Participants listened to two alternate versions of the same song, released in 1964 and 1967, but were told that another version existed. In the earlier condition, the third alternate version was presumably released in 1962 whereas in the control condition, this third version was presumably released in 1969. We predicted that the 1964 version would be preferred to the 1967 version in the control condition in which the 1964 version could be perceived as being first, but not in the 'earlier' condition in which the 1964 version was preceded by another (1962) version. This pattern of results was obtained. Perceived originality might explain why "earlier" stimuli—which are not the first—are not preferred to subsequent stimuli: only the very first stimulus may truly be considered original.

Study 3 aims to show that indicators of unoriginality have a strong detrimental impact on evaluations when consumers have an 'individualistic mindset', but not when consumers have a 'collectivistic mindset' (hypothesis 3). To test this hypothesis, Study 3 used the same design as study 1b, with one exception. Before seeing the pictures, participants were primed with individualism, collectivism or received no prime. In the no prime condition, we replicated the effect of study 1b, showing that participants rate an 'original' picture more favorably than other participants who were led to believe that that same picture was photoshopped. We obtained the same effect in the individualism condition. However, an unoriginality indicator did not have any effect in the collectivism condition: Evaluations of photoshopped pictures in this condition were as favorable as 'original' pictures in all conditions.

Our research might have practical implications as it shows that the use of originality indicators might be helpful to enhance consumer attraction. After all, we never observed negative effects of originality indicators, only indicators pointing to unoriginality appear detrimental for consumer evaluations. For several product categories, consumers are not able to identify which one is the 'original' or first brand on the market (Alpert & Kamins, 1995; Golder & Tellis, 1993; Kamins, Alpert & Elliott, 2000). For those categories, the potential power of originality indicators is enormous: Our research shows that any given brand/product may profit from the use of some sort of originality indicator to increase its attractiveness. On the other hand, the effect of originality indicators may be diluted as multiple brands are suggesting they are the one and only original. To address this latter issue, more research is needed.

How Do 'Leading-edge' Opinion Leaders Bridge the Innovation Gap? Advancing a New Adopter Category

Salah S. Hassan, George Washington University, USA
Philippe Duverger, Towson University, USA

EXTENDED ABSTRACT

Empowering users and/or involving them in the new product development (NPD) process defines the customer-centric organization. Some researchers have even argued for involving users with particular characteristics allows the firm to tap into new markets needs, develop radical innovation and move the firm closer to market orientation.

From a diffusion theory perspective, rate of adoption is dependent on the consumer's propensity to accept the new product. The traditional adoption categorization model by Rogers emphasizes the importance of opinion leadership in increasing adoption rates, and a recent study shows that users presenting high leading-edge status also have high opinion leadership qualities. These leading-edge users tend to perceive attributes that are less complex and more innovative when assessing new innovations within their particular domain of user expertise. Hence, firms that are seeking rapid diffusion of their radical innovations should target user segments that possess high levels of both leading-edge status and opinion leadership qualities.

This paper presents empirical research evidence advancing "leading-edge opinion leaders" as a new adopter category. The purpose of this paper is threefold: (1) to evaluate the influence of leading-edge opinion leaders on accelerating the diffusion rate, (2) to measure their propensity to switch brands and pay a price premium, and (3) to offer insights on the characteristics of the proposed new adopter category that will provide directions for future research and immediate application for management.

Adoption By Leading-Edge Users

Rogers observed that potential adopters assess the following attributes of innovations: relative advantage, compatibility, complexity, trialability, and observability. Several researchers have studied the diffusion phenomenon in light of the adopters categories and have explained the rate of diffusion as a function of the characteristics of each category relative to the perceived attractiveness of the innovation based on the set of attributes observed by Rogers. Within the adopters' categories, the innovators and the early adopters share similar characteristics that would allow these two groups to successfully convince the other groups to adopt the innovation at a later point in time. Modelling that phenomenon, Bass demonstrates that the diffusion follows a two-step communication process. Other researchers have challenged the two-step process in light of the level of usability or relative advantage of the innovation as perceived by the innovators and early adopters versus the mass market, while others have expanded the model to show the social networking effect.

Opinion leadership is a defining characteristic of the opinion leader. It is also a strong characteristic of the early adopter. Therefore, it explains the high personal communication effort (WOM and eWOM/ "Word of Mouse") used by the opinion leader to influence the behavior of other people in terms of search, purchasing and usage of new products. Generally, the communication mode of the opinion leaders is informal; however, they play a major role in influencing the consumer decision-making process as they represent a reliable source of information. As a result, marketers work to create communication channels to reach opinion leaders in order to encourage them to spread positive word of mouth.

Accordingly, this research identifies three types of users: 1) Leading-edge users with high levels of opinion leadership, from here on called "leading-edge opinion leaders"; 2) Leading-edge users with low levels of opinion leadership, now referred to as "leading-edge users"; and 3) consumers with low level of leading-edge status and opinion leadership referred to as "the Mass consumers". At the aggregate level, it is proposed that the behavior of a new adopter category possessing lead-user characteristics and opinion leadership attributes will accelerate the rate of innovation diffusion.

Methods and Results

This study evaluated the perception and adoption intentions of leading-edge users when confronted with a choice between a current new product, and a radical new innovation. Our first task was to develop a radical new innovation that would be believable to the participants. In the first stage, we extracted leading-edge users' ideas on innovative laptop features using an electronic ideation process (244 respondents to an electronic survey, from which 58 ideas were extracted from 52 participants). The ideas were then ranked using the Amabile consensus assessment technique (CAT) where higher scores define the most creative ideas as assessed by the expert panel composed of 11 people averaging 9.6 year of experience in the technology field.

Using a stepwise regression with the idea scores as dependant variables and the characteristics of the respondents as independent variables (participants' characteristics construct measures were taken from the existing literature and confirmatory factor analyses led to satisfactory goodness-of-fit measures greater than 0.95 and alpha coefficients greater than 0.70) led to a good fit of the model (Global F p-value < 0.0001) and significant parameter estimates for the leading-edge user and opinion leader characteristics (both p < 0.0001). Out of the 76 ideas extracted from the toolkit participants 34 of the most creative ideas (ideas above the mean of 164.45) were selected for the second stage of our analysis.

The adoption of innovation construct was measured using two manifest variables: the intent to purchase the idea if it was available on the market (a 5 point-likert scale was used) and the intent to speak (WOM) to a friend, family or colleague about the idea. Using a latent score method, an analysis of the interaction effect between the underlying characteristics: leading-edge status and opinion leadership as they relate to the adoption of radical innovation construct was conducted.

This research demonstrates that leading-edge users have a critical role in the diffusion of radical product. Beyond the widely accepted adopter categories, a new hybrid category named: "Leading-edge Opinion Leaders" can be seen as emerging from the known innovators and early adopters categories. They will help diffuse the radical new product by adopting it, propagating it to others, and will pay a price premium to acquire it. Managerial implications of this research relate directly to the possibility of an extension of the traditional adoption categories.

Consumer Creativity and Ideological Conflicts: An Investigation of the Free/Open Source Software Community

Tiebing Shi, Queen's School of Business, Queen's University, Canada¹
Jay M. Handelman, Queen's School of Business, Queen's University, Canada

EXTENDED ABSTRACT

A turn to consumer creativity is emerging (Pralhad and Ramaswamy 2000). In the literature on consumer creativity, two different streams of studies are located along a continuum anchored by individualistic creativity (IC) on one end and contextualized creativity (CC) on the other (Sawyer 2006). The first stream sees consumer creativity as a largely isolated, individual process (Bagozzi and Foxall 1996; Burroughs and Mick 2004; Dahl and Moreau 2007). The second stream sees consumer creativity as a contextualized process, assuming that a community of individuals collaborates towards a creative project (von Hippel 2005; Kozinets, Hemetsberger, and Schau, 2008). Despite this difference, both streams assume that creativity is an enjoyable, harmonious process free from ideological conflicts.

We use Berman's (1970, 1988) view of creativity as our theoretical lens. For Berman, creativity is a community-based, political-cultural process in which individuals engage in innovative practices in their daily interactions with fellow community members to achieve their ultimate life goals (e.g., self-actualization and self-expression). For Berman, the process of consumer creativity is rich in paradoxes, conflicts, ideological struggles, and political implications concerning the distribution of authority, power, and status in a consumer community and a society.

Specifically, at the individual level, individual members might experience intrapersonal paradoxes (e.g., a member simultaneously holds the values of individualism and collectivism). At the community level, there might be conflicts among collaborating members, ideological conflicts between collaborating subgroups of a community, and conflicts between individual members and the community as a whole (e.g., a consumer contributes an idea to his/her community and this idea could be rejected by authoritative community members as mediocre and/or inappropriate according to certain criteria; this consumer might feel hurt and be motivated to become an authoritative member or to challenge the criteria). At the society level, there might be competition and ideological conflicts between a consumer community and firms as well as ideological conflicts between a consumer community and copyright laws. These three levels of conflicts are intertwined with each other and reflected in the process of consumer creativity. Drawing on Berman's view, we aim to contribute to the literature on consumer creativity by empirically examining the creative process of individual members within the dynamic free/open source software (FOSS) community.

We seek to contextualize consumer creativity by considering the conflicts inherent in the creative process. In doing so, we consider the following questions: (1) How does an individual consumer negotiate the self-expressive aspects of creativity in the face of social judgment within his/her community and society? (2) How do individual consumers interact with each other and with firms to express their identities in the process of creating their common products (e.g., an idea, an experience, or a solution)? (3)

What are the political and cultural implications of consumer creativity?

Because the studied interactions, conflicts, and related political and cultural implications are sensitive to situational contexts, we adopt a netnography methodology (Kozinets 2002b). In particular, we seek a community context where members' creative contribution is central to the community. To this end, we choose the FOSS community. In their daily creative activities, FOSS developers (who are both producers and users of FOSS) generate rich ideological discourses, which we examine through a netnographic method.

Data were collected from online archives of consumer discourses of websites of Emacs (a FS project), Go-oo (an OSS project), and OpenOffice (an OSS project), and blogs and online papers and books of FOSS developers. We followed a data-driven procedure to collect data. In particular, based on our integrative analysis of the literature, we arrived at four characteristics of creativity that guided our selection and analysis of discussion threads: self-expressiveness (i.e., one engages in creative activities to actualize and express one's dynamic, multiple selves), social judgment (i.e., an activity and its outcome need to be judged as creative or not by relevant authoritative members in a community or a society), process (i.e., creativity is an ongoing, dynamic process in which an idea is generated, expressed, and socially judged), and novelty (i.e., an idea should be judged by community members as new, fresh, and original). So, we define consumer creativity as a process of self-expression that consumers engage in to individually and/or collectively generate something that is socially judged as innovative and appropriate. Our data analysis and interpretation follows a constant comparative method to seek patterns of meaning and to formulate themes (Spiggle 1994).

Two themes emerge from our data. The first one is "Ideologies and Authority Underlying Creativity." In their creative process, FOSS developers (who hold the ideology of community ownership) engage in an ongoing ideological debate with proprietary software firms (who hold the ideology of private ownership) leading to a power struggle with certain authoritative community members as some developers might not feel fulfilled, but rather, frustrated. Paradoxically, FOSS developers strategically use the ideology of private ownership to promote that of community ownership. The second theme is "Idealism Blended with Rationalism." By strategically blending idealism and rationalism in their creative process, FOSS developers construct their unique ideology—a rationality-based, idealistic, individual freedom-oriented, evolving creative anarchy, which enhances the legitimacy of their creative process and product (i.e., FOSS) and reduces the legitimacy and power of proprietary software firms (who extol their more rational software development process) in the marketplace.

Our paper contributes to the literature on consumer creativity by (1) considering the conflicts inherent in the creative process of consumer communities, (2) revealing that consumers could strategically use conflicting ideologies to fight against perceived constraining dominant forces in the marketplace for freedom of self-actualization and self-realization, and (3) illustrating that the creative process in the context of consumer communities could be full of conflicts (e.g., between individual members and their communities, and between the consumer communities and some dominant firms and copyright laws).

A Balancing Act: Governance in a Virtual P3 Community

Caroline Wiertz, City University London, UK

Charla Mathwick, Portland State University, USA

Ko de Ruyter, University of Maastricht, The Netherlands

Benedict Dellaert, Erasmus University Rotterdam, The Netherlands

EXTENDED ABSTRACT

Introduction

Since the wide-spread diffusion of networking technologies, consumers convene in various online community contexts to collectively produce and consume content relevant to their needs and interests. As a result, community forms of production and consumption of information, word-of-mouth, advice, entertainment, and even physical products are gaining in importance and have been heralded as ideal forms of collaboration (e.g., Kozinets, Hemetsberger, and Schau 2008). Much of the existing literature paints an almost utopian picture of online community, describing it as an environment characterized by altruism, mutuality, and social capital, in which consumers voluntarily sacrifice time and effort and work together to produce collective outcomes (e.g., Giesler 2006; Kozinets et al. 2008; Mathwick, Wiertz, and de Ruyter 2008). But like most voluntary social collectives that produce a public good, online communities are faced with the collective action problem, since members who free-ride can benefit equally from the public good that the community produces—for example, knowledge—as members who actively contribute to its production (Olson 1965; Wasko and Faraj 2005). Therefore, these communities have a regulatory interest to align potentially self-interested actors into producing a shared good. Yet little is known about how self-organizing online consumer communities govern themselves to encourage collaborative contribution to the shared community resource while discouraging free-riding.

Background

We propose that online communities can rely on two governance mechanisms to enhance collective action: normative governance, and meritocratic governance. Normative governance relies on the regulatory power of the specific social norms that emerge in the community through social interaction, and are enforced through peer pressure (Feldman 1984). Social norms are formed in any social group, and serve as explicit and/or implicit guidelines of appropriate behavior. As such, social norms are thought to be pro-social in nature and to foster social cohesiveness.

Meritocratic governance, in contrast, operates through non-economic incentives that accrue to individuals when they contribute to the collective community resource (Coleman 1990). One of the most powerful incentives for collective action in the community context is the attainment of social status (Lampel and Bhalla 2007), for example as enabled by online feedback systems. Feedback systems not only provide an evaluation of a member's individual contributions, but on an aggregate level, also of the member him/herself. As such, each participant constructs an online identity that is first and foremost characterized by the highly visible cumulative evaluation received through the feedback system. Prior research has consistently found that this not only fosters trust between members and improves the quality of contributions, but also motivates repeated contribution behavior, as participants strive to enhance their social status in the community (Dellarocas 2003; Lampel and Bhalla 2007; Moon and Sproull 2008).

The meritocratic governance approach incorporated through online feedback systems has dramatically risen in importance and

is considered the solution to instilling trust and stabilizing virtual communities (Dellarocas 2003). Most online market places (most famously eBay), online review sites (e.g., Tripadvisor), as well as open source communities have implemented online feedback systems. Extensive studies in recent years (e.g., Dellarocas 2003; Moon and Sproull 2008) have succeeded in demonstrating their positive effect on a variety of beneficial member behaviors. However, the potential dark sides of such systems have received much less attention. We speculate that by providing visual means of status distinction, effectively creating status groups, online feedback systems might lead to conflict between those members who are recognized by the system and have achieved status and those who have not. Status is by definition a scarce social resource that introduces competition: if status was easily attainable, its value would diminish (Weber 1978). Hence, status holders should be bent on maintaining their privileged position, while those without status should be bent on improving theirs. A number of key questions arise when considering the effect of status on those who have attained it as compared to those who have not. For example, does the elevated status of some community members facilitate or inhibit community exchange? Do all members, regardless of status, have an equal say in shaping the social norms of their community?

Method

This study was set in the context of a virtual peer-to-peer problem-solving (P3) community (Mathwick et al. 2008), which is a type of online creative consumer community (Kozinets et al. 2008) that focuses on the exchange of advice and best practice with regards to consumption-related problems (in our case, technical support). Netnography was used to explore governance, meritocracy, social norms, and status groups in this particular context (Kozinets 2002).

Findings

We find that both normative and meritocratic governance mechanisms operate in the community and that meritocratic governance enabled through online feedback systems indeed has a dark side. The online feedback system provides visual status symbols to members, effectively creating status groups. We find evidence that the high-status group is using its advantageous position to shape the community purely according to its taste and to dominate the low-status members. Our results show a widening disconnect between status groups as low-status members feel intimidated and unwanted and disengage from the community.

Balancing Intrinsic Motivation and Extrinsic Rewards: An Exploratory Investigation into User Generated Content Production

Charla Mathwick, Portland State University, USA

EXTENDED ABSTRACT

User generated content (UGC) is fast becoming one of the most valuable and influential sources of information in the on-line world, supporting millions of consumers who have come to rely on product and service reviews to support the purchase process. UGC is uncompensated and voluntary, which suggests that the motivation driving this type of consumer behavior is sustained largely by the intrinsic pleasure derived from its production. The purpose of this exploratory study is to examine the underlying intrinsic and extrinsic motives driving UGC production. The research question investigated in this study relates to how the intrinsically motivating character of UGC production is maintained while simultaneously recognizing contribution (Deci and Ryan 1985).

The context for this exploratory study is Amazon's Top Reviewer Community and the automated reward system Amazon administers for that community. Amazon's UGC is created by thousands of volunteers whose book and product reviews have become an influential decision aid for Amazon's customer base and a differentiating advantage for Amazon itself. On October 23, 2008, Amazon announced changes to the algorithm that drives the reviewer automated feedback system used to calculate UGC contributor rank in that community.

Two theoretical perspectives—Cognitive Evaluation Theory (CET; Deci and Ryan 1985) and theories of distributive and procedural justice (Rawls 1971; Rhoades and Eisenberger 2002)—frame the investigation of the impact of Amazon's announced changes to its ranking system. CET offers a framework for interpreting the effect reward systems can have on eliciting or undermining intrinsically motivated behaviors. CET is augmented with insights drawn from the electronic word-of-mouth literature and from theories of justice related to reward distribution in organizations. This theoretical framework is combined with the results of a netnographic analysis to develop propositions to guide future research.

The Motivation to Create UGC

The production of UGC provides an outlet for the autonomous self-expression of opinions and expertise. It not only serves to develop and affirm personally valued skills, it establishes a basis for relationships among the community of contributors as well as the readers who follow a reviewer's work when making purchase decisions. Readership feedback perceived to have no ulterior motive other than to express appreciation or acknowledge reviewer expertise, appears to produce a particularly strong motivation to produce UGC. This direct market feedback, however, appears to also threaten the perceived autonomy of some of the reviewers, particularly when reader feedback was experienced as an attempt to control or coerce rather than inform (Deci and Ryan 1985).

A reviewer's relationship with peers engaged in UGC production, paints a picture of a community that is as supportive as it is antagonistic. Peer interactions reflect a competitive environment, populated by contributors who are pre-occupied with issues of personal recognition, peer performance quality, and identification with the group. UGC which is a manifestation of the 'engage and co-create' economy said to be emerging online (Tapscott and Williams 2008), appears to be a complex combination of competitive, supportive, and antagonistic interactions that mirror traditional work environments.

The reviewer's relationship with Amazon is centered around the automated reward system they administer. As important as recognition appears to be in motivating UGC production, consistency, and predictability in the allocation of rewards and the perceived fairness of the procedures used to administer the reward system is perhaps more important. Reward systems offer a reason to participate for some and are irrelevant or border on insulting to others. Consequently, the procedures underlying automated feedback must strike a balance between these competing interests in ways that deepen engagement rather than alienate.

Conclusion And Discussion

Amazon has engaged their community of volunteers to produce UGC by implementing a reviewer ranking system and by supporting the review experience with a full complement of interactive tools. The intrinsic pleasure of pursuing an 'interesting hobby', the freedom of self-expression, and the social connections created as reviewers develop a loyal readership and relationships with their peers contribute to the motivation to produce UGC. Community ranking operates as a powerful extrinsic influencer of UGC production and appears to be the primary motivator for a substantial portion of the contributing base. For reviewers who are intrinsically motivated to produce UGC, however, Amazon's ranking system and the relationships built around the product review process, can undermine the fragile sense of autonomy so crucial to sustaining these voluntary contributions. The key to establishing stability in the reviewer community seems to be striking a balance between these countervailing forces.

From the perspective of a UGC producer, there are three relevant sources of feedback: the buyers who rely on UGC to support the buying process, fellow reviewers, and the community moderator who maintains the official ranking system. Feedback from buyers tends to offer some of the most important motivation supporting UGC production. For reviewers who attract a following, the social and reputational benefits they experienced appeared to mean more to them than the ranking system devised by Amazon. It appeared that the authenticity of readership comments trumped the economically-tainted feedback attributed to Amazon. Peer-to-peer relationships between reviewers also provides social benefits, however community rank appears to introduce a competitive element to the UGC experience that can be motivating for some while alienating to others.

Marketers interested in leveraging the expertise of their customer base will need to meet the challenge of balancing what are often incompatible forces, in order to encourage their users to contribute to UGC production. This view into the world of UGC production provides insight into the nature of that challenge.

The Pursuit of Identity Augmentation: Self-Expansion and Self-Extension as Distinct Strategies

Paul M. Connell, Stony Brook University, USA
Hope Jensen Schau, University of Arizona, USA

EXTENDED ABSTRACT

As consumers are active identity seekers and makers (Arnould and Thompson 2004), they sometimes engage in attempts to grow identity beyond the corporeal self (Aron, Aron, and Smollan 1992; Aron et al 1991; Belk 1988). Scholars in both consumer research (Belk 1988) and in social psychology (Aron et al 1991; Aron et al 1991) have produced impactful frameworks for how individuals engage in identity augmenting behavior. Belk's (1988) framework, originally appearing in the *Journal of Consumer Research*, was written in the context of possessions, and a large percentage of its many citations are within the realm of business or consumer research. Aron's framework (1991, 1992), originally appearing in the *Journal of Personality and Social Psychology*, was written in the context of close relationships with other people. Similarly, a very large percentage of the citations for this research are in psychology journals. While these two parallel theories have similarities, there are important differences between them as well.

In Belk's (1988) paper on possessions and the extended self, he asserts that individuals cathect objects with meaning and extend their identities from themselves into objects. Two papers by Aron and his colleagues (1991, 1992) offer a theoretical framework for how individuals envelope aspects of a close other's identity into their own identities and a scale to measure inclusion of other in the self. However, consumer researchers have tended to neglect the Aron framework and psychologists have tended to neglect the Belk framework. This is not entirely surprising, given the focus of the Belk framework on possessions and the Aron framework on relationships. In this research, we argue that neither framework is superior to the other. Rather, we believe that the Belk framework is also useful in the context of human relationships, and the Aron framework is similarly useful in the context of consumer behavior. We parse out the differences between these two theories and suggest that they actually represent two distinct strategies for growing identity beyond the corporeal self, and we offer the term identity augmentation to encompass the two different strategies.

We conducted depth interviews with 36 informants and find them using distinct strategies of self-extension (Belk) and envelopment/self-expansion (Aron) in pursuing their identity projects. Because we were interested in how individuals either seek to extend their relationships with objects of consumption to others or envelope aspects of a close other's consumption relationships into their own identities, we conducted nineteen of our interviews with individuals from nine different families. In these cases, we separately interviewed both parents and children in order to gain emic perspectives of both relationship partners when identity augmentation attempts are made.

We find that individuals indeed engage in attempts to both extend their consumption relationships to close others as well as envelope/expand aspects of consumption relationships from close others. Identity extension (active attempts to instill a consumption behavior in another) was commonly observed among parents when interacting with their children. Behavior ranged from subtle attempts to influence the child's consumption to unapologetic, overt consumption mandates. In contrast, identity expansion (enveloping aspects of another's consumption) was commonly observed among children (minor or adult) toward their parents.

When conducting our interviews, we found several instances where the identity extender's attempt to augment was met either enthusiastically or without resistance from the potential identity expander/enveloper. In this case, both parties were satisfied, as both were able to augment identity simultaneously, and shared consumption was at best extremely satisfying for both parties or at worst uneventful. We also observed instances in which the extender's attempt to augment identity through consumption was rejected. If the object of consumption was not important to the extender's identity, the augmentation attempt was typically abandoned. However, in cases where the object of consumption was indeed very important to the extender's identity, he or she was forced to negotiate with the relationship partner about which aspects of the consumption the other was willing to absorb.

We also found instances in which heavily involved partners in an identity augmentation project left others out. In this case, (1) extension was not attempted and (2) some individuals were not successfully able to self-expand/envelope aspects of identity from close others. In these cases, those left behind often felt resentful or abandoned, while those engrossed in the identity augmentation project tended not notice the feelings of the person left behind, and chalked their lack of involvement in the identity augmentation project as disinterest in it.

In summary, we find evidence that consumers engage in distinct strategies of augmenting identity. We find that neither Belk's nor Aron's framework is superior to the other in describing identity augmenting behavior, but rather describe two unique strategies of doing so. Further research could possibly reveal other distinct augmentation strategies. Finally, we observe that while successful attempts to augment identity generally yield positive results for all involved, failed attempts can lead to potential damage to close relationships.

“My Possessions are Mine and Your Possessions are Mine Too” Using Hong Kong Chinese Consumers’ Narratives to Illuminate the Boundaries between Extended Possessions and the Extended Self

Phoebe Wong, Lancaster University, UK
Margaret K. Hogg, Lancaster University, UK

EXTENDED ABSTRACT

Possessions and the extended self (Belk, 1988) have received extensive attention in consumer research. Belk (1984) has suggested that there are different cultural interpretations of the concepts of self and possessions. Western studies have focused on objects that demonstrate consumers’ interpersonal ties (Wallendorf and Arnould, 1988, Csikszentmihalyi and Rochberg-Halton, 1981, Dittmar, 1989, Richins, 1994, Schultz et al., 1989). Eastern research, in contrast, has suggested a different set of boundaries between the self and possessions compared with Western findings i.e.: “a little of you in me and a little of me in you” (Yang 1994: 297). In this paper, we aim to address this research gap in our understanding of what constitutes both the extended self and potentially extended possessions in Hong Kong Chinese culture; and investigate the nature of the boundaries between the extended self and possessions for Hong Kong Chinese consumers.

Chinese consumers tend to place more emphasis on the interdependent view of the self-construal that focuses on togetherness and embeddedness with significant others or in-groups (Triandis, 1989, Markus and Kitayama, 1991). The Chinese sense of self is defined mainly by webs of relationships (Morris, 1994) and is constructed by the connectedness to and interpersonal relationships with significant others, family and friends (Aaker and Maheswaran, 1997) so that an individual with the interdependent self-construal becomes “a single thread in a richly textured fabric of relationships” (Kondo 1990:33).

Possessions are artefacts of the self (Kleine et al., 1995). “Self-artefacts help narrate stories of the self and reflect self-developmental tasks similar to those underlying life narratives” (Kleine et al 1995, p. 341). People reveal different aspects of their selves by retelling stories of their possessions. According to Schultz et al (1989) and Kleine et al (1995), possessions involve many aspects of people’s self-development tasks, e.g. affiliation, autonomy and temporal orientations. Affiliation possessions are related to the interdependent self where people establish interpersonal connections with others in their culture through shared meanings. Autonomy possessions are often associated with the independent self, where people seek to establish autonomy from others and also to maintain a personal and unique identity. In addition, gift-receipts are often regarded as people important possessions “as a positive extension of self” (Belk 1988: 150). Gift-giving plays a substantial part in Chinese culture in terms of maintaining, harmonizing and enhancing interpersonal relationships in social systems (Wong & Ahuvia 1998, Belk and Coon 1993). As Yang (1994) noted the importance of gift-giving in Chinese society as “primacy and binding power of personal relationships and their importance in meeting the needs and desires of everyday life” (p. 6).

In the present study, informants were asked to share stories about their meaningful and important possessions. Their selves and identities are embedded in their stories as Georgakopoulou (2002) says that “if selves and identities are constituted in discourse, they are necessarily constructed in stories” (p. 428). The snowball technique was used in identifying twenty informants (ten males, ten females). Data analysis yielded a number of themes that revealed how informants interpreted what constituted their important, often extended, possessions and their extended selves.

Our findings showed that informants narrated stories not only about the gifts that they themselves had received as being their important possessions and thus constituting part of their extended self; but they also described objects that they had given as gifts to close others as part of their own possessions and these extended possessions thus constituted part of their own extended selves. Possessions create different layers of symbolic ties to other people. We examine informants’ stories about their personal relationships with close others in relation to two dimensions: firstly “Gift-receipts as part of the informant’s important possessions”; and secondly “Gifts to close others still regarded as part of the informant’s important possessions”.

The objective of this research was to explore the boundaries between the extended self and extended possessions i.e. what constituted ownership of what might be called extended possessions among Chinese consumers. Against the backdrop of Chinese interdependent culture, Hong Kong informants narrated stories about their important possessions ranging from objects that they owned to objects that actually belonged to close others, not to the informants themselves. Our research findings reveal that a broader interpretation of possessions and the extended self (as seen from these Hong Kong stories) could contribute to and enhance the existing literature on possessions and the extended self.

Heterotopias of Emerging Same-Sexuality: Spaces and Places of Consumption Among Young Female Consumers “Coming out of the Closet”

Andreas Pantazopoulos, Bradford University, UK

Shona Bettany, Bradford University, UK

EXTENDED ABSTRACT

Consumer research has exhibited an interest in non-heterosexual consumers since the early 1990s. Penaloza (1996) suggests that some features of the gay and lesbian market have been presented as more than attractive for marketers, labeling them a “dream market”. Gay and lesbian consumers, it is argued, spend in a more symbolic way, perhaps because of a felt need to promote, negotiate or display their sexual identity (Kates 2000) by buying products/brands that communicate to their peers masculinity/femininity (Rudd 1996), exclusiveness (Wardlow 1996), superior status or/and a radical lifestyle (Schouten and McAlexander 1995) and are less price-sensitive and looking for the “intangible” aspect of the goods (Tuten 2005). Although this market was viewed as a relatively new one by consumer researchers, Penaloza (1996) concluded ten years ago that things were rapidly changing and a wide spectrum of businesses started serving the needs of this group; media, vacation companies, legal, medical, financial, communications and community support services. Same-sex union agreements and the constitution of adoption rights to lesbian couples affect these consuming patterns (Borgerson et al 2006, Johnson and Piore 2004) and offer new opportunities to businesses making an understanding of non-heterosexual consumption important.

Chasin (2000) and Kates (1998) suggest that most consumer research focuses on gay men’s consumer behaviour, and lesbian women are somewhat neglected by the literature. This might be due to the perception that gay men have a much higher disposable income than lesbian women and the persistence of the myth of the “gay spender” (Kates 1999). Gay consumption is often stereotypically associated with hedonistic lifestyles and self indulgent conspicuous over-consumption (Hennesey 2000) and there is a proliferation of images in advertising and the media of white, middle class, articulate, attractive “straight looking” gay men who spend a significant amount of their income on non-utility goods (Penaloza 1996, Borgerson et al 2005). Where research has attended to lesbian consumption, this has been usually in the form of presenting lesbian women as an already existing category or segment to be studied (Wilkes and Lavernes 2002). We would argue that there is a need to develop consumer research understanding of female non-heterosexuality and to move beyond notions of viewing this phenomenon as an already existing market segment towards studies that explore the part consumption has to play within the complexities of the negotiation of female sexuality.

Living within the high tension zone of the negotiation of non-traditional identities is to navigate intensely charged flows of power and knowledge in which consumption objects and activities can act as grounding and/or transformatory nodes. It is accepted in consumer research that material objects and consumption activities are enfolded into the construction of narratives of belonging and identity, (Belk 1988, 1995, Bonsu and Belk 2003, Holt 1995, Wallendorf and Arnould 1988) particularly during moments of transition and transformation (Zwick and Dholakhia 2006). It has been noted in addition that this seems particularly prescient in negotiation of non-heterosexual identities (Perriera 2008). The consumption activities and objects enfolded into the “coming out of the closet” process, taken here to mean ontological oscillations both generative and constitutive of the formation of a non-heterosexual identity, have profound parts to play in formations of subjectivity.

In this paper we explore how such consumption activities and objects co-emerge with negotiations of sexuality and identity among four young women engaging in same-sex relations for the first time.

This work emerged from an initial phenomenological study that aimed to map consumption activities onto processes of “coming out of the closet” (that is, to “reveal” ones identity as a non-heterosexual) in female university students to explore the consumption activities engaged in during stages of this important identity negotiation (Pantazopoulos 2007). During this study recurring questions about the adequacy of the frameworks of action implied in “coming out of the closet” emerged. We found that many of our participants upon first questioning their sexuality at university were exposed to the dominant Cass process model (Cass 1979) which is employed on many university websites and through university counselling services as an explanatory framework of the processes involved in coming out as gay or lesbian (Fig.1). The Cass model carefully maps out stages in this process, from initial confusion about sexuality, leading to exploration, guilt, disclosure, pride and finally assimilation into a fully exposed gay or lesbian sexuality. Our research found that this model jarred somewhat with actual experiences and accounts of the negotiation of sexuality and the sexuality “play” engaged in by our respondents to the extent that we felt that the model was too simplistic to explain the data. Moreover, the concept of “coming out of the closet” itself seemed ontologically too simplistic to account for the complexity of our research findings, and was incommensurate with contemporary theoretical frameworks around identity negotiation. Furthermore, in our research, the assumptions underpinning the idea of “coming out of the closet” were woven into negotiations of sexuality by our participants such that it became an important actor of normalcy in the cultural terrain. This led to a reappraisal of our initial research which sought to map consumption activities onto process stages, and recognition that an alternative theoretical approach was necessary. In developing our theoretical contribution we instead utilize Persson and Richard’s (2008) alternative conceptualisation to “coming out of the closet” based on Foucault’s (1986) notion of heterotopias to explore the spaces enacted through our participants consumption activities and suggest this alternative conceptualisation as a way for consumer and marketing researchers to better understand this valuable and interesting sub-cultural group.

We found during our study that respondents produced multiple heterotopias around their emerging sexuality, summarized here as “heterotopias of nowhere”, “heterotopias of gay space” and “heterotopias of the body”. These heterotopias were imaginatively and creatively deployed and occupied by these women and facilitated sexual identity play, interwoven with consumption activities such as engaging in the consumption of drugs and alcohol, a photography hobby and the purchase and display of particular items of clothing. We suggest that the concept of heterotopias has much to recommend it as a replacement or enhancement to the traditional “coming out of the closet” model that has become habitually invoked as a universal metaphor for revealing a range of identities and conditions that might be viewed as carrying a social stigma. We argue, following Person and Richards (2008), that in the absence of careful analysis, applying this metaphor as conceptual shorthand homogenizes experiences of negotiating “stigmatized” identities, and may

hamper our attentiveness to the cultural specificities of lives and stories. Heterotopias, because they do not carry the negative burden of the assumption of gradually coming to terms with a stigmatized identity, can be used to build more sensitive accounts of identity construction among groups traditionally targeted by these models.

Tales of Invisible Cities: Methodological Avenues for Multi-sited Researcher Autoethnography

Yuko Minowa, Long Island University–Brooklyn Campus, USA

Pauline MacLaran, Royal Holloway, University of London, UK

Luca M. Visconti, Università Bocconi, Italy

EXTENDED ABSTRACT

Multi-sited consumer research, in general, and multi-sited ethnography, in particular, have gained attention and popularity in the contemporary consumer research. Belk, Ger, and Askegaard (2003), for instance, conducted a phenomenological study on desire, based on the data collected in the USA, Turkey, and Denmark. Borghini, Visconti, Anderson, and Sherry (2008) studied street arts in urban cities in Italy, the UK, Ireland, and the USA. The multiplication of sites for data collection and interpretation requires collaborating researchers to pay special attention to cultural heterogeneity of their own, as much as their informants, throughout the course of ethnographic study.

While taking advantage of cultural dynamism, the differences may spawn problems at any stage of the study, and the trustworthiness of results may become questionable. According to Hall (1976, 37), “what gives man his identity no matter where he is born—is his culture, the total communication framework.” In the communication system, meanings can be read correctly only if one is familiar with the behavior in its historical, social, and cultural context. In this regard, although a researcher’s apprehension of his/her own culture, and those of collaborators, is the key for a successful collaborative ethnographic work, there is a paucity of methodological study to address this issue.

This paper aims to propose a new research method, “xenoheteroglossic autoethnography,” as a preliminary step to full-scale multi-sited ethnographic study. Combining the Greek word *xenos*, or foreigner, and Bakhtin’s first definition of heteroglossia (1934/1981), the term signifies an ethnographically-driven researchers’ introspection (autoethnography) generating, within a given account, a multiplicity of voices attributable to the various national and cultural ties of the researchers (xenoheteroglossic).

The choice of focusing our introspection on an ethnographic inquiry of the cities we inhabit has a twofold explanation. First for methodological reasons connected to the aim of the paper, we were looking for a topic that could emphasize the preeminence of the researcher’s cultural background, and assumed the way we live our cities largely reflect our idiosyncratic cultural bonds. The second motivation is conceptual. As researchers, we are used to interrogating consumers and companies, and even the market cultures in which their interactions take place. Still, we often avoid interpreting the city context in which such market exchanges and consumption experiences bloom.

We first review literature on introspection in consumer research followed by discussion on autoethnography in social science. Then, we discuss our proposed methodology in terms of making cultural rapport within and beyond the self; gathering and documenting data; analyzing and communicating data; and ensuring trustworthiness.

1. Making Cultural Rapport Within and Beyond the Self

There are two layers of cultural rapport the researcher needs to make: with the self and with collaborators. Initially, the researcher is the sole introspector and examines him/herself as informant. Being exposed to globalizing media and cultural and social influx, the researcher may be multivalent in value system and ambivalent

in his/her cultural identity. Thus, prior to examining cultures external to the self, the very first step is the analysis of the self. On the other hand, learning about the collaborator’s cultural background and sharing the information about self examination about cultural polyvalence and ambivalence, which both affect the later polyphonic conversations, seem indispensable as the first stage of xenoheteroglossic autoethnographic study.

2. Gathering and Documenting Data

After research questions are selected, calibrated, and honed, autoethnographic researchers generate either or both generalized and/or particularistic data. Further, the data may be a direct “quotation” of the researcher’s inner feelings and thoughts without intentional articulation, or the data may be the researcher’s inscription about what he or she observes about the self as the subject of the study. An important procedural guideline while documenting the data is to make sense of cultural and social phenomena and their relation to ourselves by comparing, contrasting, replicating, and classifying the data. This leads to the necessity of constantly contrasting newly emerging interpretations amongst ourselves. This rigorous hermeneutic triad, cyclical process of explicating, explaining and exploring data, may be used in drawing inferences about patterns of co-occurrence, covariation, or mutual shaping (Wallendorf and Brucks 1993), all useful in developing theory in the later stage in multi-sited ethnographic study.

3. Analyzing and Communicating Data

In the xenoheteroglossic autoethnography, analyzing and communicating the result of the introspection is challenging. The difficulties arise as a result of differences in language and their uses in the cultural context. With respect to culture, Hall states (1976, 49), “the paradox of culture is that language, the system most frequently used to describe culture, is by nature poorly adapted to this difficult task.” When researchers from high-context cultures and low-context cultures work together, an additional caution should be noted. The implications of these differences is that in analyzing and communicating the autoethnographic data, these researchers must be extremely sensitive to the concealed or unspoken, covert feelings of other collaborators. Another difference was the style of documentation. An autoethnographer may use an essay format while his/her colleagues may use poems and an excerpt from a fiction. Since the ultimate purpose of reportage is communication, taciturn self-reliance and self-complacency should be consciously noted by the self and to the others, and colleagues should feel free to request clarification in the communication process.

4. Ensuring Trustworthy Xenoheteroglossic Autoethnography

Trustworthiness for interpreting the result of autoethnographic study is not easily measurable. Based on the evaluative criteria for ethnographic study and introspection discussed previously (Lincoln and Guba 1985; Wallendorf and Belk 1989; Wallendorf and Brucks 1993), in xenoheteroglossic autoethnography, we consider our cycle of continuous introspecting and ongoing analysis of the results as the primary component in generating trustworthy results. The iteration should be continued until saturation is felt to have

been achieved. During the procedural cycle, autoethnographers should discuss the result of introspection, then polarize particular aspects that had been absent in the previous result of the introspection. While iterating this cyclical procedure, the researchers become more sensitized to the cultural nuances. This ensures the trustworthiness in xenoheteroglossic autoethnography, and also contributes to fostering cultural sensitivity that would be integrated into full-blown multi-sited ethnographic study.

The Influence of Prototypicality and Level of Exposure on Consumers' Responses to Product Designs: Field Evidence from German Car Buyers

Jan R. Landwehr, University of St. Gallen, Switzerland

Daniel Wentzel, University of St. Gallen, Switzerland

Andreas Herrmann, University of St. Gallen, Switzerland

EXTENDED ABSTRACT

In recent years, a growing number of industries have begun to regard product aesthetics as a fundamental part of their competitive strategy (Cox and Cox 2002). Yet, there is surprisingly little research that relates specific components of a product's design to consumers' aesthetic responses (Bloch 1995). Put differently, very few studies have investigated why some product designs are considered to be more aesthetically pleasing than others (for exceptions see, Cox and Cox 2002; Veryzer and Hutchinson 1998). One factor that has been investigated as a potential determinant of consumers' aesthetic responses is a design's prototypicality. That is, product designs that are typical of their general category have been found to elicit more positive evaluations than product designs that are atypical of their category (e.g., Veryzer and Hutchinson 1998).

However, there are numerous examples showing that some products succeed in the marketplace precisely *because* their designs are unique and revolutionary. How can one account for this apparent discrepancy? One explanation may be based on the fact that most studies have only measured participants' reactions to designs varying in prototypicality after a single exposure. However, consumers usually have multiple opportunities to observe a product before making a decision. Considering decision processes of this kind is important since research from other areas demonstrates that the aesthetical appeal of a stimulus is influenced by the level of exposure (Bornstein 1989). Therefore, this research examines if and to what extent the relationship between a design's prototypicality and consumers' preferences is moderated by the extent of exposure.

The most common explanation for the positive effects of prototypicality is based on the concept of fluency, which refers to the cognitive ease that people experience when processing a stimulus. Research in this area has shown that stimuli that are more prototypical can be processed more fluently than stimuli that are less prototypical (Winkielman et al. 2006). Fluency, in turn, may be hedonically marked and may elicit positive affect that is subsequently transferred to the stimulus (Winkielman and Cacioppo 2001). From this perspective, products with prototypical designs should be preferred over products with atypical designs.

Current theorizing, however, also indicates that fluency-based affect emerges at very early stages of information processing (Winkielman et al. 2003). Hence, if consumers only have a single opportunity to observe a product, the fluency signal is a very relevant information for forming a judgment. When, however, consumers have multiple exposures, they may be able to extract additional information from the product, such that the fluency signal is not the only information available (Novemsky et al. 2007). This, in turn, may affect how consumers respond to different designs. Whereas prototypical designs may initially elicit a positive response, they may feel boring once all their features have been extracted. Atypical designs, however, may still feel interesting after multiple exposures. Consequently, we postulate that more prototypical designs will lose in aesthetic appeal after multiple exposures, whereas less prototypical designs will gain in aesthetic appeal. Two studies focusing on German car buyers were conducted to test this prediction.

Study 1 experimentally manipulated the prototypicality of a car's design (prototypical, not prototypical) and the level of exposure (3, 6, 9 exposures). We also examined two different car segments (compact cars and mid-size executive cars) to increase the generalizability of our findings. To create car designs that varied in terms of their prototypicality, we relied on image morphing techniques. To this end, we took standardized pictures of 16 compact cars and 12 mid-size executive cars and created two different morphs out of these images for each segment. One of the morphs was particularly typical of its segment, whereas the other was particularly atypical. Afterwards, we asked a total of 306 German car buyers to evaluate these images and manipulated the level of exposure. The results confirmed our predictions and showed that the relationship between prototypicality and aesthetic liking is moderated by the extent of exposure. Whereas prototypical car designs began to lose in aesthetic appeal after 9 exposures, atypical car designs were considered more attractive with increasing amounts of exposure.

Study 2 sought to enhance the external validity of these findings by examining if the interaction between prototypicality and exposure also affects sales. To this end, we calculated a prototype similarity score for each of the 28 cars in our sample (Winkielman et al. 2006). Furthermore, we assumed that the extent of exposure would be determined by how long a car has been available on the market. Again, the results confirmed our hypothesis. While sales for prototypical cars increase rapidly in the first years, they reach a peak fairly quickly, after which sales drop again at a rapid rate. Atypical cars, however, take a much longer time to reach their peak. At the same time, they also show a slower rate of decline, such that they are sold successfully for longer periods of time than cars that are prototypical.

This research makes several contributions to the literature. Firstly, our studies show that the effect of design prototypicality is moderated by the level of exposure. Assuming that consumers have multiple exposures to a product before making a decision, atypical designs may eventually be more successful than very prototypical designs. Secondly, our studies also contribute to the literature on fluency and consumer choice. Research in this area has typically found that consumers are more likely to choose a product when they experience feelings of fluency (Schwarz 2004). Building on these findings, our studies suggest that fluency effects are more likely to be observed when consumers have limited opportunity to process a product in great depth, but may be less pronounced with increasing amounts of exposure.

Blurred Boundaries between Consumers and Producers inside Brand Communities: About Some Negative Outcomes

Bernard Cova, Euromed Management of Marseille, France
Pascale Ezan, Rouen University, France

EXTENDED ABSTRACT

The erasure of boundaries between consumers and producers is a hot topic that recent theories in consumer research (Arnould and Thompson, 2005) and in marketing (Vargo and Lusch, 2004) have helped to popularize. For the CCT, the performance of the consumer turns her/him into a producer (Kozinets et al., 2004). For the SDL, the company's co-creation of value together with the consumer(s) is the key process in this new marketing logic (Lusch and Vargo, 2006). With brand communities (Algesheimer, Dholakia and Hermann, 2005; Muniz and O'Guinn, 2001; Schouten, McAlexander and Koenig, 2007), the concepts of productive consumers and of value co-creation have been pushed to the limit insofar as brands are being transformed into virtual platforms (Arvidsson, 2006) used to stage the aggregation of contact persons and consumers united by the same passion. The advantages derived from these kinds of community strategies for the brands are said to be significant (Atkin, 2004), leading to greater satisfaction and consumer loyalty, more information, an amplified word-of-mouth effect, etc. It remains that several harbingers have raised fears about the possibility that things could go wrong, damaging contact persons firstly but also consumers as illustrated by the Warhammer case. It had been said that employee-fans are also part-time consumers, with consumer-fans becoming part-time producers (Manolis et al., 2001). This is particularly true in the case of Warhammer, where the connection between contact persons and fans in the community derives from their shared passion rather than some commercial relationship. Clearly, the concept has a basis in traditional commercial transactions, but these are masked by a Warhammer universe and collective environment from which the concept of money has been eliminated. Player-consumers mainly view staff members as 'fellow fans'. Thus, through a process that some might define as reciprocal compromise, consumers try to look past the commercial aspects of their representations of contact persons whereas the latter are happy to acknowledge consumers' expertise and competency and recognize the excellence of their output (Kozinets et al., 2004).

