaviors are influenced by stereotype activa-

tion and explore when the effect of stereotype activation on instrumental behavior is likely to be attenuated.

Stereotypes are traits, attributes and behavioral tendencies that are associated with the members of a social category (Fiske and Taylor 1991; Hilton and Von Hippel 1996; Kunda 1999; Stangor and Lange 1994). Research shows that activation of social stereotypes can affect people’s behavior, increasing behavior that is consistent with stereotypical traits, attributes and behavioral tendencies even when the behavior is somewhat negative (for reviews, see Dijksterhuis and Bargh 2001; Wheeler and Petty 2001). However, existing research in this stream has not examined instrumental behaviors. For example, whereas walking slowly is associated with the elderly, the act of walking slowly does not cause a college student to become old. In contrast, however, eating more food is associated with overweight (Barker, Tandy, and Stookey 1999) and eating is causally related to becoming overweight. What implications does instrumentality have for the effects of social stereotype primes on behavior?

We propose that the stereotype of an overweight person can lead to an increase in behavior associated with overweight people (i.e., eating more “indulgent” food), even though people are motivated to avoid membership in the “overweight” group, as evidenced by the staggering number of consumers who are trying to lose weight, and believe that eating indulgent food increases the chance of becoming overweight. We explore the process by which the instrumental behavior is increased by the stereotype. Our research assesses one mechanism by which a person may succumb to, or overcome, these behavioral priming effects. In particular, we theorize that in order for the stereotype prime to give rise to an increase in the instrumental behavior, it must first decrease motivation for the underlying, competing goal. Moreover, we propose that by making salient this underlying goal and the causal link between eating and weight gain (i.e., the instrumentality of the behavior) the priming effects can be attenuated.

We present four studies that investigate the effect of overweight primes on eating behavior and the role that the salience of competing goals and behavior instrumentality play. Study 1 establishes the prime to behavior link, showing that when people are exposed to a picture of an overweight person, they eat significantly more than people who are exposed to a picture of a healthy weight person or a neutral image (the two controls in this experiment). Study 2 further examines this relationship by testing the mediating role of health motivation. Our findings show that exposure to a picture of someone overweight led to lower ratings of health motivation and that health motivation mediated the prime-to-behavior relationship.

Together, the findings from study 1 and study 2 provide additional theoretical insight into the prime-to-behavior process. In particular, we show that an instrumental behavior associated with an active social stereotype can lead people to assimilate in behavior, but the process is mediated by an important motivational variable. To lend further support to our theory that consumer motivations are important in this process we conducted two additional studies to test the moderating role of consumer health goals and instrumentality salience.

Study 3 tests our theory that if consumers have underlying goals that are in conflict with behaviors that are associated with a stereotype and are perceived as instrumental to group membership, then making those goals salient should lead to a decrease in priming effects (i.e., food consumption). The results from study 3 reveal a significant interaction such that exposure to an overweight person led to an increase in food consumption, but that asking study participants to reflect on their health goals attenuated these affects.

We likewise theorize that increasing the salience of the instrumentality of the behavior can also attenuate the impact of a stereotype prime on an instrumental behavior. The findings from Study 4 support this hypothesis. We find that manipulating the salience of the instrumentality significantly impacts the effect of the overweight prime. Specifically, whereas participants eat more cookies in a taste test following exposure to a picture of someone overweight than someone healthy weight, this effect does not arise when the salience of the instrumentality of the behavior is increased (by seeing the overweight person eating).

Overall, this set of studies contributes to the literature on stereotype priming. This highlights the idea that some behaviors are instrumental to group membership and that motivation can play an important role in stereotype prime effects for instrumental behaviors. This research may also provide some useful insight into how social network effects may arise.

"How Stereotype Targets Perceive Positive Stereotypes"

Linyun Yang, *Duke University, USA*
Tanya Chartrand, *Duke University, USA*
Gavan Fitzsimons, *Duke University, USA*

The majority of the stereotypes literature has focused on the detrimental consequences of being negatively stereotyped, but little research has focused on how stereotype targets are affected by positive stereotypes. Given the frequent portrayal of positive stereotypes (i.e. the African American athlete or the Asian math genius), it is important to understand how individuals are affected by these depictions as well as consequences for consumer behavior. Our research examines the role group identification plays in how individuals will interpret portrayals of positive stereotypes in the media.

Prior research has demonstrated that group identification determines the extent to which an individual's group membership affects a wide range of experiences and behavior (Ellemers, Spears,

& Doosje 1999 for review). Most relevant to our research is the finding that those who identify highly with their group are more sensitive to threats toward their ingroup. Because highly identified individuals are more sensitive to intergroup inequalities, they are more willing to label negative incidents as threatening to their group (Sellers & Shelton 2003). For example, Operario and Fiske (2001) found that ethnic minorities highly identified with their ethnic group were more likely to interpret the ambiguous behaviors of a White confederate as discriminatory than their less identified counterparts.

Even if a stereotype is positive and endorsed with the best intentions, it can be disconcerting to the stereotype target because it is still restrictive and based solely on group membership rather than any individuating information (Czopp 2008). More importantly, positive stereotypes can also imply and bring to mind the negative component of one's group stereotype (Fiske, Cuddy, Glick, & Xu 2002). Furthermore, these complementary beliefs can contribute to the justification of enduring intergroup differences in status and power (Jost & Kay 2005). We hypothesize that those high in group identification will be particularly sensitive to these issues and be more likely to interpret portrayals of positive stereotypes as prejudiced and threatening to their group.

In Study 1, we demonstrated that images portraying individuals engaging in activities consistent with a positive stereotype can be interpreted as prejudiced. African American and White participants viewed images of African Americans engaged in either singing or running (domains in which African Americans stereotypically excel). We found that African American participants high in group identification interpreted these images as more prejudiced toward their group than those who were low in group identification. Since these images were irrelevant to their group, White participants did not demonstrate any differences in prejudice ratings with regard to group identification.

If high identifiers were responding to the potential for threat to their group in Study 1, then we should find that they will be less likely to be affected when the positive stereotype is endorsed by any ingroup member because the threat to the group is minimized. In Study 2, we examined this hypothesis and also focus on how perceived prejudice influenced persuasion and product evaluations when positive stereotypes were portrayed in advertisements. African American and White participants viewed a print advertisement for a book called "The Ultimate Running Guide." The advertisement claimed that the book would help readers "run further and faster with the training methods of the best marathon runners in Africa." In addition, either an African American or White male spokesperson was pictured running in a race with a quote endorsing the book.

Replicating Study 1, we found that African American participants high in group identification evaluated the advertisement more negatively than those low in group identification. However, we only found this effect when the spokesperson was an outgroup member. When the spokesperson was an ingroup member (i.e. African American) these effects were diminished presumably because threat to the group was not apparent when a positive stereotype was endorsed by an ingroup member. Because the stereotypes portrayed were irrelevant to stereotypes regarding White participants, we did not find any differences in their evaluations regarding group identification and advertisement spokesperson.

This line of research demonstrates that the portrayal of positive stereotypes in advertisements can have detrimental effects on the products portrayed, particularly with regard to those highly identified with the stereotyped group. Because this negative reaction to positive stereotypes is rooted in the perceived threat to one's ingroup, specifying the source of the positive stereotype as an

ingroup member can reduce the perceived threat and minimize the negative impact on evaluations of the advertisement and product.

SPECIAL SESSION SUMMARY

Exploring Self-Control: Moving Beyond Depletion Hypothesis

Ravi Mehta, University of British Columbia, Canada

SESSION OVERVIEW

Self-control has been proposed to be one of the most important and beneficial processes in the human personality structure. Successful self-control has been linked to a broad range of desirable outcomes (e.g., healthier interpersonal relationships, greater popularity, and better mental health; see Gailliot et al. 2007). Although a large amount of research has been done on this topic, many important questions remain to be answered. For example, what is the role of self in self-control? Does resource depletion necessarily lead to more impulsivity? How do different definitions of self affect impulsive behavior? How does affect impact the self-control process? This session brings together four papers that intend to address these important questions and thus advance our knowledge of the mechanisms and boundary conditions under which consumers engage in self-control.

The first paper (Mehta et al.) aims to reconcile an existing discrepancy in the self-control literature. While traditional research on myopic behavior suggests that a high versus low construal level leads to less indulgence, more recent work on hyperopia implies the opposite. This paper demonstrates that construal level interacts with self-focus, which jointly determines an individual's indulgence level. Specifically, when self is not made salient, findings in the myopia literature are replicated, whereas when self is the central focus, effect reversal as predicted by the hyperopia literature is observed. The second paper (Ein-Gar and Johnson) further explores the role of self in self-control dilemmas. It suggests that construing the self differently influences preferences and choices such that under a "becoming" mindset consumers are more prudent whereas under a "being" mindset they are more prone to indulge. The third paper (Laran and Janiszewski) suggests that consumers' chronic self-control level affects their task perception (whether perceive as work or play) and consequently affects their self-control in subsequent tasks. Finally, the last paper (Komarova et al.) investigates the role of affect in self-regulation tasks. It demonstrates that under positive mood consumers are less likely to engage in mental accounting to justify impulsive spending.

EXTENDED ABSTRACTS

"Exploring Role of Self in Self-Control"

Ravi Mehta, University of British Columbia, Canada

Rui (Juliet) Zhu, University of British Columbia, Canada

Joan Meyers-Levy, University of Minnesota, USA

The classic literature on self-control focuses on myopic behavior, suggesting that individuals demonstrate self-control failure i.e. yield to immediate hedonic temptations when they focus on short-term benefits versus long-term goals (Trope and Fishbach 2000; Fujita et al. 2006). One way to reduce myopia is to induce a higher construal level, so that individuals focus on long-term benefits (Fujita et al. 2006; Liberman et al. 2007). However, recent research on hyperopia suggests an opposite form of self-control failure, namely many individuals have excessive farsightedness, thus they over-control themselves and constantly choose virtue over vice (e.g., Kivetz and Keinan 2006). Such a tendency is likely to evoke feelings of missing out in life and regret over time. One way to overcome hyperopia is to introduce a higher construal level (e.g., introducing greater temporal perspective; Keinan and Kivetz

2008), so that individuals will foresee their regret and consequently engage in indulgence to correct their hyperopic tendency.

The above two lines of research reveal an inconsistency. While the classic literature on myopia suggests that a higher construal level should lead to less indulgence (Fujita et al. 2006), recent work on hyperopia implies just the opposite. This research aims to offer reconciliation to the above described inconsistency.

We propose that construal level interacts with self-focus, which jointly determines an individual's present indulgence level. Specifically, when self is being explicitly primed, individuals will become aware of their chronic tendencies. Because a wide range of consumers experience some degree of tightwadness and perceive themselves as having insufficient indulgence (Kivetz and Simonson 2002), self prime is likely to make people realize their hyperopic tendency. Further, because a high construal level prompts people to think about their lives in the grand scheme of things, it may cause people to experience or foresee regret as they believe they have overly deprived themselves of pleasures in life. Thus, these individuals will try to correct their hyperopic tendency by engaging in more indulgence, such as spending more on hedonic products at the present moment. In contrast, when these self-focused individuals are primed with a low construal level, they should behave according to their immediately accessible chronic disposition. Thus, they would follow their hyperopic tendency, shying away from indulgence. In other words, when self is made salient, we expect to replicate findings from the hyperopia literature, i.e., a high versus low construal level should lead to more indulgence.

On the other hand, when self is not made salient, we expect that people may not become consciously aware of their chronic behavioral tendency. Consequently, the more salient manipulation of construal level will override any people's chronic tendency and determine indulgence level. Here, we expect to replicate the findings observed in the traditional research on myopia, namely a high versus low construal level should lead to less indulgence (e.g., Fujita et al. 2006; Trope et al. 2007).

A set of five experiments were conducted which offer support to our theory. Study 1 tests our above predictions directly by manipulating construal level (high vs. low) and self focus (self vs. control). The focal task involved presenting participants with a list of the hedonic and utilitarian products and asking them to indicate their highest willingness-to-pay (WTP) for each item. Higher WTP indicates greater indulgence. As expected, when self was not made salient, we replicated findings in the myopia literature, such that participants indicated higher WTP for both types of products (utilitarian and hedonic) when they were in low versus high construal level. However, when self was made salient, we observed the anticipated reversal as predicted in the hyperopia literature, but only for hedonic products (i.e., a high versus low construal level led to greater WTP). For utilitarian products, however, construal level did not affect these self-focused individuals' WTP, presumably because utilitarian products may not provide the kind of indulgence that hyperopic individuals are looking for at the high construal level. Thus, in the subsequent studies, only hedonic products were included.

While study 1 offer reconciliation to the inconsistency in the self-control literature, it does not shed light on the well-established

resource-depletion model of self-control. This model posits that individuals have limited resources, and depletion in resources leads to myopia (Vohs and Schemichel 2003). Although a large number of studies have established the resource-depletion effect, it is not entirely clear why resource depletion leads to myopia. Building on our theorizing and findings from study 1, we propose that resource availability can affect individuals' construal level, which consequently affects indulgence. Limited (ample) resources are likely to cause individuals to construe things at a lower (higher) level, thus leading to greater (less) indulgence. If the above hypothesis is true, we should also observe the moderating effect of self focus on the relationship between resource availability and indulgence level. We test these theorizing in the next two studies.

Study 2 tests the hypothesis that resource level affects construal level which subsequently influences indulgence. Resource level was manipulated via having participants remember either a two-digit (high resource level) or an eight-digit (low level) number, and participants' current construal level was measured via the 25-item BIF scale (Vallacher and Wegner 1989). The focal task involved having participants indicate their WTP for the five hedonic products as used in study 1. Replicating prior research, we found that resource depletion (vs. ample resources) led to higher indulgence (i.e., WTP). More importantly this relationship was mediated by construal level.

Building on study 2, study 3 aims to replicate study 1 results by replacing construal level with resource level. Thus, this study employed a 2 (self focus: self vs. control) X 2 (resource level: high vs. low) between subjects design. Results from this study provided theoretical replication of study 1. Specifically, when self was made salient, participants revealed greater indulgence when they had high versus low resources. However, when self was not primed, we replicated the resource depletion model prediction, i.e. greater indulgence when people had low versus high resources.

Study 4 extends on our basic theorizing by identifying an important moderator, namely individuals' chronic hyperopia tendency. We propose and find that the two-way interaction between resource level and self focus as shown above is only salient among high hyperopia individuals. Finally, study 5 demonstrates that our effects are specific to hyperopia individuals, who experience regret about their self-control behavior. If for certain individuals, they do not experience regret about their self-control tendency, like those who are high on the self-control scale, the above interaction was not expected, nor observed.

In sum, this research reconciles an apparent discrepancy in the self-control literature, thus bridging two separate lines of research (i.e., myopia and hyperopia). In addition, we add to the construal level literature by demonstrating that resource availability affects construal level, which subsequently determines individuals' current indulgence.

“Being Indulgent and Becoming Prudent”

Danit Ein-Gar, Tel Aviv University, Israel

Camille Su-Lin Johnson, San Jose State University USA

It is proposed that momentary self-definitions may be associated with specific mindsets and that these mindsets can impact how consumers behave in self-control dilemmas. Specifically, we suggest that defining oneself in the future leads to prudent preferences and choices while defining oneself in the present leads to more hedonic preferences and choices. The underlying process concerns the association of the momentary self-definitions with different levels of construal.

A momentary self-definition may be characterized as defining oneself in terms of the present state and condition; the being mindset, or in terms of whom one is becoming; the becoming

mindset, (Blanton, 2001; Johnson & Stapel, 2009; Markus & Nurius, 1986). We argue that the being mindset is characterized by low levels of construal in which objects are processed in terms of their concrete characteristics. In contrast, we argue that the becoming mindset is characterized by high levels of construal in which objects are processed in terms of their abstract characteristics.

Shifts in self-definition should be accompanied by shifts in construal level for a variety of reasons. First, being and becoming mindsets differ temporally and temporal factors influence construal level. That is, defining oneself in the moment may feel temporally closer than when defining oneself in the future. Hence, the being mindset should be associated with lower level construals than the becoming mindset. Second, these self-definitions are related to factors that increase psychological distance, and therefore influence construal levels (Kim, Zhang, & Li, 2008; Liberman, Trope & Wasklak, 2007). Given that descriptions of the self in the present may be higher in their probability of being correct or accurate; these self-definitions should psychologically be closer than self-definitions based on future change. Thus, the being self should be accompanied by lower levels of construal and the becoming self should be accompanied by higher levels of construal, (Todorov et al., 2007).

In addition to altering levels of construal, changes in self-definitions are expected to influence behavior in self-control dilemmas, with becoming selves associated with greater self-control than being selves. These predictions are based, in part, on previous research demonstrating that shifts in temporal focus and orientation influence behavior in self-control dilemmas because they alter levels of construal (Fujita, Trope, Liberman & Levin-Sagi, 2006; Malkoc, Zauberman, & Ulu, 2005). Similarly, because the becoming self leads to higher levels of construal and these levels of construal carryover to subsequent situations (Malkoc, Zauberman, & Bettman, 2008), people who are defining themselves in terms of the future should be better able to engage in acts of self-control than people who are defining themselves in terms of the present.

Apart from influencing preferences for products, being and becoming mindsets should be associated with differential sensitivity to product information. In general, product information that matches consumer's motivational state is valued whereas product information that mismatches consumer's goal states is devalued (Fishbach & Zhang, 2008; Hong & Lee, 2008). Accordingly, in a becoming mindset, individuals should find information regarding the practicality of a product to be more persuasive, while, in a being mindset, information regarding the indulgent qualities of a product should be more persuasive.

Study 1 ($n=67$, $age_{mean}=36.85$) examined the relation between construal levels and self-definitions. To activate becoming or being selves, participants wrote a brief self-description about “who you may become, focusing on the person you may develop into” (becoming) or about “who you are right now, focusing on the stable things that define your personality” (being). Participants in the becoming condition described themselves more abstractly (i.e. higher level construal) whereas participants in the being condition used more concrete nouns (i.e. lower level construal) ($F(1, 65)=9.93$, $p=.002$).

Study 2 ($n=64$, $age_{mean}=19.5$) examined how eliciting a being or becoming self affects spending preferences in an open-ended context. Participants wrote a brief self-description (same as in Study 1) and then imagined that they had just won \$1000 in a raffle. In the becoming mindset participants listed more prudent spending choices while in a being mindset they listed more indulgent choices ($\chi^2(4, N=64)=3.83$, $p=.05$).

In Study 3 ($n=72$, $age_{mean}=36.92$) participants were asked to imagine they were having a housewarming party. They assembled a gift registry from a selection of 20 gift items. Activation of

mindsets was the same as in Study 1. Participants in a becoming mindset preferred practical to indulgent options more than participants in the being mindset ($\chi^2(2, N=72)=6.39, p=.04$).

Study 4 ($n=89, \text{age}_{\text{mean}}=21.6$) activated becoming or being mindsets in a more subtle way. Participants were presented with what they believed was an advertisement. The advertisement exhorted the participants to think about themselves in terms of who they are becoming, or who they are now. At the end of the study participants choose one of two snack bars (hedonic vs. prudent). Participants in the becoming mindset were more likely to choose the prudent snack, whereas those in the being mindset showed the opposite ($\chi^2(1, N=84)=5.72, p=.01$).

Study 5 ($n=71, \text{age}_{\text{mean}}=48.57$) Shoppers were addressed before entering a convenience store and asked to read an advertisement that elicited a being or becoming self-definition (as in Study 4). After they completed their shopping trip, they were given a choice of a snack as a reward. Shoppers in the being mindset preferred the indulgent option (i.e. chocolate bar), whereas shoppers in the becoming mindset preferred the prudent option (i.e. apple or no snack), ($\chi^2(1, N=71)=4.12, p=.04$).

Study 6 ($n=103, \text{age}_{\text{mean}}=24.18$) examines how lower construal level (i.e. being mindset) will lead to greater valuation of a hedonically-framed product while the higher construal level (i.e. becoming mindset) will lead to greater valuation of a prudently-framed product. Accordingly, when the advertisement and mindset matched, participants evaluated a car more positively, than when they mismatched ($t(99)=2.17, p=.03$).

“An Obligation to Work or an Opportunity to Play? The Influence of Task Construal and Task Completion on Regulatory Behavior”

Juliano Laran, University of Miami, USA

Chris Janiszewski, University of Florida, USA

One of the most popular explanations of self-control failures is the depletion hypothesis (Muraven and Baumeister 2000). This hypothesis posits that people control their behavior by drawing on a limited supply of regulatory resources. We propose a different approach to understanding regulatory behavior. We argue that effortful behaviors can be construed as “work” or as “play”. When they are construed as an obligation to work, the person engages in the behavior in anticipation of a subsequent reward: work is a means to an end. Interruptions to the effortful behavior encourage a person to continue to work (so as to deserve the reward), whereas completing the behavior encourages the person to seek the reward. When regulatory behaviors are construed as an opportunity to play, completing the behavior is the reward in itself: the work is play (work is the reward). Interruptions to the behavior encourage a person to find alternative means of being rewarded (i.e., self-regulation declines), whereas completing the behavior provides an experience of gratification. We hypothesize that low (high) self-control people are more likely to interpret behaviors as obligations to work (opportunities to play). Completion (vs. interruption) of a self-regulatory task should encourage less (more) subsequent regulatory behavior for low (high) self-control people. Our studies featured a task that required self-control at time 1, a manipulation of this task as incomplete or completed, and a task in which participants could exert as much self-control as they wanted at time 2. We also measured self-control as an individual trait.

In study 1, participants were given M&M’s and Skittles and asked to put one piece of each in their mouth and take it out. They answered questions about the candies, were asked to hold one piece of each in their finger, and answered additional questions about the candies. Participants were either told that they were done with the first study (completed task condition) or to advance in order to

answer additional questions about their behavior as consumers (incomplete task condition). Time 2 involved a 20-minute filler task, which was done while the rest of the candies were in participants’ work stations. We weighed how much candy participants ate and used this as a measure of regulatory behavior. Low self-control participants ate more candy in the completed task condition ($M=34$ grams) than in the incomplete task condition ($M=22$ grams). High self-control participants ate more candy in the incomplete task condition ($M=40$ grams) than in the completed task condition ($M=29$ grams), all p ’s $<.05$. A pretest indicated that low self-control participants saw the time 1 task as more of an obligation to work than high self-control participants. Because low (vs. high) self-control participants saw the task as an obligation to work, completion led them to seek more rewarding behaviors.

In study 2, we show that if a task is framed as “work”, this will lead everyone to perform less self-regulation. In one condition, we replicated the results of study 1. In a second condition, we asked participants to choose the minimum amount of M&M’s and Skittles they needed in order to perform the initial candy task. Making participants abide by a minimum would lead them to see the task as obligation to work. In this condition, all participants ate more candy in the completed ($M=35$ grams) than in the incomplete task condition ($M=24$ grams), all p ’s $<.05$.

In study 3, we show that a task can be framed to be “play”, which will lead everyone to perform more self-regulation. When the time 1 task was said to be a fun task (the sentence “this is a fun task” was added to the instructions), all participants performed more regulatory behavior in the completed than in the incomplete task condition.

In summary, low self-control and high self-control people construe their worlds differently. Low self-control people perceive many behaviors, especially regulatory behaviors, as taxing and difficult (depleting). Upon completion of a taxing behavior, a low self-control person is more likely to exhibit regulatory failure. High self-control people perceive many behaviors as challenging and rewarding. Upon completion of a challenging behavior, the high self-control person is likely to sustain regulatory behavior. Most importantly, our manipulations show conditions under which people in general are more prone to self-regulatory failure, and conditions under which we can encourage increased regulatory behavior despite of people’s natural self-control tendencies.

“The Impact of Positive Affect on Cognitive Decision Making Strategies: The Case of Mental Accounting”

Yuliya A. Komarova, University of South Carolina, USA

Kelly L. Haws, Texas A&M University, USA

Amar Cheema, University of Virginia, USA

Mental accounting is a widely adopted cognitive method of keeping track of spending and controlling consumption (e.g., Prelec and Loewenstein 1998). Individuals often use mental accounts to constrain spending by allocating budget limits (Heath and Soll 1996). Cheema and Soman (2006) demonstrate that motivated individuals may depart from mental accounting predictions when there is sufficient ambiguity in how an expense should be categorized (e.g., a restaurant experience may be categorized as either a food or an entertainment expense), via a process of malleable mental accounting. Our primary objective is to understand the role of positive affect on this process of mental accounting.

Although affect can impact judgment and decision making directly (cf. Pham 1998), in the context of financial budgeting, the associated regulation mechanisms (i.e., coping with heightened levels of affect) may reduce one’s ability to engage in malleable mental accounting. In summary, we aim to: (1) investigate the influence of positive affect on spending, (2) examine the moderat-

ing role of expense ambiguity, and (3) explore the underlying mechanisms.

Predictions. In the past, the research on the role of mood regulation in self-control has focused on regulation of negative mood and generally, demonstrated the superiority of the neutral state (Tice and Bratslavsky 2000). However, in the context of mental accounting, one's cognitive resources are least taxed and available for flexible categorization when an individual is in a neutral state. Positive mood has been shown to lead to enhanced cognitive elaboration as well as greater efficiency in decision making (e.g., Aspinwall 1998; Pham 1998). More importantly, however, supporters of the hedonistic view on affect regulation (cf. Martin 2001) would predict that relative to a neutral state, when one is in a positive mood, their motivation to seek immediate hedonic pleasure should be lower. Consequently, in the presence of expense ambiguity, those in a less positive (neutral) state should be more likely to engage in motivated reasoning in order to construct justifications for spending. Hence, we predict that expense ambiguity should moderate the effect of positive mood on spending. We tested these predictions in two studies.

Study 1. Our studies adapt the procedure developed by Cheema and Soman (2006). A description of budgetary constraints was preceded by an affect manipulation. To test our prediction regarding the effect of positive affect on spending we conducted a 2 (affective states: happy, neutral) x 2 (expense ambiguity: low [comedy show—entertainment expense], high [restaurant—food or entertainment expense]) ANOVA with likelihood of spending as a dependent variable. The findings supported our prediction, as only participants in a neutral state took advantage of expense ambiguity and engaged in malleable mental accounting leading to higher likelihood of spending.

All participants also rated the restaurant expense as a 'typical food expense'. We then asked participants to imagine that they did go to the restaurant and invited them to predict pleasure from spending using three-items which were later combined into an index. We analyzed the index and the typicality ratings as two independent mediators of the relationship between affect and spending likelihood. Both mediation analyses were significant based on Sobel tests, suggesting that positive affect differentially impacted expense categorization and hedonic motivation, which subsequently influenced spending.

Next, we subjected our data to a simultaneous dual mediation analysis with both mediators in the model. While the index of anticipated pleasure from spending fully mediated the relationship, categorization of the restaurant expense as typical food became insignificant. This analysis provided initial evidence suggesting that the influence of positive affect on mental accounting and spending cannot be explained by the inhibitory role of affect in cognitive processing alone, but is also a consequence of differences in hedonic motivation.

Study 2. We designed our second study to rule out the possibility that failure on the part of individuals in a positive mood to engage in malleable mental accounting is simply a consequence of more efficient heuristic processing. We adapted our previous procedure slightly by keeping the expense ambiguous across all conditions. Here, our focal dependent variables were the time it took participants to categorize the restaurant expense as a 'typical food' expense and the time they spent completing the task. Our data revealed that participants in a positive affective (vs. neutral) state actually took longer to respond to the expense categorization question and to complete the task. These findings are consistent with a "greater-elaboration model" which predicts that "people take longer to read mood-congruent information compared to mood-

incongruent information, presumably due to greater elaboration of the congruent material" (Pury 2004, p. 156).

As a part of an ongoing research effort to further investigate the impact of affect on malleable mental accounting, we are also examining the role of cognitive load in the relationship between expense ambiguity, positive affect, and spending. Here, we anticipate a three-way interaction, so that when cognitive load is high, individuals in a neutral state can no longer justify incurring a hedonic expense, whereas those in a positive affective state may actually engage in affect maintenance resulting in greater likelihood of spending.

SPECIAL SESSION SUMMARY

Visualization, Imagination, and Product Choice: Affective Forecasting of Future Product Consumption and Utilization Experiences

Yanliu Huang, Chinese University of Hong Kong, Hong Kong, China

Robert Meyer, University of Pennsylvania/University of Miami, USA

SESSION OVERVIEW

Many product-purchase decisions are driven less by what consumers feel about products in the present and more what they imagine they will feel about them in the future. When buying furniture, for example, consumers typically try to mentally visualize how a piece will look when placed in their home or apartment, and then forecast the pleasure they will experience upon seeing it in this new context. Likewise, the purchaser of a new cellular phone tries to imagine what it would be like to use its novel features and how difficult they will be to learn—and the affective reactions these different experiences might trigger. How do consumers go about constructing such visualizations, and how accurate are the resulting affective forecasts? The answer to this question is far from fully known. On the one hand, there is a growing body of research that shows that affective forecasts are often prone to systematic biases, such as a tendency to presume that what is felt in the present (such as a product's appeal in a showroom) will be a good predictor of what will be felt about it in the future. On the other hand, the boundary conditions of these findings—particularly when applied to consumer-judgment contexts—are not well understood, and comparatively little work has investigated how consumers construct complex mental visualizations of future product experiences that form the basis of such forecasts.

The purpose of this session is to report the findings of recent research that has sought to close this knowledge gap. The four papers touch on different aspects of the general study of product imagination and forecasting: how consumers go about building mental representations of product consumption experiences that lie in the future, the accuracy of these representations, and how correctable forecast errors are both by consumers and firms.

The opening papers by Wood and Huang and Meyer report new findings on the structure and accuracy—the internal models that consumers use to construct future preferences. In, “Change versus Comfort: How Consumers Mis-Predict Their Openness to Innovation,” Wood offers evidence that consumers often are prone to hold mistaken beliefs about how some regulatory processes affect preferences. She shows that whereas consumers often believe that events that cause personal upheaval will induce an offsetting desire to avoid innovation in product choices, the opposite actually tends to be the case. In, “Tradeoffs in the Dark...,” Huang and Meyer offer an analysis of the micro-level process that consumers use to form inferences about products that are unfamiliar generalizations of existing offerings. The final two papers by Zhao, Dahl, and Hoeffler and Easwar and West examine corrective issues in affective forecasting. Zhao, Dahl, and Hoeffler take up the issue of how to best design visualization aids to aid consumers overcome affective forecasting biases, while Easwar and West look at the effectiveness of perhaps the simplest of all corrective devices: educating consumers about the existence of biases.

Taken together, the session is designed to provide an integrative overview of new research aimed at enhancing our understanding the process that underlies consumer affective forecasts as well as methods by which these forecasts can be improved. The concluding discussion will then have the goal of suggesting a research agenda for future work in the area.

EXTENDED ABSTRACTS

“Change versus Comfort: How Consumers Mis-Predict Their Openness to Innovation”

Stacy Wood, University of South Carolina, USA

Many can relate to desiring dearly familiar products in an unfamiliar or changing landscape. This phenomenon is so common in culinary practice that we have a term—comfort food—that encompasses the soothing function of our long-time favorites. One can argue that this practice goes beyond food; consumers may believe that they will prefer favorite movies, familiar music, and habits (e.g., smoking, a daily jog) when surrounded by changing life factors. Like other consumer coping strategies, consumers may believe they will choose familiar things in times of change because familiar choices minimize the cognitive/emotional load engendered by a new environment; a lay theory reinforced through external norms and internal cues. However, recent research on mindsets and habits offers a competing prediction. Changing circumstances may break habitual cues that favor old favorites and promote a general ‘change mindset’. This underlying openness to change may prompt choices counter to the “comfort” theory, creating a paradox in which consumers’ actual choices are opposite to what they predict.

Study 1. In study 1, 203 American participants were offered the following choice during an experimental session with several unrelated studies:

“Potato chips are a favorite American snack. They are also a favorite British snack, but in England, potato chips as we know them are called “crisps.” Crisps come in many of the same flavors that we have in American stores, but are also available in flavors that are not common here. Flavors like Sea Salt, Cheese & Pickle, Thai Chili & Lime, Smoky Wiltshire, Bombay Mix, and Camembert & Plum are very popular. *Two people from this study will be selected to win a prize pack of a variety of either British crisps or American chips. If you win, which prize pack do you want? Choose below by checking one box below: [Two boxes appeared here—one box showing a selection of American (Lay’s brand) chips and the other showing a selection of British (McCoy’s brand) crisps. The prize pack was described in the box as a selection of 6 full-sized bags of chips/crisps.]*”

Later (after several unrelated tasks, ~30-40 minutes), participants received several surveys, including five Likert items that assessed participants’ perceived personal level of “life change,” (e.g., “There has been more upheaval than usual in my life this month”). Responses were summed and participants were divided into two groups, High-Change and Low-Change, based on a median split of this index. It was hypothesized that consumers experiencing more change would be more likely to choose the British crisp than the American chip. Consistent with this, a significant Pearson chi-square analysis ($\chi^2=4.11$, $p=.04$) showed there was higher selection of the unfamiliar British crisp option for High-Change participants ($M=57.4\%$) than Low-Change participants ($M=42.6\%$) and higher selection of the familiar American chip option for Low-Change participants ($M=56.8\%$) than for High-Change participants ($M=43.2\%$).

Study 2. Study 2 was a prediction study. Participants were asked to consider two peers experiencing different levels of life change and to predict what choice these target others would make if given the same “chips or crisps” scenario from study 1. It was hypothesized that participants would predict (opposite to choices observed in study 1) that high-change others will choose the familiar option and low-change others will choose the unfamiliar option. Further, when given an opportunity to explain their prediction, it was hypothesized that participants would refer primarily to strategies congruent with a comfort-food lay theory. Consistent with this, 26.8% of participants predicted that Taylor (High-Change) would choose the British crisps and 73.2% predicted s/he would choose the American chips (median/modal response). Conversely, 59.8% predicted that Brook (Low-Change) would choose the British crisps (median/modal response) and 40.2% predicted s/he would choose the American chips ($\chi^2=56.26, p<.001$). The cognitive response measures (coded by two independent raters) indicated that participants offered reasons consistent with coping-oriented strategies that fit with a comfort food lay theory.

Studies 3–5. Studies 3–5 replicate the effect and further explore consumers’ forecasts of their future preference for comfort versus change. Study 3 demonstrates that the effect extends to non-food situations (choice of a range of new or unfamiliar products). Study 4 demonstrates that this effect occurs primarily when choices are characterized by low involvement. Study 5 demonstrates that choice of new options can be increased by manipulating perceived life change.

“Tradeoffs in the Dark: The Effect of Experience on Extrapolated Consumer Preferences”

Yanliu Huang, The Chinese University of Hong Kong, China
Robert Meyer, The University of Pennsylvania/University of Miami, USA

Many choices require consumers to extrapolate preferences formed in one domain of experience to an unfamiliar new one. Examples include decisions to adopt new goods or services, or judgments of the potential attractiveness of novel product-attribute combinations. While there has been considerable work investigating such related problems as inference formation and behavior in prediction tasks, less is known about either the process individuals use to make trade-offs among unfamiliar ranges of attributes or the algebraic structure of such trade-offs.

The goal of this work is to investigate dynamics of how consumers use preference knowledge gained over one range of product-attribute levels to predict their preferences for new attribute combinations. Prior work has suggested that given the limited direct experience in consuming products, predictive inferences may involve a blend of two processes: exemplar-based and rule-based. Exemplar-based policies are those that forecast utilities for new stimuli based on the experienced utility of similar options (Juslin, Olsson, and Olsson 2003; Meyer 1987), and rule-based policies are those that exploit generalized beliefs about the functional relationship between attribute values such as monotonicity and additivity (Delosh, Busemyer, and McDaniel 1997). In this project, we focus on two central research questions: 1) how does the use of these two processes (exemplar-based or rule-based) evolve as consumers develop judgmental experience in a product category; and 2) what does the answer to (1) imply about the likely accuracy of consumers’ hedonic forecasts for unfamiliar product-attribute combinations?

Central to the work is a hypothesis that the prevalence of each process will evolve over time as experience in a core judgment domain grows. Specifically, given limited experience predictions

will rely on meta-cognitive “guessing” rules that make no attempt to utilize what has been observed about product values in a core domain. As experience grows, however, knowledge gained in the core domain will be increasingly utilized, first by using exemplar-based prediction rules that draw analogies between novel products and previously-viewed ones, then by using functional prediction rules that exploited learned continuous associations between attribute levels and valuations. One of the consequences is that consumers will be prone to under-estimating the utility they will draw from novel product combinations that are objectively superior to familiar options and over-estimating the utility they will draw from inferior options. The magnitude of these errors, however, is also hypothesized in some cases to be U-shaped, where decision makers with virtually no experience at all in a judgment category may be able to provide more accurate utility predictions in novel domains than those with moderate amounts of experience.

We tested these hypotheses in six studies where participants acted as agents to learn to predict a target customer’s apartment preferences based on four attributes: travel time to work, apartment appearance, security of apartment location, and rent. Three initial studies explored the nature of extrapolation judgments when decision makers have reasonably high levels of judgmental experience in a given setting, and are asked to predict that likely utility of options that have systematically superior or inferior attribute values. Here we found asymmetric support for the predicted over-and-under estimation bias: when participants were asked to predict the likely attractiveness of a novel apartment, they over-estimated the likely value of inferior options, but were accurate in their hedonic forecasts for superior ones. In contrast, when participants were asked to predict the unattractiveness of an apartment, participants under-predict the attractiveness of superior options. Studies 4 and 5 explored the boundary conditions of these prediction biases based on the amount of prior judgmental experience and the underlying “true” utility-generating rule. As predicted, the forecasting bias was most pronounced among participants with moderate amounts of judgmental experience (Study 4) but this advantage of little experience vanishes when the underlying composition rule is a complex one unlikely to be naively guessed (Study 5).

Direct evidence of the hypothesized evolution of inference strategies was provided by a sixth study where at periodic junctures of the prediction task participants were asked to type a written description of the process they had used to make the previous judgment, and these statements were content-analyzed. Consistent with the hypothesized strategy evolution, statements gave strong evidence of a use of generalized principles when direct experience was limited, exemplar-based strategies when experience was moderate, and rule-based strategies when experience was more extensive.

“Matching Time Perspective and Visualization Aids to Enhance New Product Evaluation”

Min Zhao, University of Toronto, Canada
Darren Dahl, University of British Columbia, Canada
Steve Hoeffler, Vanderbilt University, USA

How will visualization aids impact new product evaluation under a retrospective versus an anticipatory perspective? In the new product domain, the common wisdom is that imagining the usage of a new product in a future scenario leads to higher evaluations than relating it to a past experience (Dahl, Chattopadhyay, and Gorn 1999). In our work, we draw on research on retrospection and anticipation in terms of people’s natural mental construal and use these results to propose different effects of visualization aids for retrospective and anticipatory visualization.

Existing work on retrospection and anticipation has indicated that past events are generally construed as more detailed and concrete whereas future events are construed as less detailed and more abstract (Van Boven, Kane, and McGraw 2008). At the same time, existing research on consumer decision making over time has demonstrated that the type of information had the greatest impact on evaluation when it fits consumers' natural mindset in terms of construal levels (e.g., high-level information such as feature upgrade had a larger impact on consumers' purchase intention for a distant future decision where consumers' natural thoughts were at a higher level, whereas low-level information such as coupon had a larger impact on purchase intention in the near future where consumers' natural thoughts were at a lower level (Thomas, Chandran, and Trope 2007). Based on these previous findings, we predict that a match of the construal levels between visualization aids and temporal perspective would increase the evaluation of new products. Since people's natural mental construal for the past tends to be concrete, we hypothesize that concrete visualization aids will be more effective in increasing new product evaluation for retrospective visualization. However, since people's natural mental construal for the future tends to be abstract, abstract visualization aids will be more effective in increasing new product evaluation for an anticipatory visualization. In addition, we predict a reversal of this pattern when people's natural temporal perspective is reversed.

We test our hypotheses in three experiments. In all three experiments, the key constructs that we manipulated were level of concreteness of the visualization aids and temporal perspective of the visualization. To manipulate temporal perspective, we asked participants to either relate the target product to a past or future scenario. In terms of level of concreteness of the visualization aids, different operationalizations were used across the three experiments.

In experiment 1, a mock advertisement of a Tablet PC was used as our stimuli. We manipulated concreteness level by providing participants with either one or five examples about using the new product. The results showed that when participants related the new product to their past experience, concrete visualization aids increased their evaluation. However, when they related the product to the future, abstract visualization aids enhanced product evaluation.

In experiment 2, we used a new technology (Tap & Go PayPass) as our stimuli. We manipulated the concreteness of visualization aids by providing participants with either usage process-related aids (i.e., how to use this new technology) as concrete aids or benefit-related aids (i.e. why adopting this new technology) as abstract aids (Liberman and Trope 1998; Vallacher and Wegner 1987, 1989). The results fully replicated our findings in experiment 1.

In experiment 3, we manipulated the concreteness of visualization aids by providing the same sample activity of using a Tablet PC, but describing it with lots of details in the concrete conditions, and describing it with very general wording in the abstract conditions. However, in this experiment, we shifted people's natural construal level by instructing them to think more abstractly for the past and more concretely for the future. If the match of the construal levels was the key driver of our results in experiments 1 and 2, the effects that we observed in experiments 1 and 2 should be reversed after we shifted the natural construal level. Indeed, we found that abstract visualization aids increased retrospective evaluation and concrete visualization aids increased anticipatory evaluation after the natural construal level was shifted.

Our work contributes to recent research on visualization and new product learning by demonstrating the importance of the match

between the specificity of the visualization aids and temporal perspective on new product evaluation.

“The Interactive Effect of Affective Forecasting and Mood on Performance and Product Goals”

Karthik Easwar, Ohio State University, USA

Patricia West, Ohio State University, USA

Many consumer decisions involve the setting of future goals. People join gyms with the goal of losing twenty pounds, buy musical instruments hoping to learn to play them, and buy new phones expecting an easier and more pleasurable calling experience (Olshavsky and Miller 1972). These goals are driven by various motivations, including our desire to maintain a positive mood. The mood-maintenance hypothesis (Isen 1983) states that we engage in activities that ensure positivity. Given that goals divide outcomes into successes and failures, mood maintenance contends that we set goals we expect to surpass. However, people often commit affective forecasting errors (AFE) by overestimating the future pain of failure and pleasure of success—potentially leading consumers to set inappropriate goals for themselves or during product related decisions (Kermer 2006). The following experiment examines how providing consumers with AFE knowledge influences their desire to engage in mood maintenance and goal-setting.

In study one, two factors are manipulated: AFE knowledge and mood. AFE knowledge was manipulated through passages that stated that the AFE is an overestimate of the impact of positive outcomes, an overestimate of the impact of negative outcomes, or a control passage. To manipulate mood, subjects elaborated on a good or bad experience. In the neutral mood condition subjects were given no elaboration task. Finally, in an ensuing anagram task, subjects set an anagram performance goal.

Subjects in a positive mood will engage in mood maintenance and set lower goals than those in a negative mood. However, this mood maintenance motivation can be removed with knowledge of the AFE. This knowledge removes the fear of losing positivity and frees people to set high goals. In a positive mood, we focus on preventing affective loss; therefore, knowledge of the AFE as affective gain overestimation will neither be relevant nor impact goals. Only under certain conditions will AFE knowledge enable subjects to set higher goals.

There were no significant differences between the different neutral mood conditions; therefore, they were pooled into a control condition. A 3 X 2 ANOVA revealed a significant interaction ($F(2, 262)=4.17, p=.016$). It was found that, in a positive mood, subjects exhibited mood maintenance, setting lower goals to ensure success ($M_{\text{positive mood, no AFE knowledge}}=25.2, M_{\text{negative mood, no AFE knowledge}}=30.8, M_{\text{control}}=30.7, t(391)=2.12, p=.02$ and $t(391)=2.32, p=.01$, respectively). However, if told the AFE was an overestimation of negative affect, subjects knew a failure would not be devastating and set higher goals than with no knowledge ($M_{\text{positive mood, negative AFE knowledge}}=34.5, M_{\text{positive mood, no AFE knowledge}}=25.2, t(391)=3.31, p<.001$). Subjects in the positive AFE passage condition set lower goals than the negative AFE passage condition ($M_{\text{positive mood, negative AFE knowledge}}=34.5, M_{\text{positive mood, positive AFE knowledge}}=25.1, t(391)=3.32, p<.001$), supporting the hypothesis that those engaging in mood maintenance focus on preventing loss.

While study one focuses on performance goals, these effects can also apply to the expectations we have for products. We often make product evaluation forecasts; how we think we will feel about the product (Zhao et al. 2009, Wood 2009). Knowing our AFE tendencies, we may realize that most products are satisfying and few overwhelm. We need neither the tiniest camera nor the loudest

speakers to be happy and one weakness should not ruin product evaluations. Future studies plan to explore how the AFE influences product goals, not just performance goals.

Mood can affect our desire to engage in product exploration. One can easily imagine how exploring a product, with difficult menus, infinite settings and peripheral features can lead to frustration. In this light, the anagram task could be considered a simplified product exploration task; both are time consuming, non-linear processes. Fearing frustration, we may engage in mood maintenance and not explore our product fully. Knowing our mood state is safe, might remove this fear of exploration. And often, the nuances we find are what make us truly pleased with our products.

SPECIAL SESSION SUMMARY

Setting the Stage: How Frames of Reference May Be Influencing Your Behavior

Rebecca Hamilton, University of Maryland, USA

SESSION OVERVIEW

Research on consumer decision making suggests that instead of having completely formed preferences prior to choice, consumers often construct their preferences at the time these are needed to make decisions (Bettman, Luce and Payne 1998). As a result, the context in which consumers make decisions can significantly influence their preferences among alternatives and even their willingness to pay for these alternatives.

In addition, there is a large literature showing that the way questions are asked can have a significant effect on consumers' self-reported judgments. For example, when consumers are asked to report the frequency with which they engage in a behavior such as watching TV, their responses are systematically influenced by the response scales used to provide the information (Menon, Raghuram and Schwarz 1995; Schwarz, Hippler, Deutsch and Strack 1985).

In this session, we bring together these two literatures, showing that managers may be able to influence important purchase-related variables such as confidence, affect and willingness to pay by using the right response scales. For example, although sensory scientists often assume that basic sensory evaluation is not as susceptible to bias as higher level evaluations such as product preferences, research by Mantonakis, Schwarz, Wudarzewski and Yoon (Paper 1) shows that the numeric values of the scale can bias tasters' perceptions and encoding of sensory attributes for wines. Moreover, the scales used predict willingness to pay for the wines tasted (Mantonakis is an Associate Fellow at The Cool Climate Oenology and Viticulture Institute).

Further, while most of the extant research on behavioral frequency judgments has focused on cognitive factors, Menon and Agrawal (Paper 2) investigate how consumers' emotions impact their use of response scales. Both the valence and the uncertainty of the emotions experienced predict the degree to which consumers rely on self-generated information as opposed to being influenced by contextually available information such as the response scales being used.

Consistent with Paper 2, Hamilton, Ratner and Thompson (Paper 3) examine emotions in addition to cognitive responses, and Ülkinen, Thomas and Morwitz (Paper 4) examine the role of certainty. Paper 3 shows that consumers who use a high-frequency scale to report how often they would use a product are less interested in purchasing it than those who use a low-frequency scale, even though they report higher absolute frequencies. Moreover, low-frequency scales increase perceived use of the product relative to other consumers and positive affect. Subsequent studies replicate these results using advertisements suggesting that either high- or low-frequency use is the norm. Relatedly, Paper 4 shows that the scale on which consumers are asked to report their budgets (one year vs. 12 months) significantly affects both budget estimates and confidence in these estimates, suggesting potential consequences for consumer spending.

Together, these papers extend the scope of research on response scale effects by examining how initial frames of reference shape downstream variables such as confidence, affect and willingness to pay. We expect this session to provide insights interesting to a wide range of researchers: those studying sensory perceptions, decision making, persuasion and survey design.

Norbert Schwarz (University of Michigan) served as the session discussant. Beginning with the classic paper by Schwarz et al. (1985), Norbert has published dozens of papers examining the

effects of initial questions on subsequent responses. With his deep expertise on this topic, Norbert concluded the session with a rich and rewarding 10-minute discussion.

EXTENDED ABSTRACTS

“How the Numbers on Your Rating Scale Influence Taste Perception and Willingness to Pay”

Antonia Mantonakis, Brock University, Canada

Norbert Schwarz, University of Michigan, USA

Amanda Wudarzewski, Brock University, Canada

Carolyn Yoon, University of Michigan, USA

Sensory scientists often assume that consumers are rational decision makers (Köster 2003). While much is understood about genetic differences leading to variations in taste perception (Bartoshuk, Fast and Snyder 2005), visual and verbal cues (Hoegg and Alba 2007) that impact perceptual and cognitive processes and can lead to biased judgment are only beginning to be understood. Similar to recent research demonstrating that factors undiagnostic to perception can lead to errors in judgment (Krishna 2006; Krishna and Morrin 2008), we investigate how information extraneous to sensory evaluation can lead to errors in perception.

Little is known about how factors completely unrelated to the product, such as the context, can influence utility derived from the sensation. It has been argued that perceptual systems have been optimized by evolution (Abdi 2002), and that sensory inputs are inherently evaluable (Hsee et al. forthcoming). Thus “sensory utilities” (versus prediction or memory utilities) should not be biased by contextual factors (Hsee et al. 2009). However, previous studies showing that context has no influence on sensory utility have manipulated context by creating contrasts of varying superiority (e.g., eating potato chips in the context of either a better–chocolate–or worse–sardines–alternative; Morewedge et al. 2009). Instead, we manipulate contextual factors completely unrelated to the consumption object: the format of the rating scale on which sensory reports are given.

Textbook discussions of rating scale formats usually focus on the number of scale points used and the extremity of the scale labels. What is often overlooked is that the numeric values of the rating scale can influence the interpretation of the scale labels (Schwarz et al. 1991; Schwarz 1994). Suppose, for example that you are asked to evaluate the intelligence of a public figure on a scale from “not intelligent” to “very intelligent”. What does “not intelligent” stand for? Does it indicate the absence of superior intelligence or the presence of its opposite, some level of stupidity? To resolve this ambiguity, survey respondents have been found to draw on the numeric values of the rating scale (Haddock and Carrick 1999). In general, a unipolar scale (e.g., 0 to 10) pertains to different degrees of the attribute (intelligence), whereas a bipolar scale (-5 to +5) pertains to degrees of the attribute and its opposite. Accordingly, bipolar scales elicit higher ratings than unipolar scales.

We apply this logic to ratings of sensory experience. We gave participants a hedonic product to sample. Half of the participants gave their ratings on various attributes on a bipolar scale, using endpoints from -5 to +5. The other half gave ratings on a unipolar scale, using endpoints from 0 to 10. We predicted that participants who rate on a -5 to +5 scale should indicate higher hedonic evaluations of the attributes than those who rate on a 0 to 10 scale. We should see the same effect for willingness to pay, such that

participants who rate on a -5 to +5 scale have a higher WTP than those who rate on a 0 to 10 scale.

The study was conducted in one session. We gave participants a glass of wine and allowed participants to taste it; they answered questions based on hedonic attributes of the wine (crispness, freshness, fruitiness and complexity), which were administered on either a 0 to 10 scale or a -5 to +5 scale. Next, we gave participants questions pertaining to the wine they had just tasted and their level of wine expertise. Of particular interest was the answer to the question, "How much would you be willing to pay for a bottle of this wine?"

Ratings on the 4 attributes (freshness, crispness, complexity and fruitiness) were correlated ($\alpha=.51$); ratings were combined to produce a single evaluation index. To examine whether the numerical values manipulation affected evaluation, we examined mean differences between the two groups, with expertise as a covariate. Evaluation was higher for the -5 to +5 endpoint group ($M=7.14$) than the 0 to 10 group ($M=6.53$), $F(1,77)=5.51$, $p<.03$. To examine whether the numerical values manipulation affected WTP, we examined mean differences between the groups, with expertise as a covariate. We found that WTP was higher for the -5 to +5 endpoint group than the 0 to 10 group (WTP means=\$17.51 and \$15.05; $\log(\text{WTP})$ means=2.80 and 2.61; $F(1,77)=4.07$, $p<.05$).

In a follow-up study, we will use a two session procedure to replicate our results and examine the effects of scale labels on retrospective evaluations of taste (cf. Braun 1999).

"When Behavioral Frequency Judgments Depend on Incidental Emotions"

*Geeta Menon, University of Pennsylvania, USA
Nidhi Agrawal, Northwestern University, USA*

There is a vast literature on how consumers use self-generated (memory-based) information, or rely on contextually-available information (stimulus-based), or combine these two sources of information (mixed) in arriving at judgments (see Lynch 2004 for a review). Feldman and Lynch's (1988) Accessibility-Diagnosticity model proposes that the likelihood that an input will be used for a judgment is directly related to its accessibility and diagnosticity, and inversely related to the accessibility and diagnosticity of alternate sources of information. This model has been empirically tested in various consumer domains including brand evaluations (e.g., Lynch, Marmorstein, and Weigold 1988) and survey responses (e.g., Menon, Raghuram and Schwarz 1995, 1997). This stream of research has focused primarily on cognitive factors in information processing and judgment formation. In this paper, we present evidence for the effects of emotional factors on the formation of behavioral frequency judgments.

We examine the effects of incidental emotions varying in valence and uncertainty (i.e., happiness, hopefulness, sadness and anxiety) on whether self-generated vs. contextually-available cues are relied on more heavily to form behavioral frequency judgments. Menon et al. (1995) show that when self-generated information is not readily accessible or diagnostic, respondents rely on contextually available information. We posit that when information is accessible and diagnostic, as in the case of regular behaviors, incidental emotions do not moderate the use of this information in forming judgments; thus, regardless of the emotion experienced, we should replicate the results of Menon et al. (1995). However, we posit a moderating effect of incidental emotions on the use of self-generated vs. contextually-available information for irregular behaviors. Based on extant work, we propose that the appraisal dimension of emotional valence leads people to systematically rely on different inputs in computing behavioral frequency judgments. Positive emotions encourage a reliance on memory and pre-exist-

ing knowledge structures, while negative emotions tend to encourage a greater scrutiny of the contextual information represented by the response alternatives.

Beyond emotional valence, however, emotional uncertainty serves as an input on whether people should trust their initial inferences or not. Uncertainty casts doubt on inferences derived based on valence-driven input and leads people to rely on the alternate input (Tiedens and Linton 2001). When feeling certain, people go along with the inputs flowing out of the emotional valence appraisal dimension. But when people feel uncertain, they attribute the uncertainty to the valence-driven judgments. This doubtfulness leads them to go with the alternate process. Specifically, for positive emotions, both happy (a certain emotion) and hopeful (an uncertain emotion) people are likely to evoke self-generated inputs. The certainty accompanying happiness leads people to trust their self-generated inputs and the uncertainty accompanying hopefulness casts doubt on the self-generated inputs and drives people to consider information beyond their memory such as that gleaned from the context. Hence, happy people rely more on self-generated input and hopeful people on the response alternatives.

A similar process occurs for people experiencing negative emotions. While both sad (a certain emotion) and anxious (an uncertain emotion) people are more likely to focus on contextual factors than self-generated information, the certainty associated with sadness leads sad people to trust the contextual inputs and base judgments on response alternatives. In contrast, the uncertainty associated with anxiety leads anxious people to doubt judgments based on their default process, i.e., response alternative based judgments, so they resort to memory cues.

We demonstrate these results in two experiments in which we prime emotions varying on valence and uncertainty. In experiment 1, we prime happiness, hopefulness, sadness and anxiety in a 2 (valence: positive vs. negative) x 2 (uncertainty: certain vs. uncertain) x 2 (response alternatives: high vs. low) x 2 (regularity of behavior: irregular vs. regular) mixed design in which the first three factors were manipulated between-subjects, and the last within-subjects. In experiment 1, we demonstrate the predicted effects of the valence and uncertainty dimensions of emotions moderated by the regularity of the behavior on behavioral frequency judgments and the reliance on self-generated versus contextually-available information. In experiment 2, we replicate these results in a similar 2 x 2 x 2 x 2 design in which we include process measures of: (i) perceptions of confidence in the behavioral frequency estimate; (ii) self-reported reliance on the input used in judgment; and (iii) response latencies for forming behavioral frequency judgments. Experiment 2 provides evidence for the lower confidence and greater response times associated with uncertain emotions.

By identifying emotional antecedents to the use of self-generated versus contextually available information, we add to the literature on information processing and emotions, as well as to the substantive domain of survey methodology.

"Will I Get My Money's Worth? Inferring Product Value Based on Predictions about Relative Use"

*Rebecca Hamilton, University of Maryland, USA
Rebecca Ratner, University of Maryland, USA
Debora Thompson, Georgetown University, USA*

When considering the purchase of a durable product, will consumers be more likely to make the purchase if they think about using it every day or if they think about using it every week? From an economic perspective, using a durable product more frequently should increase its perceived value. However, we suggest that when considering the perceived value of a product, consumers also think

about how often they will use it compared with other consumers. If consumers believe others will use the product more than they will (i.e., they are relatively light rather than relatively heavy users), they may not be willing to pay as much for the product. That is, we propose that product value is a comparative judgment rather than an absolute judgment.