Three ethnographic approaches were used during the study of the Warhammer community: quasi-participant observation (participation in community events but not in the games) was undertaken by one of the authors, whose spouse and children have been Warhammer fans for eight years; participant observation with photographs and CD recordings at the annual 'Games Day' event that brought 3,500 fans to *Stade de France* in Paris on 20 April 2008; non-participant observation and non-directive interviews conducted over a period of two years by the other author, working with a group of Warhammer fans who met every Saturday afternoon at the Games Workshop-the company owing Warhammer-store in the author's city in South France.

With the development of brand community approaches, today's contact persons are no longer only being asked to fulfil the role of simple employees but also to act as employee-fans (Rémy and Kopel, 2002). In the case of Warhammer, it is difficult for employees to remain great fans of a brand when they see things from the inside. Over the long run, the Pollyanna vision that permeates the Warhammer community, which consists of believing that employees' participation in Sunday tournaments is a sign of their passion for the brand, is irritating to staff members, who often find it hard to understand consumers' jealousy because they are working

in such fun conditions. They cannot say anything in return, however, since they too are part of the tribe. They have no opportunity to openly criticise their working conditions or wages, since this would be assimilated with treachery or a lack of loyalty that other players would likely have problems understanding. With their dual role as staff members and community members, employees put themselves into a schizophrenic situation. They can no longer disagree with the company without giving off the impression that they are betraying the community and its members.

This problem for staff members should not detract from a second problem, relating to the mood of consumer-fans. Games Workshop solicits consumers-constructed as fans-in several ways. They are asked, where need be, to offer an opinion, come up with new ideas or criticize rules. Customers' opinions, especially when communicated in online chat rooms, enable Games Workshop to improve its products and bring out new items that will solidify fans' loyalty, especially since the ultimate consumers are the people who actually came up with the idea for the innovations in the first place. However, some consumers harbour serious doubts about Games Workshop's role, accusing it making exorbitant profits from players. This criticism is embodied in many players' joke that Games Workshop's acronym G.W. actually stands for 'Great Weasel'. This theme is particularly prevalent on-line. Companies that rely heavily on a Consumer Generated Content approach such as Warhammer can ultimately exploit consumers in two ways, since the latter are ready to pay for their cult brands' products without receiving anything in return for all of the ideas, stories and connections that they produce to enhance the brand's value (Zwick, Bonsu and Darmody, 2008).

Passion, which is the cornerstone of brand communities, is what brings staff members together with consumers, offering a lever that helps people to get involved and even transcend themselves. This Warhammer case study has stressed how brand communities overcome commercial activities' traditional barrier between contact persons and consumers (Godbout, 2007). In this way, brand communities encourage a perception of brand value that prioritizes extra-commercial aspects rooted in emotional interactions amongst fans. However, thought must also be given to the negative consequences of this confusion of roles between employees and consumers in brand communities. The porosity featured here is not without risks for employees who overwork to respond to requests from consumer-fans. It also creates a situation where consumers, constructed as partners of the company, aspire to be heard (and even remunerated) for any ideas they suggest.

Lifting the Veil on Infidel Brands: Islamist Discourses of Anticonsumerism

Elif Izberk-Bilgin, University of Michigan-Dearborn, USA

EXTENDED ABSTRACT

The rapid rise of Islamism¹ in many developing countries in Asia, North Africa, and Middle East has been interpreted as a critique of modernization, capitalism, and consumerism (Ray 1993, Sklair 1995, Barber 1995). While there is a growing ideological discourse on the threat Islam poses to Western civilization as well as future integration between East and West, little is known about how Islamist sentiments actually materialize in every day life in these transitional economies. Particularly of interest is how global brands as potent symbols of a global consumer culture are interpreted in developing countries in light of growing Islamist² sentiments. Uneven economic and cultural globalization has been fostering consumer resentment to the ideals of market society and thereby also mobilizing political Islam as a counter-ideology (Ahmed 2007), which nourishes new meanings of global brands in these locales as 'infidel's and symbols of 'injustice and oppression'. Such interpretations portray a remarkably different kind of consumer resentment towards global brands than the hedonic, aesthetic, and self-expressive consumer activism examined in Western countries (Holt 2002, Kozinets 2002, Thompson and Arsel 2004), urging us to re-examine existing assumptions about anticonsumptionist discourses. As such, this paper explores what renders a global brand an infidel brand and what stimulates consumer rejection of these brands in a developing country, Turkey.

Past research on anticonsumption issues portrays the activist consumer as playfully confronting an unfettered capitalist ideology and unbounded globalization. Despite the significance of these causes, previous research concludes that such a defiant stance is driven by a profound desire to construct an authentic and sovereign self in a mass-manufactured world. Critical consumers strive to distinguish themselves from the stereotypical 'mindlessly consuming' mainstream consumer by leading fringe lives (Holt 2002), temporarily enacting gift-economy at the Burning Man festival (Kozinets 2002), performing esoteric healthcare practices (Thompson 2003), or condemning Starbucks for sanitizing and debasing the coffee experience (Thompson and Arsel 2004, Kozinets 2002b). Evidence of such hedonic, aesthetic, and self-expressive qualms abounds in the literature (exceptions (Dobscha and Ozanne 2001), Kozinets and Handelman 2004), suggesting that the postmodern consumer, liberated from the concerns of satisfying basic needs, engages in anti-materialist, anti-corporate, and environmentally conscious discourses and practices as a therapeutic and socially privileging endeavor. While this portrayal may aptly describe the identity anxieties of consumers in economically advanced countries, it hardly characterizes the lived-experiences of consumers and concomitant attitudes toward consumption in developing countries. Marked by poverty, double digit rates of unemployment and inflation, periodic devaluations of local currency, and lack of

democratic institutions, these consumptionscapes clearly bear unique motivations of anticonsumerism than those examined in the U.S. and Western Europe.

One such motivation is provided by the anticonsumptionist stance of political Islam. Amidst the economic, cultural, social, and political turmoil that generally plagues developing countries, Islamism emerges as an antidote to the disenfranchised consumers' quest for an alternative identity. By espousing modesty and promising eternal justice political Islam provides a justifying and soothing existential discourse for many disempowered consumers (Crockett and Wallendorf 2004). Furthermore, the socio-historical conditions such as colonialism, Cold War, the modernization attempts undertaken in several developing countries, the Israel-Palestine conflict, along with the recent Iraq War not only promote Islamism but also energize an anticonsumerist stance vis-à-vis global brands among Muslim consumers.

Through a critical ethnography, this paper examines Islamist anticonsumptionist attitudes in Turkey. Particularly of interest to this study are the Islamist interpretations of global brands as 'infidel's and symbols of 'injustice and oppression'. Turkey as a transitional country with a rising Islamist class presents an excellent opportunity to explore diverse readings of global brands in a non-Western context. The critical ethnography draws from participant observation, in-depth interviews, researcher's field notes, and textual material analysis. Informants include 45 individuals from diverse socio-economic and educational backgrounds, although this paper focuses on 15 informants with Islamist dispositions. The identification of Islamist informants was initially driven by their distinctive physical appearance. For the purposes of this research, I sought Islamist informants primarily among women who wore çarşaf -also known as chador, a full-length black outer garment that covers the whole body except the eyes (Saktanber 1997)-because they are among the most extreme public displays of Islamist ideology in Turkey. These informants were further identified as Islamist consumers based on their ideology and lifestyles as evinced through fieldwork. The data was analyzed following the procedures described in Penaloza (1994) and (Arnould and Wallendorf 1994).

This research identifies three unique Islamist discourses of anticonsumerism: modesty, helal-haram, and zulm (oppression) that construct the meaning of global brands as infidel brands. These discourses are analyzed and introduced in the order in which they appear in informants' emic accounts. In other words, Islamist consumers first and foremost explain their anticonsumerist attitudes through Islamic ideals of modesty and later through the religious criteria of helal-haram; yet a deeper analysis reveals the essence of Islamist resentment toward global brands: the perception of global brands as oppressors of Muslim faith and the greater Islamic community. While the discourse of modesty and helal-haram essentially concern spiritual and bodily refrainment from material world and brands, the discourse of zulm is deeply entwined with socio-historical conditions such as the colonization of Muslim countries and the establishment of an Israeli state in the Middle East as well as the tensions between secularists and Islamists in Turkey. Through the discourses of modesty, helal-haram, and zulm Islamists create the boundaries of infidel brands to include any brand that poses an ideological threat to the much espoused and romanticized Islamic lifestyle.

In addition to examining the notion of infidel brands, this study extends past research by illustrating how Islamist anticonsumerism discourses conceptually differ from the postmodern and

¹Islamism is a political ideology distinct from Islam as a body of faith and is defined as "a form of instrumentalization of Islam by individuals, groups, and organizations that pursue political objectives" as a reaction to contemporary societal challenges (Denoeux, 61).

²Islamist refers to those individuals who are not just "much more pious than other Muslims, but also search for an alternative Islamic life politics and new social order" (Saktanber 2002, p. 257).

postmaterialist consumer activism as previously explored in Western contexts. In contrast to the hedonic and therapeutic consumer resistance found in these locales, Islamist anticonsumerism not only embodies a critique of the merits of Western ideals such as modernization, capitalism, and market society, but also a strong desire for a qualitatively different social order than the one modern market society offers.

The Effects of Regulatory Focus on Consumer Judgments Involving Self and Others' Payoffs

EXTENDED ABSTRACT

Many decisions involve choices that affect not only the self or one's organization but also others and other organizations. For example, consumers can factor in both their own position and that of the dealer when negotiating a car's price. Aggressive managers may weight relative performance so heavily that they prefer options that damage their own profitability just because it is slightly more damaging to a competitor (Kalra and Soberman 2008). The current study extends such research by assessing the potential impact of regulatory focus on decisions that determine self and other payoffs.

Consider the following two scenarios. In Scenario 1, a consumer has to select between two options, A and B. Option A consists of the consumer winning \$100 for sure, whereas in Option B a chance event decides if the consumer wins either \$150 or \$80 (e.g., winning the \$150 depends on picking a yellow ball from a jar containing 100 yellow and white balls). If asked for the minimum number of yellow balls the jar must contain for the individual to still prefer Option B, consumers focused on avoiding the worst outcome should state a higher minimum acceptable probability (MAP) than those focused on obtaining the best outcome (Bohnet and Zeckhauser 2004). Scenario 2 is identical to Scenario 1 except that consumers now share payoffs with a confederate. Option A splits \$200 equally between the two so that each receives \$100. However, in Option B, a chance event determines whether the two consumers split \$300 equally (\$150 each), or whether the consumer receives \$80 while the confederate receives \$220. Consumers who like sharing money with others or who do not mind receiving less should like Option B more in Scenario 2 than in Scenario 1. However, consumers who do not like sharing money with others or who dislike receiving less than others should like Option B less in Scenario 2. The consumer's self-explicated MAP, now determined by risk for money and aversion to inequality, should reflect this potential change in Option B's attractiveness. If, as we hypothesize, consumers dislike sharing money and/or receiving less than do others, their MAP's should be higher in Scenario 2, an elevation we refer to hereafter as an *inequality premium*.

This study tests for the existence of an inequality premium as well as the possibility that regulatory focus moderates that premium. Consumers typically self regulate by focusing on either acquiring the best outcome (promotion focus) or avoiding the worst outcome (prevention focus; Higgins 1997). However, to the extent that a particular regulatory focus also involves a self-view intent on distinguishing oneself from others or integrating oneself with others (Lee, Aaker, and Gardner 2000), we expect promotion-focused consumers to be more sensitive to coming out ahead and prevention-focused consumers to be more sensitive to fitting in harmoniously. Accordingly, promotion-focused consumers should find Scenario 2's risky Option B to be especially distasteful as they now have to share any larger win with someone else or endure a loss in money not only relative to Option A's sure thing, but relative to what someone else wins as well. On the other hand, prevention-focused consumers should not be so concerned with their payoffs relative to others, such that moving from Scenario 1's non-social situation to Scenario 2's social situation should have relatively little impact on them.

In Study 1, we explore if regulatory focus affects consumers' enjoyment of winning money if they win the money alone, or others win with them. We assigned forty-nine undergraduate students (24 females) to one of two regulatory focus conditions. Following the procedure outlined by Higgins and others (1994), we asked participants in the promotion-focused (prevention-focused) condition to write a brief essay about their hopes and aspirations (duties and obligations) at present as well as five years from now. Following their essay, participants imagined that they would receive a cash prize but how much cash they would receive depended upon a lottery's outcome. We described two lotteries. In Lottery 1, the participants, playing by themselves, could win \$150 or \$80. In Lottery 2, the participant, paired with a classmate, could win \$150 (with the classmate also winning \$150), or \$80 (with the classmate winning \$220). Consistent with our expectations, promotion-focused participants were less happy with the \$80/\$220 split relative to winning \$80 alone ($M=6.29$ on a 9-point scale where 9.0=Less happy, significantly greater than the scale's mid-point of 5.0; $t(23)=4.86, p<.001$). Prevention-focused participants also expressed less happiness if a confederate came out ahead, but on a much smaller magnitude ($M=5.68$, not significantly different from the scale's mid-point of 5.0; $p>.05$).

In Study 2, we assigned fifty-two undergraduate students (16 females) to one of two regulatory focus conditions using the same priming manipulation as in Study 1. After writing their essay, participants imagined that they had to choose between Options A and B in Scenarios 1 and 2 (described above). After reading each scenario, participants indicated their MAP of selecting Option B to Option A by writing a number between 1 and 100 (smaller numbers mean a stronger preference for the risky Option B). In Scenario 1, the MAP for promotion-focused participants ($M=54.19$) was smaller than the MAP for prevention-focused participants ($M=64.42$; $F(1, 49)=4.25, p<.05$). However, as predicted, promotion-focused participants demanded a significant inequality premium when moving from Scenario 1 to Scenario 2 (M 's= 54.19 vs. 69.00 ; $F(1, 24)=43.86, p<.0001$), and one that was significantly larger than the premium demanded by prevention-focused participants (M 's= 64.42 vs. 68.50 ; $F(1, 24)=2.35, p>.10$).

These findings are important for both theory and practice. Prevailing theory and research suggests that promotion-focused consumers are more risk seeking than prevention-focused consumers. The current study shows, however, that the addition of a social dimension such as payoffs relative to others can eliminate this difference. For practice, marketers hoping to sell risk-reducing products such as established, trusted brands might be able to enhance their chances by invoking social risks. Whereas a fear tactic focusing on the embarrassment of being worse off than others might affect all consumers, it should be especially potent for reining in the risk seeking tendencies of more promotion-focused consumers who might be more inclined to try a new and unproven competitor.

Culture, Regulatory Goals, and Response Styles

Ashok K. Lalwani, University of Texas at San Antonio, USA

L. J. Shrum, University of Texas at San Antonio, USA

Chi-Yue Chiu, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

Whether and how people engage in socially desirable responding—the tendency of people to portray themselves in more favorable light on survey questionnaires than their thoughts or actions may actually warrant—is a topic of considerable interest to scholars of marketing and consumer behavior both from theoretical and methodological standpoints (Fisher 1993; Mick 1996). Recent research suggests that these tendencies span cultures (Lalwani et al. 2006; 2009; Shavitt et al. 2006).

Although research has examined the effects of culture on consumer goals and their tendency to engage in socially desirable responding, the system of relations between culture, goals, and socially desirable responding is not well understood. In fact, although factors that influence responses on surveys have received considerable attention, little research has addressed the underlying processes (see Lalwani 2009, for an exception). The purpose of the current research is to fill this gap by exploring in more detail the possible connections between culture and types of socially desirable responding, the underlying processes, and factors that impact the strength of the relations. We posit that culture would be differentially related to socially desirable responding. Individualists would tend to engage in self-deceptive enhancement, the tendency to report exaggerated beliefs of one's competence, skills, and abilities, but not impression management, the tendency to provide normatively appropriate responses to look good. In contrast, collectivists would tend to engage in impression management, but not self-deceptive enhancement.

Beyond this general set of hypotheses, however, there are still important unanswered questions regarding the processes that may underlie these links. In particular, little is known about the motivational links between cultural values and socially desirable responding. The inconsistent findings on the relation between cultural values and socially desirable responding allude to the existence of variables that may mediate or moderate these relationships. For instance, it is possible that these relationships are stronger for certain kinds of people than for others. Hence, another objective of this paper is to propose and test such mediating and moderating variables. One possibility, which we investigate in the studies to be presented, is that regulatory focus underlies these effects, and that consumers' self-consciousness (public or private) influences the strength of these relationships.

Regulatory focus theory is a theory of self-regulation that proposes two distinct foci: a promotion focus that is primarily concerned with maximizing positive outcomes and a prevention focus that is primarily concerned with minimizing negative outcomes (Aaker and Lee 2001; Higgins 1997). People who are promotion focused eagerly pursue gains or successes. Focusing on accomplishments, achievements, and the pursuit of ideals, they are oriented towards fulfilling their hopes and aspirations and they scrutinize their social world for information that bears on the pursuit of success. In contrast, people with a prevention focus strive to avoid negative outcomes. Driven by the need to feel secure and to meet their obligations, these individuals are primarily concerned with preventing failures or losses, and their information processing and interpersonal tactics are geared towards avoiding undesirable outcomes (Higgins 1997). Lee, Aaker, and Gardner (2000) pro-

vided evidence that people with an independent self-construal tend to be promotion focused, whereas people with an interdependent self-construal tend to be prevention focused.

In the following studies, we explore the possible interrelations between culture, regulatory focus, and socially desirable responding. Our overarching hypothesis is that regulatory focus mediates the relation between cultural orientation and socially desirable responding. More specifically, we hypothesize that a promotion focus mediates the relation between individualism and self-deceptive enhancement, and a prevention focus mediates the relation between collectivism and impression management.

To further explicate the mediating role of regulatory focus in the relation between culture and socially desirable responding, we were interested in exploring possible boundary conditions of this pattern of effects. Specifically, we were interested in determining whether the relations just proposed are stronger for some types of people than for others. One possible variable that we investigated is self-consciousness. Research suggests that self-consciousness can be conceived of along two orthogonal dimensions: public and private (Fenigstein, Scheier, and Buss 1975). Those who are high (vs. low) in private self-consciousness are more likely to attend to their own inner thoughts and feelings. As such, their focus is on cognitions that deal primarily with the self, they tend to reflect about themselves, and they are attentive to the workings of their mind. In contrast, those who are high (vs. low) in public self-consciousness are especially attuned to other people's perspectives. They view themselves as social objects, and are sensitive to others' reactions to their behavior. As such, they regulate their conduct by taking into account the desires and expectations of others (Carver and Scheier 1998) and are interested in getting along by going along (Schlenker and Weigold 1990).

Because people who are high (vs. low) in private self-consciousness are attentive to their inner feelings, they may be more realistic about their capabilities and skills, even when they are from individualistic cultures which tend toward self-deceptive enhancement. As a result, they may be less likely to engage in self-deceptive enhancement, a response style in which people hold exaggerated, unrealistic, and glorified notions of their skills and abilities. If so, the mediating relationship between individualism, promotion focus, and self-deceptive enhancement proposed earlier should be weaker for people who are high (vs. low) in private self-consciousness. In other words, private self-consciousness should moderate the mediating relationship between individualism, promotion focus, and self-deceptive enhancement.

In contrast, people high in public self-consciousness are the epitome of the social animal (Schlenker and Weigold 1990). They not only take the role of others to imagine their reactions, but also actively mold their behavior to appeal to others (Buss 1980; Carver and Scheier 1998). Because people who are high (vs. low) in public self-consciousness are more concerned about managing others' impressions of themselves, and are also more affected by possible rejection from others (Fenigstein 1987), they may be highly motivated to engage in impression management, even if they come from collectivistic cultures that already tend toward impression management. If so, then the mediating relationship between collectivism, prevention focus, and impression management should be stronger

for people who are high (vs. low) in public self-consciousness. In other words, public self-consciousness should moderate the mediating relationship between collectivism, prevention focus, and impression management.

Four studies provide robust support for the framework we have proposed. Across the four studies, the operationalizations of the major variables (individualism—collectivism, regulatory focus, and socially desirable responding) were varied in order to maximize generalizability. In Study 1, we compared the socially desirable responding and regulatory focus of Hong Kong Chinese and European Americans, and examined whether cultural variations in socially desirable responding were mediated by regulatory focus. In Studies 2-4, we measured participants' chronic individualism and collectivism in a U.S. sample. The research makes a number of theoretical, methodological, and practical contributions.

Generic Advertising Campaigns: A Goals-Based Perspective on the Effect of Market Trends and Solicitation Messages on Voluntary Contributions

Shweta Oza, University of Miami, USA
Joydeep Srivastava, University of Maryland, USA

EXTENDED ABSTRACT

Millions of dollars are spent every year on generic advertising campaigns that are designed to promote an entire product category. Generic advertising campaigns are intended to stimulate primary category demand (i.e., increase the size of pie) (Forker and Ward 1993). Some common examples of generic advertising are the “Got Milk?” campaign, “The New Steel” campaign, “Pork: The Other White Meat” campaign, and “Cotton: The Fabric of Our Lives” campaign. Despite the importance and prevalence of generic advertising campaigns, such campaigns have received relatively little attention in the marketing literature.

The few studies that examine generic advertising campaigns have focused either on the effect of such advertising on consumers (Borden 1965; Chakravarti and Janiszewski 2004) or the relationship between generic and brand advertising in identifying conditions under which firms should focus more on generic versus brand advertising (Bass et al. 2005; Krishnamurthy 2000). As such, relatively little is known about the trials and tribulations of organizing and funding generic advertising campaigns (Krishnamurthy, Bottom, and Rao 2003). While many generic advertising campaigns, particularly in the agriculture and commodities market, are funded via mandatory contributions (also called check-offs) of the individual producers (members); several others (like “Cotton: The Fabric of Our Lives”) are funded by voluntary contributions from the individual members (Krishnamurthy 2000).

Voluntarily funded generic advertising campaigns benefit all individual members, regardless of whether an individual member contributes towards the campaign (Forker and Ward 1993) and the benefits do not reduce for any member just because another member has benefited from it. Voluntarily funded generic advertising campaigns can thus be conceptualized as a social dilemma or more specifically as a public goods problem (Dawes 1980). First, individual members benefit from generic advertising even if they do not contribute towards the campaign. The dominant strategy for a member is thus not to contribute at all with the hope that other members will contribute. Second, if all members decide not to contribute, no one benefits. The dilemma arises because the dominant strategy based on individual rationality is for an individual member to contribute nothing whereas the optimal strategy based on group rationality is for every member to contribute the maximum (Dawes and Thaler 1988). This research views voluntarily funded generic advertising campaigns from a public goods lens and examines factors that may influence cooperation and thus increase members’ voluntary contributions. Specifically, this research examines the influence of situational (or market) factors and solicitation messages on individual members’ contribution decisions towards a generic advertising campaign.

Situational factors at the macro level such as market or industry trend, more or less, affect every firm within a specific industry and have the potential to affect the level of competition or cooperation among firms (e.g., Rotemberg and Saloner 1986). However, the findings are conflicting as some studies show that cooperation decreases among firms in periods of increasing market demand (Rotemberg and Saloner 1986) whereas others show that there is less cooperation in periods of declining market demand (Green and Porter 1984; Scherer 1980). In the present context,

industry trend provides the milieu in which individual members decide on whether to contribute to a generic advertising campaign, and if so, how much? In other words, contribution decisions may be influenced by whether the individual members face a market with an increasing versus decreasing demand (and profitability). On one hand, facing a declining trend in profitability, resource constrained members may curtail their marketing and advertising budgets. On the other hand, members may feel the need to cooperate and increase their advertising budget in tough market conditions (Krishnamurthy et al. 2003). Given the scant empirical evidence on the effect of market level factors on members’ contribution decisions towards a generic advertising campaign (Krishnamurthy et al. 2003) and the conflicting theories regarding its effect on the level of cooperation, this research examines contribution decisions towards a generic advertising campaign when a specific market faces an increasing versus a decreasing profitability trend.

The second factor that we examine is solicitation message. It is common practice for industry-wide consortiums to use solicitation messages to encourage individual members to contribute towards a generic advertising campaign (Forker and Ward 1993). The effectiveness of solicitation messages is likely to vary with the message used and the manner in which the messages are framed (e.g., Maheswaran and Meyers-Levy 1990; Rothman and Salovey 1997). Further, since contribution decisions about generic advertising campaigns are made in the context of situational factors, the effectiveness of different solicitation messages is likely to vary with the prevailing market trend. Although there is considerable research which shows that message effectiveness depends on how it is framed (e.g., Levin, Schneider, and Gaeth 1998), the findings regarding the conditions under which different frames (e.g., positive/negative or gain/loss) are most effective are mixed and inconsistent (e.g., Block and Keller 1995; Lee and Aaker 2004; Maheswaran and Meyers-Levy 1990). Some studies suggest that positively framed messages are more effective (e.g., Maheswaran and Meyers-Levy 1990; Meyers-Levy and Maheswaran 2004) whereas other studies suggest that negatively framed messages are more effective (e.g., Block and Keller 1995). In the present context, the question is how should a message be framed to maximize its effectiveness in different market conditions? This research addresses this question by examining the effectiveness of different message frames in increasing contributions towards a generic advertising campaign when a market faces an increasing as well as a decreasing trend in demand and profitability.

Importantly, we develop a conceptual framework based on goal systems theory (Kruglanski et al. 2002) that allows us to predict the simultaneous effects of market trends and solicitation messages on voluntary contributions. The results of three studies are reported that are consistent with the conceptual framework. Study 1 showed that voluntary contributions towards a generic advertising campaign were higher in the decreasing market trend relative to the increasing market trend and that the market trends induced different goals and these goals mediated the effect of market trends on voluntary contributions. Specifically, an increasing market trend primarily induced the goal of increasing profits whereas a decreasing profit trend induced the goal of preventing a decline in profits.

Study 2 showed that different solicitation messages are effective in the different market trend conditions. When the market trend was positive the solicitation message that was most effective in increasing voluntary contributions towards a generic advertising campaign was positive in action and positive in consequence. In contrast, when the market trend was negative, the most effective solicitation message was positive in action but negative in consequence. The results of Study 2 are consistent with our argument that market trends induce different goals and the solicitation message that is congruent with the mean-goal association is likely to be most effective in increasing voluntary contributions. Recognizing that goals are one of many factors that may be affected by the different market trends, Study 3 was designed to demonstrate that the findings are indeed due to the different goals induced by the different market trends. Instead of manipulating market trends, Study 3 primed the goals of "increase profits" and "prevent a decline in profits" and showed that the results are consistent with the findings of Study 2.

Together, the results point to the importance of goals in decision making. Our findings suggest that situational factors may induce different goals that then lead to different behavioral tendencies (Higgins 2002; Kruglanski et al. 2002). In the generic advertising context, the market situation that an industry confronts provides the milieu within which the voluntary contribution decisions are made. The different market trends induce different goals, which in turn influence the choice and importance of available means to attain the induced goals thereby leading to differences in voluntary contributions.

An Investigation Into Individual's Repeated Attempts at Behavior Change

Courtney Droms, Valdosta State University, USA

EXTENDED ABSTRACT

Recent research has shown that individuals make repeated attempts at behavior change prior to actually being successful. For example, typically individuals try to change their dieting behaviors on 4 to 5 occasions prior to actually being successful (Polivy and Herman 2002). Many of the dark side of consumer behavior areas identified by Mick (1996), such as smoking, drug use, shopping, and gambling, are behaviors that individuals try to change on a repeated basis. As consumer researchers, however, we do not have a clear understanding of how people interpret behavior change failures and persist in their efforts to change their behaviors after such failures. In an effort to understand these behavior change attempts, this research replicates and extends the Theory of Trying (Bagozzi and Warshaw 1990), to include feedback loops from the outcomes of behavior change attempts to attitudes towards trying to change again.

Theoretical Model

The theoretical model is based on the model developed in the Theory of Trying (Bagozzi and Warshaw 1990). The theory of trying is employed in this context because it includes two variables that seem very relevant to repeated attempts at changing behaviors (i.e. the frequency and recency of prior attempts at changing behaviors). However, the model proposed by Bagozzi and Warshaw (1990) ends at trying to change behaviors. While the author does suggest that the outcomes of these behavior change attempts feedback into attitudes, they do not explore the nature of the feedback. In order to explore the nature of the feedback from outcomes to attitudes, this paper employs three constructs—attributions for outcomes, self-esteem, and hope. Each of these factors will now be briefly discussed.

Weiner's (1974) theory of attributions posits that there are three dimensions to attributions—locus, stability, and controllability—that assist individuals in understanding the causes of their behaviors and behavioral outcomes. In the model, specific hypotheses, consistent with prior literature on attributions and the self-serving bias, have been developed that explicate how outcomes for success and failure are attributed along each dimension. These attributions also act as input to attitudes towards trying again and as such, hypotheses have been developed to examine several combinations of dimensions that will have the most impact on attitudes.

Self-esteem is defined as in individual's subjective appraisal of him or herself (Sedikides and Gregg 2003), which can be influenced by both goal achievement and goal failure (Crocker et al. 2003). As such, individuals in this study are expected to have lower levels of self-esteem post-failure rather than post-success at trying to change behaviors. Hypotheses were also developed and tested to capture the complexity of the interplay between self-esteem and attributions. Finally, an individual's self-esteem is also hypothesized to have a direct effect on that individual's attitudes towards trying to change in the future.

MacInnis and de Mello (2005) define hope as a positive emotion attached to a goal. There are three important dimensions to hope: goal congruency (i.e. the extent to which an environment is conducive to fulfilling a specific goal), certainty (i.e. the level of confidence an individual has in being able to achieve his or her goal), and importance of the goal. All three of these dimensions

should be affected by the individual's success or failure at trying to change behaviors, such that failure at trying to change behaviors should lower an individual's level of hope. Hope is also hypothesized to affect the ways in which individuals understand and attribute the causes of their behavior change outcomes. Finally, individuals with high levels of hope should have a more positive outlook on the possibilities present in the future, which should enable them to have more positive attitudes towards changing in the future.

Methodology

An internet survey of 363 people from across the United States who are currently trying to diet was completed. Modifying the procedure employed by Bagozzi and Warshaw (1990), data was collected in two stages, one month apart. Participants were asked to complete a series of measures in the first stage designed to capture their attitudes and intentions to try, the frequency and recency of prior attempts at trying to change behavior, and their current levels of self-esteem and hope. At stage two, one month later, individuals completed a second survey including measures of trying, the outcome of trying, and attitudes towards trying again in the future. Participants will also complete measures capturing their attributions for the outcome of their attempts at behavior change, as well as their updated levels of self-esteem and hope.

Results and Discussion

Overall, this research enlightens the discussion of how people repeatedly change their health behaviors. The results indicate that individuals attribute the cause of their success or failure at their most recent behavior change attempt in such a way that it enables them to have a more positive attitude towards trying to change again in the future. The results from structural equation modeling show that the participants in this study attributed their failure to achieve their behavior change goal to causes that were unstable and controllable which resulted in both the stability and controllability dimensions of attributions having a significant positive effect on their attitudes towards trying again in the future. In addition, the results show that the individual's attributions mediate the effect that hope has on their attitude towards changing in the future. Moreover, I find that attributions moderate the effect that the outcome of their behavior change attempt has on the individual's level of self-esteem. Such that, individuals who makes stable attributions for failure show a substantial decrease in their self-esteem compared to those who make unstable attributions for failure. Finally, the results also indicate that the individual's change in self-esteem from before to after their behavior change attempt has a direct effect on their attitude towards trying again, such that individuals whose self-esteem decreased after their behavior change attempt have a higher attitude towards trying to change again in the future than their counterparts whose self-esteem increased post-behavior change. There are important implications for both marketing and public policy as a result of this study.

Development of a Coding Instrument to Measure Interactivity of Websites

Hilde A. M. Voorveld, University of Amsterdam, The Netherlands

Peter C. Neijens, University of Amsterdam, The Netherlands

Edith G. Smit, University of Amsterdam, The Netherlands

EXTENDED ABSTRACT

Interactivity is often perceived as the most important difference between traditional and new media (Chung and Zhao 2004) and as a key aspect of effective online marketing (Thorbjornson, et al. 2002). Two constructs are central in the theoretical discussion about interactivity: actual (i.e. objectively assessed) interactivity and perceived interactivity (Song and Zinkhan 2008; Liu and Shrum 2002). Although there are numerous instruments to measure the perceived interactivity of a website (e.g., Liu 2003; Song and Zinkhan 2008), instruments to map the actual interactivity of a website are scarce.

In the field of marketing, several studies have investigated the actual interactivity of brand websites because such websites have become an important marketing tool. However, most studies used an outdated coding instrument which is not linked to current theoretical knowledge on interactivity. The aim of the current study is to fill the gap in the literature by developing a new coding instrument to map the interactivity of brand websites. To test the applicability of the new coding instrument, a content analysis of the interactivity of top global brand websites is performed. In addition, we tested whether the instrument was applicable to different contexts. Therefore, websites from two countries (the United States and the Netherlands) and several types of products were coded.

Following Liu and Shrum (2002, 54), in this study we used the following definition of interactivity: "The degree to which two or more communicating parties can act on each other, on the communication medium, and on the messages and the degree to which such influences are synchronized." Liu and Shrum (2002) also specified three interactivity dimensions. The first dimension is two-way communication. "Two-way communication refers to the ability for reciprocal communication between companies and users, and users and users" (Liu and Shrum 2002, 55). The second dimension, synchronicity, refers to "the degree to which users' input into a communication and the response they receive from the communication are simultaneous" or without delay (Liu and Shrum 2002, 55). The third dimension is active control. "Active control is characterized by voluntary and instrumental action that directly influences the controller's experience" (Liu and Shrum 2002, 54).

The coding instrument included 50 interactive functions that were acquired from the literature about interactivity (e.g., Ghose and Dou 1998). The 50 interactive functions were categorized into the three interactivity dimensions: two-way communication, synchronicity, and active control. To validate whether these 50 interactive functions were correctly categorized into the three dimensions, we conducted an expert test to test the face validity and content validity of our categorization. Based on the results of this expert study, three interactive functions were omitted from the instrument.

To test the applicability of the instrument, a content analysis of 66 American and 66 Dutch brand websites was performed. Two bilingual coders coded two parts of the websites: (1) the home pages of each website and (2) all hyperlinked pages from the home page.

Results showed that coders were able to use the instrument, and that reliability levels were good. Moreover, the instrument was internationally applicable and was able to differentiate between websites from the U.S. and the Netherlands. The instrument was also applicable to websites from different product categories and was able to differentiate between product categories.

The results of our content analysis also gave insight in the interactivity of brand websites. In sum, the results showed that interactive functions representing the active control dimension of interactivity were most common. Frequently used functions within this dimension were the presence of hyperlinks, sitemaps, search functions, software downloading, and an option to subscribe to a newsletter. Functions facilitating two-way communication were somewhat scarcer. Commonly used functions within the two-way communication dimension were the presence of multiple modes of contact, online job placement, and online shopping facilities. Interactive functions representing synchronicity were scarce. Only one function was present on a considerable amount of websites: an animation that displays the time it takes for the website to load. The results also showed interesting differences between American and Dutch websites and between websites for durable goods, non-durable goods, and services.

In conclusion, our study has provided a vital step towards developing a coding instrument to measure interactivity of brand websites. The instrument showed high levels of inter-coder reliability. In addition, an initial effort was made to assess face and content validity of the instrument by conducting a test among experts in the field. Furthermore, the instrument can be used in different contexts and it was sensitive enough to differentiate between brands and countries.

Now that we know which interactive functions are present on top global brand websites, future research might investigate the relationship between objectively assessed interactivity and perceived interactivity. Strikingly, little research has examined which interactive functions contribute to the perceived interactivity of a website. The coding instrument that was developed in this study might be a helpful tool for such an effort.

How to Measure Brand Values?

Hansjoerg Gaus, Saarland University, Germany
Steffen Jahn, Chemnitz University of Technology, Germany
Tina Kiessling, Chemnitz University of Technology, Germany
Jan Dregner, Chemnitz University of Technology, Germany

EXTENDED ABSTRACT

In the branding literature it has been common for a long time to speak of brand values (Aaker 1996; de Chernatony, Drury, and Segal-Horn 2004; Keller 2008). In the research presented in this paper, brand values refer to human values consumers associate with brands. A number of studies underscore both the relevance and viability of such a concept for consumer behavior (Allen 2002; Allen, Gupta, and Monnier 2008; Alsem, Wieringa, and Hendriks 2007; Lages and Fernandes 2005; Limon, Kahle, and Orth 2009; Quester, Beverland, and Farrelly 2006; Strizhakova, Coulter, and Price 2008). However, this concept is not well developed. Consequently, a sound instrument to measure brand values does not exist.

Only recently, two studies use Schwartz's Value Survey (SVS) scale (Schwartz 1992) to measure brand values (Torelli et al. 2008; Zhang and Bloemer 2008). Even if we acknowledge the strengths of Schwartz's value theory and measurement instrument, we argue that the interpretation of brand perceptions based on the original SVS may be misleading. Not only some of the 10 Schwartz value types but also many indicator items might not be applicable to the brand context (Lages and Fernandes 2005). Moreover, genuine brand value types not covered by the SVS might exist.

In this paper we report the methodology and findings of a multi-method study aimed at developing a theory-driven conceptualization of brand values and a valid and reliable brand values scale. For that, we combined knowledge from psychological values research with results from research on consumer behavior and branding.

Our first empirical step was aimed at clarifying whether it is adequate to work with the original SVS scales. 64 respondents evaluated both the single items' applicability to brands in general and with regard to different categories of products or services. Since nearly 80% of the items were not considered being applicable to specific brands, we concluded that the original SVS scale's practicality to assess a brand's perceived values is not given.

In order to evaluate more deeply the suitability of the Schwartz value types in a branding context, in the next step a focus-group interview with a panel of nine marketing experts was carried out. The experts not only discussed the values' meaning with regard to brands in general but also named brands being strongly related to each value type. Although—with the exception of conformity—all Schwartz value types were accepted as being suitable for brand values, the semantic interpretation of some value types (i.e., achievement, power, security, tradition, and universalism) seems to differ significantly from Schwartz's (1992, 1994) original definitions. Consequently, we reformulated inadequate indicator items. A further review panel consisting of 12 marketing experts tested the reformulated list of items. This led to the elimination of items judged being generally inadequate for describing brands.

In the following step, the resulting preliminary brand values scale with 39 indicators was subjected to a survey. A sample of 99 students from three German universities evaluated to what extent each of the items was descriptive of four brands from different categories. The interpretation combined results from exploratory factor analysis and multidimensional scaling with knowledge about the original content of Schwartz's value types, the empirical find-

ings in the earlier studies and recent values research in psychology and consumer behavior. From the nine brand value types identified, five were consistent with Schwartz's human value types (benevolence, hedonism, self-direction, stimulation, tradition). However, there were also significant particularities. Achievement and power were found being merged into a single brand value type. The most important finding was that there might be three brand value types not present as separate human value types in Schwartz's model (aesthetics, ecology, and health).

Since the preliminary scale had shown some limitations (brand value types with intermixed items, three brand value types measured with only one indicator), in the final research step reported here an improved version of the brand values scale with 31 items was tested. A sample of 339 students from two German universities evaluated to what degree each of the items was descriptive of the same brands as in the previous survey. A series of confirmatory factor analyses supported the proposed conceptualization with nine brand value types (achievement/power, aesthetics, benevolence, ecology, health, hedonism, self-direction, stimulation, tradition). In order to gain insights into our brand values scale's nomological validity, we assessed its explanatory strength with regard to brand emotional appeal measured with items drawn from Fombrun, Gardberg, and Sever (2000) and Keller (2008). 157 respondents from a German university completed the questionnaire for two brands. Regressions run on the brand value types revealed significant effects for almost all brand value types, thus indicating nomological validity.

This research shows that conceptualizations of brand values based solely on Schwartz's work in the field of human values do not perfectly match the brand context. Our empirical findings provide converging evidence for the existence of nine different brand value types and indicate that brands can be meaningfully differentiated on this basis. While some brand value types are consistent with their human counterparts, others have to be adjusted. However, all adjustments can be explained by the characteristics of brands that obviously do not perfectly match human characteristics. In addition, our findings corroborate the existence of three genuine brand value types, aesthetics, ecology, and health, which are not present as separate value types in Schwartz's (1992) original model. Moreover, our newly developed brand values scale measures the nine brand value types in a valid and reliable way and thus is a promising instrument for consumer research.

Digit Ratios Predict Risk Aversion for Both Sexes

Ellen Garbarino, University of Sydney, Australia

Robert Slonim, University of Sydney, Australia

Justin Sydnor, Case Western Reserve University, USA

EXTENDED ABSTRACT

Many of our most important consumption decisions, such as buying a home or car, investing for the future and choosing healthcare options involves risk taking. Despite the importance of risk attitudes and the large literature on the subject, relatively little is known about the determinants of risk taking or the sources of heterogeneity in risk attitudes. One of the most consistent findings in the risk taking literature is that women are more risk averse than men. For example, in a meta-analysis of 150 studies of gender differences in risk taking, men were found to be significantly less risk averse than women on 14 out of 16 risk taking categories (Byrnes, Miller & Schafer, 1999). Most of the explanations for this persistent gender difference involve psychological or sociological theories, such as self-regulation models, social-role theories, or power and status differences. In contrast, little research has explored the biological basis for gender difference in risk taking.

To explore a possible of a biological basis for risk taking; we examine whether differential exposure to *prenatal* androgens affects risk taking in a financially motivated decision task. A persistent biological marker of exposure to prenatal androgens exists in the ratio of the length of the index to the length of the ring finger, commonly called the 2D:4D ratio. Within and across gender a lower ratio results in part from greater exposure to testosterone and lesser exposure to estradiol (Lutchmaya et al., 2004), with men on average having a lower ratio than women. The 2D:4D ratio offers an excellent marker of biological effects since it develops in utero (Malas et al., 2006), persist through puberty (Trivers et al., 2006) and into adulthood (Phelps, 1952). The 2D:4D ratio has been correlated with a wide array of biological and psychological characteristics that show strong sex differentiation suggesting that it is an effective predictor of gender differences (e.g., Manning & Taylor, 2001; Kempel et al., 2005; Austin et al., 2002).

To examine the relationship between 2D:4D and risk taking, we ran a study that included 2D:4D measurement and three financially motivated decisions involving varying levels of risk. Sixty-five female and eighty-six male Caucasian participants made three financial decisions. Building on established procedures for measuring risk preferences (Eckel & Grossman, 2008), each decision required selecting one of six options. The expected payoff increased from options 1 to 5 and was the same for options 5 and 6. Financial riskiness (e.g., variance) increased from options 1 to 6; thus choosing higher options indicates acceptance of greater risk. For each participant, one decision was randomly chosen to be played out and paid. Afterwards, participants' hands were scanned. Second and fourth fingers were measured for both hands by three independent coders (interrater reliability 0.86). Since results are similar across measures, the analysis uses the average ratio averaging across coders and hands.

Consistent with the extant literature, we find that women were significantly more risk averse than men across all three decisions (the average female choice was 0.769 options lower than the male average; $p < 0.01$; OLS regression controlling for subject and decision effects) and men have the expected lower 2D:4D ratio (male 2D:4D ratios (.959) were lower than female ratios (.969); $p < 0.02$, $t\text{-stat} = 2.23$).

However, the main and novel results are that the 2D:4D ratio can partially explain risk taking behavior both within and between

genders. The 2D:4D ratio can explain risk taking differences *within* gender; for both sexes, people with lower 2D:4D ratios (i.e., higher relative levels of in utero testosterone exposure) take greater risk ($p < 0.011$; OLS regression controlling for subject, decision and gender). A one standard-deviation decrease in the ratio increased the choice riskiness by 0.23 options (equivalently, 0.145 standard-deviations). This 2D:4D effect was the same for men and women (coefficient=0.00, $p > 0.99$ for 2D:4D-by-gender interaction). The 2D:4D ratio also explains some of the difference *between* genders in risk taking; the average gender gap fell 11% from 0.769 options lower for women without controlling for 2D:4D to 0.685 options lower controlling for 2D:4D ($p < 0.045$, $\chi^2 = 4.02$). A quartile examination of the data reveals that this decrease in gender difference is driven by those at the high and low extremes of the 2D:4D distribution. We also find that the other physical factors we measured (height, BMI and finger length) do not affect choices across the risky decisions, reinforcing that the predictive power of 2D:4D is not spurious, and adding further support for the role of 2D:4D as an indicator of a biological basis for risk taking behavior.

Relocating Profane Consumption into Sacredness: Consumer Redemption and Resurrection through Practices of Disposal

Helene Cherrier, American University in Dubai, United Arab Emirates
Kaleel Rahman, American University in Dubai, Dubai, United Arab Emirates

EXTENDED ABSTRACT

This study focuses upon the role of disposal in relation to changes in consumption lifestyle. It argues that adopting a voluntary simplicity lifestyle can lead consumers to experience disposal as a sacrificial ritual. Grounded in anthropological studies, sacrifice is conceptualized as both a liberating act and a process of moving toward sacredness.

The data consists of existential phenomenological interviewing with twelve informants who identify themselves as voluntary simplifiers and have, at one point in their lives, voluntarily lowered the amount of their material possessions. The interviews offer descriptive details on their process of disposal and its relation to a change in values and consumption lifestyle. The hermeneutic analysis shows informants' practice of disposal organized around three main themes: redemption, resurrection, and sacredness.

The theme "redemption" describes informants' practice of disposal as a way to redeem themselves from the social norm to own and display countless objects. Similar to a 'sacrificator', each informant was a bearer of pollution and sins. According to the interviews, they had accumulated and owned objects in excess. Disposing of the material surplus provides the means for cleansing the self of material pollution and sins. Under this theme, disposal is described as a purifying act, focusing on the termination of a self that had been polluted by the ideology of consumer culture, with its emphasis on material success, accumulation, holding on and storing goods.

The second theme "resurrection" shows disposal as a necessary ritual for self-transformation. Disposing of material possessions was for the informants a rite of passage from the termination to the recreation of personhood and lifestyle. Like a sacrificial rite, informants found in the practice of disposal a way to repair equilibriums between their self-concept and their environment, which involves both a deliverance from the slavery of material accumulation and a reconciliation with their self-concept. Re-creating this equilibrium called for the disposal of material accumulation by giving to others, including friends, charity organizations and strangers.

Finally, "sacredness" notes disposal as a transcendental experience that prefigures the death of profane consumption and the birth of sacred consumption. The act of disposal represents a gift informants made to others, to nature and/or to God. Impetus for the gift is the informants' understanding that their objects are passed on to others and that their meanings are regenerated in the process. The gift and the regeneration of meanings prolong the life of objects and infuse characteristics of eternity and sacredness within the material. Just as a sacrificial rite opens doors to sacredness, disposal provides the means to participate in the circulation of objects and to enact sacred consumption practices.

The three themes support that disposal entails both a process and an act. It is not just an act of letting go of our belongings, but also a process of becoming (Cherrier and Murray 2007; Lastovicka and Fernandez 2005; Ozanne 1992; Price and Arnould 2000; Young 1991; Young and Wallendorf 1986). This study also notes that consumers do not necessarily divest the private meanings attached to particular objects prior to disposing of them. Instead, informants reflected on broad societal and sacred meanings. It is the reflections

on interconnectivity between people and the circulation of objects that lead informants to dispose of their possessions and engage in sacred consumption practice. Furthermore, this study on voluntary simplifiers shows relevant similarities between practices of intentional disposal and the concept of sacrifice. The majority of anthropological studies recognize sacrifice as a personal renunciation of a human life, an animal or a material object that nourishes a higher purpose. In this study informants felt being polluted by material surplus and letting go of their possessions offers the means for cleansing and elevating themselves to higher beings. From this perspective, the personal renunciation of objects nourishes a quest for meanings and sacredness. Here, the accent lies no longer on the suffering and the burden of disposal but on the engagement to a meaningful existence through which, similar to a sacrificial ritual, "a man can find himself anew" (Jung, 1969, p. 260).

This study turns on the very question of disposal as a gain rather than a loss for the owner. For the informants, disposal bears an ontologically promise of value, a promise that motivates and underwrites the process of disposal. Disposal redeemed informants from sins of material accumulation and resurrected them into a transformed state of sacred participation. In a more general sense, disposal was for the informants a symbolic instrument for self-realization. From this perspective, we may question whether the practice of disposal is linked to Mauss' concept of societal obligation for which individuals have to give, to receive and to reciprocate (Mauss 1954).

Religious Artefacts as Consumer Culture Products

Jeaney Yip, University of Sydney, Australia

Susan Ainsworth, University of Melbourne, Australia

EXTENDED ABSTRACT

Religion has not escaped the effects of consumer culture and is increasingly forced to compete in a spiritual marketplace (Roof 1999). This competition has resulted in constructions of new products and reconstructions of current products. Cultural effects on religious products are not well understood as studies on the consumption of these considered 'sacred' products are few. While relations to the sacred have been documented in previous research (Belk, Wallendorf and Sherry 1989; O'Guinn and Belk 1989; Arnould and Price 2004), they have been predominantly studied as a metaphoric stance rather than specifically about the 'Sacred' per se (Iacobucci 2001). As both a religious and cultural product, Christian artefacts are malleable to socio-cultural forces and consumer culture cultural products are also relatively unexplored (Askegaard 2008, Brownlie, Hewer and Horne 2005, Hirschman 1988).

It is not surprising to find the effects of consumer culture on the sacred as 'marketplace theology' is being produced by mega-churches which cater to the needs of its target audiences (Twitchell 2004). Cultural products need to be conditioned for the market (Miller 2003), much the same way as agribusiness comes up with exotic and new breeds of common produce to stimulate sales of what is otherwise 'plain tomatoes'. Featherstone (1991) noted that the locus of the sacred has shifted from traditional religious institutions to consumer culture. In so doing, "consumer culture co-opts religious subcultures and not the other way around" (Romanowski 1992, 47). The purpose of the research is not to ascertain whether contemporary churches and its artefacts is secularised or not, but to explore *how* church identity is constructed using elements of religious traditions and other familiar, appealing discourses to produce artefacts and experiences that resonate with contemporary consumption ideals of individualism, empowerment, prosperity, immediate rewards and interest in the supernatural.

In an attempt to study *how* secularisation and consumer culture inflects a religious product and a church's identity, a cross section of a church-produced contemporary style of Christian worship music dating from 1992–2007 was selected. This music is chosen due to its close relations to a successful Sydney-based mega church which combines Christian theology with business ideals. Textually-oriented discourse analysis (Fairclough 2003) was used to do a reading (Scott 1994; Stern 1989) of lyrics. This reading is accompanied and interpreted through an assortment of other texts that include visual, audio, and textual data at the church level. In the analysis of these texts, artefacts and social practices, we were concerned with identifying not only what discourses were being drawn upon but also how they were combined in order to understand the basis for their contemporary appeal.

The church and its artefacts, constructs an identity that draws upon secular and business discourses which are hybridised with religious theology. This hybridisation is comfortably reconciled through a process of differentiation (Saussure 1966) which strives to project an image and identity that is *not* religion-like and certainly, *not* like a traditional church. This '*not religion*' discourse instead offers wholeness, healing and inner transformation to the individual unencumbered by stereotypes of traditional institutional religions which connotes formal membership and allegiance. Through this discourse, secular structures and habits are reinforced by a host of practices such as using popular music in praise and

worship to heighten emotional contagion, placing a monetary value (ie., price) to church services and events, regular selling of merchandise, marketing preachers and using individualist tenets to repackage religion. The familiar structures and habits of consumer culture re-orient legitimate religious desires into the service of furthering the consumption of religion through music, books, tapes and messages which offers individual self-fulfilment.

Like language, identity can be seen as a system of meaningful differences (Saussure 1966), and in the church studied, the strategy of differentiation is particularly central to its identity construction and discourse. This strategy is enacted in different discursive mediums, for example, in songs and written text as well as through building architecture and design. Through a mixture of humanist, motivational and romantic appeals, the message of God and the Gospel exists theologically but culturally is reconstructed and repackaged to convey a dominant discourse of 'ego-centricness' and 'feel-goodness'. In a context of individualism where the erosion of traditional institutionalised religions is evident our findings support the takeover of religion by the popular discourse of 'spirituality' (Carrette and King 2005). Spirituality, as opposed to religion, is a personal quest for meaning. It is a journey of the soul in order to seek what it's searching for, or to satisfy what Roof (1999) calls 'wholeness hunger'. Through this discourse, religion is transformed into a self-centred therapeutic exercise attributable to consumer culture and commercial marketing. The discourses from the songs and church products have this kind of audience in mind. They appeal to the therapeutic and seeker self (Bellah, Madsen, Sullivan, Swidler and Tipton 1985) by offering empowerment and freedom.

While secularisation theory claims differentiation and separation between religion and other spheres of social life (Chaves 1994), the symbols, practices and myths of traditional religion that once influenced people's lives continue to do so in the form of consumer culture. Rather than separation and differentiation, what is evident in the findings of this research is a strategic combining of religious and secular discourses within the context of a 'deregulated' religious market. In so doing, religion is not able to escape ideological influences exerted by the capitalist marketplace (Thompson 2004). Exposed to the market system and dominated by discourses of freedom and individual choice, religious systems have fragmented as religious consumers can pick and choose. However such 'freeing up' of religion has also enabled religious providers to harness the appeal of contemporary discourses in marketing their own brand of religion that resonates with dominant social values of individualism, empowerment and aspiration to affluence.

Cultural secularisation has transformed religious markers and symbols, expressed through music and theology in this study to exhibit patterns of consumer culture. One might argue that this is simply an expression of a religious institution operating under consumer culture, which Slater (1997) defines as a system in which consumption is dominated by the consumption of commodities and in which cultural reproduction is mediated through markets. This is the dominant discourse that actually prevails, is being reproduced and sustained through mega-churches such as Hillsong. Through this dominant discourse, religious beliefs are re-directed into a consumption choice. The economic rhetoric of the 'marketplace' speaks of a free market and a consumer who is free to choose; a stance that most people in developed societies are comfortable and

familiar with. It is no surprise that branded churches such as Hillsong employ this rhetoric in marketing religion, enacted through the familiar consumption ideologies of choice, freedom and individual empowerment. While this model of mega-church emerged in a landscape of American Christianity (Twitchell 2004) where the consumption discourse is dominant, it is interesting to see its expansion internationally (Australia, Asia, Africa to name a few) as the practices and dispositions associated with the mega-church spread and colonize other dimensions of Christianity.

The Moral Discount: Can Being Socially Responsible Hurt Your Brand?

Stefanie Rosen, University of South Carolina, USA

Stacy Wood, University of South Carolina, USA

EXTENDED ABSTRACT

Corporate social responsibility (CSR) can be used as an effective marketing technique and, to media and consumer praise, companies spent \$4.4 billion on CSR in 2007 (Lawrence and Mukai 2008). CSR, defined as a “company’s status and activities with respect to its perceived societal obligations” (Brown and Dacin 1997, 68), can increase customer satisfaction with the company (Marin and Ruiz 2007), enhance brand evaluations (Brown and Dacin 1997), and increase consumer willingness-to-pay (Creyer and Ross 1997). However, recent research suggests consumers perceive more ethical brands to be less effective (Luchs et al. 2008). Here, we investigate this “moral discount” and find that the impact of CSR on product evaluations depends on two factors: brand strength and the nature of the “ethical element” (type of CSR attribute).

When a brand engages in a typical CSR campaign (e.g. donating money), the CSR attribute becomes an important piece of accessible information for consumers to use when evaluating the brand. According to the accessibility-diagnostics model, accessible information will be used as input into judgment if the information is perceived to be more diagnostic than other accessible inputs (Feldman and Lynch 1988). When accessible and diagnostic, consumers use memory-based and context-based information (Menon, Raghuram, and Schwarz 1995). Context-based information, information given during the time of the decision, is used when memory-based information is not accessible. When memory-based information is accessible and diagnostic, context-based information is not used. With an unfamiliar brand, consumers can not rely on previous associations of the brand and therefore, the context-based information of the CSR attribute becomes diagnostic. We predict that when context-based information is related to CSR attributes, consumers will fall prey to Luchs et al. (2008) ‘ethical equals less effective’ lay theory. However, when a familiar brand engages in CSR, memory-based cues become diagnostic when evaluating the brand. Therefore, consumers will use this context-based information in conjunction with the memory-based cues of the brand (Menon et al. 1995). Thus, the CSR attribute will be inferred to be consistent with the memory-based evaluation of the brand (Dick, Chakravarti, and Beihal 1990). We predict that a brand with a CSR attribute will increase (decrease) perceived (1) brand effectiveness and (2) willingness to pay for a familiar (unfamiliar) brand.

In study 1, we test whether the type of brand, familiar versus unfamiliar, is helped or hindered by a typical CSR attribute, donating money to non-profit organization. Participants were exposed to one of four conditions in a 2 (familiar vs. unfamiliar brand) X 2 (CSR attribute vs. non-CSR attribute) between-subjects design. Participants were shown a picture of a candy bar and told that this was a new product on the market and asked questions related to their anticipated taste ratings and willingness to pay for the product. We conducted two, 2 X 2 ANOVAs with the anticipated taste rating and willingness to pay as the dependent variables. For both variables, there is a significant CSR x Brand interaction, (taste= $F(1, 171)=5.538, p<.05$) (willingness to pay= $F(1, 171)=3.752, p=.05$). These results support our prediction above.

Study 1 addresses a typical CSR attribute, charity donations, that is extrinsically tied to the brand. CSR attributes can also be intrinsically related to the product (e.g., earth-friendly ingredients).

Consumers use both extrinsic and intrinsic cues (e.g., attributes) simultaneously when making evaluations of a brand (Jacoby, Olson, and Haddock 1973). For a familiar brand, an intrinsic CSR attribute presents contradictory evidence to the memory-based perceptions of the brand’s physical make-up. While the CSR intrinsic attribute is not necessarily negative, it possesses the same characteristics as a negative cue and alters the perceptions of the brand’s quality (Ahluwalia 2002). Therefore, one might predict that with a familiar brand, consumers will perceive a CSR intrinsic attribute more negatively than a CSR extrinsic attribute. For an unfamiliar brand, the consumer does not have memory-based information to judge the new CSR attributes and therefore an intrinsic CSR attribute does not provide inconsistent information to the consumer. We propose that an intrinsic CSR attribute therefore helps an unfamiliar brand because the attribute becomes part of the contextual cues used to define the product. However, extrinsic CSR attributes do not provide the same depth of contextual information about the unfamiliar brand and therefore are not strong indicators of the product.

In study 2, we test whether the type of CSR attribute, acting as an extrinsic vs. intrinsic cue, helps or hurts a familiar vs. unfamiliar brand. We conducted 2 (familiar vs. unfamiliar) X 2 (extrinsic CSR attribute vs. intrinsic CSR attribute) between-subjects design. Participants were shown a picture of detergent and rated the effectiveness of the detergent and their willingness to pay. We conducted a 2 X 2 ANOVA with detergent effectiveness as the dependent variable. There is a significant CSR X Brand interaction ($F(1,233)=4.07, p<.05$), which shows that with an unfamiliar brand, effectiveness ratings are higher for intrinsic versus extrinsic CSR attributes, however with a familiar brand, effectiveness ratings are equal for extrinsic versus intrinsic CSR attributes. Unlike detergent effectiveness, we do not see a significant interaction for consumers’ willingness to pay ($F=.33$). These results show that consumers perceive an unfamiliar brand with an intrinsic CSR attribute as more effective than an unfamiliar brand with an extrinsic attribute. However, for familiar brands, the data show no difference in the efficacy of extrinsic versus intrinsic CSR attributes.

This research demonstrates that, in promoting socially responsible products, managers should carefully consider both their brand’s strength and the type of CSR attribute. Familiar brands may be better able to benefit from extrinsic and intrinsic attributes. However, brands new to the marketplace may want to avoid extrinsic CSR attributes, thus avoiding the moral discount bias.

When Brands do Right but Decide Wrongly: The Impact of Perceptions of Procedural and Outcome Fairness on Brand Attitudes

Pragya Mathur, Baruch College, CUNY, USA
Neela Saldanha, University of Pennsylvania, USA
Eric A. Greenleaf, New York University, USA

EXTENDED ABSTRACT

Marketers strive to deliver benefits to consumers, such as reducing late fees on DVD rentals, expecting that such benefits will lead to enhanced brand evaluations. We demonstrate that this expectation may not be accurate and suggest that consumer perceptions of procedural unfairness may negatively impact brand evaluation.

Existing literature on perceived fairness in marketing has dealt mainly with unfavorable outcomes to consumers (e.g. price increases: Bolton and Alba 2006; Bolton, Warlop, and Alba 2003; Xia, Monroe, and Cox 2004). In contrast, the organizational justice literature distinguishes between outcome and procedural fairness (Brockner and Wiesenfeld 1996). Outcome fairness refers to the equity of outcomes (Brockner et al. 2003) and has been empirically shown to be closely related to outcome favorability (Brockner and Wiesenfeld 1996; Brockner et al. 2003; Lind and Tyler 1988). Procedural fairness refers to the fairness of the process to obtain the outcome (Lind and Tyler 1988; Thibaut and Walker 1975; Brockner 2002). Perceptions of procedural unfairness can negatively affect evaluations especially when it is made salient (Brockner et al. 2003). Across three studies we show that favorable outcomes may not lead to enhanced brand evaluations and perceptions of procedural fairness are instrumental in this result.

In Study 1, participants read a vignette about two fictitious movie rental firms and completed a baseline evaluation index ($\alpha = .93$). Respondents were then told about the favorable activity i.e. the target firm had eliminated its late fees policy. Procedural fairness was manipulated by information that highlighted the self-interested motive of the target firm: in the unfair (fair) condition, participants learnt that the competitor had recently dropped its late fees (retained its late fees). Respondents then completed a post-information evaluation index ($\alpha = .96$) and manipulation checks. As predicted, fairness ratings were higher in the procedurally fair (versus unfair) condition ($M_{\text{fair}} = 6.65$ vs. $M_{\text{unfair}} = 5.88$, $p < .05$). Evaluation was significantly enhanced in the procedurally fair condition ($M_{\text{pre}} = 5.02$, $M_{\text{post}} = 5.85$, $p < .05$) but was unchanged in the procedurally unfair condition ($M_{\text{pre}} = 4.62$, $M_{\text{post}} = 4.95$, $p > .1$).

In Study 2, we examined the impact of the salience of fairness perceptions on brand evaluations in a 2 (procedural fairness: fair/unfair) \times 2 (salience: low/high) between-subjects design. Salience was manipulated by the order in which participants were asked to evaluate fairness: before or after evaluating the brand. All other measures were identical to Study 1. Results indicated a significant three-way interaction between procedural fairness, salience, and the time of brand evaluation ($F(1, 65) = 11.43$, $p < .001$). When the action was procedurally-fair, brand evaluations were enhanced regardless of salience (Salient: $M_{\text{pre}} = 4.49$, $M_{\text{post}} = 5.72$, $F(1, 65) = 28.96$, $p < .001$; Not-Salient: $M_{\text{pre}} = 4.38$ vs. $M_{\text{post}} = 5.43$, $F(1, 65) = 16.88$, $p < .001$). In the procedurally-unfair condition, however, brand evaluations were diluted ($M_{\text{pre}} = 4.75$, $M_{\text{post}} = 4.01$, $F(1, 65) = 8.94$, $p < .01$) in the salient condition and enhanced in the non-salient condition ($M_{\text{pre}} = 4.13$, $M_{\text{post}} = 4.88$, $F(1, 65) = 8.61$, $p < .001$).

In Study 3, we provided more insight into the process by specifically measuring both outcome and process fairness. Salience was manipulated by asking respondents to keep "the outcome

(process) of the policy change in mind" after reading the manipulation.

Perceptions of procedural, but not outcome, fairness, were affected by manipulations. There was a significant two-way interaction between fairness and salience ($F(1, 98) = 6.05$, $p < .05$), and main effects for fairness ($F(1, 98) = 18.95$, $p < .001$), and salience ($F(1, 98) = 6.21$, $p < .05$). In the procedurally fair condition, perceptions of procedural fairness were unaffected by salience ($M_{\text{fairness-salient}} = 5.42$, $M_{\text{fairness-non-salient}} = 5.42$, $F < 1$), but in the unfair condition, perceptions of procedural fairness were significantly lower in the unfairness salient condition ($M_{\text{unfairness-salient}} = 4.06$, $M_{\text{unfairness-non-salient}} = 5.05$, $F(1, 98) = 10.95$, $p < .01$).

Procedural unfairness impacted brand evaluations. A significant three-way interaction between procedural fairness, salience, and the time of measuring brand evaluation ($F(1, 98) = 4.81$, $p < .05$) was observed. In the procedurally fair condition, evaluations were enhanced in both the salient ($M_{\text{pre}} = 4.67$, $M_{\text{post}} = 5.68$, $F(1, 98) = 16.93$, $p < .001$) and non-salient condition ($M_{\text{pre}} = 4.57$ vs. $M_{\text{post}} = 5.78$, $F(1, 98) = 21.11$, $p < .001$). In the procedurally unfair condition, however, brand evaluations were diluted ($M_{\text{pre}} = 4.76$ vs. $M_{\text{post}} = 4.01$, $F(1, 98) = 5.55$, $p < .05$) in the salient condition and enhanced in the non-salient condition ($M_{\text{pre}} = 4.31$ vs. $M_{\text{post}} = 4.96$, $F(1, 98) = 6.44$, $p < .05$). Respondents also reported being more satisfied when the process was fair ($M_{\text{Fair}} = 5.65$ vs. $M_{\text{Unfair}} = 5.06$, $F(1, 98) = 4.23$, $p < .05$) and when fairness was not salient ($M_{\text{Salient}} = 4.99$ vs. $M_{\text{Not-Salient}} = 5.72$, $F(1, 98) = 6.28$, $p < .05$).

To test if perceptions of procedural fairness mediated the effect of fairness and salience on brand evaluation, perceptions of procedural fairness were used as a covariate in a three-way ANOVA with brand evaluation change as the dependent variable (Gorn et al. 2004; Kim and Markman 2006; Posavac et al. 2006). Perceptions of procedural fairness significantly impacted brand evaluation change ($F(1, 97) = 4.10$, $p < .05$). The previously significant three-way interaction between fairness, salience, and time of brand evaluation became non-significant ($F(1, 97) = 3.41$, $p > .05$). Finally, procedural fairness significantly predicted brand evaluation change ($\beta = .41$, $p < .01$). An identical analysis on outcome fairness revealed no evidence of mediation.

Our research indicates the importance of both outcome and procedural fairness in predicting consumer response to marketing activities. Theoretically, our work opens up a new area within fairness research—the importance of fairness in the face of favorable outcomes. Practically, our research helps explain why beneficial marketing actions may not have the expected additional long-term lift and may even have a negative return if competitors, news media or others highlight procedural unfairness in a firm's marketing decisions.

The Underdog Effect: The Marketing of Disadvantage through Brand Biography

Neeru Paharia, Harvard University, USA

Anat Keinan, Harvard Business School, USA

Jill Avery, Simmons School of Management, USA

Juliet B. Schor, Boston College, USA

EXTENDED ABSTRACT

“We started Nantucket Nectars with only a blender and a dream...” (Nantucket Nectars label)

“Thanks to a never ending campaign by Apple’s powerful public relations machine to protect the myths surrounding the company’s origin, almost everyone believes Apple was started in a garage...actually the operation began in a bedroom... when the bedroom became too crowded operations did indeed move to the garage.” (Linzmayr 1991:1)

“I was never the likeliest candidate for this office. We didn’t start with much money or many endorsements. Our campaign was not hatched in the halls of Washington—it began in the backyards of Des Moines and the living rooms of Concord and the front porches of Charleston.” (President-Elect Obama’s acceptance speech, Nov. 5, 2008)

Despite Americans’ infatuation with winners, stories about underdogs are pervasive in sports, politics, religion, literature, and film. Both candidates in the 2008 United States presidential election, Barack Obama and John McCain, positioned themselves as underdogs to gain the support of voters, as did presidential primary candidates Hillary Clinton, John Edwards, Mike Huckabee, and Ron Paul. Underdog author J.K. Rowling, a welfare mother who wrote seven of the best-selling books of all time, created a lovable underdog character, Harry Potter, an inexperienced but passionate orphan who grew up in a closet. Television coverage of the 2008 Olympics highlighted underdog aspects of many athletes’ biographies, from swimmer Michael Phelps’s single mother to gymnast Shawn Johnson’s parents taking out a second mortgage on their home to pay for her gymnastics lessons.

In this research we examine how marketers can use underdog narratives to positively affect consumers’ perceptions of brands. Underdog narratives are often delivered to consumers through the rhetorical device of a brand biography, an unfolding story that chronicles the brand’s origins, life experiences, and evolution over time in a selectively told narrative. Many contemporary brand biographies contain underdog narratives which highlight the company’s humble beginnings, hopes and dreams, and noble struggles against adversaries. Nantucket Nectar’s label informs us that they started “with only a blender and a dream,” while brands such as Google, Clif Bar, and Apple profile the humble garages in which they started.

We argue that underdog brand biographies are effective because consumers can relate these stories to their own lives. We demonstrate that the positive effect of underdog brand biographies is driven by identity mechanisms. Specifically, we show that the underdog effect is a) mediated by a consumer’s identification with the brand, b) greater for consumers who strongly self-identify as underdogs, c) stronger in purchase contexts that are symbolic of identity, and d) stronger in consumers who are from cultures in which underdog narratives are part of the national identity. These findings suggest that the underdog brand biography is powerful, not only because it invokes a sympathetic response or because it triggers attributions of effort or quality, but because it appeals to

consumers’ identity needs. Consumers react positively when they see the underdog aspects of their own lives reflected in branded products.

This article is organized as follows. First, we introduce the concept of an underdog brand biography and explore the emergence and dissemination of underdog narratives in culture. Next, we present a series of hypotheses which examine and explain positive consumer response to underdog brand biographies. Since underdog narratives are an under-explored topic in consumer research, we then use factor analysis to develop an underdog scale that reveals two main dimensions of an underdog: 1. external disadvantage, and 2. passion and determination. Next, five studies examine the effect of using an underdog brand biography on purchase intentions, real choice, and brand loyalty, and demonstrate that identity mechanisms both mediate and moderate this process. These studies measure and prime consumers’ identities as underdogs, and manipulate the identity value of the purchase situation. We also explore how external disadvantage and passion and determination work together by comparing the effectiveness of the underdog biography to three related brand biographies. Finally, we explore the boundary conditions of the underdog effect by manipulating whether the underdog wins, loses, or is in a situation where the outcome remains uncertain. We also explore the cross-cultural boundaries of the underdog effect by testing it in two distinct cultures: American, in which underdog narratives are part of the fabric of the national identity, and Asian, in which they are not. The discussion section provides a more complete and nuanced conceptualization of an underdog brand biography based on our studies. We conclude with a discussion of the theoretical implications of underdog brand biographies and offer insight into implications for brand management.

The Influence of Romantic Mindsets on Brand Extension Evaluation

Alokparna Basu Monga, University of South Carolina, USA

Zeynep Gürhan-Canli, Koc University, Turkey

EXTENDED ABSTRACT

Prior research on brand extensions has focused on identifying a variety of factors that influence brand extension evaluations among consumers (Broniarczyk and Alba 1994; Loken and John 1993). One key factor is the degree to which consumers are able to see a connection between the parent brand and the extension. When consumers perceive some kind of fit between the parent brand and the extension (e.g., Gillette shampoo), the brand extension is evaluated favorably. However, when consumers perceive less fit (e.g., Gillette floor cleaner), the brand extension is evaluated negatively (Aaker and Keller 1990; Loken and John 1993).

Missing, however, from this research is a consideration of how transient mindsets might influence brand extension evaluations. Recent research in consumer behavior attests to the wide variety of situations in which transient mindsets affect consumer behavior (Chandran and Morwitz 2005; Liu and Aaker 2008; Xu and Wyer, 2007). In our research, we focus on a specific type of mindset—the romantic mindset, which is an emerging area of research in psychology (Griskevicius et al. 2006).

Recent research demonstrates that individuals in a romantic mindset show boosts in creativity (Griskevicius et al. 2006). For instance, male participants when primed with thoughts about short-term romantic relationships (that is, a romantic mindset) generated stories that were more creative, imaginative and original. In contrast, females did not show this effect. Since romantic mindsets increase the ability to find relationships between remote ideas and associations, they are likely to enhance perceptions of brand extension fit for a dissimilar brand extension. We draw upon this research to propose that male consumers in a romantic mindset would be able to find novel ways to connect the brand and the extension leading to more favorable brand extension fit perceptions and evaluations. This effect would not emerge for female consumers.

Study 1 tested our hypothesis in a 2 (mindset: romantic, non-romantic) x 2 (gender: male, female) between subjects design. Seventy-five students at a southern university participated in our study. Our results demonstrate that male consumers in a romantic mindset perceive higher fit and evaluate a dissimilar brand extension more favorably, compared to those in a non-romantic mindset. Female consumers, however, are not affected by thinking about a short-term mate. An analysis of relational thoughts reveals that male consumers in the romantic mindset are able to think more relationally (connecting the parent brand to the extension) than those in a non-romantic mindset, indicating that the accessibility of relational thoughts may be driving the differences in brand extension responses across romantic and non-romantic mindsets. Results of a mediation analysis demonstrate that relational thoughts mediate the effect of mindset on brand extension evaluations for male consumers but not for female consumers. Importantly, our results are not driven by positive mood, positive arousal or negative arousal. Next, we replicated the results of this study using a different parent brand from the one used in study 1.

Now, we focus on providing stronger evidence for the process mechanism. Prior research suggests that finding relations between words requires cognitive resources (Wegner and Erber 1992). We draw upon this research to propose that when cognitive load is low, male consumers would be able to engage in relational thinking and respond more favorably to a dissimilar brand extension under a romantic mindset than under a non-romantic mindset. However,

when cognitive load is high, the ability of male consumers to uncover relationships between the brand and the extension will be constrained. Therefore, the effect of a romantic mindset will diminish under these conditions.

We tested this hypothesis in a 2 (mindset: romantic, non-romantic) x 2 (cognitive load: low, high) between subjects design. One hundred and twelve male students at a southern university participated in our study. Specifically, male consumers under low cognitive load perceived higher fit and reported more favorable brand extension evaluation in a romantic mindset than in a non-romantic mindset. In contrast, when cognitive load is high, male consumers in romantic mindset respond similar to those in a non-romantic mindset. An analysis of relational thoughts reveals a similar pattern. Results of a mediation analysis show that relational thoughts mediate the effects of the mindset on brand extension evaluation when cognitive load is low, but not when it is high. Importantly, mood or arousal was not an explanation for our findings.

Coping with Guilt and Shame in the Impulse Buying Context

Sunghwan Yi, University of Guelph, Canada

Hans Baumgartner, Pennsylvania State University, USA

EXTENDED ABSTRACT

In this study we studied how consumers cope with guilt and shame in the impulse buying context. As with other instances of self-regulation failure, buying on impulse against one's intention to reduce impulse buying brings about aversive self-awareness, which, in turn, is likely to evoke negative self-conscious emotions, namely, guilt and shame. Even though often used interchangeably, guilt and shame are considered distinct emotions with different antecedents and motivational tendencies (Lewis, 1971; Tangney & Dearing, 2002).

Guilt is a feeling of remorse or regret which involves preoccupation with a particular transgression. Guilt arises when people "wish they had behaved differently or could somehow undo the bad deed that was done" (Tangney, Miller, Flicker, & Barlow, 1996). In other words, guilt involves mentally undoing some aspect of the transgression. Unlike guilt, shame is a more intense and enduring experience and is felt when people perceive that their "deep-seated flaws are revealed to oneself and to others" (Miller & Tangney 1994). As such, shame is tied to the attribution of a certain event to perceived deficiencies of one's core self (Klass, 1990). According to Hoblitzelle (1987), shame differs from guilt in that the former is associated with internal, stable, and global attributions, whereas the latter is associated with internal, specific, and temporary attributions.

Further, guilt and shame are associated with distinct action tendencies and motivation. Since the experience of guilt involves a mental undoing of the transgression rather than self, guilt evokes the motivation or desire to confess, apologize, and repair the harm (Tangney & Dearing, 2002). In contrast, as shame arises from global devaluation of the self, it evokes the motivation or desire to hide, escape, and even strike back. Furthermore, people who are prone to shame use tend to act defensively, such as rage, contempt, transfer of blame, and denial (Kaufman, 1996) and engage in dysfunctional behavior, such as withdrawal, avoidance, attacking self and others (Pattison, 2000).

The primary goal of this paper is to investigate restorative coping strategies consumers use in order to cope with discrete self-conscious emotions, specifically, shame and guilt, in the impulse buying context. Based on psychological research on distinction between guilt and shame, we propose a set of four hypotheses:

- Hypothesis 1: Compared to ordinary consumers, consumers with strong impulse buying tendency will experience more intense guilt and shame in the wake of impulse buying.
- Hypothesis 2: Consumers' impulse buying tendency will be positively associated with the frequency with which they use avoidant coping strategies, such as denial, distraction, non-disclosure and blaming others.
- Hypothesis 3: The intensity of shame experienced after impulse buying will be positively associated with avoidant coping strategies, such as denial, distraction, resignation and blaming others.
- Hypothesis 4: The intensity of guilt experienced after impulse buying will be positively associated with problem-focused coping and non-avoidant coping strategies.

Survey methodology was used in order to formally test the hypotheses and develop the coping instrument. We conducted a retrospective approach, in which participants recalled a recent impulse buying and reported the emotions and coping strategies they used. Two thousand and one hundred sixteen individuals logged on our on-line survey, but three hundred and ten people qualified for the study. Thirty six participants did not answer a substantial number of questions and had to be removed from analysis; therefore, the remaining 274 participants' data were used in the analysis. Upon completing the consent form, participants were asked to think back to the last time they went shopping and bought something on a sudden rush of desire, without thinking about whether making that purchase fits with their budget, their long term goals or plans. Furthermore, in order to qualify, participants had to spend at least \$80 on a single item for themselves within the last two months. We assessed guilt and shame items by adapting State Shame and Guilt Scale (Marschall, Sanftner, & Tangney, 1994). Next, participants' coping efforts were assessed with the 76-item coping scale specifically intended to assess consumers' coping efforts to deal with negative emotions in the impulse buying context. Participants' impulse buying tendency was assessed with Rook and Fisher's (1992) Buying Impulse Scale. We measured chronic shame and guilt disposition with the TOSCA scale (Tangney et al., 2002). Further, the questionnaire included Rosenberg's (1965) self-esteem scale, Ross & Mirowsky's (1984) depression scale (CES-D), and Faber & O'Guinn's (1993) compulsive buying scale. Lastly, participants were asked to indicate their annual income, disposable monthly income, the amount of savings, credit card debt, the balance on their credit cards in the previous month, and the amount they did not pay towards the balance on credit cards last month. Participants exited the survey after providing demographic data (i.e., age and gender).

Our hypotheses were generally consistent with our survey data. First, consistent with Hypothesis 1, participants with strong impulsive tendency reported experiencing more intense guilt and shame in the event of impulse buying. Even though the effect of impulse buying on both guilt and shame was positive, the path coefficient from impulse buying to shame was higher than the coefficient to guilt. Further, consistent with Hypothesis 2, our data showed that the effect of buying impulsiveness on avoidant coping strategies was significantly positive. Specifically, as buying impulsiveness increased, the frequency of using avoidant coping strategies, such as denial/distraction, rationalization, wishful thinking and resignation, significantly increased. In contrast, the relations between buying impulsiveness and non-avoidant coping strategies were either negative or minimal. Moreover, our data provided support for the hypothesis that the intensity of shame would be positively associated with avoidant coping strategies, whereas the intensity of guilt would be positively associated with non-avoidant coping strategies (i.e., Hypotheses 3 and 4). Specifically, our path analysis showed that the intensity of shame positively influenced denial/distraction, resignation and blaming others, whereas the intensity of guilt positively influenced planning to reduce impulse buying and to make up for monetary loss as well as wishful thinking. This structural model showed a very good fit to the model. This finding that guilt and shame are accompanied by unique coping strategies is even more interesting given that the intensity of guilt and shame is highly correlated in our data. This finding suggests that even though guilt and shame are related emotions, the acute

experience of shame is more frequently accompanied by maladaptive coping strategies than guilt.

Merry Impulsivity: Belief Systems about the Dark and Bright Sides of Being Bad Consumers

Rita Coelho do Vale, FCEE-UCP, Catholic University of Portugal, Portugal

EXTENDED ABSTRACT

Impulsivity is typically considered as a negative behaviour that should be avoided at any cost. Despite this common approach to impulsive behaviors as self-control failures that are regretted later, we propose that impulsivity may have a bright side that may explain why consumers persistently seem to not pay attention to the constant reminders from various governmental and health-care organizations to perform the adequate and right goal-pursuit activities, and to even consciously act on impulse (Baumeister et al. 1994). The present research analyzes this phenomenon, examining consumers' beliefs on the consequences of acting on impulse and its impact on consumers' happiness/well-being.

Most of the research conducted on the self-control topic implicitly assumes that if somehow consumers would be able to increase their self-regulatory ability, many social problems as obesity and impulsive behavior, would be solved, contributing to a "better world" (Baumeister 2002; Faber and Vohs 2004; Sayette 2004). The offer of self-help books, websites and courses, supposedly to help consumers to become better self-regulators, is soaring. And consumers are systematically confronted with numerous "reminders" of their ongoing pursuits. However, to our knowledge, there are no studies focused in analyzing the possible bright side of impulsivity on consumers' happiness. This is relevant if one considers that a significant percentage of consumers' daily decisions appear to comprise impulsive decisions (Rook, 1987; Rook and Fisher, 1995; Hausman 2000) and that impulsive purchases are considered to represent about 70% of the consumer decisions (Bellenger, Robertson and Hirschman 1978). Moreover, since 38 percent of the adults in an annual national survey responded affirmatively to the statement: "I am an impulse buyer" (Rook and Fisher 1995), makes such phenomenon even more interesting.

Although impulsive behaviors may impair the likelihood of long-term conscious goals' attainment, they also contribute to immediate pleasurable experiences that elicit joy and satisfaction, which may fulfill other high-order and less conscious long-term goals (e.g., to be happy), strengthening the belief that impulsive behaviors build consumers' well-being. Therefore, we suggest that one of the reasons why consumers may persistently seem to fall into temptations with disregard for its long-term consequences may be due to the fact that consumers believe they will benefit from desirable short-term and long-term outcomes by doing so.

Our main hypothesis is that impulsive consumers (low self-regulators) will be considered to be happier and will be associated with a set of higher positive personal characteristics, compared with non-impulsive consumers (high self-regulators). This Merry Impulsivity hypothesis is based on three underlying processes. First, we predict that low self-regulators, compared with high self-regulators, are considered to experience higher positive affect and lower negative affect, typically approached as an indication of happiness (Ryan and Deci 2001). Second, we also predict low self-regulators to focus more on the short-term experiences and therefore to be considered to have a more positive attitude towards uncertainty of future events than high self-regulators, indicating a more general positive attitude towards life, positively influencing consumers' subjective well-being/happiness (Diener et al. 1997; Scheier and Carver 1993). Third, we predict that low self-regulators will be considered to better develop social skills than high self-regulators and to more easily create and nurture interpersonal

relationships, a basic human need essential for well-being/happiness (Ryan and Deci 2001).

Support to our predictions offer a possible explanation why consumers pervasively tend to engage in impulsive acts. If consumers believe that impulsive acts contribute positively to a set of positive characteristics, they may engage in those acts in an attempt to enhance their well-being.

Our predictions were tested in two studies. Study 1 analyzed to what extent low self-regulators are considered to be happier and to experience more positive affect than high self-regulators. Study 2 included measures for goal-pursuit attainment as achievements in life and hard-working constructs, as also assessed consumers' beliefs in terms of sociability skills, sensation-seeking tendency, desire for control, and attitude towards life. In addition, it examined the influence of consumers' actual impulsivity (self-assessed) on their beliefs about the dark and bright sides of impulsive consumer behavior.

Findings from study 1 (n=44) showed that consumers who frequently engage in impulsive behaviors are indeed considered to be happier and to more likely experience positive affect than consumers that typically try to refrain impulses in order to pursue overarching goals. In addition, findings from study 2, which retested our predictions using 438 randomly selected members of a household panel, showed that impulsive behaviors, despite leading to fewer achievements in life, are considered to contribute to a set of personal characteristics that raise consumers' happiness.

This set of studies addressed an understudied aspect of self-regulation failure: the one of consumers willingly failing to exert self-control, amending the so far universal belief that self-control is the ultimate goal to consumers' well-being. Despite this common idea, impulsive behaviors may actually positively influence consumers' well-being, due to consumers' belief systems about the correlates of impulsivity. Our research demonstrates that consumers who tend to engage in immediate pleasurable experiences with disregard for its long-term consequences are generally believed to be happier, more social, with a more positive attitude towards life, and to experience higher positive affect than consumers who have high consumption/behavioral self-regulatory concerns. Therefore, and as outlined by Baumeister and colleagues (1994), the phenomenon of acquiescence with failure may explain a significant portion of self-control failures. To our knowledge, the present research is the first to address empirically this phenomenon, shedding some light on belief systems that are conducive to consumers persistently engaging in non self-regulatory activities.

What is Moral about Moral Emotions? Guilt Elicits Prosocial Behavior as Well as Antisocial Behavior

Iloa De Hooge, Erasmus University, The Netherlands
Rob Nelissen, Tilburg University, The Netherlands
Seger Breugelmans, Tilburg University, The Netherlands
Marcel Zeelenberg, Tilburg University, The Netherlands

EXTENDED ABSTRACT

Moral emotions have been portrayed as the social mortar of human societies because these feelings encourage us to put the concerns of others above our own and to engage in prosocial behavior. The hallmark moral emotion is guilt, which is typically described as an “adaptive emotion, benefiting individuals and their relationships in a variety of ways” (Tangney, Stuewig, & Mashek, 2007, p. 26). However, is it really the case that moral emotions make the interest of others paramount, neglecting our self-interest?

Guilt mostly arises from a moral transgression in which the actor has violated an important norm and has hurt another person. This elicits a preoccupation with the victim and the ensuing reparative action tendencies are aimed at restoring the relationship between transgressor and victim. This victim-oriented focus explains the often-replicated finding that guilty people contribute more of their endowments to others in comparison to non-guilty people. It is clear that in dyadic situations guilt produces behavior that benefits others.

However, we have reason to believe that the very characteristics of guilt that make it beneficial to the victim in dyadic interactions have disadvantageous side effects for others in the social environment. In dyadic interactions the costs of acting prosocially come necessarily at the expense of oneself. But in daily life it is also possible to act prosocially at the cost of others. We think that the generosity towards the victim has disadvantageous consequences for the social environment. Precisely because guilt induces a preoccupation with restoring the harm to the victim, it simultaneously causes a neglect of others. Consequently, a guilty state may not evoke a disregard for personal concerns (as is often assumed) but rather a depreciation of the concerns of non-victimized others. We predict that when taking such a broader, more ecologically valid perspective, it will appear that people experiencing guilt are motivated to benefit the relationship with the victim, but at the best possible outcomes for themselves. Three experiments investigated if the experience of guilt induces prosocial behavior towards the victim at the expense of others rather than the self.

In Experiment 1, participants reported a personal experience of feeling guilty (Guilt condition), or described a regular weekday (Control condition). They were asked to think of the person they felt guilty towards (guilt condition) or of a person they had met during the weekday (control condition). This person was labeled Person A. Participants then divided €50 between the birthday of Person A, the fundraising of the victims of a flood, and themselves. We found that Guilt participants offered more money to Person A than Control participants. At the same time, guilt participants offered *less* money to flood victims than Control participants. Guilt and Control participants did not differ in the amount they kept for themselves.

Experiment 2 explored whether guilty people could also act disadvantageously towards known others. Participants were randomly assigned to the Guilt or Control condition and read a scenario. Next, they divided €50 between the birthday of the victim of the scenario, the birthday of another friend, and themselves. Results showed that Guilt participants offered more money to the victim than Control participants, and offered less money to the third

party. Participants did not differ in the amount they kept for themselves. Thus, even when the social surrounding consists of family and friends, the costs of compensatory behavior befall those other people rather than oneself.

Experiment 3 tested our assumption that the preoccupation with the victim that characterizes guilt causes disadvantageous side effects for the social environment. This entails that no effects should be found in situations where the victim is not present, which was tested by adding a condition where the victim was not present. Participants were randomly assigned to the conditions of a 2 (Emotion condition: Guilt vs. Control) \times 2 (Victim Presence: Victim-present vs. Victim-not-present) design. They were told that during the lab-session they could earn lottery tickets for a lottery. The session started with two rounds of a performance task, ostensibly with another participant. In the first round they could earn 8 lottery tickets for themselves, in the second round 8 tickets for the other player. After the first round, all participants received feedback that they earned the bonus. After the second round, the other player in the Guilt condition did not receive the bonus due to the participant's bad performance. In the Control condition, the other player received the bonus. Participants continued with a three person-dictator game, either with the player from the performance task (Victim-present condition) or with a participant who knew nothing about the performance task (Victim-not-present condition). In all conditions the third player was a participant who knew nothing about the letter task. As the dependent variable, the participant divided twelve lottery tickets among the three players.

We found that participants in the Victim-present Guilt condition offered significantly more to the victim than participants in the Victim-present Control condition, and than participants in the Victim-not-present Guilt condition. They also offered significantly less to the third player than participants in the Victim-present Control condition, and than participants in the Victim-not-present Guilt condition. Higher offers to the victim did not come at personal expense: all conditions did not differ in tickets kept for oneself.

In summary, it appears that guilt, the hallmark moral emotion, can motivate behaviors that do not fit the predicate moral. When people experience guilt, they are preoccupied with repairing the harm done to the victim, leading to disadvantageous effects for others in their social environment. This suggests that the view of moral emotions as (unconditionally) beneficial for others should be rephrased. Moral emotions do not make the interest of others in general paramount, but rather motivate a selective focus on the interests of the wronged other while not forgetting self-interest. This indicates that a thorough understanding of functioning of moral emotions is necessary to fully understand their influence on consumer behavior.

Lying Your Way Out of a Bad Situation

Christina I. Anthony, University of Sydney, Australia
Elizabeth Cowley, University of Sydney, Australia

EXTENDED ABSTRACT

Introduction

Research investigating deception in consumer research has focused on transgressions of marketers (Burke et al. 1988; Deighton and Grayson 1995; Gaeth and Heath 1987). However, consumers also are motivated to be deceitful to gain rewards that are otherwise unattainable (Ekman 1997, 2009). If consumers do tell lies in pursuit of better outcomes, the transgression may have consequences for their affective outcome evaluations. In this research, we examine how lying affects the consumer's happiness with a consumption outcome.

Competing Hypotheses

The literature enables us to hypothesize that liars' affective evaluations will depend on the financial or moral outcomes considered while deliberating over their strategy. According to Decision Affect Theory (DAT: Mellers, Schwartz, and Ritov 1999; Mellers et al. 1997), as a decision becomes more deliberative, more counterfactual thinking should occur, resulting in amplified affective responses. We argue that lying is a more deliberative strategy, than truth telling. In particular, a salient source of deliberation for a person contemplating deception as a means of getting out of a bad situation, are the financial gains attainable if they succeed. Accordingly, DAT predicts that that when a lie succeeds, liars will feel happier than truth tellers because they will generate more counterfactuals about how the outcome could have been worse financially had they not lied. If a lie fails, DAT predicts that liars should feel more regretful than truth tellers because they will generate more counterfactuals about how the outcome could have been better financially had they told the truth.