In studies 1 and 2, consumers first reported their frequency of using a product with either a high- or low-frequency scale. After reporting their absolute frequency of use, they evaluated their interest in owning the product, and then they assessed whether their frequency of use was subjectively “a little” or “a lot.” In study 1, half of the participants evaluated a USB drive and half evaluated a scientific calculator. Although those who initially used the high-frequency scale reported higher absolute frequency of use ($F(1, 194)=45.1, p<.001$), consistent with earlier research (Schwarz, Hippler, Deutsch and Strack 1985), they reported lower subjective frequency of use ($F(1, 194)=4.8, p<.05$) and were less interested in buying the product than those who saw the low-frequency scale ($F(1, 194)=6.0, p<.05$). A mediation analysis shows that participants’ subjective perceptions of how much they would use the product mediate the observed scale label effects (Sobel test=2.06, $p<.05$).

Our second study replicated these results using a different product category, video games, and extended them by examining behavioral intentions towards specific products. Interest in the specific video game we showed participants was higher in the low than in the high-frequency scale condition, $F(1, 121)=9.6, p<.01$. Notably, this study also showed that participants in the low frequency scale condition reported more positive affect than those in the high frequency condition, and that positive affect was significantly correlated with perceived frequency of use relative to others ($r=.54, p<.001$). This suggests that consumers may experience an affective boost when they infer a positive comparison of their own use of a product relative to others.

Our third and fourth studies extend our analysis beyond frequency scale manipulations to show that advertising a product as appropriate for weekly use as opposed to daily use can lead to higher subjective frequency of use and higher purchase intentions. In study 3, respondents either read an ad for a sandwich press or for fitness shoes. The ad described the product as providing benefits experienced daily (high-frequency) or weekly (low-frequency). As predicted, those in the week condition predicted higher relative use compared to those in the day condition, $F(1, 83)=5.57, p<.05$, even though the ad described less frequent product use. Moreover, using the words “this week” in the advertisement significantly increased participants interest in the product relative to using the words “today” ($F(1, 83)=4.29, p<.05$). Confirming the proposed process mechanism, perceived relative use mediated the effect of the ad on interest in the product.

In our last study, we show that whether the respondent is a light or heavy user in the product category moderates the effect. Specifically, heavy users are motivated by high frequency positioning while light users are demotivated by high-frequency positioning. Participants reviewed the fitness shoe advertisements from study 3 and then reported their interest in the shoes as well as the number of times they exercised per week. As predicted, regression analysis showed that the “day” ads created more interest in the product for heavy users than the “week” ads, but the week ads created more interest for light users, $\beta=.73, t(172)=4.12, p<.001$.

Counterintuitively, manipulations that encourage consumers to predict that they would use a product more frequently may result in less interest in the product category and lower purchase intentions. Our studies show that this effect is driven by consumers’ beliefs about their own product usage relative to other consumers,

and that the effect can be produced either by advertisements or by frequency scales that communicate that either a high frequency of use or low frequency of use is the norm.

“When 12 Months is Not the Same as One Year: Antecedents of Confidence in Consumer Budgets”

Gülden Ülkümen, University of Southern California, USA

Manoj Thomas, Cornell University, USA

Vicki Morwitz, New York University, USA

Consumers’ plans are influenced by the confidence felt while making these plans (Ülkümen, Thomas, and Morwitz 2008). For example, consumers feel less confident, and therefore provide larger budget estimates for the next year than for the next month, even after these budgets are unitized (Ülkümen, Thomas, and Morwitz 2008). In this research, we examine how framing of the time period in a survey question (one year versus 12 months) can influence consumers’ confidence in different planning domains, and consequently influence a variety of outcomes such as the magnitude of budget estimates and the likelihood of starting a diet.

We examine four antecedents of confidence in consumers’ plans: (1) framing of the time period, (2) familiarity with the frame, (3) whether the sources of uncertainty are attributed to internal or external factors, and (4) perceived difficulty.

In our first study, we asked participants to provide budget estimates for time periods that differed in length or framing. Budgets for the next week, month, three months, six months and 12 months were not significantly different from each other ($M_{\text{week}}=\$701, M_{\text{month}}=\$832, M_{\text{3months}}=\$1117, M_{\text{6months}}=\$986, M_{\text{12months}}=\1066), and they were all significantly lower than the budgets for the next year ($M_{\text{year}}=\$2,196$). Consumers were less confident, and they provided larger budget estimates for the next year than for the next 12 months. Rather than the actual length, the framing of the budget period has an effect on confidence and budgets.

Study 2 tested whether this framing effect exists because people rarely use the period of a year (versus 12 months) to make predictions, and are less familiar with this frame. Participants estimated their budgets either for the next 12 months or the next year, and we manipulated familiarity by asking half of the participants to provide a series of estimates for the frame associated with their condition before providing their budget estimates. The results show that the familiarity manipulation did not affect confidence or budgets in the 12 month frame. However, confidence increased, and annual budgets decreased when the familiarity with the time frame increased.

The aim of study 3 was to examine whether consumers attribute the source of their uncertainty to both internal and external factors in the one year frame, but only to internal factors in the 12 month frame. Reminding consumers of one of these two components of uncertainty should make them discount this component. To test this prediction, we manipulated the source of uncertainty by providing some participants with a paragraph that emphasized events in life that are within (internal) or outside their control (external), before estimating their budgets. The results revealed that in the year frame, budgets were significantly lower when participants were reminded either of internal or external sources of confidence, than the budgets in the control condition. In the 12 month frame, there was no difference between budgets in the control or internal LOC conditions, but reminding participants of the external sources led to a significant increase in budget estimates.

In study 4, participants were first presented with a strict diet plan, which required avoiding a long list of foods. This diet plan was framed as either a 12 month plan or a one year plan. The results suggest that participants were more likely to adopt the diet when it

was framed as a 12 month diet than a one year diet. Participants were more confident, and found it less difficult to follow the diet plan when it was framed as a 12 month plan than as a one year plan. Perceived difficulty fully mediated the effect of time frame on confidence, and confidence partially mediated the effect of time frame on likelihood to adopt the diet.

In summary, framing the same time period in different ways can influence consumers' plans, due to changes in confidence. We examine four factors that affect confidence: (1) framing of the time period, (2) familiarity with the frame, (3) whether the sources of uncertainty are attributed to internal or external factors, and (4) perceived difficulty. Simply framing the budget period as 12 months versus one year in the survey question can increase confidence, and lead to smaller budget forecasts. Budgets for the next year can be decreased by increasing familiarity with this frame, and budgets for the next 12 months can be increased with reminders of external factors. Consumers are more likely to adopt a strict diet plan when it is framed as a 12 month diet than a one year diet, because they perceive it to be less difficult.

SPECIAL SESSION SUMMARY

When (and How) Does Metacognitive Experience Affect Consumer Behavior?

Manoj Thomas, Cornell University, USA

SESSION OVERVIEW

A growing body of evidence demonstrates that consumers' judgments and preferences are not only based on cognitions, but are also influenced by their metacognitive experience. However, there is debate about the scope and extent of the effects of metacognitive experience. On the one hand it could be argued that all judgments are characterized by some sort of metacognitive experience. Some judgments feel easier than expected, while others feel more difficult. This view suggests that the effects of metacognitive experience will be pervasive. On the other hand, it has been argued that the effects of metacognitive experience are moderated by naïve theories and an attribution process. This view suggests that metacognitive experience will affect judgments only under specifiable situations. This symposium tries to address this debate by examining when and why metacognitive experiences affect consumers' judgments and preferences. The four papers identify hitherto unexplored factors that moderate the effects of metacognitive experience.

The first paper by Labroo and Herzendienst looks at how consumer's motivational orientation determines the impact of metacognitive difficulty on consumer preferences. The second paper by Cho and Schwarz examines when choice deferral caused by metacognitive difficulty of choice may or may not generalize to subsequent decisions. The third paper by Tormala, Henderson and Clarkson examines when easy (or fast) attitude generation positively affects attitude certainty and when it negatively affects attitude certainty. Finally, Thomas and Maitre examine whether repetition of a disfluent linguistic structure will mitigate or strengthen the effect of linguistic disfluency.

EXTENDED ABSTRACTS

“Complicated Lives of the Intrinsically Inclined: Why Some Seek Metacognitive Effort”

Aparna Labroo, University of Chicago, USA

Michal Herzendienst, University of Delaware, USA

Much research has focused on how feelings of ease are good and increase people's preferences towards associated products. This occurs because people associate ease with familiarity and personal relevance; as personally relevant and familiar objects come to mind easily, people mistakenly reverse this association, to also infer that if a product is easy to think about it must necessarily be familiar (Schwarz 2004). Thus, even when feelings of ease arise independently of the characteristics of a product, the product feels more familiar, and people infer that it is personally relevant and more likeable. More recently, research has started to consider when feelings of effort might be good, and to suggest that the impact of such feelings might depend upon the naïve theories that consumers bring to bear on their judgment. For example, when consumers consider why a product will help accomplish important goals, feelings of effort (vs. ease) associated with the product exert a positive effect on its preference—as people usually associate attaining goals with exerting effort and the most effective means and they mistakenly reverse this inference as well (Labroo & Kim 2009).

Building on this research, we argue that products that feel subjectively easy (vs. effortful) to process are preferred, as shown previously, but only if consumers are extrinsically motivated. Such consumers misattribute positive feelings of ease to product superi-

ority and infer the product is more rewarding. However, intrinsically-motivated people, who engage in activities because they value the process rather than the outcome, ironically prefer products that feel subjectively effortful (vs. easy) to process. Easy to process is also seen as intrinsically less engaging, and lower engagement is attributed to inferior product quality. These effects are mitigated when intrinsically-motivated consumers believe the negative feelings reflect their own incompetence.

In Experiment 1, consumers evaluated a cooking cheese. Participants completed either an extrinsic or intrinsic orientation priming task, then either read an easy vs. effortful to read ad for the cheese (Novemsky et al. 2008), and finally indicated their willingness to pay for the cheese, how many things they would cook with the cheese, and how much they would enjoy cooking with the cheese. Participants with extrinsic orientation indicated higher WTP, more usability, and more enjoyment when they previously viewed the ease vs. effortful to process ad. The reverse was true for participants with intrinsic orientation. Experiment 2 replicated these effects using an individual difference measure of motivation (Amabile et al. 1994). Once motivational orientation had been measured, participants clicked on and evaluated a website for their current course book. The font was either difficult to read, easy to read, or difficult to read but participants attention was directed to font being the cause of feelings of effort. Extrinsically-oriented respondents indicated higher intent to use the website when its font was easy (vs. difficult) to read. Interestingly, and replicating experiment 1, the reverse was true for intrinsically oriented participants. When participant attention was directed to the true source of effort, these effects were mitigated. To further investigate underlying process among participants who are intrinsically oriented, in Experiment 3, everyone first completed a short SAT-type analogies task, for which approximately half were given false failure feedback (the rest were not given such feedback), in an attempt to associate negative feelings to ones' incompetence (vs. not). Next, all participants were primed with intrinsic orientation, and then they were assigned to read an easy (vs. effortful) ad for Omega 3 (memory) pills. As expected, non-failure participants preferred the pills when they read an effortful (vs. easy) to read ad, and their preference was mediated by perceived product efficacy and engagement. This preference for effort was attenuated when participants previously received failure feedback.

Taken together, these findings support our premise. They suggest that people who look for intrinsic value undervalue activities that feel too easy to engage in and these feelings might be misattributed to associated products reducing liking towards them. In valuing products associated with effort, these people might unnecessarily be complicating their lives, especially when effort does not signify any real benefit of engaging in an activity.

“When Choice Deferral Does (and Does Not) Generalize to Subsequent Decisions: A Metacognitive Analysis”

Hyejeung Cho, University of Texas at San Antonio, USA

Norbert Schwarz, University of Michigan, USA

When a choice is difficult to make, consumers are likely to defer it. This effect of choice difficulty on the likelihood of deferral has been observed not only under conditions where the difficulty derives from attributes of the choice alternatives (Dhar 1997), but also when the difficulty derives from incidental manipulations of

the metacognitive fluency experience. For example, presenting the information in a difficult (vs. easy) to read print font or asking consumers to provide many (vs. few) reasons for a choice has been found to increase deferral in the absence of any objective differences among the choice alternatives (Novemsky et al. 2007). Such findings highlight that the subjective experience of difficulty is the key driver of deferral. Supporting this conclusion, increased deferral is not observed when consumers attribute the experienced difficulty to an incidental source, like the print font (Novemsky et al. 2007), thus undermining its informational value for the choice at hand. These attribution effects are consistent with the logic of the feelings-as-information approach to metacognitive experiences (Schwarz 2004).

This logic further holds that any given metacognitive experience is compatible with a variety of different naïve theories of mental processes that “explain” its occurrence (Schwarz 2004). For example, a consumer who experiences a choice as difficult may attribute the experience to the nature of the choice alternatives (“This is difficult because the options are all pretty similar, making it hard to tell which one is better.”) or to her own lack of expertise (“This is difficult because I know little about digital cameras.”). In both cases, the consumer is likely to defer the difficult choice. However, the different explanations of the experienced difficulty have differential implications for subsequent choices. When the difficulty is attributed to the choice alternatives, it is silent on subsequent choice sets; but when it is attributed to one’s own lack of expertise, it may discourage subsequent choices in the same domain as well. Hence, how consumers “explain” their difficulty is likely to determine whether deferral is limited to a given choice task or generalizes across tasks. To date, the generalization of deferral, and the generalization of inferences from metacognitive difficulty in general, has received little attention. The present research begins to fill this gap.

Specifically, participants received a shopping scenario that presented them with information about four products (binoculars) available in the market. We further told them that only two of the products were available in the store they visited. These two available products were either similarly attractive, making a choice difficult, or one was clearly more attractive than the other, making a choice easy. We then induced participants through two questions to think either about the similarity of the products or about their own expertise; a control group received no questions at this stage. Finally, participants selected one of the two available products or deferred their choice until all products are available at the store. Following this first task, participants received a second scenario that presented them with two different products from the same domain (binoculars), which were of differential attractiveness, making a choice easy. They could select one of these products or defer choice. The manipulations result in a 2 (first choice: easy vs. difficult) \times 3 (attribution: product vs. expertise vs. control)-factorial design.

The results were consistent with predictions. First, replicating the usual findings, participants were more likely to defer choice on task 1 under difficult than easy conditions. Second, this effect was independent of the attribution manipulation—after all, difficult to distinguish alternatives or a lack of expertise are both good reasons for deferral. Third, and more important, how participants explained the difficulty encountered on task 1 influenced their decisions on the easy task 2. Participants who attributed the difficulty experienced on task 1 to their own lack of expertise were more likely to defer choice on the easy task 2 than participants who attributed their task 1 difficulty to the specific products presented in task 1.

These findings extend our understanding of the role of metacognitive experiences in the deferral of choice. Attributing a

previous experience of difficulty to characteristics of the specific choice set of the previous task renders it irrelevant for subsequent tasks. In contrast, attributing a previous experience of difficulty to one’s own lack of expertise renders it relevant to all tasks in the same expertise domain and the influence of previously experienced difficulty generalizes across related tasks.

“It’s Not Just the Speed that Counts: Perceived Evaluation Duration and Attitude Certainty”

Zakary Tormala, Stanford University, USA

Marlone Henderson, University of Texas at Austin, USA

Joshua Clarkson, Indiana University, USA

People hold their attitudes with varying degrees of certainty. For example, two consumers might report liking a new product or favoring a specific brand to the same degree, but differ in how certain they are of that evaluation. Attitude certainty has stimulated considerable research interest in psychology and marketing, partly because it has been shown to have a number of important consequences for consumer-relevant outcomes. For instance, the more certain one is of one’s attitude, the more predictive that attitude is of behavior and choice (e.g., Berger and Mitchell 1989; Bizer, Tormala, Rucker, and Petty 2006; Krishnan and Smith 1998) and the more resistant that attitude is to change (e.g., Bassili 1996; Tormala and Petty 2002).

Over the years, an extensive body of research has been dedicated to understanding the antecedents of attitude certainty (Tormala and Rucker 2007). One well-documented antecedent is the speed with which one’s attitude comes to mind (Fazio 1995). A number of studies have shown that the faster one’s attitude comes to mind, the more certain one is of that attitude (e.g., Berger and Mitchell 1989; Bizer et al. 2006; Holland, Verplanken, and van Knippenberg 2003; Petrocelli, Tormala, and Rucker 2007). Interestingly, however, other recent research suggests that slower evaluative processing can be associated with greater certainty. For example, the more time one has to form an impression of a person, the more certain one is of that impression (Willis and Todorov 2006). Presumably, more time spent evaluating indicates that one has been more thoughtful, and perceived thoughtfulness positively influences certainty (e.g., Wan, Rucker, Tormala, and Clarkson forthcoming).

The current research takes a new tack, suggesting that perceived evaluative speed (or duration) can have dynamic effects on attitude certainty that depend on numerous situational or individual difference factors. We explore three such factors in this research. First, the impact of perceived evaluative speed on attitude certainty might depend on whether consumers are focused on attitude expression or formation. Specifically, perceived evaluative speed might positively affect certainty when one is expressing one’s attitude, but negatively affect certainty when one is forming one’s attitude. The logic is that faster expression indicates that one has already considered the issue and decided where one stands, whereas slower formation indicates that one has been more thoughtful and rational in making one’s decision. Second, the effect of perceived evaluative speed on attitude certainty might depend on the familiarity of the attitude object or issue. When an attitude object is already familiar to consumers, faster evaluation should facilitate greater certainty because it implies that one has already invested the effort to consider one’s opinion. When an object is unfamiliar, however, the need for careful deliberation should be more salient, meaning consumers might be more certain after forming their evaluations more slowly. Third, the effect of perceived evaluative speed on attitude certainty might depend on consumers’ lay theories that quick gut reactions or more thoughtful judgments are more accurate. We present 3 studies testing these hypotheses.

Study 1 explored the possibility that perceived evaluation duration would have different implications for attitude certainty depending on whether people were focused on attitude expression or attitude formation. In this study, undergraduate participants were asked to consider their opinion of an issue. Participants were instructed to think about this issue until they had formed their opinions, and then click “continue” on the computer screen. Participants were then presented with a single scale along which they reported their attitudes. Shortly thereafter, participants received false feedback indicating that they had taken either longer or shorter than most participants to either form or express their attitudes. Results indicated that when the feedback focused on attitude expression, participants felt more certain of their attitudes when they believed they were faster rather than slower than most participants. In contrast, when the feedback focused on attitude formation, participants felt more certain when they believed they were slower rather than faster.

In Study 2, we examined the moderating role of familiarity. Participants underwent a similar procedure as in Study 1, but in this case they were asked to consider their attitudes toward an abstract painting that, based on random assignment, was either familiar or unfamiliar to them. All participants evaluated the painting and then received false feedback concerning the amount of time it took them to do so. Among participants who were familiar with the painting, greater attitude certainty was associated with perceptions of fast rather than slow evaluation. In contrast, among participants who were unfamiliar with the painting, greater attitude certainty was associated with perceptions of slow rather than fast evaluation.

Finally, Study 3 investigated the moderating role of lay theories. This study followed the same basic procedure as Study 1, but we assessed participants’ beliefs about the validity of gut reactions versus more thoughtful judgments. Among participants who believed that gut reactions were more trustworthy, we observed greater attitude certainty in the perceived fast rather than slow evaluation condition. Among participants who believed that thoughtful judgments were more trustworthy, we observed greater attitude certainty in the perceived slow rather than fast evaluation condition.

In summary, evidence from three studies highlights a dynamic link between perceived evaluation duration and attitude certainty. When consumers focus on attitude expression, evaluate familiar objects, or generally believe that gut reactions are more valid, perceived evaluative speed positively affects attitude certainty. In contrast, when consumers focus on attitude formation, evaluate unfamiliar objects, or generally believe that thoughtful judgments are more valid, perceived evaluative speed negatively affects attitude certainty. Taken together, these findings expand current understandings of the origins of attitude certainty and suggest that perceptions of evaluative speed can play an important and dynamic role in guiding people’s assessments of their own attitudes.

“The Brevity Effect in New Product Labels: When Does Linguistic Fluency Affect Consumers’ Responses to New Products?”

Manoj Thomas, Cornell University, USA

Thibault Maitre, Cornell University, USA

Which of the following two descriptions will evoke a more favorable response for a new brand of bubble bath—“Barbie Bubble Bath” or “Barbie Refreshing Bubble Bath for Adults and Kids”? Coming up with the appropriate description for a new product label is one of the difficult decisions that marketers often face. Several studies have shown that linguistic qualities of the new product description affect consumers’ responses to new products (Lowrey

and Shrum 2007; Miller and Kahn 2005; Yorkston and Menon 2004). However, most of the previous research has focused on the cognitive effects of linguistic structures. In this research we examine whether the metacognitive experience evoked by linguistic structures could affect consumers’ evaluations of new products. Specifically, we address two hitherto unexplored questions that are of substantive and theoretic importance: (i) Does the length of a label on a new product influence consumers’ responses to the product? (ii) When does brevity or length of label matter?

To investigate the effects of fluency induced by linguistic structures, we ran four laboratory experiments. In Experiment 1, participants were randomly assigned to one of the two between-subjects conditions—fluent vs. disfluent product descriptions. Participants saw six new product descriptions and were asked to indicate how much they disliked or liked each new product. Participants assigned to the fluent condition saw product descriptions that were short and fluent (e.g., Barbie Bubble Bath). For participants in the disfluent condition, we created a longer and less fluent product description by adding positive and/or neutral descriptive elements (e.g., Barbie Refreshing Bubble Bath for Adults and Kids). In both conditions, participants were first asked to evaluate how likely they were to try the new product, then to assess how easy or difficult the name was to pronounce, and finally how clear the benefit of the product was. The results from this study showed that perceived ease of pronunciation mediated the effect of linguistic fluency. Having established the role of linguistic fluency in new product descriptions, we then turned our attention to the second question: When does brevity or length of label matter? In Experiment 2, we examine whether repeated exposures to a disfluent linguistic structure will mitigate the unfavorable effect of linguistic disfluency on preferences? Participants were randomly assigned to one of the four conditions in a 2 (repeated prior exposures vs. no prior exposures) x 2 (fluent vs. disfluent) design experiment. The stimuli and procedure were similar to Experiment 1, except for the fact that participants assigned to the “repetition” conditions were exposed to the product descriptions several times before they evaluated the new products. We found that repeated exposure to the less fluent linguistic structures mitigated the effect of linguistic disfluency, even though it did not impact the ease of pronunciation. In Experiments 3A and 3B, we examine why repeated exposure moderated the effect of linguistic fluency on preferences. Experiment 3A shows that linguistic fluency influences preferences even for very familiar stimuli (e.g., Arabic numbers such as 3 vs. 23). Experiment 3B shows that repeated exposure does not mitigate linguistic fluency for unfamiliar stimuli (e.g., foreign names). Together, these results suggest that any factor that makes fluency seem surprising will encourage people to consider linguistic fluency as a diagnostic cue in evaluative judgments.

SPECIAL SESSION SUMMARY

Pre-Purchase Planning and Post-Purchase Learning: The Role of Internal and External Factors

Yanliu Huang, The Chinese University of Hong Kong, China
Wes Hutchinson, University of Pennsylvania, USA

SESSION OVERVIEW

For over 40 years, consumer planning has drawn considerable interest among marketing researchers (e.g., Kollat and Willett 1967). This session adds to our understanding of antecedents of consumer planning and post-purchase learning behavior. The central themes that unite the four papers in the session are (1) how internal factors or shopper characteristics influence planned vs. unplanned purchase behavior, (2) the role of external factors or interventions in determining planning performance, and (3) whether consumers learn from their prior planning and purchases and what shopper characteristics explain this learning paradigm.

Internal Factors

All four papers examine the role of internal factors in planning and learning from shopping. From the pre-purchase planning perspective, based on a dataset covering over 18,000 grocery store purchases in 58 categories, the Bell/Corsten/Knox paper demonstrates that both traditional demographics and other shopper “habit-related traits” such as “enjoyment of shopping” and “information gathering styles” affect unplanned buying. Based on a field study wherein respondents used a handheld scanner to record the order of purchases, the Stillely/Inman/Wakefield paper indicates that consumers have a mental budget that allocates some amount of money to make unplanned purchases on a specific grocery shopping trip. From the post-purchase learning perspective, in two simulated online shopping experiments, Huang and Hutchinson examine planning as a metacognitive process and show that previous planning experience increases consumers’ awareness of the need to plan and forces them to think more strategically. As a result, individuals successfully transfer their planning skill from one shopping context to a new one. Finally, based on the results of a series of two-stage shopping experiments, the Chang/Cho/Lee paper demonstrates that consumers often seek out information about prior irreversible purchases they have made and this information search behavior can be explained by shopper characteristics. Particularly, cognitively-oriented consumers tend to avoid uncertainty and engage in post-purchase information search to confirm that they have indeed made the right purchase decision, whereas experientially-oriented consumers engage in such behavior for emotion enhancement purposes.

External Factors

In terms of how the external factors or interventions influence consumer planning behavior, Inman, and Wakefield examine how in-store promotional savings influence mental budgeting for planned vs. unplanned purchases. Their results suggest that many promotions do not influence basket size for the planned items, although they have an impact on unplanned purchase spending after consumers’ in-store slack is depleted. Differently, the Bell, Corsten, and Knox not only replicate the classic findings on positive effect of available time and negative effect of store knowledge on unplanned buying as in Park, Iyer, and Smith (1989), but also use panel structure of their data to reconcile the positive effect of store knowledge as reported in Inman, Winer, and Ferraro (2009) — a household in a familiar store can do more unplanned buying when they have more time. Huang and Hutchinson paper indicate that

requiring consumers to explicitly verbalize their plans at a “deep” level not only benefits their initial planning performance but also facilitates their planning transfer across domains (compared to control groups that do not verbalize or verbalize at a “shallow” level). Finally, Chang, Cho, and Lee successfully manipulate participants’ post-purchase information processing style by asking them to either think or feel about a purchase decision.

The focus of this session is part of a larger literature on consumers’ pre-purchase information processing, in-store decision making, and post-purchase knowledge learning and transfer. This is consistent with many ACR members’ research interests.

EXTENDED ABSTRACTS

“Unplanned Buying by Supermarket Shoppers”

David R. Bell, University of Pennsylvania, USA
Daniel Corsten, Instituto de Empresa Business School, USA
George Knox, Tilburg University, The Netherlands

“Supermarkets are places of high impulse buying ...—fully 60 to 70 percent of purchases there were unplanned, grocery industry studies have shown us.” Paco Underhill (*Why We Buy: The Science of Shopping*)

Unplanned buying is a rich and ubiquitous aspect of consumer shopping behavior, yet surprisingly little academic research examines it in detail. Understanding why, how, and when it occurs has implications for consumers, managers, and researchers. In a recent study, Inman, Winer, and Ferraro (2009) explore consumer welfare — how might consumers safeguard themselves from “too much” unplanned buying? Acting in accordance with the widespread belief that unplanned buying is pervasive and environmentally-driven (see Paco Underhill quote above) managers allocate significant resources to “in-store merchandizing”. Wal-Mart CMO John Fleming notes: “The store is our number one media channel”; on July 28, 2008 *Advertising Age* reported “... the oft-quoted statistic ... boosted shopper marketing and made other advertising seem almost pointless.” Classic (e.g., Kollat and Willett 1967) and recent (e.g., Inman, Winer, and Ferraro 2009) academic articles study in-store decision making using cross-sectional shopper intercept data, or, alternatively develop field experiments (e.g., Park, Iyer, and Smith 1989). In this paper, we supplement these efforts by studying the costs and benefits of unplanned category purchases, from the perspective of the entire shopping process.

We decompose variation in unplanned buying as it results from the confluence of three factors: the shopper, the store in which the trip is taken, and context for the trip itself. We hypothesize that three classes of factors—shopper predispositions (including demographics and shopping habits), store environments, and shopping trip contexts—affect the cost-benefit calculus for unplanned buying. Within each factor we study a number of sub-factors that are expected to affect the net benefit of unplanned buying. Following Beatty and Ferrell (1998) and Rook and Fisher (1995), our measures of shopper “traits” are not confined to demographics alone, but also include measures of the household’s overall shopping habits. We also include a variety of store image (e.g., Bell and Lattin

1999) and trip-specific factors (Fox and Hoch 2005; Lee and Arieli 2006). Some shoppers have a greater inclination to delay planning until inside the store than others; furthermore, different store environments could engender different rates of unplanned buying from the same shopper, as could different trips with different needs.

A multi-level random effects Poisson model calibrated on a dataset covering over 18,000 purchases in 58 categories is used to explain variation in the number of unplanned categories in the shopping basket. An important (and unique) feature of the data is that they vary over time, as well as over households and stores. This allows us to report the decomposition of variance due to trips, household-store combinations, and households. We find a high degree of within-household clustering (for two trips taken by the same household, the intra-class correlation is .579). Conversely, for any two trips taken at the same store, the intra-class correlation is extremely low (less than .010). For different trips by the same household at the same store, the intra-class correlation rises to .684, since, in addition to the household and store clustering, we add the household-store interaction clustering.

Thus, the variance decomposition implies unplanned buying is largely a household-driven phenomenon, explainable in part by traditional demographics, but more by other “traits” that reflect long-run shopping habits including “enjoyment of shopping” and “information gathering styles”. Even though individual difference variables are the most important class of factors in the model, these household observables account for only 40% of the total variation. Shopping trip factors including trip antecedents, trip types, and in-store experiences can also exert substantial shifts in the base rate of unplanned buying. While we do find evidence of persistent chain level effects, we were unable to link these to perceptual differences in prices or assortments. We replicate the classic findings on time available (more unplanned buying) and high store knowledge (less unplanned buying) in Park, Iyer, and Smith (1989) and use the panel structure of our data to reconcile the positive effect of store knowledge reported in Inman, Winer, and Ferraro (2009)—a household in a familiar store can do more unplanned buying, provided more time is available.

One implication is that researchers with an interest in unplanned buying might measure other “traits” such as proclivity for impulsivity (e.g., Rook and Fisher 1995), or the propensity to be a “spendthrift” or “tightwad” (Scott, Cryder, and Loewenstein 2008). Moreover, there is a need for more comprehensive theories of “shopping styles” and their normative relationship to unplanned buying. Promising candidates are theories of shopping goals (e.g., Lee and Arieli 2006), shopping efficiency (e.g., Chandon, Wansink, and Laurent 2000), and the “pain of payment” (Scott, Cryder, and Loewenstein 2008).

“Spending on the Fly: Mental Budgets, Promotions, and Spending Behavior”

Karen M. Stille, University of Pittsburgh, USA

J. Jeffrey Inman, University of Pittsburgh, USA

Kirk L. Wakefield, Baylor University, USA

Grocery shopping is an example of a consumer domain where budgeting is commonly found (i.e., Heath and Soll 1996; Heilman, Nakamoto and Rao 2002). More recently, Stille, Inman, and Wakefield (2009) take the idea of mental budgets further by demonstrating that consumers have a mental budget for the amount of money that they plan to spend on a specific grocery shopping trip and by showing that this mental budget includes room for unplanned purchases. Specifically, they introduce the idea that the trip budget consists of both an itemized portion (amount allocated to planned purchases) and in-store slack (the portion of the mental

budget that remains available for in-store decisions). We argue that the amount of in-store slack remaining at a given point during the trip has important implications regarding the impact of promotional savings. We rationalize four hypotheses which focus on savings on planned items and then present two hypotheses regarding savings on unplanned items.

To test these hypotheses, we conducted a field study in which respondents used a hand held scanner to record the order of purchases. Specifically, 400 customers were systematically intercepted as they entered three different grocery stores located in a southwestern city. Respondents were offered a \$10 incentive that was given to them at the end of the trip (for future use to mitigate a windfall effect). Before they entered the store, respondents were first asked what items they planned to purchase. They were then asked to estimate how much they intended to spend in total and to estimate the cost of the items they planned to purchase (i.e., their itemized budget). This approach allows us to measure the respondents’ in-store slack by subtracting the itemized budget from the total planned spend. After completing these initial questions, respondents were then provided with a handheld scanner gun and instructed how to scan the barcode of each item as they placed it in their cart or basket. This methodology enables us to record the order of purchases and therefore determine which items were purchased before and after the in-store slack was exceeded. After the respondents checked out, they completed an exit interview and their receipt was copied. Respondents also provided their frequent shopper card number, which allowed us to access their shopping history.

Our research makes at least four important contributions. First, we find that savings on planned items before the in-store slack is exhausted are positively related to the amount spent on planned items, but that the amount of the increase depends on income. In fact, we find that savings on planned items before the slack is depleted have no impact on spending for below-average income households. The results support our thesis that the underlying mechanism is that higher income enables stockpiling of the planned items. Second, we find that savings on planned items are positively related to unplanned item spending, but that this relationship only obtains when the savings on planned items are realized after the consumer’s in-store slack is depleted. Third, we show that savings on unplanned items that are purchased before the consumers’ in-store slack is depleted have no impact on basket size except for high income consumers paying with a debit or credit card. This suggests that, for most consumers, the savings are simply absorbed into the in-store slack. Fourth, savings on unplanned items that are purchased after the consumer’s in-store slack is depleted are positively related to basket size for consumers regardless of income or payment method. This suggests that promotions can be effective in encouraging incremental purchases if the promotion is encountered after the consumers’ in-store slack is exceeded. Highlighting the importance of a mental budgeting perspective, our results have theoretical implications as well as implications for the placement of promotions in the store pattern and the nature of promoted items.

“Seeking Emotion Enhancement or Uncertainty Resolution? A Dual-System Approach to Examining Post-Purchase Information Search”

Hannah Chang, Singapore Management University, China

Cecile Cho, Moscow School of Management, Skolkovo, Russia

Leonard Lee, Columbia Business School, USA

Product information search is typically assumed to follow the recognition of a purchase need and to occur before decision making. Once a sale transaction is completed, searching for information

(e.g. price) on the purchased product seems futile and even irrational. Real-life observation and prior research (e.g. Russo and Leclerc 1994), however, suggest that such post-purchase search behavior is pervasive among consumers despite having no apparent consequence.

In this research, we examine the prevalence of post-purchase information (particularly prices of already purchased products) search behavior in shopping and its underlying motivations. We propose two distinct reasons for this behavior—(1) to resolve uncertainty and ascertain that the right purchase decision has been made (Shani and Zeelenberg 2007); and (2) for emotion-enhancement particularly if consumers are confident of having made the right purchase decision. We draw upon Epstein's (1994) Cognitive-Experiential Self-Theory (CEST) as an integrative conceptual framework for these two accounts, and investigate whether the two information-processing styles (experiential or cognitive) may differentially drive post-purchase information search. Specifically, we hypothesize that, while consumers who rely more on cognitive processing during decision making would seek post-purchase product information when they are uncertain about having made the right decision, consumers who rely more on experiential processing focus on their current shopping experience and tend to seek such information for emotion-enhancement purposes, particularly when they are reasonably confident that they have made the right purchase decision. We tested our hypothesis in two experiments.

In experiment 1 (N=86), we traced participants' real-time search behavior in a two-stage online shopping experiment using the mouselab paradigm (Payne, Bettman and Johnson 1993). Participants were endowed with \$10 and asked to shop at an online-shopping website selling five desktop toys (e.g. stress ball, wood-cube puzzle), each presented in the form of a picture, a short description, size specification, and price. Participants had to purchase one item with the given cash. After making their purchase, participants were asked to shop at a second store selling ten desktop toys including the five they had already seen in the first store. (We counterbalanced which five of the ten products participants could buy in the first store.) After a short filler task, participants had to complete the Rational-Experiential Inventory (REI) as a measure of their information-processing style (Epstein et al. 1996). To manipulate participants' degree of confidence in whether they were paying a good price for their purchase in the first store, we told half the participants that the prices were discounted by 50% ("large"), and the other half, 10% ("small"). We found a significant crossover interaction between discount size and participants' information-processing style on their propensity to search within the second store for the price of the product they had already purchased in the first store ($p=.05$). Planned comparisons further revealed that whereas rationally-oriented participants were more likely to engage in post-purchase price search when the discount in the first store was small (57%) than when it was large (32%), experiential-oriented participants were more likely to engage in post-purchase price search when the discount was large instead (43% vs. 27%).

We replicated this result in experiment 2 (N=273) in which we manipulated participants' information-processing style prior to shopping. Participants were asked to complete two purportedly unrelated tasks. In the first task, half the participants were asked to describe a difficult decision they had to make in the past and in which they decided based on careful thinking and it turned out to be the right decision, while the other half were asked to describe a difficult decision they had to make in which they used their feelings instead. Next, participants were asked to imagine that they needed a new MP3 player and decided to buy one after looking at various models at an electronics store; they were told that the store was

having a semi-annual clearance sale with the discount size being 5% ("small") or 50% ("large"). Subsequently, they saw another store that sells the same model of MP3 player they had just bought and had to indicate whether they would enter the store to check out the price of the player. Again, we found a significant crossover interaction between discount size and information-processing style on participants' likelihood to seek out the price of the MP3 player they just purchased ($p=.004$); while cognitively-oriented participants were more likely to search when the discount in Store A was small (61%) than when it was large (50%), experientially-oriented participants were more likely to search when the discount was large (64%) than when it was small (45%).

Together, these findings lend a first look at two contrasting motivations that spur consumers to seek post-purchase information that might appear non-consequential, suggesting disparate situations under which different types of consumers would engage in such behavior.

"There is More to Planned Purchases than Knowing What You Want: Dynamic Planning and Learning in A Repeated Multi-Store Price Search Task"

*Yanliu Huang, The Chinese University of Hong Kong, China
Wes Hutchinson, University of Pennsylvania, USA*

As consumers, our lives are full of planning. Understanding the strengths and weaknesses of consumer planning, how planning performance improves with experience, and the possible interventions that may help people form better shopping strategies have important implications for marketers, policy makers, and consumers. Despite the importance of this topic, there is a scarcity of research on consumer planning in marketing. Most research has focused on planned vs. unplanned purchases and defines planned purchases strictly as those items that were fully specified before entering the store (e.g., on a shopping list). These studies did not examine the process of planning itself and ignored the fact that an "unplanned" purchase made in the store can be the result of a well developed plan that intentionally stopped short of full specification. For example, a consumer who has a well-formed plan to choose the lowest priced brand in a small consideration set would be categorized as making unplanned purchases because he does not determine the specific brand before entering the store.

In the current research, planning is defined as developing a scheme or procedure for the accomplishment of an objective before the commencement of the task. Our definition emphasizes the metacognitive aspect of planning in that people intentionally and actively construct, retrieve, and update their plans to achieve their purposes. In order to identify a specific task to study planning, we first conducted two exploratory studies (N=260) in which we asked people to describe how they planned for their most recent shopping trips for different products (e.g., grocery, electronics, clothing). It was shown that both information search and learning from repeated shopping experience are two important components of consumer planning. Based on these pretest results, we selected an activity that is familiar to most consumers, incorporates both information search and learning, and also represents an important research area in marketing for many years—repeated multi-store price search. Specifically, participants were given a total budget and asked to take repeated shopping trips and make a purchase on each shopping trip. They were facing multiple stores that always included at least an EDLP (every day low price) store and a HILO store (charging a high regular price half of the time and a low sale price the other half of the time). Their goal was to minimize their total cost and they were paid based on their performance. In this task, planning consists of two parts: what consumers do at the very beginning to learn about

stores and what shopping strategies they adopt based on what they learn. Based on optimal search for this task, we use the percentage of consumers who both searched exhaustively on the first shopping trip and adopted optimal cherry picking (i.e., visit the HILO store first, if the price is low, make the purchase; if the price is high, switch to the EDLP store to make the purchase) on the last two shopping trips as our dependent variable to measure planning.

We showed in two simulated shopping experiments that consumers often fail to plan optimally and do not appreciate the value of early learning. Fortunately, encouraging consumers to explicitly plan and justify their store visits can improve their performance, and merely planning without thinking about the underlying rationale of the plan is not as helpful. Furthermore, after obtaining relevant experience consumers are able to transfer their planning to shopping in a different situation successfully. Finally, both explicit planning and transfer effects do not result from consumers' increased awareness to cope with memory load and keep all the critical price information in their short term memory.

SPECIAL SESSION SUMMARY

Social Comparison and Negative Emotions: Understanding Regret, Envy, and Schadenfreude in a Consumer World

Cait Poynor, University of Pittsburgh, USA

SESSION OVERVIEW

A growing body of research identifies widespread effects of social comparison on consumer behavior. For example, in the presence of others, we affiliate with them, adopt an innovation, or increase our purchase intentions for goods we see in use. Implicit in this work is the idea that social comparison can yield powerful emotions, many of which are positive for consumers and marketers. But what happens when social comparison yields powerful negative emotions? What are the consumption implications for consumers and marketers in this instance? Can this type of social outcome be managed or mitigated? Each author in this special session will report results from three empirical studies conducted to explore these questions in depth, specifically focusing on the emotions of regret, envy and schadenfreude.

Though the papers are tightly clustered around this common theme, they each also provide novel theoretical insights. Particularly, these papers not only depict these relatively understudied emotions in consumer domains, they suggest that they can be sparked by both internal and external processes. For example, Winterich, Mittal, and Inman focus on the effects of regret, which begins as a personal consumer response to their own consumption decisions. However, this individual emotion yields important external consequences, as the combination of social comparison and regret leads to distancing between the consumer and previously proximate others. Poynor and Dahl study envy, which is generated by comparing one's own personal situation to that of another consumer. As they recognize that someone else has a desired good, consumers respond with varying degrees of hostility depending on their own self-esteem levels, both in regard to the envied other and the desired product. Moving the locus of study farther outside the individual consumer, Sundie et al. highlight schadenfreude, where the driver of hostile emotion lies outside the consumer altogether, and only arises due to observation of the negative experiences of others.

Each paper also makes a compelling case that socially generated emotions are directly related to substantive marketing implications. Winterich et al., for example, show that social distancing can not only impact intentions to repeat a given behavior, but also that financial allocation decisions can be impacted by regret and consequent social distancing. Poynor and Dahl echo the impact of negative emotion on interpersonal relationships, and also demonstrate effects of envy on product value and willingness-to-pay. Sundie et al. show that schadenfreude can have important impacts on brand attitude and word of mouth.

Given the strong focus of the session, we anticipate a high degree of interest among researchers investigating issues involving social comparison, social influence, and interpersonal relationships. However, we also believe that the presentations will attract interest from a broader audience. For example, researchers exploring issues related to consumer happiness and well-being, the role of self-esteem in consumption, and importance of self-conscious emotions will see great value in this session. The range of consequences identified in this work may broaden its appeal further, as the consequences identified may be relevant for pricing, group dynamics, brand attitudes, and motivation research.

EXTENDED ABSTRACT

“The Who in Regret: How Psychological Closeness Affects Regret and Social Distancing”

Karen P. Winterich, Texas A&M University, USA

Vikas Mittal, Rice University, USA

J. Jeffrey Inman, University of Pittsburgh, USA

Regret is defined as “the emotion that we experience when realizing or imagining that our current situation would have been better, if only we had decided differently” (Zeelenberg and Pieters 2007, 3). Social comparison theory states that individuals evaluate themselves in comparison to others (Festinger 1954), suggesting that individuals not only make comparisons to forgone alternatives, but also to the chooser of the forgone alternative. We build on research examining the role of social comparison in regret (Hoelzl and Loewenstein 2005; Kumar 2004) to examine the extent to which subtle differences in psychological closeness influence regret and the relational consequences of regret, particularly social distancing.

Psychological closeness is influenced by physical proximity and/or similarities such as age or gender (Tesser and Campbell 1982). Research has found that emotional responses from social comparison are dependent on the nature of the relationship, with stronger responses when one is psychologically close (Tesser and Collins 1988). Building on this literature, we argue that regret is greater when one is outperformed by someone of high (vs. low) closeness because comparisons to less close others reduce the relevance of a forgone alternative. In doing so, this research acknowledges the “who” (chose), and not just what (was chosen), as an influential reference point for comparison affecting regret (Lin, Huang, and Zeelenberg 2006).

More importantly, we demonstrate that people may employ social strategies to regulate regret (Zeelenberg and Pieters 2007). To date, research has demonstrated distinct behavioral consequences of regret that may serve to regulate regret (Inman and Zeelenberg 2002; Kumar 2004; Tsiros and Mittal 2000). Yet, regret regulation strategies have not considered the tendency of consumers to manage their relationship with the chooser of the forgone alternative. Social distancing is viewed as informal ostracism that may occur in response to social deviance such that individuals who are distanced are not formally removed but are informally excluded from social interaction to some degree through a range of withdrawal behaviors (Westphal and Khanna 2003; Wood 1974). We argue that consumers may regulate regret by distancing themselves from those others who chose the better forgone alternative. Specifically, consumers will be more likely to engage in social distancing when the chooser is of high (vs. low) closeness because less closeness between the self and the other reduces the threat or need for regret regulation when interacting with the other.

In three studies, we prime psychological closeness to examine the effect on regret, as well as social distancing. The first study primed closeness to a cousin and examined regret regarding performance in a hypothetical stock investment scenario. The results indicated that regret was greater when participants were outperformed in a hypothetical investment scenario by a close (vs. distant) cousin. Further, participants who were outperformed by a close

cousin indicated a greater desire to distance themselves from their cousin.

In the second study, each participant brought a friend to the study. Participants then completed a computer word scramble task and received feedback regarding their friends' performance or that of a random participant to manipulate closeness. Depending on condition, participants were informed that they had performed worse than or equal to the other participant and asked questions regarding their performance. At the end of the study, participants were asked their likelihood to participate in a future study with their friend. Results indicated that participants who performed worse than their friend experienced greater regret and had lower intentions to participate in a future study with their friend than those who performed worse than a random participant. We propose that choosing not to participate in a future study with their friend is a distancing mechanism, thereby regulating regret. Importantly, regret mediated the moderating effect of psychological closeness on participation intentions.

The third study primed closeness by randomly pairing participants of the same gender for three minutes to talk and get to know each other. After this time, participants were asked to think of how their partner was similar to or different from them, priming high or low psychological closeness, respectively. Then participants completed the same word scramble task used in study 2, receiving feedback on their own performance as well as that of their partner. Lastly, participants completed an ostensibly unrelated economic (i.e., dictator) game where they were given \$5 to allocate between themselves and their partner. Unbeknownst to participants, each person was assigned to be the decision maker and the amount allocated to their partner served as an indicator of social distancing. Results indicated that those in the high (vs. low) closeness condition not only reported greater regret when they were outperformed in the word scramble task, but also allocated less money to their partner in a subsequent, unrelated economic game. Again, regret mediated the moderating effect of psychological closeness on partner allocation.

Together, we find that regret is influenced by psychological closeness to the chooser of the forgone alternative, and individuals may use social distancing as a strategy to regulate regret arising from social comparison. This research extends regret regulation theory demonstrating that through social distancing behaviors consumers can choose to "run and hide" from their regret or even go so far as to settle the score with the other in an unrelated task. It is important for consumers to regulate regret given that Schwartz et al. (2002) find that regret is positively correlated with depression and negatively correlated with both happiness and life satisfaction. In marketing, companies often attempt to elicit anticipated regret in potential customers by drawing comparisons to users of a competitor's brand to increase own brand sales through customers' regret avoidance, but consumers may or may not identify with the person using the target brand (i.e., Apple's campaign using distinct identities for a PC user and a MAC user). Such strategies are likely to be successful only to the extent that consumers feel psychologically close to the portrayed user of the target brand.

"Monster or Motivator? Understanding and Taming Consumer Envy"

Cait Poynor, University of Pittsburgh, USA

Darren Dahl, University of British Columbia, Canada*

Gerry Gorn, Hong Kong University, China

Envy's malignant effects have long been depicted in psychoanalysis, theology, literature, philosophy, psychology and political science (Smith and Kim 2007). Our fascination with envy may be

partially driven by its ubiquity, as it springs to life as soon as individuals become capable of interpersonal comparison (Schoeck 1969). Seeing another with something we desire has been shown to prompt negative social comparisons, which in turn can yield competition, hostility, alienation, and damage to both the envier and the envied individual (Schoeck 1969, Silver and Sabini 1978, Testa and Major 1990). Indeed, in a marketing context consumers have been shown to experience envy and its negative outcomes when comparing themselves to other consumers and their purchases (Belk 1985). Envy may also drain value from the market, as it leads to a desire to demean or destroy things formerly considered good (Schimmel 1993). At its most powerful, envy has been said to "lead to aggression and violence capable of destroying societies," (Foster 1972, p. 165).

Recent reviews concede that envy's antecedents and consequences remain poorly understood (Smith and Kim 2007, Zizzo 2008). A body of conflicting evidence exists on fundamental questions regarding envy and its function, particularly in a consumer context: Does envy impact consumer behavior at all (Grinblatt, Keloharju and Ikaheimo 2008)? Can we experience envy toward consumers who are dissimilar from us as well as those who are similar? Does consumer envy truly only have the malignant face portrayed in psychoanalysis, political science and theology? If so, in what circumstances is the negative outcomes of envy most likely to be realized and how can consumers be prompted to express envy in ways which are perhaps more beneficial to themselves and the marketplace?

We approach these questions by first defining envy and relating conflicting findings regarding the effects of interpersonal similarity and perceived control (defined as an individual's perceptions of their own ability to obtain an envied good on a future occasion) on envy's expression. We propose that envy, defined as the emotion generated by seeing another with a desired good (Salovey 1991) creates an "acquisition gap," that is, a sense of psychological distance that must be bridged for an individual to obtain the envied good. To the extent that the acquisition gap is narrowed by favorable combinations of trait self-esteem, perceived control, and similarity to the envied other, we argue that consumers will move away from malignant expressions of envy. Such a shift may be beneficial to consumers, who avoid the downward spiral caused by unresolved envy, to marketers, whose products can avoid devaluation, and society as a whole, which can avoid or reduce the harmful consequences of envy-driven hostility.

Results from three experiments are consistent with this framework and provide new insights into both envy and self-esteem. Study 1 considers the malignant expression of envy when an envied other is initially similar to participants. In this case, we propose that the initial acquisition gap is small. In this study, participants took part in a simulated online search "competition." In this study, a confederate, always identified as a business major allegedly wins concert tickets matched to each individual's preferences based on a survey at the beginning of the semester. Participants were then told that their search strategy was analyzed and that they could (high control) or could not (low control) have obtained the tickets, given their browsing patterns. They then provide the same product evaluation ratings as collected at the beginning of the semester. Finally, they provide their "thin slice" judgments of the confederate as part of an ostensibly unrelated task. We find that high self-esteem individuals only express less damaging envy in such cases—the feasibility of obtaining the confederate's outcome allows them to feel less hostility towards the envied individual and continue to express value for the envied product. However, low self-esteem individuals express more malignant envy (devaluing the chosen

good and disparaging the envied person) if they do not clearly believe that they might be able to obtain the envied good in the future. Failing to be able to obtain what someone like them has creates a sort of “sour grapes” effect. However, low self-esteem individuals can express a less damaging form of envy (feel less hostility towards the envied person and maintain high value for the envied good, thus, acting like high self-esteem individuals) if they are explicitly told that they are able to obtain the product in the future.

A second study shows that the interaction of perceived control and self-esteem also exists when the envied other is initially dissimilar to participants but that its direction is inverted. In this study, the confederate is always identified as a consumer science major. We argue that this dissimilarity presents a large initial acquisition gap. Here we find that providing perceptions of control over the ability to subsequently obtain the envied good produces less damaging envy among high self-esteem consumers. These individuals are able to envision themselves bridging the acquisition gap and thus, express less hostility for the envied other and maintain the value of the envied good. By contrast, for low self-esteem individuals even positive beliefs about their ability to acquire the product in the future fail to narrow the gap between themselves and the envied individual enough to offset negative feelings. In light of this gap, they consistently demonstrate malignant envy, expressing hostility toward the envied other and devaluing the focal product.

Finally, a third study demonstrates that high self-esteem individuals experiencing envy demonstrate more positive responses to a “substitute” product than do low self-esteem individuals. High self-esteem individuals’ acceptance of even a very poor substitute for the envied product (in this case, receiving an inexpensive mouse pad after watching a confederate win a Wii gaming system) may constitute an important means of coping with the negative experience of envy. By contrast, low self-esteem individuals’ rejection of a consolation prize may serve to exacerbate negative feelings and therefore, increase the negative impacts of envy-related experiences.

“Invidious Emotions in Status-Based Social Comparison: Implications for the Status Brand”

Jill M. Sundie, University of Houston, USA

James C. Ward, Arizona State University, USA

Daniel J. Beal, Rice University, USA

Wynne W. Chin, University of Houston, USA

Stephanie Geiger-Oneto, University of Wyoming, USA

Social comparisons involving status products have the ability to evoke a variety of emotions for consumers, some of which are invidious in nature. When confronted with a similar other who possesses a status symbol superior to one’s own possession, feeling envy is a likely response. Three studies examine this dark side of the emotional experience of status consumption, and explore the effects of feeling envy on downstream thoughts, feelings and consumption-relevant behaviors towards the status brand. In particular the present studies examine the effects of negative emotions such as envy and hostility on emotional and behavioral responses to status product failure.

This work contributes uniquely to the consumer literature in three ways. First, it explores a particular mediational pathway of emotions antecedent to schadenfreude in a status consumption context; a mediational pattern that has recently been conceptualized by envy researchers, but never to our knowledge tested empirically. Second, this research examines the effects of the envy-hostility-schadenfreude chain of invidious emotions on inclinations to spread negative word-of-mouth about the failed status brand, and provides

a window into what the content of such word-of-mouth is likely to be. Third, this work demonstrates that brand attitudes change (become more negative) when individuals feel schadenfreude in response to the status brand’s failure. This brand-level analysis also identifies the root of this brand attitude change by examining each of three foundational elements of brand attitudes (positive affect toward the brand, negative affect toward the brand, and brand cognitions). Brand attitude change associated with feeling schadenfreude after status product failure was driven by increased negative affect toward the brand.

Study 1 replicated some conceptually connected research in the emotion literature, but in a consumer context, demonstrating that feeling envy toward a similar other’s status product leads to feeling schadenfreude (joy) after that person’s status product fails. One novel contribution of this first study is empirical support for the recent conceptualization by envy researchers (Smith & Kim, 2007) that hostile emotions (e.g., anger, resentment) mediate the relationship between envy and schadenfreude. Consistent with other work in the emotion literature, these invidious emotions were enhanced for a higher-status product failure (a Mercedes breaking down) versus a lower-status product failure (a Ford compact breaking down). Feeling schadenfreude after product failure predicted participants’ indications they would repeat the product failure story to others—spread word-of-mouth. Content coding of what participants reported they would say to others indicated this word-of-mouth would be primarily negative in nature and thus potentially damaging to the status brand.

Study 2 replicated the pattern in study 1 that hostile emotions mediate the link between feeling envy and schadenfreude in a consumption context, and built upon those findings by examining two previous unexplored but plausibly common sources of status-linked envy: envy of the status symbol itself, and envy of the social attention that possessing the status symbol affords its owner. This study also examined how the target person flaunting (versus modestly displaying) the status symbol would influence observers’ emotional responses before and after the status product’s failure. While envy of the social attention drawn by the status symbol did lead to hostile emotions and schadenfreude, envy of the status product itself did not predict hostile feelings, or schadenfreude post-failure. The target person’s flaunting behavior did enhance schadenfreude, via enhanced envy of social attention and hostility (the positive effect of flaunting on schadenfreude was mediated by envy of social attention and hostility). Schadenfreude again predicted the likelihood to spread negative word-of-mouth about the failed brand.

Study 3 examined the downstream consequences of invidious emotions (envy, hostility) in status-based social comparison on attitudes toward the status brand post-failure. While it might be expected that witnessing a product’s failure would lead unilaterally to more negative attitudes toward the failed brand, study 3 revealed that feeling schadenfreude in response to the failure uniquely predicted lower brand attitudes. By measuring brand attitudes in a pre-test and post-test design, we were able to control for prior brand attitudes and thereby assess brand attitude change after learning of the product’s failure. Schadenfreude-prompted changes in brand attitudes were driven by increased negative affect toward the brand.

Our results contribute to broader work in the emotion literature by empirically testing a conceptualized mediational pathway involving envy, hostility and schadenfreude (Smith & Kim, 2007). Although some previous work on schadenfreude explored both envy and hostile emotions as predictors of feeling happiness about another person’s downfall, these two groups of antecedent emotions generally were presumed to have independent effects on

schadenfreude. Our results are consistent with a transmutational process for envy, and provide evidence for the crucial role that other-focused approach emotions such as anger play in the envy-induced schadenfreude.