In addition to the financial outcomes associated with lying, there are also moral outcomes that may be deliberated during decision-making; after all, most people consider lying morally questionable. The concept of morality is consistent with Higgins's notion of 'Value From Proper Means' (VFPM: Camacho, Higgins, and Luger 2003; Molden and Higgins 2005). Value from proper means occurs when the way a goal is pursued coincides with socially accepted rules or normative principles of morality (Higgins et al. 2003; Merton 1957; Pennington and Hastie 1988; Tetlock 1991; Tversky and Shafir 1992). This value is then incorporated into the evaluation of the outcome of an experience. Dishonesty may not provide a good source of 'fit' (Camacho et al. 2003; Carver and Scheier 1990). Therefore, the VFPM perspective predicts that liars will feel worse than truth tellers, as they will counterfactually consider that the outcome could have been better, had they used a morally better means. The importance of morality is also incorporated in equity theory which holds that people prefer outcomes that are fair and deserved (Adams 1965; Messick and Cook 1983; Walster, Walster, and Berscheid 1978). Receiving more than one deserves produces guilt, and receiving less than one deserves causes anger and disappointment (Oliver and Swan 1989; Van den Bos et al. 1997; Van den Bos, Peters, and Bobocel 2006; Van den Bos et al. 1998). Accordingly, equity models, predict that liars will feel worse than truth tellers as they will generate more counterfactuals about how a deal could have been better (more deserved) had they acted fairly and truthfully. However, unlike VFPM, equity models predict that liars will feel better than truth tellers encountering an

impasse, as they will counterfactually consider that the outcome could have been worse had they attained an undeserved deal.

Study 1

The purpose of study 1 was to test the competing hypotheses (DAT: financial deliberation vs. VFPM/Equity Models: moral deliberation) for differences in the affective reactions of liars compared to truth tellers. In study 1, participants played the role of consumer in a simulated negotiation task. Lying versus truth telling was induced by manipulating the nature of competitor information provided. Participants were told that the salesperson would endeavor to match currently available competitor offers. Therefore, strong-competitor-information encouraged truth telling as favorable deals were currently available. Weak-competitor-information encouraged lying as favorable deals were currently unavailable. Liars lied by claiming that a favorable but expired competitor offer was currently available. Further, the outcome of the negotiation was manipulated such that half the participants received a deal while the other half encountered an impasse. Study 1 results revealed, that given a deal, liars were happier than truth tellers, and in the event of an impasse, liars were more regretful than truth tellers. The results are consistent with DAT.

Study 2

The objective of study 2 was to examine the counterfactual thinking processes underlying the DAT hypotheses. It is our contention that liars amplified affective reactions occur because lying requires more strategic deliberation which entails increased counterfactual thinking. Therefore, in study 2, we introduce a manipulation that is designed to increase deliberation about their strategy for truth tellers (and therefore counterfactual thinking). Following this, the deliberation manipulation was introduced using an operationalization of risk. Participants were informed that there was a good chance of (not) being believed by the salesperson. Finally, the outcome was manipulated to be deal or impasse. Study 2 results revealed, that increasing the risk for truth tellers amplified their counterfactual thinking and thereby eliminated the observed differences in affect across strategy.

Study 3

The objective of study 3 was to demonstrate that liars amplified affective reactions are counterfactually referenced to the financial risks associated with lying. Priming a morality focus should eliminate the amplification effects. Further, study 3 sought to demonstrate that truth telling is a less strategic option. The outcome, a priming manipulation was introduced to encourage either a financial or morality focus. Study 3 results revealed that the financial priming condition replicated the results of earlier studies; liars displayed more amplified affective reactions compared to truth tellers. Importantly, as hypothesized, morality priming eliminated liars' amplification effects. Also, whilst the levels of the priming manipulation had differential effect on liars, truth tellers were not affected, confirming our contention that truth tellers are affected by the outcome, not their moral strategy.

Discussion

An important implication of our findings is that if marketers do not stand to lose too much financially, it may be advisable to

exercise more leniency when negotiating with suspects of deception because marketers ultimately run the risk of wrongfully accusing innocent truth tellers.

Do Bettors Categorize Bets?

Greg Durham, Montana State University, USA
Mukunthan Santhanakrishnan, Idaho State University, USA

EXTENDED ABSTRACT

In a frictionless market with rational investors, any price changes are due to changes in fundamental values of the assets. On the other hand, if investors group assets into different categories, then change in preference towards a category may cause changes in prices of assets within that group. Thus, when investors categorize assets, asset prices within a group may move together even when the fundamental values of these assets demonstrate no comovement among them. Such categorization by investors could lead to an allocation of capital that is inefficient in terms of risk and return.

Recent articles provide evidence consistent with the notion that investors categorize assets along various dimensions. Pirinsky and Wang (2006) find that stock returns of companies exhibit a strong degree of comovement with returns of other companies headquartered in the same geo-graphical area. They also find, however, that underlying cash flows (measured as earnings) exhibit negative comovement with cash flows of other local companies. Barberis, Shleifer, and Wurgler (2005) focus on stocks that are added to the Standard & Poor's 500 Index and find that the returns on the newly added stocks co-move more with returns on other S&P 500 stocks than with returns on stocks that are not part of the index. Besides geographic location or membership in an index, another dimension by which investors appear to categorize investments is stock-price magnitude (Green and Hwang (2008)).

A limitation of the Pirinsky and Wang (2006) study is that assets under consideration are multi-period assets; these assets' returns may co-move in a given period of time in anticipation of comovement in earnings in any subsequent periods, without any comovement in contemporaneous earnings. Also, studies of comovement around index additions and stock splits must be cautious of changes in underlying fundamentals surrounding the events of interest: while fundamental values should not change surrounding either type of event, some evidence suggests that market participants' perceptions of future cash flows are influenced by these events (Denis et al. (2003), Kalay and Kronlund (2009)).

The market in which we conduct our study is not characterized by these same limitations or precautions. Each asset (i.e., each sports bet) in the college football betting market has a life of only one period, thereby eliminating the possibility that comovement in current prices is caused by comovement in any cash flows other than contemporaneous ones. Another useful feature of this market is that a sports bet's value is unambiguously realized at the instant a game ends—the cash flow associated with that bet is easy to measure. Another advantage of our marketplace is that required rates of return are nearly constant across all wagers in our entire sample, because risk is the same across all wagers. Therefore, fundamental value of a wager—defined as expected future cash flow discounted at an appropriate required rate of return—is likely to change only if the underlying cash flow changes. This unambiguous relationship, together with the fact that we can clearly measure the single relevant cash flow for each wager, make our market an advantageous venue in which to test whether comovement in prices is driven by comovement in fundamental values.

Bettors may very well be constrained by attention scarcity due to the number of games played each week. In addition, the assets' short lifespans of approximately one week require bettors to update their information sets every week, complicating their task of processing information. In order to simplify the task and the choices

involved, bettors may categorize games based on teams involved in each game.

We are interested in the possibility that bettors separate games into different categories based upon the types of teams involved in each contest: (1) Games involving two major-conference teams and games involving at least one non-major-conference team and (2) Conference games and non-conference games. We explore whether percent change in point spread for a game (our market's analog to percent change in prices in financial markets) is influenced more by percent changes in point spreads for other same-category games or by percent changes in point spreads for the complement set of games. We also examine whether any relationships exist among underlying cash flows within and/or across different categories of games.

We test for comovement consistent with categorization, using bivariate regressions, and find that point spreads for a particular category of games co-move with point spreads for other similar games. We further find that the underlying cash flows among similar games do not co-move. Traditional finance theory suggests that if we observe comovement in spreads among a set of games, we should expect to see comovement in underlying cash flows for those games. Our findings that spreads co-move (in the same direction) among similar games, while the underlying cash flows appear to co-move in opposite directions, together are consistent with the presence of "style bettors" in the college football wagering market.

The Budget Contraction Effect: Cutting Categories to Cope with Shrinking Budgets

Kurt A. Carlson, Georgetown University, USA
Jared Wolfe, Duke University, USA
Dan Ariely, Duke University, USA
Joel Huber, Duke University, USA

EXTENDED ABSTRACT

Economics provides a clear prediction for how consumers adjust spending when income declines. Consumers will move down the utility surface to an allocation that represents the highest utility for the new income level. *Ceteris paribus*, this allocation should be the same as the allocation when they were previously at this budget level. Put differently, the income contraction and the income expansion paths should be equivalent. As such, a consumer should arrive at the same allocation whether approached from a prior budget that was smaller or larger than the current budget. This paper presents evidence that budget contraction and expansion paths are not equivalent. Rather, consumers who arrive at a budget from a higher initial budget purchase fewer different types of products or services than consumers who arrive at the same budget from an initially lower one.

Participants in Study 1 (N=398) made nine budget allocations—three allocations for three different domains (groceries to buy with \$40, \$80, or \$120; cities to visit in Europe in 7 days, 14 days, or 21 days; lottery tickets to buy with \$5, \$10, or \$20). For each domain, participants made the three sequential budget allocations with the budget either expanding (e.g., \$40, \$80, \$120) or contracting (e.g., \$120, \$80, \$40).

Results reveal that participants in the expanding grocery budget condition spread their \$80 budget across more different products ($M=4.69$) than did participants in the contracting budget condition ($M=4.27$; $t(396)=2.76$, $p<.01$). Additionally, the difference in number of items purchased (expanding budget minus contracting budget) decreased as the size of the budget increased from \$40 ($D=.59$) to \$120 ($D=.38$). Though each of these differences is statistically significant (all $p<.05$), the pattern is important because it suggests that the contracting budget is the main driver of the effect. To see why, consider that the comparison between \$40 budget allocations involves a comparison of participants who faced two budget contractions to those making their first budget allocation without a prior budget change. If the effect is due to contraction of budgets, the difference should be largest here (e.g., larger than the differences between \$120 budget allocations), as it is.

Allocations in the travel and lottery ticket domains mirror these findings. Participants with 14 days to travel planned to visit more cities when the travel budget increased to 14 days ($M=6.47$) than when it contracted to 14 days ($M=5.64$; $t(396)=2.71$, $p<.01$). And the difference in number of cities visited (increasing budget minus decreasing budget) decreased from 1.34 ($p<.001$) at the smallest budget (7 days) to .32 ($p=.33$) at the largest budget (21 days). Likewise, participants in the expanding lottery budget condition selected more different types of lottery tickets ($M=3.07$) with the \$10 budget than participants whose budget contracted ($M=2.81$). And the difference in allocations is largest and significant for the smallest budget level (mean difference=.31; $t(396)=2.32$, $p<.05$), and not significant (mean difference=.27; $t(396)=1.24$, $p>.20$) for the largest budget level.

Study 2 used an investment domain to test whether the budget contraction effect would extend to situations in which there was carryover from one budget allocation to the next. Participants (N=189) made investment allocation decisions for three different budgets under conditions of an expanding budget (\$500, \$1000,

\$1500) or a contracting budget (\$1500, \$1000, \$500). The second and third allocations presumed that the results of the prior allocations were still relevant (i.e. participants still had the allocations from those budgets as part of their retirement portfolio).

When allocating \$500 to the four investments, participants in the contracting condition invested in fewer different investments than those in the expanding condition (2.55 versus 3.03; $t(187)=2.79$, $p<.01$). Allocations for the \$1000 and \$1500 budgets did not differ significantly for budget contraction versus budget expansion (\$1000 budget: 3.08 versus 2.95; $t(187)=0.83$, $p=0.41$; \$1500 budget: 3.21 versus 3.17; $t(187)=.27$, $p=.79$, respectively). These data strongly support the two-path model and confirm that the driver of the effect is the contracting budget.

Study 3 tested whether the effect extends to real choices consisting of a large number of options. Participants (N=129) selected three assortments of mp3s (4 songs, 8 songs, 12 songs) to purchase from over a million songs available at amazon.com. Participants were told that one participant would be selected at random to actually receive one of their selected assortments. Assortments were made under conditions of an expanding budget (4 songs, 8 songs, 12 songs) or a contracting budget (12 songs, 8 songs, 4 songs). Breadth of each assortment was assessed by coding the number of different artists/bands present in each assortment.

For the 4-song budget, participants in the contracting budget condition chose songs by a significantly smaller number of artists/bands ($M=3.40$) than those in the expanding budget condition ($M=3.76$; $t(122)=-2.603$, $p<.01$). However, there were no significant differences in the number of different artists/bands selected between the two groups in either the 8-song budget (Contracting $M=6.21$, Expanding $M=6.61$, $t(122)=-1.099$, $p=0.27$) or the 12-song budget (Contracting $M=9.18$, Expanding $M=9.11$, $t(121)=.129$, $p=.90$).

These studies have demonstrated an asymmetry in budget expansion and contraction paths such that for a given budget, consumers who arrive at a particular budget from a higher initial budget purchase fewer different products or services than a consumer who arrives at that same budget from an initially lower budget. This asymmetry in budget expansion and contraction paths stems mainly from a decrease in variety of the selected assortment under budget contraction rather than from an increase in variety selected under budget expansion.

Trying Harder and Doing Worse: How Grocery Shoppers Track Their In-Store Spending

Koert van Ittersum, Georgia Institute of Technology, USA
Joost M. E. Pennings, Maastricht University, The Netherlands
Brian Wansink, Cornell University, USA

EXTENDED ABSTRACT

Introduction

An estimated one in three American households has to carefully plan their budgets and spend accordingly. Budget-allocation and spending-behavior models often implicitly assume that budget-constrained shoppers are knowledgeable about the total price of their shopping basket as they shop (Bénabou and Tirole 2004). Because shoppers' price estimates of their shopping baskets mediate the relationship between budget allocation and actual in-store spending, it is critical to understand whether and how shoppers determine the total price of their baskets. Inaccuracies in their estimates likely have implications for consumer welfare (Heath and Soll 1996) and retail performance (Gómez, McLaughlin, and Wittink 2004).

Despite the importance of understanding how budget-constrained shoppers estimate the total price of their baskets while shopping, it remains largely unclear whether, when, and how they keep track of their in-store spending.

Pilot Study: Do Grocery Shoppers Track Their In-Store Spending?

To assess whether, when, and how budget-constrained grocery shoppers keep track of how much they are spending while shopping, a field study was conducted that involved 293 shoppers who were intercepted at the end of their shopping trip in one of two supermarkets: one located in a lower (\$22,540/yr) and one located in a higher household income area (\$46,478/yr). We find that 84.6% of the 293 participants claim to keep track of how much they are spending while shopping for groceries. By far the most dominant reason for tracking their in-store spending is having budget constraints (87.6%). Three distinct tracking strategies are identified: mental computation strategies (57.4%), calculators (26.4%), and shopping lists (14.5%). Of those who rely on mental computation strategies, 92.3% predominantly add prices up on a price-by-price basis: 45.2% round prices up before adding them, 24.0% round prices up and down to \$0.00, \$0.10, and \$0.25, 14.4% add the exact price of each item, and 11.5% focus only on the dollar amount, ignoring the dollar-cents. The results also show that shoppers who have to pay more than expected based on their own estimate attribute this to the retailer, which in turn negatively influences store satisfaction.

While the pilot study established the relevance of in-store tracking and the predominant reliance on mental computation strategies, the results also raise questions. For instance, why is the rounding strategy the seemingly dominant mental computation strategy? To answer this and other questions, we first discuss the relevant literature and then present the results of two lab studies.

Computational Estimation Strategies

To avoid the stress associated with *calculating* the *exact* total basket price, shoppers are proposed to *estimate* the *approximate* total basket price using *computational estimation strategies*—strategies to find an *approximate* answer to arithmetic problems without actually calculating the *exact* answer (Dowker 1992; Reys 1986). The most common computational estimation strategies are: *a) Front-end Estimation Strategy*. A front-end strategy would lead

shoppers to estimate the total price of their shopping basket based on the left, front-end dollar digits, ignoring the right-most digits, the dollar-cents (Lemaire et al. 2000). *b) Rounding Estimation Strategy*. The rounding strategy involves rounding numbers up prior to adding them (Lemaire and Lecacheur 2002). *c) Compatible Numbers Estimation Strategy*. The compatible numbers strategy involves organizing numbers into groups of compatible numbers to make the computation easier (Dowker 1992). *d) Special Numbers Estimation Strategy*. The special numbers strategy involves identifying numbers near “special” values that are easy to compute with (Reys 1986), such as those that are powers of ten or common fractions and decimals, including \$0.00. *e) Clustering Strategy*. The clustering strategy is a non-additive strategy that estimates the total basket price by multiplying the number of products in the basket by the estimated median price of the items in the basket.

To gain a better understanding about how people estimate the total price of their baskets using mental computation strategies, we explore if shoppers are adaptive estimators who weigh the importance of being accurate against the cognitive effort they can and are willing to invest and select the strategy that is perceived to offer the best combination of accuracy and complexity given the estimation conditions (Johnson and Payne 1985).

Lab Experiments

To examine the adaptivity of estimators, we take an experimental approach to manipulate specific context and task variables of the estimation task: price endings of the basket items, motivation to be accurate, and estimation task experience. We measure 1) which estimation strategies shoppers rely upon under which conditions, 2) their estimation accuracy, and 3) the perceived task complexity.

We demonstrate that short-term memory constraints prevent shoppers to effectively rely on the *calculation strategy* to estimate the *exact* total price of shopping baskets. Reliance on the calculation strategy results in more biased, less accurate estimates than reliance on *computational estimation strategies*. These results explain why estimation performance reduces with shoppers' motivation to be accurate—motivated consumers are willing to incur more cognitive cost to achieve a higher estimation performance by relying on the calculation strategy. Although motivation has a counterproductive effect on the estimation performance among inexperienced consumers, it improves estimation performance among experienced consumers. We further demonstrate that shoppers adapt their strategy to different price-ending conditions based on the perceived cognitive complexity and accuracy, which explains why shoppers in the pilot study predominantly rely on the rounding strategy to estimate the total price of their shopping baskets.

Field Study

To provide evidence for the assumption that shoppers' estimates influence actual in-store spending, another field study was conducted involving 46 grocery shoppers. The results demonstrate that estimation biases relate to spending biases, putting shoppers underestimating the total price of their basket at risk of spending more than they budgeted for.

Conclusion

Because shoppers' price estimates of their shopping baskets mediate the relationship between budget allocation and actual in-store spending, it is critical to understand whether and how shoppers determine the total price of their shopping baskets. Understanding which estimation strategy is most efficient and accurate in which specific context, among others, allows for more effective consumer education, which in turn may help improve consumer welfare as well as retail performance.

Tracking Costs of Time and Money

Robin L. Soster, University of South Carolina, USA
Ashwani Monga, University of South Carolina, USA
William O. Bearden, University of South Carolina, USA

EXTENDED ABSTRACT

People often incur costs first, and receive benefits later, but track both via mental accounts (Thaler 1980, 1985, 1999). For instance, the purchase of a basketball-game ticket could initiate a basketball-game account in the consumer's mind, which eventually gets closed as a net gain (i.e., pleasure) or a net loss (i.e., pain). That is, the account is settled in the black if the consumer receives the benefit (i.e., attends the game), but in the red if the consumer forfeits the benefit (i.e., misses the game) (Prelec and Loewenstein 1998). Because of several reasons, such as the desire to avoid waste (Arkes and Blumer 1985) and the need to justify prior choices (Staw 1981), people often refuse to close an account in the red even when closing it makes economic sense. For instance, after people have incurred costs on tickets to a game, they are willing to brave a snowstorm to attend the game, even though they would readily miss it if they had received the tickets for free (Soman 2001; Thaler 1980, 1999). Such a tendency has been termed the sunk-cost fallacy (Arkes and Blumer 1985; Thaler 1980) because, from an economic standpoint, the decision of going to the game should be based on future benefits (attending the game) and future costs (traveling in a snowstorm), but not on prior costs (cost of ticket). However, because of the pervasiveness of mental accounts, prior costs do influence the propensity to seek future benefits.

Soman (2001) discusses how the mental-accounting processes described above apply to costs of money, but not time. He argues that individuals lack the ability to account for time because, unlike doctors and lawyers, most people do not routinely keep track of time the way they keep track of money. Consequently, unless interventions (e.g., education about the value of time) are employed to make time seem like money, mental accounting for time breaks down. That is, future benefits are not linked to prior costs, and the sunk-cost effect does not emerge.

In the current research, we demonstrate that people do engage in mental accounting for time, and via a process that can be seen as more elaborate than that for money. Specifically, accounts for time consider not only costs and benefits, as accounts of money do, but also "accounting periods" (day, vacation, etc.). Consequently, people link temporal costs to benefits when both costs and benefits belong to the same accounting period, but do not link them when they occur in different periods. In the case of monetary costs, this moderating effect of accounting periods is relatively weak.

The current research adds to prior work on mental accounting (Thaler 1980, 1985, 1999) by introducing the concept of accounting period, which aids our understanding of the process by which people track costs and corresponding benefits. It also augments our understanding of time-money differences. For example, Soman (2001) argues that people are not good at keeping track of prior costs of time, because of which the sunk-cost effect (Arkes and Blumer 1985) does not emerge for time as it does for money. We show that, contingent on the accounting period, people do exhibit sensitivity to past costs of time, and the sunk cost effect does emerge. The concept of accounting periods also provides a new perspective of prior findings in time discounting, consumer search, risk preferences, and other areas.

Relative vs. Absolute Comparison of Prices

Keith S. Coulter, Clark University, USA

Pilsik Choi, Clark University, USA

EXTENDED ABSTRACT

The widely used practice of comparative price advertising has been a focal point of consumer and marketing research for decades (e.g., Compeau and Grewal 1998). Marketers may engage in comparative price advertising by: a) contrasting a higher “regular” price with a lower “sale” price, or b) comparing a “competitor’s” price to the marketer’s own sale price (Compeau, Grewal, and Chandrashekar 2002). In either case, the higher regular (or competitor’s) price serves as an externally supplied frame of reference, which leads consumers to perceive less benefit from continued search (Urbany, Bearden, and Weilbaker 1988), and to associate less sacrifice with the lower sale price (Compeau et al. 2002). Consequently, comparative price advertising tends to engender more favorable consumer value perceptions, and marketers embrace this form of advertising as a means to affect consumers’ purchase decisions and stimulate sales.

Comparison of regular-to-sale or competitor-to-marketer (sale) prices may also lead consumers to assess a price discount. That discount could be perceived in relative (i.e., as a percentage) or absolute terms. Absolute discount is defined as higher price minus lower price, whereas relative (percentage) discount is defined as $[(\text{higher price} - \text{lower price}) / \text{higher price}]$. Although the latter may involve a more complicated computational procedure, research has demonstrated that consumers exposed to comparative price advertisements containing regular and sale prices are able to assess relative price discounts with a fairly high degree of accuracy, even in relatively low involvement settings that evoke minimum cognitive expenditure (e.g., Coulter and Norberg 2009).

A preponderance of studies in the numerical cognition literature has demonstrated that numerical magnitude comparisons typically follow the Weber-Fechner Law. That is, numerical comparisons follow a log-linear function such that the perceived difference between numbers is compressed as the size of those numbers increases (Dehaene et al., 1990). Consequently, when making quantitative comparisons, one’s ability to distinguish between two numbers (e.g., determine which is larger or smaller) is directly related to the *relative* difference between them (Deheane, 1992). Studies within the pricing literature confirm that perceived numerical differences may involve relative, rather than absolute, amounts (e.g., Kruger and Vargas 2008; Coulter and Norberg 2009). However, other recent studies suggest that consumers’ evaluation of a price discount can be impacted by the *absolute* difference between the two prices (Thomas and Morwitz 2009). Therefore, a primary goal of the present study is to examine the circumstances under which a price difference might be assessed and encoded in relative versus absolute terms.

Understanding such a distinction is important because it allows the marketer to present his/her price comparison in the most favorable possible light. For example, consider two price discounts: \$222/\$211 and \$45/\$40. If consumers were more likely to assess absolute (relative) discounts in the former (latter) instance, then marketers might communicate the \$11 (rather than 5%) difference for the \$222/\$211 discount, but the 11% (rather than \$5) difference for the \$45/\$40 discount. In addition, research has shown that both conscious and non-conscious processes may operate at encoding to impact the perceived magnitude of a price discount. Price discount

effects reported in the literature that are theoretically grounded in these processes include the “physical font size effect” (Coulter and Coulter 2005), “discount-distance congruency effect” (Coulter and Norberg 2009), “left digit effect” (Thomas and Morwitz 2005), “right digit effect” (Coulter and Coulter 2007), and “ease-of-computation effect” (Thomas and Morwitz 2009). All of the aforementioned effects depend on the manner in which prices are compared (i.e., in relative versus absolute terms). Thus knowledge of this comparison procedure allows the marketer to understand (and manipulate) the *other* perceptual processes that operate at encoding to impact discount assessments.

In this paper, we suggest that a comparison of sale price to regular price may be more likely to involve a relative (percent) assessment, whereas a comparison of the marketer’s own sale price to a competitor’s price may be more likely to involve an absolute difference assessment. We further suggest that the physical placement of prices in a comparative price advertisement may impact how those prices are contrasted. Because horizontal (i.e., side-by-side) physical placement hinders digit-by-digit comparison, that type of format may result in more holistic price processing and a greater tendency to estimate discounts in relative terms. Conversely, vertical (i.e., columnar) placement facilitates digit-by-digit comparison, and therefore may result in a greater tendency to calculate the absolute numerical difference.

We examined our hypotheses in the context of two Experiments. In E1 subjects were asked to evaluate the magnitudes of a series of price discounts, which were represented by two prices presented to them on successive computer screens. The instructions did not specify whether the magnitudes were to be assessed in absolute or relative terms, but did specify that the higher prices referred to either a competitor’s prices, or the seller’s own “regular” prices. We measured the perceived magnitude of the discounts on a 10-point semantic differential scale anchored by “small” (1) and “large” (10). Reaction time (i.e., the 2nd dependent variable) was measured in milliseconds using a commercially available response-time software. A 2 (separation: horizontal, vertical) x 2 (higher price: competitor vs. regular) x 15 (absolute difference: range=1-92) x 27 (relative numerical difference: range=1.10%-50%) mixed between/within-subjects design was employed. Preliminary ANOVA results revealed that when subjects were told that the higher price referred to a competitor’s (regular) price, the absolute (relative) difference between prices affected both discount magnitude perceptions and reaction time. Further when prices were viewed in vertical (horizontal) format, the absolute (relative) difference between prices impacted both discount magnitude perceptions as well as reaction time.

In order to assess the degree to which absolute versus relative difference drives consumer purchase in a forced choice scenario, we conducted a second experiment. In E2 eighteen participants are asked to choose between *two* sets of discounts, and choice/reaction time was assessed using the same response-time software. Logistic regression revealed that participants chose the greater relative discount for 91% of horizontal comparisons, but for only 56% of vertical comparisons; vertical format was 2.13 times more likely to predict choice of the higher absolute difference than was horizontal format. Participants chose the greater relative discount for 78% of

regular high price cases but for only 67% of competitor high price cases; the regular high price was .55 times *less* likely to predict choice of greater absolute discount than competitor high price.

Initial results from our two experiments support our contention that serial/columnar price presentation format and regular/competitor reference price designation will impact whether prices are compared in absolute or relative terms. These results have important implications for the marketing practitioner.

What Do these Clinical Trial Results Mean for Me? How Personally Relevant Decisions are affected by Data Framing, Partitioning, and Quantification

Dipayan Biswas, Bentley University, USA
Cornelia Pechmann University of California, Irvine, USA

EXTENDED ABSTRACT

If I take a prescription pain reliever such as Maxalt, what is the probability that I will get relief? If I drive a Toyota Prius and I get in a car crash, what is the probability that I will get seriously hurt? Consumers often make judgments about personal well-being while evaluating products, and regulations increasingly require that clinical trial and product test data be provided to consumers (Landro 2004). However, such data can be quite complicated to interpret and how the interpretation is done may depend on many factors. When consumers make a decision about their own personal well-being or behavior, it is called a personally relevant decision (Levin, Schnittjer, and Thee 1988). Research indicates that for personally relevant decisions, consumers want to process any given data in an unbiased way to make the best judgments (Levin, Schneider, and Gaeth 1998; Levin et al. 1988). However, whether consumers are actually able to do so may depend on the data format. The data format may vary in several ways, but we focus primarily on three factors that have theoretical and practical significance: (1) data partitioning—that is, whether product efficacy results from multiple studies or subject groups are reported separately or aggregated (Morwitz, Greenleaf, and Johnson 1998), (2) data quantification—whether the product efficacy results are presented as frequencies or equivalent percentages (Cuite et al. 2008), and (3) attribute framing—whether the product efficacy results are framed in terms of successes or equivalent failures (Levin and Gaeth 1988).

Prior studies have examined the effects of data partitioning versus aggregation (Cheema and Soman 2008; Morwitz, Greenleaf, and Johnson 1998). However, these studies did not examine the interaction effects between data partitioning and data framing or data quantification. Attribute framing refers to describing outcomes “in terms of success versus failure rates” (Levin, Schneider and Gaeth 1998, p. 159). Numerous studies indicate that framing attribute information about products in terms of successes rather than the equivalent failures enhances product evaluations (Levin et al. 1998; Mittal, Ross, and Tsiros 2002; Zhang and Mittal 2005). It is believed that the positive frame or cue (e.g., 75% lean) evokes favorable thoughts whereas the negative frame or cue (e.g., 25% fat) evokes unfavorable thoughts, generally without conscious awareness (Levin et al. 1998). However, researchers have found that when decisions have personal relevance, the frame is rendered inconsequential (see Levin et al. 1998 review; also Janiszewski et al. 2003; Levin et al. 1988; McElroy and Seta 2003). People are motivated to evaluate the alternate frame in addition to the given frame due to their high level of personal interest in the issue. In other words, people are motivated to consider both the probability of success and failure, regardless of how the data is framed. The question we ask is whether the frame might sometimes bias judgments despite personal relevance. In particular, might the frame bias judgments when the data are in a partitioned frequency format and there is low processing ability? Our research is the first to examine this issue. We conducted four experiments to test our hypotheses.

The results of our first experiment (which used sunscreen as a product) replicated the findings of prior literature, whereby personal relevance enhanced processing motivation. Hence, for deci-

sions made under personal relevance, there were no framing effects. However, framing effects emerged when there was no personal relevance.

The results of our second experiment (which used prescription pain reliever Maxalt as a product, and its actual package insert as experimental stimuli material) showed that the combination of partitioned data and frequency data reduces the ability to process, relative to aggregated data or percentage data. Therefore, the combination of partitioned data and frequency data evoked a framing bias despite personal relevance, in that a success versus failure frame favorably biased judgments. Aggregated data or percentage data did not evoke this bias.

The third experiment again used sunscreen as a product, and examined how data variance might influence the effects of partitioning and framing. This experiment also examined actual consumer choice behavior in terms of choosing between a focal versus a control sunscreen. We wanted to examine if when the partitioned data points have high variance or variability, the frame may be invalidated or discredited as a heuristic cue (Schwarz and Clore 1983, 2003). The results of this experiment supported such a hypothesis. That is, under low data variance, framing bias was observed with partitioned frequency data. However, high data variance nullified the framing bias with partitioned frequency data.

Finally, in our fourth experiment, we attempted to empirically verify our assumption that data partitioning is the major cause of the framing bias that is observed with low variance frequency data. We showed participants a single data point and asked for personally relevant judgments. Then we showed participants a second and a third data point, rendering the data partitioned, and asked for their judgments after each subsequent data point. We posited that there would be no framing bias with a single data point, but that the framing bias would emerge with the second data point and especially with the third data point. That is, the framing bias would appear and strengthen as the data became more partitioned and processing became increasingly difficult. The results of this experiment supported our hypothesis.

In conclusion, the results of our experiments would have implications both for marketers as well as for regulators, in terms of designing optimal formats for presenting information from product and/or clinical trials and tests. In terms of academic implications, this research is the first to examine the interaction effects between data framing, partitioning, and quantification; while prior studies found lack of framing effects under personal relevance, our experiments demonstrate that even when there is personal relevance, framing effect biases can emerge for partitioned frequency data.

It's Been My Number One Source of Stress for Months: The Decision to Pay for Care

Aimee Dinnin Huff, University of Western Ontario, Canada

June Cotte, University of Western Ontario, Canada

EXTENDED ABSTRACT

The experience of choosing care for a family member—a young child or an elderly parent—is not unfamiliar to many consumers. Child and elder care represent a significant area of consumer spending: the American adult nursing care and child care industries include nearly 140,000 facilities, which generated revenue in excess of \$160 billion in 2008. Although care decisions and outcomes have been explored in other disciplines, including sociology, gerontology, and economics, we are not aware of any consumer research that has addressed care decisions. Therefore, there is an opportunity to explore and understand the experiences of these decision makers as they interact with the market for care services.

Care decisions are also an important area of study because they are typically experienced very differently than decisions for standard consumer products. Prior research in other fields has shown that care decisions are complex and emotionally distressing, and from a consumer research perspective it seems doubtful that choosing care for one's infant is comparable to shopping for an automobile or choosing a vacation. In this research, we take an interpretive approach to understand how care decisions are experienced within the sociological context. Elder and childcare decisions were chosen because they both involve role transitions pertaining to the needs of immediate family members.

We began with the question, "How do everyday consumers experience care decisions for family member?" Related prompts pertained to the types of emotions and reactions experienced during the decision process, the identification of other factors influencing the decision, and reflections on what informants felt was expected of them. We conducted 18 depth interviews with adults who had recently made a care decision for a child or elderly parent, or who were in the process of making that decision. Following the phenomenological interview method, we asked informants to share their stories about making a care decision. Interviews were conducted one-on-one, face-to-face, and typically lasted 75 minutes. Most interviews took place at informants' homes.

In the spirit of rigorous interpretive analysis, we began our data analysis by reviewing and reflecting on the audiotapes, field notes, and transcripts. After thematically coding individual transcripts, we discussed emergent themes and sought to reveal idiosyncratic and shared meanings. The interpretation process involved part-to-whole comparisons and our findings were developed through much iteration.

At a descriptive level, our research uncovers anxious, often naïve decision-makers, unprepared for the situation and experiencing great difficulty negotiating their new role in the family. What resembles a traditional consumer search process is overlaid with nervousness, anxiety, guilt, and exhaustion, forcing consumers to create and adhere to priorities that help them legitimize their ultimate choices. From our data, it is clear that decision-makers are overwhelmed and exhausted by the decision context and the outcomes related to the choice. Other important aspects of the care decision experience include various coping strategies, and reconciling self-conflict through conscious struggles to come to terms with guilt, real and perceived obligation, and the reality of the choice situation. Although commitment and love for the family members requiring care are unmistakable, our informants' experiences with care decisions are charged with negative emotions.

In our interpretation of the data, we relied on literature pertaining to role transitions, family identity, and production and consumption of caring. Choosing care for a family member marks an important role status transition, and prior research has demonstrated that in times of liminality, consumption can both facilitate and complicate role transitions. As consumers become aware of a need to choose a care service, they experience a turning point where they must juggle multiple roles (e.g., care-giver and professional), interact and make decisions with different relational units within the family, and manage the production and consumption of caring for the family member in need. At each stage of the transition, the decision maker must balance his/her own needs with those of the child or elderly parent. Thus, the turning point ultimately creates tension between the desire for self-fulfillment and feelings of obligation to family members.

The concept of ambivalence is useful for understanding the contradictory normative expectations felt by consumers as they interact with the marketplace to choose care services. Ambivalence is not a state of internal conflict, per se; rather, it can be conceptualized as an awareness of irreconcilability, and a link between individual action and social structure. In this way, an understanding of ambivalence—both at the individual level and the social structural level—can facilitate an interpretation of data because it accounts for contradictory emotions and thoughts experienced as consumers attempt to negotiate incompatible expectations imposed by themselves and relevant social structures (e.g., culture, family, gender).

Our interpretation revealed four themes tied to ambivalence: the desire to prioritize one's own needs and wishes when choosing care for a family member; unease tied to the conscious awareness that reality differs from an ideal situation; consciousness of one's role within the family; and guilt that the outcome is somehow less than optimal and real or perceived expectations have not been met.

We focus on individual decision-makers within the family. Recent advances in consumer literature have demonstrated that the family is an important unit of analysis, and future research could explore how selection of care services is accomplished within the family. It would also be useful to examine childcare and eldercare experiences separately, thereby allowing for a richer understanding of the unique complexities and contexts of each phenomenon. Additionally, future research work could productively focus on the lack of coherent public policy and public support for children and elder care, and the cultural role of stay-at-home parental caregivers.

What is the Relation between Cultural Orientation and Regulatory Mode?

David Silvera, University of Texas at San Antonio, USA
Ashok K. Lalwani, University of Texas at San Antonio, USA
Ashley Arsena, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Research delineates two distinct self-regulatory modes, which have been labeled *assessment* and *locomotion* (Kruglanski et al. 2000). Assessment is the aspect of self-regulation that focuses on comparisons and critical evaluations of entities or states (i.e., goals or means) in relation to different alternatives, whereas locomotion is the aspect of self-regulation that focuses on movement between states and commitment of psychological resources to initiate and maintain goal-related movement. Thus, both assessment and locomotion are important components of any self-regulatory activity. Indeed, regulatory mode has been shown to influence numerous and important marketing phenomena, ranging from product preferences and assessment of value to the relation between product decision strategies and willingness to pay for the selected product (Avnet and Higgins 2003; Higgins et al. 2003). The current article examines the association between cultural orientation and regulatory mode.

A number of findings suggest that collectivists are more likely to engage in detailed processing regarding social relationships, which is consistent with the focus of the assessment regulatory mode (Avnet and Higgins 2003). Within a collectivist culture, it is important for the individual to be sensitive to transgressions from consensual standards (Lalwani et al. 2006; 2009a; 2009b), and information regarding deviations from collectively shared standards is crucial to developing more appropriate behaviors for the future, affirming one's sense of belonging, and promoting harmony within the group (Kitayama et al. 1997). Because an assessment orientation has direct implications for a person's sensitivity to discrepancies from standards (Kruglanski et al. 2000), this suggests that assessment might be associated with a collectivist cultural orientation. Other evidence confirms that collectivists have a greater tendency than individualists to assess the reactions of others to their behavior in order to maintain harmonious relationships with them (Lalwani 2009).

With regard to locomotion, collectivist cultures are often characterized by clear in-group/out-group distinctions and a high degree of rigidity and inflexibility that makes it difficult for individuals to move from one group to another (Triandis 1989). The relative lack of social mobility in collectivist cultures suggests that locomotion goals might be less compatible with a collectivist cultural orientation. Conversely, the relatively high social mobility that characterizes many individualist cultures suggests that locomotion goals might be more compatible with an individualist cultural orientation. Research also suggests that assessment involves making decisions based on careful analysis and rationality (e.g., cost-benefit analysis; Weber, Ames, and Blais 2004), a decision-making style that has also been associated with individualism (Mintzberg 1989). Indeed, the logical thought process has its roots in individualism (Markus and Kitayama 1991; Gelfand and Dyer 2000). Similarly, in the context of negotiations, research indicates that collectivists are less likely to rely on logical analysis than individualists (Gelfand and Dyer 2000; Goldman 1994). This suggests that individualists will emphasize assessment more than collectivists, and preliminary support for this proposition is provided in a study by Weber et al. (2004), who conducted a content analysis of decisions made by characters in 29 bestselling and classic novels in China and the United States. Weber et al. (2004)

found that decisions in Chinese novels were less rational and assessment oriented (i.e., less focused on careful evaluation and making the right or ideal choice) than those in American novels.

Several research findings are also consistent with the proposition that collectivists are more locomotion oriented than individualists. For example, research suggests that locomotion involves making decisions on the basis of intuition, set rules (e.g., time spent on a task) or personal roles (Weber, Ames, and Blais 2004). Collectivists have been shown to be more likely to rely on intuition and emotions than individualists (Mintzberg 1989). This suggests that collectivists may emphasize locomotion more than individualists, which is consistent with Weber et al.'s (2004) content analysis of novels in China and the United States which showed that Chinese decisions were more rule/role based and locomotion oriented than American decisions.

Four studies using a variety of operationalizations of culture (both situational and chronic) and regulatory mode suggest that individualists are more likely to emphasize assessment over collectivists, who in turn are more likely to emphasize locomotion. Moreover, we extend the findings to behavioral scenarios that consumers encounter in their day-to-day lives.

The article makes a number of theoretical and substantive contributions. Previous literature makes conflicting predictions regarding the link between cultural orientation and regulatory mode. The current article contributes to theory by delineating the exact relationships between the cultural values of individualism and collectivism and locomotion and assessment. Moreover, the article sheds unique insights into the goals of individualists and collectivists. For instance, because individualists are found to be assessment oriented, they might be relatively more perfectionistic than collectivists, as they attempt to compare all options available to them before arriving at decision, even if this process takes a long time (Kruglanski, Pierro, and Higgins 2007). Conversely, because collectivists are found to focus on locomotion, they might be especially concerned about making discernible progress on tasks and about making headway, even if the process results in sub-optimal decisions (Pierro, Kruglanski, and Higgins 2006). Substantively, the differential self-regulatory functions emphasized by individualists and collectivists have potentially interesting implications in a number of domains, including decision making, self-consciousness, discomfort with ambiguity, decisiveness, and openness to change (Higgins et al. 2003). For instance, because a locomotion orientation has been associated with an increased likelihood of following an "elimination by aspects" decision strategy in choosing products (Kruglanski et al. 2007), collectivists might prefer similar decision strategies that enable them to make steady progress toward a goal.

FILM FESTIVAL

SUMMARY

*Russell Belk, York University, Canada
Robert Kozinets, York University, Canada*

Not only does the filmmaking craft continue to advance, but as seen in this year's Film Festival, so does the technical and artistic merit of the films and their theoretical orientation and sophistication. Because more of the raw footage for these films is being shot in high definition, many of this year's films seemed to leap off the screen in their clarity. And better miking is simultaneously leading to higher sound quality. Such craft considerations are among the criteria used by jurors (the film equivalent of reviewers) in screening and choosing films to accept from among those submitted to the festival. When it came to choosing the two prize-winning films, craft considerations no doubt continued to play a role, but the treatment and interpretation offered in the film were likely of greater importance. Theoretical sophistication was evident in the winning films' attention to prior literature and their concise condensation of their field-based data's contributions to knowledge. It is the combination of all these factors that influence the People's Choice voting, for they all contribute to how the film engages its audience. These audiences vote for their favorite film. The Jurors' Award is based on a narrower audience composed of the jurors and the Film Festival Co-Chairs.

This year's People's Choice Award went to "**Black Friday: A Video-Ethnography of an Experiential Shopping Event**" by Robert Harrison, Timothy Reilly, and James Gentry. Set in the American Midwest, it is a film about the "Black Friday" opening of Christmas shopping on the day following American Thanksgiving. The film analyzes the shopping strategies of families who plan in advance how to get the special bargains offered on this one day of the year when merchants know they can get people up early in the morning or even get them to spend the night in front of their stores in order to take advantage of limited stock price specials. The film follows these families from their home planning sessions through the pre-opening lines, and into the stores. It provides typologies of different specialized shopper roles and strategies. In so doing, it shows how what seems like frenzied swarming can actually be well-coordinated strategic shopping in pursuit of the bargain in a spectacular environment.

The Jurors' Award this year went to "**Brothers in Paint: Practice-Oriented Inquiry into a Tribal Marketplace Culture**" by Joonas Rokka, Joel Heitanen, and Kristine De Valck. The film uses the extreme sport of paint ball to examine consumer neo-tribalism. What was once an inexpensive informal sport played in the woods, has become an organized, sponsored, and expensive sport with standardized man-made barriers, well-trained teams, and prize money for champions. Like the Black Friday shoppers, these teams use carefully planned strategies in their quests to be victorious in the tournaments. Despite sponsorship and prize money, team members may spend \$20,000 a year of their own money equipping themselves and travelling to contests. Building on a recent emphasis on community and consumer tribes in the consumer culture theory literature, the film's narrative analysis helps make sense of such expenditures in terms of a consumer tribal culture.

This year's films continue to show geographic diversity with filmmakers and subjects from the US, England, Brazil, Finland, France, Japan, China, Slovenia, Scotland, Ireland, and Canada. It does not exaggerate to say that the Film Festival is a window on the world. There is a rich variety in the topics and approaches of the films as well as can be seen in the abstracts below. At least one of the films shown this year has already been offered to the wider public through YouTube, an act we heartily endorse. Those wishing to view the films are encouraged to contact the filmmakers for further information.

PRESENTATIONS

"Black Friday: A Video-Ethnography of an Experiential Shopping Event"

*Robert Harrison, Western Michigan University, USA
Timothy Reilly, University of Nebraska-Lincoln, USA
James Gentry, University of Nebraska-Lincoln, USA*

The day after Thanksgiving, also known as Black Friday, has become a consumption event with more than 130 million people braving the elements, snarled parking lots, hours of waiting, and early morning crowds to shop on a day that has come to signal the beginning of the American Christmas shopping season. This video-ethnography provides an understanding of this consumer culture by examining the most unusual shopping day in U.S. culture. Based on our interpretation, we identify three categories of Black Friday shoppers, each with different roles, rules, and shopping strategies. Our investigation of the motivations of Black Friday shoppers offering insights into understanding shopping as a cultural spectacle and consumer competition, in addition to understanding extended family and organizational rituals.

“Blogs-Consumption, Behaviour, Interaction”

Carlos Rossi, PPGA-EA/UFRGS, Brazil
João Fleck, PPGA-EA/UFRGS, Brazil
Cristine Schweig, PPGA-EA/UFRGS, Brazil
Francini Ledur, PPGA-EA/UFRGS, Brazil
Oscar Evangelista, PPGA-EA/UFRGS, Brazil
Renato Barcelos, PPGA-EA/UFRGS, Brazil
Ricardo Perlin, PPGA-EA/UFRGS, Brazil
Simone Vedana, PPGA-EA/UFRGS, Brazil

What’s the best hair moisturizer? Does that base work as well as in the TV commercial? This and other questionings are made by thousands of women in a daily basis. And what do these vain consumers have in common? They search beauty products with the promised benefits. Here come into place the consumption blogs: by testing, using, researching and reviewing these products, the four interviewed bloggers took the role of advisors, personal beauty consultants of their readers. They evaluate, recommend, defend or warn different products and services. Differently from the usual medias, the interaction allowed in blogs is capable of producing an impact in both buying behaviours: not only the readers, but also the bloggers are affected.

“Fashion, Consumption and Identity”

Carlos Rossi, PPGA-EA/UFRGS-Brazil
João Fleck, PPGA-EA/UFRGS-Brazil
Teniza Silveira, PPGA-EA/UFRGS-Brazil
Alejandro Ojeda, PPGA-EA/UFRGS-Brazil
Christian Albrecht, PPGA-EA/UFRGS-Brazil
Cláudia Lanfredi, PPGA-EA/UFRGS-Brazil
Luís Moura, PPGA-EA/UFRGS-Brazil
Martina Basile, PPGA-EA/UFRGS-Brazil
Priscila Esteves, PPGA-EA/UFRGS-Brazil

What makes somebody uncomfortable with her own appearance? Why look like the others bother us so much? Such questionings show us a conflict in the consumer mind in the search for an unique style against the need of group recognition, creating a reflexive thought on the importance of fashion in our society. The consumers on the video value their dressing way and they help us understanding how consumers build and express their identity through fashion.

“VINILEIROS – Those Crazy Guys that Love Their Vinyl Records”

João Fleck, PPGA - EA/UFRGS, Brazil
Carlos Rossi, PPGA - EA/UFRGS, Brazil
Nicolas Tonsho, EA/UFRGS - Brazil

How much is a record collection worth? Is it possible to complete a collection? What makes someone buy a vinyl record today and pay more for this big black vinyl record than for a small silver CD? Or just download for free the same music from the internet and listen to it on an MP3 Player? Until what level is it just consumption and when does it becomes the passion of an aficionado? Find the answers for these and other questions in VINILEIROS.

“Brothers in Paint: Practice-Oriented Inquiry into a Tribal Marketplace Culture”

Joonas Rokka, Helsinki School of Economics, Finland
Joel Hietanen, Helsinki School of Economics, Finland
Kristine De Valck, HEC Paris, France

The objective of this videography is to explore what opportunities and challenges the emerging practice-oriented approach opens up for conceptualizing tribal consumer culture and marketplace dynamics. Drawing on Schatzki’s theorization of the ‘site of the social’, tribal marketplace culture and change are examined based on findings from a multi-sited ethnography of consumer tribes gathered around the extreme sport of paintball. In doing so, the tribal marketplace culture is conceptualized via constantly evolving nexus of practices and material arrangements; a specific context of human and non-human co-existence where, and apart of which, social life and the marketplace inherently transpires.

“Pirates of the Web: The Curse of Anti-piracy Advertising”

Barbara Culiberg, University of Ljubljana, Slovenia
Domen Bajde, University of Ljubljana, Slovenia

This short video unpacks the discursive contours of a prominent anti-piracy ad and the mashups created in response to it. Fairclough’s critical discourse analysis and Kress and Leeuwen’s guidelines on “reading images” are applied to 58 piracy-related videos uploaded on Youtube in response to MPAA’s “Downloading is stealing” campaign. We seek to actively include the consumers’ voices in the piracy debate and provide a snapshot of the struggles for meaning taking place on online platforms. Our study shows how the representations and practices of “piracy” merge in acts of subversive creative consumption as consumer infringe on copyrights to resist and play with corporate representations of piracy.

“Restrained Pursuit of Luxury: Wealthy Shanghainese Attitudes towards Upscale Consumption”

Junko Kimura, Hosei University, Japan
Hiroshi Tanaka, Chuo University, Japan

In order to examine the Chinese perception of luxury, we visited Shanghai in September 2008 and interviewed four families there with annual income of more than 100,000 US Dollars. Our finding was the restrained perception of luxury shared by wealthy Shanghainese. Their perception was restrained compared to their Western counterparts, probably because by the traditional Confucian values. They are still under the influence of their parents' generation which had undergone the atrocious hardship during the Great Cultural Revolution. They also feel luxurious when they are filled with nonmaterial gains.

“POV: Point of View... Consumers and Ethnographers in Perspective... ”

Wendy Hein, University of Edinburgh, Scotland, UK
Anmarie Ryan, Lancaster University, UK
Robert Corrigan, Limerick Institute of Technology, Ireland, UK

This film is based on a female ethnographer's research exploring young Scottish men's consumption practices. It shows how applications of mobile phones helped overcome some of the challenges the ethnographer faced in the field to generate data in a less invasive way. It also describes consumers' own use of mobile phones to record their experiences, legitimising and authenticating their masculinity. This emphasised the importance of consumer experiences for constructing gender identities through culturally situated consumption. We suggest that the role of mobile phones advances the researcher's capability for reflexivity and creates a richer understanding of consumers' points of view.

“Does Green? ”

Gary J. Bamossy, Georgetown University, USA
Basil G. Englis, Berry College, USA

In recent years the American market place has seen the re-emergence of a vigorous public discourse around the issues of what are variously called “Environmentalism,” “Global Warming”, “Sustainable Consumption”, “The Environment”, or in its simplest and most generic term, “Green”. National surveys regarding U.S. consumers' *awareness* regarding “things green” consistently report that over 80% of the American population is aware of Green issues (Mintel, 2008; American Environics, 2008; Makower, 2009; Englis and Bamossy, 2009). Levels of consistent commitment in terms of actual green *behaviors*, however, do vary greatly across segments of American consumers, with lifestyle variables tending to be better predictors of green behavior than demographic variables (Makower, 2009; American Environics, 2008; Englis and Bamossy, 2009). In short, American consumers know about Green, but do not always act on that knowledge. Given the tremendous Green push from both the public and private sectors, along with the never ending coverage of *Things Green* from the media, it seems reasonable to predict that while forms of the Green discourse are likely to change over time, they are not likely to wane.

One of the recurring perspectives that characterizes Green and sustainability research from both the academic and commercial research sectors is to begin with descriptive statistics that are meant to shock us by describing our (potentially disastrous) consumption and disposition behaviors, and then use these research findings as a basis for developing communication strategies which are meant to motivate consumers to become more involved. The orientation of the research is to make action seem perfectly rational, in fact so rational, it can NOT be resisted. The inner logic of the argument assumes that once people understand what is happening to the environment, they will act in positive, constructive ways. The assumption is that once people process this information, their best alternative will be Green action. “*Any sane person will adjust their consumption lifestyle once they learn this,*” seems to be the rationale underlying Green strategies of persuasion.

The video, “Does Green?” critiques this logic in a very subtle way, and suggests that this approach is not working. “Does Green?” points the viewer in a number of theoretical directions that may lead to new ideas of how to combine green awareness with green *action*. Capturing consumers' reactions to products as diverse as hybrid cars, light bulbs, and tote bags, this video explores the gaps between consumers' attitudes and behaviors, and sheds light on the strong connections between our sense of Green coupled with fashion, and Green coupled with self representation. Currently, the role of cultural discourse and social change around Green is often seen as a countervailing discourse. We need a new paradigm to frame our thinking about how to motivate acts of green and sustainable consumption, and the intent of this video is to help get this dialogue started.

“Remade China: The Re-Production of Chineseness in a Multi-Cultural Society”

Eric Ping Hung Li, York University, Canada

Russell W. Belk, York University, Canada

The intensified global interaction and between different ethnic groups creates problems that related to ethnic identification and representation. This video examines the intersection between ethnicity, immigration, food consumption and festival celebrations among overseas Chinese in Toronto, the most ethnically diverse city in the world. By capturing how Chinese immigrants interpret the notion of multicultural and how they mix and match elements from different cultures in their everyday consumption activities, this video aims to provide a better understanding of how members of the Chinese diaspora re-construct and present their cultural identity through the re-production of “Chineseness” in their new “homeland”.

ROUNDTABLE

Advancing the Production/Consumption Dialectic in Consumer Culture Theory

Chairs:

Ahir Gopaldas, York University, Canada
Sarah J. S. Wilner, York University, Canada

Participants:

Lisa Peñaloza, EDHEC Business School, France
David Crockett, University of South Carolina, USA
Kent Grayson, Northwestern University, USA
Bernard Cova, Euromed Management Marseilles, France
Hope Jensen Schau, University of Arizona, USA
Jean-Sébastien Marcoux, HEC Montréal, Canada
Fuat Firat, University of Texas-Pan American, USA
Julie Ozanne, Virginia Tech, USA
Clinton Lanier, University of St. Thomas, USA
Robert Kozinets, Schulich School of Business, York University, Canada
Richard Kedzior, Hanken School of Economics, Finland
Jill Avery, Simmons School of Management, USA
Aron Darmody, Schulich School of Business, York University, Canada
Gokcen Coskuner-Balli, Chapman University, USA
Ashlee Humphreys, Northwestern University, USA

The purpose of this roundtable is to provide a forum for interdisciplinary researchers to discuss new concepts, frameworks, and theories that can reformulate and advance the study of the production/consumption dialectic in consumer culture theory (CCT). Though the concepts of production and consumption are defined diversely within and across the disciplines of anthropology, consumer research, cultural studies, economics, marketing, sociology, and media studies, they are widely understood in opposition to one another. However, the relative emphasis on production, consumption, or hybrid conceptualizations has always been contingent on sociohistoric conditions. For example, as capitalism and globalization matured through the 20th century, both business practice and social theory gradually de-privileged production and divided their attention between production and consumption in more equal measure. This trend roughly coincided with shifts from modern ideologies and mass production to postmodern ideologies and market segmentation (Cohen 2004; Firat and Venkatesh 1995; Zhao and Belk 2008).

CCT has a long history of considering production, in addition to consumption, in its analyses (for a review, see Arnould and Thompson 2005). Within CCT, it is often argued that the production/consumption dialectic structures intra-person (e.g. Tian and Belk 2005: work self/home self); inter-person (e.g. Thompson and Coskuner-Balli 2007); and inter-group (e.g. Giesler 2008) identities and activities. Long-standing questions about cultural construction, reproduction, opposition, and transformation in the market sphere remain at the heart of contemporary CCT research: How do dominant cultural producers transform the core ideologies of a society (e.g. Zhao and Belk 2008)? How do marketers employ mass-mediated and micro-cultural discourses to craft compelling offerings and reformulate historical discourses in doing so (e.g. Thompson and Tian 2008)? How do producers imagine and interpellate consumers and consumption communities (e.g. Cayla and Eckhardt 2008; Kozinets 2008)? How do producers and consumers negotiate the (dis)junctures of market and social logics (e.g. Giesler 2008; Thompson and Coskuner-Balli 2007; Tian and Belk 2005)? The agenda of this roundtable may be articulated accordingly:

- What underexplored and unexplored concepts, frameworks, and theories can help researchers explicate the myriad intersections of production and consumption in practice?
- Which contexts, informants, and phenomena are appropriate for investigating these intersections?
- What insights can be gleaned from production/consumption research not only for theory, but also for consumer empowerment, political engagement, and social justice?

Exploring new theoretical directions for this domain of research is perennially important for a number of reasons. First, the production/consumption dialectic is at the core of CCT and its sibling fields of interpretive consumer research (for a review, see Cova and Elliott 2008), consumption anthropology (for a review, see Miller 1995), consumption sociology (for a review, see Zukin and Smith Maguire 2004), and critical marketing studies (for a review, see Saren et al. 2007). What all these fields share is an interest in how market logics are produced, reproduced, opposed, and transformed by cultural, economic, political, and social forces, both within and beyond the marketplace. Accordingly, the production/consumption dialectic gives an extensive network of scholars a node to link their sometimes complementary, sometimes contradictory trajectories of scholarship.

Second, the production/consumption dialectic links to numerous other dialectics that shape the agenda of CCT. For example, the dialectic links to the supply/demand dialectic in economic discourse, the management/marketing dialectic in business discourse, and the work/spend (Schor 1991) or work/life (Tian and Belk 2005) dialectics in social discourse. To advance the reach of CCT, it would behoove consumer culture theorists to challenge such discursive divides and forge links with compatible theorists in other areas of the business academy (e.g. critical management studies [Alvesson and Willmott 1992]) with whom we share critical and interpretive research agendas and domain boundaries.

Third, along with structure/agency theoretics and identity politics, the production/consumption dialectic has inspired increasingly sophisticated understandings of production and consumption and their multi-level (institutional and individual) and multi-sphere (cultural and economic) roles in social reproduction and transformation (e.g. Bourdieu 1984; Giddens 1991; Ritzer 1993). These interlinked understandings of production/consumption, structure/agency, and identity politics are not universal but situated resolutions to theoretical debates. For example, while marketing researchers have proposed that the service-dominant logic of co-creation/co-production is a substantive merger of production and consumption logics (Vargo and Lusch 2004), consumer researchers have argued that these concepts are rhetoric bandages over a sustained divide between the production of exchange-value (i.e., production) and the production of use-value (i.e. consumption) (Humphreys and Grayson 2008). It is through cycles of such dialectic discussions, syncretic conceptualizations, and reformulated dialectics that business practice and theory evolves in society and the marketplace (Giesler 2008).

ROUNDTABLE

Towards a Theoretical Vocabulary for Consumer Research on Sustainability

Chairs:

Melea Press, University of Wyoming, USA
Eric J. Arnould, University of Wyoming, USA

Participants:

David Crockett, University of South Carolina, USA
Diane Martin, University of Portland, USA
Guliz Ger, Bilkent University, Turkey
Pierre McDonagh, Dublin City University, Ireland, UK
Krittinee Nuttavuthisit, Chulalongkorn University, Thailand
Alice Grønhoj, Aarhus University, Denmark
Robert Fisher, University of Alberta, Canada
Benet DeBerry-Spence, University of Illinois at Chicago, USA
Julie Ozanne, Virginia Tech, USA
John Schouten, University of Portland, USA
Stacey Baker, University of Wyoming, USA
Jenny Mish, University of Notre Dame, USA
Susan Dobscha, Bentley College, USA
Vladas Griskevicius, University of Minnesota, USA
Robert Caruana, University of Manchester, UK
Gokcen Coskuner-Balli, Chapman University, USA

Purpose

The purpose of this session is to bring together individuals who are conducting, or interested in conducting, research in the broad areas of intersection between sustainability, consumer behavior and marketing. Discussion will focus on how to develop a theoretical vocabulary for sustainability research that transcends the specific contexts that we currently associate with “sustainability,” such as subsistence consumers, disaster mitigation, quality of life, equitable development, voluntary simplicity, and above all “green marketing.”

Rationale

Consumer research is glaringly absent from conversations and writing about sustainability, even though there is a long tradition of interest in the so-called green consumer segment, consumer resistance, and quality of life issues. Research on sustainable business practice in the private sector has been led by systems engineers, architects, economists, and CEOs. Consumer research scholars can enrich the discussion of consumer issues in all areas of sustainability, including natural resource consumption (energy, water, etc.), purchasing and lifestyle choices, co-creation and assessment of value, and community health and development. Contributions from consumer researchers to the emerging sustainability paradigm would increase the viability of current and future sustainability initiatives.

Approaches to consumer behaviors associated with sustainability tend to focus on change through information processing or social marketing models, and presume that unsustainable consumer behavior may be changed significantly through such approaches. However, these tactics have not been successful, as evidenced by the fact that exactly 40 years since the founding of Earth Day, and 35 years since the first oil shocks, and despite efforts to promote various “green” practices, we live in an economy that is ever more ecologically unsustainable. And the average consumer if s/he thinks of sustainable consumption at all, probably thinks that shopping at Whole Foods is contributing to sustainability. Unfortunately, the normal habitus of consumer culture, that is, the mundane practices of everyday consumption, build in unsustainability. Perhaps we need to think about approaches to changing consumption that despectacularizes sustainable consumption activities, such as engaging in voluntary simplicity, local food systems, off-grid green homes, and “alternative” practices in general. The effort to provide more information, or “educate” has not resulted in behavior changes that lead to or signal a more sustainable society. We need to address our absence in the sustainability conversation and the weaknesses of our current tools to address the sustainability challenge.

What is the emerging sustainability paradigm? From a marketing perspective, sustainable business practice entails developing strategic thinking that positively impacts firms’ long-term economic sustainability in an increasingly volatile and resource constrained world; firms’ environmental footprint; and the firms’ long-term relationships with stakeholder communities. It also requires not only full, but far more efficient use of company resources. It places innovation at the heart of attempts to move toward clean technology, and resource efficient, climate- and ecology-friendly products and services. It strives to balance the need to develop economically with the need to maintain social and environmental consideration.

Sustainable business practice also involves consumer-centered thinking, approaches that view customers as people with needs beyond material consumption and temporary gratifications. It also includes issues that affect customers’ fundamental quality of life, access to air, water, health, markets, and so on. It incorporates a long-term perspective to consider the needs of stakeholders, not just of the present but of future generations. Finally, sustainable business practice also involves the extension of consumer and market-based solutions to under-served local, regional and global populations.

We could look outside consumer research to find research that calls for systems approaches to sustainability problems. Rudolf Steiner’s deep belief in the connection between the spiritual and natural world led to a focus on systems, rather than individual parts of

people, society, and activities. His lectures and writings influenced medicine (anthroposophical extended medicine), education (Waldorf schools), and agriculture (Biodynamic farming). In each of these areas he proposed that issues be examined from a whole systems perspective. For example, biodynamic agriculture looks at the farm as an organism. The farm is then seen as a complex organism that can nourish itself. Challenges of growing food and treating disease are approached from the systemic level; that is, as an issue of the entire organism, not an individual piece.

Edward Abbey, a nature writer, pushed the preservation of wilderness through his many works of fiction and non-fiction. His meditations on nature, self-hood, and consumer culture provide a moral foundation for rethinking relationships among the person, civilization, and nature. He points to understanding the limits of ecological constraints, which is seen with growing urgency as we move more deeply into the 21st Century.

Elinor Ostrom, a prolific political scientist, calls for intensely interdisciplinary approaches to addressing the ecological and governance issues we face today. She pulls in experience from medicine to illustrate that simple solutions often lead to unanticipated problems, and suggests that a smart approach to a viable solution to our unsustainable economy is to build strong interdisciplinary research that addresses issues at multiple levels, taking into account the social sciences and ecological constraints. She looks at social and scientific solutions to complex problems facing our world.

Each of these three examples highlights the need for systems thinking and interdisciplinary research, pushing the necessity of breaking down silos to accomplish our goal of sustainable lives, societies, and ecosystems.

Some people are recognizing that “sustainability” has become a more complex and comprehensive consumer research topic than is captured in the traditional “green consumer” framing. Linkages between new consumer practices responding to a host of corporate initiatives new and old, such as green marketing, corporate social responsibility, fair trade, and social entrepreneurship, within an environment of perceived global risk and global Commons crises (global warming, environmental strain, global unrest) offer the potential for renewed research trajectories in consumer research.

Preconference discussions will be facilitated by the organizers. It will happen in two parts. First, we will give participants different ideas and statements to respond to, compile the information, and email it back to them. Then, we will bring participants together with postings on the ACR Knowledge Exchange Forum, and through email. Pre-conference idea exchange is very important for the success of this roundtable, because it may be hard to stay on-topic discussing sustainability from a *theoretical* perspective.

Diversity is an important part of discussions about sustainability, and this session brings together new and veteran ACR-goers, as well as people with different methodological orientations. Different points of view are important in working through this topic.

Key questions the roundtable will address include

1. What is sustainability as it pertains to consumer research?
2. What role can consumer researchers play in guiding this conversation?
3. How can we use ecological theories of sustainability to build theory in consumer research?
4. Are we poised to lead interdisciplinary research in this area? What would that look like?

ROUNDTABLE

Navigating the Networked Rivers of the Social Web: Emerging Themes for Consumer Behavior Research on Web 2.X

Chair:

Donna Hoffman, University of California at Riverside, USA

Participants:

Robert Kozinets, Schulich School of Business, York University, Canada
Nicholas Lurie, Georgia Institute of Technology, USA
Wendy Moe, University of Maryland, USA
Albert Muniz, DePaul University, USA
Thomas Novak, University of California at Riverside, USA
Thomas O'Guinn, University of Wisconsin-Madison, USA
Hope Jensen Schau, University of Arizona, USA
Ann Schlosser, University of Washington, USA
Allan Weiss, University of Southern California, USA
Tiffany White, University of Illinois, USA
Jill Avery, Simmons School of Management, USA
Kristine De Valck, HEC Paris, France
Uptal (Paul) Dholakia, Rice University, USA
Markus Geisler, York University, Canada
Andrew Gershoff, University of Michigan, USA
Ashlee Humphreys, Northwestern University, USA
Charla Mathwick, Portland State University, USA
Constance Porter, University of Notre Dame, USA

In a little over a decade and a half, the consumer Internet has evolved from a few directories and online storefronts into a vast, sophisticated network of information stores that millions of people from around the globe interact with on a regular basis. As the Internet matures, it has moved from a static, rigid mechanism for data access into an *operating system* that seamlessly connects applications—and people—across the global network. Increasingly referred to by many as Web 2.0 or the “social Web,” this evolving Internet offers online consumers unprecedented opportunities to create and control their online experiences.

More than simply a set of features or applications, new social media forms (such as the social bookmarking site StumbleUpon or the micro blogging application Twitter) are contributing to the evolution of the Web as a social technologies platform that connects consumers in innovative ways with often startling implications for traditional marketing efforts. It is a profound fact that consumers are now both the producers and consumers of their own online content and services. The purpose of this proposed roundtable is to explore the emerging research implications of these social Web consumer behaviors.

The Early Internet—Flat and Static

In the early Web, let's call it “Web 1.0,” consumers were required to navigate through relatively inflexible and often rigid online paths. Web 1.0 was a conduit for information, largely consisting of basic text and images. The basic infrastructure for online commerce was built in Web 1.0, in the form of static sites which evolved to include limited dynamic content and interactivity.

Web 2.0—A State of Mind

We are now witnessing Web 2.0, the next logical iteration of the Internet, where the Web is more of an operating system that facilitates sharing and participation. The seamless connection of Web 2.0+ applications and services such as the “mobile+social” *dodgeball.com* to track one's friends' current geographic locations and *Zoomr* for photosharing and text messaging in real-time has been referred to as the “mash-up” phase of the Internet with parts that connect (Markoff 2006). Rather than follow relatively inflexible paths and existing navigational structures, Web 2.0 consumers are more in control of their online navigational experiences and are more easily able to engage in only those applications that interest them. Web 2.0 is less about navigating through individual Web sites and more about Web-based applications and environments that can be installed and experienced as the consumer sees fit.

Web 3.0—It Can Think!

If Web 2.0 puts consumers in control, then Web 3.0 will augment that control and give it a brain. Web 3.0, sometimes called the “Semantic Web” (Berners-Lee, Hender and Lassila 2001), is the next evolution of social networking technologies pioneered in Web 2.0. As the Web begins to “understand itself,” it becomes less of a catalog and more of a guide. This phase involves integration of artificial intelligence and the Web and involves human effort integrated across the network. Very early examples are Amazon's Mechanical Turk Web service or Google's Image Labeler game. Virtual Worlds like *Second Life*, where humans in avatar form serve as guides and mentors and answer questions well beyond the scope of today's search and FAQ technology, provide a glimpse into what information search in the online world of the future may be like.

FIGURE

Emerging Social Web Research Themes Organized According to The “Four C’s of Online Consumer Behavior

Create: User Generated Content (individually created content)

- Community identity
- Posters vs. lurkers
- Social dynamics of posting behavior

What is the Social Web?

Some definitions may be useful. We define the social Web as consumers interacting with each other through Web 2.0+ based social media applications. *The currency of interaction is user-generated content.* Social media are Web-based applications that permit creation, sharing, manipulation and consumption of user-generated content. Social networking focuses on the nature of interactions among consumers within a specific category of social media applications—social networking sites.

Roundtable Themes and Objectives

The four C’s of online consumer experience (Hoffman and Novak 2009) serve as the organizing framework for the proposed roundtable research themes. As depicted in the Figure, social Web research topics are organized according to consumer creation, connection, consumption and control themes. Key objectives of this proposed roundtable are to: 1) offer a new framework for organizing emerging consumer behavior research on the social Web research frontier, 2) expose interested ACR members to exciting research streams in this emerging area, and 3) generate insights and ideas that can serve as the basis for future collaborations among ACR members.

A total of 19 ACR members, including the organizer, have committed to participate should this roundtable be accepted. These committed participants come from across the globe and run the gamut from assistant professors who have just completed their Ph.D.s on emerging social Web topics to well known academic experts with established reputations in online consumer behavior. As such, ACR attendees, as well as roundtable participants themselves, can expect to participate in a highly engaging roundtable discussion concerning the emerging social Web research themes.

We anticipate that the roundtable is likely to be of interest to a wide variety of consumer behavior researchers, including both “newbies” who are Web 2.X curious and experienced online consumer behavior researchers. *Each roundtable participant has agreed to serve if the proposal is accepted.*

Pre-Conference Interaction Among Participants

Roundtable participants will interact before the roundtable via email exchanges. These exchanges will culminate in a face-to-face dinner in Pittsburgh during the conference in advance of the roundtable, sponsored by the UCR Sloan Center for Internet Retailing.

Recommendation Agents as Consumer Response Heuristic to Information Overload and the Joint Effects on Choice Quality, Choice Confidence, and Website Evaluation

Muhammad Aljukhadar, HEC Montreal, Canada

Sylvain Senecal, HEC Montreal, Canada

Charles-Etienne Daoust, Cossette Communication Group, Canada

The debate on the antecedents and consequences of information overload is ongoing. Given the low online search costs, consumers are particularly exposed to elevated information amounts during product choice. This research integrates the traditional and structural methods in product information measurement to investigate (1) the relationship between information amount (bits) in a product choice set and information overload perceptions, (2) consumers' tendency to employ information processing reduction heuristic (by consulting a recommendation agent) as information bits and overload perceptions increase, and (3) the joint effects on several performance measures.

"In the age of the Internet, developing an understanding of how information-rich environments affect consumer decision making is of crucial importance. Given the disparate ways in which information can be presented to consumers and the high potential for information overload in online environments, it is important to use measures that capture the multiple dimensions of information." (Lurie 2004 p. 484). The literature further indicates that consumer decision support systems (e.g., product recommendation agents) are decision heuristics that alleviate part of processing effort required by consumers while maintaining an acceptable level of choice accuracy (Häubl and Trifts 2000; Todd and Benbasat 1992). Recommendation agents have the potential to reduce consumers' information overload and search complexity while improving decision quality (Haubl and Trifts 2000; Maes 1994).

Researchers studied the consequences of information overload on consumers' choice and purchase of different products, such as laundry detergent (Jacoby, Speller, and Berning 1974a), rice and prepared dinner (Jacoby, Speller, and Berning 1974b), peanut butter (Scammon 1977), houses (Malhotra 1982), calculators (Lurie 2004), and CD players (Lee and Lee 2004). Theory implies that information overload is an expected event because of well-defined limits in humans to assimilate and process information within any timeframe (Jacoby 1977; Jacoby, Speller, and Berning 1974a; Malhotra 1982).

In general, researchers indicate that, faced with large product information amounts (or information bits; the term is adapted and used as in Lee and Lee 2004; Lurie 2004), consumers' limited capacity to process information becomes overloaded, resulting in dysfunctional consequences such as cognitive fatigue and confusion (Hahn, Lawson, and Lee 1992; Keller and Staelin 1987; Malhotra 1984; Scammon 1977; Winzar and Savik 2002). Malhotra (1982 p. 419) concludes that "perhaps the most important generalization that emerges is that an individual is a limited information processing system."

This research contributes to the literature as it (1) simultaneously assesses the traditional and structural methods (see Lee and Lee 2004; Lurie 2004) to measure the information in a product choice set, (2) integrates a perceptual self-reported measure of information overload to show its relationship with information bits as well as performance measures, (3) manipulates three levels of alternatives, three levels of attributes, and two levels of attributes' distribution across alternatives in product choice set conditions to increase the study range and allow for curvilinearity inspection of the relation bits-overload perceptions, (4) includes a robust, observed measure (choice to consult recommendation vs. no consultation) to reflect the occurrence of information overload besides the perceptual measure, (5) inspects the effects on reactance besides the effects on choice quality and consumers' post-choice psychological states (choice confidence and difficulty). Thus the hypotheses developed and supported are:

- H1: Information overload perceptions increase as information bits increase; in addition, the relationship between information bits and overload perceptions is curvilinear.
- H2a: A main effect is expected for information bits on recommendation consultation; that is, the probability of consulting a recommendation agent increases as information bits increase.
- H2b: An interaction is expected so that as information bits increase, consumers low on need for cognition are more probable to consult a recommendation agent than consumers high on need for cognition.
- H3a: A main effect is expected for information overload perceptions on recommendation agent consultation; that is, the probability of consulting a recommendation agent increases as overload perceptions increase.
- H3b: An interaction is expected so that as overload perceptions increase, consumers low on need for cognition are more probable to consult a recommendation agent than consumers high on need for cognition.
- H4: An interaction is expected between information bits and recommendation agent consultation so that as information load or bits increase, consumers who consult a recommendation agent will have higher choice quality than consumers who do not; in addition, an interaction is expected so that recommendation consultation improves choice quality particularly for product choice sets with proportional (vs. disproportional) distribution of attributes' levels across alternatives.
- H5: An interaction is expected between information overload perceptions and recommendation agent consultation so that as overload perceptions increase, consumers who consult a recommendation agent will have higher choice quality than consumers who do not.
- H6: As information overload increases, reactance to recommendation decrease.
- H7: Whereas choice confidence increases as information overload perceptions increase, an interaction is expected so that choice confidence is lower for consumers who consult a recommendation agent and do not choose the recommended product than consumers who consult and choose the recommended product.

A completely randomized experiment (that followed pretests to insure manipulation success and product suitability) with three levels of alternatives, three levels of attributes, and two levels of attributes' distribution across alternatives (proportional vs. disproportional distribution, Lurie 2004) that involved 466 consumers choosing one laptop with the option to consult a recommendation agent prior to final choice was performed. ANOVA and binary logistical regression was used in data analysis (measures adapted scales from the literature).

Results support the hypotheses, show a curvilinear relation between information bits and overload perceptions, and favor the occurrence of information overload because the consumers' tendency to employ a decision heuristic (by consulting the recommendations) increases as information bits and overload perceptions increase. In addition, while recommendation agent consultation upholds choice quality in general as information bits increase, recommendation consultation was particularly salient in enhancing choice quality when product information was less diagnostic (attributes' levels are proportionally distributed across alternatives in the choice set). Recommendation agent consultation further interacted with information overload to improve choice quality, and choice confidence (but mainly for consumers that ended by choosing the recommended product).

One Without the Other: The Effects of Priming and Perceived Relationships Among Products on Consumer Choice

Jim Alvarez-Mourey, University of Michigan, USA

Daphne Oyserman, University of Michigan, USA

Carolyn Yoon, University of Michigan, USA

Abstract

Relational priming has been shown to influence individuals in the domains of self-construal (i.e., individualism and collectivism), but, to date, the research has been limited to studying self-construal with respect to interpersonal relationships. The current paper extends the theory into the realm of inter-product/service relationships by examining the effect relational priming has on product selection given perceived relationships among products and services. A series of three studies employing priming methodology explore differences in consumption choices based on prime type, perceived product/service relationships, and implied relationships. The results suggest that priming does, in fact, influence consumer choice among related products, elicit reluctance for subjects to break apart items perceived as related, and produce said effects via realistic advertisements beyond traditional laboratory priming techniques. Limitations and future studies are discussed, as are potential managerial implications for the marketing practices of up-selling, cross-selling, and advertising/point-of-purchase displays as priming tools.

Introduction

What is peanut butter without jelly? Barbie without Ken? What is a belt without its buckle or a shirt without pants (aside from slightly risqué)? In a variety of consumption settings, products and services can exist not only as independent items but also as items sharing a

relationship or a coexistence with other items. Thus, while a shirt may simply be only a shirt, most clothing retailers take great care in presenting that shirt in the context of an outfit, complete with a matching tie and pants, to illustrate the connection among these items with the hope that consumers will purchase more than just the shirt. Furthermore, consumers may feel a sense of emptiness or incompleteness if they only purchase one of a perceived pair or set of products/services, perhaps explaining why consumers so often go into a store with the intent of purchasing only *one* item and return with several.

Research Objective

The research objective of the current paper is to explore the relationship between self-construal (i.e., individualism and collectivism) and product preference/selection, as well as commitment to those preferences/selections, in the consumer context both inter-culturally and intra-culturally. Previous studies have shown that relational priming influences individuals' self-construal, which then affects their behavior, but most of these studies have been with respect to *interpersonal* influence. Thus, making consumers more aware of "relationships" makes them more susceptible to social or peer influence. Unlike the previous research, however, the current paper posits that priming consumers with relational primes will influence their subsequent consumption choices given the perceived relationships *among products*, not people, with respect to being 1) more/less likely to select products that are perceived as related, and 2) more/less likely to select a product if doing so separates that product from related products. In other words, whereas previous studies emphasized the role of self-construal, its effect on interpersonal relationships, and the role of interpersonal relationships on product selection, the current paper investigates the role of self-construal, a heightened awareness of relationships among products/services, and the subsequent preference and selection behaviors of consumers and their commitments to those selections.

Methodology

A series of studies exploring these predictions rely on a priming methodology to influence the self-construal of subjects completing the studies. Previous literature has shown that self-construal can be manipulated via subtle priming techniques, and, as expected, we see differences based on our priming approaches. More specifically, we prime subjects with traditional self-construal primes to activate the notion of relationships and then, following the priming, present subjects with several consumption decisions. In each study we then manipulate the availability of the goods perceived as being related to see how subjects from both conditions respond to the notion of breaking apart related items or the permitted consumption of related items. As expected, we see significant differences between the two groups, their consumption preferences, their satisfaction with the consumption experience, and several other variables including their willingness-to-pay for the products presented. In addition, to show that the effect of priming works regardless of default cultural self-construal, we replicate our findings with East Asian and Hispanic subjects.

Specific Studies & Results

The studies consist of several tests linking self-construal priming with differences in product selection and reluctance to break apart items perceived as being related. In Study 1, the Snack Study, consumers were primed, presented with a beverage, and allowed to select a snack. Somewhat surprisingly, independently-primed subjects were significantly more likely to choose *related* items in their initial selection, whereas collectives were significantly likely to choose *unrelated* items. One potential explanation for this is that collectives "see" more relationships among items, in general, which was supported by thought listing comments. Study 2, the Cute Puppy Study, replicated the findings from Study 1 and found a significant difference between how collective and independents deal with separating related items, with collectives experiencing greater dissonance and opting to consumer entirely different items to prevent separating related products while independents experienced no such dissonance when separating products. Study 3 replicated the results from Studies 1 & 2 in a realistic consumption setting—Amazon.com—while also finding support for *implied* product relationships as operationalized via Amazon's "Better Together" feature. Furthermore, Study 3 showed that priming techniques integrated into realistic advertisements produce the same effects as controlled laboratory priming techniques, which is an important contribution to marketing practitioners.

Theoretical & Managerial Implications

Theoretically, this paper's biggest contribution is the extension of relational priming from basic, interpersonal influence to the influence of perceived relationships among products and services, including the notion of experienced dissonance when such relationships are destroyed or broken. Additionally, the exploration of applied priming methodologies in the laboratory setting, such as advertisements or mock point-of-purchase displays, lends credibility to the external validity of such an approach as opposed to traditional self-construal priming techniques, such as the I/We pronoun-circling task or the Sumerian Warrior task. These contributions, among others, provide great insight to future research in this area.

Another motivation for pursuing this project rests in the significant impact the results of the study have for marketing managers as they develop strategies for marketing their products and services, both domestically and internationally. Implications of the results would be far-reaching, literally impacting each of the core components characterized by the traditional 4 Ps of marketing—product, price, placement, and promotion—in a way that may vary on the international level, culture to culture. To help illustrate the potential impact of the proposed study, let us consider specific examples as they related to these core marketing concepts:

Product: impacting product design decisions emphasizing either a stand-alone product or a product that is considered and included as one part of a related set of products

Price: impacting the ability to charge more for product bundles for collective consumers or taking advantage of up-selling or cross-selling tactics in particular markets

Placement: impacting the decision to sell products individually or as given sets or related items in different markets based on differences in self-construal across cultures

Promotion: impacting the creative design of advertisements emphasizing individualism or collectivism; impacting point-of-purchase displays that influence consumer behavior at the moment of product selection

Given the substantial theoretical and managerial implications presented by this paper's findings, it is the hope of the author that future research exploring the perceived relationships among products/services and measured/manipulated differences in consumers regarding their perception and maintenance of such relationships is pursued.

How Does the Unconscious "Think"?

Nelson Amaral, University of Minnesota, USA

Research indicates that when consumers' information processing capacity is limited (e.g., people operate under time pressure), their reliance on normative conscious processing can result in less optimal decisions than if people use a heuristic processing strategy (Payne, Bettman, & Johnson, 1988). This has been attributed to the fact that more elaborate and normative conscious strategies work well only if one is able to take all of the information into account. Extending on this, it also follows that even if external factors do not limit people's processing capacity, individuals' decisions about complex stimuli (e.g., individuals' choice of a vacation destination from a set where all destinations are described on many dimensions) still may not be optimal because of inherent limitations in human's processing capacity. Indeed, it is estimated that the conscious mind can process only about 40-60 bits of information per second (Wilson 2002), whereas the processing capacity of the entire human system (*i.e.* conscious and unconscious processing) is 11,200,000 bits per second (Dijksterhuis, 2004).

Due to people's limited processing capacity, when individuals are presented with a great deal of information in a relatively short period of time, much of the information that is represented in memory is likely to be poorly organized. That is, individual pieces of information are inadequately associated and integrated. Interestingly, recent findings suggest that unconscious thought may circumvent such problems (Dijksterhuis, 2004; Dijksterhuis, Maarten, Nordgren, and Van Baaren, 2006; Payne, Samper, Bettman, and Luce 2008). At present little empirical investigation offers insight into how the unconscious might perform such consolidation. The current research aims to address this question by drawing on recent evidence that potentially sheds some light on the kind of processing that the unconscious employs.

This evidence comes from a recent report, which indicates that when people are in positions of high social power, the decisions they render based on conscious thought are similar to those made under conditions of unconscious thought (Smith, Dijksterhuis and Wigboldus, 2008). In light of research which shows that people in positions of higher power construe information in a more abstract (versus concrete) way (Smith and Trope, 2006), the preceding implies that the unconscious may rely on fairly abstract cognition. To investigate this possibility we sought to replicate the findings of Liberman, Sagristano, and Trope (2002), which found that participants planning a camping trip farther into the future grouped the items they would pack into larger more inclusive groups. The results also indicated that this was a result of thinking more abstractly about far future events than near future events. Our goal was to replicate the results of this grouping task by using the manipulations of the original sets of experiments conducted by Dijksterhuis and his colleagues in which they had participants read information about a set of related products and would subsequently either distract some participants or ask them to deliberate for several minutes before making a judgment or choice about the products they had seen before the period of deliberation (conscious thought) or distraction (unconscious thought). (Dijksterhuis, 2004; Dijksterhuis, Maarten, Nordgren, and Van Baaren, 2006). Our goal was to investigate the following initial hypothesis:

H1: Compared to conscious thought, reliance on unconscious thought will prompt individuals to organize information into broader, more inclusive groups. Thus, individuals who engage in conscious versus unconscious thought will both assign a set of items to a larger number of groups overall and assign fewer items to each group that is formed.

We employed a single factor, between subjects design: thought condition (un/conscious). Participants were undergraduates who entered a lab and were seated in individual cubicles or rooms. Participants were all shown the same list of 37 camping items from Liberman et. al (2002) and asked to study the list for 2 minutes. Participants were told that the information would be used later for an unspecified task. After two minutes passed, all lists were taken away.

Two thought conditions were manipulated in the same manner as employed in studies by Dijksterhuis and his colleagues (Dijksterhuis, 2004; Dijksterhuis et. al 2006). Specifically, in the conscious thought condition, participants were allotted 3 minutes to “think about the list” they had just seen. Alternatively; in the unconscious condition, participants were given 3 minutes to solve a series of anagrams that were unrelated to the listed items. After 3 minutes passed, all participants were provided a blank sheet of paper and asked to write down as many of the items from the list as they could remember. In addition, they were instructed to place the items into groups by drawing circles around similar items. Participants were allowed to take as much or as little time as they needed to perform the tasks.

Supporting our hypothesis, participants in the unconscious versus conscious condition formed larger, more inclusive groups. Specifically, those in the unconscious condition created significantly fewer groups ($p < 0.01$), and on average they assigned more items to each group ($p = 0.01$). An analysis of variance that included the total number of items recalled as a covariate confirmed that the difference in both the number and size of the groups was not attributable to participants’ greater recall of the items in the conscious versus unconscious condition (significance levels remained at $p = < .01$). Further, no treatment differences emerged in the number of items that participants accurately recalled, ruling out the possibility that these differences accounted for the outcomes. Finally, neither the number of groups participants formed nor the number of items they assigned to each group differed as a function of the number of anagrams that participants solved in the unconscious condition.

Overall, this study provides some important empirical insight into the “black box” of unconscious thought. Whereas work by Payne et. al (2008) indicates that certain boundary conditions can limit the advantage of unconscious thought when rendering complex decisions, the present research offers clues about why this might be so. Specifically, we found that compared to individuals who engage in conscious thought, those who process information unconsciously construe data at a more abstract (versus concrete) manner. This implies that any advantage offered by unconscious processing should be limited to contexts in which decisions are likely to benefit from abstract as opposed to concrete cognition—an observation that nicely aligns with Payne et al’s (2008) findings. Our hope is that by gaining a better understanding of how unconscious thought operates, we can not only better illuminate other boundary conditions that limit the advantage of unconscious thought, but also better anticipate the precise kinds of decision and judgment tasks for which conscious or unconscious processing is best suited.

Exploring the Differential Nature of the Appeal of Visual Advertising to Consumers

Steven Andrews, University of Oregon, USA

Guangxin Xie, University of Massachusetts Boston, USA

David Boush, University of Oregon, USA

Two relatively new streams of research on consumer response to visual advertising, visual fluency and visual rhetoric, suggest that consumers rate visual advertising that is more pleasing to process as more appealing, presumably leading to some advantage in terms of persuasive impact. Both these streams of research adhere to the ideas of Scott’s (1994a; 1994b) reader response theory. Reader response theory sought to conceptually link the psychology of the consumer with the attributes of the ad text. Thus, the intention of the author and the response of the reader were connected by shared cultural knowledge, and highly agile, culturally aware, and sophisticated critical readers derived as much (or more) meaning from contextual cues as from the form of the text itself. Thus, aesthetic judgments revolving around the processing of visual information occur primarily through the mental experiences of the person perceiving the visual information.

Visual fluency is defined as the ease or difficulty in which image information can be processed (Winkielman, Schwarz, Reber and Fazendeiro, 2003). Research on visual fluency, derived from research on affect as information (Schwarz and Clore, 2006), suggests that ads which are visually rich yet easy to process cognitively are more appealing to consumers. In contrast, research on visual rhetoric (McQuarrie and Mick, 2003b) in advertising shows that consumers both like and remember ads with rhetorical communication devices such as metaphors and puns to a greater extent. Visual ads containing rhetorical communication devices tend to be simpler visually, e.g. they may contain more white space (Pracejus, Olsen and O’Guinn, 2006) or they may contain two distinct elements juxtaposed together (Phillips and McQuarrie, 2004), yet slightly more complex cognitively. Therefore the point of divergence between these two streams of

research seems to lie along the dimensions of visual and cognitive simplicity/complexity. This paper explores this divergence more closely in order to discover some insights into the differing nature of the appeal of visual advertising to consumers.

Approximately 150 participants at a university in the Pacific Northwest examined two pairs of ads which differed from each other in terms of visual and cognitive simplicity/complexity. We attempted as much as possible to control for brand name familiarity, using four fairly popular brands (Guess Jeans, Subaru, Visine, and Columbia Sportswear) that were deemed highly familiar to college students. In each ad pair, one ad was a rich visual ad which contained no rhetorical device while the other ad was visually simple but contained a purely visual rhetorical trope (McQuarrie and Mick, 1999). The non-rhetorical Subaru ad contained vivid colors of blue sky and green country side, while the non-rhetorical Guess Jeans ad contained two highly attractive models, one female and one male. The rhetorical Visine ad contained a very simple visual pun relating to the popular slogan "Visine gets the red out", while the rhetorical Columbia Sportswear Techlite sandals ad contained a visual metaphor linking the sandals to butterflies, for example implying "lightness". After viewing each pair of ads, participants chose which one they liked the most and then expounded on which ad they thought was more memorable and why. After taking a series of filler tests not related to this study, participants were asked to recall as many brand names as possible or if not the name then something about the ad.

Overall 51% of the participants liked the visually rich non-rhetorical ads better while 55% thought the visually simpler rhetorical ad was more memorable. Approximately 6% of the participants thought the ad in the opposite likeability category was more memorable. An overwhelming percentage (81%) of the people changing their answer thought that the rhetorical ad was more memorable despite claiming to like the non-rhetorical ad more. Double blind examination of response patterns suggested that the primary reason for this shift involved either a pleasant or unpleasant reaction to spontaneously trying to interpret the meaning behind the ad. Chi-square analysis showed that unaided recall did not differ significantly across rhetorical vs. non-rhetorical ads.

Response patterns for memorability differed markedly between the two types of advertisements. Collapsing the responses for both non-rhetorical ads together, the reasons for memorability were fairly uniform. About 70% of the subjects listed "rich, appealing visual ad features" as the reason they believed the ad to be more memorable. For the Subaru ad most responses focused on the vivid colors. For the Guess Jeans ad most responses focused on the sexy models. In contrast, collapsing responses across both the rhetorical ads revealed several prominent response categories. The most popular reason participants gave (61%) for rating the rhetorical ads as more memorable was the presence of and/or the interpretation of the meaning behind the rhetorical device. The other popular response patterns included the uniqueness (22%) and simplicity (15%) of the ad.

The patterns of the responses in these findings point to promising avenues for research into individual differences with respect to factors affecting the appeal of processing of visual ads. Specifically, research that suggests inherent tendencies to process information affectively vs. cognitively such as need for cognition (Cacioppo, Petty and Kao, 1984), affect as information (Gohm and Clore, 2002; Schwarz and Clore, 2006) and general information processing individual differences (Giese and Sojka, 1998; Sojka and Giese, 1997) may provide useful insight into psychological mechanisms that influence differential consumer response to visual advertising along the dimensions of visual and cognitive simplicity/complexity.