Consumer-relevant consequences of schadenfreude studied here included word-of-mouth that is prompted by schadenfreude (studies 1 and 2), and changes in brand attitudes subsequent to experiencing schadenfreude (study 3). Although negative word-of-mouth is typically prompted by personally experienced product or service failures, studies 1 and 2 suggest that feeling schadenfreude after witnessing a product failure can also prompt the spread of negative word-of-mouth when people relate the elements of the story to others. The current data suggest this word-of-mouth will routinely contain information about the product failing, and may also be likely to contain other kinds of disparaging remarks about the product or brand. Another important downstream consequence demonstrated in study 3 is that feeling schadenfreude predicts brand attitude change, to the detriment of the failed brand. We found that when a status product failure is witnessed, those who felt greater schadenfreude in this context were more likely to experience negative affect toward the brand and change their overall attitude as a consequence. This suggests that certain emotional responses to status product failure (i.e., pleasure) can influence subsequent brand evaluations.

SPECIAL SESSION SUMMARY
The Wellbeing of Subsistence Consumers
Laurel Anderson, Arizona State University, USA

SESSION OVERVIEW

Poverty is a form of violence that arises from conflicts between competing visions of wellbeing.
(Research Group on Wellbeing in Developing Countries, University of Bath)

As transformative consumer research is further blossoming within ACR, an aspect of value that has emerged is the confluence of a number of different paradigm and methodological perspectives around this interest area. As such we see it paralleling the theme of the conference, "A World of Knowledge At the Point of Confluence."

In this session, we will illustrate different perspectives of wellbeing and their blending. The definitions at the start of this paper give rise to the focus of this session because understandings and prescriptions for transformation/change depend on conceptions of wellbeing. Acknowledging that there are different and often competing definitions of wellbeing among stakeholders, one of the most haunting questions in transformative consumer research derives from this contestation. If change/transformation is advocated in order to bring about wellbeing of the consumer, how is wellbeing defined and who defines wellbeing? The objective of session is to examine different perspectives of wellbeing informing and deriving from our research projects.

Briefly, the discourse on wellbeing seems to contain a number of defining, yet at times contradictory and overlapping frameworks:

1. The dominant concept has been an economic one. In this view, wellbeing is defined as the material resources consumers control, utilize, consume, dispose of and their individual and aggregate levels of income. This view has been challenged!
2. Human Development. This perspective of wellbeing is founded on the premise of the universality of human needs and core dimensions of human wellbeing. Amartya Sen (1999) focuses on human capabilities and freedom—the extent of people's freedom or access to live the life that they value—the person's actual ability to be or do something. This approach's explicit goal is reversing power relations in a way that creates agency and voice for poor people enabling them to have more control in their lives. Others add to or constitute their own list of universal needs.
3. Livelihood/Resource Frameworks. This area is most represented by the later work of Sen, Chambers (Chambers and Conway 1992), and those at the University of Bath. Here wellbeing is predicated not only on economic vulnerability, but social and political. Research focuses on the resources and strategies that people use to mitigate their vulnerability. Various renditions of this framework identify resources such as natural, social, material, environmental, physical, financial, human, and social. The University of Bath places great emphasis on the social and is distinctive in including the cultural dimensions of the "exercise of agency in the struggle for livelihood" (Gough and McGregor 2007).
4. Subjective wellbeing. This framework recognizes that all resources, freedoms and other aspects of wellbeing are ultimately acted upon not objectively, but through the

meanings to and goals of the subsistence consumers. Socio-cultural structures and agency inform this subjectivity. Thus this approach accounts for power and social identities. Consumers may have objective access to the life that they may want and the resources needed for this wellbeing, but the purpose to which these resources are assigned and power relationships circumscribe their use (Said 1985, Bourdieu 1990).

The definition of wellbeing put forth by the University of Bath incorporates four different perspectives of wellbeing: Wellbeing is a state of being with others, where human needs are met, where one can act meaningfully to pursue one's goals, and where one enjoys a satisfactory quality of life."

These perspectives of wellbeing raise questions and controversies regarding:

1. Who is ultimately accountable for wellbeing: individual consumers or collectives that create and maintain social structures?
2. The conflict between individual freedom and social justice.
3. The universality of human needs. This question, especially with regard to developing nations and to subsistence consumers is most hotly debated by post-colonial scholarship who attest that "universals" are still caught within a particular cultural view.
4. There is an increasing stream of research in "positive psychology" focusing on subjective happiness and positive emotions. Critiques suggest that well-being has been commercialized and has become an affirmation of consumerist values. Others suggest that this perspective North American based and is a narrow, unrealistic and potentially damaging view. To be happy is an ideal consistent with a culture dominated by individualism and independence and may fit poorly with other cultures that value social relationships and interdependence (Markus and Kitayama 1997).
5. Others suggest that consumerist lifestyles are the cause of discontent, disharmony, depression and division. They cause harm to the environment and neglect the spiritual, moral, ethical aspects of life (Maxwell 2003).

Anderson's work in a Native-American subsistence community focuses on the extraordinarily high rate of diabetes. She finds considerable hopelessness and a sense of illbeing reflecting perceptions of the inevitability of diabetes for tribal members and the sense of marginalization. However, there are exceptions to this more prevalent view. Her work reflects the resource framework for wellbeing that focuses on cultural resources and the subjectivity paradigm that foregrounds consumers' perceptions of socio-cultural structures and agency within power dimensions.

Mahi's work with health literacy programs for women in India illustrates Sen's capability perspective of wellbeing. It further incorporates the socio-cultural perspective in recognizing the role of women in the family to promote/maintain health.

Viswanathan's work on the creative solutions of subsistence consumers illustrates the livelihood-resource model with a focus on the economic aspects.

EXTENDED ABSTRACTS

"Wellbeing Out of Hopelessness"

Laurie Anderson, Arizona State University, USA

Diabetes and related wellbeing can be envisioned as a problem involving individual consumer decision making, such as choices to eat a healthy diet and get regular exercise (Moorman et al. 2004). Alternatively, diabetes can be conceptualized as a community phenomenon in which social and cultural forces and resources have a significant impact on community wellbeing and health (Kreuter et al. 2003). For example, diabetes is at near epidemic rates in many Mexican American and Native American communities, and, in fact, in many indigenous communities throughout the world (Giachello et al. 2003). In this study, participatory community action methods are used to examine diabetes within a town where 23% of its Mexican American and Native American citizens suffer from diabetes. The community is characterized by concentrated economic disadvantage in which about 25% of the population is below the federal poverty line and two-thirds of these people are 200% below the federal poverty line. There are numerous diabetic preventive programs and services, but health care professionals in the community felt that these were ineffective in stemming the rise in diabetes.

This research involved a two year field study encompassing participant observations, visual documentation, collage led interviews, and in depth interviews with subsistence consumers, health professionals and wellbeing advocates. This was a collaborative, participatory research project where subsistence consumers took part in the research planning, data collection, data analysis, action plans and presentation of the project results.

The definition of wellbeing impacts the way this research is understood and the transformative component/change that is suggested. Additionally, the results give rise to a certain perspective of wellbeing. As mentioned, there have been numerous efforts to transform consumer behavior in the community. There is even a town committee on diabetes. The efforts have not been deemed successful. Wellbeing definitions focused on the individual consumer and their "objective" access to goods and services appear not to have been successful as there are numerous services and goods available.

To emphasize the individual, as is most frequently the case in consumer research, means that we miss many of the social aspects that have increasingly been shown to be of major impact on health

(Krieger 2001). It is most frequently the case that we expect consumers individually to be responsible for their own wellbeing. However, this begs the question of the degree of consumers' freedom and agency. The result of this study's community focus is the highlighting of ecosocial contexts that allows us to identify in a more nuanced way the structural elements that are impactful on consumers' well being but often beyond the direct control of the individual. Much sociological theory (c.f. Giddens 1984) submits that individuals are supported or constrained by larger structural and political orderings. Consequently an emphasis on the individual to the diminishment of the ecosocial contexts reflected in the focus on community would be shallow and leave larger problems unresolved. Even worse, it could lead to a narrow understanding of consumer well being such that any threat to wellbeing is attributed solely to the individual. Sontag (1978: 11) notes this in discussion about the view of illness "as the price one pays for excesses of diet...life-style—are the result of weakness of will or lack of prudence..." Thus arises the additional issue of blaming and marginalizing further those affected. Forefronting the community as the consumer unit of analysis in wellbeing and health makes it more difficult to lose sight of the socio-political and historical contexts and structures, goes beyond individual consumer's responsibilities and/or blame and highlights potential areas of social change.

Reflecting aspect of, in particular, the cultural component of the resource framework and the structural and agency informed subjectivity of these subsistence consumers, we found pervasive feelings of hopelessness about wellbeing and health. Comments such as "it is in our (tribal) blood," "why do we want to worry about that. I am already one foot and a half in the grave because of it," "who's gonna give a darn. I'm just an Indian, you know; you're insignificant" demonstrate the feelings of both hopelessness and marginalization. However, there was a group within the community that did not convey this feeling of hopelessness. These were families with children. These children through educational resources were knowledgeable about diabetes and influenced their parents' and grandparents' behavior. As one parent put it, "we would do anything for our children." Thus the children were also a positive resource influencing wellbeing and feelings of hope. Note that this change in consumers' behavior was not a reflection of access to services and programs, but in response to the socio-cultural importance and resource that the children represented.

Thus this study combines the resources available to consumers while emphasizing cultural and structural aspects that make them feel powerless and without agency. So the preventive programs and services were not being utilizing. Cultural and structural aspects emerged as dominant ones along with the subjective view of resources.

"Women-Oriented Health Literacy as an Asset/Capability in a Subsistence Community"

Humaira Mahi, San Francisco State University, USA

This work examines the value and effectiveness of delivery of women-oriented health literacy communication programs in a subsistence (low to no income) community by measuring changes in health outcomes over time. The research draws upon current literature in cultural sociology, public health, medicine and business to construct a programmatic research stream on underprivileged groups and how to improve health outcomes in these groups. The work focuses on women as key players in affecting change and thus examines health literacy programs as agents of social justice and empowerment in a subsistence setting.

A recent study of the evolving concept of health literacy from public health and medicine (Nutbeam, 2008) indicates that health literacy has been conceptualized so far in literature in two key ways. In the first way, health literacy is seen as a risk factor and is defined as the set of individual literacy capacities that act as a mediating factor in health and clinical decision-making (Baker, 2006). From this perspective, poor literacy skills are seen as a potential risk factor that needs to be managed in the process of providing clinical care. In the second way, it has been characterized as an asset. Health literacy in this case is seen as a means to enable individuals to exert greater control over their health and the range of personal, social and environmental determinants of health.

Nutbeam (2000) argues that the conceptualization of health literacy as an "asset" offers great promise in terms of potential impact on health and the range of actions it may enable. He also argues that ... "the potential of health education as a tool that enables action on the social determinants of health has been somewhat neglected" (Nutbeam, 2000).

Literacy is a focal issue in developing countries and is interwoven with many other transformative consumer concerns such as health, poverty, homelessness. The definition of literacy has expanded from its traditional definition as a set of skills surrounding reading and writing. "A newer stream of definition and conceptualization of literacy (the New Literacy Studies, c.f. Street 2001) firmly places literacy within a socio-cultural context. In this ideology, literacy, conceptualized as a social practice that is culturally constructed and contested, (Ozanne 2008) is of most interest rather than a specific standardized set of skills. This is manifested in the recognition of multiple literacies, varying according to social practices but also defining relations of power (Street 2001). Broadly, literacy is the ability to interpret and communicate meaning through socially constructed symbols and texts." (Anderson and Viswanathan 2009).

The recognition of this socio-cultural embeddedness, in particular the contested and power dimensions, is especially pertinent to India. In India there are prevailing gender prejudices where, especially in rural areas, there is low enrollment of girls in schools; high engagement of female children in domestic work and high school dropout rates that present major obstacles in the path to raising the rate of literacy among Indian women. UNICEF says that in India, girl children tend to be taken to health centers less

frequently than boys, receive less food than boys and are given less education than boys. About 41 percent of Indian girls under the age of 14 do not attend school, according to the report. This disempowerment of women through the lack of access to education and literacy thus has far reaching implications for health when one considers that women hold the health maintenance roles in the family.

Criticisms of narrow indicators of poverty that are confined to income and consumption led to interest in asset/vulnerability approaches to understanding poverty (Moser 1998) that focus on sustainable local-level poverty reduction strategies which strengthen people's own inventive solutions. Amartya Sen argues for creation of more opportunities or capabilities as he calls it for women in particular (1979, pg 218) that would empower and provide social justice. Sen's argument is that only when barriers are removed by providing capabilities can people be truly said to act out of personal choice. This is especially true for women in subsistence communities in India where women are the main caregivers and maintainers of family health.

The "asset" model of health literacy from literature and Sen's notion of capabilities is used in this work to examine the impact of a specific women-oriented health literacy program in a subsistence community in India. The research is designed to 1) inform and educate community members on health care and its connection to wellbeing 2) to educate the community on the strong link between ill health and particular food consumption patterns in a village in South India. The health literacy program foregrounds women community members' literacy. The health outcomes are monitored at the individual and community level longitudinally to assess the changes in food consumption patterns and the changes in the level of self-management of disease and its impact on disease control. From a transformative consumer research standpoint, this study advances knowledge by bringing in very current dialogues from cultural sociology, public health and medical literature on the conceptualization of health literacy to examine and develop measures to assess health literacy oriented towards women as an asset in improving food consumption patterns and self-management of chronic diseases among subsistence communities.

"Well-Being at the Intersection of Subsistence and Sustainability"

Madhu Viswanathan, *University of Illinois, Urbana-Champaign, USA*

Srinivas Sridharan, *University of Western Ontario, USA*

Kiju Jung, *University of Illinois, Urbana-Champaign, USA*

A desired outcome of sustainable development is to enhance well-being among those living in subsistence. The concept of sustainability in a broad sense integrates issues relating to "Triple Bottom Line" or "Profit, Planet, and People" (Elkington 1997). As business, government, and social enterprise endeavors to create sustainable solutions, a number of top-down notions of sustainability serve to guide them. However, from the perspective of transformative consumer research, these top-down approaches beg a number of questions such as the following: what does sustainability mean from the perspective of those living in subsistence and how does it translate to enhanced well-being from the perspective of those living in subsistence.

Whereas there are a number of approaches to poverty and well-being, our approach is consistent with the sustainable livelihoods approach to poverty, sustainable development (see Chambers and Conway 1992), and a bottom-up community level approach to poverty and sustainable development (see Chambers 1997 and Pound et al., 2003). Criticisms of narrow indicators of poverty that are confined to income and consumption led to interest in asset/vulnerability approaches to understanding well-being and poverty that focus on sustainable local-level poverty reduction strategies which strengthen people's own inventive solutions. "A livelihood comprises the capabilities, assets (including both material and social resources) and activities required for a means of living. A livelihood is sustainable when it can cope with and recover from stresses and shocks and maintain or enhance its capabilities and assets both now and in the future, while not undermining the natural resource base." (Chambers and Conway 1992). The livelihoods approach begins with a need to understand the livelihoods of individuals living in subsistence and the constraints that inhibit a realization of rights improvement of livelihoods on a sustainable basis. This framework identifies different forms of capital/resources—human, social, cultural, and economic capital (Bourdieu 1986; Cohen 1999; Coleman 1988; Putnam 1993) that enhanced well-being.

We draw from research on subsistence marketplaces and a related social initiative on providing marketplace literacy education in South India (Viswanathan, Gajendiran, and Venkatesan, 2008) with implications for well-being in the economic realm. Specifically, our research program has provided a range of insights on well-being as it relates to marketplace activities. Our educational program and its assessment in terms of actual impact on subsistence individuals provide a platform to understand well-being and its relationship with skills, confidence, and awareness and exercise of rights. In turn, our focus has also been on sustainable consumption and production.

Our ongoing research examines sustainability and well-being from the perspective of those living at the lowest strata of society through qualitative research in South India. Subsistence marketplaces with severe resource constraints represent an ideal context in which to study sustainability and well-being. In subsistence marketplaces, severe resource constraints make for a natural sense to conserve and to do more with less. Also subsistence is intertwined

with under-consumption and a natural tendency to conserve precious basic necessities by strategic reusing, exchanging, sharing, and saving and reinvesting in future well-being, such as through education. However, the need to use available resources in unsustainable ways to survive the short-term is also crucial; for example, the use of firewood for cooking adding to pollution and causing respiratory illnesses. Conservation may be economically beneficial for well-being (short-term) as well as be socio-culturally beneficial for well-being (long-term; e.g., building trust in communities and tightening community network and solidarity). However, social costs from unsustainable consumptions may degrade and dismantle physical ecology and a sense of community, and hence decrease well-being of both individuals and communities. Our research examines the tension that exists between conserving and consuming from the perspective of customers and entrepreneurs.

Our research is examining the spheres of life where subsistence individuals view conflicts between social, ecological and economic realms and, as a consequence, decreased well-being. Some areas of concern include the local physical environment (e.g., pollution, garbage disposal, plastic use and burning, deforestation, overuse of chemicals such as pesticide in agriculture), basic physical needs (e.g., scarcity and contamination of drinking water, lack of nutritious food), the socio-cultural environment (e.g., weakening of human relationship as well as changes in culture and tradition), and the local economy. In each of these areas with the lack of action among powerful interests as well as the lack of infrastructure and resources that characterize subsistence contexts, individuals adjust to makeshift solutions and try to conserve resources (e.g., reusing plastic containers for storage, using clothes to screen against pollution at home or during travel, using public transportation, shopping and purchasing as a group, making rather than buying to save money and enhance nutrition, harvesting rainwater, locally producing products, using both innovative and traditional cooking methods to retain nutritive ingredients). Our research findings suggest notions of sustainability and well-being which are holistic—an interconnected web of issues ranging from struggles from the deterioration of the physical environment, the lack of civic values (especially trust) and social networks, and the erosion of local culture and human relationships to efforts for overcoming the struggles and moving forward.

SPECIAL SESSION SUMMARY

Looking on the Bright Side: The Effects of Optimism on Goals and Behavior

Elaine Chan, Hong Kong University of Science and Technology, Hong Kong

EXTENDED ABSTRACTS:

“The Counteractive Optimism in Goal Pursuit”

Ying Zhang, University of Texas at Austin, USA

Ayelet Fishbach, University of Chicago, USA

The current research proposes counteractive optimism as a self-regulatory process in consumer goal pursuit. Because the presence of obstacles to the attainment of important long-term goals triggers people's internal self-control efforts, and because an optimistic prediction, compared with a more conservative one, can be a more challenging and thus more motivating performance standard, we propose that individuals who are concerned about their performance in goal pursuit will generate an optimistic prediction of their future goal pursuit when anticipating obstacles and use these predictions to direct their subsequent effort. This is called counteractive optimism. For example, a dieter who is concerned about being fit will predict increased ability to resist when shown promotional ads for tempting food items, so as to actually increase the effort to resist the temptation and maintain goal pursuit.

While counteractive optimism increases a person's motivation to invest efforts in pursuing an important goal, this comes at the cost of being less accurate in predictions. Because an obstacle objectively increases the difficulty in attaining a goal, achieving accuracy in prediction requires a more conservative prediction to account for this negative impact. Therefore, we expect individuals to stop using expectation as self-control mechanism and reverse the counteractive optimism whenever the incentive for providing an accurate prediction outweighs that for securing higher performance. In these cases, anticipation of obstacles should result in a more conservative prediction, compared with no obstacles. Because less optimistic predictions set lower standards and are less motivating, individuals will accordingly invest less effort in actually pursuing the goal.

Three studies were conducted to test these hypotheses. Study 1 demonstrated the impact of counteractive optimistic predictions. Participants were asked to perform certain tasks and were offered incentives to perform well. Half of the participants were told the task would be difficult, and the other half were told it would be easy. Before commencing the task, participants were either asked to predict their performance in the task, or not. We found that for participants who were asked to predict their performance, those who expected the task to be difficult (vs. easy) predicted a better performance, a pattern that is consistent with counteractive optimism, and in the end showed higher motivation (i.e., persistence) in completing the task; in contrast, participants who did not predict their performance before commencing the task did not show any difference in task motivation regardless of whether they believed the task was difficult or easy.

Study 2 demonstrated the mediating role of an optimistic prediction. In this study, participants needed to complete a take-home exam and were asked to either give an accurate prediction or a rough one before leaving the lab with the exams. Before they made their predictions, half of them were told the exam would be difficult, while the other half were told that it would be easy. We found that participants who were told to give a rough prediction expected to complete the exam sooner if they believed it would be difficult (vs. easy); however, for participants who were told to be accurate, these results reversed. Participants' actual completion times were highly

consistent with the predictions, and were mediated by the predicted times.

Study 3 demonstrated an important moderator for counteractive optimism: the controllability of the obstacle. This study showed that when the obstacles were believed to be beyond one's control, the counteractive optimism effect does not obtain. Specifically, participants in this study were asked to predict their susceptibility to certain health risks. We found that if this risk was believed to be acquired and correctable through behaviors, people predicted themselves to be less susceptible to it when they were told that they were among the high (vs. low) risk group, and they adjusted their subsequent health behaviors accordingly to ensure that their predictions were fulfilled. This pattern, however, went away if the risk was believed to be inherited and no actions can alter one's susceptibility to the risk. In this case, people predicted themselves to be more susceptible when they were told that they belonged to the high (vs. low) risk group, and made no behavioral changes.

Taken together, in this research we identified counteractive optimism as a self-control mechanism that helps people overcome obstacles. Whenever the performance in goal pursuit is critical, anticipated obstacles elicited a counteractive optimistic prediction, which in turn increased people's effort to meet these standards. This self-control mechanism, however, disappears when individuals are concerned about the accuracy of their predictions. In these cases people generate more conservative predictions when anticipating obstacles in goal pursuit, and as a result, their effort drops accordingly.

“Enhancing Self-Control through Future Consequence Elaboration”

Kelly Haws, Texas A&M University, USA

Gergana Nenkov, Boston College, USA

Consumers draw upon a variety of strategies when attempting to exercise self-control (Hoch and Loewenstein 1991), many of which are directly related to the time inconsistent preferences underlying most self-control dilemmas. Self-control strategies specifically bringing attention to future periods of time should allow individuals to consider consequences consistent with their higher-order goals (Fujita et al. 2006). Indeed, many self-help books and old sayings advise people to think before they act, look before they leap, and measure twice before cutting once. Academic research has also established the beneficial effects of considering the outcomes that might occur in the future for the effective control of one's behavior in the present (e.g., Baumeister and Heatherton 1996, Nenkov et al. 2008). However, the question arises: is future outcome consideration always beneficial for people's effective self-control or is it possible that some types of outcome elaboration (e.g., positively biased) might actually hinder it?

In Study 1 we examine the role of providing outcome cues in enhancing self-control effectiveness. Participants (n=137) were asked to indicate how much they would pay on a credit card account. We provided participants with either just basic account information (account balance, minimum payment due, APR, balance due date) or basic information plus future outcome cues (length of time to pay-off and total finance charges, given minimum payments). After filler tasks, we measured consumer spending self-control (Haws and Bearden 2009). A significant interaction between participants' spending self-control and condition ($p < .01$) indicated that the

nature of information provided did not affect payment amounts for high self-control consumers, while future outcomes cues significantly increased the intended payments of low self-control consumers.

In our second study, we investigated whether providing outcome cues aided consumers' self-control by focusing them on the potential outcomes of their behavior. Participants (n=142) were asked to imagine that they encountered a desirable product at an electronics store, but that purchasing the item would cause them to reach their credit limit. In the no outcome cues condition, no further information was given, but in the outcome cues present condition, specific potential negative consequences were provided (e.g., unable to repay, credit rating implications). Participants were then asked to decide whether they would buy the item or not and to indicate the extent to which they thought about future outcomes when making the decision. Providing negative outcome cues enhanced self-control for consumers not inherently inclined to exercise it, whereas consumers inherently high in self-control did not differ significantly in the amount of self-control exercised based on the presence or absence of outcome cues in their environment. Furthermore, based on differences in consumer self-control, we found a significant interaction in the extent to which the presence of the cues caused participants to think about the future consequences of their decision. Specifically, those participants high in self-control reported that they thought about future consequences quite a bit in both conditions, while for those consumers low in self-control, the cues significantly increased their focus on future consequences. As such, this study indicates that part of the reason that consumers who are high in self-control might be more successful in exerting self-control is because they naturally elaborate on the potential consequences of their actions more, regardless of environmental cues.

In Study 3 (n=97) we examine the effects of focusing consumers differentially on the positive vs. negative future outcomes on their subsequent self-control. In this study we also extend our effects to different consumer domains and assure personal relevance of the issue to each participant by allowing them to choose one of four self-control issues (i.e., weight management, budgeting, time management, or exercising). Furthermore, we use another related individual difference variable—proclivity to elaborate on potential outcomes (EPO) (Nenkov et al. 2008), which should be relevant to all four contexts. We employ a 2 (outcome elaboration priming: positively biased vs. negatively biased) x 2 (elaboration task framing: self-control success vs. failure—yielding to temptation) between subject design. After engaging in a condition-specific elaboration task in which they listed potential outcomes (e.g. positive outcomes for exerting self-control), participants were asked to respond to a scenario representing a temptation in their chosen domain. Using EPO as a third factor, a three-way interaction emerged suggesting the circumstances under which high EPO consumers might be harmed and low EPO consumers might be helped. Specifically, while consumers high in EPO were generally more effective in exercising self-control, elaborating on the positive outcomes of yielding to temptation (e.g., enhanced life enjoyment) actually decreased their self-control. Low EPO consumers, on the other hand, enhanced their self-control when asked to elaborate on the positive consequences of yielding to temptation or the negative consequences of exerting self-control, both of which serve to draw attention to the fact that the long-term consequences of present indulgence may not be that significant.

Overall, our research has provided new insights into an important strategy that can be utilized by consumers when trying to make decisions. Both our findings from studies 1 and 2 and past research

(Nenkov et al. 2008) have found that high EPO consumers are generally more likely to engage in effective self-control. Our study 3 results suggest that different approaches need to be employed to motivate consumers to engage in effective self-control based on their level of EPO. Interestingly, focusing on positive outcomes tended to backfire and decrease self-control for high EPO consumers. On the contrary, improvements in self-control for consumers with low outcome elaboration came from both external negative outcome cues and a “forced” focus on the consequences of indulgence.

“Understanding Optimism: Buying What You Can’t Use Today but Hope to Use Tomorrow”

Elaine Chan, Hong Kong University of Science and Technology, Hong Kong

Anirban Mukhopadhyay, Hong Kong University of Science and Technology, Hong Kong

Jaideep Sengupta, Hong Kong University of Science and Technology, Hong Kong

Consumers often purchase products that they are unable to use at the time of purchase, in anticipation that they may be able to do so in the future. For instance, why might people buy (as they often do) clothing that is one size too small for them? One possibility is that such purchase decisions are driven by expectations of being able to realize the consumption at some future time. As optimists hold more favorable expectations of the future than pessimists, optimists should be more likely to engage in such behaviors. In this research, we present a more nuanced view of when and why optimism might have such an effect, and in so doing, provide new insights into the different mechanisms underlying optimism.

Optimism, as a positive illusion of the future, is often considered to be a result of mental imagery (Taylor and Brown 1988). Such imagery-based processing, as opposed to more data-driven analytical processing, is marked by increased consideration of self-related expectations. Accordingly, we propose that under imagery processing, the more favorable expectation held by optimists should make them more inclined to engage in anticipatory purchasing than pessimists, but the effect should be diluted under analytical processing. Further, this effect of imagery can be driven by two possible routes: optimists may either imagine the outcome of the purchase as being positive, or the process required to realize the benefits of the purchase as being easy. We propose that either route prevails depending on the depth of processing. Anticipatory purchase typically involves some uncertainty as to whether one can take the steps needed to use the product. When processing is unconstrained,

the required confidence level is higher (Eagly and Chaiken 1993), and therefore, focusing the imagination on the process required gives optimists the confidence that they can easily accomplish those steps. This leads them to be more likely to make anticipatory purchases than pessimists. This effect should decrease when focusing on the outcome, because optimists have to think directly about the end result without deliberating on the intervening steps, which reduces their confidence and therefore purchase likelihood. The situation is different when cognitive capacity is constrained, as decisions are now based on a heuristic of whether the final outcome is favorable or not. As optimists think of the outcome as being more positive than pessimists, focusing their attention on the outcome should make them more likely to make anticipatory purchases than pessimists. On the other hand, as their ability to generate steps is constrained by the limited cognitive resources, the effect should be dampened when they are required to think about the intervening process. In sum, we hypothesize that the outcome-focus route to optimism operates under constrained capacity, while the process-focus route operates under unconstrained capacity.

Four experiments tested these hypotheses. Experiment 1 used a 2 (method of processing: analytical vs. imagery) x 2 (optimism: optimists vs. pessimists) between-subjects design to test whether the effect of optimism is obtained under imagery processing, but not under analytical processing. Participants first took part in a survey, which included a question about the size of jeans that they could just fit in. After a filler task, they took part in a different survey about buying jeans. We manipulated method of processing by asking participants either to rely on their imaginations or be careful and well-reasoned while making their decisions. Next, they read the description of the jeans under purchase consideration, which were always one size smaller than their current sizes (as recorded in the earlier survey). They then reported their likelihood to purchase these jeans. Lastly, participants filled out a standard optimism scale (Scheier and Carver 1985). As hypothesized, the imagery instruction induced a higher purchase intention for optimists than pessimists, but there was no such effect under analytical processing.

Experiment 2 used a 2 (focus: outcome vs. process) x 2 (manipulated optimism: optimists vs. pessimists) between-subjects design to look more specifically at the mental simulations leading to the effect of optimism under unconstrained processing. The procedure was similar to that of Experiment 1, except for two changes. First, before the jeans purchase scenario, we manipulated optimism by asking participants to list either 2 vs. 8 examples of optimistic thinking. In accordance with the ease of retrieval effect (Schwarz et al. 1991), participants should find it difficult (vs. easy) to generate 8 (vs. 2) instances, and hence should conclude that they were pessimistic (vs. optimistic). Second, this experiment manipulated thought focus by asking participants to make their decisions by visualizing either the end benefits of wearing the jeans or the process they would go through in order to be able to wear the jeans. In support of our hypothesis, results revealed that optimists were more likely to make anticipatory purchases than pessimists under process-focus, but this difference disappeared under outcome-focus. This pattern of results was replicated in another study (Experiment 2B) using a different product category (musical instruments).

Experiment 3 rounded out the picture by testing the prediction that optimism exerts its effect through an outcome or a process route depending upon the availability of cognitive resources. This experiment used a 2 (cognitive load: high vs. low) x 2 (focus: outcome vs. process) x 2 (optimism: optimists vs. pessimists) between-subjects design. The procedure was similar to that of Experiment 2, except for two changes. First, we measured optimism

as in Experiment 1. Second, before the jeans purchase scenario, we manipulated cognitive load by asking participants to memorize either a 2-digit (low load) or an 8-digit number (high-load). Replicating previous findings, results showed that under low cognitive load, optimism enhanced the purchase likelihood under process-focus, but not outcome-focus. Of interest, under high cognitive load, optimists were more likely to purchase than pessimists under outcome-focus, but not process-focus. In effect, Experiment 3 showed that optimism can operate through either process- or outcome-focus, depending on the depth of processing.

Taken together, results from four studies, which included both chronic and situational inductions of optimism, as well as different purchase contexts, provide a theoretically-supported pattern that explains both when and how optimism might have an effect on anticipatory purchase. In doing so, this research both offers new insights into the substantive domain of anticipatory purchasing, and builds theoretical knowledge about optimism.

SPECIAL SESSION SUMMARY

Multidisciplinary Approaches to Communicating Health Risks

Adriana Samper, Duke University, USA

SESSION OVERVIEW

The importance of improving the communication of health risks and prescriptive actions is clear, yet there are many stumbling blocks associated with translating health risk information into consumer action. Questions emerge regarding how accurately individuals may interpret risk information, how they may respond to this risk information (engagement vs. denial or avoidance) and how health risk communications designed in the lab can be effectively presented in the field and scaled up to produce broad impact. This session brings together papers across the spectrum, from micro (e.g., perceptual and emotional) to macro (societal) approaches to understanding consumer reactions to risk. By bringing together papers that take perceptual, emotional, behavioral and societal views of health risk communication, this session will help move consumer research towards integrative solutions for motivating beneficial action.

First, Raghurir models, and empirically documents, fundamental (hard-wired) perceptual bias in risk assessment. Next, Samper, Luce and Purohit suggest emotion-based communication interventions to circumvent consumer bias in risk estimation, revealing that these types of communications can help or hurt depending on the degree of threat present. Keller and Lehmann demonstrate how to integrate across perceptual, emotional and other variables of these kinds to design effective interventions. Finally, Bloom, Block and Trabold address the need to integrate insights from individual studies and “scale up” to improve societal actions. This fourth paper facilitates discussion and integration of all of the papers in the session.

EXTENDED ABSTRACTS

“The Psychophysics of Estimated Risk”

Priya Raghurir, New York University, USA

This paper proposes a psychophysical function that translates raw base-rate information about health risk into perceptions of risk for the average person and one’s self. Unlike the standard power functions, in our formulation the exponent of the power function is endogenously determined as a function of the size of the base rate denominator, and varies as a function of base-rates. The value of the exponent is also modeled to be the parameter used to adjust risk estimates for oneself from the starting anchor of estimates of an average person. The model is parsimonious, requires no exogenous assumptions, is based on the psychology of how people process denominator information and an anchor-adjust model of risk estimation, and fits the data from two studies across 13 different causes of death, well.

A base rate is the likelihood of occurrence of an event ($n=1$), in terms of the size of the population from which it is drawn (“N”):

$$\text{Base Rate} = 1 / N$$

Psychophysical models of estimation have shown that people’s estimates may be biased and follow a power law with an exponent < 1 (Chandon and Wansink, 2007; Krider et al., 2001; Krishna, 2007), leading to smaller numbers being overestimated relative to larger numbers. In a risk perception context, we propose that the denominator, N, is the focal property being estimated. Therefore, rather than the exponent, α , being applied to the numerator (as is

common in other psychophysical representations), it is applied to the denominator, or:

$$\text{Perceived Risk} = 1 / N^\alpha, \text{ where } 0 < \alpha < 1,$$

When $\alpha \rightarrow 1$, perceptions are more accurate, and as $\alpha \rightarrow 0$, base rates are overestimated. The size of α has been typically modeled to be a constant, independent of the base estimate to which it is applied. We suggest that α is endogenously determined with its size contingent on the estimation quantity (or base rate) itself, or:

$$\alpha = f(N)$$

This is because the larger the population (denominator N), the more difficult it is to identify with (Raghurir, 2008), leading to a smaller exponent, $\alpha \rightarrow 0$. The larger the overall number of people who are at risk, or the incidence of an event ($n \rightarrow N$), the easier it is to imagine oneself being a part of this group, and the larger the exponent, α , or the closer it is to 1. One representation of this model that satisfies the above conditions is:

$$\alpha = K (\log N)^\chi,$$

where K is a scaling constant, and χ is a fraction between 0 and -1. This representation allows the rescaling of large numbers through the use of Log (N) versus N (e.g., 5 and 340,733 are scaled down to 0.70 and 5.53). The fractional exponent, χ , further rescales large differences closer to 1 (e.g., $\chi=1/8$, transforms Log (5) from .70 to .9562, and Log (340,733) from 5.53 to 1.2384). This representation implies the following psychophysical function:

$$\text{Perceived Risk} = 1 / N K (\log N) \exp(\chi).$$

The prevalent belief in health risk is that self-perceptions are related to the perception of risk of others with the latter used as a starting anchor (Lin et al. 2003, Raghurir and Menon, 1998). We model self-estimate of risk as a function of the actual estimated risk of the average person (AP):

$$\text{Self Perception} = K (\log N)^\chi * AP [AP / \text{Perceived Risk}]$$

This formulation recognizes that the AP in the numerator serves as a starting anchor against which self perceptions of risk are formulated. The AP/ Perceived Risk ratio captures differences in risk perception due to other causes such as the perceived controllability of a cause of death (Lin et al. 2003). The closer the ratio is to 1, the better the fit of the psychophysical function, and the lower the effect of causes external to the actual base-rate itself (e.g., controllability). The constant, α , is a scaling parameter that is itself contingent on the base-rate and is the level of adjustment that people make after they anchor on the risk of the average person. The closer $\alpha \rightarrow 1$, the lower self-other biases in risk estimates, and the closer both perceptions are to actual base-rates.

Two studies were designed to test these two representations. In Study 1, we examine risk perceptions for 13 different causes of death varying odds. Study participants ($n=100$) were asked to estimate how likely a cause of death was for both themselves and the average person. A 13 (causes of death) x 2 (targets) ANOVA on risk

estimates revealed that estimates of risk of the average person are higher than estimates of risk for one's self: the self-positivity bias. There was also main effect of cause reflecting different perceptions of risk for the various causes of death. A significant interaction revealed that the self-positivity bias was absent for three of the causes of death: MVAs, pedestrian accidents, and earthquakes.

We then fitted the psychophysical function to the mean estimate of risk for the average person. The function is characterized by an exponent that ranges from .7843 (for cancer) to .6056 (for fireworks discharge). The scaling constant, k , is .75, and the exponent for $\log(N)$ is 1/8. The fit follows actual estimates well. Study 2 examines the moderating role of manner of presentation of risk estimates as numeric versus graphic on risk perceptions.

“Imagine Yourself in This Patient’s Shoes: The “Identifiable Patient” and Health Threat”

Adriana Samper, Duke University, USA

Mary Frances Luce, Duke University, USA

Devavrat Purohit, Duke University, USA

Identifiability—the presentation or description of a single, often named, individual as the subject of a message—has been shown to be a powerful instigator of emotion and affective processing (e.g., Small, Loewenstein, and Slovic, 2007). Most of this work has focused on the domains of altruism and helping behaviors. Researchers have coined the “identifiable victim effect” (Small and Loewenstein, 2003), pointing out that “society is willing to spend far more money to save the lives of identifiable victims than to save statistical victims” (Jenni and Loewenstein, 1997, p. 236). Affective processing has been shown to underlie these differences in giving (Small et al., 2007).

The effect of identifiability on health risk perceptions and behaviors has yet to be addressed. This is a critical gap because health communications aim to motivate recipients to take actions to benefit themselves, whereas prior work on identifiable victims aims to motivate actions to benefit others. Moreover, effective health messages are increasingly “self-relevant,” targeting information toward specific demographic groups. To date, research has yet to examine how the self-relevance of a communication might moderate the benefits of specifying an affect-inducing identifiable individual to motivate action.

We address the important questions of whether and how the presentation of an identifiable patient can motivate desired behavior in a health communication context. This research examines the conditions under which identifiability does, and does not, have beneficial effects. In Study 1, college undergraduates were instructed to read a pamphlet about the threat of genital herpes among college students vs. middle-aged adults. This pamphlet was accompanied by a picture of an individual college student (middle-aged adult) said to have genital herpes or a picture of a group of college students (middle-aged adults) with a statistical risk for genital herpes. The identifiable pictures were matched on sex. Underneath all pictures was a caption describing the statistical risk of genital herpes. We find that identifiability increases perceived vulnerability to disease, but only for those individuals presented with the identifiable college student. Thus, self-relevance is necessary for identifiable presentation to increase perceived threat.

Given that a great deal of health information is presented in situations of higher stress (e.g., physician's office, hospital or clinic), in Study 2 we examine the effect of ambient stress on identifiable patient presentations, examining perceived vulnerability to herpes, concern about contracting herpes and intent to be tested for the disease. Participants were presented with herpes information depicting only college students, either identifiable or in a group. Next, we manipulated stress levels by asking participants

to complete an easy (difficult) timed anagram task. We find that following the easy task, at low stress levels, identifiable patient presentation increases perceived vulnerability to herpes. However, following the difficult (high stress) anagram task, participants reported significantly reduced perceived vulnerability, suggesting a denial of risk under high stress, identifiable conditions.

Study 2 also revealed that group presentation may be better for promoting concern and screening in high-stress conditions. An interaction of stress by group presentation on concern and intent to be tested indicated that high-stress group presentation leads to both increased concern about contracting herpes as well as increased intent to be tested for herpes relative to low-stress group conditions. Finally, a moderated mediation analysis examining the effect of stress at identifiable and group presentation levels revealed that whereas there are significant positive relationships between stress and concern and stress and intent to be tested (and indirectly, concern and intent to be tested) in the group conditions, in the identifiable conditions, the effect of stress is actually no longer significant and is in fact negative. This supports the notion of a denial response under identifiable patient presentation, whereby increased stress leads to reduced concern and intent to be tested.

This research has important implications for the communication of health messages. While we find that identifiability increases susceptibility under low stress conditions, this effect is no longer present under high stress conditions. In addition, we find that group (non-identifiable) presentation may be optimal for generating behavioral intentions and appraisals of concern under high stress conditions. These findings support the notion that both avoidant and action-oriented responses arise from high threat, and examines how identifiability may activate these mechanisms. Given that identifiable patient advertisements are ubiquitous in the public health space, it is important to understand the boundary conditions that moderate their intended response.

“Promoting Health-Related Consumer Research: ARC Model Application to CDC’s Health Campaign”

Punam Anand Keller, Dartmouth College, USA

Donald R. Lehmann, Columbia University, USA

The massive costs of health care (\$1.7 trillion and counting) and the problems posed by various diseases (e.g., AIDS, obesity, diabetes, cancer, heart disease, mental illness) are well known and documented. People worry more about their personal health care costs than losing their jobs, being a victim of a violent crime, or terrorist attacks. As a consequence, massive efforts to improve knowledge about detection, prevention, and treatment have been undertaken. Despite growing realization that health communication strategies need to be improved possibly by tailoring them to audience segments, there is no model that guides the design of health communications.

Currently, four barriers prevent the application of consumer research studies to improve the effectiveness of public service health campaigns. First, the focus on one or two message tactics makes it difficult to generalize the results to situations where the audience is faced with a wide variety of message tactics in the same or different health campaigns (cf. Raghurir and Menon, 1996). Second, most consumer research studies do not provide guidelines for tailoring since they do not examine how message formats interact with measurable individual differences such as demographics. Third, small cell sizes in most lab studies raise concerns about whether lab findings can be replicated in the field. Finally, there is no evidence that message formats determine health intentions when other factors such as peer influence are accounted for.

We developed a model, Advisor for Risk Communication (ARC) to overcome these barriers. ARC examines the effects of 22

message tactics and 6 individual differences on intentions to comply with health recommendations. ARC is based on a meta-analysis of 60 studies, 584 different experimental conditions and 22,000 participants

Our results can be viewed as making two key contributions to consumer research: 1) our results indicate which of twenty-two message variables remain significant when the effect of other message variables have been accounted for, 2) our model can be used to predict the effectiveness of health messages for audiences that vary in age, race, gender, regulatory focus, and involvement.

We propose the following model application steps:

- 1) Code the health communication message to reflect the levels of multiple message formats. What is the social effect? Does it contain pictures? Does it tell a story? Are there a lot of dry numbers? Is the communicator male or female?
- 2) Use ARC to predict the effectiveness of the health message.
- 3) Improve the effectiveness of the health message by changing it according to the recommendations in ARC.

The ARC model supports the use of several message tactics: case information (e.g., a story about a real or hypothetical person rather than numbers or percentages), social consequences (e.g., embarrassment works better than physical pain), other-referencing (e.g., focus on people around you rather than yourself), female communicators (are better than male communicators), a message that arouses emotions other than fear, and messages on detection behaviors (rather than prevention or remedial behaviors) to enhance health intentions.

ARC also recommends focusing on discouraging unhealthful behavior rather than promoting healthful behaviors and de-emphasizing source credibility and vividness (e.g., pictures, cf. Keller and Block, 1997). The results of our meta-analysis also indicate that communication dollars may be saved by not spending money on message factors that don't enhance intentions unless they are matched with audience characteristics. For example, contrary to popular use, framed health messages (loss or gain frames) are not advisable without knowledge of target audience goals (promotion vs. prevention, cf. Lee and Aaker, 2004).

The ARC model also identifies effective matches between message tactics and audience characteristics. For example, ARC indicates that low-involvement audiences are more persuaded by moderately fearful gain frames, other-referencing, vivid messages, and strong source credibility, whereas highly involved audiences prefer base information and strong messages that are also moderately fearful, but they do not distinguish between levels of vividness, source credibility, and referencing. Younger audiences prefer social consequences over multiple exposures, whereas older audiences are more influenced by physical consequences regardless of the number of message exposures.

We demonstrate how ARC may be used for improving the effectiveness of public service campaigns by testing its ability to predict health intentions for CDC's VERB campaign to encourage youth to exercise more in their free time. We find the ARC predictions and stated intentions are in close correspondence to each other. ARC predictions are significant predictors for stated intentions and behavior when socio-economic, social influence, beliefs and attitudes, number of ads, and exposure frequency are accounted for. Intention and behavior predictions are approximately equally sensitive to family and social influence, parent

education, and recall of message exposures, and in general have less impact than the child beliefs/self-view and ARC predictions. Finally, ARC health intention predictions are significant predictors of self-reported exercise behavior. Taken together, these findings offer many opportunities to use consumer research to tailor health communications for different target audiences.

“Communication Strategies for Scaling Health-Focused Social Entrepreneurial Organizations”

Paul N. Bloom, Duke University, USA

Lauren G. Block, Baruch College, USA

Lauren Trabold, Baruch College, USA

The term “social entrepreneur” is typically used to describe individuals who start up and lead new organizations or programs that are dedicated to mitigating or eliminating a social problem, deploying change strategies that differ from those that have been used to address the problem in the past. Notable social entrepreneurs include (a) Wendy Kopp, founder of Teach for America, which places recent college graduates as teachers in inner-city schools for a two-year stint, and (b) Paul Farmer, founder of Partners In Health, which has provided low-cost treatment for AIDS, TB, and other diseases throughout the developing world. These innovators—and their social entrepreneurial organizations—pursue scaling because they want to have as big an impact as possible on social problems and because their donors and supporters are hungry to achieve high “social” returns on their investments.

The social entrepreneurial organizations that focus on health problems tend to emphasize Prevention, Treatment, or Advocacy, or some combination of the three. Figure 1 presents a way of categorizing these organizations, based primarily on their “change strategy,” or on what some would call their “Theories of Change.” They have a causal model in mind that links their programs or interventions to a series of outcomes that eventually will help resolve a social problem (Colby, Stone, and Carttar, 2004). We suggest that the “Theories of Change” of health-focused social entrepreneurial organizations tend to fall in one of seven different categories:

- “Promoting Healthier Lifestyles” (a purely prevention approach).
- “Developing/Distributing Medications/Equipment” (a purely treatment approach).
- “Creating Healthier Environments” (a combination prevention and treatment approach).
- “Providing Patient Care/Therapy” (a combination prevention and treatment approach).
- “Training Health Workers” (a combination prevention, treatment, and advocacy approach).
- “Supporting/Assisting Patients” (a combination prevention, treatment, and advocacy approach).
- “Advocating for Better Health Policies” (a purely advocacy approach).

Bloom and Chatterji (2009) propose that successful scaling of social impact by a social entrepreneurial organization will require the possession of some combination of seven organizational capabilities, identified using the acronym SCALERS. This stands for: Staffing, Communicating, Alliance-building, Lobbying, Earnings-

generation, Replicating, and Stimulating market forces. They also propose that the extent to which an individual SCALER (i.e., driver or capability) will influence scaling success will depend on certain situational contingencies. Each social entrepreneurial organization may find itself facing rather unique situational contingencies, indicating that the most important capabilities for effective scaling of better health outcomes will vary across organizations.

It is extremely common for health-focused social entrepreneurial organizations to face a situational contingency of having weak public acceptance or support for the behaviors they would like their beneficiaries to engage in. They often have had only limited success in persuading individuals to (a) take preventive actions like wearing sunscreens, using condoms, eating healthier or obtaining inoculations, (b) obtain screening tests for HIV/AIDS, cancer, or other diseases where early-detection can save lives, or (c) comply with therapy and drug regimens. Communicating persuasively about the value of engaging in healthier behaviors has become a critical scaling challenge for many organizations.

In this paper, we offer propositions about communications strategies that have a higher likelihood of changing the behavior of beneficiaries. Based on the literature in consumer behavior, social marketing, and health communications, we identify several communication strategies that can help guide a health-focused social entrepreneurship organization to scale its impact. We provide additional support to the propositions by analyzing several case studies of organizations that seem to have had scaling success, in part, by using some of the identified communications strategies.

As just one example, we illustrate our proposition "When targeting younger audiences, messages that emphasize social consequences are more effective than those that emphasize physical consequences" with the communications experiences of the organization Girls on the Run (Bloom, 2007). This self-esteem enhancement program for pre-teen girls uses games involving running to teach lessons about topics like healthy eating, peer pressure, bullying, and community service, and has grown from serving 13 girls in 1996 to serving over 40,000 per year by 2008. One of the keys to their scaling success appears to be the emphasis they have in their communications and lessons about the value for girls to be themselves. By stressing the social benefits of "being yourself," in part by providing social support for this from the coaches and other girls in the 12-student classes, the program has achieved more success in enhancing self-esteem—and also encouraging healthier eating and exercise behaviors—than if they had stressed the physical consequences associated with diet and exercise.

SPECIAL SESSION SUMMARY

Deviating From or Resetting Consumers Ethical Standards

Shahar Ayal, Duke University, USA
Francesca Gino, University of North Carolina, USA

SESSION OVERVIEW

Recent studies in the marketing literature have started exploring how consumers face purchase decision that entail tension between behaving honestly or ethically and maximizing one's own self-interests. This research has shown that consumers often resolve this tension through a creative interpretation of ambiguity around dishonest behaviors. Specifically, they behave dishonestly enough to profit from their unethicality but honestly enough to maintain a positive self-concept and balance their own ethical scale (for example, Mazar, Amir & Ariely, 2008). Building on this prior work, the papers in the current symposium will address two main questions (1) how do people evaluate products that are ethically tainted and how does using such products affect their behavior? and (2) what mechanisms help consumers maintain a balance between their moral self and their use of unethically made products and unethical actions? That is, how might consumers go about cleansing themselves from the guilt of their previous immoral behaviors?

The first two papers explore factors impacting the likelihood that ethically questionable behavior will occur during consumption or during purchase decisions. Gino and Norton examine the influence of wearing and using counterfeit products on both one's own dishonest behavior and on one's perceptions of others' dishonest behavior. Cavanaugh and Fitzsimons' work, instead, explores how people choose products when information about the unethical manufacturing practices of such products is available to them. In the third paper, Ayal and Ariely examine the effects of confession and forgiveness on one's dishonesty acts and its role as a mechanism for turning over a new leaf. Finally, Inbar, Pizarro and Gilovich report findings showing that individuals with feelings of guilt seek to metaphorically "balance the scales" through self-induced physical punishment.

We believe the session will draw the attention of a diverse audience, including scholars interested in deceptive advertising, corporate social responsibility, and dark side marketing behaviors, as well as scholars interested more generally in the influence of emotions on consumer behavior. In addition, this symposium will make an important contribution to consumer research by highlighting when and why consumers might regularly cross ethical boundaries, even without being aware of it.

EXTENDED ABSTRACTS

"The Counterfeit Self: The Deceptive Costs of Faking It"

Francesca Gino, University of North Carolina at Chapel Hill, USA

Michael Norton, Harvard Business School, USA

As with their other consumption decisions—the products people buy to adorn themselves or decorate their homes and offices (Belk, 1988; Gosling, Ko, Mannarelli, & Morris, 2002)—people buy counterfeit products to signal positive traits, to themselves and others (Bodner & Prelec, 2002). Counterfeits, however, have an additional property, in that they signal an aspiration to be something one is not—for example, to feel wealthier than one's income allows. We contend that counterfeit products do cause people to be something they are not, but in ways they do not expect: Counterfeit products cause people to be not admirable but unethical, generating in them

a feeling of a "counterfeit self" that leads them to behave unethically.

As with other research exploring signaling conflicts, such as between public and private signals (Goffman, 1956; Kuran, 1995), counterfeits serve as an interesting case in which desired signals (I am an admirable person) may conflict with actual signals (I am a fake). We suggest that counterfeit products create a particular kind of conflict: Though the wearer intends them to signal positive traits, wearing counterfeits can in fact send a negative signal to the self. Indeed, given the well-documented effects of primes on behavior, such that the mere presence of objects can influence behavior (Berger & Fitzsimons, 2008; Berkowitz & LePage, 1967), we suggest that the negative impact of wearing counterfeit products is likely to occur despite their owners' desire to use them for positive signaling.

If wearing counterfeits can influence the signals one sends to oneself, what are the likely consequences? We hypothesize a link between wearing counterfeits, feeling "fake" or inauthentic, and behaving unethically: We suggest that a product's lack of authenticity may cause their owners to feel less authentic themselves—despite their belief that the product will actually have positive benefits—and that these feelings then cause them to behave dishonestly and to view others' behavior as more dishonest as well. In short, we suspect that feeling like a fraud makes people more likely to commit fraud.

We tested these predictions in four experiments. We first show that wearing purportedly counterfeit sunglasses causes people to cheat more on tests when given the opportunity—both when they believe they have an inherent preference for counterfeit products (Experiment 1A) and when they were randomly assigned to wear counterfeits (Experiment 1B). Indeed, the impact of counterfeits extends even beyond the individual, causing individuals not just to behave unethically but also to see the behavior of others as more unethical as well (Experiment 2). Finally, we investigate the mechanism underlying these effects, showing that wearing counterfeits causes people to feel inauthentic, and these feelings of inauthenticity—their counterfeit self—drive unethical behavior (Experiment 3).

While people adopt counterfeit products because they are trying to improve their self-image, our studies show that counterfeits have the ironic consequence of harming self-image via inauthenticity, inducing a "counterfeit self." Why then do people buy counterfeit products? One view, of course, is that the benefits of counterfeits simply outweigh these costs, and that people are making a calculated tradeoff between the two. We suspected that people may not be making this tradeoff, however, but rather may simply overlook the possible negative consequences of adopting counterfeits. Indeed, when we asked a separate set of students ($N=86$; $M_{age}=22$, $SD=2.20$) to predict the impact of counterfeits, they were unaware of the consequences for ethical behavior. We gave these students the average performance on the matrix task of our study participants, and asked them to predict the self-reported performance in three experimental conditions: Counterfeit sunglasses, authentic sunglasses, and a control condition. The students correctly predicted that, overall, participants across conditions would cheat ($M_{real}=9.62$, $M_{fake}=9.59$, $M_{control}=9.34$; $F[3,255]=43.67$, $p_{rep}>.99$). However, they did not anticipate that

cheating would vary across the three described conditions ($F[2,170] < 1$, $p_{rep} = .56$; $p_{rep} < .72$ across all comparisons). This difference between people's predictions about the impact of counterfeits and their actual behavior in our experiments suggests that the influence of wearing counterfeits is deceptive, in that they have an unexpected influence on individuals' ethicality.

The obvious differences between laboratory settings and real-world contexts aside, our results have worrisome implications for the many consumers who buy counterfeit goods. Given the economic and social relevance of the counterfeiting epidemic, future research on the psychology of counterfeits and their potential moral costs seems warranted. Indeed, given that cost savings is a primary motivation for the purchase of counterfeits (Eisend & Schuchert-Guler, 2006), individuals who buy counterfeits for themselves or gift them to others may believe that they are simply getting similar products for less money, but in fact may be paying a price in terms of their long-term morality. Perhaps most troublingly, our results from Experiment 2 demonstrate that the negative impact of counterfeits accrue not just to the buyer, but extend more broadly to the social environment, suggesting that overlooking the negative impact of counterfeits may have far-reaching negative consequences.

“Mirror... Mirror on the Wall, Whose the Greenest Giver of Them All?": Understanding When and Why Men and Women Gift Ethically-Made Products"

Lisa Cavanaugh, University of Southern California, USA
Gavan Fitzsimons, Duke University, USA

While most people claim they care about ethical issues and view themselves as honest individuals, it is likely that, in the past, they have chosen to purchase unethically produced products (e.g., products produced through child labor, unsafe working conditions, or environmental degradation). Companies making these products are often the subject of scrutiny as suggested by the large literature on corporate social responsibility (CSR). To date, very little is known about the role that consumers play in propagating a system that implicates harm (Devinney et al., 2007), and, more specifically, little is known about what drives consumers' demand for products that are produced in less socially responsible ways.

The present research addresses this gap and asks the following questions: 1) when and why do consumers buy unethically made products for themselves or for others? and 2) how do their choices for unethically vs. ethically made products vary based on the relationship they have with the person they are buying the product for?

In our first study we were interested in understanding how people choose products that will be gifted to a romantic partner when price and ethicality in the way the product was produced are in conflict with each other or not. The study employs a 2 (media exposure: yes vs. no) x 2 (respondent's gender: male vs. female) x 2 (pair type: conflict vs. no conflict) between-subject factorial design. Our media exposure manipulation consisted of participants watching a 4-minute video clip from NBC's Today Show about opportunities to buy ethically responsible products for Valentine's Day prior to making their choices (media exposure condition) or not watching such a clip (no media condition).

Our pair type manipulation consisted of participants choosing between different pairs of products whose features varied on two different desirable attributes. As a gift giver, we argue, people are likely to be motivated to choose a product that looks expensive so that they can signal they really care about the other person (gift recipient). Indeed, prior research has demonstrated that people commonly associate price with product quality—i.e., they often infer

quality from price based on the belief that the two factors are positively correlated (Monroe, 1973; Monroe & Petrosius, 1981; Ordonez, 1998). Thus, we assume product quality (as signaled by product cost) is a desirable attribute of products that gift givers take into account when making their purchase decisions. A second attribute we are interested in is whether the product is ethically produced or not. We assume that, as a gift giver, people consider products that are ethically produced as more desirable than products that are unethically produced (e.g., products manufactured using child labor). This assumption is supported by survey evidence showing that a large number of consumers incorporate ethical considerations into their product purchase decisions (e.g., Cone 2009; Crane, 2001; Strong, 1996; Rogers, 1998). We manipulated whether there was conflict between these two desirable product attributes (price and ethicality) or no conflict when participants selected one of the two products included in each pair.

We used two pairs of products, which varied on the same dimensions of price and ethicality for both women and men. The first pair consisted of an inexpensive product which was ethically produced, and an expensive product which was unethically produced (pair involving conflict between two desirable product dimensions, namely price and ethicality). The second pair consisted of an expensive product which was ethically produced, and an inexpensive product which was unethically produced (pair not involving conflict). We used chocolate as a product category for men (gifting their chocolate to their partner), and greeting cards as a product category for women (gifting the card to their partner). We chose these products (chocolates and cards) because these are the types of products that are regularly purchased for romantic partners by these two genders around Valentine's Day.

In the study, participants were asked to choose one of the two products in their assigned pair as a Valentine Day gift for their romantic partner. Only participants who were currently in a relationship could participate in the study. The study was conducted during the week prior to Valentine's Day, and 5% of the participants (randomly chosen) received the actual product of their choice during the study to give as a gift to their partner.

Studies 2-5 push these findings to demonstrate when and how consumers' decisions change based on the venue in which the gift is given (e.g., public vs. private), the type of product (e.g., durable vs. non-durable), and the type of relationship with the recipient (e.g., romantic partner, friend, colleague). Together the study results suggest that there are important differences in the way men and women weigh ethical considerations in their product purchase decisions and use products to signal their commitment to relationships in different ways. The results also demonstrate that, under certain circumstances, making an ethical standard salient can reduce the desire to buy attractive products that have been unethically produced (e.g., produced through the use of child labor).

We argue and find that asymmetries exist between the genders in their motivations to buy green gifts for different significant others in their lives. Compared to men, women are more likely to choose the unethical / cheap option as a gift for their romantic partner. However, they are willing to choose the ethical/expensive option for a female friend when the ethical cue is durable or explicit. Specifically, the probability of choosing a green gift depends largely on the giver's perception of its signal value to the recipient (i.e., it is more about what the green gift signals about the giver than the receiver). We find that women derive more meaning when choosing green gifts for other women than when choosing green gifts for men.

“Finding Balance on The Moral Scale: The Effect of Forgiveness on Dishonest Behavior”

Shahar Ayal, Duke University, USA

Dan Ariely, Fuqua School of Business, Duke University, USA

Consumers face ethical choices on a daily basis. In some cases, they know that if they succumb to dishonest behavior, forgiveness may be available to them. Do the expectation of being forgiven and forgiveness itself influence an individual's likelihood to engage in unethical behavior? The current paper aims to test the psychological mechanisms underlying forgiveness and their implications to dishonest behavior of consumers. In particular, three studies explore whether the likelihood of dishonest behavior varied before and after simulation of confession, and if so, how the effect of this confession is influenced by temporal distance.

Generally, expectations of receiving forgiveness might influence the likelihood that consumers will engage in dishonest behavior in two main ways. The first concerns the saliency of ethicality at the moment a particular behavior is considered. Previous research has found that drawing consumers' attention to moral standards could reduce dishonest behavior (Mazar, Amir & Ariely, 2008). These results suggest that when unethical behavior is made salient, consumers may pay greater attention to the importance of ethical behavior and moral standards. Thus, the saliency account predicts that consumers will avoid dishonest behavior after receiving forgiveness. Furthermore, it suggest that any type of self reflection on one own sins should decrease the level of dishonesty.

The second way in which forgiveness might influence dishonesty is captured by consumers' reactions to their current self-moral image, or their concerns-for-moral-balancing. According to this explanation, consumers resolve the tension between honesty and economic interests through a creative interpretation of ambiguous dishonest behaviors: they behave dishonestly enough to profit, but honestly enough to maintain a positive self-concept (Baumeister 1998; Gino, Ayal & Ariely, 2009; Mazar & Ariely, 2006). Thus, this account predicts that expected forgiveness allows consumers to protect their moral self-image from damage, so that they can maximize their profits by increasing the level of dishonest behavior.

The predictions of these two mechanisms were tested in three studies. The first two studies use hypothetical scenarios to examine individuals' intuitive beliefs about the effects of both expected and received forgiveness. In Study 1, we used a scenario describing a woman (Laura) who faced a strong temptation to engage in unethical behavior either before or after an important event. We manipulated two independent variables: The first manipulation concerned the nature of the event that Laura is scheduled to attend (confession vs. control). The second manipulation concerned the timing of the potential dishonest behavior in regard to the event.

The results show that participants' sensitivity to the timing manipulation was obtained only in the confession condition but not in the control condition. In particular, people expect dishonest behaviors to be more likely before rather than after confession. These results are consistent with the predictions of the concerns-for-moral-balancing account. Study 2 used the same Laura's scenario to examine if this effect can be replicated within participants and test the influence of time distance. Similarly to the results of Study 1, the lowest likelihood to act in a dishonest manner was obtained a short time after the confession. In addition, in line with the saliency account this positive effect of confession was eliminated and even reversed with time distance.

Finally, a third study tested for the effect of confession on one own sins in a laboratory setting where we could directly measure dishonest behavior. The study employed a computerized perceptual task, in which participants placed in situations that induced conflict

between honesty and maximizing one's self-interests and we observed their number of dishonest responses. The perceptual task was divided into two phases, and we introduced our manipulation (i.e., different types of introspective writing tasks) between these phases. Half of the participants who were assigned to the confession condition, were asked to describe one bad thing that they have done, and then to close their eyes and ask "God" or any other entity for forgiveness about that event. The other half who were assigned to the control condition, were asked to describe typical evening activities such as how they make dinner.

As expected, the two groups did not differ in their behavior in phase 1, and both groups exhibited very similar level of dishonesty behavior with moderate increase within that phase. However, the main difference between the two groups occurred after our manipulation. The level of dishonesty behaviors in phase 2 was significantly lower in the confession condition than in the control condition. That is, participants in the confession condition reduced their level of dishonest behavior as a result of the writing task, but participants in the control condition continued in their tendency to cheat more as a function of time. Taken together, our findings suggest that reflection on one's own sins might produce beneficial effects on honest behavior (at least for a certain extent of time) only when consumers do not expect to receive forgiveness. Thus, it appears that societies should be open to granting sequential forgiveness, while remaining silent about their capacity to do so.

“Morality and Masochism: Feeling Guilt Leads to Physical Self-Punishment”

Yoel Inbar, Harvard University, USA

David Pizarro, Cornell University, USA

Tom Gilovich, Cornell University, USA

Past research has demonstrated that people deal with feelings of guilt and immorality in numerous ways: For example, studies have shown that guilt and immoral thoughts can motivate subsequent prosocial behavior and lead people to make amends in order to repair a relationship (Baumeister, Stillwell, and Heatherton, 1994). Another important way in which people seem to deal with feeling guilty is through metaphorical actions, such as physical cleansing in order to "wash away" misdeeds (Zhong & Liljenquist, 2006). In the current research, we investigated whether individuals with feelings of guilt seek to metaphorically "balance the scales" through self-inflicted physical punishment. Physical self-punishment has been a common theme in purification rituals (e.g. self-flagellation) across many religious traditions throughout history, so we predicted that participants who felt guilty would be more likely to desire to purify themselves by engaging in self-punishment.

Study 1

Forty-six participants (25 female) wrote about a time that they felt guilty or sad, or about a neutral event. They then took part in an

ostensibly unrelated task in which they administered electric shocks to themselves. The task was comprised of six trials; shocks always started at 30 volts, and on subsequent trials participants decided whether to increase or decrease the voltage up to a maximum of 80 volts.

Five participants expressed suspicion of our hypotheses and were removed from the analysis. Shock voltages from the remaining participants were subjected to a repeated-measures analysis of variance with condition as a between-subjects factor, and gender as a covariate. This analysis revealed the expected main effect of condition, $F(3, 37)=3.29$, $p<.05$: participants in the guilt condition gave themselves more powerful shocks ($M=53.5V$) than did those in the sadness condition ($M=43.7V$) or the neutral condition ($M=43.1V$). Follow-up contrasts showed that the guilt condition differed significantly from the neutral condition, $F(1, 37)=5.81$, $p=.02$; and from the sadness condition, $F(1, 37)=3.29$, $p=.05$. The latter conditions did not differ significantly from each other, $F(1, 37)=.20$, ns.

Study 2

Study 2 was intended primarily as a replication of Study 1. Twenty-seven undergraduates (19 male) wrote about a time that they did something unethical, or, in the control condition, wrote about the last time they went grocery shopping. They then followed the same six-trial shock procedure used in Study 1. We predicted that participants in the unethical condition would choose to increase the shock level more rapidly than participants in the control condition, leading to a condition \times trial interaction for voltage level.

Three participants expressed suspicion of our hypotheses and were removed from the analysis. Shock voltages from the remaining participants were subjected to a repeated-measures analysis of variance with condition as a between-subjects factor, and gender as a covariate. This analysis showed the expected condition \times trial interaction, $F(4, 18)=2.93$, $p=.05$: Shock voltages were nearly identical between conditions on Trial 2 ($M_{\text{unethical}}=38.2$, $M_{\text{control}}=35.4$) but participants in the unethical condition increased the voltage more quickly, leading to a 10-point difference between conditions on the last trial ($M_{\text{unethical}}=63.5$, $M_{\text{control}}=53.5$).

We also assessed the effect of shock voltage on participants' feelings of guilt. At the end of the study, participants were asked how much they felt guilt, regret, and shame ($\alpha=.90$). Participants in the shock condition scored marginally higher on this guilt index ($M_{\text{shock}}=1.70$, $M_{\text{control}}=.38$, $t(22)=1.31$, $p=.06$), but the more shock participants in the guilt condition administered, the less guilty they felt at the end of the study, $r(11)=-.66$, $p=.03$. There was no relationship between shock voltage and guilt in the control condition, $r(13)=-.15$, ns.

Discussion

Participants who wrote about a time that they felt guilty (Study 1) or about a time that they did something unethical (Study 2) administered more intense shocks to themselves, and increased the level of shock more quickly, than did participants who wrote about a time that they felt sad or about a neutral event. This study adds to the extant research concerning the ways in which people deal with guilt by showing that people react to guilty feelings by engaging in symbolic atonement through physical self-punishment.

This suggests that under some circumstances (i.e. when they are feeling guilty), consumers might show a preference for physically unpleasant or uncomfortable experiences.

SPECIAL SESSION SUMMARY

Assimilation and Contrast: Comparison Processes in Judgments and Evaluations

Xianchi Dai, University of Chicago, USA

SESSION OVERVIEW

How happy are you with a \$5 prize? How much do you like the dinner you are having now? How big is the cake on the plate? Answers to such kind of questions are usually affected by comparison standards people have in mind. This session investigates factors that affect the selection of comparison standards and their effects on judgments and evaluations.

Research in marketing and social psychology has shown that human judgments are comparative in nature (Kahneman and Tversky 1979; Mussweiler 2003; Gilbert, Giesler, and Morris 1995), that the comparison processes systematically affect consumer preference and decision making (Dhar and Simonson 1992; Dhar, Nowlis, and Sherman 1999; Hsee 1996), and that characteristics of evaluation targets and comparison standards determine whether assimilation or contrast will result (Herr 1986; Herr, Sherman, and Fazio 1983; Brewer and Weber 1994; Mussweiler and Bodenhausen 2002).

Despite the extensive research done in this field over the years, this session demonstrates that it remains a fertile area for continued research. The session presents three papers, each focusing on different aspects of comparison processes. In particular, they demonstrate that 1) need states and ownership status systematically affect the construction and the use of comparison standards. 2) Selection of comparison standards is determined by consumers' motivation as well as their cognitive capacity to compare. 3) Forward looking comparison standards are more impactful than backward looking ones, and their impact on evaluations of current experiences depends on characteristics of the current experience.

The first paper by Dai and Hsee demonstrates in three studies that motivational states induce expectation, which in turn serves as a reference point for evaluations. Furthermore, these evaluations can be contrasted against or assimilated toward the expectation, depending on ownership status. Specifically, when a person owns an object (e.g., a piece of cake), evaluation of a target contrasted against expectation; whereas when he or she does not own the object, evaluation of a target is assimilated toward expectation.

Kassam, Morewedge, and Gilbert show that the selection of comparison standards is determined by both motivation and cognitive capacity to compare. They distinguish between present standard, those that are physically present at the time the comparison, and absent standard, those that are physically absent at the time the comparison is made and must therefore be retrieved from memory or generated by imagination. In two studies they demonstrate that people automatically compare their own gains with present standard, whereas they compare with absent standard only when they are motivated and have cognitive capacity to compare.

Finally, Meyvis and Nelson examine the effect of anticipated experience on the enjoyment of current experience. Across 7 studies they find that, while people do not compare current experience with proceeding experience (Novemsky and Ratner 2003), they do compare it with anticipated experience. However, this contrast effect is not always present. When the valence of the current experience is ambiguous, evaluation of current experience actually assimilates toward the anticipated experience.

Overall, the three papers were chosen for this session because (1) they center on the same topic of comparison processes and examine intriguing new directions in reference point construction and selection, (2) they all demonstrate contrast and/or assimilation effect in evaluations of products, experiences, or feelings, and (3)

in terms of methodology, the session represents experimental work from both behavioral decision making and social psychology perspectives. Different approaches complement each other and can potentially inspire new insights for future research. Together, the three papers form a cohesive set of explorations into some fundamental issues of judgment and evaluation processes that is central for understanding consumer decision making.

EXTENDED ABSTRACTS

“How Does Motivation Affect Evaluations?”

Xianchi Dai, University of Chicago, USA

Christopher Hsee, University of Chicago, USA

Does a hungry person perceive a piece of cake bigger or smaller in size than a person who is not so hungry? Does a consumer who cares about quality very much perceive the quality of a product higher or lower than a consumer who cares less about quality? These kinds of questions are ubiquitous in our daily life and are very important antecedents of consumer decision making. They concern the effect of motivation (e.g., need states) on evaluations (i.e., quantity, quality, probability, or other judgments).

Two lines of literature provide opposite predictions for these questions. On the one hand, new look psychology (e.g., Bruner and Goodman 1947) and its recent development (Balcetis & Dunning, 2006; Brendl, Markman and Messner 2003; Kunda, 1990) found that consumers usually see what they want to see. That is, a hungry person would perceive the same cake to be bigger than a less hungry person would, and a consumer who cares about quality a lot would perceive the quality of a specific product to be higher than a consumer who cares little about the quality. On the other hand, Dai and colleagues (Dai, Wertenbroch and Brendl 2008; Dai, Brendl and Wertenbroch 2009) demonstrated that the more people value a product, the more scarce they perceive it to be. In other words, consumers high in need would perceive a piece of cake smaller, the quality of a specific product lower, than their counterparts who are low in need.

In the current paper, we propose a model that reconciles these opposite predictions and systematically explains the effect of motivation on evaluations. Specifically, we propose that when a person owns an object (e.g., a piece of cake), the more the person wants it, the smaller (or worse) she perceives it to be; whereas when she does not own the object, the more she wants it, the bigger (or better) she perceives it to be. We argue that this is because motivation (e.g., need states) automatically activates expectation, which serves as a reference for judgments. This reference can lead to either contrast or assimilation effect, depending on ownership status. For what people own and value (e.g., they have high level of need for it), they want the object to be as big (or good) as possible. They automatically compare what they have with what they ideally want to have (expectation), and thus feel that the reality is not as big (or good)—perceived reality is contrasted away from the expectation. Whereas for what people do not own, the more they want it, the bigger they perceive it to be because of wishful thinking—perceived reality is assimilated to the expectation.

We tested the predictions and the underlying processes of our model in three studies. Study 1 tested our model in quantity estimations. Participants were first induced high or low levels of thirst and were then asked to estimate the volume of a cup of water.

Consistent with our prediction, when participants were told that the cup of water was for them to consume, those who were thirsty estimated the volume to be smaller than those who were not thirsty. Conversely, when they were told that the cup of water was not for them to consume, the reverse was true. In study 2, participants were first asked to imagine and elaborate on either an experience of cliff climbing (with a rope) or an experience of jump roping. Then they were asked to evaluate the thickness of a rope. When the rope was described to be the one that they were using in the imagined experience, those who imagined a cliff climbing experience (and thus wanted to have a thick rope) estimated the rope to be thinner than those who imagined a rope-jumping experience. However, when the rope was described to be one that is irrelevant to the imagined experience, those who imagined a cliff climbing experience estimated the rope to be thicker than those who imagined a rope-jumping experience. Furthermore, the correlation between measured expectation (expected thickness of the rope they were using in the imagined experience) and rope thickness judgment was negative when the rope was described to be the one that they used, and was positive when the rope was described to be irrelevant. These results suggest that expectation leads to contrast when the object is “mine” and assimilation when the object is not “mine”. Finally, study 3 replicated the same pattern of results in product quality judgment. Specifically, consumers who cared about product quality a lot perceived a specific product to be lower in quality when the product was the one they used for a specific experience, and higher in quality when the product was one that was irrelevant to their experience, than consumers who cared less about product quality.

Overall, these studies provide strong support for our model, confirming that motivational state induces expectation, which in turn serves as a reference point for evaluations. Furthermore, these evaluations can be contrasted to or assimilated toward the expectation, depending on ownership status.

“Motivation and Capacity in the Selection of Comparison Standards”

Karim Kassam, Harvard University, USA

Carey Morewedge, Carnegie Mellon University, USA

Daniel Gilbert, Harvard University, USA

Gains may be valued by comparing them with alternatives that are present at the time the comparison is made or with alternatives that are absent at the time the comparison is made. We offer a two-stage model in which people (a) initially make “present comparisons,” and (b) subsequently make “absent comparisons” when they have the cognitive resources and motivation to do so. This model predicts that when a present comparison is favorable (“What I got is better than what I didn’t get”) people will be unmotivated to make a subsequent absent comparison; but when a present comparison is unfavorable (“What I got is worse than what I didn’t get”) people will be motivated to make a subsequent absent comparison (“But at least what I got is better than what I had”).

People’s affective responses to outcomes are influenced by the standards with which they compare them, and one factor that determines the selection of a standard is the person’s motivation. People may compare their outcomes with a wide variety of standards including previous outcomes, alternative outcomes, and other people’s outcomes, and research suggests that people tend to select those standards that produce the most favorable comparison. For example, people tend to compare with those who are less fortunate than themselves, to avoid comparing with those who are more fortunate than themselves, to compare on those dimensions on which they are more fortunate than others, to perpetuate misfortune

for those with whom they compare, to exaggerate how unfortunate they once were, and so on.

But in addition to motivation there is a second factor that determines the selection of standards and that is a person’s cognitive capacity. Some comparisons require conscious deliberation and others arise spontaneously and are made with little effort. Morewedge, Gilbert, Myrseth, Kassam and Wilson (2009) distinguished between (a) present standards (those that are physically present at the time the comparison is made and can thus be perceived through the senses) and (b) absent standards (those that are physically absent at the time the comparison is made and must therefore be retrieved from memory or generated by imagination). They argued that it is typically more effortful to imagine or remember “that which isn’t” than to perceive “that which is,” and thus, all else being equal, people are more likely to compare with present standards than with absent standards.

Our two-stage model therefore suggests that people spontaneously and effortlessly compared their prizes to present standards because it’s easy to do so. Those for whom that comparison is favorable are not motivated to generate or remember an absent standard. Those for whom present comparison is unfavorable, on the other hand, will be motivated to generate or remember absent standards that would produce more favorable comparisons, if they have sufficient cognitive capacity.

We tested several basic predictions of this model in two studies in which participants learned that they had won one of two cash prizes. We defined “winners” as participants who had won the superior prize and “losers” as participants who had won the inferior prize. We also varied the face value of the prize won (\$7, \$5, \$3, or \$1). In Experiment 1, we expected that winners would naturally compare their superior prize to the inferior prize, feel good, and stop comparing. Because the difference between the superior and inferior prizes was the same in the large and small conditions, winners’ feelings were uninfluenced by the face value (\$7, \$5 or \$3) of their superior prizes. On the other hand, we expected losers to naturally compare their inferior prize to the superior prize and feel bad, motivating them to make absent comparisons and resulting in sensitivity to face value. This is in fact what we found, losers’ reported happiness depended on the value of the prize won (\$5, \$3 or \$1). In Experiment 2, we put some participants under cognitive load, which we expected would impair their ability to compare their current and previous states of wealth. We found winners’ feelings to be uninfluenced by the face value (\$5 or \$3) of their prizes whether they were or were not under load. Losers’ feelings were influenced by the face value (\$5 or \$3) of their prizes when they were not under load, but were not influenced by face value when they were under load.

In summary, we present data supporting a two-stage model which suggests that people initially compare with present standards and subsequently compare with absent standards if they have both the motivation and capacity to do so.

“Contrast Against the Future: The Unexpected Effect of Expectation”

Tom Meyvis, New York University, USA

Leif Nelson, University of California at Berkeley, USA

We do not just derive utility from our current experience, but also from the anticipation of future experiences (Loewenstein 1987): we dread a visit to the dentist and we savor an upcoming trip to a tropical island. Yet, aside from this direct effect on our current happiness, the anticipation of future events can also change our enjoyment of a specific current experience. For instance, knowing that we are about to embark on a vacation may change how we

experience our time at the dentist. Or, similarly, knowing that we are about to visit the dentist may change how much we enjoy our time at the beach.

One possibility is that the anticipatory dread or savoring contaminates our current experience. Or, stated differently, the current experience may be assimilated towards the upcoming experience: the visit to the dentist becomes less painful when anticipating the vacation, while the time at the beach becomes less enjoyable when anticipating the visit to the dentist. This contamination effect has some intuitive appeal: anticipating the vacation makes the visit to the dentist more tolerable, while thought of the dentist office makes it harder to enjoy the beach.

However, a second possibility is that we contrast the enjoyment of our current experience against the enjoyment of the anticipated experience: the visit to the dentist becomes even more painful when anticipating the vacation, while the time at the beach becomes even more enjoyable when anticipating the visit to the dentist. Yet, although perceptual contrast is a very robust phenomenon, and although people routinely believe in hedonic contrast, there is little evidence that it actually occurs (Novemsky and Ratner 2003). Then again, past research has exclusively focused on comparisons with preceding experiences rather than anticipated experiences. Although the current dinner may not taste worse when the previous dinner was fabulous, it may actually taste worse when the next dinner is expected to be fabulous. Indeed, consistent with the forward-looking view of emotion (Frijda 1988), previous research has shown that the anticipation of future experiences is more intense than the reflection on past experiences (Van Boven and Ashworth 2007). If this generalizes to hedonic comparisons, then a visit to the dentist may be more painful when anticipating a vacation, even though it is not more painful following a vacation.

Before testing between these two possible effects (hedonic assimilation versus hedonic contrast), we assessed people's intuitions about the effect of hedonic comparisons. We simply asked participants how their experience of a pleasant (unpleasant) experience would change if it preceded (followed) an unpleasant (pleasant) experience. Consistent with prior research, a clear majority believed in retrospective hedonic contrast effects: 84% believed that being preceded by an unpleasant experience would make a pleasant experience even more pleasant, while 74% believed that being preceded by a pleasant experience would make an unpleasant experience even worse. Interestingly, they had the opposite intuition for comparisons with upcoming events: 92% believed that the anticipation of an unpleasant event would make a pleasant event less pleasant, while 84% believed that the anticipation of a pleasant event would make an unpleasant event less aversive. In other words, participants' intuition suggested forward-looking hedonic assimilation, rather than forward-looking hedonic contrast. We next tested whether these intuitions corresponded to people's actual experiences.

In a first study, all participants listened to pleasant piano music and were asked to indicate how much they enjoyed this music. People in the control condition only listened to the music, while people in the retrospective comparison condition first listened to an annoying sound (noise + music). Finally, people in the prospective comparison condition also first listened to the annoying sound, but in addition anticipated that the sound would return after the pleasant music (noise + music + noise). The results were the exact opposite of the intuitions from the pilot study: Whereas the music did not become more enjoyable when people first listened to the annoying sound, it did become more enjoyable when participants anticipated that the annoying sound would return after the music—consistent with forward-looking hedonic contrast.

We replicated this forward-looking hedonic contrast in a series of subsequent studies. In study 2, we asked participants to listen to a vacuum noise and found that their irritation with this noise did not change as a function of the sound they heard earlier (pleasant piano music or an even more irritating drilling sound), but did depend on the sound they were anticipating to hear afterwards. The vacuum noise became more irritating when people anticipated pleasant music than when they anticipated the drilling noise. In study 3, we demonstrated that this effect was not purely driven by the comparison with the even more irritating drilling noise: 50 secs of vacuum noise was experienced as more irritating when participants anticipated 10 secs of pleasant music than when they anticipated 10 more secs of vacuum noise. In study 4, we found that the comparison was not just sensitive to changes in valence, but also to changes in the magnitude of (dis)pleasure: An annoying sound became more annoying when people anticipated listening to a moderately enjoyable pop song, but even more so when they anticipated listening their favorite pop song.

If people engage in forward-looking hedonic contrast (rather than the hedonic assimilation they intuit), then their preference for improving sequences may sometimes be misguided. Indeed, in study 5, we find that people who taste improving sequences of jellybeans enjoy these jellybeans less than those who taste declining sequences of jellybeans—even though people in both groups strongly prefer the improving sequence. Finally, we conducted two studies to examine the boundary conditions of this hedonic contrast effect. In study 6, we replicate the contrast effect with an unambiguously valenced target experience (a looped vacuum noise), but we observe an assimilation effect with an ambiguously valenced target experience (looped new age music); and in study 7, we replicate the comparison effect when the anticipated experience is expected to immediately follow the target experience, but not when participants first expect more of the target experience.

SPECIAL SESSION SUMMARY

Cue Substitution: Inferential Processes in Judgements and Experiences of Time

David Faro, London Business School, UK
Claire Tsai, University of Toronto, Canada

SESSION OVERVIEW

Many consumption settings involve time as an important evaluation variable. For example, assessing how long a drug typically takes to show its effect can affect its evaluation and the timing of its future consumption. Assessing how time seems to pass (“flying” or “dragging”) during a song or a movie may affect people’s evaluation of how enjoyable that experience was. Similarly, deciding how much time to allocate to leisure activities or unpleasant chores can affect people’s plans and decisions for other activities. The judgment of time and the evaluation of experiences that take place over time is a complex task subject to various influences and judgment strategies (see McGrath & Tschan, 2003 for a recent collection of work in this literature). This session focuses on one such judgment strategy, bi-directional use of correlated cues (cue substitution), as a way to judge time and evaluate experiences over time.

Cue substitution is a common judgment strategy in many consumption settings (Frederick & Kahneman, 2002; Kardes et al., 2004). When people are uncertain about one variable but have access to a correlated variable, they tend to use the latter variable to infer the level of the first. Researchers have examined different instances of this process in several domains, including price-quality inferences (Cronley et al., 2005; Rao & Monroe, 1988) and familiarity-liking judgments (Zajonc, 1968; Monin, 2003). The papers in this session show three examples of this judgment strategy, each with time as either the substituted or substituting cue. Further, we discuss the implications for the accuracy and consistency of consumer time judgments and the consequences of biased retrospective hedonic evaluations. The three papers also elucidate the underlying mechanisms of the cue-substitution judgment strategy by identifying some of its moderators and mediators.

The first paper (Faro) shows that when consumers are uncertain about how long products have taken to show their effects, they rely on their causal beliefs to judge elapsed time. The second paper (Tsai et al.) shows that when consumers are uncertain about the duration of future activities but have access to information about the component parts of the experience and their valence, they use that information to estimate future duration. And the third paper (Sackett et al.) shows that when consumers are uncertain about how much they enjoyed an experience but have access to the perceived speed at which time passed, they use that apparent time distortion to retrospectively infer the level of hedonic experience.

Faro demonstrates that people’s recollection of the time elapsed before they experienced an effect of a product is influenced by the degree to which they believe the product was responsible for that effect. The current research extends previous research in this area (Faro et al., 2005; Haggard et al., 2002) by focusing on the influence that biased time estimates of a previous experience have on future consumption. In one study, for instance, participants estimated that chewing a piece of gum took less time to improve their performance on a concentration task when they focused on the gum as the sole cause of improvement than when they considered it along with another possible cause. On a later consumption occasion, because they held shorter perceptions of time-to-onset, these participants decided to use the gum closer in time to a similar concentration task,

started working on a similar task earlier upon use of the gum, experienced its effect on their performance earlier, and were less inclined to try competing products.

Whereas the first paper shows cue substitution of causal beliefs for product onset time, the second paper (Tsai et al.) shows the substitution of anticipated affective aspects of activities for predicted time allocation. Tsai et al. find that time estimates of a target event are systematically influenced by the valence and by the representation of that event (unpacking an event into several of its constituent activities or packing the constituent activities into one single event). For example, thinking of visiting a museum as visiting exhibits X, Y, and Z, rather than just the museum, increases the time estimates for the museum visit, whereas thinking about visiting mind-numbing exhibits X, Y, and Z for a school assignment, rather than just the museum, decreases the time estimates for the museum visit. Using a series of lab and field experiments in the context of discrete and continuous events—social and leisure activities and watching video clips—Tsai et al. demonstrate that unpacking an event into its constituent activities increases the time estimate for pleasant events but decreases the time estimate for unpleasant events. As an underlying mechanism for this effect, we hypothesize and show that unpacking increases the extremity of the predicted enjoyment/pain of the target event, which in turn mediates this pattern of the results. The studies also address issues including task-related knowledge, task complexity, mood, and mental accounting.

Faro and Tsai et al. show that when time is the uncertain variable to be judged, people base their judgments on a correlated semantic or affective cue. This is indeed often necessary because the mind is not equipped with a reliable time organ (Tourangeau et al. 2003). However, objective temporal information sometimes becomes available and contradicts subjectively experienced duration. In such cases, that discrepancy can act as the cue that people rely on to judge experiences. Through a series of five studies, Sackett et al. show that people do indeed use perceived time distortion as a cue to judge consumption experiences. Specifically, when time seems to “fly by” (because more time passes than one realizes), tasks retrospectively seem more engaging, noises less irritating, and songs more enjoyable. People conceptualize apparent time distortion as a metacognitive cue and in fact relying on, the naive theory that “time flies when you’re having fun.” Understanding the role of experienced duration as a variable that affects the evaluation of experiences suggests, for example, ways for service providers to improve consumers’ subjective evaluations without changing the core features of the experience.

This special-topic session features three recent papers that connect research on time judgments and the evaluation of experiences over time with issues important to marketers. Specifically, this session will bring to light how time durations can be inferred and estimated from consumption cues (Faro; Tsai et al.), as well as how its perceived passage can be used as a cue to evaluate consumption experiences (Sackett et al.). Session participants should come away with an increased understanding of the bi-directional relationships of time and causal beliefs (Faro) and time and affect (Tsai et al.; Sackett et al.). Participants will also discover how these tempo-

ral relationships affect variables directly important to marketers, such as preferences, repeat purchases, and inferences about future consumption.

EXTENDED ABSTRACTS

“Changing the Future by Reshaping the Past: The Influence of Causal Beliefs on Recollections of Time-to-Onset”

David Faro, London Business School, UK

Consumers' assessments of the time-to-onset of an effect refer to the amount of time they believe it takes for a product to show its effect after consumption. These assessments play an important role in many consumption settings. For some products, such as pharmaceuticals sold by prescription and over-the-counter medications, consumers care not only about whether the product has an effect, but also how quickly it begins. Furthermore, time-to-onset must often be assessed by consumers to plan future consumption. In particular, they may need to experience the effect of a product before starting another activity. Examples include caffeine before an exam, digestion aids before food consumption, relaxation drugs before a flight, and erectile dysfunction drugs before a sexual encounter. In such cases, assessments of time-to-onset can affect the timing of consumption, the timing of subsequent activity, and, consequently, both the perceived and real effectiveness of the product.

Two studies show that people's recollection of the time elapsed before they experienced an effect of a product is influenced by the degree to which they believe the product was responsible for that effect. Specifically, the studies show that a) stronger causal beliefs shorten time-to-onset estimates for past consumption and b) these shortened estimates later have an independent effect on future consumption and experience. Therefore, people appear to substitute their causal impressions about products to judge time-to-onset, and their altered estimates later affect future consumption decisions and experience

In the first study participants chewed a chewing gum in one part of the study and then took part in an attention task. Later in the study they were told that chewing a gum increases attention, and were asked some questions about its effect on their performance. Some participants considered only the effect of chewing the gum, while other participants considered an additional factor, the effect of practice with the task. All participants later estimated how much time elapsed until chewing the gum had an effect on their performance in the task (if it did). After some filler studies, participants consumed a second chewing gum and took part in a second task. They indicated the moment at which the second gum had an effect on their performance, and indicated whether they wanted to try a competing product (energy bar).

Results showed that participants who considered only the gum (and hence believed more strongly in its causal role) gave shorter estimates of time-to-onset for the gum than participants who also considered practice with the task. On a later consumption occasion, these participants reported to experience the gum's effect earlier, and were less interested in trying a competing product. Estimates of time-to-onset mediated the effect of causal beliefs on future consumption.

The second study showed two additional consequences of the effect and examined the underlying process. Participants chewed a chewing gum in one part of the study and later took part in an attention/memory task. They were then told that the chewing gum contained an ingredient which could (or was unlikely) to improve their performance. All participants estimated how much time elapsed until chewing the gum had an effect on their performance.

After a filler study, participants were presented with a second gum, followed by a similar task. They indicated the latest time they would like to have the second piece of gum before beginning the next task, and once they consumed it, indicated when they wanted to begin the task. A manipulation of cognitive load took place prior to making time estimates for the first gum and was completed prior to making decisions about the second gum.

Results showed that participants who believed more strongly that the ingredient could improve attention/memory gave shorter estimates of time-to-onset for the gum. These participants were comfortable using the second gum closer to the task, and began working on the task earlier than their counterparts. There was an interaction effect of cognitive load and causality on time-to-onset estimates, as well as on future consumption decisions. The time shortening effect was strongest under cognitive load. This suggests that the effect of causal beliefs on time estimates reflects a low-effort, default, possibly unconscious use of causality as a cue to temporally bind causes and effects. Further, because the cognitive load manipulation was completed prior to making any decisions about the second gum, the interaction suggests that time-to-onset estimates for the first consumption drove future decisions.

Overall the two studies show that causal beliefs about products can shape consumers' perceptions of time-to-onset for past consumption, and these perceptions can have an independent effect on future consumption. The first study suggests that shortened perceptions of time-to-onset may give the target product an added advantage. Participants who held shorter perceptions of time experienced the gum's effect earlier on a future consumption occasion, and were less interested in trying other products. The second study suggests some possibly negative consequences for the product and for consumers. Participants who held shorter perceptions of time were more likely to use the product too late, and more likely to begin an activity which depends on the effect of the product too early. The paper concludes with a discussion of the implications of the findings for consumers and marketers.

“The Effect of Unpacking and Valence on Future Time Estimates”

Claire Tsai, University of Toronto, Canada

Min Zhao, University of Toronto, Canada

Jing Wan, University of Toronto, Canada

The present research examines how subdividing a multifaceted event with different valences will influence time estimates of those events. Drawing on findings regarding probability judgments in support theory (Rottenstreich and Tversky 1997; Tversky and Koehler 1994) and hedonic editing (Thaler 1985), we propose that unpacking systematically influences time judgments. Specifically, we propose an interactive effect of unpacking and the valence of the target event on its time judgment.

Using a series of two field and three lab experiments, we demonstrated that unpacking a pleasant, multifaceted event into several pleasant sub-activities increases the time estimated to spend on the event; whereas unpacking an unpleasant, multifaceted event into several unpleasant sub-activities decreases the time estimated to spend on the event. In addition, we found that predicted enjoyment/pain mediates the interaction between the representation and valence of the target event on the time estimation.

In the first field experiment, we borrowed the research paradigm from the support theory literature (Tversky and Koehler 1994). We varied the representation of a museum visit by unpacking it into the experience of several exhibits and asked visitors to estimate the time they expected to spend (unpacked condition) or simply asked visitors to predict how long they would stay in the

museum without mentioning the specific exhibits (packed condition). As predicted, time estimates were greater in the unpacked condition than that in the packed condition, replicating the support theory effect on time judgments.

However, the effects can be attributed to the knowledge that visitors had about the exhibits at the museum. That is, when making the time estimate, participants in the packed condition were not aware of all the exhibits in the museum or not considering as many exhibits as participants in the unpacked condition did. To control for the knowledge about the target events in experiments 2-4, we provided all participants with identical information about the target activities and only varying the representation of the events. This method provides direct assessments of the extent to which representation of a target event influences time estimates.

In experiment 2, participants were asked to estimate the time they would spend on two social activities: meeting a blind date and attending a birthday party. In the pleasant conditions, the date was attractive and the birthday party was something they were looking forward. In the unpleasant condition, the date was unattractive and the party was something they wanted to avoid. The results showed that for pleasant activities, the derived sum of the time estimates in the unpacked condition was greater than the single time estimate in the packed condition, whereas the pattern of the results was reversed for unpleasant activities.

One possible explanation for experiment 2 is the similarity of the sub-activities. It is possible that the effect of unpacking only occurs for activities similar in nature because it is easier to consider them as one multifaceted activity. Thus, we tested this account in experiment 3 by replacing the social activities with two dissimilar leisure activities: reading for leisure in either a quiet or noisy coffee shop, and chatting with either a good friend or a dislikeable acquaintance over the phone. The results fully replicated the findings of experiment 2.

Another potential account for the results of experiments 1-3 is the amount of attention that participants paid to the task. Perhaps the more finely the event is unpacked, the more attention will be paid to the prediction task and thus time estimates will increase regardless of the valence of the event. We addressed this issue in experiment 4 by providing participants with three activities (date, birthday party, and phone conversation). In addition, we asked participants to predict the pleasantness of each individual activity. Again, we replicated the pattern of results of experiments 2-3 even with increased number of sub-activities. Also, as expected, we found that predicted levels of enjoyment/pain mediated this interactive pattern.

How does unpacking affect the accuracy of time judgments? In another field experiment we asked participants to self-generate either pleasant or unpleasant activities. We have preliminary evidence to show that unpacking led to more accurate prediction for pleasant activities but had an opposite effect for unpleasant activities.

In conclusion, our research showed that unpacking can influence the time estimates for that event but the direction of that change depends on the valence of the event. Our research adds to the time judgment literature by identifying an important mechanism that influences time perception or estimation, namely, the interaction of event presentation (packed vs. unpacked) and event valence. At the same time, we contribute to the support theory literature by extending its findings to time estimation and attesting to its robustness in different domains.

“You’re Having Fun When Time Flies: The Hedonic Consequences of Subjective Time Progression”

Aaron Sackett, University of Chicago, USA

Benjamin Converse, University of Chicago, USA

Tom Meyvis, New York University, USA

Leif Nelson, University of California at Berkeley, USA

Anna L. Sackett, University at Albany, SUNY, USA

People walking out of dark theaters, finishing transactions after waiting in long lines, or driving home from a day on the town may catch a glimpse of a clock and find themselves surprised at how much (or how little) time has passed. Duration estimates are influenced by many factors, including attentional engagement (Chaston and Kingstone 2004), arousal (Gruber and Block 2003), and motivation (Conti 2001). Thus, subjective duration often diverges from objective duration. When this occurs, time feels distorted: When more time passed than one realized, it feels like time flew by; when less time passed than one thought, it feels like time dragged on.

The feeling of time distortion may prompt people to seek an explanation, and a ready answer may come from overgeneralization of the common naïve theory that “time flies when you’re having fun.” Given that attentional demands shorten duration estimates (Block and Zakay 1997; Chaston and Kingstone 2004) and that highly enjoyable activities can monopolize attention (Csikszentmihalyi 1975, 1990), time and enjoyment may come to share an intuitive link in people’s perceptions of experience. The current work is concerned with how, in the face of otherwise inexplicable time distortions, this presumed relationship may be overgeneralized, leading to causal inferences. We predict that people’s sense that time “flew” will enhance their evaluations of experiences, whereas their sense that time “dragged” will worsen their evaluations.

In the first experiment, we created the illusion of fast or slow time progression by misleading participants about how much time had actually passed. In experiment 1a, students completed a mundane word-underlining task in the absence of external time cues. All participants learned that the task would last for precisely 10 minutes. The task actually lasted for 5 minutes in the time-flies condition, and 20 minutes in the time-drags condition. As expected, participants in the time-flies (vs. time-drags) condition rated the task as more enjoyable. To ensure that the observed effect could not be explained merely by differences in actual duration (i.e., underlining words for only 5 minutes might be better than underlining words for 20 minutes), we replicated experiment 1a, but held actual time constant while manipulating perceived duration. In experiment 1b, all participants actually did the task for 10 minutes but they were either told that it lasted for 20 minutes (time flies) or 5 minutes (time drags). Again, participants rated the task as more enjoyable in the time-flies than in the time-drags condition. Experiments 2 and 3 replicated this basic effect for a more positive experience (listening to popular songs), a more negative experience (listening to synchronized dot matrix printers), with a different manipulation of time distortion (accelerated vs. decelerated timers), and compared to a normal-time control condition.

In experiments 4a and 4b we tested the proposed role of the “time flies” naïve theory more directly. In 4a, participants solved anagram tasks for exactly 7.5 minutes. The task was either described as a 10-minute task (time flies) or a 5-minute task (time drags). Participants rated their enjoyment and, after some filler items, indicated the extent to which they endorse the saying “time flies when you’re having fun.” Once again, those in the time-flies (vs. time-drags) condition reported greater enjoyment of the task.

More importantly, this effect was significantly more pronounced among participants who more strongly endorsed the “time flies” naïve theory.

In experiment 4b we manipulated endorsement of the naïve theory. Participants read fabricated news stories, ostensibly as part of a memory test, that either supported or refuted the “time flies” belief based on scientific evidence. Then they completed a word-underlining task with timing procedures identical to experiment 1a. Among those who read an article supporting the time-flies theory, the word task was rated more positively in the time-flies (vs. time-drags) condition. Among those who read the article refuting this theory, there was no significant difference in enjoyment across the two time conditions.

Experiment 5 followed the procedures of 1a, with two important differences. First, all participants wore foam earplugs during the task. Second, after completing the task, but prior to evaluating it, half of the participants read a survey item suggesting that wearing earplugs may distort their sense of time (in the direction of the current time condition) because of differences in sensory input. As predicted, participants reported greater enjoyment of the task in the time-flies (vs. time-drags) condition only when they did not receive the alternative attribution. Among those who read the survey item saying that time may have flown (dragged) because of the earplugs, there was no difference in reported enjoyment across the two time conditions. When time distortion could be explained by some external cause, there was no need to invoke the enjoyment explanation, thus eliminating the time-flies effect.

Taken together, these findings have important implications for understanding and influencing hedonic experience. There can be value in improving subjective experience without changing core features of the task at hand, and influencing subjective time perception may provide such an opportunity. The current research thus provides insight into new ways to improve people’s subjective enjoyment of a wide range of consumption experiences.

SPECIAL SESSION SUMMARY

Effects of Minor Language Variations on Consumer Persuasion

Aner Sela, Stanford University, USA

SESSION OVERVIEW

A great deal of research on consumer persuasion has focused on explicit factors such as the quality of arguments, the characteristics of the message source, or the perceiver's motivation to process information, and the effects of these types of variables are well understood. However, little attention has been devoted to the effects of much more subtle features of marketing communications, such as minor language variations in the message, on persuasion. What effect, if any, do these more subtle factors have on consumer persuasion?

The present session seeks to provide an in-depth look at the significant effects of seemingly inconsequential wording variations on preferences, brand perceptions, and attitude change. For example, what are the mechanisms by which specific word use can influence the construction of preferences? Might different consumers respond to the same wording in different ways? The session will address these and other related questions as it works to deepen our understanding of the role of language in persuasion.

One of the interesting conclusions that emerge from the present session is that subtle language variations can influence consumers' actual experiences when consuming products. Jongmin Kim, Jing Wang, Nathan Novemsky, and Ravi Dhar (paper 1) reveal in their research that asking product evaluation questions using fancy words (e.g., "velvety wine") can increase actual liking for the product, as compared to logically equivalent but less fancy words (e.g., "smooth wine"). The research suggests that the use of fancy words activates associated knowledge in memory nonconsciously, which in turn biases the processing of ambiguous experiences in a confirmatory manner. In contrast, when fancy language is perceived as unambiguously inconsistent with the evaluation target, it can actually decrease liking for the product.

Another surprising finding is that minor wording variations can influence perceptions of real-life brands with which consumers have had long-lasting working relationships. Aner Sela and Christian Wheeler (paper 2) demonstrate how subtle changes in the use of relationship-implying terms (e.g., "you and Wells Fargo" vs. "we") can affect perceptions of brand attributes and, consequently, attitudes toward the brand among its customers. They find that subtle linguistic changes have different effects among current customers and non-customers of the brand, because these groups have different perceptions of the ongoing relationship with the brand. These effects depend further on the brand category and its associated relationship norms.

Finally, Nicole Mayer and Zakary Tormala (paper 3) examine the effect of minor language variations, such as saying "I feel" versus "I think", on persuasion among people whose attitudes are either affectively or cognitively oriented. They find that when a persuasive message appears to reflect the source's feelings versus thoughts, it will be more persuasive to recipients whose attitudes or general orientations are primarily affective versus cognitive, respectively.

Marketers carefully manage their communications with consumers in order to shape beliefs, attitudes, and behavior. The three papers in this session extend and deepen our understanding of the impact of seemingly inconsequential language variations and how they interact with concrete features of the target (e.g., product quality), perceptions of consumer-brand relationships, and consumers' affective vs. cognitive orientations. Thus, the session

speaks to the importance of tailoring the exact message wording to the situation. It would be of interest to researchers and marketers interested in consumer persuasion and implicit social cognition.

EXTENDED ABSTRACTS

"Persuasion under the Radar: Effects of Question Wording on Product Evaluation"

Jong Min Kim, , Yale University, USA

Jing Wang, Singapore Management University, Singapore

Nathan Novemsky, Yale University, USA

Ravi Dhar, Yale University, USA

Consumers' preferences are often constructed and largely determined by the task characteristics, the choice context, and the description of options (e.g. Simonson, 2008). Some research suggests that if the task or context is perceived as being manipulated by a marketer and having persuasive intent, consumers are likely to protect themselves from the marketing actions (Friestad and Wright, 1984). The present research reveals that asking evaluation questions on scales that are associated with high quality (e.g. velvety) vs. regular quality products (e.g. smooth) can influence preferences for the product in a nonconscious manner. Specifically, consumers who rated a product on dimensions described using fancy words (e.g., How velvety would you say the texture of the wine is?) make more positive evaluations than those who rated the same product on dimensions described using typical words (e.g., How smooth would you say the texture of the wine is?). We posit that the effects occur because answering the rating questions evokes a mental representation of the product without any suspicion. By answering the rating questions people engage in positive hypothesis testing (e.g. Klayman and Ha, 1987) and test the possibility that the product has the provided set of attributes. This increases the accessibility of the fancy/non-fancy attributes of the product and this accessible knowledge is used in overall evaluations of the product (Strack and Mussweiler, 1997). We demonstrate these language effects across a series of studies.

In Study 1, participants were shown pictures of chocolates and asked to rate the product on five dimensions described using either fancy or non-fancy words (e.g. how velvety/smooth would the texture of the chocolates be?). Participants who rate the chocolates on fancy attributes indicate that they would like the chocolate more and that they are more likely to purchase the chocolates. In study 2, we find that the effects persist even after direct experience with a product. Participants in this study were members of a Wine Club and were given a wine sample. They were randomly assigned to evaluate it on either the fancy or the non-fancy rating scales. Participants who evaluated the wine on fancy attributes (e.g. velvety, harmonious, lingering, etc) liked the wine more and were more likely to purchase the wine compared to those who rated it on non-fancy attributes (e.g. smooth, balanced, long-lasting, etc).

Study 3 and Study 4 replicate and extend these findings, identifying boundary conditions for the language effects. Study 3 shows that the language effect occurs only when the target product is ambiguous. This study manipulates ambiguity by presenting either agreeing or disagreeing expert opinions (Hoch and Ha, 1986). This information about the wine was provided to participants before a wine sample was given to them. In the ambiguous condition, participants read a set of scores varying widely across experts,

while participants in the unambiguous condition saw scores that were quite consistent across experts. The results show that only when the product is ambiguous, do we observe any effect of the language used in rating scales. When participants have information that is diagnostic of the product, the scales (fancy vs. non-fancy) have no effect on overall evaluation.

Study 4 examines another moderator for the language effect: fit between fancy scales and the product. Using fancy words that do not seem to fit the target product category may not result in a positive evaluation of the product. In this case, it is possible that the fancy rating scales can result in lower evaluations than a rating task involving less fancy words. To examine this moderating role of fit, we choose wine as a fancy product and Soju, a Korean lowbrow alcoholic beverage, as a non-fancy product (Study 4 was conducted in Korea). Participants were given a sample of either wine or Soju and asked to rate the product on either fancy or non-fancy scales. Replicating our previous results, participants are willing to pay more for wine when they answer the questions asking about fancy attributes. They even consumed more wine in the fancy scale condition. However, the effect of language on evaluation reversed for Soju. Participants were willing to pay less for Soju when they rated it on scales anchored by fancy words compared to those rating it on non-fancy scales. They also consumed less Soju in the fancy scale condition.

In summary, we posit that different language embedded in a ratings scale can influence preference for a product. These effects arise without any explicit claim about any aspect of the product. This is precisely why consumers keep their defenses down and do not consider the rating task a persuasion attempt (Williams et al, 2004). As result they may be more persuaded than if an explicit claim had been made.

"You and We: Causal Effects of Minor Language Variations on Brand Perceptions"

Aner Sela, Stanford, University, USA

S. Christian Wheeler, Stanford University, USA

Marketers often desire to promote consumers' feelings of being in a close relationship with the brands they market. Accordingly, they frequently portray brands as intimate partners with consumers, believing that this should lead to more favorable

attitudes. This belief has intuitive appeal, but does it actually foster favorable brand perceptions? The present research examines this issue by studying whether subtle differences in marketing communications, such as using the terms "we" versus "you and us," can affect attitudes and perceptions toward the brand. Although these types of terms are linguistically equivalent, we suggest that they can subtly convey information about a consumer's relationship with the brand that can have either positive or negative effects.

Research on consumer-brand relationships has suggested that consumers often relate to brands in ways that correspond to different relationship profiles, each entailing different relational scripts and norms (Fournier 1998). This literature suggests that people may respond positively to brand actions that are perceived as consistent with the believed consumer-brand relationship, but might respond negatively when these actions are inconsistent with the relationship (Aggarwal 2004).

Consistent with earlier research (e.g., Brown and Gilman 1960), we expect more intimate and informal language use (e.g., "we") to be perceived as consistent with consumer-brand relationships that are believed to be closer and based on shared goals. In contrast, we expect language that emphasizes the separateness of relationship partners (e.g., "you and I") to be perceived as consistent with consumer-brand relationships that are more distant. We predict that language consistent with the believed consumer-brand relationship norms will lead to more favorable attitudes.

Several factors can affect the perceived closeness between consumers and brands. Specifically, consumers may associate some product categories with a relationship based on closeness, cooperation, and shared goals. Other product categories, however, may be associated with a more distant relationship, one that is based less on mutual goals and more on "zero-sum" behavior. Another important dimension concerns whether one is a customer of the brand or not. Whereas existing brand customers may have specific expectations of their relationship with the brand and corresponding communication norms, non-customers may have different expectations.

In sum, we examine the following questions. First, can subtle changes in the use of relationship-implying terms (e.g., "you and [the brand]" vs. "we") affect perceptions of brand attributes and, consequently, attitudes toward the brand? Second, do these subtle changes have different effects among current customers and non-customers of the brand? Third, do these effects depend further on the brand category and its associated relationship norms?

We test two mediation hypotheses for these effects. First, the effect of language on attitudes could be mediated by perceptions of brand honesty. Specifically, when the intimacy implied by language is in harmony with consumers' perception of their ongoing relationship with the brand, the brand may be perceived as more trustworthy and consequently more favorable overall. However, when the language is inconsistent with the relationship, the brand might be perceived as less trustworthy, leading to less favorable attitudes. Alternatively, people could respond more favorably to relationship-congruent language simply because it is easier to process (i.e., fluent), being consistent with their expectation (Lee and Labroo 2004; Schwarz 2004).

To test our hypotheses, we first conducted a pretest, which suggested that people tend to perceive their working relationships with their bank as relatively close and intimate, but perceive their relationships with a health insurance provider as more distant.

Consequently, in experiment 1, we predicted that existing customers, but not non-customers, of a prominent banking brand would have more favorable attitudes toward the brand when a message referred to the brand and the consumer as "we" than when it referred to the brand and the consumer as "you and [the brand]".

Participants read a short message about a prominent banking brand, allegedly taken from an advertisement. Some participants read a message that used the phrase “you and [the brand],” whereas others read a message in which “you and [the brand]” was replaced with “we”. Then, they were asked to rate their attitudes toward the brand. At the end of the experiment, participants were asked whether they were actually banking with the brand.

As hypothesized, consumers with an ongoing working relationship with the banking brand reported more favorable attitudes when the message used the pronoun “we”. Conversely, non-customers had somewhat more positive attitudes toward the brand when the message used the term “you and Wells Fargo”.

Experiment 2 replicated the results of experiment 1, using the same procedure with additional banking brands, and tested our two mediation hypotheses. Mediated moderation analyses suggested that the moderated effect of language and customer status on attitudes was fully mediated by perceived brand honesty. In contrast, although the interaction of language and customer status predicted fluency, fluency was not a significant predictor of attitudes.

Experiment 3 used a banking brand and a health insurance brand as our stimuli. We predicted that referring to the brand and the consumer as “we”—rather than “you and [the brand]”—would lead to more favorable attitudes among existing customers when the brand is a bank. In contrast, we predicted that using “we” would lead to less favorable attitudes when the brand is a health insurance provider, because our pretest indicated that these brands are perceived as partners in a distant relationship. We also predicted that non-customers in both categories would prefer less intimate language. The results of this experiment support our hypotheses, suggesting opposite effects of language on attitudes toward the bank vs. health insurance brands. Furthermore, these effects were mediated by perceived brand honesty in both cases.

The present research contributes to the literature on language in interpersonal cognition by suggesting that language conveys meaning and influences attitudes not just directly, in an assimilative manner (e.g., Fitzsimons and Kay 2004), but also through implicit assessments of the congruity between the language and prior beliefs about the relationship. From a practical viewpoint, these findings promote the idea that marketers should not only think of their consumers as relationship partners in general, but also mind the differences in how specific types of consumers relate to their brands in the context of its product category.

“‘Think’ Versus ‘Feel’ Framing Effects in Persuasion”

Nicole Mayer, Stanford University, USA

Zakary L. Tormala, Stanford University, USA

When people express opinions or share ideas, they often do so by referencing their thoughts or feelings. When attempting to persuade someone to adopt a new product, for example, one might frame the exact same substantive argument in terms of thoughts (e.g., “I think this camera is the best on the market”) or feelings (e.g., “I feel that this camera is the best on the market”) without changing the essence of the appeal. Whether one says “I think” or “I feel,” or even “my thought is” or “my feeling is,” the common assumption is that one is introducing a statement that reflects one’s subjective impression of an object or issue. The current research explores the possibility that although think and feel message frames are used interchangeably, their effects might not be interchangeable at all. In particular, we investigate whether think and feel message frames might be differentially persuasive, even when the substantive content of the message itself is held constant.

Over the years, considerable research attention has been paid to the notion that attitudes can vary in their underlying cognitive or affective bases. Moreover, this distinction has important implications for persuasion. In general, affective attitudes are more susceptible to persuasion by affective messages, whereas cognitive attitudes are more susceptible to persuasion by cognitive messages (e.g., Drolet and Aaker 2002; Edell and Burke 1987; Edwards 1990; Fabrigar and Petty 1999; Haddock et al., 2008). In the current research, we propose that even when one receives the exact same arguments from a persuasive message, believing those arguments reflect their source’s thoughts or feelings can interact with one’s own cognitive/affective orientation to determine persuasion. Our primary hypothesis is that messages that appear to reflect their source’s feelings (thoughts) will be more persuasive when the target attitude or message recipient is primarily affective (cognitive) in orientation. Furthermore, building on past research linking matching, or fit, effects with processing fluency (e.g., Lee and Aaker 2004), we propose that this effect will be mediated by ease of processing. That is, matched messages will be experienced as easier to process than mismatched messages, and this ease will translate into greater persuasion.