Effects of Evaluability on Goal Fulfillment and Satisfaction

Zachary Arens, University of Maryland, USA
Rebecca Hamilton, University of Maryland, USA

Goal theory suggests that goal fulfillment involves evaluating an outcome against the goal's criteria. However, goals differ in their evaluability (Hsee 1996; Hsee et al. 1999). We propose that goals are easy to evaluate when they are specific, defined in terms of product features, or when there is a standard of comparison, but difficult to evaluate when they are vague, defined in terms of benefits or lack standards. These differences in evaluability impact goal fulfillment, product satisfaction and motivation to pursue the goal. Thus, easy-to-evaluate (difficult-to-evaluate) goals create polarized (moderate) levels of satisfaction and motivation, depending on product performance.

Of particular interest to marketing managers, goal evaluability differs for purchase goals depending on whether the goal is defined in terms of product features or benefits (Huffman, Ratneshwar, and Mick 2000). Consider, for example, two consumers who enter a store to buy a set of cookware. The first consumer's goal is to buy a set of cookware that is easy-to-clean; while the second consumer's goal is to buy a set of cookware made of infused anodized aluminum, which creates a nonstick, easy-to-clean surface. Though both may end up buying the same set of cookware, the purchase was motivated by goals that were defined at different levels. The desire for easy-to-clean cookware is a benefit goal, whereas the desire for infused anodized cookware is a feature goal. Although these goals are related, the difference in conceptualization should lead to different motivation to purchase supplementary products. Feature goals are easily evaluated because the evaluation simply requires determining the presence or absence of the desired feature, leading to a high or low degree of goal fulfillment. In contrast, benefit goals lack a natural scale to provide a standard of comparison, making product evaluation difficult. Because benefit goals cannot be definitively achieved, they will lead to a moderate degree of goal fulfillment.

Therefore, if the purchased cookware is infused anodized and easy-to-clean, we expect that the consumer with the feature goal should evaluate the product more positively and be less willing to purchase supplementary products (e.g., brushes that make it easy to clean cookware) than the consumer with the benefit goal. However, when the purchased cookware is not infused anodized and is difficult-to-clean, the consumer with the feature goal should evaluate the product more negatively and be more willing to purchase supplementary products than the consumer with the benefit goal.

To test this, we conducted two studies. In our first study, participants were given a scenario of purchasing a safe car. The goal for a safe car was defined in terms of features (i.e., airbags and anti-lock brakes) or benefits (i.e., feeling safe). The purchased car was described as either having safety characteristics or not. Results suggested that viewing the goal in terms of features or benefits exhibited the predicted moderating effect on participant's evaluations of the product. In other words, participants with a feature goal gave more polarized evaluations of the product than those with a benefit goal.

The second study plans to show that goal evaluability can be impacted by evaluability information and goal specificity. Participants will be given a goal of improving their score on a mental ability test. In order to help them achieve their goal, they will consume a ginseng-based beverage after the first test which they are told can improve mental performance on the next test. Goal specificity will be manipulated by providing participants with a specific goal (i.e., "improve your score by 5 points") or vague goal (i.e., "improve your score substantially") on the mental ability task. Evaluability information will be manipulated by either providing or omitting the average increase in mental ability score (i.e., "the average person's score improves 4 points after consuming ginseng"). Scores will be manipulated such that the ginseng beverage appears to perform well (i.e., score increases 6 by points) or poorly (i.e., score decreases by 6 points). The results are expected to demonstrate that specific goals and evaluability information make the goal easier to evaluate. When the ginseng product performs well (poorly), easy-to-evaluate goals should create high (low) product satisfaction and low (high) motivation to purchase products that enhance mental performance such as omega-3 vitamins, brain teaser exercises and newsmagazines. However when the goal is difficult-to-evaluate, satisfaction and motivation should be moderate regardless of the product's performance.

This research demonstrates that goal evaluability moderates the effect of product characteristics on goal fulfillment, satisfaction and motivation. These results have important implications for managers. Managers of high-performing products that are expected to satisfy consumer's goals can increase customer satisfaction by increasing goal evaluability. For instance, their advertisements should emphasize specific product features or create standards to allow customers to evaluate product benefits. In contrast, managers of poorly-performing products should decrease evaluability by emphasizing product benefits and avoiding comparison standards.

Differences in Self-Regulatory Strength as a Function of Self-Construal

Ashley Rae Arsena, University of Texas at San Antonio, USA

Jaehoon Lee, University of Texas at San Antonio, USA

L. J. Shrum, University of Texas at San Antonio, USA

Yinlong Zhang, University of Texas at San Antonio, USA

Joy L. Row, University of Texas at San Antonio, USA

Research examining self-regulation has shown that people possess a limited amount of self-regulatory resources and that an initial act of self-control depletes these resources. Depletion of self-regulatory resources results in poor performance on subsequent tasks of self-regulation. For example, Baumeister et al. (1998) found that when individuals forced themselves to eat radishes instead of more appealing chocolates, they quit sooner on unsolvable puzzles than did individuals who did not engage in this initial act of self-control.

Yet, not all individuals have the same self-regulation abilities. Anecdotal and empirical evidence suggests that differences in self-control exist. For example, research has shown that regular exercises in self-control can increase self-regulation capacity. Muraven, Baumeister, and Tice (1999) found that repeated practice of self-control (i.e., spending weeks monitoring posture) improved self-regulatory ability measured by a handgrip task, much like repeated exercise of a muscle increases its strength (Muraven and Baumeister 2000). Similarly, Gailliot et al. (2007) found that after writing about an obese or homosexual person without using any stereotypes, participants with low motivation to avoid prejudice performed worse on a subsequent self-regulation task than did those with high motivation. Individuals with high motivation to avoid prejudice performed better on subsequent acts of self-regulation presumably because they had engaged in regular exercises of self-control by continually suppressing prejudice thoughts, whereas those who performed poorly on the self-regulation task (low motivation to avoid prejudice) presumably did so because they had little practice at self-control (they rarely engaged in suppression of prejudice thoughts). Thus, not only does motivation increase the likelihood of exercising self-control across situations, but repeated exercise of self-control as a function of this motivation also increases the ability to exercise this self-control.

Another individual difference measure that may be related to both the motivation and ability to exercise self-control is self-construal. Self-construal refers to how people perceive themselves to be linked to others (Markus and Kitayama 1991). People with a predominantly independent self-construal see themselves as independent and autonomous, distinct from the group, and tend to rely more on attitudes than subjective norms when making behavioral decisions (Ybarra and Trafimow 1998). In contrast, interdependents perceive themselves in the context of a larger group, are concerned more with group harmony than individual happiness, rely more on subjective norms than attitudes when making behavioral decisions, and place a high value on conformity and connectedness.

Research shows that interdependents tend to display less impulsive behavior than independents (Kacen and Lee 2002; Zhang and Shrum 2009). However, this does not appear to be the result of naturally occurring desire; independents and interdependents showed no difference on measures of trait buying impulsivity. Rather, the differences appear to be due to greater motivation on the part of interdependent to suppress those buying impulses (Zhang and Shrum 2009). If this is so, then just as with the case of motivation to suppress prejudice, continued exercise of the self-control “muscle” may increase its strength, thereby increasing the ability of interdependents to successfully exercise self-control compared to independents.

To test this hypothesis, the current research investigated whether self-construal influences self-regulation capacity. Specifically, we tested whether interdependents would show more self-control after a self-control depletion task than would independents. Chronic self-construal was measured because repeated practice at self-control is needed to increase self-regulation ability. Self-regulatory resources were depleted using a task adopted from DeWall et al. (2008) in which participants are required to learn a habit, and then are forced to break the habit. Breaking a habit is an act of self-control because it requires one to alter an initial impulse and act in line with a new standard. Participants were given a journal article and instructed to cross out every instance of the letter *e*. In depletion conditions, participants were then required to adhere to new rules (i.e. do not cross out *e*'s if the *e* is followed by a vowel). Participants in no-depletion conditions were asked to continue crossing out the letter *e*, and no other instructions were given. Participants were then asked to indicate the number of chocolates they would want to receive as a reward. The number of chocolates served as the main dependent variable for self-control. As ostensibly part of a second study, participants then completed a 31-item Self-Construal Scale (Aaker 2000; Singelis 1994).

We first classified participants on their level of independence and interdependence separately. We then constructed two groups, one high on interdependence and low on independence (and thus maximally likely to exercise self-control across situations), and the other high on independence and low on interdependence (minimally likely to exercise self-control). The results showed that, consistent with our hypotheses, interdependents took fewer chocolates in the depletion condition than did independents. These results suggest that interdependents perform better on subsequent acts of self-regulation than do independents. This finding supports our reasoning that the self-regulation ability of interdependents is superior to that of independents because interdependents have engaged in regular exercises of self-control (continually suppressing impulsive thoughts or behaviors). In contrast, because independents generally act on their interests and impulses, they have relatively less practice at self-control and thus perform worse on self-regulation tasks. However, contrary to our expectations, there were no differences between self-construal groups in no-depletion conditions. If continual practice at self-control does increase self-regulation ability, then independents should have also taken more chocolates than interdependents in no-depletion conditions. Yet, no differences were found. This may have been because the self-control task (resisting chocolates) was not strong enough to detect initial differences. Nevertheless, the results suggest that differences in self-regulation capacity do exist as a function of self-construal.

Imagine Instructions: When Do They Help or Hurt Persuasion?

Ashley Rae Arsenia, University of Texas at San Antonio, USA
R. Justin Goss, University of Texas at San Antonio, USA
David H. Silvera, University of Texas at San Antonio, USA
Frank R. Kardes, University of Cincinnati, USA
Bruce Pfeiffer, University of New Hampshire, USA

According to current models of persuasion such as the elaboration likelihood model (Petty and Cacioppo 1983) and the heuristic systematic model (Chaiken 1987), high amounts of thought or elaboration have been found to increase advertising effectiveness and attitude strength. For example, Petty and Cacioppo (1983) found that participants who elaborated on an advertisement message under the central route to persuasion showed a greater increase in attitude strength and persistence of attitudes over time relative to participants who did not engage in extensive elaboration.

Elaboration has been induced in a variety of ways. Pictures, concrete information, and personal relevance have all been found to increase elaboration and, subsequently, increase persuasive impact and attitude strength for the target advertisement message (Haugtvedt and Strathman 1990). Yet, another way to effectively increase elaboration is to instruct consumers to imagine additional information supporting the persuasive message. This imagine technique has been used in many advertisements; for example, consumer protection groups like TheTruth.com have used this technique in a number of anti-tobacco advertisements in which people are presented with an exemplar (e.g., memos indicating that tobacco companies knew smoking increased cancer risk) and then asked to imagine additional related information (e.g., systematic attempts to conceal the association between tobacco and cancer risk).

Research examining the imagine technique has found that instructions to imagine increase elaboration, thus enhancing advertising effectiveness (Kisielius and Sternthal 1984, 1986). However, conditions under which imagine instructions are more or less persuasive have not been identified. The current research aimed to identify conditions under which the imagine technique facilitates greater adherence to the advertisement message.

Several motivational and capacity variables were examined as potential moderators of the tendency to seek out and access unrepresented information in a judgmental context. In particular, need for cognitive closure (NFCC) was investigated as a potential moderator of the effectiveness of imagine instructions. Given that individuals with high NFCC have been shown to desire immediate answers over ambiguity (Webster and Kruglanski 1994), high NFCC individuals might fail to elaborate on presented information unless they are specifically instructed to do so. However, because low NFCC individuals are more willing to elaborate, they might imagine additional information and adjust their attitudes to correspond with that information regardless of whether they receive imagine instructions. Thus, imagine instructions should be less influential for low NFCC than for high NFCC individuals.

Construal level was investigated as another potential moderator of the tendency to seek out and access unrepresented information in a judgmental context. Construal level theory proposes that high versus low construal level influences peoples' responses by changing the way they mentally represent events (Liberian and Trope 1998). High level construal is associated with abstract and general representation, whereas low level construal is associated with more concrete and detail-oriented representations. Because imagining requires abstraction beyond the provided message, high level construal should facilitate imagination and increase adherence to the target message.

Three studies were conducted to test potential moderators of the imagine technique. All three studies presented participants with a fictitious advertisement and asked them to evaluate the product in the advertisement. In the imagine condition, participants were asked to imagine further information that supported the advertisement's message (e.g., "Imagine what else Special K can do to improve your health"). In the no imagine condition, no further instructions were given.

In the first study, participants viewed an advertisement with a negative message about McDonald's (i.e., McDonald's exploits children). After viewing the advertisement, participants answered questions that assessed attitudes and purchase intentions toward

McDonald's along with the NFCC scale. Participants in the imagine condition expressed more negative attitudes toward McDonald's, which indicates that the imagine technique is an effective persuasion tool because it caused greater adherence to the advertisement message. In addition, high NFCC participants formed more positive attitudes (thus going against the advertisement's negative message) in the no imagine condition relative to the imagine condition. However, low NFCC participants in the no imagine and imagine condition expressed similar negative attitudes toward McDonald's. Thus it appears that the imagine technique is particularly effective for high NFCC individuals but not for low NFCC individuals.

Study 2 investigated whether construal level influenced whether imagine instructions affect attitudes about a positive message about Subway (i.e., Subway can improve your health). Construal level was manipulated via a prime adapted from McCrea et al. (2008) where participants were asked to view a painting by Seurat that drew their attention either to the overall effect of the painting (abstract condition) or to the technique of pointillism (concrete condition). Participants then viewed a positive message and completed an attitude assessment. Participants in the abstract/imagine condition formed more favorable attitudes than participants in the concrete/imagine condition, which indicates that abstract processing facilitates imaginative thinking and increases persuasion.

In the third study, participants viewed an advertisement with a positive message about Special K (i.e., Special K is healthy), with promotion focus measured as a potential moderator of the effectiveness of imagine instructions. Because high promotion focused individuals tend to have strong positive dispositions (Higgins et al. 1994), they might spontaneously imagine additional information to support a positive message; conversely, low promotion focused individuals might generate supporting positive information only when specifically instructed to do so. The results support this proposition; participants in the low promotion focus and no imagine condition rated Special K more negatively than all other groups (thus not supporting the advertisement's message). Thus, presumably because low promotion individuals are predisposed to be less positive, the imagine technique is useful in encouraging attitudes that support a positive message. Consequently, the imagine technique appears to significantly increase adherence to a positive message for low promotion focus individuals but not for high promotion focus individuals.

The present studies expand on previous research examining the effectiveness of the imagine technique by identifying conditions under which imagine instructions are more or less effective. Future studies will continue to examine characteristics of the message, the recipient, and the advertising context that moderate the effectiveness of the imagine technique.

Unwanted Objects and Situations: Experiencing Disgust in Consumption Contexts

A. Selin Atalay, HEC Paris, France
Melea Press, University of Wyoming, USA

The goal of this paper is to understand how consumers respond to feelings of disgust. Disgust is experienced in response to unwanted stimuli (Olatunji and Sawchuck 2005). There are two categories of disgust: core and socio-moral disgust. Core disgust refers to physical repulsion (Haidt, Rozin, McCauley and Imada 1997). It is protective of one's body. Socio-moral disgust is elicited by contact with objects that are evil (i.e., a shirt worn by an evil person). It is protective of social order.

In this paper a new elicitor of disgust, *inconvenience*, is discovered. Individuals' responses to disgust in consumption settings are explored.

Study 1

Study 1 was conducted with 107 undergraduates to explore disgust elicitors. Participants were asked to reflect on the last time they felt disgusted, and rate their disgusting experiences.

Results. From 107 participants we collected 101 disgusting experiences. Core and socio-moral elicitors of disgust were prevalent (21% and 41% respectively). Further, the elicitors of disgust have broadened to include a new elicitor; *inconvenience*. *Inconvenience* refers

to products, situations or experiences that did not work out as planned, hoped, desired, or imagined and caused discomfort to the person. Thirty-one percent of our respondents stated that they experienced disgust elicited by inconvenience.

Participants rated their experiences on a 0-10 scale where 0 indicated not at all disgusting and 10 indicated extremely disgusting. The elicitors were equally disgusting ($F(2,92)=1.179, p>.3, M=7.57$ (core), $M=8.40$ (socio-moral), $M=7.97$ (inconvenience)).

Study 2

Study 2 was conducted with 88 undergraduates, to verify the *inconvenience* disgust elicitor. Three scenarios that evoke core, socio-moral, or inconvenience disgust were constructed based on the disgusting incidents reported in study 1. Participants were asked to complete a survey indicating how they expected to feel in response to each scenario. They rated 34 positive and negative emotions on a 0-10 scale.

Results. Participants reported that all three scenarios made them feel equally disgusted $F(2, 260)=.683, p>.5; M=7.03$ (core), $M=7.07$ (socio-moral); $M=6.56$ (inconvenience)).

Feelings of being upset, angry, frustrated, annoyed and irritable are associated with disgust (Holbrook and Batra 1987, Nabi 2002). We factor analyzed the emotions that the participants rated and created a composite score. The composite score is a weighted average based on the factor analysis. The elicitors made participants feel different levels of the emotions associated with disgust. $F(2,262)=3.657, p<.05; M=5.44$ (core), $M=5.86$ (socio-moral), $M=6.22$ (inconvenience). The core disgust elicitor did not elicit as much of the disgust related emotions as the socio-moral and inconvenience elicitors did.

Discussion. Study 2 verified that inconvenience elicits disgust as well as the emotions associated with disgust.

Study 3

Study 3 was conducted with 41 undergraduates to explore the action tendencies associated with the inconvenience disgust elicitor.

Two scenarios demonstrating the inconvenience disgust elicitor were created. Participants were asked to indicate how they would feel and what they would do in response to each scenario. Participants also rated how disgusting each scenario is on a 0-10 scale where 0 indicated not at all disgusting and 10 indicated extremely disgusting.

Results. The first scenario involved a frustrating telephone conversation with tech-support. In response participants indicated that they would feel disgusted ($M=6.20, t(40)=2.59, p<0.05$ two-tailed, test value=5). The second scenario involved encounter with an unhelpful sales associate. In response participants indicated that they would feel disgusted ($M=7.00, t(40)=4.88, p<0.0001$ two-tailed, test value=5).

Action Tendencies. In response to Scenario 1, 95.1% participants indicated that they would talk about this experience. Sixty-one percent indicated they would leave the disgusting situation. Only 2.4% indicated that they would complain while 19.5% said in the future they would prefer a different company. In response to Scenario 2, 87.8% participants indicated that they would talk about this experience. Sixty-three percent indicated they would leave the disgusting situation. Only 14.6% indicated that they would complain while 39% said in the future they would prefer a different company.

Discussion. Participants indicated, in response to the inconvenience disgust elicitor, they will talk about their experience, but not complain. Talking about disgusting experiences has the potential to create negative word of mouth. Also when customers do not complain the company does not get a chance to rectify the situation.

Study 4

Study 4 explores how a different population responds when they experience disgust. Participants were 28 staff members at a northeastern university. Participants were asked to elaborate on two disgusting consumption experiences that they had. They were asked to explain each experience, and indicate how they responded.

Results. From the 28 participants we collected 45 scenarios. The 45 scenarios were composed of 36% core, 9% socio-moral and 53% inconvenience disgust situations. The socio-moral disgust elicitor was not prevalent in consumption contexts, as such these scenarios were not further analyzed.

Participants rated how disgusting each scenario is on a 0-10 scale. Disgust elicitors are equally disgusting. $F(1, 37)=0.56, p>.4; M=6.44$ (core), $M=6.96$ (inconvenience).

In response to the disgusting situations participants reported that they got rid of the product or terminated service (core: 50%; inconvenience: 12.5%); and complained (core: 25%; inconvenience: 54%). Participants also indicated that in the future they are equally likely to complain and talk about their disgusting experiences, measured on a 0-10 likelihood scale where 0 indicated not at all likely and 10 indicated extremely likely ($p>.4, p>.9$) (Complain: $M=6.6$ (core), $M=7.5$ (inconvenience); talk about it: $M=7.9$ (core), $M=7.9$ (inconvenience))

Discussion. We replicate the findings with a different population. In consumption contexts core and inconvenience disgust elicitors were mainly reported. This study further demonstrates the prevalence of inconvenience disgust elicitors in consumption contexts.

General Discussion

The definition of disgust is not static (Nabi 2002). It evolves as the society evolves. In the four studies presented here we provide evidence that *inconvenience* a new category of disgust emerges in the consumption context. We showed that individuals feel disgusted by core, socio-moral and inconvenience disgust elicitors, and the action tendencies evoked by the feeling of disgust namely creating word of mouth and not complaining are potentially damaging to businesses.

The Liberating Effect of Guilt-Sharing on Consumers' Preference for Indulgence

Ozge Yucel Aybat, Baruch College, CUNY, USA

Thomas Kramer, Baruch College, CUNY, USA

In choices between indulgent and non-indulgent options, the latter are often preferred because indulgence tends to be associated with guilt. However, we propose that the amount of guilt experienced, and hence preference for indulgence, depends on whether consumers are in a lone versus shared consumption situation. Specifically, relative to choice of fruit salad, we found that respondents were more likely to choose two pieces of chocolate cake to be shared with another consumer than one piece of chocolate cake to be consumed alone. Further analyses support the hypothesis that reductions in feelings of guilt appear to be driving this effect.

Understanding the Situational Appeal of Local Brands in Emerging Economies: The Case of Turkey

Nilufer Z. Aydinoglu, Koc University, Turkey

Rajeev Batra, University of Michigan, USA

Aysegul Ozsomer, Koc University, Turkey

Many multinational companies today are altering their brand portfolios in favor of global brands, out of a belief not only that this will yield various economies of scale but also that consumers around the world prefer such global brands to otherwise equivalent local brands. Previous research has in fact shown that consumers do often prefer such global brands, because of inferred higher quality, perceived prestige, and because owning and consuming such brands offers the consumer a chance to vicariously become a part of global consumer culture (e.g. Batra et al. 2000).

Despite these findings, there is also evidence from other research that in many countries consumers are not rushing headlong into purchases and lifestyles that symbolize global consumer culture, but instead are seeking to blend aspects of local consumer culture with that of incoming global consumer culture. There is by now a significant literature on the phenomenon of consumers "hybridizing" or "creolizing" their lifestyles and consumption patterns, including brand choices (e.g., Sandikci and Ger 2002). This suggests that consumers are pulled in two directions, not only by global cultural flows but also by their local cultures.

While the power and influence of these global cultural forces is understood quite well, that of local cultures is not understood as well. There is indeed work that suggests that local consumers might prefer local to foreign/global brands because of a "home country bias" (Papadopoulos, Heslop and Bemossy 1990) or because of an "ethnocentric" desire to boost local economies (Shimp and Sharma 1987). However, what is less well understood is the ways in which consumers balance and integrate these two forces, such as the situational contingencies that make them weight one over the other, and the reasons why these situational contingencies might occur. Hence, our first objective in this paper is to address this issue by simultaneously exploring the reasons behind local and global brand preference.

The definition of the global brand itself is a controversial issue. Different scholars have provided different definitions and operationalizations as to the degree of globalness a brand holds. However there is no consensus on the degree of standardization required (if any at all) for a brand to qualify as global and also about the extent of availability across different nations. This causes ambiguity in interpreting and comparing the findings of different studies, whose definitions of globalness may be different to start with. In line with this debate, our second objective in this paper is to clarify the distinction between local and global brands. We believe that the degree of brand globalness lies in the perceptions of consumers.

In addressing these objectives, we use two waves of data collection. The first wave consists of focus groups and in-depth interviews to provide insight into consumer perceptions and preferences. We utilize this insight from the qualitative wave to identify the dimensions of (1) consumer perceptions of degree of localness/globalness, (2) perceived benefits of local/global brands and corresponding preferences, and (3) the situational variables affecting consumer preference between local and global brands. This first wave is conducted in two different cities of Turkey, an emerging economy. The second wave, then, tests our proposed model (based on the dimensions we identify) using survey data from Turkey with multivariate analysis.

Based on the insight from our first wave of qualitative data (four focus groups and fifteen in-depth interviews), we identify three dimensions which affect the degree of localness/globalness for a brand as perceived by consumers. The first dimension relates to 'product

and company positioning' and measures consumer familiarity with the brand across different countries, and how the product is designed to address the needs and wants of a local versus a global audience. The second dimension relates to 'business behavior' and measures the perceived availability of the brand across countries and the company's ties and relationships with other local and global businesses and institutions, again as perceived by consumers. Finally, the third dimension relates to the brand's 'culture positioning' and investigates how the brand uses associations from the local or the global consumer culture in its promotional activity.

In our proposed model, each brand is measured on the aforementioned three dimensions to arrive at degrees of perceived localness and perceived globalness separately. Next, we investigate how these perceptions translate into consumer benefits under four dimensions of quality, prestige, tradition/values, and price. Finally, perceived benefits feed into determining an overall degree of preference for localness and globalness. We should stress that in all facets of our model, consumers rate both the local and the global dimensions of a brand and report their corresponding preferences. Our simultaneous focus on consumers' global and local brand preferences makes it possible to investigate the situational factors acting on such preferences. We find that the social signaling value of choice and perceived risk of choice are important moderators relating to product category. Furthermore, susceptibility to external influence, cosmopolitanism, and nostalgia proneness come up as individual difference moderators.

Accordingly, we are able to integrate findings from two streams of research discussed earlier, advocating a dominant consumer preference for global brands versus a dominant consumer preference for local brands, by shedding light into some of the situational contingencies determining such preference. While studying consumer preference, our work also contributes to the literature by systematically measuring the degree of globalness and degree of localness as perceived by consumers. Such attempts to identify global versus local brands through direct measurements of consumer perceptions might clarify some of the confusion about the definition of the global brand itself. Further, the dimensions we use to measure perceptions might guide companies trying to move their brand towards a more global (or local) positioning through signaling globalness (or localness).

Prototype or Exemplar? Effects of Self Construal on Brand Extension Evaluation in a Multi-Product Brand Context

Pronobesh Banerjee, University of Kansas, USA

Ze Wang, University of Kansas, USA

Sanjay Mishra, University of Kansas, USA

Surendra N. Singh, University of Kansas, USA

Increasing attention has been paid to the stretchability of a brand (Ahluwalia 2008). The traditional view is that consumers will evaluate a brand extension in a favorable manner if the brand extension fits with the parent brand and the parent brand has a positive evaluation. Recent research (Mao and Krishnan 2006) extends this view by specifying two-dimensional fit construct that are often used by consumers to assess an extension—prototype fit (congruency with the beliefs associated with the brand) and exemplar fit (similarity with the existing product of a brand). For example, Nike kneepad, has a prototype fit, which shares the generalized imagery of Nike—"athletic"; Nike car audio, has an exemplar fit, which is analogous to an existing product—"car audio." This research attempts to investigate how consumers with different self-construal (interdependence vs. independence) may vary in their evaluation of different types of brand extensions. Also, this research also examines how consumers' self-construal moderates the dilution effect of extension failure and the enhancement effect on its success.

This research first argues that the evaluation of prototype-based and exemplar-based extensions may be influenced by consumers' self-construal. Recent research in self-construal (e.g., Lee, Aaker and Gardner 2000; Monga and John 2007) provides robust evidence that the nature of self-construal affects the mode of cognition one adopts in their decision making process. Consumers with independent self-construal see themselves as distinct from others and are more likely to involve in a de-contextualized mode of processing. Thus, they focus on the overall brand beliefs derived from the abstraction of behaviors rather than the concrete examples of the brand. In contrast, consumers with interdependent self-construal see themselves as related to others and are more likely to involve in a contextualized mode of processing when evaluating an object. They are then more concerned about the concrete associations or exemplars of the brand. Therefore, the abstract concept of a brand (stylish for Sony) will be more assessable to consumers with independent self-construal compared to a concrete exemplar of a brand (Sony TV). The reverse will hold true for the interdependent.

Based on this idea, this research also proposes how the brand extension success (failure) may enhance (dilute) consumers' evaluation of the parent brand and the flagship product of the same brand. We argue that for individuals with independent self-construal ("independents"), brand extension outcome may impact their attitude at the brand level, but not attitude at the flagship product level. More specifically, the success (failure) of prototype-based extension will enhance (dilute) independents' attitude toward the brand, but not their

attitude toward the flagship product. For individuals with interdependent self-construal (“interdependents”), brand extension outcome will impact their attitude at the product level, but not at the brand level. More specifically, the success (failure) of exemplar-based extension will enhance (dilute) interdependents’ attitude toward the flagship product, but not their attitude toward the parent brand.

Study 1 tests the hypotheses that consumers’ self-construal level will moderate their evaluations of prototype-based and exemplar-based extensions. Based on the pretest results, we designed two fictitious extensions of Johnson & Johnson—hair color (exemplar fit with J&J shampoo) and fabric softener (prototype fit with “softness”). We manipulated the self-construal level using standard procedures (Aluwalia 2008). The hypotheses were supported. Independents evaluated the prototype based extensions more favorably compared to the interdependents, while the interdependents evaluated the exemplar-based extensions more favorably compared to independents.

Study 2 and 3 tested the hypotheses that consumers’ self-construal will also impact the dilution/enhance effect based on the failure/success of the extension. We manipulated self-construal using similar methods as in study 1. Two news paper articles were used to manipulate extension failure/success. The pattern of results supported the proposed hypotheses.

In summary, we show that companies should be cautious in designing an extension of a multi product brand for consumers with different self-construal. Findings of this paper show that differential accessibility of the various brand associations across self construal exerts a disproportionate influence in evaluating an extension in the multi product brand context. Therefore, companies should take into consideration the differential accessibility of the various brand associations while launching a multi-product brand extension. We also demonstrate the moderating role of consumers’ self-construal in the dilution effect of extension failure and the enhancement effect on its success. Interestingly, we find that a brand’s flagship product is not always shielded from the effect of dilution as previously found (e.g., John et al. 1998). Our research shows that consumers with interdependent self-construal will negatively evaluate the flagship product on failure of an exemplar-based extension.

The Production and Dissemination of Conscious Consumption Discourse in Brazil

Denise Barros, EBAPE/FGV-RJ, Brazil
 Alessandra Costa, EBAPE/FGV-RJ, Brazil
 Eduardo Ayrosa, EBAPE/FGV-RJ, Brazil
 João Felipe Sauerbronn, ECSA-Unigranrio, Brazil

The consumption-driven society holds consumption as central in social life (Kozinets & Handelman, 2004). Consumers live not only for the things, but also through them (Baudrillard, 1995; Belk, 1988). The relationship between consumers and organizations seems to take a central role in consumption studies. However, the study of consumer resistance movements is still a new area (Cova, Kozinets & Shankar, 2007; Hemetsberger, 2006), particularly in Brazil, one of the most important markets for big corporations such as Nestlé, Volkswagen and Coca Cola (O Globo, 2005). This paper aims to suggest a wider discussion on the movements of resistance to consumption in Brazil.

In Brazil, softer forms of resistance predominate: consumers or companies discourses do not emphasize the end of consumption, but rather, more consensual forms of relationship between consumers and markets, based on the concepts of *conscious* and *sustainable consumption*. Brazil's most important voice in this subject is "Akatu Institute for Conscious Consumption", created in 1990 by major Brazilian and global companies to promote responsible consumption. Considering the wide penetration of Akatu's ideas among Brazilian consumers and companies, it would not be an overstatement saying that the discourse of conscious consumption in Brazil has been created by the market itself. So, we ask whether such discourse actually represents a legitimate society claim, or, at the other end, it simply serves to the interest of the big corporations that fund Akatu. By raising such question, we intend to discuss, with a critical approach, the process of social construction of the concept of conscious consumption in Brazil.

An initial discourse analysis of Akatu's website shows that the conscious consumption discourse in Brazil can embed a shift of responsibility from the producer to the individual consumer. Saha & Darnton (2005) point out that 'green' consumption refers to environment, corporate social responsibility, social investment, labor and job conditions, fair trade, responsible communication, transparency and so on. Cohen (2007) posits that more emphasis has been given in the "more efficient consumption", as opposed to "less consumption". It is interesting to notice how the addition of the idea of efficiency can change the direction of the actions. This author says that even if the sustainable development has been described as a "three-party process that gives rise to a careful balance among the social equity, economical and environmental objectives, it has been proven in practice that keeping this multi-objective focus is very difficult" (p. 58).

In Brazil, the discussion seems to be restricted to the so-called sustainable and conscious consumption. Back in the 1970s, several institutions were created in Brazil with the purpose of offering some room for businessmen to discuss and implement projects related to the social, environmental and human rights practices. Such institutions have become experts in the defense and promotion of the collective interests of businessmen, also working as reference models that guided business strategic choices (Cappellin *et al.*, 2002). The most successful one, Ethos Institute for Social Responsibility has created Akatu Institute in 1990 with the mission of "mobilizing and making Brazilian citizens aware of their major role, as consumers, in the construction of sustainability of life on the planet" (Akatu, 2008).

Akatu's guiding principles seem to focus solely on individual consumption choices. It assumes that the best way to reach the ideal of a 'cleaner' world is through consumer education. Such principles, stated in Akatu's homepage, are: (1) plan your purchases; (2) evaluate the impact of your consumption; (3) consume only the necessary; (4) reuse products and packages; (5) separate your garbage; (6) use your credit consciously; (7) value company's social responsibility practices; (8) do not buy pirate or smuggled products; (9) contribute with the improvement of products and services; and (10) spread conscious consumption. Note that, as Akatu has been born in the market and is nurtured by corporations, it does not question business' objectives.

The arguments used in the construction of the concept of conscious consumption follow a clear and accurate logic. First, a situation of crisis is presented: "humanity already consumes 25% more natural resources than the capacity of renewal of the Earth (...) if consumption and production standards are kept on current level, in less than 50 years two planets Earth will be necessary to meet our needs of water, energy and food" (Akatu, 2008).

Second, the situation is deemed as unquestionable: “it is needless to say that this situation may make life in the planet difficult, including human life itself” (Akatu, 2008). Also, the solution to the problem seems precise: “the best way of changing this lies in consumption-related choices” (Akatu, 2008).

Within this context, the consumer is the social actor who can—or must—change by being aware of his consuming actions, “maximizing the positive impacts and minimizing the negative ones, therefore contributing with his consumption power for the construction of a better world” (Akatu, 2008). Ironically, the production process and its consequences are not actually challenged. There is a vicious transfer of responsibilities from production to consumption.

Saha and Darnton (2005) noticed that the main motivations for becoming a ‘green’ company are social pressures, opportunity of businesses, and improvement of corporate image. Therefore, it seems appropriate to suggest that, also in Brazil, companies can benefit from such label without effectively having contributed to the sustainability. Although we can identify a group of companies that seek options of sustainability, alternative consumption behaviors end up being absorbed in the prevailing conscious consumption discourse fostered by companies and used to legitimate social roles and positions. The acknowledgment of environmental and social impact of business activities is dissolved in concepts, such as “conscious consumption”, “partnership”, “sustainable development”, “social alliances” and “sustainability”. The creation of solutions with large impact such as the decrease in the emission of gases in the atmosphere becomes a lesser focus when compared to consumer behavior changes (Getz and Shreck, 2006). The power relations are hidden, and the individual consumer acquires the same status as the businessman/producer, of being *equally responsible* for the future of the planet and for the salvation of life.

Cultivating Hope

Mariam Beruchashvili, California State University, Northridge, USA

Risto Moisis, California State University, Long Beach, USA

James Gentry, University of Nebraska-Lincoln, USA

Hope, the elusive feeling that our lives will somehow be better tomorrow, constitutes an essential aspect of the human experience (Farran, Herth, and Popovich 1995). It represents perhaps “...the very heart and center of a human being” (Lynch 1965, 31) that is crucial to not just our day-to-day existence, but more fundamentally, also to our survival. Our research is positioned in relation to the prevailing cognitive perspective, the view in consumer research that hope is an outcome of an individual’s cognitive appraisal of a situation where the possibility of attaining a valued goal gives rise to the experience of hope (de Mello, MacInnis, and Stewart 2007). Such psychological treatises of hope do not illuminate how hope may bind collectivities around the pursuit of common goals, the capacity of hope widely theorized in other scholarship such as history, theology or political science (e.g., Braithwaite 2004a; Braithwaite 2004b; Drahos 2004). Thus, existing perspectives tell us very little about whether and how social settings cultivate hope. Our purpose is to deliver a conceptual insight about how hope is cultivated.

To examine the cultivation of hope, we chose the Weight Watchers as our research context. Our choice is purposive in that prior research leads us to expect that hope permeates the Weight Watchers group meetings, allowing us to extend existing theory on hope (Price, Arnould, and Moisis 2006). Our data collection procedures involved non-participant observation at Weight Watchers’ official group meeting sites in three different locations in a midsized Midwestern city over a ten-month period in 2006. Field notes taken during the observation of 100 meetings in the three Weight Watchers weekly group-meeting locations constitute the body of the non-participant observation data. In addition to non-participant observation, we conducted a series of long interviews (McCracken 1988) with 32 Weight

Watchers members who were at varying stages of their weight loss journeys. We followed Burawoy's (1998) suggestion to thematize participation in the social world and use theory to guide our inquiry.

Our findings center on the three processes, hope anchoring, hope reframing, and hope bolstering, grounded in social relationships and interactions that cultivate hope for weight loss through the membership in the Weight Watchers support group. Hope anchoring represents one process through which hope is cultivated. Hope anchoring focuses on connecting members' immediate hope for weight loss through the Weight Watchers—the support group represented by its members and the practices within the group—to a nexus of other mutually reinforcing hopes to uphold the hope for weight loss. Hope reframing, on the other hand, focuses on rendering an individual pursuit for weight loss through the Weight Watchers organization into a more meaningful and broader collective endeavor. Finally, hope bolstering focuses on practices that routinely take place at the Weight Watchers weekly group meetings that strengthen the individual's hope for achieving weight loss through participation in these practices.

Our contributions are the following. First, we advance sociological theorization on the role of emotions in consumption absent from consumer research. Converging on the sociology of emotions tradition (Hochschild 1975; Kemper 1978; Thoits 1989), our findings reveal, in line with Durkheim's (1912/1965) theory of collective sentiments, that hope is a collective product grounded in symbolically charged social interactions and relationships. Second, we also advance a branch of institutional theorizing on emotions in Consumer Culture Theory. Specifically, our findings show that Weight Watchers, as the world's largest support group, specifically focuses on the emotion of hope; it houses, orchestrates, and perhaps even rationalizes the experiences of its members' emotions. The Weight Watchers anchors members' hope to lose weight in the support group and fosters connections to other reinforcing hopes to improve physique, self-esteem, self-control, and health. Third, complementing the psychological theory of goal setting and goal striving (Bagozzi and Dholakia 1999), our research contributes by advancing consumer culture theoretic work on goals. In particular, our research informs understanding of how consumers address their failures to reach goals. Our findings suggest that having failed at a weekly weight loss goal, consumers leverage on fellow members' experiences. Other members' experiences in the perspective of a shared "Weight Watcher" identity offer an additional energy reservoir that boosts Weight Watchers' attempts at losing their own weight. Hearing other members' stories of successes as well as of failures seems to energize members, propelling them to continue on their weight loss journeys despite failures. Our findings contrast directly with the recent psychological research, which suggests that when consumers default on their goals, they are more likely to abandon those goals altogether (Soman and Cheema 2004). Thus, rather than provoking consumers to abandon their goals, our findings indicate that the shared identity and the social interactions within the group may act as antidotes to salient failures to reach goals.

The Placement of Code-Switched Ads within a Medium: Investigating Reciprocal Effects of Ad and Media Involvement

Melissa M. Bishop, University of New Hampshire, USA

Code-switching in advertising—the practice of alternating between two or more languages in a single message—is gaining attention among marketing practitioners and academics. However, little is known about how the use of language in general impacts message involvement. Involvement concerns the personal relevance of a stimulus, and is often cited as being composed of two dimensions—the cognitive and the affective. Cognitive involvement addresses informational processing activities whereas affective involvement stresses

emotional processing activities (Zaichkowsky 1994). Involvement is important for advertisers because when individuals are more involved in ad content, they are more motivated to process ad information (Swasy and Munch 1985). Thus, the purpose of this study is two-fold: to examine if and how the language of the medium and the main language of a code-switched ad interact to influence cognitive and affective involvement in 1) the ad itself and 2) media content that surrounds the ad. These issues are dealt with from an information processing perspective with testing among Spanish/English bilinguals.

Media Language and Ad Involvement

In terms of language, messages presented in a bilingual's lesser known language are harder to process (Luna and Peracchio 2001). Regarding code-switching, Spivey and Marian (1999) provide evidence that by switching back and forth between two main (or "matrix") languages in a conversation, processing difficulty is increased. They demonstrated through neuroscience that when the matrix language of a conversation changes, a complete deactivation of one language occurs in order to activate another, resulting in increased cognitive processing demands. However, when a second language is alternated to only briefly—as in single word switches rather than entire matrix language switches—the brain does not deactivate one language to process another. In other words, a complete deactivation/activation process does not occur, thus lightening cognitive demands.

In terms of code-switched ad research, when ad information is presented primarily in a language that differs from the medium, it is proposed to be more taxing for the individual to process. This should lower evaluations of cognitive involvement with the ad. Further, Speech Accommodation Theory (Giles, Taylor and Bourhis 1973) states that the more effort the message sender is seen as putting into accommodating the message receiver, the more favorable he will be perceived. Thus, by keeping the main language of a code-switched ad the same as the medium, the advertiser will be perceived as more accommodating, increasing affective ad involvement.

Ad Language and Media Involvement

Although there is considerable debate over how media involvement influences ad involvement (Lloyd and Clancy 1991), how ad involvement affects media involvement is much less in the spotlight. It is examined here whether increasing (decreasing) involvement with an ad, involvement in the medium can also be subsequently increased (decreased). Media content that both precedes and follows exposure to a code-switched ad is addressed to examine this issue.

In the pre-ad exposure stage, the language of the media content (i.e., magazine article) that comes before a code-switched ad sets the stage for language processing as it establishes the original matrix language of the medium. At this stage, the message receiver has only been exposed to content in a single language—which language this is should not make a difference. Therefore, differences in evaluations of cognitive involvement in the media content that precedes ad exposure should not occur in any of the experimental conditions (to be discussed) as the individual has not had to change matrix languages to process information.

However, media content that is viewed *after* exposure to these materials may subject message receivers to increased processing demands in cases where they are required to alternate between matrix languages to process information. For example, if an individual originally reads an article in English, then a code-switched ad that primarily is written in Spanish, and then reads the following article in English, the bilingual has changed matrix languages three times (from English to Spanish to English) in one setting to process the information. In cases such as this, lower cognitive involvement (as processing difficulty is greater) as well as lower affective involvement (as the principle behind Speech Accommodation theory has not been met) should result in media content that follows ad exposure.

Study 1

122 bilingual Hispanics viewed either a code-switched ad composed primarily of English with brief, one-word switches to Spanish or the reverse. The ad was placed between two articles written in either all-English or all-Spanish. Cognitive and affective involvement were measured for both the articles and the ad based on Zaichkowsky (1994). Results showed that cognitive and affective involvement in the ad and in the article that followed the ad were lower when the main language of the ad differed from that of the medium (all p -values $< .05$). No differences were found in involvement in the article that preceded the ad, as predicted. In sum, this study shows that by keeping the main language of a code-switched ad the same as that of its medium, cognitive and affective ad involvement can be increased. Furthermore, involvement in the media following ad exposure can also be increased, pointing towards important implications for media planners.

Study 2

The purpose of this study was to examine lengthier code-switching in advertising to investigate its effects on both ad and surrounding media content involvement. It is proposed that code-switching entire phrases rather than single words (as in Study 1) entails more cognitive effort on the part of the message receiver, thus nullifying the effects based on ease of cognitive processing and speech accommodation. Results from this study nullified most of the effects of Study 1, such that there were no differences in affective ad involvement and affective and cognitive media involvement across conditions. However, cognitive ad involvement was still significantly higher ($p < .05$) when the main language of the ad matched that of the medium despite the lengthier style of code-switching.

Study 3

To extend the results of Study 1, a third study is in progress investigating the effects on involvement when the main language of a *monolingual* ad does not match that of the medium.

Thinking Makes Me Hungry: Differences in Restrained and Unrestrained Eating Behaviors in a Rich Food Environment

Melissa Bublitz, University of Wisconsin-Milwaukee, USA

Lauren G. Block, Baruch College, CUNY, USA

Laura Peracchio, University of Wisconsin-Milwaukee, USA

Researchers are concerned with the over-consumption of food and its negative effects on society. This paper synthesizes research from the field of psychology in the area of dietary restraint with research on how marketplace and product cues influence overeating, particularly of unhealthy as compared to healthy foods. Using these two research streams as a platform, we examine the differences between how some consumers, those classified as restrained eaters, respond to consumption cues. Specifically, we propose that the cognitive demands of perpetual restraint may make diet conscious consumers more susceptible to some triggers to overeat and less susceptible to others. Understanding these differences has important public policy implications because food packaging and labeling may not have the intended effect for restrained eaters, resulting in more, rather than less, consumption for this group. In addition, understanding how the behaviors of restrained eaters differ may help nutrition advocates better educate these consumers.

The characteristics and behaviors of restrained and unrestrained eaters have been widely explored in the field of psychology over the past 40 years (Herman and Mack 1975; Herman and Polivy 1980; Heatherton, Striipe, and Wittenberg 1998). Restraint is the perpetual "cognitively mediated effort that an individual makes to combat the urge to eat and restrict food intake to control body weight" (Herman and Mack 1975). Restrained eaters constantly monitor and regulate the food they eat through "self-imposed dietary rules and restrictions" (Ward and Mann 2000, 755). However, this constant focus on food does not result in dietary perfection. In fact, the continuous attention and effort required to restrain ones' eating behavior despite the plethora of temptations faced daily, often results in dietary lapses and overeating by this group (Herman and Mack 1975). By contrast, unrestrained eaters spend less time and cognitive effort focusing on food; they eat when they feel hungry or want the food and generally stop eating when they are full. This important distinction may make restrained eaters more likely to rely on product cues such as package size, specific product claims such as "low-fat" or "high fiber" or their own health beliefs such as the perceived healthfulness of one restaurant as compared to another to determine how much they should eat rather than their own body's signal of satiety.