In Study 1, we introduced participants to the topic of blood donation and assessed their initial cognitive versus affective orientations toward the issue. Following this assessment, we presented both cognitive and affective individuals with a persuasive message advocating frequent blood donation. This message contained numerous arguments in favor of blood donation, and these arguments were framed in terms of their source’s thoughts or feelings. For instance, in the “feel” condition, the message opened with the line: “I feel that donating blood is one of the most important contributions I can make to society.” By contrast, in the “think” condition, the opening line was: “I think that donating blood is one of the most important contributions I can make to society.” Aside from the use of the word “think” or “feel” throughout the message, the content of the arguments was identical. Immediately following the message, participants reported their intentions to donate blood in the future. As hypothesized, we obtained a significant interaction between initial orientation and message frame. Cognitively oriented individuals reported greater intention to donate blood following the “think” message, whereas affectively oriented individuals reported greater intention to donate blood following the “feel” message.

Study 2 had several aims: to manipulate affective versus cognitive orientation, to directly measure attitudes following the persuasive message, and to test the processing fluency mechanism. This study essentially replicated Study 1, but we primed affective

versus cognitive orientation by giving participants an initial message, negative toward blood donation, that was affective (e.g., “The nurse gripped my arm with one hand and slid the large spike of the needle into my skin.”) or cognitive (e.g., “I learned some surprising facts about human biology that make me think blood donation would be unwise.”) in tone. Following this prime, participants received the “think” or “feel” advocacy from Study 1, reported attitudes, and indicated how easy it was to process and comprehend the second (positive) message. Results indicated a significant interaction on both attitudes and ease of processing. When participants received the affective prime, they reported more favorable attitudes toward blood donation, and greater processing ease, in response to the “feel” rather than “think” message. When participants received the cognitive prime, these effects were reversed. Furthermore, perceived ease of processing mediated the attitude effect.

Finally, Study 3 tested a practical application of these findings by presenting male and female consumers with an advertisement containing think- or feel-framed arguments. Past research suggests that women self-identify as experiencing and expressing more intense emotions than do men and that women are more attuned than men to the emotions of others (for a review see Hall and Schmid Mast 2008). In a pilot study, we confirmed that women self-reported being more emotionally oriented than did men. Consistent with this notion, Study 3 revealed that female participants were more persuaded by the feel-framed advertisement, whereas male participants were more persuaded by the think-framed advertisement.

In summary, using both measured and manipulated approaches, we found that attitudes and message recipients with cognitive (affective) orientations were more susceptible to persuasion by arguments framed in terms of their source’s thoughts (feelings). This effect was particularly striking given that the substantive content of the arguments was exactly the same across conditions. Moreover, the persuasion outcome was mediated by processing fluency. Participants found it easier to process the matched rather than mismatched message, and they attributed this feeling of ease to the message’s persuasiveness. Implications for attitude structure and consumer behavior are discussed.

SPECIAL SESSION SUMMARY

Psychological Distance and Metacognitive Experience

Claire Tsai, University of Toronto, Canada
Manoj Thomas, Cornell University, USA

SESSION OVERVIEW

There is a growing interest among consumer researchers to understand the antecedents and consequences of psychological distance. Psychological distance is a fundamental construct in human cognition and it can manifest itself in the perceived geographical distance (close vs. remote), temporal distance (recent vs. distant), or construal level (concrete vs. abstract; how vs. why mindset). Psychological distance can have a direct effect on consumer behavior by changing the perceived distance to stores and cities (e.g., Raghuram and Krishna 1996) and thus influence preferences, choices, and willingness to pay (WTP). It can also have an indirect effect by changing how consumers construe the available information (e.g., Liberman, Trope, and Wakslak 2007). In this special session, we address an issue that has received limited attention in the extant literature: the role of metacognitive experiences in perceived psychological distance. We bring together four papers that examine the interplay of metacognitive experience and psychological distance in judgments and decisions. The first two papers in the proposed session investigate how metacognitive experience influences perceived distance and its consequences. The third and fourth papers examine how psychological distance moderates the effect of metacognitive experience on judgments. Together, these four papers offer new insights into how metacognitive experience and psychological distance interactively influence judgments and decisions.

Using a series of seven experiments, Alter, Oppenheimer, and Shah manipulate metacognitive experiences arising from different sources of processing fluency—font, conceptual priming, and linguistic structure—to investigate its influence on perceived geographical distance, construal levels, and its consequences. Thomas, Lindsey and Lakshmanan extend this work to show that metacognitive experience induced by familiarity has a similar effect on perceived geographical distance. They test the origins of this effect, ascribing it to misattribution for expectancy disconfirmation.

Tsai and McGill further investigate metacognitive experiences by uncovering conditions in which consumers may reverse the cue relationship between judgments and fluency. Using a series of three experiments, Tsai and McGill demonstrate that choice confidence is systematically influenced by fluency but that these effects are moderated by levels of construal (how vs. why mindset), which evoke different theories to interpret the subjective experiences of ease. At lower construal levels, fluency informs the feasibility of achieving the outcome but at higher construal levels fluency signals low investment in decision and thus lack of confirmation for outcome desirability.

Similarly, Smith and Schwarz show that when consumers make inferences based on the reported experiences of others, such inferences are moderated by temporal distance from the event and the vividness of this report. Specifically, experiences closer in time should be more relevant to predictions of enjoyment than experiences that occurred long time ago, a concept consumers understand in the abstract but which they may reverse when the experience is highly vivid (and so seemingly better remembered) due to the metacognitive belief that more extreme events are better remembered (i.e., more vivid).

These four papers feature on-going work that connects research on psychological distance with issues important to marketers. Session participants should come away with increased understanding of the influence of met cognition on variables directly important to marketers such as shopping distance, confidence in choice, inferences of future quality based on word of mouth reports. These papers also explore seemingly incongruent findings to help map the interactive effect of fluency and psychological distance on judgments and decisions.

EXTENDED ABSTRACT

“Fluency and Psychological Distance: Consequences for Construal and Discounting”

Adam L. Alter, New York University, USA

Daniel M. Oppenheimer, Princeton University, USA

Anuj K. Shah, Princeton University, USA

Psychological distance—the subjective experience of distance from a target stimulus—influences many important judgments and decisions, including how objects in the environment are represented mentally, and which of two future monetary rewards people prefer. Researchers typically show these effects by manipulating how far the target stimuli are from the perceiver. In contrast, we suggest that people make such distance calculations spontaneously, even without explicit instruction. In particular, we argue that a stimulus feels psychologically close to the extent that it is easy to process. In Studies 1 and 2, we began by showing that people use processing fluency—the ease with which they process a stimulus—as a cue to determine the psychological distance of a stimulus (for related research, see: Alter and Oppenheimer, 2006, 2008, 2009; Alter, Oppenheimer, Epley and Eyre 2007).

In Study 1, participants believed that cities printed in a disfluent font were farther away than cities printed in a fluent font. Replicating this effect using a different instantiation of fluency, participants in Study 2 estimated the distance of cities whose names they either had or had not read in an earlier, ostensibly unrelated phase of the study. As expected, participants rated the cities as nearer when their names had been primed, and were therefore more fluent.

Having shown that fluency influences distance estimates, we examined the effects of fluency on mental construal, and future reward preferences. According to Construal Theory (Trope and Liberman 2003), the nearer we are to a stimulus, the more likely we are to focus on its concrete, specific details. As we move further away, we focus on its abstract, global properties. Participants in Study 3 were asked to write a one-sentence description of New York city. The request was printed in either an easy to read or a difficult to read font. As expected, participants generated more abstract descriptions of New York when the request was printed in the difficult to read font.

Study 4 replicates this effect using the conceptual fluency priming paradigm described in Study 2. Participants in Study 4 preferred concrete descriptions of Los Angeles when they had earlier been primed with the name of the city, but relatively preferred abstract descriptions when they were not earlier primed.

In Study 5, we showed that this effect also holds in a naturalistic environment, using a third instantiation of fluency: linguistic fluency. We collected archival data from a web-based community of Balderdash contestants. In the game of Balderdash, players attempt to generate plausible definitions for obscure English words. Consistent with Studies 3 and 4, participants generated more abstract definitions for words that were difficult to pronounce.

Psychological distance has similarly profound effects on intertemporal choice. When making intertemporal choices, people often discount the value of delayed rewards. This discounting is best modeled by hyperbolic or hyperbola-like functions (Green and Myerson 2004). These models of choice predict that adding a constant delay in front of two rewards might lead to preference reversals. For example, a person choosing between \$10 immediately versus \$15 in one week might prefer the immediate reward. However, when choosing between \$10 in ten weeks versus \$15 in 11 weeks this person might prefer the later reward, even though the absolute time difference between the two rewards is still one week.

Consistent with these findings, in Study 6, we found that participants were more likely to choose a larger, later reward (LL) than a shorter, sooner reward (SS) when the questionnaire was printed in a disfluent font rather than a fluent font. Since disfluency made both rewards seem more psychologically remote, the displeasure of waiting for the larger reward figured less prominently in participants' choices.

In contrast to this result, for immediate vs. delayed reward choices, we might expect disfluency to lead to diminishing preferences for the LL reward, because it would be perceived as farther away while the perception of the immediate reward would not change.

To test this prediction, participants in Study 7 imagined receiving a \$75 Visa gift card that had no expiration date. Half of the participants were told that the gift card could be used immediately, half were told that the card could only be used after waiting for one year. They were then asked to imagine having to wait an additional two months before using the gift card and asked how much more they would need to be paid in order to wait. Half of the participants received questionnaires printed in a fluent font, whereas the other half received questionnaires printed in a disfluent font. As expected, when considering the immediately available gift card, participants in the disfluent condition asked for more money to wait than did participants in the fluent condition, whereas, when considering the delayed gift card, participants in the disfluent condition asked for less money to wait than did participants in the fluent condition.

This research therefore suggests that processing fluency is one plausible mechanism behind several fundamental processes in human cognition. Since fluency is cheap and easy to manipulate, these studies have useful implications for marketing researchers and practitioners who seek to shape how people construe goods and services.

- The burgeoning literature on the role of psychological distance in everyday decisions has prompted researchers to examine factors that influence distance judgments. In this research we focus on the role of metacognitive experience in distance judgments. Recent work by Alter and Oppenheimer (2008) has shown that distance judgments are influenced not only by the available cognitive information but also by the metacognitive experience evoked by the information. We extend this research by addressing two important questions about the role of fluency in distance judgments. First, we examine the generalizability of this effect by testing whether the metacognitive experience induced by familiarity has the same effect as that caused by manipulations of font, conceptual priming, or linguistic structure. While the latter manipulations are very useful tools to delineate the role of processing fluency in judgments in laboratory settings, familiarity is a more ubiquitous antecedent of metacognitive experience in everyday judgments. Some cities are more familiar than other ones. So distance judgments will feel easier for the familiar than for the unfamiliar cities. Will the metacognitive experience induced by familiarity with cities affect peoples' judgments of distance from the city? The first two experiments (Experiments 1A and 1B) reported in this research were designed to address this question. Our hypothesis is that people will judge familiar cities to be more proximal than unfamiliar cities and further, the familiarity effect in distance judgments will affect their economic decisions.
- Second, we examine when and why familiarity affects distance judgments. Several researchers have suggested that familiarity is hedonically marked and that it elicits a positive affective response (e.g., Alter and Oppenheimer, 2008; Garcia-Marques and Mackie, 2000; Winkielman and Cacioppo, 2001; Winkielman, Schwarz, and Nowak 2002). For example, Winkielman & Cacioppo (2001) showed that familiarity affects physiological measures of positive affect. They found that familiar stimuli generated an incipient smile that manifested as higher activity over the zygomatic major region of the face (cheek muscle). It has also been suggested that the relationship between familiarity and positive affect is bidirectional: illusions of familiarity can be produced through unobtrusive inductions of positive affect (Garcia-Marques & Mackie, 2000). However, all researchers do not agree with this perspective. Some have suggested that familiarity is affectively neutral and is subjectively interpreted based on contextual factors

(Mandler et al., 1987; Whittlesea and Williams 2001a; 2001b). Proponents of such familiarity-attribution models suggest that familiarity influences judgments only when it is perceived as surprising or discrepant. Experiments 2 and 3 were designed to test this discrepancy misattribution hypothesis.

Experiment 1A: Distance Judgments. The purpose of this study was to test the hypothesis that familiarity of a city can bias participants' distance judgments. In this experiment participants were asked to judge the distance between a famous US city (New York) and a relatively less known city (Ithaca). The same question was asked to resident of Ithaca as well as to residents of New York City. Participants were students recruited from university campuses in Ithaca and New York City were paid \$5 for completing a short questionnaire. As predicted participants in NYC judged the distance between the two cities to be longer ($M=5.92$) than those in Ithaca did ($M=5.18$; $F(1, 57)=4.07$, $p=.048$). Experiment 1B demonstrates that such familiarity-induced bias could also affect participants WTP for products.

Experiment 2 & 3: Hedonic Familiarity or Discrepancy Attribution? These experiments were designed to investigate whether the familiarity effect in distance judgments is better characterized by the hedonic familiarity account or by the discrepancy misattribution account. Participants were asked to judge the relative distance to 24 US cities. We selected 12 pairs of US cities such that each pair was equidistant from the experimental location, but one city was relatively better known than the other (e.g., Los Angeles, CA and Hemet, CA are equidistant from the experimental location but the latter is unfamiliar). Some of these pairs were in the same state as the experimental location, while the other pairs were in far-flung states. If familiarity is hedonically marked, then we would expect the familiarity effect for all pairs irrespective of their actual distance from the experimental location. In contrast, the discrepancy misattribution hypothesis suggests that people expect themselves to be familiar with proximal but not distant cities. Therefore, they will find unfamiliarity to be discrepant only for the proximal cities. Results support the discrepancy misattribution hypothesis. The familiarity effect manifested only for proximal cities. Further, in Experiment 3, we identified the locus of the bias and found that the bias in distant judgments is caused by unfamiliarity and not by familiarity. These results do not support the hedonic familiarity hypothesis.

"On the Psychology of Confidence-The Effects of Fluency and Construal Level on Confidence Judgments"

Claire Tsai, University of Toronto, Canada

Ann McGill, University of Chicago, USA

The present research explores the influence of the meta-cognitive cues on consumers' confidence judgments and proposes an important moderator for the fluency effect on confidence judgments, specifically, construal level (Trope & Liberman, 2003). We find that when consumers adopt a low construal level, which highlights the feasibility of an outcome, fluency increases confidence. However, when consumers adopt a high construal level, which highlights the desirability of an outcome, fluency decreases confidence. We trace this latter effect, a reversal of prior findings regarding the role of fluency, to lay theories regarding the relationship between outcome desirability and effort.

Recent research has shown that fluency may not always have a positive effect on the underlying judgment, depending on the extent to which meta-cognitive experiences are judged to be diagnostic, the judgmental heuristics or theories used to interpret the subjective experiences of ease, and processing motivation. The present research adds to this emerging literature by positing that people interpret feelings of ease differently depending on construal level.

We hypothesize that when people think about feasibility, that is, at a low construal level, feelings of subjective ease should bolster confidence. Greater ease logically signals greater likelihood of achievement. By contrast, when thinking about desirability, that is, at a high construal level, people will reverse the effect. When people are confident that an outcome is desirable, they are willing to allocate more resources to achieving that outcome (Simmons & Nelson, 2006; Tsai et al., 2008) and would probably put forth greater effort. Hence, they may reverse this association and interpret greater effort to reflect greater confidence in the outcome. These hypotheses imply an interaction of fluency and construal level on confidence. This prediction distinguishes our work from two alternative explanations, sunk cost fallacy and cognitive dissonance. Both of these accounts predict a main effect, that is, greater effort leads to greater confidence in choice, but not an interaction effect.

We tested our proposition in two ways. In studies 1 and 3, we manipulated retrieval fluency by asking participants to think either of a few (easy) or many (difficult) reasons for their choice. In study 2, we manipulated processing fluency and presented a choice set using either an easy or a difficult to read typeface. Across all studies, we manipulated people's construal levels by using a priming task that appears to be irrelevant to the choice task.

In studies 1 and 2, we demonstrated the interactive effect of fluency and construal level on confidence judgments. In study 1, participants finished the priming task first and then proceeded to the main choice task where they were presented descriptions of two digital cameras and they generated either two or ten reasons for preferring one camera to the other. They were then asked to choose a product and indicate their confidence in their choice. As predicted,

participants at lower construal levels exhibited the retrieval fluency effect and reported greater confidence when thought listing was easy (two reasons) than when it was difficult (ten reasons). On the contrary, participants at higher construal levels reversed the fluency effect and reported greater confidence when processing was difficult than when processing was hard. Study 2 replicated the results of study 1 with the typeface manipulation.

Study 3 was designed to obtain direct evidence for the role of retrieval fluency and construal level. We used a misattribution paradigm and showed that when participants attributed processing difficulty to the background music rather than the decision, the effects of retrieval fluency on confidence were eliminated. Study 3 not only generalized the findings of study 1 in a different product category (movie) but also showed that the effects of retrieval fluency and construal level on confidence were moderated by the interpretation of that feeling.

These findings provide a clearer picture of how fluency affects confidence judgments and identify construal level as an important moderator. To the extent that choices vary in their mode of presentation and that consumers vary in their internal states, the fluency experienced during choice and levels of construal will also vary. This variation will induce changes in confidence in choice and thus affect actual purchase decisions and the amount that consumers are willing to pay for an item.

"When it Happened Tells Us What Happened: The Effects of Temporal Distance and Metacognitive Inference on Word-Of-Mouth"

Robert Smith, *University of Michigan, USA*

Norbert Schwarz, *University of Michigan, USA*

A growing body of research shows that consumers draw inferences from their own metacognitive experiences (Lee 2004; Schwarz 2004), such as their subjective ease or difficulty of recall (Schwarz et al. 1991). What consumers conclude from these experiences depends on their naïve theories of mental processes. Most people assume, for example, that recent or important events are easier to remember than distant and unimportant ones. Hence, they conclude from ease of recall that the event was recent or important (Schwarz 2004). We extend this research by showing that consumers also draw inferences from the memory performance of others, an observation that is particularly important for the impact of word-of-mouth (WOM) information. Moreover, we document use of a naïve theory that has not been addressed in earlier research, namely that extreme events are better remembered than less extreme ones. Applying this theory to WOM reports, consumers are likely to infer from otherwise identical WOM information that a described service episode was more extreme, the more distant it is in time.

As a first test of these assumptions, participants in experiment 1 imagined that a friend was telling them about his experience at a restaurant. They then read a vivid, highly detailed paragraph about an enjoyable or unenjoyable restaurant visit that happened one

week or one year ago and answered questions about how their friend felt about his restaurant experience. This 2 (valence) x 2 (temporal distance)-factorial experiment revealed an interaction of both factors: when the event was negative, participants inferred that the experience was worse when it occurred one year rather than one week ago; the influence of temporal distance was less pronounced, and not significant, when the event was positive.

Follow-up experiments tested whether these inferences influence consumers' own behavioral intentions. On the one hand, the inferences observed in experiment 1 suggest that consumers may express less interest in going to the restaurant after receiving negative WOM information about a temporally distant rather than recent service experience. On the other hand, WOM accounts of distant service events are less diagnostic of the likely current service quality than accounts of recent service events—the unfriendly staff from last year may long have left, but the staff from last weekend will probably still be there. Hence, consumers may infer that the distant event was very bad, given that it is still remembered in detail, but may discount it as irrelevant when deciding whether they want to visit the restaurant themselves.

To assess whether consumers realize that distant service events are less predictive of what they might expect if they went to the restaurant now, experiment 2 asked participants to imagine that they are considering a restaurant visit. They then reported whether they would prefer to talk to someone who went to the restaurant a week ago or to someone who went there a year ago. Participants nearly unanimously preferred talking with someone who visited the restaurant a week ago, indicating that they clearly understand that recent service experiences are more diagnostic than distant ones. However, does this insight imply that they discount vivid reports of distant service events once they receive them? Or is the inferred extremity of the event so compelling that WOM information is nevertheless more influential when it pertains to distant rather than recent service events?

Experiment 3 addressed this question. Participants again read about a friend's positive or negative restaurant experience that happened one week or one year ago, resulting in a 2 (valence) x 2 (temporal distance)-factorial between-participants design. Replicating experiment 1, they inferred that their friend's negative experience was more extreme when his otherwise identical report pertained to last year rather than last week. However, the influence of temporal distance on inferences from positive events was small and nonsignificant. Paralleling this pattern, participants reported less interest in going to the restaurant if the recounted negative event occurred one year rather than one week ago; their intention to visit the restaurant was unaffected by temporal distance when the described event was positive. Thus, consumers' own intentions were influenced by their metacognitive inferences from the observation that a friend still remembered a negative service experience one year later, despite their general insight that distant service events are less diagnostic than recent ones.

On the theoretical side, these findings extend the analysis of metacognitive inferences in several ways. First, they provide first evidence that metacognitive inferences are not limited to inferences from one's own memory performance; instead, people also attend to others' memory performance as a source of information. However, second, they may only engage in this additional inferential work when the declarative information signals a problem that warrants extensive thought, that is, when the information is negative. This adds to the growing body of research showing a negativity effect in WOM (e.g., Ahluwalia 2002). Third, our findings also add to the growing list of naïve theories people use in drawing metacognitive inferences (Schwarz 2004): extreme events are

better remembered than less extreme events. Hence, detailed memory of a distant event implies extremity; we term this the Distance-Extremity Bias. Finally, it is worth noting that this bias influenced consumers own intentions (experiment 3) despite the fact that they generally understand that distant events are less predictive of future service experiences than recent ones (experiment 2). On the managerial side, our findings highlight the importance of service recoveries, stressing the counterintuitive notion that service errors that occurred long ago may actually do more damage through WOM than recent service errors.

SPECIAL SESSION SUMMARY
New Insights into Consumers' Inherent Preferences
Itamar Simonson, Stanford University, USA

SESSION OVERVIEW

"Inherent preferences" (Simonson 2008a, 2008b) refer to preferences that are established prior to a decision context and are thus distinguished from "constructed preferences" (e.g., Bettman et al. 1998). Following a lively debate on the subject in the JCP Dialogue (Summer 2008) as well as a lively ACR session in October 2007, the next challenge is to start an empirical research program on the determinants of inherent preferences. The objective is to gain a better understanding of often dormant inherent preferences (e.g., the preference for the experience involved in using a motion-sensitive remote that existed before Nintendo introduced the Wii videogame system) and the manner in which they may be revealed. That is the overarching goal of the proposed session.

There are different types of inherent preferences, ranging from previously constructed preferences to "hard-wired," inherited preferences. Regardless of the specific type, it has been proposed that dormant (i.e., yet to be uncovered) inherent preferences are most likely to be revealed through product experience, rather than during the decision process. The first paper in the session, by Chris Hsee and Adelle Yang, examines alternative sources of information regarding future experiences and corresponding inherent preferences. In particular, Hsee and Yang show (in a series of already completed studies) that other consumers' subjective experience evaluations with an object, especially if those were elicited in separate (rather than joint) option evaluations, are better predictors of a target consumer's inherent preference for the object than if the consumer him/herself tries to assess the object based on its objective attribute values.

The two other papers in the session use different methodologies to examine specific inherent preferences that can be described as hard-wired or even genetically-based. Shane Frederick examines the impact of inherent sex differences on time preferences and risk attitudes. Using his "Cognitive Reflection Test" or CRT (Frederick, 2005), he disentangles inherent vs. acquired origins of such fundamental differences. He also shows that, after controlling for CRT, the female "advantage" in time preference widens, and the female "deficit" in risk tolerance diminishes. The data further yield the surprising result that in the domain of losses, women are more risk-seeking than men. These studies have been completed.

Itamar Simonson, Aner Sela, and Gary Swann examine genetic influences on consumers' inherent preferences. Contrasting the preference similarity between identical twins and nonidentical twins, they identify the types of consumer preferences for which genetics appears to be a significant determinant and those that are not inherited. In particular, according to the data already available (at this point, about 70 pairs of each twin type), the tendency to not/compromise appears to have a significant genetic origin, whereas the tendency to not/seek asymmetrically dominating options does not differentiate identical and nonidentical twins. This finding is consistent with the notion that the reasoning function (involved in the decision whether to compromise) evolved more recently than the perceptual system (involved in the perception of relative attractiveness), which is more universal and less dependent on individual genes.

We believe that the session will be of much interest to attendees of the ACR conference regardless of their particular area

of research (i.e., not just BDT types). It explores a new domain, which has not previously received much attention, and the various studies and sources of data are rather novel to our field and may lead to further research.

Our discussant will be Drazen Prelec of MIT, who will present his insights on the subject and the papers and moderate what is likely to be a lively discussion.

All participants have agreed to their role in the session.

EXTENDED ABSTRACT

"The Supremacy of Subjective Evaluations as Indicators of Inherent Preferences"

Christopher Hsee, University of Chicago, USA
Adelle Yang, University of Chicago, USA

Prior research suggests that inherent preferences are most likely to be revealed through experience. This project examines alternative predictors of experience. Suppose that you are shopping for a stereo system and have narrowed your options to two models. The two models are identical, except for the following: Model A can be remotely controlled and Model B cannot, whereas Model B delivers more output power than Model A. Since you are shopping online, you cannot hear their sound and therefore cannot tell how much more powerful Model B is relative to Model A. However, you could obtain one of the following three types of information regarding their sound powerfulness: (a) *Objective specifications*, that is, objectively measured output wattages (e.g., Model A is 100 watts and Model B is 200 watts); (b) *Subjective ratings elicited in comparison*, as obtained using the following procedure by an impartial research firm: A group of consumers similar to you were asked to audition and to compare the two models and then rate their sound powerfulness. You are then given the mean ratings of the two models; (c) *Subjective ratings elicited without comparison*, as obtained using the following procedure by an impartial research firm: Two groups of consumers similar to you were each asked to audition one of the two models without comparison. Each group then rated the sound powerfulness of the model they had auditioned on the 10-point scale. You are then given the mean ratings of the two groups/two models.

Suppose that you can receive only one of these three types of information, which one do you prefer, and which type of information will enable you to choose the model that best matches your inherent preferences and maximizes your overall satisfaction? The present research seeks to answer questions like the above. Through a large-scale experiment involving stimuli analogous to those described in the example above, we find, among others, the following two results. First, most consumers prefer objective specifications to subjective ratings elicited in comparison, and most consumers prefer subjective ratings elicited in comparison to subjective ratings elicited without comparison. Second, in contrast to their lay preferences, our study shows that consumers who receive the subjective ratings without comparison are most likely to choose the option that renders the best consumption satisfaction, and those who receive the objective specifications are least likely to do so. The reason is: subjective ratings without comparison best match consumers' inherent preference during consumption. Consump-

tion is a matter of subjective experience rather than objective specifications, and consumption usually takes place in the non-comparative mode rather than in the comparative mode.

As will be discussed in presentation, this research both advances theory and yields significant practical implications. Theoretically, the present research extends three previous lines of research, relating not only to inherent preferences, but also to “lay rationalism” (Hsee et al. 2003), specification seeking (Hsee et al. 2009), and distinction bias (Hsee and Zhang 2004). In particular, the research shows that non-comparative subjective information provided by others can be better than objective specifications, because such subjective information best matches consumers’ inherent preference during consumption. Practically, the present research suggests a new way of conveying information to potential buyers, especially online buyers. Currently, most online stores do provide objective specifications of their products, but do not often provide other consumers’ (subjective) evaluations. Even if other consumers’ evaluations are provided, they are not elicited systematically. Our research suggests a need for independent research firms to elicit non-comparative subjective ratings of the relevant attributes of target products, and for marketers to provide potential buyers such subjective information rather than objective specifications.

“Antecedents of Inherent Preferences: Cognitive Reflection and Other Sex Differences”

Shane Frederick, Yale University, USA

For most decision theorists, inherent dispositions (to avoid risk, maximize payoffs, seek variety, live close to campus, and minimize rent, ...) are taken as a given, and analyses revolve around the contextual features that highlight or suppress varied considerations which alter the weight that competing motives receive. By contrast, evolutionary biologists who study decisions usually focus on explaining the origins of the motives themselves in terms of historical selective pressures which may apply differently to different groups (e.g., women vs. men). In a distinction championed by Simonson (2008), decision theorists usually focus on “constructed preferences,” in which choices are seen to shape preferences, whereas biologists focus on “inherent preferences,” which choices merely reveal. Inherent preferences can accommodate constructed preferences provided the observed behavior is not so inconsistent as to invalidate the putative existence of the construct being assessed. Moreover, both approaches can coexist. For example, there may be evolutionary reasons why individuals are more risk seeking in losses than gains, but you can also “create” or accentuate this preference by focusing respondents attention on losses rather than on, say, probability or expected value.

In work which falls within the “inherent preferences” paradigm, Frederick (2005) found: (1) that scores on a “Cognitive Reflection Test” predict fundamental decision making characteristics, such as time preferences and risk attitudes, and (2) that males score much higher on this test. Those two facts jointly imply a third result which that paper did not discuss: (3) that controlling for CRT scores may modify conclusions about sex differences. For example, since lower scoring people are less patient, and since women score lower than men, the finding that men and women were equally patient suggests that sex would emerge as a significant predictor of time preferences if CRT scores were controlled for.

To test this logical implication, a composite patience index was formed for each respondent according to the proportion of times they chose a later, larger reward over a smaller, sooner reward (in choices such as \$3,400 this month vs. \$3,800 next month, \$100 now vs. \$140 next year). Although this index showed no significant

sex differences, sex emerged as a significant predictor of time preferences after CRT scores were controlled. Indeed, for any given CRT score, females were significantly more patient than males. Thus, sex differences in CRT act to mask other (perhaps more essential) sex differences that affect time preference. These results suggest a rethinking of claims that sex plays a small role in determining time preferences, such the conclusion from Silverman’s meta-analysis (2003, p. 459) that “gender accounts for only a small proportion of the variance in the ability to delay gratification.”

In the domain of risky choice, including CRT as a covariate also has opposite implications for conclusions about sex differences. Specifically, since women score lower than men, and since lower scoring respondents are more risk averse, the marked sex differences in risk preferences is due partly to CRT differences (that is, to the cognitive variables that mediate performance on the CRT). Thus, though controlling for CRT does not affect the qualitative generalization that women are more risk averse than men (Byrnes, Miller, & Schafer, 1999), it does suggest that sex, per se, becomes a less potent predictor of risk preferences once CRT scores are controlled. Risk attitudes were assessed in terms of the proportion of times each respondent chose a gamble over a sure reward with smaller expected value (in choices such as \$100 for sure vs. a 75% chance of \$200, \$100 for sure vs. a 3% chance of \$7000, and so on). Men chose the gambles significantly more often than women (43% vs. 30%; $p < 0.0001$), but these differences were smaller after CRT was controlled for.

A final analysis examined the effects of CRT and sex on risk seeking in the domain of losses. Surprisingly, there is next to no research on this topic. Even more surprisingly, the general finding that women are more risk averse than men is reversed in this domain. When faced with hypothetical choices between a sure loss and a gamble with a more negative EV (e.g., between losing \$100 for sure or taking a 3% chance to lose \$7,000), women chose the riskier gamble significantly more often than men (54% vs. 45%; $p < 0.0001$). A control for CRT did not affect the average size of this effect, but did reveal that the sex difference increased with CRT score: among men and women who scored a “0” (out of 3), women chose the gambles only slightly more often than men (53% vs. 49%), but among those scoring a 3, the difference was considerable (55% vs. 42%; $p < 0.05$).

Evolutionary or “socio-biological” accounts can accommodate some of the presented findings. For example, Baumeister (2008) conjectures that men’s greater appetite for risk may reflect their historically larger reproductive upside of big payoffs. For example, a man might rationally prefer a 3% chance of 70 over 1 for sure if those reward units translate into offspring (since a man could father 70 children). However the upside of the great payoff is much smaller for women, who cannot birth more than a dozen or so children. Moreover, as a consequence of their rationally greater appetite for risks, males may expect to die sooner, which could help explain why males discount the future more than women (holding cognitive ability constant).

However, much more investigation is needed to separate the truthful components of these reasonable, but ad hoc conjectures. First, the evolutionary story does not account for the large effects of cognitive ability on such preferences. Second, sex differences in risk taking may be explained in terms of differences in probability weighting (see Fehr-Duda, De Gennaro, & Schubert, 2006), not differences in the curvature of the underlying value function. Third, the finding here that women are more risk-seeking in the domain of financial losses is not readily fitted into the customary evolutionary accounts.

**“On the Heritability of Choice, Judgment, and
“Irrationality”: Are People Born To Live On the Edge or in
the Mainstream?”**

Itamar Simonson, Stanford University, USA

Aner Sela, Stanford University, USA

Most consumer preferences may appear too specific and context-driven in nature to be determined (in part) by genes. We were probably not born with any microwave oven gene, a Coke versus Pepsi gene, or even a peach ice cream gene. One does not need to be a strong (preference) “constructionist” (e.g., Bettman et al. 1998; Simonson 1993; Lichtenstein and Slovic 2006; Tversky et al. 1988) to know that most such product preferences are acquired, based largely on things such as experience, adaptation, social influence, and information. However, recent research does suggest the possibility that genetics plays a role in certain preferences and choices, such as jazz music (Tesser 1993), alcohol (e.g., Prescott and Kendler 1999), and voting behavior (Fowler et al. 2008). Moreover, there is robust evidence that intelligence (Bouchard 1996) and personality, especially the extroversion and neuroticism factors (e.g., Pedersen et al. 1988), are largely (~50%) genetically determined. The genetic origins of personality, in turn, lead to other predictable differences, including people’s well-being (Weiss et al. 2008).

In the current project, we identify types or categories of preferences that might be, in part, genetically determined. Although we cannot have a strong theoretical basis for predicting that one particular preference will have a genetic component and another will not, we seek types of preferences for which we could develop reasonable hypotheses regarding genetic influence, because they appear to represent potentially inherent differences. To clarify, consider, for example, the difference between the tendency to compromise (versus selecting an “extreme” option from a given set) and the tendency to perceive an asymmetrically superior or dominating option as attractive (Huber et al. 1982; Simonson and Tversky 1992). Prior research has shown that the decision whether to compromise is conscious and “cognitive” whereas perceptions of (and preferences for) asymmetrically dominating options are “perceptual” and mostly unconscious (Dhar and Simonson 2003; Simonson 1989). Considering that the perceptual apparatus has evolved much earlier than the reasoning system, the latter is likely to be associated with greater variance across different pools of genes (e.g., families).

Accordingly, we expect to observe a stronger genetic effect on the tendency to not/compromise than on the tendency to select dominating options. Similarly, we selected several other preference types for which we believe that genetic influences could emerge and be explained based on general principles. These preference types include: (a) the tendency to select a variety of options across consumption occasions (e.g., Simonson 1990); (b) the tendency to balance rather than highlight/“go all the way” (Dhar and Simonson 1999); (c) consumer experiences that involve exhilaration/stimulation, such as riding motorcycles, roller coasters, and extreme sports, (d) artistic preferences, and (e) unique flavors (e.g., licorice, cilantro, and dark chocolate). In addition, we test whether certain judgment biases (e.g., representativeness, anchoring) have a genetic component.

Alternative methodologies for measuring the relative influence of genetics and the environment, and their respective shortcomings, have been discussed and debated extensively (e.g., Billings et al. 1992; Borkenau et al. 2001). The most commonly used method involves contrasting identical (or monozygotic) twins with nonidentical (dizygotic) twins (e.g., Fowler 2008; Weiss et al. 2008). If identical twins (with 100% identical chromosomes) tend to be

more similar than nonidentical twins on a certain dependent variable, controlling for shared environmental factors, then one can conclude that that DV has a genetic component. It is noteworthy that this methodology is not flawless, for example, because identical twins have been shown to meet (later in life) more often, and they might be treated differently by others (including their parents). We will use suitable covariates to try to control for these potential confounds.

We rely on this methodology in the current ongoing project, using the SRI International Twins Registry. Participants (N=140 pairs; expected final N=200 pairs) complete a 30-minute questionnaire online, which includes a broad range of previously pretested tasks from the decision making literature. Our data analysis has focused initially on the contrast between preferences for compromises and perceptually dominating options. The results so far appear to support the proposition that compromising, but not dominance, have a significant genetic component. More generally, this project has the potential to provide “deep” insights into the determinants of inherent preferences and enhance our understanding of the drivers of consumer decision making.

SPECIAL SESSION SUMMARY

Where's My Bailout? A New Look at Factors Affecting Consumer Fairness Perceptions in the Age of Vengeful Populism

John Pracejus, University of Alberta, Canada

SESSION OVERVIEW

Populist outrage has arisen over a wide variety of behaviors in the wake of the financial crisis. Perceived unfairness seems to be a key driver of this outrage. Consumer research is uniquely situated to understand the factors that impact perceived unfairness, as we have been investigating it (in the context of prices) for over 20 years. The present special session proposal, therefore, brings together researchers who are exploring important factors affecting fairness perceptions of consumers. The session looks at how cultural, psychological and situational factors impact perceptions of fairness. Specifically, Bolton, Keh and Alba provide evidence that consumers in collectivist cultures are more influenced by group membership in their appraisal of fairness than are consumers in more individualist cultures. Furthermore, within a given culture, Popa and Pracejus demonstrate that a consumer's social value orientation can impact the degree to which they perceive it to be fair to pay more for something. Finally, Gneezy and Epley show that the perceived fairness of breaking (or exceeding) promises seems critically dependent upon whether the consumer is the maker or receiver of the promise. Taken together, these research streams converge to reveal that fairness assessments are far from universal, both across individuals and across situations. Given the particular importance of understanding how people assess fairness at this point in history, we believe that this session will not only be of interest to fairness researchers, but to a wider ACR audience who are certainly considering the new importance of such constructs in many consumer domains. The format of the session will be three presentations, no discussant. The session chair will briefly outline the idea of the session and the relationship between the presentations (2 minutes) followed by each presentation (18-20 minutes) and questions about individual presentations (4-5 minutes). After questions about the third presentation, if time allows, the session chair will encourage a general discussion about our evolving understanding of consumer fairness perceptions.

EXTENDED ABSTRACTS

"How Do Price Fairness Perceptions Differ Across Culture?"

Lisa E. Bolton, Penn State University, USA

Hean Tat Keh, Penn State University, USA

Joseph W. Alba, University of Florida, USA

A developing stream of research on consumer price perceptions has examined perceived fairness, including how reference points affect perceptions (Bolton, Warlop, and Alba 2003; for a review, see Xia, Monroe, and Cox 2004). More recently, Haws and Bearden (2006) found that price differences across customers (i.e., paying a higher price than another customer for the same product from the same vendor at the same time) led to particularly strong unfairness perceptions relative to price differences across products, vendors, or time. Following Haws and Bearden, we examine how dynamic pricing affects price fairness perceptions; however, we do so from a cross-cultural perspective. Previous research has examined the influence of culture on various aspects of consumer behavior, but cross-cultural research is scant with regard to price fairness. The present research addresses this issue by contrasting price fairness perceptions in two dominant economies: China and the United States.

China serves as a compelling contrast to the United States for several reasons. First, Chinese culture is commonly characterized as higher in collectivism and lower in individualism than American culture. Whereas Western cultures tend to define the self in terms of individual autonomy (i.e., that individuals are independent of one another), Eastern cultures define the self in terms of social connectedness (e.g., Markus and Kitayama 1991). The latter orients the Chinese toward in-groups and away from out-groups, given the in-group's greater self-relevance (Oyserman 1993; Oyserman, Coon, and Kimmelmeier 2002). Second, collectivist cultures are more concerned with face (i.e., status earned in a social network; cf. Ho 1976), scoring higher on measures of face concern (Zane and Yeh 2002; Oetzel and Ting-Toomey 2003) or face consciousness (Bao, Zhou, and Su 2003). In addition, Chinese language has more words for concepts related to face (such as losing face, and emotions related to loss of face) than does the English language (Ho, Fu, and Ng 2004; Bedford 2004; Hu 1994).

In a price-fairness setting, it seems reasonable to expect differences in price fairness perceptions arising from these cultural factors. We argue that paying a different price from others summons concern about face such that consumers gain (lose) face when paying a lower (higher) price than another consumer. In a collectivist (Chinese) culture, consumers are oriented toward the in-group, and therefore face concerns are stronger for in-group than out-group comparisons. Put simply, the gain (loss) in face of paying less (more) than another consumer is greater for in-group than out-group comparisons. Thus, collectivist (Chinese) consumers should experience a greater loss of face when a friend pays a lower price than when a stranger pays a lower price. (Similarly, collectivist/Chinese consumers should experience a greater loss of face when paying a higher price to a vendor with whom they have a long-term relationship than to a newly encountered vendor.) In contrast, face concerns among individualist (American) consumers are not expected to differ between in-group and out-group comparisons.

In a series of studies we investigate how cultural differences affect price fairness reactions to across-customer price differences. Study 1 provides an initial test by examining price fairness judgments by individualist (American) and collectivist (Chinese) consumers who pay a higher or lower price than an in-group or out-group member. Studies 2-4 provide evidence for psychological process. Special effort is made to determine the causal role of cultural differences through a manipulation of self-construal (study 2), measurement of the emotional role of shame evoked by face concerns (study 3), and analysis of the moderating role of public/private price comparisons (study 4). Finally, studies 5 and 6 test the robustness of the phenomena, utilizing an alternative operationalization of the in-group/out-group construct to extend our findings from customer-only relationships to customer-firm relationships (study 5) and to establish boundary conditions arising from other transaction factors (study 6).

The present research makes several contributions to the price fairness literature. First, we illuminate the role of culture (individualism/collectivism) in determining fairness reactions to across-customer price comparisons. Second, we provide evidence for multiple moderators in determining fairness response to across-customer price comparisons, including the type of referent (in-group/out-group and loyal/first-time buyer) and the public/private

nature of the comparison. Third, we provide evidence for psychological process through causal evidence for the role of culture (via manipulations of independent/interdependent self-construal) and the role of face (via the face-related emotional responses of shame and anger across culture). Finally, we discuss the implications of our results for dynamic pricing and relationship marketing. To our knowledge, past research has not investigated price fairness reactions from a cross-cultural perspective nor, naturally, factors that would contribute to cross-cultural differences.

From a theoretical standpoint, we suggest that future cross-national research on price fairness should consider two fundamental dimensions: cultural differences and marketplace differences. We agree with other researchers who call for a more expansive consideration of cross-cultural variation beyond individualism/collectivism and believe that face merits particular attention. Moreover, we suggest that the cultural environment “on the ground” also merits further attention—in this case, the characteristics of the marketplace (such as social norms, traditional practices, and socio-economic history) experienced by consumers that likely shape their attitudes, expectations, beliefs and behaviors. Further research on fairness and culture would contribute to a greater understanding of marketplace metacognition (Wright 2002)—how consumers think the marketplace does and should work—and how it is shaped by culture and developed through experience.

“Not Just Fairness: Understanding Consumers’ Intentions to Buy Fair Trade Products”

Monica Popa, University of Alberta, Canada

John Pracejus, University of Alberta, Canada

As disparities between developed and developing countries became more apparent, the recognition that different nations do not benefit to the same extent from growth of trade gave rise to the phenomenon of FairTrade. The principle of FairTrade advocates the sale of products at greater than free trade prices based on the premise that producers in developing countries have the right to a living wage, safe working conditions and human dignity. In practice, FairTrade allows consumers to help disadvantaged producers by paying higher prices for agricultural products, textiles and handcrafts. The process is overseen by the Fair Trade Labeling Organization, an international certification body that works with producers in over 55 countries.

Although the notion of fairness plays a crucial role in the FairTrade ideology, research has yet to establish whether consumers are indeed driven by fairness concerns when purchasing FairTrade products. The present paper examines this issue building on the marketing literature that studied perceived fairness (e.g. Bolton and Alba, 2006; Campbell, 1999; Haws and Bearden, 2006; Xia, Monroe, and Cox 2004) from the standpoint of equity and distributive justice. Equity theory (Adams, 1965) posits that individuals gauge the fairness of an exchange by comparing the ratios of their contributions versus the resulting outcomes. An exchange is perceived as fair if all parties receive the same outcome or ratio, whereas disparate ratios result in perceived unfairness. However, consumers often accept to pay higher prices to support a charitable cause, because this act is seen as a good deed and is encouraged by society norms. Importantly, research has pointed out that charitably paying a higher price is perceived as fair only for basic products, but not for luxury items such as chocolate truffles (Martins and Monroe, 1994).

Extending these ideas to the FairTrade domain, it is expected that consumers will be willing to pay the premium for FairTrade if they believe that it is equitable, and furthermore, this premium will be perceived as fair only in the case of basic products. Luxury items are, almost by definition, more expensive than basic products. Because a luxury-items-producer is typically able to command high prices, consumers will not find necessary to help it by paying an extra premium for FairTrade. In contrast, because a producer of basic commodities is less able to reap decent compensation, consumers will perceive a FairTrade premium for such products as being justified/ equitable. Thus, we hypothesize based on equity theory that consumers will be more willing to pay the FairTrade premium if the product is basic rather than a luxury.

An opposite prediction can be forwarded based on the charitable donations literature. Strahilevitz and Myers (1998) used the notion of affect-based-complementarity to show that donations are

more likely to occur when bundled with hedonic/frivolous products (as opposed to utilitarian/practical products), because the monetary contribution alleviates the guilt associated with purchasing hedonic items such as chocolate truffles. Thus, affect-based-complementarity suggests that consumers will be more likely to contribute to FairTrade if the products offered are hedonic (rather than utilitarian). To the extent that luxury products can be equated with hedonic/frivolous products, and basic products can be approximated with utilitarian/practical products, equity theory and affect-based-complementarity generate contradictory predictions regarding the role of product type in consumers' willingness to buy FairTrade. These conflicting perspectives were experimentally tested in our research.

A pretest involving thirty-nine undergraduate students from a large North-American university identified rice and chocolate as appropriate utilitarian/hedonic stimuli. Respondents classified rice as primarily utilitarian and basic necessity, and chocolate as a primarily hedonic, luxury item.

In experiment 1, ninety-three participants who were prescreened to have no prior experiences with FairTrade products were randomly assigned to the utilitarian or the hedonic condition. Participants were presented with general information about FairTrade, followed by the dependent variable-likelihood to pay the FairTrade premium. Specifically, participants were asked to indicate if a FairTrade product costs 10% more than a regular product, how likely they would be to choose the FairTrade one (1= very unlikely; 7= very likely). The price premium of 10% was controlled based on prior research guidelines (e.g. Maietta, 2003). The results produced no main effect of product type, suggesting that neither equity theory nor affect-based-complementarity can be used as stand-alone frameworks for explaining consumers' likelihood to pay the FairTrade premiums. However, to investigate the possibility that both frameworks might be applicable, albeit for different consumer segments, individual differences were taken into account. Participants' social value orientation (SOV; a stable dispositional variable that reflects an individual's concern with equity) was measured following Kuhlman and Marshello (1975). Participants were classified as either prosocial or proself based on their SOV. Because prosocials are sensitive to fairness, whereas proself individuals do not have such concerns, we assumed that prosocials' behavior would be predicted by equity theory, and hypothesized that prosocial (but not proself) individuals would be more likely to pay the FairTrade premium if the product is utilitarian rather hedonic. Results supported this prediction, as a significant two-way interaction between product type and SOV was obtained. The mean difference between likelihood to pay the FairTrade premium when the product was utilitarian as compared to hedonic was significant and positive for prosocials, and insignificant for proself individuals.

In study 2, the influence of product type on consumers' likelihood to pay the Fair Trade premium was again assessed using a sample of seventy-eight North American undergraduates with no prior FairTrade product experiences. As in study 1, no main effect of product type was found. Fairness concerns were gauged using a priming procedure (e.g. Aart et al. 2005). Specifically, it was assumed that situational cues may impact individuals' concern with equity. As such, priming consumers with the concept of fairness should make them more likely to pay the FairTrade premium if the product is utilitarian. Participants in the equity-prime condition received a scrambled sentence task containing the words "equitable", "fair", "even", and "just", while those in the neutral-prime condition received words unrelated to any particular motivation. As expected, a significant two-way interaction between product type and priming was found. Participants primed with equity were more

likely to pay the FairTrade premium if the product was utilitarian (vs. hedonic), whereas participants in the neutral prime condition were not significantly influenced by product type.

“Doing More, Doing Less: Consequences of Exceeding vs. Falling Short of Promises”

Ayelet Gneezy, *University of California—San Diego, USA*

Nick Epley, *University of Chicago, USA*

Promises are a part of our daily lives; everyone makes promises, some of which are kept and others that are not. People make and receive promises from friends, family members, and colleagues. Children may promise their parents things they do not intend to deliver, and parents sometimes make promises they cannot keep.

Despite the prevalence of promises in social interactions, relatively little research investigates the consequences of making and keeping promises. This research takes a first step in understanding how promise makers and receivers account for promise keeping, and in particular examines how their judgments vary as a function of delivery level—whether the promise maker delivers more, less, or exactly as promised. We further look at the effect that one's role (promise maker or receiver) has on the way people account for promise keeping.

Based on past research that looked at how people integrate fairness considerations when evaluating others (Folger & Cropanzano, 1998; Tyler & Smith, 1998), supplemented by the pervasive dominance of negativity bias (Amabile, T. M., & Glazebrook, A. H., 1982; Cacioppo & Berntson, 1994), we predict that people's judgments of promise keeping will be systematically asymmetric, and specifically that relative to keeping a promise, falling short of one's promise will result in extremely negative responses, whereas exceeding a promise would have no effect. This prediction is further supported by the fact that people's fairness judgments tend to follow a binary scale where a behavior is either fair or unfair. We predict that keeping and exceeding promises would both be labeled as fair whereas falling short of a promise would be labeled as unfair.

Our second hypothesis stipulates that promise makers will consistently mispredict the effect that their behavior has on recipients, and in particular will tend to underestimate these effects. We expect promise makers to predict that recipients will be less appreciative of promises that are kept or exceeded, and more forgiving toward unfulfilled promises, than they actually are. Factors that contribute to this effect include egocentrism (Gilovich, Savitsky, & Medvec, 1998; Kruger, Epley, Parker, & Ng, 2005), the use of private information (Van Boven, Dunning, & Loewenstein, 2000), motivated reasoning (Kunda, 1990), and Social Contract Theory (Cosmides, 1989).

The first three experiments use hypothetical scenarios to test our hypotheses by manipulating participants' role and the extent to which the promise was kept (less, exactly, or more than promised). After reading the scenario participants reported happiness with the outcome, likelihood to trust the promise maker in the future, and interest in helping them in the future. The results provide an initial support for both the asymmetry, and misprediction hypotheses.

Experiment 1b used the same scenario to elicit responses, only this time we asked participants to characterize promise makers and in particular rate the extent to which they are selfish, fair and generous under each of the six scenarios. Consistent with our predictions, participants rated promise makers that delivered more than promised to be as generous and fair as promise makers that merely kept a promise. However, falling short of a promise resulted in significantly less favorable ratings. The results further support the misprediction hypothesis, indicating a significant difference between predicted and actual ratings of individuals' fairness and selfishness. The difference in generosity rating was non-significant. In Experiment 1c we explore whether, as would be predicted

by Social Contract Theory, promise makers and recipients differ in the way they perceive promises, and consequently in their perceptions of individuals that fall short of promises. This was achieved by asking participants to rate the extent to which various personality traits (e.g., reliability, trustworthiness) describe promise makers. As predicted, promise makers failed to predict the extent to which recipients would perceive them as untrustworthy when falling short of a promise. Role had no effect on participants' ratings when promises were kept and exceeded. An additional scenario-based experiment provides support to our postulation that recipients' judgments of outcomes that follow promises are different than their judgment of outcomes that follow 'simple' reference points (Kahneman & Tversky, 1979).

The next experiment uses a more ecologically validated manipulation to test the asymmetry and misprediction hypotheses. Specifically, we asked participants to recall past experiences that involved promise making and keeping, and use those to elicit happiness ratings. This experiment used a 2(role: promise maker, promise recipient) X3(delivery level: less, exact, before) experimental design. Results support the asymmetry and misprediction hypotheses. Additionally, the results suggest that exceeding promises does not increase happiness because keeping a promise is highly regarded, not leaving space for improved evaluation of exceeded promises. A mediation analysis suggests that recipients are using actual delivery level to infer how much effort their counterparts expended in the attempt to keep their promises, which in turn influences their evaluations.

The final experiment utilized a natural setting that required students to complete an assignment for their class in pairs. In this experiment, we instructed one student in each pair to promise the other student that he will send his part of the assignment after 3 days. We instructed these students on what promise to make (complete 3/6 questions) and to what extent to keep their promise (complete either, 2, 3 or 4 questions). In addition to further supporting the two main hypotheses, the results of this experiment suggest that in addition to effort, recipients use promise makers' actual behavior (the extent to which they keep their promise) to infer their sincerity in making the promise. These inferences mediated recipients' overall attitude towards, and judgments of, promise makers.

To sum, it seems that contrary to lay belief, doing more than one promised has the exact same effect as merely keeping a promise. Falling short of one's promise, however, produces extremely negative evaluations. Interestingly, our results suggest that recipients' judgments of promise makers are guided by fairness judgments, perceived sincerity and inferred effort. Due to asymmetric information and motivated reasoning, promise makers consistently fail to predict the effect that their behavior has on recipients.

SPECIAL SESSION SUMMARY

A Voter Among Voters: Political Decisions in the Social Context

Yesim Orhun, University of Chicago, USA

SESSION OVERVIEW

There has been a resurgence of interest recently in looking at politics and voting as a context in which to investigate broader issues in consumer decision making (e.g. Bechwati and Morrin 2007; Goldstein, Imai and Gollwitzer 2009, Hedgcock, Rao, and Chen 2009; Kim, Rao, and Lee 2009, Phillips, Urbany and Reynolds 2008, Zemborian and Johar 2007).

This session takes the point of view that political contexts are often an ideal environment in which to investigate the role of social influences on choice, judgment and evaluation, and the resulting consequences. For example, in an election, voters are largely responding to the same events as other voters as the campaign proceeds, and are simultaneously affected by pivotal events in a campaign, such as a debate or a high-profile negative advertisement. Furthermore, voters encounter information about how others are reacting to the campaigns and often spontaneously form inferences about the attitudes and intentions of other voters. The combination of information and inferences that voters have are then an important driver of the choices they make, and of the actions taken by campaigns.

In the first paper, Orhun and Urminsky study the inferences voters made about the electorate in the 2008 presidential election. They extend the intuition of false consensus to projection of evaluations underlying choice, providing evidence that it is this projection of candidate evaluations that underlies projection of candidate choice. They further demonstrate that voters project the way in which own evaluations led to choice, rather than evaluations themselves, onto both like-minded voters and supporters of the opposing candidate, contrary to the literature.

In the second paper, Ramanathan, McGill, Phillips, Schill and Kirk study the effect of social influences on undecided voters watching the general election debates. They find that evaluations made by people attitudinally distant from each other to begin with tended to co-vary to a greater extent with each other when such individuals sat next to each other as opposed to separately, while those who were attitudinally close to each other to begin with were not affected by seating arrangement. In particular, sitting next to someone with very different views led to greater polarization in post-debate attitudes.

In the third paper, Lovett and Shachar use a detailed secondary dataset on recent US congressional and presidential races to investigate the impact of voters' knowledge on campaigns decision to "go negative" in their advertising. They present an econometric model in which ads inform voters on the good traits of the candidate or the bad traits of his opponent. They find that, consistent with the model, the proportion of negative ads increases with voters' knowledge and candidate budget, helping to explain why negative ads are more prevalent in close races.

This special session is aimed at furthering current interest in the area and will help identify promising directions for future research. Akshay Rao, who has himself conducted influential research in this area, will serve as discussant, encouraging an audience discussion of the papers as well as a more general discussion of the role of social influences on political behavior and the implications of these findings for understanding social influences on consumer behavior.

EXTENDED ABSTRACTS

"Choosing Differently But in the Same Way: How Self Impacts Beliefs About Other Voters"

Yesim Orhun, University of Chicago Booth School, USA

Oleg Urminsky, University of Chicago Booth School, USA

Political decision-making fundamentally involves strategic behavior, such that decisions about who to vote for, how much resources to devote to a candidate and whether to vote involve beliefs about what others are likely to do. Traditional economic approaches assume that beliefs about others are not systematically biased. In contrast, psychological research has provided evidence for systematic biases, with own choices impacting inferences about others' choices, such as false consensus (Ross, Greene and House 1977) and other projective biases (e.g. Monin and Norton 2003).