Research on the role of marketplace and product cues in consumption has increased our understanding of how package size (Scott et al. 2008), serving size (Rolls, Morris, and Roe 2002), serving dishes and utensils (Wansink and Cheney 2005) and product assortment and variety (Kahn and Wansink 2004) influence how much consumers eat. We have also learned more about the underlying factors that prompt eating behaviors. For example, Scott et al. (2008) explore the emotional response of restrained eaters to food. By prompting restrained eaters to consciously think about the food they would consume as nonfood objects, these researchers were able to reverse the consumption differences between restrained and unrestrained eaters (Scott et al. 2008).

Beyond their emotional response to food, restrained eaters are susceptible to dietary lapses whenever outside factors interfere with their ability to devote the cognitive attention required to restrict what they eat. Consumption differences have been attributed to the depleted cognitive (Ward & Mann 2000) or self-control (Baumeister 2002) resources restrained eaters possess due to their continuous efforts to regulate their behavior. One challenge restrained eaters face is the steady stream of daily activities that require their cognitive attention and self-control resources. Recent research shows how the act of continuous decision making during a shopping trip actually reduces both the accuracy and persistence consumers display in subsequent cognitive tasks (Vohs et al. 2008). Similarly, constant pursuit of specific eating goals by restrained eaters may deplete their self-control resources, leading to choices that conflict with their restraint goals.

A wide variety of cues in the marketplace may prompt similar differences in the amount of food restrained and unrestrained eaters consume. This research explores how the variety and assortment of foods may stimulate different consumption patterns. Research by Kahn and Wansink (2004) shows that increasing the variety and assortment increases consumption by enhancing the anticipated pleasure consumers expect to derive from eating more. Similar to the response of restrained versus unrestrained eaters to smaller package sizes (Scott et al. 2008), we expect restrained and unrestrained eaters to respond differently to an increased variety and assortment of food choices. We hypothesize that like the larger package sizes, restrained eaters will anticipate the danger increased variety and assortment present and exercise more vigilance in restraining their consumption. By contrast, we expect unrestrained eaters to follow the pattern Kahn and Wansink (2004) observed, eating more as variety and assortment increase. We also investigate how restrained eaters respond to variety and assortment changes when they are placed in a cognitively taxing situation. Lastly, this research explores how the addition of healthy choices to the variety and assortment of food affects the consumption decisions of restrained eaters. Wilcox and his colleagues (2009) find that the mere presence of healthy choices among less healthy alternatives may actually increase indulgence. We hypothesize that while large assortments of unhealthy foods, such as sweets and snacks, prompt restrained eaters to concentrate on fighting the temptation placed before them, large assortments of foods they view as healthy choices, such as fruits and vegetables, will license restrained eaters to let their guard down resulting in increased consumption of both types of foods.

In this presentation we discuss early findings that explore how restraint behaviors, cognitive processing and a rich food environment interact to affect consumption. This research adds to our understanding of how product and marketplace cues influence consumption for restrained and unrestrained eaters. In addition, we hope our research provides information to empower consumers to use their cognitive and behavioral resources to facilitate healthy food choices. As public policy officials work to combat the obesity epidemic, understanding the influences on food consumption will inform decision-makers as they implement remedies designed to reduce over-consumption and promote healthy lifestyles.

Motivated Bias in Affective Forecasting

Eva Buechel, University of Miami, USA

Carey Morewedge, Carnegie Mellon University, USA

Joachim Vosgerau, Carnegie Mellon University, USA

Affective forecasters exhibit an impact bias, overestimating the intensity and duration of their emotional reaction to future events. We suggest that forecasters make extreme forecasts to motivate themselves to produce desirable outcomes. In two studies, affective forecasts were more extreme when outcomes were more important, and when forecasters could influence an outcome than when it was determined but unknown. Subsequent studies found that the extremity of forecasts determined the amount of mental and physical effort forecasters expended to produce desirable outcomes. Errors in affective forecasting may thus not be solely cognitive in origin, but have a motivated component as well.

To Do with Others or to Have (or To Do Alone)? The Value of Experiences over Material Possessions Depends on the Involvement of Others

Peter Caprariello, University of Rochester, USA

Harry Reis, University of Rochester, USA

How does money promote happiness? Recent studies have addressed this question. People may intentionally buy hedonic goods to increase their happiness (Dhar & Wertenbroch, 2000). Spending money on others makes people happier than spending money on themselves (Dunn, Aknin, & Norton, 2008). Finally, spending money on experiences makes people happier than spending money on material objects (Van Boven & Gilovich, 2003). The present research focuses on the distinction between experiences and material possessions, and their relative effects on happiness.

There are a number of possible reasons why experiential purchases might make people happier than material purchases, but one that has received little attention is the social nature of many experiences. It may be that experiences bring people more happiness than material goods to the extent that others are involved in the activity. Csikszentmihalyi (2000) noted the importance of consumption for satisfying desires for belongingness and connectedness, and recent research has verified that experiential purchases satisfy relatedness needs more

than material purchases (Howell & Hill, in press). We take these findings one step further by proposing that an experience by oneself may make people less happy than an experience in which others are included. The current research tests this hypothesis with experimental designs.

In the first study, 89 undergraduates were given a survey in which they were shown pairs of 9 experiences, each framed once as involving others and once as done alone. Participants were asked how happy the purchases would make them and how much money they would spend to acquire each. Results supported the hypothesis that experiential purchases are more valuable when framed as social than as solitary. Participants reported feeling happier with an experience when it involved others than when it was solitary, $t(89)=18.55, p<.001$, and were willing to spend more money to acquire it, $t(87)=13.50, p<.001$. These data suggest that an experience gains value—in terms of willingness to spend money to acquire it and happiness gained upon doing so—when it involves others.

A second study compared the value of social and solitary experiences to material objects. In this study, 84 participants were shown sets of three purchases—material, experiential with others, and the same experience alone—all matched for cost. For each set, participants were asked to indicate which of the three they would choose and which of the three would make them most happy. Partially replicating the results of Van Boven and Gilovich (2003), participants chose the social experience over the other purchases the majority of the time ($M=8.75$ times per 13 opportunities). Importantly, participants chose material objects significantly more ($M=3.47$) than solitary experiences ($M=0.76$). The same pattern was found for happiness ratings. These results suggest that the value of experiential purchases over material objects depends on others being included in the experience. When experiences are solitary, the relative value of material objects increases.

A final study addressed a methodological shortcoming in the second experiment. Namely, when participants pick one purchase from a set of three, the relative value of the two remaining purchases is not clear. Therefore, the final study broke down three purchase options into three between-subjects comparison conditions—material vs. social, material vs. solitary, and solitary vs. social purchases—and asked participants which they would choose and which would make them happier. The final study also included a fourth condition in which material purchases were presented alongside ambiguously social experiences (e.g., “taking a road trip” without specifying whether or not others were involved). Subjects in this condition provided an unprompted, open-ended description of the experience. If participants spontaneously describe the experiences as involving others, this adds support to the overarching hypothesis that the reason experiences promote happiness is because they involve others.

In the final study, 327 participants were randomly assigned to conditions in which they were presented 1 of 4 possible choices—between material objects and social experiences, material objects and solitary experiences, solitary and social experiences, and material objects and ambiguous experiences—and were asked to pick which one they would choose and which would make them happier. Results participants chose social experiences relatively more than material possessions ($M=7.63$ times per 12 opportunities). Participants chose material possessions relatively more than solitary experiences ($M=7.53$). Participants chose social experiences relatively more than solitary experiences ($M=9.83$). Finally, participants were no more likely to choose ambiguous experiences than material objects ($M=6.16$). However, participants reported that experiences would make them happier than material objects ($M=7.20$ times) and described the experiences in terms of people involved significantly more than would be expected by chance (63.3% of the time).

The results of three studies suggest that the value of experiential purchases, both in terms of willingness to consume and happiness after consumption, depends on others being involved. Consistent with Van Boven and Gilovich (2003), experiences with others are more desirable and make people happier than material possessions. Experiences without others, though, are less desirable and make people less happy than material possessions. These results are consistent with research by Rosenbaum (2006) suggesting that some consumers consistently patronize establishments that offer feelings of connectedness and social support. In addition, Russell, Norman, & Heckler (2004) demonstrate that television consumption represents an outlet for feeling connected to television characters. Taking into account the relationship context of experiential purchases may be critical to predicting how they best promote happiness.

Online and Offline Advertising Media: Exploring the Antecedents to Advertising Trust

Jeffrey Carlson, University of Connecticut, USA
 Jacqueline Anderson, Forrester Research, USA
 Joseph Pancras, University of Connecticut, USA

Abstract

Breaking through the clutter of advertising to reach consumers is no easy feat. Getting consumers to believe and act on the messages delivered is even harder. By understanding which specific media and channels consumers are more trusting of, marketers can more wisely choose where to place their messages for the highest levels of efficiency. This study looks to create a conceptual model outlining the predictors of advertising trust so that marketers can choose an advertising medium based on their target audience. By identifying which

sources are most or least trusted by a given type of consumer, marketers will know which channels to choose or avoid when determining their media mix in a campaign.

Introduction and Conceptual Overview

The landscape for advertising is continuously changing with the explosion of new media options. With the options becoming endless, the question turns to the consumer. How do they want to be reached? How will they listen? Specifically, which channel is most trustworthy? Consumers' trust of the messages companies are putting into their advertising has not been increasing. In fact, according to Forrester Research (Kim, 2006), in 2002 only 13% of North American heads of household indicated that they thought companies generally tell the truth in advertisements.

However, the fragmentation of the advertising market into a multitude of marketing channels makes these generalized trust statements hard to subscribe to. Consumers are well aware of the differences in advertising channels and are judging the messages contained in each differently. Recently, Nielsen (2007) surveyed consumers on their attitudes toward thirteen types of advertising, and found vast differences among the types.

Numerous studies have also found that consumers have a higher level of trust for content in traditional media sources (Ganguly, 2007; Parr, 2006; Soh, Reid, and King, 2007). Despite conclusive results indicating that channels differ in trustworthiness, previous research has not reached a consensus on how specific media differ. Flanagin and Metzger (2000), for example, found that beyond newspapers, media trust differed very little. These seemingly contradictory findings reveal that how specific media differ from one another (i.e., TV vs. Internet) should be further explored.

From a marketing perspective, trust of specific channels is essential. Without trust, consumers are less likely to openly receive messages. Furthermore, classic persuasion research shows that trust is an antecedent to attitude and behavioral change. Thus, understanding levels of trust not only across various channels but also between forms on a given channel will help determine the most effective channel and form to use for a given marketing campaign. Although secondary research clearly indicates that consumers do, in fact, trust certain channels more than others, it fails to clearly identify factors that influence consumers' trust perceptions. If one could determine factors (i.e., reliance) that impact trust, a marketing manager could better decide which channel(s) to utilize.

The trust consumers have with various advertisement channels may be impacted by the consumers' experience and reliance with a given channel (e.g., Greer, 2003; Johnson and Kay, 2000; Johnson and Kaye 2004; Nail, 2005). Nail (2005) found that young consumers who were rated as technology optimists (consumers who are comfortable with technology and like to use it) were more likely to notice online ads than technology pessimists. Kim (2006) also suggested reaching out to consumers in the environment that they engage with most. Essentially, people who are trusting of magazine ads are more likely to be trusting of other offline advertising. From this, one could theorize that consumers who spend more time online would be more trusting of online advertising while those who spend more time with any offline channels would be more trusting of offline advertising.

While there have been other analyses undertaken to examine the predictors of consumers' trust levels of web content, there has been little examination of the predictors of consumers' trust levels of online advertising. Shankar, et al (2002) built a model of online trust which helped in predicting consumers' trust of a given online channel. Much of this work centered upon the actual attributes of the website, the consumers' experience with online channels (specifically e-commerce interactions) and security issues. While the study did not speak to trust of online advertising the underlying framework lends itself to further exploration of this specific topic. Thus, we will use this model as a basis from which we will build out a model of online advertising trust predictors. Similarly, the study done by Bart, et al (2005), while focusing on specific determinants of trust in e-commerce experiences across site categories, demonstrates that allowances for differences across types of sites is important. Similarly, we will address differences across types of internet advertisements.

For this particular study we've developed the following preliminary hypotheses:

- Consumers with a higher level of online media usage will be more trusting of online advertising
- Consumers will trust advertising messages more when they are delivered through the medium they spend the most time with
- Demographic factors influencing technology adoption will also influence trust of online advertising

Method

Because of the need for respondents that used both on and offline media we chose to use data collected in a mail survey. The data used was from Forrester Research's 2008 Benchmark mail recontact survey. This survey is part of the Technographics product. The questionnaire was administered by mail to respondents aged eighteen and older from TNS' North American mail survey panel. The survey respondents had also responded to an early Forrester Benchmark survey. Thus, the available sample to pull from was a subset of the original respondents of the Benchmark Survey which had been fielded in January of 2008. The survey respondents were selected to be representative of the North American household and individual population. Targets were used in pulling the sample to match the predicted returns to look like the general US population. Survey respondents were incented with an entry into a sweepstakes to win one of five cash prizes. The total collected sample size was 4,605 respondents.

The survey was fielded in September of 2008. Six weeks were allotted for fielding. The mail based survey was a total of eight legal sized pages with a cover letter asking participants to complete the survey for a chance to win one of five cash prizes. As returns came into TNS they were processed by a DP team at TNS. This team was responsible for reviewing the returned surveys to ensure they were filled out properly and completely. The surveys were then cleaned and coded into a data set.

Preliminary Results

Thus far, we have yielded several general conclusions from preliminary data analyses. The sample consisted of 4,605 adults, ranging from age 18 to 95 (M=48.85). All 50 states were represented in this sample. Of the respondents, 48.7% were male, while 51.3% were female. When analyzing a ranked order of means, respondents indicate that yellow-page advertisements are the most trusted form of advertising (M=3.29) among 24 different types of advertising. Following yellow-page advertisements, the next top 6 forms of advertising

are: Online consumer reviews (M=3.18); In-store displays (M=3.16); Newspaper ads (M=3.12); Email ads (M=3.08); Magazine ads (M=3.05); and TV ads (M=2.98). The bottom five types of advertisement (the least trustworthy), are as follows: Celebrity endorsements (M=2.29); Social networking site advertisements (M=2.28); Videogame ads (M=2.25); Blog ads (M=2.24); and Text cell ads (M=2.18).

Multiple regression analyses reveal that both age and gender significantly predict levels of trust in the six ad types (yellow page ads; online customer reviews; in-store displays; videogame ads; blog ads; and cell text ads). The older a respondent is, the more negative reviews will be for both ad types. Furthermore, females rate videogames ads more negatively, but rate online consumer reviews more positively. In addition, preliminary exploratory factor analyses have yielded several technology usage factors (e.g., New Tech Uses such as blogging, wikis, etc.; Online product research and Purchase; Traditional Ad Trust; Newer Tech Ad Trust).

Using AMOS 6.0, a path model also yielded many interesting findings (RMSEA=.024; CFI=.988). First, there were no significant differences among consumers that predicted trust levels in traditional media advertising such as TV, radio, newspapers or magazines. Second, the use of newer Internet technologies (such as blogs and wikis), Internet product use (i.e., the research and purchase of products online), and the overall reliance upon the Internet had a positive impact on trust levels for “controlled” forms of Internet media (e.g., consumer reviews, custom emails, etc).

Other demographic variables were also found to have an impact. Age had a negative impact on trust levels of “controlled” forms (i.e., forms that that consumer typically controls exposure of such as blogs and consumer reviews) of Internet media and for new forms of Internet media. Females had higher trust level ratings for forms of media than males did. And finally, having a college degree negatively impacted a consumer’s trust level for most forms of media advertising.

The initial results show that there are differences among individuals who trust offline advertising and those who trust online advertising. The fact that there are no significant differences among consumers that will predict trust levels in traditional media advertising can be attributed to the established nature of these mediums. This only strengthens the need to further explore the predictors of trust among emerging advertising mediums so that consumers can be properly identified. Similarly, the apparent differences among controlled forms of Internet media versus un-controlled media should be explored as well. This is especially important with the rise of user-generated content on the Internet.

Creating a model of consumer ad trust will greatly empower marketers to make better choices about where to place messages. Further analyses will be connected to more deeply examine the predictors of online advertising trust. The end goal of the analyses will be to not only construct a model to illustrate the predictors of online trust but to create consumer profiles for each type of advertising. These consumer profiles will illustrate to marketers who is and who isn’t likely to trust each type of advertising.

When Preferences Differ Among Friends: How Positive Affect Influences Choosing to Accommodate Others vs. Choosing to Express Oneself

Cindy Chan, Cornell University, USA
Alice M. Isen, Cornell University, USA

Are people in positive affect more likely to accommodate the preferences expressed by their friend when making consumer choices? Or are they more likely to stay true to their own personal preferences? Indeed, the answer to both questions is yes. Results show people

in positive affect are *more likely* than controls to accommodate their friend's preference when their preferences are not extremely different, or when their decision affects both parties. Conversely, they are *less likely* than controls to accommodate their friend when their friend's preference is very different, even when their choice is made in the company of their friend.

Unintended Consequences of Fundraising Tactics

Zoe Chance, Harvard Business School, USA

Michael Norton, Harvard Business School, USA

Prosocial behavior has been correlationally linked to happiness, with individuals who report a greater interest in helping others, an inclination to act in a prosocial manner, or intentions to perform altruistic or courteous behaviors being more likely to rate themselves as dispositionally happy (for a review, see Lyubomirsky, King, & Diener, 2005). Recent studies have shown that prosocial behavior leads to increased happiness (Lyubomirsky, Tkach, and Sheldon, 2004), and, more specifically, that spending money on others may make us even happier than spending the same amount of money on ourselves (Dunn, Aknin & Norton, 2008). Recently, 89% of American households have donated to one or more charitable causes (Independent Sector, 2001), totaling approximately 2% of GDP each year (Andreoni & Petrie 2004). Experimental results from laboratory and field settings finding that incremental giving tends to make people happier (Dunn, Aknin and Norton, 2008), and the uncontroversial assumption that increased funding for charities will have a positive impact on their beneficiaries lead us to believe that the optimal level of national giving has not yet been reached. With that in mind, we are interested in learning how to increase individual charitable donations beyond their current level. In particular, our studies provide warnings to charitable fundraisers that some familiar tactics for increasing donor participation may have the unintended consequences of reducing future contributions.

Charity fundraisers use a variety of methods to increase donations, with three of the most common ones being matching funds, seed money, and thank you gifts. Field experiments have shown that matching funds (Eckel and Grossman, 2008) and seed money (List and Lucking-Reiley, 2002) do, in fact, increase donations during the time of the fund drive. List and Lucking-Reiley, for example, found that increasing seed money from 10 percent to 67 percent of the campaign goal produced a nearly six-fold increase in contributions, with significant effects on both participation rates and average gift size. But few field researchers have examined the long-term results of any fundraising tactics (see Frey and Meier 2004, and Shang and Croson 2006 for exceptions), and we are unaware of any published studies investigating long-term impact of seed money or thank-you gifts.

In our laboratory experiments, we study the impact in future periods of using seed money, matching funds, and thank you gifts to increase giving in the present period, finding that certain levels of all these commonly used "sweeteners" can decrease giving in the long term. In our seed money study, we find that those who donate at the end of a successful capital campaign donate less money in the future—25 percent less than those who donate at the beginning or middle of the campaign, holding initial donation constant. We speculate that perhaps the "warm glow" of altruism (Andreoni 1989, 1990) can at times make us feel as though we have actually done more than we have, decreasing our motivation to give more, since we may feel we have given enough. This hypothesis could help explain our additional finding that high levels of matching funds can decrease future donations—those whose initial contributions were matched at 300 percent subsequently gave 18 percent less than those whose contributions were matched at 100 percent. We found that thank you gifts such as music CDs given away by public radio stations to encourage participation in their fund drives can backfire as well. When donors received a small thank you gift in exchange for their contribution, they gave 20 percent less when solicited again. We propose that the psychological mechanism underlying this behavior may be that structuring the donation event as a trade turns it into an economic rather than a social transaction in the mind of the donor, and this may decrease one's intrinsic motivation to donate. Many studies have shown that extrinsic motivation can undermine intrinsic motivation and impair performance (see Deci, Koestner and Ryan, 1999, for a review), and, in agreement with Gneezy and Rustichini (2000) we suggest this effect extends to charitable giving. We are currently investigating our hypotheses regarding the mechanisms behind the major drops in charitable giving that can result from seed money, matching funds, and thank you gift strategies.

Economists and psychologists have long been investigating the phenomenon of why people give, with crossover between disciplines making this a simultaneously fruitful and challenging line of inquiry. Economists models of giving, such as Andreoni's heavily-cited "warm glow" model of altruism (1989, 1990), typically rely on psychological constructs; and psychologists often turn to evolutionary theories for rational explanations of generosity, such as kin selection and reciprocity (Penner et al, 2005). At the crux of this overlap in disciplines is the issue of motivation. As we explore this area further, we hope to shed some light on how and when using common fundraising strategies can be demotivating despite increasing participation rates. With greater understanding of how their strategies can backfire, charitable organizations may be able to employ similar tactics with less risk.

Confidence, Mindset, and Self-Efficacy in Goal Pursuit

Chiu-chi Angela Chang, Shippensburg University, USA

Xiaojing Yang, University of Wisconsin-Milwaukee, USA

Consider what is happening at this moment in time: economic downturns make despair palpable to many individuals, who feel unconfident in achieving their retirement or other savings goals. How could these low confidence individuals persevere to save and work toward their goals? The current study is motivated by scenarios like this and examines the possibility of boosting self-efficacy (i.e., a belief in one's ability to achieve something) in view of low confidence.

The marketing literature on hope indicates the effect of strong versus weak hope on product evaluation and choice (e.g., MacInnis and de Mello 2005). In particular, De Mello et al. (2007) find that when consumers have low confidence about achieving their hoped-for goals, they are engaged in motivated reasoning about the effectiveness of products touted as problem solutions. Yet, in an effort to restore hope, besides a biased perception about products, could consumers have biased views about themselves? Indeed, a likely side effect of reduced confidence in a hoped-for goal is low perceived self-efficacy, as both low confidence and low perceived self-efficacy may result from a lack of mastery experience (cf. Bandura 1997). A vicious cycle can occur such that low perceived self-efficacy would, in turn, prevent a consumer from making vigorous, persistent efforts or enhancing the commitment to achieving a goal (Mukhopadhyay and Johar 2005). Therefore, it is relevant to investigate how to boost perceived self-efficacy when consumers have low confidence in reaching their goals.

This study proposes that mindset activated (deliberative vs. implementational) may affect perceived self-efficacy for low confidence consumers. Theoretical support comes from the research on construal levels and self-control (Fujita et al. 2006). Their experiments demonstrate that construing a situation in high-level terms (such as priming a deliberative [vs. implementational] mindset) would promote self-control (such as reduced preferences for immediate over delayed outcomes). To boost self-efficacy in a discouraging, low confidence situation certainly requires self-control, thus it is likely that a deliberative mindset would similarly have a favorable effect on self-efficacy. In addition, it is likely that a deliberative (vs. implementational) mindset would engender a fair and balanced evaluation of the situation (Taylor and Gollwitzer 1995), which may be lacking especially for low confidence consumers. In sum, the prediction is that a deliberative (vs. implementational) mindset would help boost self-efficacy for low (not high) confidence consumers.

To test the aforementioned relation among confidence, mindset, and self-efficacy, a 2 (confidence: low vs. high) x 2 (mindset: deliberative vs. implementation) between-subjects design was employed. Eighty-nine undergraduate respondents were divided into high and low confidence groups based on their answer, on a nine-point scale, to the item: "I am confident that I would get good grades by the end of the semester," which was embedded in a lifestyle survey. They then were primed with either a deliberative or an implementational mindset, following the procedures in Taylor and Gollwitzer (1995). Specifically, respondents in the deliberative mindset condition were asked to consider the immediate and long-term consequences of a personal project, whereas respondents in the implementational mindset condition were asked to write down the implementation steps involved in an intended project. The main dependent measure was perceived self-efficacy. Four domain-specific items of perceived self-efficacy were constructed; for example, "There is a lot that I as a student can do to get the best grades that I can," and "With enough effort I can get very good grades." Questions regarding the extent of studying were also included. Additional measures collected (and later used as covariates) included self-control, self-regulatory focus, mood, involvement, gender, and GPA.

Significant main effects of mindset and of confidence, as well as a moderately significant interaction effect of confidence and mindset on perceived self-efficacy were found ($F(1, 71) = 2.82, p = .097$). The interaction pattern was such that high confidence respondents were not influenced by the mindset manipulation, whereas low confidence respondents had higher perceived self-efficacy when they were primed with a deliberative (vs. implementational) mindset, as hypothesized. Another intriguing finding was that prevention-focused low confidence respondents said they would study more in the following week than did promotion-focused low confidence counterparts (no significant effect was found for high confidence respondents).

The finding of the interaction effect of confidence and mindset is consistent with the rationales provided by Fujita et al. (2006) and Taylor and Gollwitzer (1995). That is, a deliberative mindset makes consumers consider both pros and cons (i.e., high-level features), and that helps our low confidence respondents boost perceived self-efficacy because the appraisal of self-efficacy was not colored by low confidence. In other words, a deliberative mindset makes consumers resist the crippling effect of low confidence. On the other hand, it seems that priming an implementational mindset may not be helpful in enhancing perceived self-efficacy for low confidence consumers because these consumers simply lack the confidence about achieving their goals and even taking the necessary steps.

During goal pursuit consumers differ in their confidence about reaching their hoped-for goals (e.g., exercising, dieting, savings). It is important to understand how reduced-confidence consumers can boost their perceived self-efficacy and keep trying persistently. This working paper found that priming a deliberative or an implementational mindset can make a difference in consumers' perceived self-efficacy in a low confidence situation. Follow-up studies are needed to shed more light on our understanding of boosting self-efficacy. Possible directions include: (1) manipulating confidence in reaching a goal; (2) studying the prediction in a different context for generalizability; (3) monitoring, as a dependent measure, real behavior needed for reaching a goal; and (4) exploring additional ways to boost perceived self-efficacy (e.g., inducing a promotion or a prevention self-regulatory focus).

The Impact of Implicit Theories on Family Brand Evaluations

Joseph Chang, Vancouver Island University, Canada

Introduction

Previous studies examining reciprocal extension effects on family brand evaluations mainly focus on the accessibility and diagnosticity of brand extension information (e.g., Ahluwalia and Gurhan-Canli 2000; Chang 2002, 2007; Chang and Lou 2006), the categorical similarity between brand extensions and their family brands (e.g., Chang 2002; Chang and Lou 2005; Loken and John 2003; Milberg and Sinn 2008; Salinas and Perez 2009), and the nature of family brands, such as varieties and perceived entitativity of family brands (e.g., Chang 2007; Chang and Lou 2005, 2006; Gurhan-Canli, 2003). In social cognition, research on lay theories (entity vs. incremental) indicate that subjects who begin social perception with different initial assumptions follow various cognitive paths and reach various social endpoints of expectations, perceptions, and inferences (Levy, Plaks, Hong, Chiu, and Dweck 2001). As with social cognition, the impact of implicit theorists may also affect reciprocal extension effects on family brand evaluations.

Conceptualization

Entity theorists believe that personal characteristics are fixed or static despite person's efforts or motivation to change them, which means that personal characteristics are beyond personal control. They believe that "everyone is a certain kind of person, and there is not much that can be done to really change that" (measure statement). In contrast, incremental theorists believe that personal characteristics are dynamic or malleable and can be changed over time and with efforts. They believe that "anyone can change even their most basic qualities" (measure statement). Research results indicate that entity theorists are more likely to elicit greater stereotype endorsement, greater perceived outgroup homogeneity effects, more susceptibility to the ultimate attribution error, greater intergroup bias, and more biased behavior toward outgroup members (Levy et al. 2001).

As believing that personality is dynamic or malleable (vs. static or fixed), incremental (vs. entity) theorist are more open to, and lay more weight on, latest relevant information about brand extensions to update their impression about the family brands if they are motivated to process the information on-line. Therefore, it is hypothesized that new brand extension information is more influential or diagnostic on family brand evaluations for incremental (vs. entity) theorists (Study 1). Moreover, as believing that personality is static or fixed (vs. dynamic or malleable), entity (vs. incremental) theorists are more likely to expect the existence of underlying essences of family brands and the congruency of brand extension information. Given the congruency, the processing of integrating the extension information with the family brand is expected to be a relatively easier task for the entity theorists, who subsequently are more highly motivated to spontaneously process new relevant information about the family brands. Therefore, it is hypothesized that, as expecting the existence of underlying essences about family brands, entity theorists tend to perceive the entitativity of family brands higher (Study 2-1). Moreover, as being more highly motivated, entity theorists tend to have spontaneous on-line (vs. memory-based) extension information integration for the impression formation about family brands (Study 2-2). Based on the theory of group level trait transference (GLTT) model (Crawford, Sherman, and Hamilton 2002), the information integration for the impression formation about family brands may involve the three-stage process of attribute abstraction (or inference), stereotyping, and attribute transference. As entity (vs. incremental) theorists are more likely to have spontaneous on-line extension information integration, it is hypothesized that stereotyping and attribute transference within family brands are more likely to occur to entity (vs. incremental) theorists, where as attribute abstraction occurs to both entity and incremental theorists (Study 3-1). Moreover, the processes of stereotyping and attribute transference may amplify the magnitude of extension information and lead to more salient polarization extension effects on consequent family brand evaluations (Chang and Lou 2006; Crawford et al. 2002; Study 3-2).

Methodology

This research consists of three studies. The first study is to verify if new brand extension information is more influential or diagnostic on family brand evaluations for incremental (vs. entity) theorists. The study consists of eight experimental conditions with respondents randomly assigned to groups in a 2 (implicit theorists: static vs. incremental) x 2 (valences of extension information: positive vs. negative) x 2 (categorical similarity: similar vs. dissimilar) between-subjects factorial design; around 200 student participants are expected. The second study is to verify if entity theorists tend to perceive the entitativity of family brands higher and have spontaneous information processing to form on-line (vs. memory-based) impressions about the family brands. The study consists of eight experimental conditions with respondents randomly assigned to groups in a 2 (implicit theorists: static vs. incremental) x 4 (family brand entitativity: high similarity/high goal-derived, high similarity/low goal-derived, low similarity/high goal-derived, low similarity/low goal-derived) between-subjects factorial design; around 200 student participants are expected. The third study is to verify if the stereotyping and attribute transference within family brands, and extension polarization effects on family brand evaluations, are more salient for entity (vs. incremental) theorists. The study consists of a 2 (implicit theorists: entity vs. incremental) x 4 (family brand entitativity: high similarity/high goal-derived, high similarity/low goal-derived, low similarity/high goal-derived, low similarity/low goal-derived) x 6 (attribute counterbalancing) x 2 (trial types: inference vs. transference) mixed-measures design with repeated measures on the fourth factor. The experimental process will follow the procedure of the paradigm of previous research by Crawford et al. (2002); around 180 student participants are anticipated.

Results

The following findings are expected. Firstly, new brand extension information is expected to be more influential or diagnostic on family brand evaluations for incremental (vs. entity) theorists. Secondly, entity (vs. incremental) theorists are expected to perceive the entitativity of family brands higher. Thirdly, entity (vs. incremental) theorists are expected to have spontaneous information processing to form on-line (vs. memory-based) impressions about the family brands. Finally, stereotyping and attribute transference within family brands, and polarization effects on family brand evaluations, are more salient for entity (vs. incremental) theorists.

Varieties of Family Brand Entitativity

Joseph Chang, Vancouver Island University, Canada
Yung-Chien Lou, National Cheng-Chi University, Taiwan

Introduction

Research in social cognition has recently paid a considerable amount of attentions to the influence of perceived entitativity on the impression formation of social groups. Entitativity refers to the wholeness of a group defined as the degree to which a social aggregate is perceived as "having the nature of an entity" (Campbell 1958, p. 17). The concept of perceived entitativity was also just implemented to the research domain in family brand evaluations. Previous research results indicate that high (vs. low) entitative family brands are more favourably evaluated, and perceived entitativity yields asymmetric reciprocal effects on family brand evaluations (Chang and Lou 2005, 2006), which parallel to the results of group perceptions in social cognition (Crawford, Sherman and Hamilton 2002). As categorization

is the basis of stereotyping and judgments, as with social groups, family brands with various perceived entitativity are likely to be categorized differently, which leads to different subsequent psychological processes and results in asymmetric reciprocal effects on family brand evaluations. Therefore, this research examines the applicability of the entitativity measures of group perceptions for family brand evaluations.

Conceptualization

The categorization of social groups involves five dimensions with nine entitativity measures, including the global entitativity measure (Lickel, Hamilton, Wiczkowska, Lewis, Sherman, and Uhles 2000). The first dimension is similarity or homogeneity of group members to each other. The second one is group size. The third dimension is the importance of group membership. The fourth one is the interdependence among the members of a group. The interdependence among the members of a group is comprised of the three sub-factors of interaction among group members, common goals among group members, and common outcomes for group members. The last one is inalterability of a group with an essential or basic nature, which is comprised of the two sub-factors of permeability of group boundaries and duration of group.

Groups vary along an entitativity continuum (Hamilton, Sherman, and Lickel 1998). As discussed above, the significance of the eight group properties differs among different social groups, which induces different levels of perceived entitativity. The perceived entitativity of social groups is defined by a pattern of properties, and these patterns differ meaningfully. Perceivers engage in different extents of stereotyping and make different judgments with respect to different degrees of perceived entitativity. Lickel et al. (2000) further identify the importance of the eight antecedents for the social group categorization by rating the perceived entitativity of 40 various social groups. The five properties of interaction, importance, common goals, common outcomes, and similarity are observed to be determinant to the perceptions of entitativity (or groupness), whereas the rest of three factors of size, duration, and permeability are less correlated with the perceived entitativity. Based on the antecedents of eight group properties, social groups are further categorized into four distinct types of groups with different perceived entitativity, which include intimacy groups, task groups, social categories, and loose association groups. Each type of group is comprised of a unique pattern of entitativity-related properties and varies along a considerable range of entitativity continuum. For example, *intimacy* groups are small, significant in interaction, important to their members (significant in the importance of group membership), generally impermeable (or with clear impermeable boundaries), and more durable (or having been in long existence).

Methodology

Following previous research (Lickel et al. 2000), nine measures of perceived entitativity including interaction, importance, outcomes, goals, similarity, duration, size, permeability, and the global measure of perceived entitativity are utilized to cluster 40 prominent family brands (e.g., Coca-Cola, Microsoft, IBM, etc.), which were selected from the Top 100 Global Brands of Businessweek (2008). However, pilot tests showed that respondents were exhausted and bored after spending around 45 minutes in evaluating the 40 brands with the nine entitativity measures (overall $360=9 \times 40$ evaluative judgments), which may yield respond bias (Aaker 1997, p 349). In order to prevent the respond bias, the research design was further revised to significantly reduce respondents' workload from 40 brands down to 10 brands. By doing like this, the overall evaluative judgments for each respondent are significantly reduced from 360 down to 90. The original 40 brands are firstly reduced down to 37 brands and then divided into four Brand Groups with a common brand, SONY, in each Brand Group. The common brand is included in each Brand Group so that the extent to which the four Brand Groups differs in their brand entitativity measures could be assessed (Aaker 1997).

Overall, two hundred undergraduate participants are expected, in addition to the 70 respondents for the pilot tests. Participants are randomly assigned to one of the four Brand Groups. Each participant evaluates the 10 family brands in the assigned Brand Group with the nine entitativity measures on a 9-point scale ranging from 1 ("Not a brand family at all") to 9 ("Very much a brand family"). A booklet with color brand extension portfolios and brand logos of 10 popular family brands in consumer goods industries (Businessweek 2008) is provided for perceived entitativity evaluations. The family brands are shown to the respondents in random orders to avoid systematic responding biases.

Results

Correlation analysis, factor analyses, regression analysis, cluster analysis, and multidimensional scaling (MDS) are to be performed to select appropriate measures and form dimensions of perceived entitativity for family brand categorization. As with social groups, it is expected that several of these properties, except permeability, are strongly correlated with, and account for a substantial portion of the variation in, the global perceived entitativity (Lickel et al. 2000). Properties of perceived entitativity are effective antecedents that may cluster family brands into groups, which subsequently elaborate different cognitive processes for family brand evaluations.

More reliable results from the revised research design are further expected, while the pilot tests with a sample size of 70 yield some interesting findings. Namely, the five-cluster solution was found to be the relatively stable solution for the interpretation. Cluster 1 family brands (e.g., American Express) are small and have high levels of goals and similarity. Cluster 2 family brands (e.g., GE and Panasonic) are low in similarity, interaction, and outcomes, but of moderate duration and size. Cluster 3 family brands (e.g., Disney) are high in duration and size, but low in outcomes and similarity. Cluster 4 family brands (e.g., AVON) are relatively low in outcomes, size, importance, and interaction. Cluster 5 family brands (e.g., Toyota) are high in duration, goals, and similarity. As expected, results of Correlational analysis indicate that seven properties, except permeability, are positively correlated with entitativity. Further studies are also developed to examine other factors that may affect family brand categorization, such as product ownership with the theory of self-identity (Study 2) and cultural differences with holistic (vs. analytical) thinking (Study 3).

Wrath of the Monsoons: Effect of Marketplace Evolution on Acquisition and Storage of Possessions in Recurring Natural Disasters

Sarita Ray Chaudhury, New Mexico State University, USA

Every year, the monsoon season in India occurs approximately from June through September. People await its annual advent with a mix of anticipation and dread. Monsoons provide much needed water resource for the predominantly agricultural country. The rains bring respite from the fierce summer heat simultaneously causing floods and heavy loss of life and property. The United Nations claimed 2007 as "the worst year in living memory" as 2200 lives were lost across South-East Asia, leaving millions homeless and destitute due to Monsoonal floods. In 2008, the Indian government sanctioned approximately \$230 Million in aid to victims of Monsoonal floods which claimed 800 lives across the country (The Associated Press 2008).

India's booming economy has led to unexpected windfalls for its middle class. With call centers and retail outlets (such as malls and shopping complexes) mushrooming in small towns, young people are in a position to earn money before finishing college. Therefore, despite living with their parents, adult children manifest their newfound independence in the acquisition of personal possessions. These consumption acts lead to conflicts and tensions in the family due to limited storage space in the house and is further intensified during the monsoon season. This study examines the interplay of family dynamics (between generations such as parents and adult children residing in the same household) and the role of an evolving marketplace in creating such tensions and how family members negotiate to resolve them.

To explore these issues, personal life-history interviews (Mick and Buhl 1992) of eighteen individuals are undertaken in a mid-size city in eastern India. Heads of families, their wives and adult children participated in the interview process which took place during a recent monsoon season. Participants were given a digital camera to take pictures of the storage spaces in their homes. They provided detailed description of the use of the storage spaces during the course of the interview process. All participants are from the lower middle class socio-economic stratum with annual incomes between Rs.25, 000 to Rs.1, 00,000 (approximately \$530-\$2130 earned by primary household earner). Their homes are located in low-lying areas and are prone to flooding. Almost every year they experience disruption of daily lives, loss of possessions and sometimes even human lives during the monsoon season. In order to understand how evolving marketplace conditions in recent times shape consumption practices, participants were asked to compare the current monsoon season with past experiences. Families with employed adult children living at home experience the most conflict with evolving marketplace conditions. With limited storage space in the house, new acquisitions posit a conflict of interest amongst the different generations of family members living under one roof. Some emergent themes are briefly highlighted and theoretical contributions of this study are discussed.

The EMI factor:

Indian banks experiencing rapid growth in recent years are more moderate in their lending conditions than in the past. With availability of relatively accessible credit, participants acquired televisions, motorbikes and other high-end products that are paid back in EMI-s or equal monthly installments. Fathers wield considerable power in the patriarchal society of India. Consequently, when the head of the household purchased an expensive product, he attributed it towards the benefit of the family. If a son acquired the same product with his own resources, there was conflict in the household as it was then considered an individual and not a family possession. For example, the head of the household purchased a television set which was kept in the family living area for everyone's viewing purposes. However, if the father was present, everyone watched the channel of his choice. The adult son (residing in the household) purchased another television set (with credit) for his own viewing purposes and kept this set in a bedroom shared with other family members. This act of consumption created several sources of conflict amongst family members. Participants worried about keeping these newly acquired possessions safe from flooding during monsoon season. Burdened with paying back loans, participants reported mental stress and strain on finances to safeguard these expensive assets during monsoon season in addition to familial tensions.

Keeping up with the Joneses (or in this case, the Jhas)

Participant's homes are surrounded by newly developed high-rise apartments where only a few short years ago there was nothing. The prosperity of their new neighbors often influenced them to investigate latest marketplace offerings. Participants, specifically young adult children in the family, visited newly built shopping complexes to purchase equivalent or close substitutes of clothing and accessories similar to their more privileged neighbors. Apart from additional drainage of monetary resources which is viewed as wastage (most parents want adult children to save as much of their earnings as possible) by the parents (typically the fathers), storing these possessions during the monsoon season became an issue of discontent in the family as it took up precious space in the house.

Consumer Culture theorists over the last two decades have examined numerous ways in which marketplace resources are used to construct, communicate and legitimize distinctive consumer identities (Arnould and Thompson 2005; Oswald 1999; Penaloza 1994; Schouten and McAlexander 1995). Although India is acknowledged as an emergent market with vast growth potentials, there is little understanding of how consumer identities are shaped and contested in the country's present dynamic marketplace (Varman and Belk 2008). As marketers seek authentic "consumer experience" in consumer research (Richins 2005; Thompson, Locander, and Pollio 1989), this study draws attention to consumers who experience the impact of natural disaster on a recurring basis. It highlights previously unexplored ways in which such consumers; collectively and individually, navigate a radically evolving marketplace to offset challenges such as family role conflicts in storage of possessions during annual monsoon flooding in India.

The Influences of Price Dispersion and the Manufacturer's Suggested Price on Consumers' Boundaries of Acceptable Price: Expected Price as a Mediator

Etta Y. I. Chen, Yuan Ze University, Taiwan

Lien-Ti Bei, National Chengchi University, Taiwan

Price dispersion is defined as the price variability across stores for a specific brand or product (Grewal and Marmorstein 1994; Pan, Ratchford and Shankar, 2004; Stigler 1961; Urbany 1986). The effect of price dispersion on the consumer's internal reference price is most concerned of manufacturers. Therefore, many manufacturers use the suggested price on the package of a product or in advertising to prevent retailers from excessive mark ups or to counteract the negative impact of unexpected retailing prices. The manufacturer's suggested price (MSP) as an anchor may assimilate the expected price under high price dispersion as well as the acceptable price. The boundaries of the expected price and the acceptable price are important for the consumer's price judgment and purchase decision. However, the effect of price dispersion and the MSP on the consumer's expected and acceptable prices are still unknown. Besides, the MSP of a prestige or an inferior brand may have differing impacts. The purpose of this study was to investigate the joint effects of price dispersion, the MSP, and the brand image on the expected price. Furthermore, the research demonstrated how the expected price mediated their effects on the acceptable price.

In this study, high price dispersion was defined as the market price range of a product that exceeded the consumer's acceptable price range of that product category. The manipulation of price range for high price dispersion represented the noticeable price difference for consumers. Also, the highest market price was higher and the lowest market price was lower than those under low price dispersion. Past market prices and contextual factors that consumers encounter in their purchase experiences shape their price expectations (Jacobson and Obermiller 1990; Kalwani et al. 1990; Kopalle and Lindsey-Mullikin, 2003). Therefore, the boundaries of the expected price cannot avoid being influenced by the range effect from price dispersion (as predicted by Range Theory) and the anchoring effect of the MSP. The extreme range of the high price dispersion is expected to enlarge the distance of both boundaries of the expected price, while the MSP is expected to raise both upper and lower boundaries. Based on the assimilation effect (Sherif and Hovland 1961), one can further predict

that the upper boundary of the acceptable price will be assimilated toward the anchor value of the MSP, but not the price dispersion. In contrast, the lower boundary of the acceptable price should be assimilated toward the low market prices of high price dispersion. Both effects are expected to work via the boundaries of expected price as mediators.

The expected price corresponds to the cognition of a product's market prices and contributes to the construction of an acceptable price. The expected price is also found to influence the width of the acceptable price (Kalyanaram and Little 1994). Therefore, the mediating effect of the expected price was further hypothesized. This study expected that the lower boundary of the expected price might mediate the effect of price dispersion on the lower boundary of the acceptable price, while the effect of the MSP on the upper boundary of the acceptable price was mediated by the upper boundary of the expected price. In addition, the MSP is closely linked to a manufacturer's reputation and the brand image. Brand image is found to influence the consumer's internal reference price (Grewal et al. 1998). A prestige brand helps to raise the internal reference price more effectively than an inferior brand. The interaction of brand image, the MSP and price dispersion on the range of the acceptable price was included in this research.

The main study employed a 2 (price dispersion: high or low) x 2 (MSP: with MSP or without MSP) x 2 (brand image: prestige or inferior) between-subject experimental design. Three pretests were conducted to decide the focal product category, representative brands, and price range. In pretest 1, 2-liter milk was selected from a list of consumer products. Two real brands, i.e., the representatives of the prestige and inferior brands, were chosen based on respondents' overall impression and quality evaluation. In addition, the operational definition of price dispersion was the difference between the highest and lowest prices across retailers on the market at a given point of time. The levels of the manipulation of price dispersion were decided in Pretest 2 and 3. The ranges of high/low price dispersion were manipulated beyond/within the range of acceptable prices that were acquired from the results of Pretest 2. In the main study, the price stimulus was disguised by a one-page fictitious excerpt from *Consumer Reports* in which the main topic was the quality and price survey of major milk brands on the market. A matrix of seven retailer outlets and five major milk brands (including either the prestige or the inferior brand with four other real median level major brands on the market) was presented. A total of 207 undergraduate students participated in this experiment.