The literature on social projection has generally demonstrated that endorsement of an attitude leads to higher estimation of the degree of endorsement in a population, and that this effect will be moderated by perceived similarity to the reference population (e.g. Ames 2004). We argue that, beyond simple endorsement, the intensity of attitudes and preferences plays a key role in social projection onto beliefs about the attitudes and preferences of others, which has not been systematically investigated in the literature. Furthermore, the literature has largely concluded that there is little or no projection of own attitudes when making estimates for an out-group population (e.g. meta-analysis by Robbins and Krueger 2005). In contrast, we argue that while voters do not directly project their own evaluations onto out-groups (i.e. supporters of the opposing candidate) they do in fact utilize their own preferences in making these evaluations. Specifically, voters will recognize the difference in candidate preferences between themselves and the out-group, and will instead project the way their own views gave rise to their own choice in estimating the views in the out-group. This notion of conditional preference projection implies that the more strongly a voter supports their own candidate, the more they will infer that supporters of the opposing candidate strongly support their own candidate as well.

We present data from three studies conducted during the 2008 presidential election, as well as a reanalysis of historical data from the 2000 and 2004 elections. These include a national poll of voters making inferences about other national voters conducted shortly before the general election, a two-wave national poll conducted directly before and after the first presidential debate and an incentive-compatible lab study in which participants were compensated based on the accuracy of their inferences. Across the studies, we also addressed some methodological limitation in the literature, which generally involves estimating binary responses or typical responses on a continuous scale, which confounds inferences about summarizing the population as a whole with inferences about a single exemplar. In our studies participants estimated the entire distribution of responses for the reference population. Furthermore, our data enables us to account for the distinction between the effects of actual similarity and perceived similarity, to both in-group (like-minded voters) and out-group (supporters of the opposing candidate).

Across the studies, we replicate the false consensus effect for estimates of choices among all voters, and demonstrate that this

choice projection is driven by the projection of underlying candidate evaluations. Furthermore, for the in-group of voters supporting one's own candidate, we find that projection of evaluations explains differences in beliefs across voters making the same choice. Inferences about the candidate ratings of other like-minded voters are systematically biased towards one's own candidate evaluations. Thus, we demonstrate that the projection of attitudes extends beyond mere endorsement to intensity of attitudes and preferences.

For the out-group of voters supporting the opposing candidate, our studies demonstrate a novel effect of projecting the way one's evaluations lead to choice onto others with opposing views. Our findings are consistent with our proposed framework of conditional preference projection, but are inconsistent with the processes proposed to account for social projection, particularly the anchoring hypothesis, which assumes that projection does not extend to the out-group. Specifically, we find that the higher voters rated their preferred candidate, the more they believed that supporters of the opposing candidate would rate that opposing candidate highly. Importantly, we find no effect on same-candidate evaluations: the degree of liking of own candidate (e.g. Obama among Obama-voters) did not affect the estimated liking of that candidate in the out-group (e.g. Obama among McCain-voters). This supports our argument that the inference that occurs is a higher-level projection of a rule of liking (e.g. they support their candidate in the same way I support mine), and helps rule out alternative explanations such as scale bias, motivated responding or simple assimilation-contrast effects.

These effects are found to be highly robust across populations and elicitation methods and are demonstrated both across individuals as well as within respondents who have changed their views over time. We will also discuss the impact of these findings on inferences for related actions (such as donating and volunteering) as well as the implications of our findings for strategic behavior in general.

“Are Political Opinions Contagious? An Investigation on the Effects of Seating Position and Prior Attitudes on Moment-to-Moment Evaluations During the Presidential Debates”

Suresh Ramanathan, University of Chicago Booth School, USA

Ann McGill, University of Chicago Booth School, USA

Joan Phillips, Loyola University, USA

Daniel Schill, Southern Methodist University, USA

Rita Kirk, Southern Methodist University, USA

Political opinions evolve as a result of a variety of factors including information gathered from news sources and opinion leaders, and interactions with friends, family and neighbors. Casual remarks made by a friend or discussions with neighbors across the backyard fence may guide people's attitudes towards a candidate. Individuals are thus embedded in a larger social network that may determine the degree of exchange of information (Eulau 1986, Huckfeldt and Sprague 1987). However, most prior research has focused on tangible exchange of information in well-formed social networks. In this paper, we show that social influence may color political views despite no obvious or tangible communication among individuals brought together in an ad hoc social group of undecided voters. Specifically, we show that people who are more distant from each other in their attitudes towards candidates are more sensitive to social influences, but in a direction leading to greater polarization of attitudes. We contrast our findings to Ramanathan and McGill (2007), who showed that greater synchrony among strangers sharing an experience led to more positive evaluations of the experience.

The data for this study were the responses of 30 undecided voters on a CNN rating panel during the third Presidential debate in

2008. Respondents (12 Democrats, 11 Independents and 7 Republicans) provided their political identification, degree of liberal or conservative values and initial attitudes towards Obama and McCain, both as a summary judgment on a 100 point scale as well as in the form of evaluations on a 12-item scale (qualified, sophisticated, honest, believable, successful, attractive, friendly, sincere, calm, aggressive, strong, active). They then evaluated the candidates' performance on the debate via a rating dial anchored on 0=Not at all positive and 100=Very positive. The debate lasted approximately 90 minutes and data were collected every second. Following the debate, respondents were again asked to provide their attitudes towards each candidate on both the summary scale and the 12-item scale. They were also asked to indicate whom they would be voting for. A seating map indicated the position of each respondent in the room.

After mean-centering the time-series data, we applied a band-pass filter to remove high frequency noise. Our interest was in a band of frequencies ranging from every minute to every 15 minutes. Given that each candidate spoke for at least one minute at any time, and the length of the longest segment in the debate was about 15 minutes, this band of frequencies seems reasonable. We wished to see if there was any influence of the two people to the immediate left and right of a focal respondent. A cross-spectral analysis of each pair of participants was used to determine the “coherence” in the two time series (see Ramanathan and McGill 2007). A high coherence at a given frequency indicates that one person's evaluations predict the other's evaluations very well at that frequency. For each triad, we computed a measure called multiple coherence, which represents the coherence between one person's evaluations and an optimal linear combination of the evaluations of the persons to the left and right (Jenkins and Watts 1968). For each triad, we also computed the attitudinal distance among the respondents. This was done by treating the attitudes of the neighbors as forces of influence along two dimensions—support for Obama and support for McCain. The magnitude of the resultant vector is computed as the square root of the sum of the squares of the net pull towards Obama and the net pull towards McCain. For a statistical control, we constructed arbitrary triads of participants from the same data, using people not sitting next to each other, but sharing the same political leanings and opinions as the ones actually sitting next to each other. Thus, we created false triads with the same political characteristics as the true triads.

A regression on the multiple coherence for each triad was run with seating arrangement (true versus false neighbors), mean-centered attitudinal distance and the interaction term as predictors. Results showed a significant main effect of seating arrangement with a greater coherence among true versus false neighbors. This was qualified by a significant interaction between seating and attitudinal distance. Attitudinally distant participants had a greater coherence when they sat next to each other compared to the false neighbor condition; people who were attitudinally close to each other did not experience any greater coherence due to seating. Importantly, the greater coherence among attitudinally distant people sitting close to each other was not due to agreement but rather more predictable disagreement—the evaluations of these participants were always out of phase by between 90-180 degrees in the spectral analysis, suggesting lack of synchrony.

Further, we found that the increased coherence in evaluations led to more sharply polarized attitudes post-debate. This effect was particularly pronounced among McCain supporters, suggesting that social signals emitted by Obama supporters during the debate may have been particularly impactful on McCain supporters, leading them to polarize in their attitudes. The effect of initial attitudinal

distance on final distance was mediated by coherence, but only for those seated next to each other.

Our findings suggest that political opinions can indeed leak via subtle social influence and cause people to alter their own opinions. We are presently analyzing the data from the second debate and will be able to present findings from both debates at the conference.

“The Seeds of Negativity: Knowledge and Money”

Mitchell J. Lovett, University of Rochester, USA

Ron Shachar, Duke University, USA

In commercial environments firms can improve their standing (profits, stock value, etc.) either by becoming more attractive to their audience (i.e., positive appeals) or by making their competitors less appealing (i.e., negative appeals). While some combative acts, such as sabotaging competitors' products, are forbidden by law, comparative (which implicitly includes negative appeals) advertising is not only allowed, but even encouraged by the Federal Trade Commission. Furthermore, the portion of comparative advertisements out of all advertisements has been approximated as close to one out of three (Niemann 1987), representing a substantial advertising volume. Further, recent media claims even suggest that negative advertising in commercial settings is on the rise (York 2008).

This study presents a model of negative advertising and examines it empirically. In order to learn the most about negative advertising, we focus on an application in which negativity is frequent and exhibits high variation—political campaigns. In their own right, political campaigns represent an important advertising market with over \$2.5 billion in ad spending in 2008 (Atkinson, Dec. 2008) and, of course, important consequences. Further, political campaigns present an understudied, interesting empirical regularity about negativity—that is, the greater tendency to go negative in competitive elections. For example, in the 2000 Senate elections the portion of all ads that were negative was 33% in noncompetitive races but 65% in competitive races (Goldstein and Freedman 2002a). This empirical regularity is important both because it is a central feature of the application studied here (i.e., political campaigns) and because, more generally, it is an intriguing relationship between competition and advertising tone. Thus, we believe that a model that can explain this regularity is likely to be insightful about the strategic forces behind negative advertising. Thus, we model candidates' decisions to go negative in political advertising and aim to explain this regularity.

We present a model of electoral competition with two candidates—a Republican and a Democrat. Each candidate has good traits (e.g., effective manager) and bad traits (e.g., performs badly under pressure). Of course, voters' utility increases in the candidate's good traits and decreases in the bad traits, but not all of the traits are known to the public. Each candidate faces a limited budget and tries to maximize total votes by allocating his budget between ads that present his good traits (i.e., positive advertising) and ads that present his opponent's bad traits (i.e., negative advertising). Voters combine this information from ads with other sources of information to form impressions of candidates. As a point of departure from existing studies, we incorporate recent psychological evidence that supports nonlinear asymmetric responses of overall attitudes to positive and negative beliefs (Holbrook et al. 2001). We find that in equilibrium the proportion of negative ads increases with voters' knowledge and the candidate's budget. Interestingly, close races are not only characterized by high negativity, but also by (a) high media coverage (West 1994) which can lead to high knowledge and (b) large marketing spending (i.e., large budgets) by the candidates

(Goldstein and Freedman 2002a). In this sense, our model can tie together these three empirical regularities.

In order to examine the model and its implications, we collect data on the elections for the US House of Representative in 2000, 2002 and 2004 and for US president in 2000 and 2004. Our key theoretical variables of interest are the portion of all ads that are negative, the total budget of ads, the closeness of the race, and voter knowledge. There are various challenges in the data collection. The most dramatic of which is getting information on voters' knowledge, particularly measures that distinguish the positive and negative aspects of knowledge about a particular candidate. Furthermore, this task is especially difficult for the congressional elections, where very little candidate specific information is available through surveys. Still, the evidence is supportive for our theory. Our results suggest that our theoretical variables contribute significantly to the explanation of candidate negativity. As expected by our model, as budget increases negativity increases and as both positive knowledge about a candidate increases and the negative about the opponent increases, the candidate goes more negative. Further, once accounting for knowledge and budget, the effect of closeness is significantly attenuated. Thus, the data is quite supportive for the effects of knowledge and budget on negativity and the theory helps to explain why close political races are more negative.

We finish with a discussion of the implications of this study. We discuss future directions for research in political advertising including extending this research to a dynamic context. Finally, we discuss the potential for transfer of the ideas to commercial settings.

SPECIAL SESSION SUMMARY

Long-term Decisions and Focusing on the Future

Daniel M. Bartels, University of Chicago, USA

SESSION OVERVIEW

How people think about and choose between immediate outcomes and those in the more distant future has been one of the central issues in consumer behavior, and behavioral science more generally (Loewenstein, Read, and Baumeister 2003). Building on the existing diverse literatures on time discounting (Frederick, Loewenstein, and O'Donoghue 2002), construal level theory (Trope and Liberman 2003) and the philosophy of personal identity (Martin and Barresi 2002), the proposed session will contribute to a better understanding of how evaluations and decisions are driven by perceptions of how our future-self will experience potential long-term outcomes. The papers investigate how the degree to which we both attend to the future and feel connection to that future self affect the pursuit of gains over concern for losses, the exertion of self-control in the face of depletion and the willingness to defer compensation in favor of longer-term gains. This session will unify the findings of the individual papers into a broader framework for investigating the impact on consumer choice of how we think about the self in the context of the future.

Given the relevance of the proposed topic to central issues in consumer research, this session is likely to have a significant effect on future research in a number of areas and contribute to a cross-pollination of approaches to studying long-term outcomes. The papers employ a variety of approaches (lab and field experiments, as well as neuro-imaging), and the session will offer a broad perspective on the ways in which the degree of goal proximity plays a role in consumer behavior.

In the first paper, Shu provides evidence that while individuals focus on losses in immediate choices (per prospect theory), they instead focus on gains when thinking about themselves in the more distant future. This long-run focus on gains leads to a systematic difference in outcome valuations and choice in gambles and political choices for the long vs. short-term.

Both the Bartels, Urminsky, and Rips and the Ersner-Hershfield, Wimmer, and Knutson papers examine the influence of perceived psychological connectedness (i.e. continuity with future selves) on intertemporal choice. Bartels, Urminsky and Rips demonstrate that to the degree people anticipate changes in identity, they are less willing to defer benefits. They show that when people's own sense of continuity with the future self is reduced, they accept smaller, sooner monetary rewards, become less willing to wait to buy a computer in order to save money, and demand a larger delay premium to receive a gift card. Neuro-imaging research by Ersner-Hershfield, Wimmer and Knutson provides further evidence for the link between perceiving discontinuities and greater discounting of long-term outcomes. They ask participants to make judgments about the current and future self, and other people and compare levels of activation in areas of the brain associated with thinking about the self to those associated with thinking about social targets. They find that those people for whom thinking about the future self resembles thinking about other people (in terms of the neural activation elicited) had a stronger tendency to devalue delayed monetary rewards.

Lastly, research by Agrawal and Wan examines how drawing attention to the future vs. the present (construal level) influences the performance of consecutive self-control which requires sustained effort and is vulnerable to self-control resource depletion effects. When thinking about the future, individuals focus on goals relevant

to the future self (e.g., health goals) and exert self-control depending on the importance of the task to their long-term goal. In contrast, when focused on the present, individuals attend to the resource accessibility experienced by the current self and will exert self-control depending on their perceived fatigue.

Given the centrality of long-term outcomes in this session, we anticipate that it will build toward an integrated intuition that contrasts a short-term decision maker, disconnected from the future self, who is impatient, loss-averse and impacted by depletion with a long-term decision maker, connected to the future self, who is more patient, gains-seeking and focused on goals. The session chair will facilitate audience discussion that explores relationships between the papers.

EXTENDED ABSTRACTS

“The Role of Self-Connectedness in Short Run Losses and Long Run Gains”

Suzanne Shu, UCLA, USA

Research on optimistic predictions finds that thinking about positive outcomes can affect judgment. For instance, as individuals think about a desirable focal outcome, they often put undue weight on that outcome relative to other possibilities; this has effects on probability estimates, affective forecasting, and other judgment tasks (Koehler 1994; Wilson et al. 2000; Rottenstreich and Kivetz 2006). Additional work has looked at how these optimistic predictions vary over time. Individuals are typically more optimistic the farther they are from the point at which the outcome will become known (Gilovich, Kerr and Medvec 1993), while work on resource slack, temporal construal, and regulatory focus also offers evidence that individuals see far-off things more holistically and positively than immediate events (Trope and Liberman 2003; Zauberman and Lynch 2005; Pennington and Roese 2003; Eyal et al 2004).

While much of the prior research has focused on outcome predictions or reasons for or against an option, less has been done to explore how optimistic predictions influence valuation and choice for future risky outcomes. For example, we know that for immediate gambles, individuals are loss averse (Kahneman and Tversky 1979). But for far-off gambles, is it possible that some form of optimism bias or wishful thinking causes the individual to focus on the gain outcome rather than the loss outcome? And what might this imply for valuation of those future outcomes within a Prospect Theory framework?

The research presented here suggests that individuals put more focal attention on gambles' gains for long-run outcomes, but shift attention toward losses in the short run. This occurs both for scenarios when the loss is incurred immediately (lottery ticket purchase) or expected to occur in the future (casino gamble). This overall pattern suggests that losses dominate in the short-run but that gains become the focal outcome as distance from the loss increases. Stronger focal attention on gains relative to losses for long-run outcomes has implications for how choices are evaluated, with the result that gains are more heavily weighted for a far-off outcome. This differential attention to gains and losses for temporally removed risky outcomes applies to many decision-making domains; for example, a study of two messages, matched for overall content, finds that participants prefer a hope message focused on

future gains over a “reverse losses” message when the choice is for a future term, but they prefer a “reverse losses” message when the choice is for the present term.

These findings suggest that curvature of the Prospect Theory value function may change once time is incorporated. Prior research on loss aversion has suggested that loss aversion has a basis in emotional reactions to the outcomes—specifically, a more emotionally charged reaction to negative outcomes, consistent with work on visceral effects and empathy gaps. Solicitation of individual Prospect Theory value functions once temporal distance has been manipulated shows that loss aversion diminishes as individuals feel themselves to be farther in time from the gamble they are considering.

The final study examines whether the differential focus on losses and gains is a function of how connected the individual feels to their future self. A test of Prospect Theory style gambles for individuals considering themselves at future times shows that gamble choices shift according to the degree of connectedness participants feel with that future self, based on a connectedness measure from Parfit (1984) and used by Bartels, Urminsky, and Rips (2009), suggesting that high connectedness is an important aspect of short-run loss aversion. Thus, it is actually degree of connectedness, rather than absolute temporal distance, which affects valuation.

Together, these studies provide evidence that individuals focus on loss outcomes in the short run but gain outcomes in the long run, that this long-run focus on gains has measurable impact on choices and valuations, and that this focus is moderated by individuals’ feelings of connectedness to their future selves. A better understanding of how individuals evaluate short run losses and long run gains may provide useful insight into human capital investment, risk taking, and other long run behaviors.

“How the Perceived (Dis)Continuity of Identity Affects Intertemporal Choice”

Daniel M. Bartels, University of Chicago, USA

Oleg Urminsky, University of Chicago, USA

Lance J. Rips, Northwestern University, USA

The literature on time preference has documented extremely high implicit discount rates in both hypothetical choices and observed behavior as well as inconsistency in the discount rate over time (Ainslie 1975; Thaler 1981; Frederick, Loewenstein, and O’Donoghue 2002). Economists offer several reasons why a rational actor might choose to consume a smaller amount of some good now, rather than a larger amount later—most of which concern the way that time affects the magnitude (or probability) of utility conferred by a delayed consumption experience. Most of these accounts of rational choice assume, however, that the preference for sooner-smaller options is due to the need to be compensated for the delay of benefit being received only by the future self, who is otherwise undistinguished from the current self. In this view, rationality demands acting in a manner consistent with maximizing some function of self-interest over time, and that the implied discount rate should relate to the cost of capital, and perhaps a risk premium relating to illiquidity or loss of the delayed outcome (Samuelson 1937); deviation from this rule has been characterized as myopia (e.g. Strotz 1955).

One account that differs radically from standard economic views is offered by Parfit (1984), who maintains that rationality does not require you to treat all parts of your life equally: He argues that personal identity consists of a series of partially-overlapping persons extending over time. One implication is not all descendant future selves are equally “you”. Thus, just as you are not rationally required

to care as much about others’ welfare as your own, so too, if your descendent future self is sufficiently different in terms of personality, beliefs, and desires from your current self, you are not rationally required to care as much about your future self’s welfare. Impatience can thereby be justified, distinct from normative discounting, by anticipated changes in connectedness over time.

In the current studies, we test the influence of people’s intuitions about the (in)stability of personal identity over time on (im)patience for future utility. Study 1 investigated the relation between elicited patience and perceptions of psychological connectedness in people’s judgments about their own future selves. Participants in this study rated the connectedness between their present state and their likely state at different times in the future and made judgments about the equivalence of present and future goods. We observe greater impatience in time periods with larger decreases in connectedness, consistent with connectedness explaining non-constant discounting.

In Study 2, we rule out a time perception explanation, using a projective method, in which participants read about fictional characters experiencing symbolically life-changing events (such as a religious conversion) that would normally decrease psychological connectedness but not impact monetary outcomes. We balanced the life-changing events so that they happen to different characters at different points in the future. Participants made timing decisions for annuity payouts on behalf of these characters. In time intervals perceived to represent large changes in psychological connectedness, participants made relatively impatient decisions—choosing to cash in annuities more quickly than for those intervals where they perceive smaller changes in connectedness.

In Study 3, we presented underclassmen with hypothetical choices between sooner, smaller valued gift cards versus gift cards plus a delay premium after reading either that identity changes radically in early adulthood (especially during the college years) or that the core features of one’s identity are fixed in early childhood (and stable during college). Participants demanded a greater delay premium after reading about how they would change than after reading stability of identity.

In Study 4, we manipulate people’s certitude in the stability of their identity indirectly, by asking them to judge how difficult it would be to generate either 2 or 10 reasons why their identity will remain very stable over the next 12 months. Participants in the 2 reasons condition reported less difficulty with the reason-generation task, and subsequently exhibited greater patience about when to buy a computer expected to decline in price over the next 12 months.

In Study 5, we conducted a field study using similar methods as Study 3. College seniors who were about to graduate read a passage that described graduation as either a major life-changing experience or one not impacting self-identity and chose between lotteries for delayed gift cards of increasing value over time. When participants were told their impending graduation presaged a major (vs. trivial) change in self-connectedness, they exhibited more impatience and were more likely to choose the smaller-sooner gift card. The effect was robust controlling for their individual beliefs about future availability of money and time after graduation.

In all five studies, we find evidence that when large changes in psychological connectedness are anticipated, people behave relatively impatiently—choosing to speed up the consumption of utility. Conversely, when anticipating small changes, people appear more patient. Our findings have the potential to shed light on the long-standing issues of “excessively” high discount rates as well as nonconstant discount rates.

“Saving for the Future Self: Neural Measures of Future Self-Continuity Predict Temporal Discounting”

Hal Ersner-Hershey, Stanford University, USA

G. Elliott Wimmer, Stanford University, USA

Brian Knutson, Stanford University, USA

Why do some people fail to save for the future? Theorists from economics, philosophy, and psychology have characterized saving as an “intertemporal choice” problem involving a decision between benefits that occur now versus in the future (Frederick, Loewenstein, and O’Donoghue 2003). Research shows that people often care less about future outcomes than they do about present ones, a phenomenon known as temporal discounting (Frederick 2003). According to an early model of temporal discounting, while people devalue future gains as a function of temporal distance from the present, individuals vary in the degree to which they devalue future gains. This tradeoff between time and magnitude was originally described with an exponential function (Samuelson 1937), but is better fit by a hyperbolic or quasi-hyperbolic function (Laibson 1997).

Theorists have argued that temporal discounting might emerge from conflicts of interest between temporally different selves (Parfit 1971; Schelling 1984). According to this view, psychological connectedness of the present to the future self varies as a function of time, such that people feel more connected to their potential self of five years than their potential self of fifty years. Thus, people might care less about more temporally distant future selves to the point at which an extremely distant future self may seem like a different person altogether (Parfit 1971; Pronin and Ross 2006). This “multiple selves” view has implications for financial saving. If people consider the future self as a stranger, then they may rationally have no more reason to save money for themselves than to give the money to a stranger. Critically, this account predicts that the degree to which an individual feels disconnected from his or her future self should correlate with the degree to which that individual discounts future rewards (i.e. the “future self-continuity hypothesis.”)

Neuroimaging methods allow for a novel way of testing this hypothesis. Previous neuroimaging research suggests that people show decreased activation in cortical midline structures when considering information about others versus the self (Kelley et al. 2002), and increased activation when engaging in self-reflection or introspection (Raichle et al. 2001). If people effectively consider their future selves as others, judgments about the future versus current self should elicit reduced activation in cortical midline structures. Further, individuals with greater decreases in activation for the future vs. current self should more steeply discount future rewards.

The goal of this experiment was to determine whether neural indices of future self-continuity could predict temporal discounting. To test these hypotheses, subjects were scanned with event-related fMRI while making judgments about the extent to which trait adjectives applied to their current self, a future self, a current other, or a future other. A week later, subjects completed a temporal discounting task that yielded an estimate of the degree to which each individual discounted future rewards. Analyses focused on changes in activation in the MPFC and rACC during current vs. future self-ratings. First, we predicted that rating the self versus another person would increase activation in the MPFC and rACC (Kelley et al. 2002), consistent with previous findings. Second, we predicted that rating the current versus future self would increase MPFC and rACC activation. Finally, based on the future self-continuity hypothesis, we predicted that individual differences in current versus future self rating elicited MPFC and rACC activation would predict individual differences in temporal discounting, tested behaviorally at least a week later. This represents the first attempt to link a neural index of future self-continuity to temporal discounting.

Results indicated that there was a neural difference between thoughts about the current self versus thoughts about the future self: there was greater activation in a portion of the anterior cingulate cortex for current self compared to future self judgments. Importantly, lending support to the future self-continuity hypothesis, individual differences in the magnitude of this effect predicted the tendency to devalue future rewards. That is, the greater the difference in neural activation between current self and future self judgments, the more a given individual discounted future rewards. If individual differences in savings partially depend upon future self-continuity, then savings behavior might be modified either by altering perceptions of the future self or by projecting the current self into the future. The findings thus may hold implications both for understanding and encouraging saving for the future self.

“Goals or Means: How Psychological Distance Influences Depletion Effects”

Kellogg Nidhi Agrawal, University of Hong Kong, China

Echo Wen Wan, University of Hong Kong, China

Consumers often need to exert self-control in multiple activities in succession. Previous research has suggested that self-control relies on self-control resources (Muraven and Baumeister 2000). Performing consecutive self-control is particularly vulnerable to suffer the depletion effect: individuals reduce control on a self-control task after having exerted great self-control on a preceding task (Baumeister et al. 1998). This research examines how temporal perspective affects consecutive self-control (depletion effects) by systematically highlighting either goals or resources.

In the current research we employed the goal-means approach to examine how construal influences depletion effects. Construal level theory (Trope and Liberman 2003) posits that the same event or object can be represented at multiple levels. Higher-level construals (e.g. associated with long-term outcomes) highlight central goals associated with an event, while lower-level construals (e.g. associated with near-term outcomes) highlight means and resources (Liberman and Trope 1998). At higher-level construals, individuals focus on self-relevant goals. Thus, they should show more self-control on the second task when they view this task as important (vs. unimportant) to their goals, regardless of their depletion state. In contrast, at lower-level construals, individuals will focus on resources accessible to the self (e.g., their fatigue) rather than on goals. Thus they will perform poorer on the second task when they are in a depletion (vs. non-depletion) state.

Three experiments examine our proposition in a consumer health context. In all experiments participants performed two consecutive self-control tasks. The first task manipulated initial depletion by having participants process messages about Hepatitis that communicated a high or low self-risk perception. Prior research has suggested that processing high-risk health messages presents a trade-off between long-term benefits and short-term interests (e.g., Agrawal, Menon, and Aaker 2007; Menon et al. 2007) and thus requires self-control. The second task involved processing health messages about a different disease that also require self-control. Construal levels were manipulated between the two tasks.

In Experiment 1 participants first read a Hepatitis message and then worked on a mindset task that manipulated construal levels by thinking about near future versus distant future in a writing task (Fujita et al. 2006; Liberman and Trope 1998). Then participants read an article about dental health describing symptoms, prevention, and treatment of dental diseases. Time spent reading this article served as the measure of self-control. The results show that for participants primed with lower-level construals, those who read a high-risk message spent less time reading about dental health than those who

read a low-risk message. For participants primed with higher construal levels, because dental health is highly relevant to their health goal, participants spent substantial time on reading the dental health article whether they processed a high or low-risk Hepatitis message. The same results pattern emerged on an additional behavior measure of self-control-flossing.

Experiment 2 followed a similar procedure as used in Experiment 1, using a different type of disease in the second task. The importance of this disease to participants' own health goal was manipulated. The results are that participants at lower-level construals exhibited a depletion effect whether the unfamiliar disease was described as important or unimportant. Focus on fatigue mediated this effect. Participants at higher-level construals spent more time reading the disease article when the disease was described as highly relevant to themselves (and thus to their health goal) than when it was described as irrelevant to them, regardless of initial depletion. Participants' perceived higher-level benefit of reading this article mediated this effect.

Experiment 3 employed a similar procedure to that used in Experiment 1, with an additional independent variable: Participants were told that the Hepatitis task was effortful or non-effortful when they finished this task. The results suggest that individuals at higher-versus lower-level construals systematically differ in their reliance on this effort information. While lower level construal use this information to assess their ability, higher level construal interpret the same effort cue in terms of their own goals.

These findings suggest that differences in construal level, due to taking either a short-term or long-term perspective, influence self-control due to inducing assessment of either the self's current resources or the self's longer-term goals.

SPECIAL SESSION SUMMARY

The Influence of Lay Beliefs on Consumers' Food Consumption Decisions

Rajagopal Raghunathan, University of Texas at Austin, USA

SESSION OVERVIEW

The purpose of this proposed special session is to explore the impact that lay beliefs have on consumers' food consumption decisions. The obesity epidemic has emerged as one of the most challenging problems of our time (Flegal et al. 2000; Mokdad et al. 2000; Ogden et al. 2006), and its prevalence and links to numerous health problems (Manson and Bassuk 2003) underscore the importance of understanding why people make poor food choices. The four papers in this session (all of which contain at least two completed studies) propose previously unexplored psychological factors that can explain why consumers choose unhealthy foods.

The first paper (by Raghunathan et al.) explores whether a specific lay belief, namely, that the healthiness of food is negatively correlated with its tastiness (i.e., the "unhealthy=tasty" intuition in Raghunathan et al. 2006), leads those who believe in this intuition to make unhealthy food choices. The second paper (by Bhattacharjee et al.) demonstrates that erroneous consumer beliefs about drugs and supplements underlie a boomerang effect of weight management drug marketing, resulting in unhealthy consumption. The third paper (by Deng et al.) shows that consumers infer the perceived weight of a food product based on the location of the product imagery featured on the packaging, with images located on the top of packaging leading consumers to believe that the product is less filling, encouraging them to eat more. The fourth paper (by McFerran et al.) examines the impact of consumers' views of others on food consumption decisions, exploring the implications that body type of serving personnel may have for restaurateurs and consumers.

The session's focus on the influence of lay beliefs on food consumption decisions will hopefully contribute not only to the literature on obesity and food choices, but will also appeal to a diverse range of conference attendees, including researchers with an interest in decision making, lay beliefs, and self-control. Lastly, the session theme is consistent with ACR's support of transformative consumer research. Identifying the type of psychological causes for unhealthy food consumption discussed in this session (vs. physiological or genetic causes) is crucial, since such causes are more amenable to control through policy interventions (Loewenstein, Brennan, and Volpp 2007; Ratner et al. 2008; Vandevier 2008).

EXTENDED ABSTRACTS

"Evil Intuitions: Why Belief in the "Unhealthy=Tasty" Intuition Leads to Unhealthy Food Choices"

Kelly L. Haws, *Texas A&M University, USA*

Karthik Sridhar, *The State University of New York at Buffalo, USA*

The purpose of this research is to document the role that the "unhealthy=tasty" intuition—which refers to the belief that the healthiness of food is negatively correlated with its tastiness (Raghunathan, Naylor, and Hoyer 2006)—plays in steering people's preferences toward more (vs. less) healthy foods. There are at least three reasons why the intuition steers preferences towards unhealthy (vs. healthy) options. First, assuming that people develop their (lay) theories about the relationship between healthiness and

tastiness by observing the correlation between these two dimensions in the items they typically consume, it follows that, while those with strong belief in the intuition are likely to choose among items that are healthy or tasty, those with weaker belief in it are more likely to choose among items that are healthy and tasty. This leads to a greater proportion of less healthy items in the consideration (and consumption) sets of those with stronger (vs. weaker) belief in the unhealthy=tasty intuition. Second, we propose that consumers with stronger (vs. weaker) belief in the unhealthy=tasty intuition derive greater utility from unhealthy (vs. healthy) food options since: (1) they expect the unhealthy (vs. healthy) items to taste better—in accordance with the hypothesis confirmation bias—and (2) they attach greater relative importance to tastiness (vs. healthiness) in deciding what to consume. Finally, because consumers with stronger (vs. weaker) belief in the intuition encounter more frequent and more emotionally draining tradeoffs between tastiness and healthiness, the self-regulatory resources of those with stronger belief in the intuition are more likely to be depleted when making food consumption decisions (Vohs et al. 2008), resulting in more self-control failures (i.e., consumption of unhealthy food).

We conducted four studies to test these predictions. The first study used a combination of two data sources: (1) scanner panel choice data from a grocery chain and (2) data gathered from a survey that was mailed to a subset of the panelists. Results showed that, as belief in the intuition increased, the proportion of unhealthy (vs. healthy) purchases in two popular categories—ice cream and beer—increased, $\beta_{\text{Ice cream}} = .06$; $t(2, 88) = 2.03$; $p < .04$ and $\beta_{\text{Beer}} = .09$; $t(2, 95) = 2.69$; $p < .001$. Thus, consumers with stronger belief in the unhealthy=tasty intuition exhibited a higher propensity to purchase less (vs. more) healthy food—a finding that is consistent with the idea that those with stronger (vs. weaker) belief in the intuition are less likely to consider (and hence consume) more (vs. less) healthy food. Results from the second study showed that the same snack—M&Ms—are: (1) enjoyed more and (2) consumed in larger quantities by participants with stronger (vs. weaker) belief in the unhealthy=tasty intuition when the snack is perceived to be more (vs. less) unhealthy (through labels identifying the candy as either regular plain M&Ms or new, "low fat" M&Ms). This finding indicates that those with stronger (vs. weaker) belief in the intuition derive greater utility from less (vs. more) healthy options.

Study 3 was designed to assess whether the self-control resources of those with stronger (vs. weaker) belief in the unhealthy=tasty intuition are depleted to a greater extent when contemplating the consumption of healthy food, leading, thereby, to a greater propensity to consume less (vs. more) healthy food on a future consumption occasion. Participants were first asked to imagine consuming a certain set of healthy dinners over the course of the next five evenings. Then, participants indicated the extent to which the consumption of the healthy meals would deplete their self-control resources and how likely they would be to consume, for the next day, each of a set of unhealthy and healthy options (e.g., pizza, broccoli, etc.). Finally, participants indicated the extent of their belief in the unhealthy=tasty intuition. Consistent with our expectations, participants who more strongly believed in the unhealthy=tasty intuition reported a greater preference for the less healthy food, $\beta = .31$, $t(129) = 2.31$, $p < .05$. Further, participants who expressed greater belief in the intuition reported greater depletion of self-control, $\beta = .11$, $t(1, 129) = 2.46$, $p < .05$. Finally, consistent

with our expectation that depletion of self-control resources enhances preference for unhealthy food, we found that the more depleted one's self-control resources, the higher the preference for less healthy options, $\beta=.73$, $t(1, 129)=3.51$, $p<.01$. When both belief in the unhealthy=tasty intuition and depletion of self-control were jointly used as predictors of preference for the unhealthy food, only the latter was significant, $\beta=.76$, $t(1, 129)=2.68$, $p<.01$, and the effect of belief in the intuition was reduced to non-significance, $t<1$, indicating that the depletion of self-control resources fully mediates the relationship between belief in the intuition and the propensity to consume unhealthy food. Finally, results from Study 4—a real-world survey in which participants reported the extent of their belief in the unhealthy=tasty intuition and also provided their heights and weights—indicated that belief in the intuition was positively related to BMI, $\beta=.33$, $F(1, 382)=3.09$, $p=.08$.

“License to Lapse: The Effects of Weight Management Product Marketing on a Healthy Lifestyle”

Amit Bhattacharjee, University of Pennsylvania, USA

Lisa E. Bolton, Pennsylvania State University, USA

Americus Reed II, University of Pennsylvania, USA

Even as obesity rates have risen dramatically in recent years (Ogden et al. 2006), consumers have been trying increasingly harder to maintain a healthy lifestyle; the coincidence of these trends has been dubbed the “American obesity paradox” (Heini and Weinsier 1997). Given these developments, the demand for safe and effective weight management solutions has intensified, and an assortment of weight management and fat-fighting products has proliferated. Though such weight management solutions appeal to many consumers, recent research suggests that there may be unintended consequences of the marketing of these products that actually undermine consumers' intentions to engage in a healthy lifestyle. Hence, marketing of such products may unwittingly exacerbate risky decision making and reduce, rather than improve, consumer welfare.

Consistent with the notion that consumers adaptively cope with perceived risk in the environment (e.g., Floyd, Prentice-Dunn, and Rogers 2000), recent research suggests that remedy messages undermine risk avoidance and increase risky behavioral intentions, particularly for those consumers most at risk. Specifically, problem status (or the relative attractiveness of the problem domain) moderates the effects of remedy marketing messages (Bolton, Cohen, and Bloom 2006). Recent evidence suggests that two psychological mechanisms drive this boomerang effect. First, drug marketing reduces consumer perceptions of health risk and lessens the perceived importance of complementary health-protective behaviors, so consumers are less motivated to engage in these healthy behaviors. Second, drugs are associated with poor health, reducing consumers' perceptions of their own health and their self-efficacy, and thereby diminishing their perceived ability to engage in complementary behaviors (Bolton, Reed, Volpp, and Armstrong 2008). Lacking both motivation and perceived ability to undertake health-supportive behaviors, consumers are unlikely to do so, leading to less healthy lifestyle intentions and a reduction in consumer welfare. Interestingly, this pattern does not hold for supplements: unlike drugs, supplements are not associated with poor health and are perceived as just one aspect of an overall health-protective regimen.

Building on prior research, we present a series of five studies conducted across samples of university students and field samples of adults from a daycare center and members of a fitness club. To examine the role of weight management product marketing, we focus on consumer beliefs that guide the processing of such mes-

sages and underlie corresponding behavior (c.f. Chandon and Wansink 2007; Raghunathan, Naylor, and Hoyer 2006). Results can be summarized as follows: (1) Actual consumption of high-fat foods increases with a single exposure to weight management drug versus supplement marketing messages, particularly for those participants who are hungriest, and thus most attracted to the problem domain; (2) Healthy behavioral intentions decrease when participants imagine taking a weight management drug versus supplement, particularly for those participants who suffer from body image issues and have a problematic relationship with this domain of unhealthy behaviors; (3) As theorized, the boomerang effect of weight management drug marketing on healthy behavioral intentions is mediated by decreased motivation and a perceived decrease in ability to engage in health protective behaviors; (4) Evidence from two field samples of real consumers with a range of knowledge levels suggests that erroneous consumer beliefs about drugs and supplements underlie the boomerang effect of weight management drug marketing. While the boomerang is partially mitigated by more accurate knowledge, only the highest levels of knowledge (reflecting specialized medical training or expertise) are sufficient to eliminate it completely.

Our findings make several notable contributions. To our knowledge, the present research is the first to demonstrate the boomerang effect of drug marketing on actual behavior and the first to demonstrate a boomerang arising from a single exposure to a drug marketing message. Our research also indicates that the boomerang effect can be influenced by both transient visceral factors (e.g., hunger) and relatively stable individual differences (e.g., body image), suggesting that it is not just certain “types” of consumers that are susceptible. Together, these results provide initial evidence that while drug marketing can influence mindful, intentional consumer behavior, it can also impact consumer behavior in relatively mindless eating contexts, highlighting the power and robustness of the boomerang phenomenon. Moreover, the present research provides evidence for the underlying role of erroneous consumer beliefs, suggesting that lay theories regarding weight management products lead consumers to reduce healthy lifestyle behaviors in response to weight management marketing. Finally, the present research investigates the role of consumer knowledge across a range of consumer samples. Only highly specialized medical training appears to mitigate the erroneous beliefs underlying the boomerang, suggesting that the beliefs held by most consumers are not “normative.” Even otherwise well-educated consumers are susceptible, supporting the robustness of the phenomenon.

“Using the Product Image “Location Effect” to Help Consumers Control Eating Patterns”

Xiaoyan Deng, University of Pennsylvania, USA

Barbara E. Kahn, University of Miami, USA

Sara Michalski, University of Miami, USA

Recently, consumer researchers have shown that marketing attempts designed to help consumers control their eating habits can cause boomerang effects. For example Mandel et. al (2008) showed that consumers who were self-identified as “restrained eaters” tended to eat more from smaller, portion controlled packages than from larger packages because consumers experienced a lapse in judgment due to the conflict inherent in experiencing high caloric food packaged as diet food. Pieters et.al (2008) found similar behavior, although they hypothesized that the problem was due to a lack of self-regulation on the part of the consumers because of the perceived regulation the packaging provided. This latter explanation mirrors the “Subway effect” identified by Chandon and Wansink

(2007) where it was shown that people tended to eat more side dishes and desserts when the restaurant claims to be healthy as opposed to when it does not.

Consistent with these previous findings, we hypothesize that consumers who eat by cognitive "rules," as opposed to consumers who eat as a function of hunger desires, are more likely to overeat when they believe that their responsibility for watching calories has been deliberately taken care of by the marketer, for example through portion controlled sizes, "100 calorie bags," or healthy eating claims. However, if the marketer can cue the desirability of smaller portions through a perceptual, automatic route rather than through a deliberate claim, the marketer may be more successful at controlling overeating.

Deng and Kahn (2009) showed that when product images are placed at the top of a package, the product seems lighter than when product images are placed at the bottom of a package. In this research, we extend this result to show that the perceived weight of the product as a function of image location on the package can extend to consumers' perceptions of how filling and satisfying in terms of taste that the food product will seem. Further we show that this perceptual conclusion is an intuitive process, as opposed to a rule-based analytic process. Thus, we hypothesize that although deliberate, highly cognitive marketing tactics to help consumers control eating may backfire, that boomerang effect will be mitigated if the product imagery can be used to automatically cue that the product is more filling and more tasty, and hence eating less will be satisfactory.

We have conducted several experiments to test this theory. In one computer-based experiment, we show participants large bags of cookies or smaller, portion controlled size bags of cookies labeled "100 calorie" portions. We also vary whether the image of the product is at the top of the package (the light location) or at the bottom of the package (the heavy location), and we tell the participants to indicate how filling the cookies look and how many they want to eat. We also measure whether the participants use cognitive rules to control eating or not. We find that all of the consumers think that cookies in "100 calorie" packs will be less filling than those in unmarked packs ($p < .001$), supporting past results. However, for restricted eaters this effect of "100 calorie" packaging making cookies appear less filling goes away when the product image is in the heavy location, whereas non-restricted eaters continue to see the "100 calorie" packages as less filling when the product image is in the heavy location or light location (interaction $p < .05$). When asked how many cookies they would like to eat, none of the packaging effects affected the quantity of cookies chosen for unrestricted eaters, but the restricted eaters indicated wanting a cookie and a half more when the product image was in the light location as opposed to the heavy location ($p < .05$).

In another experiment we asked participants to look at cookie packages and to taste the cookies from that package where we had manipulated whether the cookie image was on the top or bottom of the package. We further manipulated load to test whether the product image effect was automatic or cognitive. The interaction between cognitive resource and product image location was significant ($p < .05$). When participants did not have the cognitive resources to process the cue, the location effect occurred. Cookies from the package using the heavy location tasted more satisfying than did cookies from the package using the light location. However, when participants had sufficient cognitive resources, this effect disappeared. These results show that when participants are processing the packaging automatically they are likely to eat less when the product is in the heavy location than when in the light location. We are in the process of running several other experiments to further test and replicate these findings.

"Might a Heavier Waitress Make You Eat More, Less, or Differently?"

Brent McFerran, University of British Columbia, Canada

Darren W. Dahl, University of British Columbia, Canada

Gavan J. Fitzsimons, Duke University, USA

Andrea C. Morales, Arizona State University, USA

Consumers make over 200 food choices per day (Wansink 2006), and thus it is important to understand the antecedents to unhealthy food choices. However, little research in marketing has examined context effects influencing how consumers make the food choices they do. For instance, what if a heavy waitress recommended an indulgent choice or something very healthy? Would her weight influence your choice? Might her weight cause you to eat more food or less than if she was thin? Past research has shown that consumption decisions are influenced by those who are physically present. In a food context, studies have found that social influence can have either a facilitating or attenuating effect on consumption, depending on the context (see Herman, Roth, and Polivy 2003 for an excellent review). They argue that food choice is influenced by a desire to convey a certain impression or adhere to social norms (Leary and Kowalski 1990; Roth et al. 2001). Although, Herman et al. (2003) argue that making a good impression usually means eating less, other research has found that people may eat more, rather than less in the presence of another person (e.g. Conger, Conger, Costanzo, Wright and Matter 1990). Another line of research has examined the impact of obesity on consumption. Priming people with overweight images has been shown to lead to an increase in quantity consumed (Campbell and Mohr 2008).

The above lines of research have focused either on how much others eat or on the social influence of obesity, but little research has examined the influence of the two jointly. In social influence work more generally, the effects of the social "other" have been shown to be moderated by whether the person is a member of an aspirational or dissociative group (Escalas and Bettman 2005; White and Dahl 2005, 2008). Since thin models are seen as an ideal standard in North American society (Durkin and Paxton 2002) and obesity is a stigma that most wish to avoid (Johnson 2002), the body type of others should interact with their food choice (indulgent vs. moderate) in forming evaluations of them. Specifically, Campbell and Mohr (2008) found that overweight (vs. thinner) images led consumers to believe they would eat less food, and thus it would be reasonable to predict that a thinner server would lead to greater consumption and be a more persuasive recommender of a food choice. However, we also argue that there may be another factor at play in determining how social others impact food consumption. Research has shown that dieters often do not make the same food choices as non-dieters (Federoff, Herman, and Polivy 1997; Polivy and Herman 2002). Specifically, studies have shown that dieters sometimes exhibit a backfire effect, eating more when small food is placed in small packages (Scott, Nowlis, Mandel, and Morales 2008) or eating more (rather than less) following a "preload" of calories (e.g. Knight and Boland 1989; Polivy 1976). We propose, based on recent research on reference groups (Berger and Heath 2007; 2008; Berger and Rand 2008; White and Dahl, 2008) and dieting (Scott, Nowlis, Mandel, and Morales 2008), that consumers should react differently in a food choice context to obese versus thin servers.

Using a professionally-constructed obesity prosthesis, an identical confederate portrayed both a thin and a heavy experimenter in identical clothes. Study 1 was a one factor design (obese vs. thin experimenter) plus a measured variable capturing participants' dieting orientation and was conducted as a taste test. The experimenter (wearing the prosthesis or not) told participants they must choose only one of two sweet snacks (bite size cookies or glazed

rice cakes) to evaluate, but that they could eat as much of their choice as they wished. She then recommended the chocolate cookies to participants. Results showed that while participants' snack choice did not vary as a function of the confederate's body type, their consumption quantity did. An interaction effect (treating dieting orientation as a continuous variable) showed dieters ate more snacks when the recommender was heavy, but non-dieters ate more when she was thin.

Study 2 used a sample consisting only of dieters, and the procedures were the same as Study 1, but we directly manipulated the snack the experimenter recommended by including a healthy choice in a 2 (obese vs. thin experimenter) x 2 (recommends cookies or carrot sticks) between subjects design. Results of a logistic regression showed a significant interaction effect: when cookies were recommended, dieters chose cookies more often when the experimenter was heavy (vs. thin), but when carrots were recommended, they selected cookies with a greater frequency when she was thin (vs. heavy). Dieters followed the recommendation of the heavy server more, choosing both the healthy and the unhealthy snack more often when it was recommended to them by a heavy (vs. a thin) experimenter. These two studies point to the implications that body type of serving personnel may have for restaurateurs and consumers.

SPECIAL SESSION SUMMARY
Consuming in Self-Defense: Consumer Responses to Self Threat
Eugenia Wu, Duke University, USA

SESSION OVERVIEW

“Self-defence is nature’s eldest law.”
—John Dryden, poet and playwright

As living beings, we have a fundamental need to protect ourselves when we come under threat. Thus, we bristle with indignation when someone insults us, we come out with fists flying when someone physically attacks us and we invest in insurance policies to guard against unpredictable events that may threaten our wellbeing. This need for self-protection underlies each human existence and influences every aspect of human behavior, including consumption behaviors. The three papers in this session all focus on how the need to defend against threats to the self influence the way consumers think, feel and make decisions. More specifically, each of the three papers examines how a threat to the self may cause consumers to engage in very different consumption behavior than they might otherwise have. Broadly construed, this symposium aims to examine how consumer behavior is affected when consumers are focusing on self-protective needs.

The self is a multi-faceted entity where each facet may become threatened and in need of protection at one point or another. The papers in this session examine threat to two particular aspects of self: threat to the self’s sense of its place in the world and threat to the self’s very existence. To offer a fuller understanding of how self threats may impact consumption behavior, each paper examines a distinct type of behavior that is affected by self threat and provides a unique perspective. First, Cutright, Wu, Kay and Fitzsimons (2009) examine the extent to which product choices and ad attitudes change when consumers’ sense of the self as part of a legitimate and just external system (e.g., government organizations, etc.) is threatened. Second, Schmid and Argo (2009) explore how self threat in the form of mortality salience causes individuals to adopt previously extraneous possessions to form a new self identity. Finally, Fernandes, Mandel and Smeesters (2009) focus on how existential self threat can lead individuals to engage in increased variety seeking behavior as a way to experience unrestrained freedom. Together, these papers suggest that when a given aspect of the self is threatened, consumers will alter their consumption patterns in order to cope with and defend against that threat. Importantly, each of these papers also suggests important boundary conditions for the role of threat on consumption, particularly with respect to individual differences.

Though consumer behavior clearly takes place within the context of self-threat, consumer research has generally treated such threats as unacknowledged background factors rather than as interesting topics in their own right. In the increasingly competitive and rapidly changing environment that we live in today however, aspects of the self may be frequently threatened, leading to significant changes in the way individuals feel, think and behave. This symposium aims to contribute to consumer research by bridging the gap between research on consumer behavior and on protecting against self-threats.

We hope that this symposium will attract a wide ACR audience, from researchers interested in self-threat specifically to the broad range of researchers who examine the role of situational influence in consumer psychology. This symposium is also relevant

for marketers interested in identity and emotional coping. Of note, these papers are all in advanced stages of completion.

EXTENDED ABSTRACTS

“When Your World Must Be Defended: Consuming to Justify the System”

Keisha Cutright, Duke University, USA

Eugenia Wu, Duke University, USA

Aaron Kay, University of Waterloo, Canada

Gavan Fitzsimons, Duke University, USA

In this age of unceasing social, political and economic turmoil, individuals are increasingly likely to be faced with threatening information about the legitimacy of their socio-political systems. How do they deal with such information? System justification theory (Jost and Banaji, 1994) suggests that individuals are generally motivated to maintain the view that the external system that they interact with (i.e. overarching institutions, organizations and social norms) is fair, legitimate, and justifiable (Kay & Zanna, in press). This tendency has been shown to have a variety of important consequences including support for inequality (Laurin & Kay 2008) and decreased interest in social change (Kay et al. 2008). The present research is designed to explore how this tendency to defend the status quo against threat might also have important consequences for consumption-related behavior. Additionally, this research aims to further enhance system justification theory by introducing important individual difference moderators.

The system justification motive is assumed to help people avoid the psychological threat of perceiving that the system in which they live is illegitimate, unfair, and undesirable (Jost & Hunyady 2002). Consequently, the system justification motive is especially active in contexts which exacerbate this threat (Kay & Zanna, in press). Such contexts include situations where one feels that the legitimacy of the system is being directly attacked (“system threat”; Jost & Hunyady 2002; Kay, Jost & Young 2005), when one feels a high sense of dependence on the system (“system dependence”; Laurin & Kay 2008) and when one seeks a sense of control in the system to compensate for a lack of personal control (“personal control”; Kay et al. 2008).

We leverage these three contexts across a series of four studies to demonstrate the effects of the system justification motive on consumption-related choices. We predict that the enhanced need for system justification will lead participants to prefer consumption alternatives that represent traditional and well-accepted norms in society over those that do not. Importantly, we also suggest that there are key individual difference factors that will more precisely determine when the system justification motive will have the greatest impact on consumption preferences. We propose that one’s chronic level of confidence in the legitimacy of the system will be especially important. Perhaps counterintuitively, we expect to see the greatest effects of threat on people who have low levels of confidence in the system (“low system endorsers”). We reason that low system endorsers experience a significant gap between their current state and the need for system justification that is aroused as a result of certain threatening contexts. In other words, their fragile sense of confidence in the justness of the system is highly salient and threatening when the system justification motive is activated.

Thus, in line with classic principles of motivation, they are especially motivated to justify the system, and do so through means that provide immediate and concrete symbols of system endorsement such as consumption. By contrast, consumers that are highly confident in the system ("high system endorsers") maintain a strong sense that the system is just, regardless of threat, and therefore have no need to rely on consumption for justification.

In the first study, we examine the impact of system threat and chronic levels of system endorsement (as measured by Kay & Jost's 2003 System Justification Scale) on preferences among pairs of national versus international brands. Participants are asked to read an article which describes a writer's negative opinion of America or a neutral article. We find that low system endorsers prefer fewer international brands when threatened than when not threatened, while high system endorsers do not differ in their choices across conditions.

In study 2, we use a system dependence manipulation and examine its effects on attitudes towards sales people who represent traditional vs. nontraditional values. Participants are asked to read about the U.S. government having a significant impact on their future outcomes in life vs. a neutral paragraph. They are then asked to rate a series of print ads. Half of the ads reflect traditional American values, while the others reflect nontraditional values. We find that low system endorsers rate the nontraditional salespersons as significantly lower in attractiveness and likeability when threatened than when not threatened. As predicted, high system endorsers do not differ in their ratings across conditions.

In study 3, we again use a system dependence manipulation. Participants are then asked to rate a series of ads which we predicted would be more threatening and salient to men than women. Thus, we expected to see a pattern similar to studies 1 and 2, but only among men. Indeed, among men, we find that low system endorsers rate nontraditional ads lower in the high system dependence condition than the control. High system endorsers show no differences across conditions.

In study 4, we activate the system justification motive by manipulating participants' sense of personal control, thereby generalizing our findings beyond contexts that involve direct threats to one's system. Participants are asked to write about something positive that happened to them that was out of their control (threatening condition) versus something positive that happened which was in their control (neutral condition). After the writing exercise, participants are asked to review a list of movies and choose 10 that they would like to watch. Our results indicate that low system endorsers choose fewer movies with a negative tone towards the United States when their sense of personal control is threatened versus the control condition.

In sum, we find that when the threatening consequences of living in an unjust system are made salient, individuals who are generally the least confident in the legitimacy of the system are the most likely to justify it through consumption (by embracing traditional versus nontraditional consumption options). Conversely, individuals who are highly confident in the system are able to withstand threats and do not turn to consumption to justify the system.

- Consumers are ever increasingly exposed to news coverage about topics of crime, murder, and terrorism. During the period from 1990-1998 alone, while the total number of murders in the US decreased by 20 percent, media coverage on network newscasts about stories on the topic increased by an astonishing 600 percent (Glassner 2004). To date, the limited research that has studied the impact of fear has investigated the impact of reminders of mortality on consumers' acquisition decisions (Ferraro, Shiv, and Bettman 2005, Mandel and Heine 1999, Mandel and Smeesters 2008). However, this is only one side of the consumption equation as according to Holbrook (1987) consumption entails more than just acquisition but also disposition. Given this in the present research, we seek to build on this initial work by investigating the influence of mortality salience on product disposition and do so using a new conceptual framework guided by research on the self and in particular self-affirmation theory (Aronson et al. 1999; Sherman and Cohen 2002, 2006; Steele 1988).
- The basic premise of self-affirmation theory is that individuals are motivated to protect the perceived integrity and worth of the self (Steele 1988). One way people may cope with a threat to the self is to implement indirect psychological adaptations by affirming other elements of the self not threatened. In the present research we propose a novel mechanism through which one can self-affirm when faced with a threat: morphing the self through the possession with which one identifies. Given that possessions can serve as an extension of the self (Belk, 1988) it seems reasonable to conclude that consumers may use possessions within their extended self to protect the self through self-affirmation in the face of a threat. More specifically, similar to the notion that the acquisition of new products can signify a change in consumers' extended self-concept when the self is threatened, we argue that the disposal of older possessions can complete this transition into a new self (i.e., morph) as such possessions are constant reminders of the old identity and until they are let go one cannot move on. Support for the expectation that once important possessions will decrease in importance when

faced with a mortality reminder is found in qualitative consumer research (e.g., Pavia and Mason 2004).

Our unification of previous work that has been conducted on acquisition in the time of threat with insights into disposal behaviors presents a more complete picture of consumers' relationships with products. In addition, we qualify our findings by reporting materialism as a boundary condition. Indeed, the findings are especially likely to occur for those consumers who are highly invested with material objects but are attenuated for those lower in materialism. Three studies are reported that support the notion of a morphing self.

The first study examined the likelihood of consumers distancing themselves from possessions after they encounter a threat. We used a 2 (mortality salience threat: present vs. absent) x 2 (possession importance: important vs. unimportant) x (materialism) mixed design. We find that when mortality is salient, as consumers' material values increase, they tend to be more likely to distance themselves from possessions as compared to consumers in the control condition who are less likely to distance themselves from material objects as material values increase. This is especially the case for possessions with lower importance to consumers' self.

The second study had two primary objectives. First, the study sought to determine whether the type of threat to the self is critical to consumers' disposition tendencies of possessions once included as a part of the extended self. Second, the study explored if a threat is powerful enough for consumers to actually separate the self completely from a once previously important possession when mortality is made salient. To achieve this second objective, participants completed a baseline assessment of their identity as defined by the possession they associated with in the absence of a threat and a second assessment of their identity after facing a threat, one week apart. We used a 2 (type of threat: mortality salience threat vs. social threat) x (possession importance) x (materialism) mixed design to examine whether the type of threat affects which possessions consumers include into their selves. We find in the mortality salience condition that the more materialistic consumers are the less likely they are to identify important possessions as part of their selves during both time periods. We find the opposite pattern in the social threat condition as participants who were more materialistic were increasingly more likely to identify important possessions at both points in time.

In study 3 we explored what happens within consumers' selves for those possessions that are retained after consumers encounter a mortality salience threat (vs. no threat). If our main premises are correct, mortality salience should disrupt the self and as a result possessions that were formerly an important aspect of the self should become less important. At the same time, possessions that were an extraneous part of the immediate self should gain in importance. We used a 2 (mortality salience threat: present vs. absent) x (possession importance) x (materialism) mixed experimental design. Results reveal that in the presence of a high mortality salience threat participants distanced themselves from possessions that in the control condition they had considered closely related to their selves while possession deemed unrelated to the immediate self in the control condition became more strongly associated with the self in the face of a threat. This effect was qualified by material values. Participants who had high material values used possessions to a significantly greater extent to redefine their self-concept when MS was present (versus absent).

In three studies, we demonstrate that mortality salience threats have important effects on consumers' selves. When a mortality salience threat is present, self-concept consistency is disrupted and a change in consumers' extended self-concept as defined by the

possessions that are part of their identity can be observed. The notion that reminders of mortality can disrupt the stability of the self-concept has important implications for consumers' well-being.

"The Spice of Life: Effects of Mortality Anxiety on Preference for Variety"

Daniel Fernandes, Erasmus University, The Netherlands

Naomi Mandel, Arizona State University

Dirk Smeesters, Erasmus University, The Netherlands

Terror management theory (Greenberg, Solomon, and Pyszczynski 1986) posits that people's survival instincts, coupled with their knowledge of inevitable death, can trigger high levels of internal conflict and anxiety. When reminded of their mortality, people can mitigate this conflict by defending their cultural worldviews, bolstering their self-esteem, or both. Recently, several studies have shown the effects of mortality salience (MS) on consumer behavior. Priming death thoughts can lead consumers to choose products that bolster their self-esteem (Ferraro, Shiv, and Bettman 2005), overconsume to escape self-awareness (Mandel and Smeesters 2008), or prefer domestic over foreign products (Liu and Smeesters in press).

Although research has shown how MS affects product preference and the quantities one wants to purchase, it is unclear how MS affects the variety in one's choices (i.e., the number of switches between products or brands over a series of choices; Kahn and Isen 1993). Prior research suggests that MS might lead to either more

variety-seeking or less variety-seeking. For example, variety seeking increases with mild positive mood, because novelty gained from experiencing nonthreatening stimuli provides pleasant stimulation and because positive mood heightens a person's desire for such stimulation (Menon and Kahn 1995). This suggests that threatening stimuli, such as death thoughts, might decrease variety seeking. Furthermore, research by Rindfleisch, Burroughs, and Wong (in press) has shown that individuals form stronger connections with brands when death anxiety is high, because they perceive their brands as an important source of meaning in their lives. Again, this finding suggests that consumers might search for less variety when they are reminded of the inevitability of their death, due to stronger loyalty to their favorite brands.

On the other hand, there is reason to believe that MS may lead to increased variety-seeking behavior. Koole, Greenberg, and Pyszczynski (2006) argued that unrestrained freedom might be a way to buffer against death-thoughts. When mortality is salient, individuals might want to experience the feeling of freedom by seeking for excitement and novelty. Hence, consumers might be more willing to try other alternatives to experience unrestrained freedom when death-thoughts are accessible. Individuals in a liberal mindset should be particularly more open to new experiences than conservatives (Jost et al. 2003). Moreover, prior research on left-right wing differences related conservatism to mental rigidity, stimulus aversion, and close-mindedness (Wilson, 1973). Therefore, we hypothesize that the increasing effect of MS on variety-seeking should only occur for individuals with a liberal mindset, but not for those with a conservative mindset.

We conducted three experiments to examine the effects of MS on variety seeking behavior. In study 1, we examined the effect of MS on exploratory behavior. First, participants completed either the Fear of Death scale (Boyar 1964) in the mortality salient condition or the Depression scale (Zung 1965) in the control condition. Next, all participants completed Raju's (1980) Exploratory Behavior Scale ($\alpha=.77$; 7-point scale). Participants primed to think about their own eventual deaths exhibited a higher level of exploratory behavior ($M=4.33$) than did control participants ($M=4.07$; $F(1, 301)=5.92, p<.01$). This finding provides preliminary evidence that MS increases variety seeking.

Study 2 extended study 1 by testing the effect of mortality salience on actual behavior, rather than on responses on a scale. Participants were randomly assigned to either the MS or control condition. Next, participants chose ten jellybeans to eat while completing a presumably unrelated questionnaire. The number of flavors they chose served as the dependent measure of variety seeking. Mortality salient participants chose significantly more flavors than did control participants ($M_{MS}=7.49$ vs. $M_{control}=6.81$ out of 10 possible flavors; $F(1, 227)=4.11, p<.05$).

Study 3 extended the earlier studies by testing the effect of MS on the choices made in a sequential variety-seeking paradigm (whereas study 2 used a simultaneous variety-seeking paradigm). In addition, we also primed a liberal versus conservative mindset in participants, by using a scrambled sentences test. Hence, we used a 2 (mortality salience vs. control) \times 2 (liberal vs. conservative) between-participants design. After the manipulations, participants were asked to imagine that they were doing their weekly grocery shopping at the nearby grocery store (cf. Menon and Kahn 1995, experiment 2). On each of four sequential shopping occasions, participants chose the brand of snack (among four brands) that they wanted to purchase. Variety seeking was coded in three ways (Mitchell, Kahn, and Knasko 1995): (1) the number of different choices participants made, ranging from 1 (same choice made across all weeks) to 5 (each week a different choice), (2) the number of switches in the choice history, ranging from zero (no switches

to six (no repetition), and (3) the number of switches between successive choices. The interaction effect of MS and primed mindset on the number of different choices made was significant ($F(1, 64)=5.84, p=.01$). Planned contrasts showed that MS led to more variety seeking behavior among those primed with a liberal mindset ($M_{MS}=2.76$ vs. $M_{control}=1.58$; $F(1, 64)=2.51, p=.01$) and not among those primed with a conservative mindset ($M_{MS}=2.52$ vs. $M_{control}=2.15$; $F(1, 64)=0.85, p=.40$). Similar effects were found for the two other measures of variety seeking.

Overall, in three studies, we show that mortality salience leads to enhanced variety seeking. Further, we demonstrated that the effect mainly occurs among those having a liberal mindset, but not among those with a conservative mindset. Future studies will explore the underlying process by which MS increases variety seeking behavior. Specifically, we will examine whether individuals (and especially those with a liberal mindset) have a higher need to experience freedom following a MS manipulation, and whether this mediates the MS effect on variety seeking. Furthermore, we will also examine whether MS leads consumers to make more unique choices, which is also a way to self-express and assert freedom (Kim and Drolet 2003).

SPECIAL SESSION SUMMARY

In Pursuit of the Prime Suspects: Insights from Second Generation Research on Nonconscious Influences of Consumer Behavior

Robin J. Tanner, UW Madison, USA

SESSION OVERVIEW

The last two decades of research in social cognition have produced many findings indicating that much of human behavior is driven by factors and processes that operate outside of immediate conscious awareness. For consumer behavior researchers in particular, demonstrations that environmental cues can nonconsciously influence consumer behavior (Chartrand et al. 2008) are both challenging and exciting. Challenging because a world where consumers are exposed to an ever increasing onslaught of marketing cues and primes raises the stakes for researchers trying to understand the processes by which such cues may combine and interact to influence choice and consumption. Exciting because the very idea of a parallel nonconscious goal system opens the door to new directions for research. Previously unexplained behaviors may now find resolution in the context of richer theories of consumer behavior, which recognize and integrate both conscious and nonconscious elements. In this session three papers present insights from second generation research into nonconscious influences of consumer behavior with a particular focus on improving our understanding of the mechanisms by which environmental cues can influence consumers. The papers in the session demonstrate several unexpected ways in which specific marketing-relevant primes influence behavior and explore a method for measuring/diagnosing the relevant goal activations that these primes invoke.

All three papers in this session share a common focus on deepening our theoretical understanding of how marketing-relevant primes can influence downstream consumer behaviors. The first paper, by Laran, Dalton and Andrade, demonstrates unexpected differences between the priming efficacy of sentences, brands, and slogans. In particular, the authors find that slogans, by virtue of their overt persuasive intent, invoke a form of nonconscious reactance that can actually prime behaviors opposite to those intended by the slogan writers. Fascinatingly, this negative priming effect transfers to sentences presented simultaneously with subliminal exposure of the word "slogan". This result not only reinforces the nonconscious nature of the core effect, but also constitutes initial evidence of the capability of subliminal cues to hijack and modify the meaning of consciously perceived stimuli.

The second paper, by Goldsmith and Dhar, demonstrates an entirely different mechanism by which environmental cues can ironically influence consumer behavior. The authors show that when choosing between two goal congruent options, incidental activation of a conflicting goal actually increases choice of the option which most conflicts with the new goal. Thus Goldsmith and Dhar identify circumstances where goal activation can actually invoke behavior that is entirely inconsistent with the goal, a result which they demonstrate is driven by consumers' desire to justify their choices.

One implication of these first two papers is to provide a salient reminder of the variety of (often unexpected) ways in which peripheral cues can conspire to automatically influence consumer behavior. This presents considerable challenges both to researchers concerned with identifying possible priming effects in their stimuli and for practitioners desirous of fully understanding the totality of possible effects caused by their marketing efforts. The final paper, by Carlson et al., speaks directly to this issue by presenting evidence

that goals automatically invoked by peripheral cues, and which operate outside of conscious awareness, can actually be measured. By interrupting choice tasks before they are complete (where goal activation levels should be maximal), and using sensitive measures, these authors demonstrate the important finding that it is actually possible to measure the activation of goals invoked by supraliminal primes, subliminal primes, or the choice context itself. The methodological ability to measure online goal activation opens the possibility of testing a range of theories that hypothesize the role of specific goals, like Goldsmith and Dhar's goal of justifying choices.

These three papers all feature research that makes substantial theoretical contributions to contemporary research in psychology while also being grounded in consumption phenomenon that are relevant to many consumer researchers. Taken together, these three papers substantively deepen our understanding of the psychological processes underlying automatic effects on behavior caused by peripheral environmental cues.

EXTENDED ABSTRACTS

"The Curious Case of Behavioral Backlash: Nonconscious Reactance to Marketing Slogans"

Juliano Laran, University of Miami

Amy Dalton, Hong Kong University of Science and Technology

Eduardo B. Andrade, University of California, Berkeley

Marketing practitioners rely on an impressive arsenal of persuasion tools, including brands, salespeople, prices, and slogans, in their attempt to influence consumer spending. A solid foundation of research in psychology and marketing would suggest that these tools can "persuade" consumers under the radar of consciousness. This research would further suggest a process whereby marketing tools have a positive impact on consumers' responses, with incidental exposure to, say, a brand or slogan triggering behaviors that are consistent with that brand or slogan. However, while this priming process may occur in most environments, it may not generalize to marketing environments. Marketing environments have idiosyncrasies that could dampen or even reverse the intended effects of marketers' tools.

One idiosyncrasy of marketing stimuli is that, unlike other environmental stimuli, people believe marketing stimuli exist to persuade them. That being said, this belief exists to varying degrees as a function of the marketing stimuli themselves. For instance, while people may relate to brands as innocuous relationship partners, the persuasive intent of slogans is much clearer. To address this issue empirically, we conducted a pretest examining consumers' perceptions about the persuasive intent of two common persuasion tools: marketing slogans and brands. For this pretest, 50 participants were shown a series of five slogans, brands, or sentences, and asked to rate on a 7-point scale the extent to which they perceived each stimulus as an attempt to persuade them. The purpose of asking about the persuasive intent of sentences was simply to establish a baseline. Results showed that participants perceived the persuasive intent of brands ($M=3.20$) to be only trivially higher than that of sentences ($M=3.00$), while the persuasive intent of slogans was perceived to be quite high ($M=5.13$), and significantly higher than that of brands ($F(2, 44)=3.47, p<.05$).

Thus, while brands were perceived to be innocuous (no different than common sentences in their persuasive intent), slogans were perceived more clearly as persuasive appeals.

The perception that marketing tools are persuasive appeals sets these stimuli apart from other environmental stimuli. However, it is unclear how consumers respond to persuasive tools on a nonconscious level. One might argue that because the impact of priming on behavior is nonconscious (or, at least, people are not sufficiently aware to verbalize it), any defense mechanism against persuasion tools should not work. On the other hand, perhaps people can react against a persuasion tool without awareness of its presence or potential influence. This response could develop in the same way that other processes become automatic. That is, if people repeatedly and consistently responded to a persuasion tool with conscious reactance, over time they should come to nonconsciously react against it. In the context of the current research, we would therefore predict nonconscious reactance against slogans because consumers consciously perceive that slogans are persuasion tools. We would not, however, predict nonconscious reactance against brands because consumers lack the perception that brands are persuasion tools. These predictions were tested in study 1.

Study 1 used a 3 X 3 design (N=435), with prime tool (brand, slogan, or sentence) and prime message (save, spend, or neutral) manipulated between-subjects. Participants' first task was a bogus memorization task in which we presented sentences, brands, or slogans that were related to either saving money (e.g., "He wore cheap attire", "Dollar Store", "The Best Deals Are Always Here!"), spending money (e.g., "He wore high-end attire", "Tiffany", "Luxury, you deserve it"), or were neutral (e.g., "He wore blue pants", "Barnes and Noble", "Time is what you make of it"). In a supposedly unrelated second experiment on shopping tendencies, we asked participants to imagine that they went shopping with \$500, and indicate how much of the \$500 they would like to spend. Their response was our dependent variable.

We included the sentences as a control condition and predicted that participants who were exposed to sentences would show prime-consistent behavior. This is precisely what we found. Relative to neutral sentences (M=\$145.93), sentences with a message to save decreased spending (M=\$105.91) and sentences with a message to spend increased spending (M=\$185.18). As predicted, the same pattern of results was obtained among participants primed with brands. Willingness to spend in the neutral brands condition (M=\$150.70) fell in between the savings brands condition (M=\$94.29) and the spending brands condition (M=\$189.27). Importantly, however, this pattern of results failed to hold among participants primed with slogans, who actually showed the exact opposite pattern of spending. Relative to slogans with a neutral message (M=\$142.93), slogans with messages to save increased spending (M=\$184.58) and slogans with messages to spend decreased spending (M=\$105.23), all $p's < .05$. Thus, while priming with brands (and sentences) produced prime-consistent behavior, priming with slogans produced prime-inconsistent behavior—a behavioral backlash.

We propose that consumers need not be consciously aware of a marketing tool's persuasive intent for this behavioral backlash to occur. However, because participants in study 1 were exposed to prime tools supraliminally, conscious responses could have influenced consumer spending. Extensive debriefing suggested this was unlikely; nevertheless, in study 2, we used a more conservative, subliminal priming procedure to minimize conscious mediation, demand effects or hypothesis guessing. In addition, we dropped the brand condition and controlled for the stimuli presented by using the exact same phrases in both the sentence and slogan

conditions. Therefore, the only difference between the conditions was subliminal priming of the word "sentence" or "slogan".

Study 2 used a 2 X 3 design, with prime tool (slogan or sentence) and prime message (save, spend, or neutral) manipulated between-subjects (N=229). Participants were instructed to memorize the same sentences used in study 1's bogus memorization task. However, while the sentences were presented in the center of the screen, the word "sentence" or "slogan" was presented for 60 ms in alternating, randomly-determined quadrants. Participants indicated whether each "flash" appeared on the left or right. Results revealed that among participants subliminally primed with the word "sentence", messages to save reduced spending (M=\$115.94) and messages to spend increased spending (M=\$211.68) relative to neutral messages (M=\$156.82). Conversely, among participants subliminally primed with the word "slogan", messages to save increased spending (M=\$197.22) and messages to spend decreased spending (M=\$106.68) relative to neutral messages (M=\$151.06), all $p's < .05$. Thus, while activating the concept "sentence" produced prime-consistent behavior, "slogan" produced prime-inconsistent behavior.

In summary, certain persuasion tools may backfire and generate effects opposite to those intended by marketers. Our results provide an initial demonstration of this phenomenon by showing that stimuli structured as slogans (study 1) or represented as slogans (study 2) can incite a nonconscious behavioral backlash. Our findings suggest that this behavioral backlash is rooted in consumers' conscious beliefs about the persuasive intent of marketing tools. These results underscore the necessity of understanding marketing's idiosyncrasies before we can fully understand priming effects in marketing environments.

"Ironic Effects of Goal Activation on Choice"

Kelly Goldsmith, Northwestern University

Ravi Dhar, Yale University

Consider a consumer who is choosing between two indulgent desserts. Further imagine that prior to choosing a dessert she notices a health magazine on a nearby table. How would exposure to the health magazine affect her choice? While it is now well established that consumer choice is goal driven, relatively little is known about how the incidental activation of a goal that conflicts with the goal associated with a choice task (hereafter referred to as the "choice goal") will affect the choices that people make. For example, would this person be more or less likely to choose a more indulgent and less healthy dessert in comparison to a person for whom the health goal was not activated?

This paper explores how choice between two options is impacted when these alternatives pose a violation to another goal that has been activated prior to the choice. We draw from research on goal systems theory and behavioral decision theory to propose that when an incidental goal (e.g., health) that conflicts with the choice goal (e.g., to enjoy an indulgent treat) becomes activated prior to the choice, all available choice options will present a violation of the incidental goal. Thus when making their choice, consumers will experience the need to justify their incidental goal violation. As a consequence, consumers will be more likely to choose the option in the set that offers maximum attainment of the choice goal (e.g., a more indulgent special treat) than when the conflicting goal is not activated. Options providing maximum goal attainment may be easier to justify, when they offer the consumer a special or unique experience. Thus we predict an ironic effect of goal activation on choice: Goal activation can increase choice of the option that conflicts most with that goal.

Our predictions are tested in a series of six studies. Study 1 demonstrates the proposed effect. Using non-conscious goal priming, we manipulate if a conflicting goal (e.g., savings) is incidentally activated prior to choice (e.g., a choice between two expensive, luxury rental cars). The results demonstrate that the activation of a conflicting goal can ironically increase choice of the option the presents a greater conflict to that goal (e.g., the more expensive, luxury rental car). Study 2 demonstrates an important boundary condition. By manipulating both incidental goal activation (health goal vs. control) and goal conflict (a choice between two high calorie options that conflict with a health goal vs. a choice between two low calorie options that do not conflict), we show that goal activation leads to ironic effects only when none of the options in the choice set allow for pursuit of the incidentally activated goal. Study 3 rules out an alternate account for the pattern of results, replicating the choice effect and demonstrating that the incidental goal prime increases the accessibility of that goal, as intended. Testing for the mechanism behind this effect, Study 4 replicates these ironic effects with real choices (e.g., a choice between two unhealthy donuts for consumption), and assesses how goal conflict affects consumers' interests in special or unique options. The results demonstrate that goal conflict increases interest in special or unique options, and further that this increase in interest in special or unique options mediates the effect of goal conflict on choice. Study 5 further examines the underlying process and rules out a second alternate account for the pattern of results by showing that these results cannot be explained by goal conflict increasing interest in options that offer "maximum violations". Finally, in Study 6, we test if external prompts to justify a choice result in similar effects, by manipulating both goal conflict and an additional need for justification. The results show that goal conflict and the additional need for justification have an analogous effect on choice.

As the need for justification can affect consumer decisions and shift preference towards options that are supported by the best reasons, this research has clear implications for marketers seeking to maximize their understanding of consumer decision processes at the point of choice. For example, in an additional study we manipulated if a savings goal was incidentally activated (vs. a control), then gave participants a choice between two expensive, luxury suitcases that were priced equally (\$695), one of which was labeled "only two left." The results of this study showed that participants experiencing goal conflict (savings goal prime) were significantly more likely to choose whichever option was labeled as "only two left." Building on the current set of studies, these results suggest that goal conflict and the need for justification may increase interest in products supported by many different reasons (e.g., limited availability). We hope that the current research will prompt future inquiry into this area.

"Catching Goals in the Act of Decision Making"

Kurt Carlson, Georgetown University

Robin J. Tanner, University of Wisconsin, Madison

Margaret G. Meloy, Pennsylvania State University

J. Edward Russo, Cornell University

Although consumers may prefer to think that their decisions are guided by conscious thought, accumulating evidence suggests that many choices are influenced by subtle and unrecognized environmental cues. Perhaps nowhere is the relevance for understanding consumer behavior more profound than in the advances that have been made in the area of nonconscious goal pursuit (Chartrand and Bargh 1996). Though the very idea of a parallel nonconscious goal system opens the door to new directions for research, many of these directions are challenged by the complexities of studying goals of which consumers are not aware. This paper

introduces and validates a method for measuring goal activation levels during the consumer choice process. Rather than using free-form responses, or all-or-none measures of goal activation, we use a goal log that requires participants to assess the activation of a set of goals on an 11-point scale. Assessment happens midway through the decision to align assessment with the period of maximal goal activation. The method is tested across three studies.

In study 1, two goal primes, Memorize or Form an Impression, and the priming task (sentence completion) were borrowed from Chartrand and Bargh (1996). After the priming task, participants (N=51) made a choice between two scholarship applicants. Midway through the choice process, participants were interrupted and reported how active nine different goals were at that moment. Goal activation levels were recorded on an 11-point scale (0 =not at all active; 10=maximally active). Participants then resumed reading the remaining information about the candidates, and selected the one they preferred. After their choice they reported whether the focal goals had been active (yes/no) during the choice process. If participants were aware of their goal activation levels, the difference in goal activation (Form an Impression–Memorize) should have been greater when the Form an Impression goal was primed than when Memorize was primed. This comparison revealed a greater difference when the Form an Impression goal was primed (M=5.08) than when the Memorize goal was primed (M=2.71, $p < .05$). However, post-choice measures revealed such no difference—the same proportion of Ps indicated that the Memorize goal was active (68%) in both conditions, and slightly more indicated the Form an Impression goal was active in the Memorize condition (91%) than in the Form an Impression condition (88%). Whereas the mid-choice continuous assessment revealed prime consistent differences in goal activation, the post-choice measure produced the null result found repeatedly in prior research (e.g., Chartrand and Bargh 1996).

Other research has established that the consistency goal can be activated subliminally and that its activation influences consumer choice processes (Russo, Carlson, Meloy and Yong 2008). In study 2, we follow Russo et al. (2008) by activating the Consistency goal via parafoveal priming. We then measure goal activation levels for several goals, including the Consistency goal. We do so twice, once midway through and once just before the end of the choice. After the choice, participants (N=110) were debriefed for awareness (Chartrand and Bargh 1996).

Similar to study 1, activation of the consistency goal measured midway through the choice was greater for participants who had been subliminally primed with consistency words (M=7.27) than it was for participants who were exposed to goal-neutral words (M=6.58; $p < .05$). The same was true for the measure of consistency taken after participants had seen all six of the attributes ($M_{\text{consistency}}=7.58$; $M_{\text{neutral}}=6.89$; $p < .05$). Importantly, the activation levels of the other goals did not differ across condition for the early assessment (all $p > .38$) or the late assessment (all $p > .24$).

To deal with difficult tradeoffs, consumers often seek out choice alternatives that allow them to avoid making those painful tradeoffs (Luce 1998). When no such alternatives are available, the desire to avoid negative emotions "in-process" can become active (p. 21, Luce, Bettman, and Payne 2001). That is, difficult tradeoffs can activate the goal to avoid negative emotions. Following this logic, we reasoned that making tradeoffs salient would cause the Avoid Negative Feelings goal to increase in activation. We posited that having participants engage in attribute-based processing of non-alignable information for three appealing alternatives (hotels), would make the difficulty of the tradeoffs salient, which would lead to substantial activation of the Avoid Negative Emotions goal. In contrast presenting the alternatives serially (thereby requiring alter-

native-based processing), would not highlight tradeoffs across the alternatives, which would keep the Avoid Negative Emotions goal relatively inactive (i.e., at something like its chronic or background level of activation during a typical choice).

In Study 3, participants (N=50) decided between three hotels described by three attributes (Location, Pool, Services) in one of two information conditions, attribute-based or alternative-based processing. After reading all of the information, but before selecting their preferred hotel, participants reported the activation levels for 11 processing goals, including Avoid Negative Emotions.

As expected, participants in the attribute-based processing condition reported higher activation of the Avoid Negative Emotion goal (M=6.96 on the 0-to-10 scale) than participants in the alternative-based processing condition (M=2.92, $p < .01$). This result shows that the choice architecture, with no change in information content, can influence the activation of processing goals.

In conclusion, this research explores whether consumers can report goals that have been activated outside of their awareness. Perhaps the key takeaway is that even though consumers are typically unaware of what factor(s) in the environment caused a goal to become active, they can report if that goal is active when a sensitive assessment method is used. Our hope is that this method for catching goals in the act of decision making will help researchers identify goals that (a) underlie important consumer behaviors, (b) are activated by common contextual factors, and (c) are related to each other either through causal activation or through simple relatedness to a higher order goal.

SPECIAL SESSION SUMMARY

The Rosy Side of Negative Emotions

Uzma Khan, Stanford University, USA

SESSION OVERVIEW

Recent decades have witnessed a burgeoning interest in the role of emotions in decision-making across several different fields including, marketing, psychology and economics (Pham 2007, Schwartz 2000; Vohs and Baumeister 2007). Conventional wisdom and most of past research suggests that emotions, especially negative ones, can adversely affect decision-making and can have both short and long-term consequences. For example, a study by Shiv, Loewenstein and Bechara (2005) showed that people who do not experience negative emotions after losses (due to brain damage) end-up making more money than those who do. The idea being that experiencing of negative emotions can guide bad decisions. Similarly, Tiedens and Linton (2001) showed that negative affect (e.g., anger) leads to impulsiveness and shallow-processing of information. Others have similarly documented detrimental effects of negative affect on performance (Zeelenberg and Beattie 1997), product evaluation and brand attitude (De Houwer, Thomas, and Baeyens 2001). Hence a picture that emerges from the above literature consistently portrays that negative emotions generally impair judgment and decision-making.

Papers in the present session take another in-depth look at the functioning of commonly experienced negative emotions and uncover how negative affect, despite its reputation, can help improve decision-making and wellbeing in certain contexts. The session includes three papers, which are all in advance stages of completion. Contrary to the established findings, the papers show positive effects of everyday negative emotions, such as anger, regret and sadness in several different domains including, product evaluations and choice satisfaction, self-control, learning, and judgment-biases.

In the first paper, Nelson, Malkoc and Shiv examine the upside of regret. They argue that, unlike past literature which has mainly focused on negative impact of regret, regret can play a functional role in learning from past mistakes. They show that manipulation of only the emotional component of experienced regret leads to better performance on decisions within the domain where regret is experienced, but not in dissimilar domains.

In the second paper, Khan, Maimaran and Dhar show positive influence of anger-an emotion generally perceived to have adverse effects-on choice behavior and satisfaction. For example, they find that angry people are less likely to defer choice and end up being more satisfied with their chosen options. They also demonstrate that anger decreases a bias to choose the compromise option and can induce more goal-consistent actions.

Finally, the third paper by Zemack-Rugar shows how negative emotions can improve self-control. She shows that sad individuals increase self-control as compared to a neutral baseline. These findings are contrary to existing research which argues that negative emotions are detrimental to self-control (Tice et al., 2001) and are explained by accounting for emotion-regulation goals and a new variable-emotion regulation cognitions.

Taken together, the papers in this session shed a new light on the functioning of common negative emotions and deepen our understanding of their role in judgment and decision-making with particular implications for choice satisfaction, learning, brand evaluations and self-control. Given the prevalence of negative emotions in everyday life, it is important to not only understand their detrimental effects but also to appreciate how they can improve decision-making.

EXTENDED ABSTRACTS

“Functional Regret: The Positive Effects of Regret on Learning from Negative Experiences”

Noelle Nelson, University of Minnesota, USA

Selin A. Malkoc, Washington University in St. Louis, USA

Baba Shiv, Stanford University, USA

Popular wisdom encourages people to “learn from experiences”, but not regret past actions, implying that people can gain all necessary information from their mistakes without enduring the pain. Academic literature can also view regret and negative emotion as somewhat detrimental. For example, participants who lost money in a negotiation task lose even more money on a subsequent negotiation task when they anticipate regret (Zeelenberg and Beattie 1997). Also, Shiv, Loewenstein and Bechara (2005) showed that brain damaged patients who do not suffer negative emotional feedback after a financial loss end up making “better” decisions (i.e., stick to high-risk, high-return investments).

Regret has both cognitive and emotional components (Zeelenberg 1999). Most work on regret deals with the cognitive feedback (i.e. correctness of decision) and finds that regret hurts later decisions or induces switching from a regretted choice (whether appropriate or not). To our knowledge, no research has examined the role of the emotional component. We attempt to fill this gap by taking the evolutionary perspective that regret is functional and necessary for learning from negative experience and that regret is useful beyond simply inducing switching behavior; it affects effort.

First, our research argues that feeling the negative emotion associated with an experience leads to learning in a subsequent situation. Second, regret will not always have a positive effect on learning. Some stimulus in the new environment must trigger the emotion associated with the initial event (Baumeister et. al. 2007) for it to be functional. The stronger the trigger (i.e. initial emotion) the more effective regret is for learning.

- H1: Experiencing more emotional regret will demonstrate more learning in subsequent similar decisions.
- H2: Experiencing more emotional regret will demonstrate no learning in subsequent dissimilar decisions.

To test our hypotheses, study 1 examined field data from the 2008 Olympics. We analyze swimmers who swim multiple final races of the same (similar domain) and different (dissimilar domain) strokes. The change in time from one race to another is our dependent variable. We operationalized regret based on prior research indicating that athletes who win silver medals (second place) experience greater negative emotion than people who win bronze medals (even though they perform objectively better; Medvec, Madey and Gilovich 1995). Therefore, swimmers who placed second (third) in their first race serve as our high (low) regret condition. We find that swimmers who come in second (third) in a previous race perform relatively better (worse) in a subsequent similar race. There is no effect for swimmers who competed in two dissimilar races. Because second place swimmers feel more regret, their performance is enhanced in a subsequent similar trial.

Study 2 tested whether the negative emotion experienced in an earlier web search task would carry over to affect subsequent search behavior. Participants searched the internet for the lowest price they could find for a blender (which they thought would win them a cash

prize). All participants “missed” the prize by a small amount. Regret was manipulated with the size of the prize (\$5 vs. \$50). After a filler task, participants searched for a knife set they would give as a gift. As expected, participants who missed \$50 (\$5) and felt high (low) regret put more (less) effort (i.e. time) into searching a gift.

Our third study manipulated the intensity of emotional regret felt, while keeping the experience (and cognitive feedback) constant. Sawyer et al (1992) demonstrated that caffeine heightens emotion. Accordingly, we manipulated regret with caffeinated or decaf coffee. After drinking coffee, subjects completed a yoked buying task where they were given 5 tokens. Participants were told that they would see a random number of products in a random order and that they should indicate whether or not they wanted to buy each product. The rigged task resulted in everyone buying the U of Minnesota decal for 2 tokens and ending up 1 token short when the more desirable electronic game was presented. Therefore, all subjects felt regret. Lastly, participants indicated their willingness to pay for a related item (U of M keychain; triggering the initial experience) and an unrelated item (notebook).

We analyzed only the infrequent coffee drinkers, as these participants were expected to display sensitivity to the manipulation. A significant interaction emerged between the product type and caffeine level. Participants who consumed caffeine (high regret) were willing to pay less for the U of M keychain than those drank the decaf (low regret). However, there was no effect of caffeine on WTP of the dissimilar product (notebook).

Study 4 was similar to study 3, but regret level was manipulated by the attractiveness of the product the participant “missed”. Participants went through the rigged buying task, bought the car decal and were unable to buy either an electronic game (low regret) or an iPod (high regret). The resulting design was a 2 (felt-regret: high vs. low) x 2 (decision domain: similar vs. dissimilar). Participants then indicated WTP for the similar (U of M keychain) and dissimilar (Eiffel tower keychain) products. We found a significant interaction such that participants who had felt high (low) regret over buying the U of M decal were willing to pay significantly less (more) for the U of M keychain, but there were no differences in WTP for the Eiffel tower keychain.

Overall, we propose and demonstrate that regret is necessary for learning from mistakes and can be functional. Unlike previous literature, we examine experienced emotional regret and find that in domains they have failed before, regret actually helps consumers’ make higher quality decisions.

“Positive Upshots of Anger in Decision-Making”

Uzma Khan, Stanford University, USA

Michal Maimaran, Kellogg–Northwestern University, USA

Ravi Dhar, Yale University, USA

The role of emotions in decision-making is gaining increased attention (Schwartz 2000). Generally, emotions have been shown to have negative effects on decision quality (Shiv et al. 2005). For example, one of the most frequently encountered emotions, anger, is perceived as a negative affect that leads to impulsiveness and shallow-processing (Tiedens and Linton 2001), higher action tendencies against others (Frijda, Kuipers and Schure 1989), careless thought and increased risk-seeking (Lerner and Tiedens 2006). Hence, the conventional wisdom is that anger leads to hasty and inferior decisions. In the current research, we argue that negative emotions like anger can have positive effects on decision-making. Specifically, we suggest that in certain decision contexts anger can lead to better outcomes due to a less careful processing of local tradeoffs.

We examine this proposition for two well-established context effects—choice-deferral and compromise-effect. Tradeoff difficulty, resulting from effortful processing of available options and greater focus on local comparisons, has been implicated in both choice-deferral (e.g., when all options are highly attractive; Dhar 1997) and a tendency to choose the middle option (e.g., to avoid loss on either dimension; Simonson 1989). To the extent that angry individuals engage in less careful processing of local tradeoffs, we predict that they will be less susceptible to choice-deferral as well as a compromise-effect as both these biases arise due to in-depth processing of difficult tradeoffs. In summary, we predict that angry individuals are less likely to base their choice on in-depth processing of the local characteristics of the decision context. This in-turn reduces decision biases that results from a focus on the local context of the decision and hence increase long-term decision satisfaction. We tested these propositions in five studies.

In Study 1 participants were induced with anger or neutral emotion and asked to choose between two flight-tickets or defer the decision. Past research has shown that people often defer a choice when provided several attractive options even though each option by itself is seen as sufficiently attractive (Iyengar and Lepper 2000). We hypothesize that angry individuals are less likely to suffer from such decision-inertia. Consistent with our prediction significantly fewer participants deferred the decision to purchase the flight ticket in the anger condition as compared to the neutral-condition (17% vs. 42%).

In Study 2 we examined the effect of anger on choice of the compromised option. Participants chose from either a 2- or 3-options choice-sets in four product categories (laptops, binoculars, restaurants and flashlights). Collapsing across the categories we found the expected compromise effect among neutral-mood participants i.e., a 28% increase for neutral participants in the share when an alternative became a middle-option compared to only a 9% increase in its share among angry participants. We explain that since anger leads to shallower processing and lower risk-aversion, angry people are less likely to go for the middle option which is generally the result of trade-off difficulty and need-for-justification

We tested our prediction regarding reduced reliance on local tradeoffs in Studies 3 and 4 and found that 1) angry people reported fewer attribute-level tradeoffs in the explanations of their choice and 2) the decreased tendency to choose the compromise option observed among angry participants was mediated by the level of attribute-level tradeoffs.

Finally, Study 5 used real choices between two different packs of cookies and showed that angry participants were 1) more likely to choose a pack as opposed to taking the no-choice option and 2) reported greater satisfaction with their choice a week later than sad or neutral-mood participants. Besides illustrating the positive affect of anger on choice-satisfaction, the study also demonstrates that the affect of anger are unique and different from other negative emotions such as sadness.

These findings suggest that anger plays an important role in determining individuals' tendency to make a decision, the type of decisions they make, and how satisfied they are with their decisions in the long-run.

"Negative Emotions Can Lead to Increases in Self Control: The Mediating Role of Emotion-Regulation Cognitions"

Yael Zemack-Rugar, Virginia Tech, USA

Negative emotions and self control are considered antithetical. Contrary to this view, this research shows that under certain conditions negative emotions can increase self-control.

Previous theory on an emotion-as-motivation framework. It argues that the goal to emotion-regulate (i.e., feel better in a negative emotion) is contrary to self control. We extend this theory by accounting for a heretofore unaccounted for variable—emotion-regulation cognitions. These cognitions refer to thoughts individuals have regarding what (self-control) behaviors they believe would make them feel better. We draw a more nuanced theoretical and empirical mapping of the relationship between negative emotions and self control.

We applying the two basic premises of goal theory: (1) that emotion-regulation cognitions (i.e., thoughts individuals have about what behaviors are useful for goal attainment) should affect emotion-regulation goal-related behavior, and (2) that these cognitions should only affect behavior when the goal is active. In three studies we demonstrate the centrality of emotion-regulation cognitions in predicting behavior and rule out alternative explanations.

In study 1 we manipulate emotion-regulation cognitions (ERC henceforth), making participants believe that reducing self-control will make them feel either better/worse. We expected an interaction of emotion by ERCs such that in a sad (negative) emotion condition, where the emotion-regulation goal (to feel better) is active, participants will increase/reduce self control in accordance with ERCs. We expected that in a neutral condition, where the emotion-regulation goal is inactive, ERCs will not affect behavior. These predictions were confirmed. Additionally, sad participants whose ERCs suggested reducing self-control was harmful for emotion-regulation showed an absolute increase self control.

These results are contrary to resource-depletion theory. Equally depleted (sad) individuals show different self-control levels; these levels occur despite equal activation of the emotion-regulation goal. Further, these differences emerge due to differences in ERCs and disappear when the emotion-regulation goal is inactive (neutral), lending initial support for our theory.

In study 2 we measure ERCs across two different negative emotions (sadness and guilt) in a pretest. The data shows that guilty individuals' ERCs indicate self-control is less useful for emotion regulation than sad individuals' ERCs. Given the hypothesized importance of ERCs, we predicted that guilty participants would show higher self control than sad participants.

Consistent with goal theory, this effect should disappear when the emotion-regulation goal is inactive. We deactivate this goal for half of our participants; when the emotion-regulation goal was inactive, no differences were expected. We also include a neutral condition as a baseline.

Our predictions were confirmed showing (a) guilty participants showed higher self control than sad and neutral ones, and (b) these effects disappeared when the emotion-regulation goal was deactivated. These findings show the importance of ERCs in predicting behavior and provide a second demonstration of absolute increases in self control in a negative emotion, even when the emotion-regulation goal is active.

In study 3 we seek to demonstrate the mediating role of ERCs and to rule out an alternative explanation based on appraisal theory. We also identify a moderator that helps in the prediction of ERCs.

We conducted a three-phase study (same participants in all phases) inducing sadness/guilt/neutral in each phase, and measuring ERCs, self-control behavior, and cognitive and appraisals and EPO. First, this design allows us to test the mediating role of ERCs in determining self-control behavior.

Second, this design allowed us to examine an alternative explanation based on cognitive appraisals. One might argue that the appraisal of control/responsibility (which differs between sad/guilty) leads to differences in self-control behavior. We argue that appraisals and ERCs are distinct theoretically; the former has to do with how we came to feel the way we do, and the latter has to do with how we can stop feeling the way we do. There is also empirical evidence for this distinction. In our study 1 appraisals were identical for all sad participants, but self-control behavior differed; this difference was based on ERCs. Given these empirical and theoretical points, we predicted appraisals would not predict behavior or ERCs.

Third, we examine in study three the actual relationship between ERCs and appraisals. We predicted this relationship was

moderated by a third variable—EPO. EPO is a measure of the degree to which consumers focus more on the negative vs. positive outcomes of self control. Those high in EPO, tend to focus more on the negative outcomes of reducing self control.

We predicted when control appraisal was low, consumers would feel that no effort would affect their emotional outcome. Thus, their ERCs would suggest that exerting self-control effort is useless for emotion-regulation. However, if control appraisal was high, consumers would consider whether exerting self-control effort was worthwhile based on whether they thought the outcome of that effort would be positive/negative; this is measured with EPO. Those consumers high on EPO (think the outcome of reducing self-control is relatively negative) would have ERCs suggesting reducing self control is hurtful for emotion-regulation; the opposite would be true of those low in EPO.

All of the predictions for study three were confirmed. Consistent with study 2, guilty participants' ERCs showed reducing self control was less useful for emotion regulation than sad and neutral ones; they, therefore showed higher levels of self control in choice. Importantly, ERCs mediated the effects of emotions on self-control behavior.

Appraisals did not predict ERCs directly, nor did they predict behavior. Instead, the predicted interaction of appraisals by EPO predicted ERCs. This interaction did not predict behavior. In models including all variables, ERCs was consistently the only significant predictor.

These findings together suggest the important role that ERCs play in the relationship between negative emotions and self control. They demonstrate that we should account for ERCs in order to create a more nuanced view of this relationship.

SPECIAL SESSION SUMMARY

Morality, Suspicion, and Modification: New Directions After 15 Years' Persuasion Knowledge Research

Guang-Xin Xie, University of Massachusetts Boston, USA
Tracy Rank, DePaul University, USA

SESSION OVERVIEW

Although marketing is essentially used by companies to communicate with consumers, sometimes, marketers use tricky, devious, and even immoral persuasion tactics. Due to the constant exposure to marketers' tactics consumers may then become habitually suspicious about marketplace persuasion. Over time, routine suspicion can turn into more schematic knowledge about the tactics that marketers use in persuasion attempts (Friestad and Wright 1994). During the past fifteen years, researchers have examined how the persuasion knowledge (PK) can change the perceived meaning of a persuasion attempt in ways that were not originally intended by marketers. This special session provides a new direction that extends the current persuasion knowledge research.

Existing literature has documented that PK-induced judgments of an influence agent tend to be negative due to the general defensive mechanism of suspicion (Campbell and Kirmani 2000; Darke and Ritchie 2007). The consequential responses can be either relatively automatic leading to bias (Darke, Ashworth, and Ritchie 2008); or more deliberate and modified by consumers' goals, experiences, and preferences (Kirmani and Campbell 2004). This special session further explores these intriguing and sometimes contradictory issues regarding the potential boundary conditions for suspicion and inference. More specifically, the four papers proposed for this session investigate consumer perceptions of the morality of marketers' persuasion tactics, the effects of suspicion, and motivational and situational cues that modify the initial PK-induced judgments and reactions. Under what conditions are marketing tactics viewed as being more (or less) morally acceptable to consumers, and under what conditions are consumers more (or less) suspicious about these tactics? The findings throughout this session shed further light on how consumers cope with persuasion attempts.

Paper 1 (Kirmani et al.) examines how consumers make tradeoffs between an influence agent's competency (an intrinsic utilitarian judgment) and morality (an extrinsic moral judgment) when suspicion is activated. A "sinful success" vs. "virtuous failure" dilemma appears salient. This dilemma, however, can be accounted for by the immediacy of the decision and the consumer's relationship with the influence agent. Paper 2 (Grayson and Rank) further demonstrates that consumers differ in their intuitive theories about the extent to which a persuasion tactic is socially appropriate. Consumers with more advanced persuasion knowledge tend to view tactics normatively appropriate, but morally inappropriate. Paper 3 (Darke) describes strategies for combating the persistent negative bias induced by the defensive suspicion. Multiple trust cues, knowledge of government regulation, and the use of aschematic tactics are all effective in buffering against the otherwise persistent effects of defensive suspicion. Finally, paper 4 (Xie et al.) identifies situations when proactive or reactive responses occur as a result of suspicion, depending upon consumers' regulatory focus and persuasion knowledge to manage interactions with an influence agent.

Combined, these four papers examine how consumers react against marketers' potentially immoral persuasion tactics and how their suspicions about these tactics can be enhanced or attenuated. These papers advance the literature in three ways. First, these studies provide insights about a number of factors that either

strengthen or weaken consumers' suspicion. Second, the results suggest that consumers do not view persuasion tactics used by marketers as simply black and white, wrong or right; instead consumers rely on both utility value and moral value to judge the appropriateness of a persuasion tactic. Third, the studies extend previous research on persuasion knowledge by specifying situations when consumers can pragmatically adjust the PK-induced negative judgments of the influence agents. After fifteen years of persuasion knowledge research, scholars continue to ask new thought-provoking questions. This session captures cutting edge research that contributes to the theoretical advancement of consumer behavior in response to marketplace persuasion.

EXTENDED ABSTRACTS

"Which Agent Do You Prefer: A Sinful Succeeder or a Virtuous Failure?"

Amna Kirmani, University of Maryland, USA
Rebecca W. Hamilton, University of Maryland, USA
Debora V. Thompson, Georgetown University, USA

We examine how consumers' trade off competence and morality when evaluating marketing agents. Although the general information formation literature predicts that individuals place greater weight on morality than competence, we predict that in marketing contexts, consumers may value an agent's competence more than morality. We investigate three factors that might affect how consumers weigh competence and morality: 1) the immediacy of the decision making horizon; 2) self vs. other perspective; and 3) the target-agent relationship. Three studies find support for the predictions.

Competence and morality are two fundamental dimensions in social perception (Rosenburg, Nelson, and Vivekananthan 1968). Morality encompasses traits such as honesty and caring, while competence includes traits such as cleverness and skill. An interesting question that has not been addressed in prior research is how consumers trade off morality and competence when choosing a marketing agent.

The literature on general impression formation predicts that morality-related traits are more important than competence-related traits. For example, Wojciszke (1994) finds that evaluation of individuals is more favorable under *virtuous failure* (the behavior is moral, but incompetent) than under *sinful success* (the behavior is competent, but immoral). In contrast, we propose that in marketing contexts, consumers may place greater weight on competence than morality. Particularly in short-term transactions, the consumer's objective is likely to be to achieve his/her purchase goals (Kirmani and Campbell 2004). If the consumer is focusing on the agent's ability to help achieve purchase goals, competence-related traits should be salient.

We examine several conditions under which sinful success may be preferred to virtuous failure: 1) the immediacy of the decision making horizon; 2) self vs. other perspective; and 3) the target-agent relationship.

The immediacy of the decision making horizon refers to how quickly the consumer must accomplish his/her marketing goals. We predict that immediacy will encourage a consumer to prefer a sinful

success over a virtuous failure. This was tested in a 2 (Type of Agent: virtuous failure vs. sinful success) X 2 (Immediacy of Decision making: high vs. low) between-subjects design. Participants were asked to imagine that they were looking for a real estate agent to sell their house. The agent was described as moral but less successful (virtuous failure) or as deceptive but successful (sinful success). Immediacy was manipulated by informing participants that they needed to sell their house in three months (high immediacy) or without mentioning a time horizon (low immediacy). Consistent with our prediction, participants in the low immediacy condition were significantly more likely to hire the moral, less successful agent, while those in the high immediacy condition were marginally more inclined to hire the deceptive but successful agent.

In the second study, we predicted that, consistent with the fundamental attribution error, participants would believe these factors would influence others' decisions more than their own. This study was a 2 (Type of Agent: virtuous failure vs. sinful success) X 2 (Perspective: self vs. other) between-subjects design. The agent factor was manipulated through the real estate scenario described earlier. Perspective was manipulated by asking participants to imagine that they (or their neighbor) were looking for a real estate agent to sell their house. An ANOVA revealed a significant interaction effect, indicating that, for themselves, participants were more likely to hire the virtuous failure than the sinful success agent, but thought others would be marginally more likely to hire the sinful success agent.

In the third study, we used a within subjects manipulation of type of agent in order to highlight the trade-off between competence and morality. The study was a 2 (Type of agent: virtuous failure vs. sinful success) X 2 (Target-Agent relationship: short vs. long term) X 2 (Tactic: harmful vs. not harmful) mixed design. Participants read about two sales agents, Dave and Eric, who work in a sporting goods store. Dave's description will with sinful success, while Eric was described as a virtuous failure. The target-agent relationship was manipulated through specifying the purchase situation as one-time or as an ongoing relationship. Tactic was manipulated by whether the sinful behavior directly affected the consumer or not. We predicted that in short-term relationships, sinful success will be preferred to virtuous failure, but that this preference was reversed in long-term relationships. When the tactic could hurt the consumer, however, the morality effect prevailed in the short run.

"Persuasion Knowledge and Moral Judgment"

Kent Grayson, Northwestern University, USA

Tracy Rank, DePaul University, USA

Previously, persuasion knowledge (PK) research has focused primarily on how consumers' beliefs about motives and tactics help them to cope with persuasion attempts. Friestad and Wright (1994) also propose that PK will influence consumers' perceptions of the appropriateness of marketing tactics. However, they make no specific suggestions about the nature of these judgments. *Do consumers with high levels of PK tend to judge persuasion tactics to be more appropriate—or less?*

The answer to this question is not immediately obvious. Those with higher levels of PK could be more sensitive to the manipulateness of persuasive tactics and therefore tend to view them as being *less* appropriate. Alternatively, those with higher levels of PK might be more comfortable with the "rules of the game" of persuasion and therefore judge persuasion tactics as being *more* appropriate.

Exploratory Study. Independent Variables: We asked respondents (N=63) to rate Campbell and Kirmani's (2000) scenario in which a salesperson flatters a customer either before the sale or

after, and then asked them to respond to the Bearden et al. (2001) PK scale. *Dependent Variables:* Appropriateness was defined and operationalized as "normatively acceptable" (Friestad and Wright 1994, p. 10). *Results:* Although level of PK predicted differences in perceived honesty of the salesperson, it did not predict significant differences in perceived appropriateness.

Study One. Based on the results of Campbell and Kirmani's (2000) study three, we hypothesized that priming respondents with PK might prompt perceived differences in appropriateness. Study one was the same as our exploratory study, with the exception that half of our respondents (N=228) were asked to complete the PK scale before evaluating the sales scenario, and half after. *Results:* Unprimed respondents mirrored the null results of our exploratory study. However, when primed, those with low PK significantly lowered their perceptions of overall appropriateness. Therefore, Study One suggests that (when primed) those with low PK view sales scenarios as being less appropriate than those with high PK.

Study Two. Will those low in PK always rate a sales scenario as being less appropriate than those high in PK? We hypothesized that when the salesperson is also a friend, this may create a conflict in normative expectations: is it more appropriate for the person to act like a friend or like a persuasion agent? Results (N= 268) show that those with high PK rated the salesperson's flattery as being more appropriate when it occurred after the sale (as opposed to before), whereas those with low PK rated the salesperson's flattery as being more appropriate when it occurred before (as opposed to after). These results add evidence to the proposition that those with high PK differ from the expectations of those with low PK.

Study Three. Appropriateness has two dimensions—whether the behavior is appropriate to the situation and whether the behavior is ethically or morally appropriate (Friestad and Wright 1994, p. 5, 10). We hypothesized that while those with high PK may believe that persuasive behavior is more normatively appropriate in sales situations, their high level of knowledge in such situations makes them more sensitive (than those low in PK) to the moral implications of persuasive tactics.

The protocol for this study drew from Cohen and colleagues' (1991, 1993, 2001) moral judgment research. One of Cohen's test scenarios describes a store salesperson who behaves in a morally questionable way, while other scenarios focus on morally questionable behavior in other business situations. Results (N=123) show that those with high PK rated the salesperson scenario as being less morally acceptable than those with low PK. However, regarding two other scenarios, there were no differences in the ratings of those with high (versus low) PK.

Combined, the results of our three studies suggest that PK does influence perceptions of tactic acceptability. However, our studies also find that the direction of the link between level of knowledge and acceptability depends on how "acceptability" is defined. When defined as normatively appropriate, those with higher PK view tactics as being more appropriate. When defined as morally acceptable, those with higher PK view tactics as being less appropriate.

"Shedding the Veil of Suspicion: Avoiding the Effects of Defensive Suspicion"

Peter R. Darke, York University, Canada

The defensive suspicion model (DSM; Darke and Ritchie 2007) recognizes that judgments of suspicion involve both deliberative and automatic information processing. Moreover, while accuracy goals may drive judgment, suspicion often involves more defensive, self-protective goals. The latter involve ego-threat, and lead to persistent biases in judgment aimed at reducing such threat. Like the PKM, the DSM is essentially a dual process model.

However, the PKM focuses more on deliberative forms of information processing and accuracy goals whereas the DSM is more focused on automatic processing and defense goals.

The DSM model was tested in series of experiments (Darke and Ritchie 2007; Darke et al. 2008). Consistent with predictions, consumers deceived by an initial advertisement were less trusting and had more negative attitudes towards second-party advertisements. This generalized suspicion effect operated through defensive stereotyping (Sinclair and Kunda 1999), where deception evoked the broad stereotype that no advertising could be trusted. Ego threat was a necessary condition for generalized suspicion to occur. Generalized suspicion also proved difficult to counteract. For instance, strong arguments were no more effective in combating generalized suspicion than weak arguments, and the existing reputation of the second advertiser did little to protect it from generalized suspicion. This talk presents new research identifying factors that moderate the otherwise robust effects of defensive suspicion.

Study one examined whether *multiple trust cues* would provide greater evidence a firm can be trusted through cross-validation. To test this idea, deception was manipulated in an initial advertising study (Darke et al. 2008) and the effects of generalized suspicion were examined in a “different study” concerning the purchase of a used book from a second-party retailer. The brand name (trusted vs. unknown) and the consensus of customer satisfaction ratings (high, average, low) for the retailer were varied in a between subjects design. The results showed that while brand name and high satisfaction ratings alone were ineffective, their combination successfully buffered against generalized suspicion.

Monitoring by regulators is known to be important in maintaining trust in economic exchanges (Pavlou and Gefen 2005). Study two tested whether *regulation* would thwart generalized suspicion in an investment context. Subjects read financial statements from the CEO of an initial firm and half of them were informed these statements were false. Subjects then completed a purportedly unrelated investment game, where they were given financial information from an unrelated firm and could purchase the company’s stock using real money. This financial information was either reported in accordance with Sarbanes-Oxley (SOX), or no mention of SOX was made. Consistent with predictions, fraud induced generalized suspicion and lowered investment when SOX was absent, whereas SOX fully neutralized generalized suspicion.

Study three examined sales promotions. The question was whether an EDLP claim would be less vulnerable to generalized suspicion than a discount claim. Consumers are often highly suspicious of discounts (Fry and McDougall 1974), whereas EDLPs provide a relatively straightforward means of providing good value (Darke and Chung 2005). If so, EDLPs should fit less with stereotypes for deceptive advertising practices, and suspicions should generalize less readily to EDLP versus discount offers. Subjects were exposed to either a discount or EDLP offer on flooring materials and a fake debriefing informed deception subjects the level of savings was overstated. Subjects then completed a filler task, followed by a final study where they indicated the deal value for either an EDLP or discount offer for a television from a second firm. Regardless of its origin (discount or EDLP), deception induced greater suspicious towards the second-party discount offer, whereas it actually led to an increase in the perceived value of the subsequent EDLP offer. That is, advertising deception led to suspicion of discounts in particular, whereas consumers actually became more positive towards the aschematic, no-nonsense of an EDLP.

“A Tale of Two Modes: When Do Consumers Approach or Avoid Persuasion Attempts?”

Guang-Xin Xie, University of Massachusetts Boston, USA

David M. Boush, University of Oregon, USA

Lynn R. Kahle, University of Oregon, USA

Peter L. Wright, University of Oregon, USA

Persuasion knowledge does not only consist of schema about an influence agent’s motives and tactics, but also how to respond effectively (Friestad and Wright 1994). In some situations consumers actively approach the salesperson to achieve their goals while others avoid, resist, or withdraw (Kirmani and Campbell 2004). The current study extends previous research by further examining the role of persuasion knowledge and regulatory focus. We predict that consumers are more likely to approach an influence agent when they are promotion-focused to achieve positive outcomes, and more likely to avoid when they are prevention-focused to prevent negative outcomes. Persuasion knowledge moderates the effect of the regulatory fit between consumers’ goals and persuasion situations on coping tendencies.

Study One: We used a 2 (Suspicion: high vs. low) X 2 (Regulatory Focus: prevention vs. promotion) X 2 (Persuasion Knowledge: high vs. low) between-subject design. Participants read a shopping scenario in which a salesperson made positive remarks on his/her choice of a more expensive jacket. Suspicion was manipulated by the timing of positive remarks before or after the purchase decision (Campbell and Kirmani 2000). Regulatory focus was manipulated by priming goals to achieve a positive outcome or avoid a negative outcome (Lockwood, Jordan, and Kunda 2002). Persuasion knowledge was measured independently (Bearden et al. 2001) and tested using a median split. Two dependent measures (approach/avoid tendencies) were adapted from the “sentry vs. seeker” framework (Kirmani and Campbell 2004) based on a factor analysis of eighteen behaviors. The results show that promotion (prevention) focus predicts approach (avoid) tendencies. Also, participants high in persuasion knowledge were less likely to avoid interacting with the salesperson than those low in persuasion knowledge, while persuasion knowledge was not found to regulate approach tendency.

Study Two: We used a 2 (Regulatory Focus: prevention vs. promotion) X 2 (Purchase Relevance: high vs. low) X 2 (Persuasion Knowledge: high vs. low) between-subject design to control for personal relevance in making a purchase. Only the high suspicion condition was retained. Relevance was manipulated by the purpose of the purchase: “...for an important interview” or “...for those just in case times.” The results show that promotion/prevention-focused participants in the high relevance conditions were equally suspicious about the salesperson’s ulterior sales motive. In the low relevance conditions, however, promotion-focused participants were more suspicious than prevention-focused participants. Further, a three-way interaction was evident with regard to the avoidance tendency. For those low in persuasion knowledge, prevention-focused participants were more vigilant when relevance was low. When relevance was high, promotion/prevention focus did not make a significant difference. In comparison, for those high in persuasion knowledge, when relevance was high, prevention-focused participants were more likely to avoid a persuasion attempt. However, when relevance was low, promotion-focused participants were more inclined to act defensively.

Study Three: We used a 2 (Regulatory Focus: prevention vs. promotion) X 2 (Message Framing: positive vs. negative) X 2 (Persuasion Knowledge: high vs. low) between-subject design to further examine the regulatory fit between goals and messages. Only the high suspicion/high relevance conditions were retained.

The salesperson's remarks were framed as positive ("...that's a great jacket. I think it looks very professional, and it will be a good choice for an interview") or negative ("...that's a nice jacket. But I think it looks too casual, and it will not be a good choice for an interview"). In both conditions, the salesperson recommended the more expensive jacket as a better choice. This experiment replicated the findings regarding regulatory focus effect on avoidance tendency. However, no support was found regarding the effect of regulatory fit on suspicion or coping tendencies.

In three experiments, we demonstrated that persuasion knowledge, regulatory focus, and purchase relevance can influence approach/avoid coping tendencies in response to interpersonal marketing persuasion. In particular, promotion-focused consumers can be more vigilant than prevention-focused consumers when the purchase relevance is low. Also, high persuasion knowledge consumers must be motivated enough to simply react against a persuasion attempt.

SPECIAL SESSION SUMMARY

The Distinct Effects of Hope in Consumption

Karen Winterich, Texas A&M University, USA

SESSION OVERVIEW

Whether yearning to achieve your goals or rewarding yourself for a job well-done, feelings of hope and feelings of pride are regularly regarded as important emotional triggers of consumption behavior. Hope is pervasive in marketing and consumer acquisition in numerous industries such as diet and exercise, medicine, and finance (MacInnis 2005). In addition, consumers often take pride in the products they purchase or avoid, making hope and pride two prevalent positive emotions in consumption. Previous research on hope (e.g., de Mello et al. 2007; MacInnis and de Mello 2005) and pride (e.g., Tracy and Robins 2007; Williams and DeSteno 2009) has shown that these two positive emotions are important motivators of behavior; however, it is unclear whether these distinct positive emotions influence different consumption behaviors in a similar way. Do hope and pride influence behavior similarly across different consumption contexts (e.g., purchasing novel products, eating behavior, and investment decisions)? Moreover, do hope and hopefulness have distinct effects on consumption decisions? This session highlights important differences in the behaviors motivated by hope in contrast to other positive emotions such as pride and hopefulness across distinct consumption contexts.

Hope is a positive emotion, which represents the degree to which one yearns for a good outcome that seems possible even if it might not be likely (MacInnis and Chun 2007). In the first paper, Cavanaugh et al. explore how two specific positive emotions—hope and pride—influence cognitive processing and purchase behavior. They find that hope causes consumers to be willing to pay more for novel products than does pride when resources are constrained (i.e., non-optimal time of day). Further, hope improves performance relative to pride on tasks requiring fluid intelligence. These findings suggest an interesting interaction between experienced emotion and consumption context and raise an important question—when might hope and hopefulness help (versus potentially harm) consumers?

While some previous research demonstrates that positive affect may lead individuals to control their impulses, other research suggest positive affect leads to indulgence. In the second paper, Winterich and Haws try to reconcile these findings through considering the differential effects of hope in contrast to pride and happiness on eating and spending self-control. In a series of four studies, they find that hope may increase self-control relative to neutral, proud, or happy emotional states.

The third paper by Nenkov, MacInnis, and Morrin, distinguishes hope from hopefulness, demonstrating the distinct effects of these two emotions on retirement investment decisions. Defining hope as the extent of yearning for and hopefulness as the perceived likelihood of a goal-congruent outcome, their work finds that consumers' levels of hope and hopefulness are differentially associated with personality traits such as optimism and risk aversion. Furthermore, hopefulness influences 401(k) participation rates whereas hope influences information search and risky decision making.

Addressing the effects of positive emotions which are pervasive in consumption, this symposium presents findings suggesting that hope may differentially impact processing, self-control, and decision making. In contrast to traditional research on positive affect, the three papers in this session demonstrate that positive

emotions can have vastly different and even opposing consequences. Theoretically, the set of papers clarify the characteristics of hope, pride, and hopefulness that are influential in consumption. As such, specific positive emotions such as hope, pride, and hopefulness can be used by marketers as strategic tools. Moreover, consumers and public policy makers need to consider the extent to which positive emotions may unknowingly influence consumers' decisions, resulting in poorer health or financial security (Baumeister et al. 2007).

EXTENDED ABSTRACTS

“Hope, Pride, and Processing During Optimal and Nonoptimal Times of Day”

Lisa A. Cavanaugh, University of Southern California, USA

Keisha M. Cutright, Duke University, USA

Mary Frances Luce, Duke University, USA

James R. Bettman, Duke University, USA

Most research involving positive affect and emotion argues that various positive emotional states have similar effects on behavior (Fredrickson 1998, 2001; Isen 2001), such as problem-solving and cognitive flexibility. In this research, we show that specific positive emotions can differentially influence cognitive flexibility and consumption behavior, particularly when inhibitory resources are low.

Work on mood freezing and cognitive load suggests that the magnitude of emotion's effect can be increased or decreased based on the availability or perceived availability of an individual's resources (e.g., Shiv and Fedorikhin 2002). One naturally occurring factor that influences the availability of cognitive resources is an individual's circadian rhythm (Kruglanski and Pierro 2008; Yoon, May, and Hasher 2000). During different times of day (i.e. morning vs. evening), individuals have been found to feel and operate at their personal best or not (i.e. optimally or nonoptimally) based on their personal circadian rhythms. Thus, one important factor that may amplify or lessen the effects of emotion is time of day. Specifically, during nonoptimal times of day resources are less readily available, and therefore automatic, association-based processing (Kahneman and Frederick 2005; Stanovich and West 2002) is more likely (Bodenhausen 1990; May et al. 2005). We contend that association-based emotion mechanisms are likely to be more prevalent during nonoptimal times of day when processing resources are reduced and inhibitory control is lower (Hasher et al. 1999).

Based on reasoning about distinct emotion associations, we contrast the emotions hope and pride. The unique associations with hope suggest that a valued goal is possible, while associations with pride suggest a valued goal has already been achieved. Hope is differentially associated with concepts such as striving, possibility, effort, or the future, whereas pride is associated with concepts such as achievement, fulfillment, or the past. We believe that the distinct set of associations for each emotion can have important processing implications, particularly for fluid processing tasks requiring mental exploration or cognitive flexibility.

We hypothesize that during nonoptimal times of day hope will promote more fluid processing, i.e., more mental exploration and generation of possibilities, than pride. In Experiment 1 we use a preference valuation task where fluid processing seems likely to

facilitate generation of possible or potential uses for considered items; in experiment 2 we use an intelligence task where fluid processing appears to facilitate generation of possible solutions and ultimately performance. As a result, we expect hope, but not pride, to increase valuation of items in assessing preferences in real-time, i.e. constructive preferences (experiment 1), and performance on measures of fluid problem-solving (experiment 2) during nonoptimal times of day.

Experiment 1. Experiment 1 consisted of a 2 (time of day: optimal vs. nonoptimal) x 3 (emotion induction: hope, pride, neutral) between subjects factorial design. Approximately one week before participating in the main experiment, participants completed the Horne and Ostberg (1976) Morningness-Eveningness Questionnaire (MEQ), a validated individual measure of when people reach their functional peak during the day (i.e. "optimal time of day"). Participants were categorized as morning-types or evening-types based on established scoring procedures and then randomly assigned to take the main experiment in the morning or the evening. Thus, participants were randomly assigned to take the study at their "optimal" time of day or "nonoptimal" time of day. Upon arrival for the main experiment, participants were randomly assigned to an emotion induction condition (hope, pride, neutral) following Lerner and Keltner's (2001) procedure. Participants were then asked to indicate how much they would be willing to pay for a variety of items for which they had little repeat-purchasing experience (Vohs and Faber 2007) and thus little crystallized knowledge to draw from in constructing their willingness to pay estimates.

We found a 2-way interaction of emotion condition and time of day for the total amount of money that a participant was willing to pay for the collection of items. Hope led to greater valuation of items than pride or neutral in the nonoptimal time of day condition. No difference was found between neutral and pride, although pride was directionally lower. For the pride condition, participants in the nonoptimal condition were willing to pay significantly less than their counterparts in the optimal condition. Further, the emotion inductions did not significantly impact performance at optimal times of day.

Experiment 2. The purpose of experiment 2 was to better understand the process underlying our experiment 1 findings using a measure of fluid processing performance. Experiment 2 consisted of a 2 time of day (optimal vs. nonoptimal) x 3 emotion induction (hope, pride, neutral) between subjects factorial design. The time of day and incidental emotion manipulations were accomplished as in Experiment 1. Participants were then asked to complete two well-established measures of intelligence. The first task was a measure of fluid intelligence called "matrix reasoning." The second task required participants to complete a test of crystallized intelligence consisting of vocabulary related questions (see Goldstein et al. 2007) using analogies and sentence completion.

Analyses replicated the established time of day findings that participants in a neutral emotional state perform better on fluid, but not crystallized, intelligence measures at optimal times (Goldstein, Hahn, Hasher, Wiprzycka, and Zelazo 2007). There was no effect of time of day on crystallized intelligence. We found the expected 2-way interaction of emotion condition and time of day for fluid intelligence performance. As predicted, hope led to better performance than pride or neutral at nonoptimal times of day. No difference was found between neutral and pride. As predicted, the difference between emotions did not impact performance at optimal times of day. Interestingly, within the hope condition, participants at their nonoptimal time of day actually performed better than their optimal counterparts.

Thus, the results of two experiments demonstrate that two different positive emotions, hope and pride, affect processing

differentially at nonoptimal times of day. Specifically, hope increases individuals' willingness to pay for items with which they have little prior knowledge or experience compared to pride and a neutral condition. Moreover, hope improves objective performance on tasks requiring fluid processing compared to pride and a neutral emotional state.

"Helpful Hopefulness: The Positive Impact of Hope on Self-Control"

Karen P. Winterich, Texas A&M University, USA

Kelly L. Haws, Texas A&M University, USA

If you receive an "A" on an exam and feel hopeful about your future class performance will your self-control differ than if you experience happiness from receiving this "A"? We propose that the characteristics of specific positive emotions influence whether positive affect increases or decreases self-control. For some time researchers utilized a global category of "happiness" to cover all positive emotions, but recent research has differentiated positive emotions, finding critical differences (Siemer et al. 2007). Some research finds that positive mood can stimulate eating (Macht et al. 2002) and lead individuals to feel both unconstrained and deserving (Rook and Fisher 1995). However, research also suggests that positive affect may enhance self-control (Raghunathan and Trope 2002), particularly when no mood maintenance goal is accessible (Fishbach and Labroo 2007). Given these divergent findings, we focus our investigation on impact of incidental hope in contrast to other incidental positive emotions on self-control.

Hope is a positively-valenced emotion evoked in response to an uncertain but possible goal-congruent outcome, which results in a determination to find pathways to achieve goals (Lazarus 1991; Snyder et al. 1991). The goal-driven characteristics of hope (de Mello et al. 2007), in combination with the desire to expend effort (Ellsworth and Smith 1988), allow hopeful individuals to overcome obstacles and achieve objectives, which should positively influence self-regulation in that present decisions will be more consistent with the achievement of long-term goals (MacInnis and de Mello 2005). Therefore, we argue that hopeful individuals will demonstrate greater self-control than those in a neutral state.

In our first two studies, we used a two-factor between subjects design with either hopeful or neutral emotion manipulations, in which participants wrote about something that makes them most hopeful or their typical evening (neutral condition). In study 1, participants were given a bowl containing 50 grams of pretzels (2.5 servings) at the start of the emotion induction which was said to be a thank you for completing the studies. Pretests suggested the pretzels were perceived as hedonic enough to enact self-control mechanisms. Remaining grams of pretzels were measured at the end of the study. An ANCOVA including the emotion condition with time of day and gender as covariates indicated that those in the hopeful condition ate significantly fewer pretzels than those in the neutral condition.

In study 2, participants indicated their willingness to pay for a movie pass and a restaurant gift card at the present time and six months in the future with the order of both products and timeframe counterbalanced. The premium was the dependent measure, previously used as a proxy for self-control (Fujita et al. 2006). ANCOVA analyses revealed that the premiums participants were willing to pay to speed up consumption differed by emotion condition, such that those who were hopeful demonstrated enhanced self-control as expressed by a smaller premium to speed up consumption than their neutral counterparts. Across domains of eating and spending, hope appears to increase self-control. How is this effect related to other distinct positive emotions, as research has suggested positive affect can decrease self-control?

Pride is a positively-valenced self-conscious emotion, derived from known accomplishments, and as such is more present and inward focused than hope (Ellsworth and Smith 1988). This focus on one's achievements may lead one to feel worthy or deserving of present indulgence, resulting in decreased self-control in unrelated domains (Baumeister and Exline 1999; Giner-Sorolla 2001). As such, when individuals feel they have accomplished a goal, pride may provide a license to indulge in other areas. Overall, we anticipate that pride will decrease self-control relative to hope.

In study 3, participants were randomly assigned to one of three emotion inductions: hope, pride, and neutral. Procedures were the same as Study 1 with pretzel consumption as the dependent variable. An ANCOVA including time of day and gender as covariates revealed a significant effect of emotion on pretzel consumption. Follow-up contrasts revealed that hope resulted in less pretzel consumption than either pride or neutral.

Finally, in study 4 we examined product type as a potential boundary condition. We chose two products that clearly differed in hedonicness (raisins and M&Ms) and allowed participants the opportunity to consume either or both of these snack foods. We anticipated that emotion would impact the consumption of the hedonic M&M option but not raisins. We focused our investigation on hope in contrast to another positive emotion, happiness. The effect of emotion condition was moderated by product type such that participants in a happy state consumed a larger portion of the hedonic food than those in a hopeful state but there was no difference in consumption of the less hedonic food between emotion states.

Together our experiments demonstrate that specific positive emotions can differentially impact a consumer's ability to exercise self-control. Hope tends to increase self-control relative to other positive emotions such as pride and happiness. Replicating the effect both with eating and spending enhances our confidence in the generalizability of these findings. The uncertain, future outcome associated with the emotion of hope along with a focus on more situational factors contrasts with the certain, self-focused, and past-oriented outcome that engenders feelings of pride and happiness. These differential effects of positive emotions on goal-relevant behaviors are important given the current lack of control individuals' exhibit (Baumeister et al. 2007).

“Differentiating the Psychological Impact of Threats to Hope and Hopefulness”

Gergana Y. Nenkov, Boston College, USA

Deborah MacInnis, University of Southern California, USA

Maureen Morrin, Rutgers University, USA

Recent work identifies hope (the degree to which one yearns for a good outcome that seems possible even if it might not be likely) as an under-explored and potentially important emotion (e.g., MacInnis and Chun 2007). That same work suggests that hope can be differentiated from an often confused emotion—hopefulness (the extent to which one believes that a positive outcome is actually likely), as these two emotions are not necessarily related and can operate differently. Previous research has not made a distinction between hope and hopefulness, nor has it examined their separate behavioral effects.

In this paper we investigate the effects of both hope and hopefulness on consumers' decisions and actions related to retirement investing. For this purpose we ran a field experiment where 272 real world consumers had to decide 1) whether to invest in a 401(k) retirement plan offered by their employer and 2) how to allocate their money across eight available mutual funds. We first measured participants' current levels of hope and hopefulness for having enough money to retire. Hope was measured by asking

respondents about their desire to retire with enough money, the importance of having a financially secure retirement for their psychological well-being, and the pleasure that this outcome would give them. Hopefulness was measured by asking participants to assess the likelihood of having enough money to retire using a scale of 0% to 100%.

Participants were then randomly assigned to one of two experimental conditions: a control condition, in which current levels of hope and hopefulness were not manipulated but only measured and a condition, in which hope and hopefulness were threatened. Specifically, in the threat condition, respondents read a document indicating that recent reports have revealed that the likelihood of attaining a secure retirement is worse than they thought since many experts now agree that Americans are doing an even worse job of saving for retirement than the industry typically proclaims. In the control condition they read a similar document, but it presented neutral information that stated that the likelihood of attaining a secure retirement is unchanged and that prior projections about Americans' retirement saving are correct and consistent with their likely need.

After reading this information, participants had to decide whether to invest in a hypothetical 401(k) plan offered by their employer. Respondents were shown detailed descriptions of eight mutual funds with various levels of risk and return. They were then asked to indicate what portion of the \$15,500 they are allowed they would actually invest, and how they would allocate the money across the eight funds. After they made their allocations, participants' information search patterns were measured by asking them to check all the funds they had considered investing in, whether or not they actually invested in them.¹

Influence of prior levels of hope and hopefulness. First, the correlations of participants' hope and hopefulness with their psychological traits and investment decisions were examined. Analysis, performed in the control condition of the experiment, where prior levels of hope and hopefulness were not manipulated, revealed that strong hope and strong hopefulness for retiring securely tend to be related to different consumer traits and characteristics.

Overall, stronger hope seems to be related to less rational behavior. Results revealed that participants with higher hope seem to have more anxiety about investing and search for more information before making a decision—perhaps because they are less experienced with investment decisions. They think about the consequences of their decisions to a greater extent and seem to be slightly more risk averse in general. Paradoxically, they tend to expect a higher return from their investments, but tend to invest more conservatively. Stronger hopefulness, on the other hand, seems to be related to more rational behavior. Participants with higher hopefulness are more knowledgeable about investments, less risk averse, and more optimistic. They find the investment decision less difficult and are more satisfied with it once they have made it. In sum, these individuals seem to have more peace of mind with their decisions—yet they take more risks.

Influence of threats to hope and hopefulness. Results revealed that threats to hope and threats to hopefulness have different effects on consumer's responses to the investment scenario. Specifically, threats to hopefulness were found to affect 401(k) participation rates. Compared to the control condition, threatening hopefulness increased the likelihood of joining a 401(k) plan for those with high

¹Next, we administered manipulation and confound checks, measured several individual traits (optimism, consideration of future consequences, risk aversion, and knowledge about investing), and collected demographic information.

initial levels of hopefulness. However, people with low initial levels of hopefulness, who were slightly less likely to enroll in the control condition, reduced their participation rates even further as a result of the threat. It seems that threatening individuals' high hopefulness motivates them to constructive action, such as enrolling in the proposed plan, while this threat backfires for people who are less hopeful. This result is consistent with past research, which has suggested that hopefulness is a major condition for motivation and action (MacInnis and Chun 2007).

Threats to hope impacted different aspects of the investment decision process by affecting the extent of information search and risky decision making. First, when people's strong hope was threatened they searched for more information regarding investment choices by considering more mutual funds and more asset classes, compared to participants in the control condition. It seems that when the hoped for outcome is seen as less likely, people increase their efforts to find information confirming the possibility of the outcome. These findings are consistent with past research that argued that the amount of information search is affected by the extent to which information supports the possibility of achieving the goal (de Mello, MacInnis, and Stewart 2007).

Threats to hope were also found to affect the level of risk participants were willing to take. Even though people with stronger hope were more risk averse in the control condition, when their hope for a secure retirement was threatened, they allocated more money to the riskier stock funds and less to the risk-free money market fund. These findings are consistent with a previously untested hypothesis that strong yearning for an outcome makes people willing to bear more risk in order to achieve this outcome (MacInnis and de Mello 2005).

These results underscore the value of differentiating the construct of hope from the construct of hopefulness and also reveal the differing psychological impact of threats to each of these constructs. Findings from this project are likely to have important implications for the design, presentation, and communication of defined-contribution retirement plans and financial products in general, and for the growing practice of developing investor education programs and campaigns targeted at improving investment practices and boosting retirement savings.

SPECIAL SESSION SUMMARY

Why Reproduction Involves More Than Sex: The Diverse Effects of Mating Motivation on Consumer Behavior

Vladas Griskevicius, University of Minnesota, USA

SESSION OVERVIEW

Consumer behavior is often thought to have little to do with evolution or biology. After all, our ancestors did not shop at Wal-Mart, we do not have genes for preferring Coke over Pepsi, and consumers rarely consider how a purchase helps propagate their genes. Emerging research at the intersection of evolutionary biology and cognitive science, however, shows that our evolved social motivation systems have important implications for modern consumption and decision-making. The papers in this session examine how activation of the most evolutionary-critical social motivation system—the mating system—influences consumer behavior.

From an evolutionary perspective, social motivation systems have been shaped by natural selection to produce behaviors to increase reproductive fitness. For any social animal, including *Homo sapiens*, reproduction involves a great deal more than sex. Because successful reproduction is influenced by a wide variety of behaviors (many of which are not overt acts of sexual reproduction), recent research demonstrates that mating motives operate across a remarkably diverse range of behavioral outcomes, including conspicuous consumption, aggression, altruism, conformity, and creativity. The first two papers in this special session investigate how sexual cues influence risky financial decisions and the desire for distinctiveness. The last paper presents a field study that examines how mating motives vary as a function of the ovulatory cycle, showing how women's hormonal changes across the cycle influence tipping.

Van den Bergh, Millet, and Griskevicius examine how mating motivation influences financial risk-taking and intertemporal choice. They find that exposure to sexual cues leads to a preference for smaller but certain monetary rewards, over larger but uncertain monetary rewards. Berger and Shiv examine how the mating motivation system shares features with other evolved systems such as hunger. They find that exposure to sexual images or activation of hunger has similar effects, such as increasing desire for distinctive goods and choices. Miller examines how mating motivation varies as a function of the female ovulatory cycle. In a unique field study conducted in gentlemen's clubs, he finds that lap dancers earn significantly more money in tips specifically when they are most fertile in their ovulatory cycle.

After the three papers, Griskevicius will lead a 20-minute discussion. The first part of the discussion will integrate the three talks. The second part will be a broader audience-involved discussion of the strengths and weakness of evolutionary approaches to studying behavior. For this broader discussion, Griskevicius will be joined by Dr. Miller (the third presenter). Miller is a renowned world expert on evolution and consumer behavior. He has written a best-selling book on evolution (*The Mating Mind*, 2000) and has a forthcoming book on evolution and consumer behavior (*Spent: Sex, Evolution, and Consumer Behavior*, May 2009). The proposed session would be of interest to a breadth of consumer researchers, and of special interest to those interested in field experiments, motivation, nonconscious processes, mating and sex, evolutionary theory, and hormonal influences on consumption. We hope that this session will spur discussion, debate, and ideas for further research.

EXTENDED ABSTRACT

“Sex, Certainty, and Financial Risk: Why Bikinis Lead People to Want a Sure Thing”

*Bram Van den Bergh, K.U. Leuven, Belgium
Kobe Millet, K.U. Leuven, Belgium; Free University Amsterdam,
the Netherlands*

Vladas Griskevicius, University of Minnesota, USA

After touching lingerie, rather than a T-shirt, men have a heightened preference for immediate, but small monetary rewards rather than delayed, but large monetary rewards (Van den Bergh, Dewitte, and Warlop 2008). Temporal discounting might arise because with longer delays, there is a greater risk that the expected or promised reward will not be received. Delayed benefits may be lost during waiting time and less likely to be realized. In this research, we propose that the tendency to devalue temporally distant outcomes (‘temporal discounting’) is driven by the tendency to devalue improbable outcomes (‘probability discounting’). Indeed, the distinction between the present and the future can be conceptualized as the certainty of the former and the inherent uncertainty associated with the latter. We hypothesize that exposure to sexual cues should lead to a disproportionate increase in the desire for sure gains.

Researchers have suggested that the discounting of subjective value produced by delay and by probability are fundamentally the same process (e.g., Halevy 2008). Indeed, individuals who value immediacy (e.g., “I’d rather get \$1 immediately than \$2 tomorrow”) tend to value certainty (e.g., “I’d rather get \$1 for sure than \$2 with 50% probability”) (Frederick 2005). If discounting of value produced by delay and probability are fundamentally the same process, exposure to sexual cues should not only lead to a preference for immediacy (Van den Bergh et al. 2008) but also to a preference for certainty. In three experiments, we obtained evidence for the hypothesis that activating mating motivation produces risk aversion in the presence of sure gains.

In the first experiment, we hypothesized that mating motivation would instigate a preference for a smaller, more certain reward over a larger, more risky reward. After exposure to sexual cues, proposers in an ultimatum game should be more likely to make higher, more fair offers to responders, as fair offers are less likely to be rejected. Consistent with our hypothesis, we found that proposers made significantly higher offers after exposure to pictures featuring sexy women dressed in a bikini (rather than pictures featuring women in casual clothes). Upon sex cue exposure, proposers in an ultimatum game maximized the likelihood of a reward rather than the size of the reward.

In the second experiment, we predicted that individuals would prefer a smaller, certain reward (\$1 for the self, \$1 for the anonymous other) rather than trusting an anonymous individual who could increase the size of the reward (\$2 for the self, \$2 for the anonymous other), but who could also take away the reward (\$0 for the self, \$3 for the anonymous other) (i.e., trust game). The results confirmed the hypothesis that sexual cues instigate risk aversion: After exposure to pictures featuring sexy women (rather than

pictures featuring women in casual clothes), individuals preferred a smaller, certain monetary reward over trusting an anonymous individual, thereby giving up the chance of a larger, but more uncertain reward.

In the third experiment, we tested our hypothesis more directly by using an ecologically valid manipulation. We offered individuals several choices between a smaller, certain reward and a larger, uncertain reward (e.g., receive \$1000 for sure versus flip a coin and receive \$2000 if heads or \$0 if tails). After exposure to a female experimenter in sexy attire, individuals were more likely to choose the smaller, certain reward.

These experimental studies suggest that mating motivation leads to a disproportionate increase in the desire for sure gains, so that seeking risky alternatives is decreased. These findings are consistent with the Somatic Marker Model (Bechara and Damasio 2005), which predicts that when one is in a positive state (i.e., after exposure to sexual cues), risk aversion in the face of sure gains is enhanced. Neuroscientific observations are also consistent with our results: Increased activation of the amygdala, a brain structure highly responsive to sexual cues, is associated with the tendency to be risk-averse for sure rewards (De Martino et al. 2006). These findings potentially explain why men devalue delayed monetary rewards after touching lingerie (Van den Bergh, Dewitte, and Warlop 2008): Because there is a greater risk that the delayed reward will not be received, men prefer immediate, certain rewards upon sex cue exposure.

"Sex, Food, and the Hunger for Distinction"

Jonah Berger, University of Pennsylvania, USA

Baba Shiv, Stanford University, USA

Similarity and distinction play an important role in identity processes, decision making, and motivation more broadly. People avoid giving their children names that are too popular and buy clothes that let them fit in, while also feeling unique. Indeed, researchers have long noted that while the strength of these motives varies across individuals and cultural-contexts, people have a need for distinction (Brewer, 1991; Snyder and Fromkin, 1980).

The exact nature of this "need," however, is less clear (Vignoles et al. 2000). Most existing research has treated distinction as a secondary motive, valued only as it enhances self-image and contributes to self-enhancement (Lynn and Snyder, 2002; Tian, Bearden, and Hunter 2001). Another perspective, however, argues for the intriguing possibility that distinctiveness may be a fundamental human need (Brewer, 1991; Vignoles et al. 2000). This debate has important implications for understanding the role of

distinctiveness in identity processes, but lack of empirical tests has made it hard to reach any conclusions.

We examine the nature of distinctiveness by testing whether it shares kinship with other basic rewards arising from physiological needs such as mating motives. To do so, we turn to recent work on motivation. Physiological drives (e.g., sex) can increase the desirability of relevant reward stimuli, but this link can also work in the opposite direction, such that reward stimuli can themselves strengthen relevant drive states. Further, by activating dopaminergic reward systems, such stimuli can increase reward responsiveness more generally (Van den Bergh, Dewitte, and Warlop, 2008; Wadhwa, Shiv and Nowlis 2008).

If similarity and distinction share kinship with basic physiological drive states such as mating, then they should have similar motivational properties. To the extent that distinctiveness is rewarding, exposure to basic reward cues should influence the desirability of distinction. Sexually arousing images, for example, ought to influence preferences for distinctive goods. Conversely, manipulations that activate distinctiveness should have corresponding effects on the desirability of basic physiological rewards. Priming distinctiveness, for example, should influence people's desire for romantic partners.

Five experiments test these possibilities. First, we examine whether exposure to sexual cues or a strong desire for food influences the desirability of distinctive products. In Study 1, participants were approached either right after they had eaten dinner or right before (when they were hungry). In Study 2, we built on prior work in indicating that sexual images activate reward circuitry (Aharon et al. 2001) and exposed participants either swimsuit model or control pictures. We then asked participants in each study to choose amongst options that varied in their distinctiveness (i.e., some had been selected by prior participants, or were preferred by a greater percentage of others). As predicted, differences in basic physiological needs influenced preferences for distinction. Study 1 found that hungry participants (those approached before dinner) were more likely to avoid options selected by another participant ($M=4.12$ vs. 3.35 ; $F(1, 36)=6.25$, $p=.02$). Study 2 found that participants exposed to sexual images preferred more distinctive options (2.20 vs. 1.88 ; $F(1, 58)=11.34$, $p<.001$).

The first two studies illustrate that activation of basic physiological drives such as mating can influence preferences for distinction, but if distinctiveness is truly a basic human need, the effects should work in the opposite direction as well. Distinctiveness itself should influence the desirability of other reward stimuli. The next two studies tested this possibility by priming half the subjects with distinctiveness and then measuring the desirability of other rewarding stimuli. As predicted, (Study 3) priming participants with distinctiveness increased the desirability of other rewards such as romantic encounters and led participants to reporting willingness to walk more blocks to get their favorite food ($M=12.28$ vs. 7.82 ; $F(82)=4.56$, $p=.04$).

The last study provides further evidence for our conceptualization by examining whether the observed effects would reverse for cultural groups (East Asians) who find assimilation (rather than distinctiveness) rewarding. Using a similar set-up to Study 2, participants were exposed to either swimsuit models or control images and we measured their preference for distinctive products while also recording their cultural background. As expected, exposure to other reward cues had opposite effects on European Americans and East Asians participants, ($F(1, 73)=13.33$, $p<.001$). Compared to the control condition, a general appetitive state increased the choice of distinctive products among European Americans ($F(1, 73)=12.12$, $p<.001$) but it decreased the choice of

distinctive products for East Asians ($F(1, 73)=5.37, p<.05$). Taken together, these results suggest that distinction has similar motivational properties to other basic needs such as mating. The findings provide insight into the nature of distinctiveness and its motivational effects more generally.

"What Marketers Can Learn From Lap-Dancers: A Field Study of Ovulatory Cycle Effects on Consumer Behavior"

Geoffrey Miller, University of New Mexico, USA; Queensland Institute of Medical Research, Australia

Evolutionary psychology has revolutionized our understanding of human female sexuality in the last 15 years. This new research has profound implications for understanding women's consumption patterns and preferences, but it remains almost unknown to the consumer research community.

In particular, dozens of papers have found that women of reproductive age (c.15 to 40) think, feel, and behave quite differently depending on whether they are in the menstrual, follicular, estrus, or luteal phases of their monthly cycle. This work has overturned the century-long assumption that human females uniquely had 'lost' estrus. Estrus is the phase around ovulation (maximum fertility) of increased sexual receptivity, increased sexual attractiveness to males, and increased sexual attraction to males who show signs of high genetic quality. Female estrus now appears to be universal across all vertebrate species such as the 10,000 birds and 5,400 mammals, including all 394 primates such as humans (Gangestad & Thornhill, 2008).

This talk reviews the evolutionary logic of estrus and previous research on ovulatory cycle effects in women, presents some striking new example of cycle effects on cash earnings by lap-dancers working in gentlemen's clubs, and discusses implications of this research program for understanding women's behavior as both consumers and marketers.

The evolutionary benefits of estrus arise from sex itself. In sexually reproducing species, two individuals combine their genes to produce offspring, so the genetic quality of one's mate determines half the genetic quality of one's offspring—and thus their likelihood of surviving and reproducing in turn. Thus, in the 530 million years that nervous systems have been evolving, one of their key jobs has been to prefer good mates with good genes—the oldest version of a consumer preference for a luxury good. The stakes are especially high for female mammals, who invest more energy in parental care throughout pregnancy and breast-feeding, and who therefore cannot produce as many offspring per lifetime as a highly

promiscuous male. So, females evolved to be choosier about their sexual partners, and to be especially choosy when they might actually get pregnant from a sexual encounter—i.e. just before ovulation, during estrus. Previous research has now shown that women during estrus compared to other phases of the cycle do show stronger preferences for males who are healthier, taller, more athletic, more muscular, more masculine-looking, more socially dominant, and more creative, whether painting works of art or launching start-up companies (Haselton & Miller, 2006).

Ovulatory cycle effects are not limited to women's preferences; they also affect women's sexual attractiveness. Given that fertile females had to compete against each other for the attentions of the few highest-quality male sires (whose own long-term partners resented infidelity), women evolved to be maximally attractive during estrus, when it was most important to 'poach' the good genes. Previous lab and questionnaire research has shown that women during estrus compared to other cycle phases are indeed more attractive to men with regard to body scent, voice quality, facial appearance, breast symmetry, waist-to-hip ratio, verbal fluency, self-confidence, mental health, and overall mood. Also, women in estrus dress in more stylish and revealing clothing, travel more miles per day, go out more often at night to crowded night-spots, have more sexual fantasies about men other than their current boyfriends or husbands, receive more cell phone calls from jealous boyfriends, and have more actual one-night stands and affairs.

Use of hormonal contraception such as the Pill (which eliminates ovulation) eliminates all of these cycle effects on women's mate preferences, sexual attractiveness, mate search effort, and short-term mating. Conversely, dissatisfaction with a current long-term mate (boyfriend or husband) seems to amplify all of these effects.

However, it was not clear whether women's estrus shifts in attractiveness cashed out in the real world of women's work as marketers and service providers. To investigate the economic effects of estrus, my colleagues and I examined ovulatory cycle effects on earnings by professional lap dancers working in Albuquerque gentlemen's clubs. Eighteen dancers recorded their menstrual periods, work shifts, and cash earnings for 60 days each on a study web site. Hierarchical linear modeling of the data (representing earnings from about 5,300 lap dances) showed main effects of cycle phase [$F(2, 236)=27.46, p<.001$] and Pill use [$F(1, 17)=6.76, p<.05$], plus the expected interaction between cycle phase and pill use [$F(2, 236)=5.32, p<.01$]. Normally cycling dancers (those who did not use the Pill, and thus had an estrus phase) earned about \$335 per 5-hour shift during estrus, \$260 per shift during the luteal phase (after ovulation) or the early follicular phase (before ovulation), and \$185 per shift during menstruation. By contrast, dancers using the Pill showed no estrus earnings peak, but did show the menstrual-period drop. Also, Pill use reduced earnings by an average of more than \$80 per shift—more than \$10,000 per year in lost earnings. This is the first economic evidence for the importance of estrus in a real-world work setting.

Taken together, these findings have many implications for consumer behavior research. Since so much of consumer behavior is driven by unconscious mating effort, especially among young single adults (Griskevicius et al., 2007; Miller, 2009), cycle effects may profoundly influence women's consumer behavior. If estrus affects women's mate preferences regarding male height, facial features, body types, social dominance, and creativity, it may also shift their consumer preferences regarding the appearance and behavior of male service providers, entertainers, spokesmen, and sales staff. If estrus affects women's scent, voice, appearance, self-image, and mood, it may also affect their consumer preferences

regarding cosmetics, clothing, fitness products, self-help books, and mood-altering products such as chocolate, alcohol, tobacco, and romance novels. Finally, if estrus provokes more travel, going out in the evenings, and sexual affairs, it may affect women's consumer preferences and consumption patterns regarding cars, restaurants, night clubs, movies, hotels, cell phones, and social internet sites. Thus, consumer behavior researchers and marketers could better understand female consumers by routinely measuring their current cycle phase and Pill use, which can be done reliably with a one-page questionnaire.

SPECIAL SESSION SUMMARY
Effects of Social Influence on Consumer Spending Decisions

Didem Kurt, University of Pittsburgh, USA

SESSION OVERVIEW

The majority of research on the effects of social influence in the marketplace has documented the impact of the simple presence or absence of others in a given consumer choice situation (e.g., choice under public versus private settings). Less is known about the impact of the source of the influence and the process of transmission of the influence from the source to the receiver. Although the importance of some sources of influence is readily apparent (e.g., salespersons), consumers may be subject to the social influence stemming from more subtle, unexpected sources as well. This session focuses on these subtle, but powerful, sources of social influence on consumer decisions. For instance, how does the presence of an accompanying friend influence the amount spent? What happens when the influencer is not physically present at the time purchase, but is instead physically associate with the object of purchase (e.g., deciding on how much to pay for objects that were once owned by well-liked or despised individuals)? And finally, how does subtle physical contact by another person influence the type of decisions that a consumer makes? The goal of this session is to present papers that address these subtle, incidental sources of social influence on consumer decision-making.

The three presentations also look at different degrees of connectedness between the consumers and the influencer. The first paper (by Kurt, Inman, and Argo) examines whether the presence of a friend can create an unintentional financial cost to the consumer when in the marketplace. They show that consumers spend more when they shop with a friend compared to when they shop alone and that individual differences in consumers' agency-communion orientation and self-monitoring moderate the relation between an accompanying friend and consumers' spending. The second paper (by Argo and Levav) examines how a gentle, open-palmed touch affects individuals' feeling of security and financial risk-taking propensity. They find that such a touch on the shoulder generate higher risk-seeking. Finally, the third paper (by Newman, Diesendruck, and Bloom) focuses on the case where the influence is transmitted through the object considered to be purchased by the consumer rather than a direct connection between the influencer and the consumer. Specifically, they examine why celebrity objects are valued and whether consumers value the items once owned by disliked figures for the same reasons that they value those previously owned by liked figures. They find that a contagion model can better explain the valuation of objects previously owned by liked people, whereas presumed marketability of items previously owned by disliked people is the sole driver of their valuation.

Collectively, the three papers in this session will provide new insights regarding psychological mechanisms underlying the process of social influence shaping consumers' decision making. The set of papers should lead to an interesting discussion regarding subtle and unexpected social influence in the market place (e.g., negative and unintended consequences of shopping with a friend). In addition, we believe that the variation in the degree of connection between the influencer and the consumer examined in the papers will lead to a lively session. We expect this session to generate considerable interest among ACR members because the papers draw upon a variety of theoretical perspectives (agency-communion theory, law of contagion) and the studies range from lab experiments (Newman et al., Argo and Levav) to field studies (Kurt et al.) to analysis of secondary data sets (Kurt et al.).

EXTENDED ABSTRACTS

“How Friends Promote Consumer Spending”

Didem Kurt, University of Pittsburgh, USA

J. Jeffrey Inman, University of Pittsburgh, USA

Jennifer Argo, University of Alberta, Canada

It is well-established in the literature that social influences play a pervasive role in shaping consumers' affect and behaviors (e.g., Argo, Dahl, and Manchanda 2005; Dahl, Manchanda, and Argo 2001). For instance, while high levels of attractiveness and persuasiveness of a salesperson have been shown to enhance the effectiveness of an influence attempt (e.g., Argo, Dahl, and Morales 2008; Doney and Cannon 1997), high levels of persuasion knowledge and cognitive capacity of consumers have been shown to inoculate them from such an influence (e.g., Campbell and Kirmani 2000). However, not all occurrences of influence may be intentionally inflicted, and as such, it seems likely that consumers may not always be prepared to draw from their repertoire of protective strategies to shield themselves from the influence. An example of such an occurrence may be when the social influence arises from an unexpected source such as the presence of individuals for whom the consumer cares about (i.e., our friends). The goal of this research is to examine whether an accompanying friend in the marketplace can create an unintentional cost to the consumer.

Previous research has shown that friends can be influential, serving as not only sources of product information (e.g., Urbany, Dickson, and Wilkie 1989) but also through their activation of impression management concerns on the part of the consumers (e.g., Childers and Rao 1992). For instance, Ratner and Kahn (2002) demonstrate that consumers seek more variety in public (versus private) contexts as they expect others to evaluate a varied set as more interesting. Thus, we predict that consumers spend more when they shop with a friend as compared to when they shop alone.

Furthermore, we argue that the direction of consumer spending is moderated by consumers' agency-communion orientation (i.e., the tendency to focus on the self or others; Bakan 1966). Specifically, we predict that agentic consumers (i.e., males) spend more when they shop with a friend than when they shop alone, whereas communion consumers (i.e., females) are more likely to control their shopping in the presence of a friend. This prediction is consistent with “feminine modesty effect” (e.g., Heatherington et al. 1993) suggesting that in response to normative pressures, females are more likely to be modest in public versus private contexts. In contrast, society deems it acceptable for males to engage in self-promotion (Griskevicius et al. 2007). Finally, given that consumers differ in their responsiveness to interpersonal cues of situationally appropriate behavior (Gangestad and Snyder 2000), we argue that this interactive effect is moderated by self-monitoring such that friends are especially influential for consumers who are high in self-monitoring despite their orientation, albeit the effects occur in opposite directions (i.e., agentic (communion) consumers spend more (less) in the presence of a friend).

In Study 1, we use the data provided by the Point of Purchase Advertising Institute (POPAI). In-store intercept interviews were conducted at 14 mass merchandise stores. Consumers were intercepted randomly as they entered the store and were asked several questions, including how much they planned to spend in the store. After respondents finished shopping, they returned for the exit

interview. Agency-communion orientation was operationalized as gender (78% of 1,208 respondents were female). We estimated a model with OLS regression where the dependent variable was the amount spent and the main independent variables were the amount planned to be spent, social influence categories (indicator variables for being accompanied by friend, spouse, etc.), gender and social influence*gender interactions. We found a significant main effect for friend ($\beta_2=0.12$, $p<.05$) and a significant friend x gender interaction ($\beta_{18}=0.15$, $p<.01$). Specifically, male (i.e., agentic) consumers spend 56% more when they shop with a friend than when they shop alone, while female (i.e., communion) consumers spend 4% less when they shop with a friend than when they shop alone, albeit this latter difference is not statistically significant.

Study 2 employs a 2 (orientation: agency vs. communion) x 2 (social presence: alone vs. accompanying friend) between-subjects design. 87 students (51% female) completed the study. Orientation was operationalized as gender. We manipulated the friend's presence via a trained confederate assuming the role of a friend that is present during the shopping trip. Participants were given \$5.00 and asked to purchase a package of four AA batteries at the bookstore. After categorizing the brands into three groups based on price level, we ran an ordered logistic regression with price level as the dependent variable. We found a significant main effect for friend ($\beta=0.81$, $\chi^2=11.64$, $p<.01$). Importantly, the analysis revealed a significant friend x gender interaction ($\beta=0.65$, $\chi^2=7.58$, $p<.01$), suggesting that the probability of a male (female) consumer choosing a more expensive brand is greater (attenuated) when a friend is present as compared to when the consumer is alone.

Finally, in Study 3, we conducted a field study where customers were intercepted as they entered a shopping mall in Turkey. Only customers who were either shopping alone or accompanied by a single friend were invited to participate in the study (52% of 126 respondents were female). In this study, the exit survey also included scales measuring agency/communion and self-monitoring individual differences. By conducting OLS regression where the dependent variable was the amount spent, we found a significant main effect for friend ($\delta_2=0.14$, $p<.05$). The interaction between friend and ACDIF (difference between a respondent's agency and communion scores) was also significant ($\delta_{13}=0.27$, $p<.05$). Furthermore, there was a significant three-way interaction between friend, ACDIF, and self-monitoring ($\delta_{16}=0.30$, $p<.05$). The results support our prediction that agentic (communion) consumers who are high in self-monitoring spend significantly more (less) in the presence of a friend.

Our findings suggest that the friend effect has the greatest implications for agentic consumers (i.e., males) because shopping with a friend is likely to have negative ramifications for their pocketbook—they spend more and tend to buy the most expensive brand with an accompanying friend. However, this caveat does not appear to hold for communion consumers (i.e., females). In fact, communion consumers who are high in self-monitoring spend significantly less when they shop with a friend than when they shop alone.

“Once More, With Feeling: The Effect of Touch on Risk-Taking”

Jennifer Argo, University of Alberta, Canada

Jonathan Levav, Columbia University, USA

Physical contact is a fundamental aspect of both the human and other mammalian experience. It is the cornerstone of the connection between mother and infant, and is the most primitive form of interpersonal expression. Among its many effects, touch can increase people's likelihood of accepting requests (Kleinke 1977)

and can be used to communicate status (Mehrabian 1970). In this paper we focus on an aspect of touch whose effect originates in the earliest moments of life: touch as a source of security.

In his classic experiments on the nature of love, Harlow (1958) shows that infant monkeys can become attached to a “mother” made of soft cloth that the infant monkey likes to touch, but not to a “mother” made of wire that he does not. According to Harlow, infant monkeys placed in a room with the soft mother use “her” as a base of operations and source a source of security, and are more likely to explore stimuli around the room. This is not the case for the untouched, wire mother. The connection between touch and security at infancy and exploratory behavior is even more apparent in Ainsworth's (1978) strange situation paradigm, wherein young children are placed in a room with strange stimuli and are left to explore on their own. Children with stronger attachment patterns—physical and otherwise—are more likely to engage in exploratory behavior.

In this paper we argue that certain forms of touch can similarly increase consumers' sense of security and in turn lead them to engage in similar form of exploratory behavior. Specifically, we study how touch affects financial risk taking. Our prediction is partially drawn from work by Hsee and Weber (1999) that shows that Chinese are more willing to take financial risks because of their strongly interdependent culture provides a measure of security should their risk fail. Hsee and Weber call this “the cushion hypothesis,” as the potential fall is cushioned by the tight social network that is characteristic of Eastern cultures. Although in the Hsee and Weber studies the sense of security experienced by Chinese participants is real, in our study the sense of security is perceived, rather than actual (more below).

The touch that we focus on in our studies is an open-palmed, comforting light pat on the shoulder. We present three experiments with both hypothetical as well as real payoffs.

In our first study participants are greeted by an experimenter and are either verbally ushered to a table where the experimental task awaits or are verbally ushered and touched lightly (not pushed!) on the shoulder. The experiment was run individually for each participant; this was the case for the next two studies as well. The experimenter was a mildly attractive female. The experimental task was taken directly from Hsee and Weber (1999) and consisted of a series of choices between sure, low payoffs and risky, higher payoff gambles. We find that participants in the touch condition were significantly more likely to accept the riskier gambles (i.e., they showed greater risk tolerance). We find no interaction with gender; both male and female participants were equally influenced by the experimenter's touch (this was a consistent finding in all three studies and will not be discussed further).

In our second study we contrasted different security-evoking and non-security-evoking forms of touch and tested whether a measure of sense of security could mediate our effect. To this end, in addition to our no touch and shoulder touch conditions, we also added a handshake condition wherein the experimenter greeted the participants with a handshake also prior to presenting the experimental task. Based on previous research, we reasoned that a handshake would not provide the same perceived sense of security as a touch on the shoulder, and that as a result we would not see elevated levels of risk taking in the handshake condition. The task this time was an investment decision wherein participants were given \$10 in cash and received financial data about an unnamed publicly-traded company. They were then given a choice between investing all or some of the \$10 in the company's stock (to make matters more realistic, each \$1 in cash was made equivalent to \$100) and investing the money in a government bond with a fixed

payoff. The payoff for the stock investment was probabilistic and was based on the company's financial performance. Participants kept their winnings. Having completed the investment task, participants then completed a battery of measures to assess their mood and feelings of security. We find that participants were significantly more likely to invest their money in the riskier equity in the shoulder touch condition than in either the no touch or handshake conditions. There were no differences in mood between conditions, suggesting that affect does not drive our effect. Importantly, however, we do find that feelings of security mediate people's propensity to take risk and invest in the risk equity.

Finally, in the third study we further probed the role of perceived security using a manipulation approach. Participants were either asked to write about a situation in their past where they felt insecure or a situation where they felt secure. They were then sent to a different room, where a mildly attractive female experimenter either touched them on the shoulder or not as in the previous two studies. The task was the same investment decision as in study, again with a real monetary payoff. We find that participants in the insecure essay conditions made riskier choices if they were touched versus not touched. The levels of risk taking in the insecure essay/touch condition were equally high to those in either of the secure essay conditions. The interaction is significant. In other words, touching participants in the insecure essay condition reversed the effect of insecurity on people's risky choices, making them more risk-seeking.

"Celebrity Contagion and the Value of Objects"

George Newman, Yale University, USA

Gil Diesendruck, Bar-Ilan University, Israel

Paul Bloom, Yale University, USA

Artifacts are usually valued because of their utility—a watch tells time, a coat provides warmth, and so on. But, in some cases, they also get value by dint of their histories. People have paid large sums of money for a tape measure owned by President Kennedy, an autograph by astronaut Neil Armstrong, and the pop star Britney Spears' chewed-up bubble gum (see Bloom and Gelman 2008; Hood and Bloom 2007). Curiously, there is also a substantial market for items once belonging to despised individuals, such as Charles Manson's hair, a painting by John Wayne Gacy, and the personal effects of Saddam Hussein (Stone 2007). Why are these celebrity objects valued? And, do people value 'negative' celebrity items for the same reasons that they value 'positive' ones?

One explanation is that these objects are valued because of their associations. Objects that were owned or touched by specific people remind us of those people. This captures the fact that objects associated with admired individuals are positively valued, however it predicts as well that objects belonging to individuals that are explicitly disliked should carry no value at all.

A second account has to do with intuitions about how these objects are valued by others. For instance, we might value objects that belonged to celebrities because we believe that there are other people who would later purchase them from us at higher prices, or because others would be impressed that we own such things.

A third account is rooted in "the law of contagion" (Frazer 1959; Mauss 1972; Rozin et al. 1986). This is the belief that through physical contact, a person's immaterial qualities or 'essence' can be transferred to an object. For example, people are reluctant to purchase a t-shirt if it was just tried on by someone else (Argo, Dahl, and Morales 2006), but they are more likely to purchase a product if it came into contact with someone attractive (Argo, Dahl, and Morales 2008). This provides a potential explanation for why people value objects that have been touched by admired people,

though it fails to explain the appeal of objects that have been in contact with despised individuals.

The goal of the present studies was to explore these alternative accounts. Experiment 1 recruited 219 adult participants ($M_{\text{age}}=35$). Using a method similar to Nemeroff and Rozin (1994), participants first were asked to list the name of either a person that they deeply admired or a person that they despised. Participants were then asked report the maximum amount of money they would be willing to bid on an item that belonged to the person they had just listed. After reporting this initial amount, participants in both conditions were asked on subsequent pages to imagine that the object was "transformed" in several different ways. The transformations included sterilizing the object such that no physical traces of the previous owner remained, purchasing the object with the stipulation that they could never resell it, purchasing the object with the stipulation that they could never tell anyone that they owned it, and increasing the number of such objects in existence. Participants again reported their willingness-to-pay for the item in light of each transformation, which was repeated for all four transformations.

Experiment 1 revealed an interaction between the valence of an object, and the effectiveness of a transformation in changing its perceived value ($p<.01$). For items owned by a positive target, sterilizing the object was the only transformation that significantly impacted judgments value ($M=-29.5\%$), $p<.001$. The effects of "can't resell", "can't tell others" and "increase number" were comparatively minimal ($M_s=+10.4\%$, $+0.7\%$, and -9.8% , respectively, all $p_s>.2$, except for a marginal effect of "increase number," which was $p=.064$). In contrast, only the "can't resell" transformation had a significant impact on the negative items ($M=-31.5\%$), $p<.001$, while the effects of "sterilization", "can't tell others", and "increase number" were comparatively minimal (-10.1% , -16.0% , and $+6.3\%$, respectively, all $p_s>.2$). This result suggests a contagion account best explains the value of positive objects, while a market account best explains the value of negative objects. The effect of sterilization, as well as the fact that at least some participants said they would pay money for negative objects, rules out a strict version of the association account.

In Experiment 2 we assessed the interaction between object valence and transformation type more directly by making two changes in the design. First, we included only the two transformations that proved most effective in Experiment 1: sterilization and can't resell. Second, we manipulated these transformations between-, rather than within- subjects. We also included an additional measure regarding participants' willingness to have contact with the object.

Results from 310 new participants ($M_{\text{age}}=33.4$) indicated a significant interaction between valence (positive vs. negative) and transformation type (sterilization vs. can't resell), $p<.001$. Consistent with the results of the previous experiment, sterilizing the "positive" object decreased its value, significantly more than did limiting the ability to resell it ($p<.05$). Conversely, limiting the ability to resell the negative object decreased its value significantly more than did sterilizing it ($p<.05$).

Analysis of willingness-to-wear, however, revealed a different pattern. Sterilizing the 'positive' sweater made participants want to wear it significantly less than did limiting the ability to resell it ($p<.05$). However, sterilizing the 'negative' sweater made participants want to wear it significantly more than did limiting the ability to resell it ($p<.01$).

These experiments suggest that people value objects that have come into contact with famous vs. infamous individuals for different reasons. Valuation of positive objects is best accounted for by a contagion model—these objects are believed to hold some physi-

cal remnant of their previous owner, and people are willing to pay money for the possibility to have contact with such remnants. Objects previously owned by negative figures, in contrast, were valued for their presumed marketability. In cases where negative objects were valued, prohibiting participants from reselling the object significantly decreased the amount of money they were willing to pay for it. Interestingly, while sterilization did not affect participants' willingness to pay, it did affect their willingness to wear a negative object. This finding suggests that while people seem to believe that negative objects contain possibly contagious remnants of their previous owners, these beliefs do not affect people's monetary valuation of objects (also see Rozin et al. 2007).

Previous work on contagion has demonstrated that the belief in a physical transmission of 'essence' is arguably pervasive across cultures (Frazer 1959; Mauss 1972). The present studies offer a new perspective on this phenomenon as they illustrate the ways in which contagion and monetary valuations of objects may either converge, or diverge, depending on the valence of the individual who touched them and the market demands surrounding them.

SPECIAL SESSION SUMMARY
Consumer-Generated Advertising: Creators and Spectators
Burçak Ertimur, Fairleigh Dickinson University, USA

EXTENDED ABSTRACTS

“Consumer-Generated Advertising: Creators and Spectators”

Burçak Ertimur, Fairleigh Dickinson University, USA
Mary C. Gilly, University of California, Irvine, USA

The emergence of consumer-generated advertising (CGA) has greatly affected the advertising landscape by eroding the separation between the producer and the consumer and challenging the traditional view of advertising as non-personal, unidirectional, and paid-for communication (Berthon, Pitt, Campbell 2008). Many companies jumped on the CGA bandwagon; however, the results have been inconsistent (Petrecca 2007), leaving the question of whether the hype of CGA can live up to the standards of traditional advertising unanswered. There has been very limited research on the new concerns brought up by CGA, hindering our understanding of consumers' capabilities in crafting CGAs as well as their perceptions and interpretations of these new types of ads. This symposium explores the phenomenon of CGA from the perspective of both the creators and the spectators through the presentation of three completed empirical studies. The objective of this session is to provide a better understanding of CGA's effectiveness, specifically in terms of its content and communication value, and to stimulate further research exploring the realm of CGA.