The results indicated a hierarchical relationship between price dispersion, the MSP, the boundaries of the expected, and then the acceptable prices. Price dispersion and MSP influenced both boundaries of the expected price. Price dispersion lowered the lower boundary of the expected price while the MSP raised the upper boundary of the expected price. Also, the lower boundary of the expected price fully mediated the effect of price dispersion on the lower boundary of the acceptable price. In contrast, both boundaries of the expected price fully mediated the effect of the MSP on the upper boundary of the acceptable price. In Lichtenstein and Bearden's (1989) scale of internal price standards, the range of the acceptable price was restricted in that of the expected price and was biased toward the direction of lower prices. The findings of the current study corresponded to their works that the upper boundary of the acceptable price was mediated by the lower boundary of the expected price. Furthermore, for the prestige brand, the range of an acceptable price was higher than the inferior brand when the price dispersion was high. This study explored the mechanism, during which the boundaries of acceptable prices were influenced by the negative impact of high price dispersion and the counterbalance effect of the MSP. The results of this study also provided manufacturers a strategic perspective of employing MSP to shape consumers' price perceptions.

The Influence of Advertising on Decision Strategy

Hui-Yun Chen, Virginia Polytechnic Institute and State University, USA

Jane E Machin, Virginia Polytechnic Institute and State University, USA

Decision strategy is the process used to make a choice: a rejection-based decision strategy occurs when the primary focus of the decision is on rejecting undesired option(s) whereas a selection-based decision strategy occurs when the primary focus of the decision is on selecting the desired option. Prior research suggests that selection and rejection are not complementary strategies and can have different and non-trivial effects on which options are chosen and subsequent satisfaction with those options (e.g. Shafir 1993). Most prior research manipulates decision strategy (e.g. Shafir 1993; Wertenbroch and Dhar 2000). There is currently little understanding therefore of what motivates consumers to *spontaneously* make decisions using either a selection- or rejection-based decision strategy. Our research investigates one potential antecedent: the influence of advertising on decision strategy and, in particular, comparative advertising. In doing so, we improve our understanding of the psychological mechanisms through which comparative advertising works and may help to explain some inconsistencies in research on the effectiveness of comparative advertising.

Comparative advertising is a long-thriving advertising strategy in which comparative evaluations of the advertised brand and the comparison brands on one or more attributes are presented (Goodwin and Etgar 1980). Comparative advertising can be further subdivided into positive and negative comparative advertising. While negative comparative advertising shows how the comparison brands are inferior to the advertised brand, positive comparative advertising claims the advertised brand as superior to the comparison brands (Jain 1993). We hypothesize that negative comparative advertising will direct consumer attention to the undesirable features of the competitor brand, leading them to use a rejection-based decision strategy to avoid those features. In comparison, positive comparative advertising, with its focus on the positive attributes of the advertised brand, will encourage consumers to use a selection-based decision strategy.

Two experiments provide early support for this hypothesis. Study 1 investigated the influence of advertising type on decision strategy and introduced motivation as a potential moderator. Consistent with much prior research on motivation, whereby advertising claims only influence evaluations under conditions of high motivation (Maheswaran and Meyers-Levy 1990; Shiv, Britton, and Payne 2004), we expected that advertising type (positive versus negative versus non-comparative) would only influence decision strategy when consumers were highly motivated to process the claims. As predicted, advertisement type did not influence decision-strategy under conditions of low motivation. However, under conditions of high motivation, negative comparative advertisements led participants to adopt a rejection-based decision strategy relative to positive comparative and non-comparative advertisements.

Study 2 held motivation constant and high for all participants and instead examined the moderating role of brand familiarity on the relationship between advertising type and decision strategy. Prior research has demonstrated that comparative advertising is more effective for new brands compared to established brands (Iyer 1988). Thus, we hypothesized that, for brands that are highly familiar, consumers would rely on their prior knowledge and simply select the brand they normally use, irrespective of advertising type. However for new, unfamiliar brands, consumers should rely more on the advertising claims. In this case, negative comparative advertising should lead to a more rejection-based decision strategy while positive comparative advertising should induce a more selection-based decision strategy. Results support this hypothesis. Across three product categories (toothpaste, fast food restaurants, and canned soup,) when the advertised brands were familiar, there was no difference in decision strategy by advertising type. However, when the brands were unfamiliar, negative comparative advertisements led consumers to use a rejection-based decision strategy relative to positive comparative and non-comparative advertisements. Study 2 also generalized the findings by showing the same pattern of results when both single and multiple comparison brands are used.

These two studies provide early evidence that negative comparative advertisements induce a rejection-based decision strategy relative to positive and non-comparative advertisements. Subsequent studies (data currently being collected) seek to understand how the differential adoption of decision strategy after exposure to a certain advertising type influences attitudes towards the advertisement, attitudes towards the brand and ultimately choice. Prior research on the effectiveness of comparative advertising versus non-comparative advertising and, more specifically, positive versus negative comparative advertising has had mixed results (Block and Keller 1995; Sorescu and Gelb 2000). Furthermore, surprisingly little research has been conducted to investigate the underlying psychological mechanisms through which comparative advertising operates. We believe adding decision strategy to these models may help explain inconsistencies in advertising effectiveness results and also provide insight into the process.

Comparative advertising encourages consumers, explicitly or implicitly, to choose between two or more alternatives. At a general level, therefore, we hypothesize that comparative advertising induces a choice frame, while non-comparative advertising induces a rating frame. Much prior research suggests that the task type (choice or rating) can lead to preference reversal (e.g. Nowlis and Simonson 1997), similar to the kinds seen in studies assessing the effectiveness of comparative versus non-comparative advertising. More specifically, as decision strategy has been shown to influence preferences, we further hypothesize that the effectiveness of positive versus negative comparative advertising will be influenced by the decision strategy used. Specifically, we propose that evaluations of the advertisement and brand will be elevated when advertising type and decision strategy are congruent than when they are incongruent.

To summarize, our initial findings demonstrate that advertising type influences decision strategy, providing one of the first investigations of the antecedents of decision strategy. As decision strategy can influence both the actual choice and subsequent satisfaction with that choice, understanding how consumers spontaneously adopt one strategy over another is important. Our findings also contribute to the literature on comparative advertising by shedding light on the process by which positive, negative and non-comparative advertising works and, with data currently being collected, may ultimately help determine the relative effectiveness of such advertising.

Design It, Your Self-Experiences (DIY): Social Creativity and the Social Function of DIY Experiences

Steven Chen, California State University, Fullerton, USA

Jennifer D. Chandler, University of Hawaii, USA

Advancing the creativity literature, this study explores specifically the *social motivations* for consumers to engage in creative DIY experiences. Design-It-Yourself, or Do-it-Yourself (DIY), is a type of creative experience in which consumers create handmade, customized objects for private and commercial consumption (Levine and Heimerl 2008). At the time of writing, DIY has broken out of its origins in home improvement (Davidson and Leather 2000) and underground music cultures (Spencer 2005) to encompass a broad range of craft cultures—scrapbooking, art-making, altered books, knitting, jewelry and apparel—all of which privilege the doctrine of the handmade (Lupton 2006, Wherry 2006).

The primary research question asks: From a social networks perspective, why do consumers engage in DIY experiences? Referring to the appropriation and reconciliation of social bonds through creative experiences and artifacts, a theory of *social creativity* is introduced. Social creativity is seen when designers simultaneously create DIY artforms and their own social networks through the: 1) transformation of intangible, fleeting relations and experiences into representative, tangible, permanent DIY artifacts, 2) inadvertent reconciliation and appropriation of social bonds vis-à-vis the design of DIY artifacts, and 3) departure from ordinary marketscapes through a multi-layered legitimization of social capital. Through a qualitative, grounded theory study that involves long interviews with 14 DIY designers (Strauss and Corbin 1998; Charmaz 2006), the findings reveal that social creativity enables an assertion of self into a world that is wrought with market-centered meanings that claim responsibility and recognition for drawing consumers together (Diamond, Sherry, et al., forthcoming).

DIY industries have witnessed phenomenal growth in recent years, leading experts to refer to this "new wave of craft" (Levine and Heimerl 2008) to include, for example, the home improvement industry with sales almost doubling from approximately \$160 billion in 1999 to \$290 billion in 2008 (Home Improvement Research Institute 2009) and the scrapbooking industry, rising from a \$500 million industry in 2000 (Fram 2005) to a \$2.9 billion industry in 2007 (Craft and Hobby Association 2007). Knitting, once an association of elderly women, has become a cool activity for the young, with a resurgence in popularity for women under 30 who embrace the social, meditative, and political aspects of knitting (Gschwandter and Shirobayashi 2007; Stoller 2004; Greer 2008). Finally, DIY-oriented Internet services such as Etsy and Cafepress offer online resources for consumers to design and sell their products. Since Etsy opened in 2005, over 100,000 DIY designers have opened virtual stores on the web portal.

The recent surge in DIY activity and the increasing number of consumers engaging in creative experiences is suggestive of changing socio-cultural trends among consumers. However, previous studies of creativity largely focus on either the individual psychological motivations from a consumer's perspective or the factors that affect industrial design from the firm's perspective. For example, the consumer research literature explores creative experiences as linked to cognitive motivations such as gaining self esteem (Csikszentmihalyi 2000), competence (Watson and Shove 2008) and autonomy (Dahl and Moreau 2007). Meanwhile, the industrial design literature focuses on individual producers' frames of mind, and how various factors and techniques, such as imaginative thinking, analogic thinking, input constraints and empathy, lead to creative results (Dahl, Chattopadhyay and Gorn 1999; Dahl and Moreau 2002; Moreau and Dahl 2005; Dahl and Moreau 2007; Durgee 2004). In short, there is a gap in the consumer creativity literature regarding social motivations of creativity.

The findings begin to address this gap by revealing that the outcomes of DIY as an artform are not limited to the creation of beautiful meaning-laden arts and crafts, but also include the transformation of mundane minutiae of everyday objects into representations of social bonds and experiences. In this way, consumers engage in DIY experiences to mitigate social isolation and the perceived and actual fragmentation of social networks. More specifically, consumers impute meanings that are gleaned from past times, faraway places, and sought after relational spaces into their current lives. DIY designers actively reconcile the lack or conflict of meaning that exists in their

current contexts by assembling and integrating banal objects and meanings into DIY artifacts such as scrapbooks, wood sculptures, or quilts that are more representative of their sought after social experiences.

Surprisingly, even though consumers engage in DIY experiences to transform and create artifacts, DIY designers are themselves transformed because the creativity process re-creates the importance they ascribe to their social bonds through an affirmation of social relations, positions and roles imbued into the DIY artifacts. On one level, consumers essentially create storybook social narratives by selectively creating objects that memorialize and legitimize social ideals and happy times, as opposed to lived realities. On the second level, when these artifacts are displayed in their homes or given as gifts, for example, the importance ascribed to their social bonds and social networks is affirmed by others. In this way, consumers bridge their actual lives and their social ideals by transcending and deviating from traditional expectations of social relations. In some situations, social bonds extend beyond nuclear family relations to include friendship relations that are deemed more important than familial relations. In other situations, social bonds that have gone sour are re-created through snapshots of happy times and happy places made permanent because of DIY artifacts.

DIY experiences provide a modern-day 21st century mechanism for consumers to re-establish century-old humanist traditions of group bonding through craft-making and story-telling that takes place outside of markets but is enabled by DIY market processes. Most important, DIY experiences enable consumers to take comfort in social bonds that exist beyond the disintegrating nuclear family (Graham-Niderhaus and Graham 2007) by allowing them to express fondness and confirmation of extended family bonds, non-familial social bonds, and other types of bonds. At a time when fragmentation and uncertainty are at their highest, consumers engage in DIY experiences to reify their experiences of community-building and social bonding to provide evidence—through DIY artifacts—that social bonds still matter.

From Why and What to Where I Post: Online Poster Behavior

Yu-Jen Chen, University of Maryland, USA
Amna Kirmani, University of Maryland, USA

Suppose you want to tell others about your recent experience with a new Nikon digital camera. You are a user of the Internet, and you have been on various websites related to digital cameras. Among the numerous websites and online discussion forums that provide digital camera discussion platforms, which type of website might you choose to post your review: a heterogeneous audience, product category website, such as Digital Photography Review, or a more homogeneous audience website that is focused on the Nikon brand, such as Nikonians.com?

There is a large amount of research on word of mouth (WOM) in general (Dichter 1966; Herr, Kardes, and Kim 1991; Ward and Ostrom 2006) and online word of mouth in particular (Godes and Mayzlin 2004). Although research has addressed the importance of online consumer communication, the focus of previous research has been on the effectiveness of online WOM from the information receiver standpoint (Mayzlin 2006; Chevalier and Mayzlin 2006). Some researchers have examined why people might participate in online communication (Ward and Ostrom 2006; Schau and Gilly 2003) or what the content of such communication might be (Schlosser 2005); however, they have not related this to where to post. For instance, Schlosser (2005) finds that online posters tend to provide more negative product reviews than do lurkers (those who only read reviews). However, her research setting is limited to poster behavior on a single website rather than dealing with multiple sites.

In this paper, we examine how consumers' motivation to post (why) as well as the valence of the message (what) affects the decision of where to post. We define posters as people who use the Internet to post public product related information or experience. Such product information could be on a discussion site, a forum, or a bulletin board, but not private communication such as E-mail or personal website. In terms of where to post, we compare two types of online forums: 1) a more heterogeneous audience forum frequented by category users with varying brand preferences (e.g., a product category forum); and 2) a more homogenous forum of consumers who like the specific brand. We examine two motives that might lead consumers to participate in online posting: 1) the motive to influence others' behavior and 2) the motive to affiliate with others. The motive to influence others reflects consumers' desire to persuade others to their own point of view (Engle and Blackwell 1982), to build a reputation as an opinion leader (Robertson, Zielinski, and Ward 1984), or to be seen as knowledgeable. The motive to affiliate with others reflects a desire to associate with others who have similar interests, such as members of relevant reference groups, e.g., brand users.

We predicted that, in general, consumers with an influential motive will be more likely to post on the product category forum because of its heterogeneous audience that provide more potential impact of the post (H1a). In contrast, consumers with an affiliative motive may be more likely to post on a brand forum, since this satisfies their relatedness needs to affiliate others with similar brand interest and attitude (H2a). Moreover, we propose that the relationship between social motives and the choice of where to post is moderated by the valence of the message (e.g., positive or negative). Specifically, H1a and H2a are based on the positive valenced message. However, the salient and diagnostic nature of negativity effect of message could lead to different posting outcomes (Ahluwalia, Burnkrant, and Unnava 2000; Shiv, Britton, and Payne 2004). That is, when the message is negative valenced, posters with influential motive may switch to a brand website either to warn or affect those brand lovers (H1b). Those with affiliative motive might less likely to choose a brand website to avoid weakening relationship with other brand lovers (H2b).

We conducted two studies to test our hypotheses. In Study 1, we manipulate the motivations as well as the message valence by asking participants to imagine the product experience depending randomly assigned conditions. Specifically, the scenario was that participants were instructed to imagine their digital camera (e.g., Nikon D700) experience as either good or bad and were asked to choose a website to post their experience (in the control motive condition) or to make their post have as much impact as possible (in the influential motive condition). Then, participants indicated which website is more appealing to them to post their D700 experience on a seven-point scale (1= definitely Nikonians, a brand website; 7= definitely Digital Photography Review, a product category website). The result of the 2 (motive: influential vs. control) x 2 (valence: positive vs. negative) between-subjects ANCOVA with Nikon familiarity as a covariate supported our predictions. First, as suggested by H1a, when posting positive messages, consumers' where to post decision shows no difference between influential motive and control motive, namely, they are as likely to post on a product category website ($M_s=5.9$ and 5.4 , respectively; $F(1,55)=.89$, $p=.35$). Second, as suggested by H1b, when posting negative messages, posters whose primary motive is influential were more likely to choose a brand site than posters in the control group were ($M_s= 4.2$ and 5.3 , respectively, $F(1,55)=3.62$, $p<.06$).

The proposed Study 2 will include the second posting motive, affiliation motive, and conduct the experiment in the similar manner as we did in the study 1. While the Study 1 focuses on testing only hypothesis 1, the Study 2 attempts to test H1 and H2 simultaneously. We further include two posting options for participants. First, participants will have the alternative to choose not to post to reflect their low involvement in the study or low posting motivation. Second, we provide a new forum option, an anti-brand forum with homogeneous negative brand attitude audience. This allow us to further explore H2b in whether consumers choose not to post negative message on a brand is driven by punishment avoidance (if similar posting preference on a product category forum and on an anti-brand forum) or by affiliation with similar others (if higher posting preference on an anti-brand forum than on a product category forum).

Understanding the Role of Brand Personality Fit and the Moderating Effect of Self-Connection in Brand Extension Evaluations

Zhuohao Chen, University of Warwick, UK
Zhi Lu, Fudan University, China

Brand extension has become an increasingly critical research issue as the scope, stretchability or extension potential determines the boundary of a brand (Ahluwalia 2008; Meyvis and Janiszewski 2004). Prior research asserts that fit or perceived fit between original category and the brand extension serves as an important antecedent of consumer brand extension evaluations (Aaker and Keller 1990; Park et al. 1991). In marketing practice, however, more and more brands extend to apparently unfit or dissimilar categories. Successful examples include Pepsi music, BMW sportswear, and Virgin airlines, media, cola and mobile. We can find that all these brands are embedded with a distinct brand personality. Although they are not necessarily accepted by all the consumers, these brand extensions are favoured by a specific group of consumers, who love and are emotionally connected to the brand. Such brand extensions based on personality are beyond existing understanding of perceived fit. In this research, therefore, it is proposed that brand personality fit, which is supposed to be another dimension of perceived fit and refers to the consistency of consumer brand personality perceptions before and after brand extension, influences consumer brand extension evaluations, and that this brand personality fit is more easily accessible when an individual has self-connection with the brand.

To explore whether a brand with unique brand personality is easier to extend to dissimilar categories, we need to understand the role of brand personality fit. A large amount of literature in brand extension argues that “fit” or “perceived fit” affects consumer brand extension evaluations (e.g., Aaker and Keller 1990; Boush and Loken 1991; Broniarczyk and Alba 1994; Park et al. 1991). In terms of balance theory (Heider 1958), a consumer tends to support a brand extension if he or she has favorable attitude toward the parent brand and perceives fit between core category and the brand extension. Three types of perceived fit can be concluded from prior research. First, category-based fit assumes that feature similarity is the basis of categorization (Tversky 1977) therefore similar category or feature (e.g., white appliance) leads to a favorable brand extension (Boush and Loken 1991). Next, further research finds consumers evaluate fit with a specific benefit or goal (Broniarczyk and Alba 1994; Martin and Stewart 2001). Specifically, similar context of usage aiming at a benefit (e.g. tooth brush and toothpaste for the benefit of dental health) increases perceived fit (Joiner 2006; Ratneshwar and Shocker 1991). Third, brand-based fit theory underlies the fit of brand image or brand concept (Park et al. 1991), which is accessible when consumers evaluate symbolic brand extensions. Here, brand-based fit is a relatively broad concept (Czellar 2003) so that brand personality fit can be viewed as a critical facet of it. Thus, brand personality fit is hypothesized to positively influence consumer brand extension attitude.

However, not all of the consumers achieve the understanding of brand personality fit, which is retrievable when the consumer is emotionally self-connected to the brand. Generally, we can view the process of fit as a cognitive evaluation process, after which brand extension attitude is formed, but some emotional consumers do not evaluate brand extensions step by step. Research finds that consumer brand extension evaluation process can be an affective process, i.e. parent brand attitude can be directly transferred to brand extension attitude without mediation of perceived fit if a consumer has a high brand affect (Yeung and Wyer 2005). Recent research on affective evaluation process (Barone 2005; Barone and Miniard 2002; Barone et al. 2000) also supports that original brand favorability moderates the process of brand extension evaluations. Therefore, it is likely to argue that consumers with various brand relationship will follow different evaluation paths in brand extension attitude formation. Self-connection, which reflects the sense of belonging of a consumer to a brand, is a key dimension of brand relationship (Fournier 1998). In addition, this variable is also influenced by brand personality. If an individual finds his or her personality or expected personality is congruent with the brand personality, he or she will feel more connected to the brand, therefore favors the brand (Aaker 1997; Sirgy 1982). Consider such an extreme situation: a consumer who is firmly connected to a brand will regard himself as a part of the brand, therefore unconditionally favors whatever extensions the brand makes, regardless of perceived fit. In this case, it is congruency between self and brand, rather than fit between original category and brand extension, that determines brand extension attitude. The focus of brand extension evaluation shifts from product to person. So, we hypothesize that self-connection moderates brand extension process. For highly self-connected consumers, core brand attitude directly affects brand extension evaluation without mediation of perceived fit. For low self-connected consumers, core brand attitude affects perceived fit, and perceived fit affects brand extension evaluations.

A main study with three steps of analysis is designed to investigate these effects. Two pretests were conducted to test brand personality (Aaker 1997) and select fictitious brand extensions before the 2 (brands) × 2 (category medium fit vs. unfit) × 2 (brand personality fit vs. unfit) main study. We collected data in China. Two well-known telecommunication brands under China Mobile were selected: M-zone with unique brand personality of excitement and G-tone with unique brand personality of competence. Digital products (PDA and MP3) represented medium category-fit extensions, while wristwatch represented unfit extensions. G-tone PDA, M-zone MP3, G-tone dress watch, M-zone sports watch represented brand-personality-fit extensions, while G-tone MP3, M-zone PDA, G-tone sports watch and M-zone dress watch were brand-personality-unfit extensions. Respondents were asked to report their attitude and purchase intention toward these extensions. Perceived fit (category-based fit, benefit-based fit and brand personality fit), core brand attitude, self-connection were also measured in the questionnaire. The first step of analysis is aimed to investigate the effect of brand personality fit on brand extension evaluation. Results indicate that personality fit brand extensions have significantly higher evaluations than personality unfit ones, while there is no significant difference between category fit and unfit extensions. In the second step of analysis, we testify a general model, in which perceived fit, including the dimension of brand personality fit, has significant influence on brand extension attitude. In the third step of analysis, we split the samples in terms of self-connection and compare the models by means of grouped structural equation modeling. It is found that the influence of brand personality fit on brand extension attitude differs significantly between the two models. Consumers of highly self-connection yield greater influences than those of low self-connection, which supports the moderating effect of self-connection.

Once Bitten, Twice Shy: Differences in Social Efficacy Affect the Perceived Efficacy of Anthropomorphizable Products

Bart Claus, K.U. Leuven, Belgium

Luk Warlop, K.U. Leuven, Belgium

Anthropomorphism as a marketing practitioners' technique of imbuing brands and products with human-like qualities such as faces, names, and intentions, has longtime been used, and has proven to be efficient in the development of brand personality (Aaker 1997) and the building of brand relationships (Fournier 1998). Consumer literature has mainly dealt with the effectiveness of anthropomorphism as a practitioners' technique in influencing brand perceptions. The work by Aggarwal and McGill (2007) signals a recent shift in attention from brands towards anthropomorphic products, showing that a fit between the imbued human scheme and the nature of the products helps in anthropomorphizing the product, and that affect towards the evoked human scheme influences the evaluation of the product. A more fundamental shift is that lately, anthropomorphism—the evocation of the human scheme by means of the design or qualities of an object—has been studied from a more phenomenological stance. Instead of studying the anthropomorphic objects, research has turned its attention to the human mind where the anthropomorphization of the product takes place. This shift also comprises interest in the dispositional and situational drivers of anthropomorphization (Epley et al. 2008a; Epley et al. 2008b; Epley, Waytz, and Cacioppo 2007), and ultimately might allow us to understand some human reactions and behavior towards non-human objects in terms of their interpersonal correlates—think of irrational anger towards a failing tool or machine.

Epley and colleagues have conceived a three factor model of anthropomorphization, in which sociality motivations are one of the driving factors (Epley et al. 2007). When people are lonely, they seek human company, and this increases their susceptibility to anthropomorphization of non-human entities, like alarm clocks and pets (Epley et al. 2008a). This might lead to the inference that lonely people are more prone to anthropomorphization in consumer settings, and therefore unambiguously prone to preferring and seeking out products that are easy to anthropomorphize.

However, loneliness can be a result of difficulties in maintaining satisfactory social contact with other humans. Loneliness is usually considered to be co-driven by personal factors and circumstances (Jones, Freemon, and Goswick 1981; Leary 2001). Indeed, loneliness can be the result of social exclusion (Gardner et al. 2005; Leary 1990), rejection (Boivin, Hymel, and Bukowski 1995) and ostracism (Cacioppo and Hawley 2005; Zadro, Williams, and Richardson 2004). Although people may want to reconnect to others to compensate

for the experiences of loneliness, social anxiety and fear of negative outcome might influence their attitude towards new social contacts (Maner et al. 2007). In short, some—not all—loneliness can be a result of poor social efficacy, this latter having profound effects on how people approach subsequent social interactions. With regard to anthropomorphization of products, we expect that lowered social efficacy will translate into lower a priori expectations towards the anthropomorph at hand. We tested this inference in two studies, one gauging for chronic social efficacy, the other using an experimental manipulation.

In the first study we built on Leary et al.'s Sociometer Theory (Leary et al. 1995), in assessing people's chronic efficacy in social interactions. This theory states that self-esteem is a gauge for people's perceived efficacy in their social interactions. We had participants evaluate the expected number of times (out of twenty) that they would indicate the same number (one to five) as a random number generator that was depicted as an ordinary personal computer. In the control condition, we explained that this was in fact a computer that drew random numbers. In the experimental condition, the depicted computer was added with three buttons, of which the configuration resembled that of a human face (one broad button at the bottom resembling a mouth, two at the top left and right corner of the screen to resemble eyes). Also, the description of the computer was altered to a more anthropomorphic one, by giving it a name—"Puck the pc"—and stating that it "has a number in mind". Afterwards, a trait measure of self-esteem (Rosenberg 1965) was administered. Results demonstrate that in the experimental condition, trait self-esteem is positively related to people's estimation of future outcomes the product will deliver—more than in the control condition.

In the second study, we manipulated social efficacy between subjects, using a task that evokes ostracism (Williams, Cheung, and Choi 2000). The product that had to be evaluated was an automatic vacuum cleaner, and we asked participants about their expectations about the efficacy of the product. We manipulated anthropomorphism by describing the product either in terms of its technical characteristics and product code "Samsung VC-RS60H"—in the control condition—or in terms of more human traits ("a helping hand in the household") and the more friendly name "Roomba"—in the experimental condition. A pretest earlier had ruled out differences in liking for the two descriptions. Consistent with study 1, results show that people's estimates of the product's efficacy are lower when they have been ostracized—but only in the experimental condition. A manipulation check confirmed that the manipulation was indeed successful in eliciting human qualities in the product, and that ostracism did not interact with the manipulation of ostracism, ruling out an explanation that would attribute the effects to ostracism leading to a greater susceptibility to anthropomorphize.

In these two studies, different operationalizations—visual and verbal as well as different objects—of anthropomorphism are used, and the anthropomorphization manipulation is checked. We show that differences in social efficacy affect a priori evaluations of the efficacy of products, and we rule out a potential alternative explanation—differences in the degree of anthropomorphization induced by ostracism—of these results. These studies bring anthropomorphization as a phenomenological process into the field of consumer research, relating the effects of anthropomorphization to the anthropomorphizing consumer, and fit the recent shift in attention from anthropomorphism in brands towards anthropomorphism in products. Future studies will further assess the exact nature—trust, anxiety, retreat—of these effects, by including process measures, and establish boundary conditions where the need for humans might overpower these effects.

To Be American Is To Be Rich: Immigrants Use of Possessions Both in the US and in Their Native Countries to Convey Consumer Acculturation

Garrett Coble, Oklahoma State University, USA

Consumer acculturation is a topic that has been investigated in our literature (Oswald 1999; Peñaloza 1994; Thompson and Tambyah 1999). It has been broadly defined as a "general term that encompasses intercultural interaction and adaptation and includes assimilation of a new culture, maintenance of the old culture, and resistance to both new and old cultures" (Peñaloza and Gilly 1999). Scholars have sought to better understand the process immigrants go through in terms of consumption when moving from one culture to another (e.g., Thompson and Tambyah 1999; Ustuner and Holt 2007). The author has looked at the role immigration policy plays on that consumer acculturation process (Coble, Jiménez, and Mason 2008). In the process, a question that has arisen is why some product categories are adopted quicker than others. Another pressing question is how those product categories are consumed when immigrants visit their native countries. Every year, small towns in countries such as Mexico are flooded with immigrants visiting with arms and cars full of possessions from countries such as the US. From the author's experience living in a small Mexican town, he has seen almost an inflated level of consumer acculturation in terms of the possessions returning immigrants have, the language they speak, and the currency they use. This brings to light several questions. If consumer acculturation is inflated, why? What new insight does that give us in terms of acculturation theory? Also, if acculturation is inflated, what is the mechanism behind that?

This paper will contribute to the consumer acculturation literature by examining the role different product categories play in the acculturation process and how that is lived both in the host country and back in the home country. Some questions to be addressed are "how are products adopted and consumed in the host country?" "when traveling back to their native countries, how do immigrants use possessions?" and "what type of possessions do immigrants value during the transition?" These questions should also address the bigger issue of what role different product categories play in the acculturation process.

Methods

To begin this study, key informants have been questioned regarding their experiences both in the US and back in their native countries. Through those initial interviews, several themes have started to emerge. They are the meaning of the American dream, the expectations of living and working in the US, and the opportunities for conspicuous consumption.

The contexts the author will use to better understand this phenomenon are a large city in the Midwest with a large population of Mexican Americans and a southern state of Mexico where hundreds of Mexicans return every year for the Christmas season. The author has conducted extensive fieldwork and interviews in the US city for other projects regarding immigration and marketing issues. He has worked with the Hispanic chamber of commerce, a local Spanish TV station, and is on the board of directors for the coalition of Hispanic organizations. The town in Mexico where the work will be conducted is small (about 8,000 people), but it was chosen because of the flood of immigrants that return every year for the Christmas season. The author has lived in this small town as an exchange student, but starting in the fall, he will spend extensive time there as a researcher, conduct semi-structured depth interviews, collect artifacts, and use field notes to investigate the consumer acculturation process the returning immigrants are going through as they return to their native country. The entire project will entail training local Mexicans who are returning immigrants to help with the interviews and interpretation of the findings. The work will be conducted both in the US and in Mexico. Interviews and fieldwork in the US will focus on the issues of product categories in the acculturation process. Work conducted in Mexico will center around the issue of the meaning of those products in the transition back home. This work should give us better insight into the acculturation process in terms of product categories and open the door to future work on re-acculturation.

Anchors in Range Pricing: How Do Consumers Choose What to Pay?

Annie Peng Cui, West Virginia University, USA
Jennifer Wiggins Johnson, Kent State University, USA

How do consumers decide what price to pay when they are asked to choose a price within a range of acceptable prices? We suggest that consumers interpret the price range as a range estimate reference price. We show that consumers perceive the endpoints of the range as external anchors and adjust their willingness to pay in the direction of both anchors. In addition, the introduction of a midpoint into the price range increases the likelihood that consumers will choose the midpoint as their price. We further show that different consumers rely more heavily on different anchors in their pricing decision.

The Influence of Regulatory Focus on the Interpretation of Verbal Versus Numerical Probabilistic Information

Ahmad Daryanto, Newcastle Business School, UK

Abstract

This research examines the link between regulatory focus and people's interpretation of verbal versus numerical probabilistic. Our study shows that people's goals associated with regulatory focus influence the interpretation of verbal versus numerical uncertainty information. The findings indicate regulatory fit occurs when prevention focus is matched with numerical information, whereas no fit effect occurs when promotion focus is matched with verbal information. Our study reveals that people in fit effect assign more values to an advocated program and show a higher motivation to engage in the program.

Overview of the Research

In everyday life, people encounter with uncertainty information. The information can be expressed either in words or numbers. For instance, recently, the US presidential candidate, John McCain, commented about current US economic situation: "I would say that it's very likely and more and more economists are saying that, that we are probably in a recession" (CNN Live Feed, Atlanta, GA, 3/7/08). In another occasion, Alan Greenspan, a former US Federal Reserve chairman, preferred to describe the economic situation by using numbers instead of words: "There is more than a 50 percent chance the United States could go into recession" (www.bloomberg.com). Considerable research has examined how people interpret these two modes of information, i.e., verbal versus numerical expression (e.g., Von Winterfeld and Edwards, 1986). However, research findings regarding people preference for these two formats is unequivocal. Some have shown that numerical formats are preferable than verbal formats (e.g., Von Winterfeld and Edwards, 1986), some others demonstrated a greater preference for verbal formats (e.g., Brun and Teigen, 1988), whereas others have documented equal preferences for both formats (e.g., Wallsten, Budescu, and Zwick, 1993; Budescu, Weinberg, and Wallsten, 1988). Although, some research has examined the influence of moderating variables (e.g., perceived risk with respect to the consequences of information; Merz, Druzdzel and Mazur, 1997; availability of specific data in the large amount; Wallsten, Budescu and Zwick, 1993), which may play a role in the preferred mode of information, the potential influence of people's motives in processing of information has received less attention (for an exception Halamish et al., 2008). Therefore, the primary objective of the present research is to examine regulatory focus as another potential moderator. In the present study, we considered the role of regulatory focus (i.e., promotion and prevention focus) on the interpretation of verbal vs. numerical probabilistic information. Our aim is to contribute to the extant literature of probabilistic information processing.

Significance and Implication of the Research

Studies of numerical versus verbal probabilities generally found that verbal information was perceived to be more highly imprecise, vague, and subject to multiple interpretations and was influenced by the severity of the consequences associated with information (e.g., Merz, Druzdzel, and Mazur, 1991). For example, low probability of getting a lower grade was interpreted differently than low chance of passing an exam. Nevertheless, verbal expression was perceived to be more natural than numbers, easier to understand, and better suited to express vagueness (Wallsten, Budescu, and Zwick, 1993). However, Brun and Teigen (1988) found that verbal information is less preferable for patients because they find it difficult to comprehend and imprecise (e.g. "how low is my chance to get the disease?"). Authors who support the preference for verbal over numerical formats argued that verbal probability expression is more consistent with human intuitive thinking than numerical probability expression (e.g., Douppnik and Richter, 2004). Therefore, these calls for a need to gain a deeper understanding how people process probabilistic information.

With respect to processing verbal vs. numerical probabilistic information, we proposed that regulatory fit occurs when promotion focus is matched with verbal formats, whereas when prevention focus is matched with numerical format. In these situations, we expect that promotion-focused people will assign more value to an object and exhibit stronger goal pursuits when they are presented with verbal probability expression rather than numerical probability expression. In contrast, we expect prevention-focused people to assign more value to an object and exhibit stronger goal pursuits when they are presented with numerical probability expression rather than verbal probability expression. To support this prediction, the link between RF and verbal versus numerical processing is established as follows. First, the preference for either a verbal or a numerical format relates to the preference for either abstract or concrete information (Budescu, Weinberg, and Wallsten, 1988, Wineschilt and Wells, 1996). In the context of RF, the issue of how people process abstract and concrete information also appears. Semin, Higgins, and Montes (2005) demonstrate that prevention-focused people prefer concrete information because of its relation to a strategic focus on vigilance to maintain security and ought goals (i.e., duty and obligations). In contrast, promotion-focused people prefer abstract information to concrete, because of its relation to a strategic focus on eagerness and ideal goals (i.e., hopes and

aspirations). Semin, Higgins, and Montes (2005) also reveal that promotion-focused people indicate greater intentions to exercise when the benefit of that exercise is communicated with abstract terms, such as “exercise can increase endurance levels and energy.” In contrast, prevention-focused persons show a higher intention to exercise when its benefits are communicated in more concrete ways, such as “exercise can burn approximately 440 calories per hour.”

To test our prediction, we designed a 2x2 between-subjects experiment in which we manipulate regulatory focus (promotion vs. prevention) and the mode of presentation (verbal vs. numeric). We investigate the regulator fit effect in the situation of moderate-to-high probabilities, because under low-to-moderate probabilities (i.e., around 30%), both promotion and prevention-focused respondents have the same subjective interpretation of the likelihood of an event (Kluger et al. 2004). This prediction was tested in a study involving hypothetical scenarios. Participants in the promotion condition read an appeal about the possibility of join unique career training which may help them getting a future job that they really want. Participants in the prevention condition read an appeal about the possibility of joining unique career training which may help them avoiding a future job that they do not want. After reading this text, participants read either verbal (e.g., “it is very likely that you get the job you want”) or numerical probabilistic information regarding the benefits of the program (e.g., “an 80% chance of getting the job”). After reading the scenario, participants rated their attitudes toward the program (3 items), their intention to join the program (2 items), using 7-point scales, anchored by strongly disagree [1] and strongly agree [7]. We also included items for manipulation checks for the modes of uncertainty information. The scale is adapted from a scale developed by Windschilt and Wells (1996) with the objective of cross checking whether respondents have the same interpretation about the magnitude of verbal and numerical uncertainty information. Participants who viewed the numerical format (i.e., 80% chance) indicated their verbal interpretations of these chances on 11-point scales ranging from impossible to certain. Participants in the verbal format condition (i.e., quite likely) instead indicated their numeric interpretation of this information on 11-point scales ranging from 0% to 100%.

With regard to presentation modes, the results show a non-significant difference between the numerical ($M_{\text{NUMERIC}}=3.2, SD=1.16$, i.e., between rather likely–quite likely) and verbal ($M_{\text{VERBAL}}=3.82, SD=0.81$, i.e., 70%-80%, $t(85)=1.35, p>0.05$). This result highlights respondents interpret verbal and numerical probability expressions as in the range of moderate-to-high.

To test the regulatory fit effect, the three attitude items ($\alpha=0.94$) and two intention items are averaged (0.92). As predicted, an analysis of variance yielded a highly significant interaction between regulatory focus and mode of presentation on program attitude $F(1,85)=5.43, p<0.05$ and intention, $F(1,85)=4.33, p<0.05$. As predicted, participants who read program benefits framed in prevention had more favourable attitude toward the program when presented with numerical uncertainty information ($M=6.21$ vs $5.36, t(36)=2.77$). Contrary to what we expect, no fit effect was found when participants read program benefits framed in promotion with verbal information.

These finding highlights the importance of fitting regulatory focus with probabilistic information. Additional research is needed to investigate the underlying mechanism of the fit effect (e.g., perceive confidence of the likelihood of event occurrence, the influence of problem context (on-going study)). For instance, the context of our study is promotion. Therefore, this may explain why we did not observe fit effect in the promotion-verbal condition.

The Impact of C-executives' Babyfacedness on Purchase Intention

Diana Dávila, Instituto Tecnológico y de Estudios Superiores de Monterrey, Mexico
Olivier Trendel, Grenoble Ecole de Management / Customer Equity Institute, France

Abstract

Business leaders often use their face to strengthen the organizational brand. The objective of this research is to understand the impact of C-executives' facial appearance (babyfacedness vs. maturefacedness) on purchase intention. We show that it is important for a company to match the face of the top executive delivering a message with the topic they articulate. Babyfaced executives should be favored when the topic concerns corporate social responsibility whereas maturefaced executives should be favored when the topic concerns technology or competitor orientation. Perceived benevolence, leadership or competence mediates these effects.

Research Background

Research on appearance-based impressions has demonstrated that people can form strong and reliable impressions about a target's character based on his/her facial appearance (Todorov and Uleman 2002). Babyfaced people who possess round face, large eyes, high eyebrows and small chin are universally attributed child-like characteristics and traits such as trustworthiness, warmth or honesty (Montepare and Zebrowitz 1998; Zebrowitz 1997). On the other side, maturefaced individuals are often attributed traits of leadership and competence (Todorov et al. 2005; Zebrowitz and Montepare 2005).

Perhaps more than at any time, business leaders are putting a public face on their company's brands. Building on the literature on first impressions, we suggest that the facial appearance of top executives can impact consumer purchase intention. Gorn et al. (2008) recently showed that the babyfacedness of a CEO can affect consumer judgments in a public relations crisis. They found that babyfaced CEO were perceived as having a lower intention to deceive than maturefaced CEO. Yet, situational cues, such as the severity of the crisis, can suppress or reverse this effect, thus babyfacedness is not always an advantage (see also Todorov et al. 2005).

Interview is a very common public relation tool for top executives and we suggest that it is important for a company to match the face of the top executive giving the interview with the topic they articulate in the interview. The topics selected in this research are directly linked to the dimensions of market orientation: customer orientation, competitor orientation and technological orientation (Narver and Slater 1990; Gatignon and Xuereb 1997). We also included an interview on corporate social responsibility (CSR) as CSR orientation has been suggested as being part of market orientation (Narver and Slater 1990).

We hypothesized that for an interview concerning customer orientation or CSR, purchase intention will be higher if the top executive has a baby face than if he has a mature face. On the other hand, for an interview concerning competition or technology orientation, purchase intention will be higher if the top executive has a mature face than if he has a baby face. The rationale is that customer orientation and CSR require the interviewee to be perceived respectively as warm and benevolent and these traits are associated with babyfaced individuals (Brown et al. 2002; Choi and Wang 2007). Interview on competition and technology require the interviewee to be perceived as competent and leader (Spence and Helmreich 1983). These traits are associated with maturefaced individuals and are contradictory with the perceived submissiveness of babyfaced individuals (Zebrowitz and McDonald 1991).

Empirical evidence of the impact of babyfacedness on purchase intention

304 students from a major Mexican business school participated in an experiment using a 2 (face: babyface vs. matureface) x 4 (interview: customer, competitor, technology and CSR) between subject design. Average age of the participants was 20 (62.5% girls). Participants were asked to carefully read a Business Week interview of the CEO of a communication company named Dalmex. The interview featured a photograph of the CEO. Eyes form, eyebrows and chin were manipulated on the photo to make two different versions (baby and mature face) of the same individual. A pretest enabled us to check the successful manipulation of perceived babyfacedness ($p < 0.001$). We also checked that perceived age and attractiveness were similar between the 2 pictures. The 4 interviews had the same length and we controlled that readability was the same between interviews. Finally, using the scale developed by Narver and Slater (1990) we used 4 contrasts to check that the manipulation of the topics was successful (all $p < 0.001$). Purchase intention was measured on a 1 (definitively would not purchase) to 7 (definitively would purchase) scale.

A 2 (face) x 4 (interview) ANOVA on purchase intention revealed the expected significant interaction effect ($F(3,275)=3.69, p=.012$). As hypothesized, we found a significant main effect of face for the CSR interview ($F(1,64)=4.80, p=.032$) such that babyfaced executives lead to higher purchase intention than maturefaced executives. This was however not the case for the customer orientation interview ($F < 1$). As hypothesized, we also found a significant main effect of face for the technology interview ($F(1,65)=4.04, p=.048$) as well as for the competitor interview ($F(1, 68)=4.61, p < .035$) such that maturefaced executives lead to higher purchase intention than babyfaced executives.

We used ANCOVAs to test for the mediational role of benevolence for CSR and of competence and leadership for the technology and competitor interviews. The previously significant effects of babyfacedness on purchase intention were no longer significant when the covariates were entered in the analysis (all $p > 0.12$). The mean square for the face effect was reduced on average by 55%.

Discussion

This research confirms the effect of top executives' babyfacedness on purchase intention. The topic of the interview given by C-executives moderates this effect such as babyfaced executives should be favored when the topic concerns corporate social responsibility whereas maturefaced executives should be favored when the topic concerns technology or competitor orientation. The facial appearance of C-executives should hence be matched with the topic he or she will articulate. The underlying process was also detailed and it should thus be feasible to extend these findings to other topics (e.g. financial performance). The null effect for customer orientation needs further research.

This research also adds to the body of research studying the role of public relations in shaping brand equity. We provide a case in which corporate associations built through public relations have an impact on purchase intention (a product level outcome) (Brown and Dacin 1997).

Mental Rumination: How Unwanted and Recurrent Thoughts Can Perturbate the Purchasing Behavior

Alain Debenedetti, Universite Paris-Est, France

Pierrick Gomez, Reims Management School and Université Paris-Dauphine, France

Rumination is a set of long-lasting, recurrent, unwanted, and counter productive thoughts. In clinical psychology, rumination is often mentioned as a consequence of post-traumatic events (Horowitz, 1976) or as an antecedent of depressive disorders (Nolen-Hoeksema, 1996). Martin and Tesser (1989, 1996, 2006) endorse a general view of rumination, removing it from its clinical context. Whereas individuals have many occasions to ruminate in their consumer's life, especially during their purchase decision process, ruminative thoughts have never been integrated into consumer behavior paradigm. Based on Martin and Tesser's motivational approach, we will first present rumination, then suggest some avenues for future research.

What is rumination?

In Martin and Tesser's model, rumination refers to thoughts 'that recur in the absence of immediate environmental demands requiring the thoughts' (Martin and Tesser, 1996, p.1). Rumination differs from other thinking processes because:

- It does not only occur once: what is central to rumination is not the content or any other quality of the involved mental activity but the circularity of the process.
- If some situations favor their apparition, ruminative thoughts are unintentional insofar as they revolve in the absence of immediate environmental cueing (Koole *et al.*, 1999).

Put differently, rumination is intrusive, anchored into a temporal dimension, and differs from other thinking processes which often deal with wanted tradeoffs.

Martin and Tesser's theory is based on one core principle: people's thoughts are always goal-directed. People continually compare their desired goal to their current states to regulate their behaviors. When a lack of progress towards the goal is perceived, ruminative thoughts are likely to appear (Martin and Tesser, 1996; Scott and McIntosh, 1999). In theory, each interrupted goal can initiate rumination (e.g. to do well on one's life / to buy a muffin), but the centrality of the goal in the individual's life defines the duration and the frequency of ruminative thoughts. In Martin and Tesser's model, emotions can not be considered as antecedents of rumination but as signals which inform the individuals that a major goal is threatened. The failure in problem solving strategies (instrumental thoughts) initiates ruminative thoughts and the emotions that go with them (affective thoughts).

Rumination is divided into 3 dimensions: the emotional valence of the thoughts (negative vs. positive), their temporal orientation (past, present or future) and the polarisation of thoughts (discrepancy focus vs. attainment focus, i.e., definitively non-attained goal vs. lack of progress towards the goal).

Given the intrusion of these recurrent thoughts into consciousness, rumination leads to an important consumption of cognitive resources (Martin and Tesser, 1989) and more specifically to:

- Increases in the intensity and duration of emotions (Martin and Tesser, 1989 ; Rusting and Nolen-Hoeksema, 1998);
- Lower cognitive performances (Scott and Mc Intosh, 1999): rumination leads to less awareness and less ability to solve problems (Sukhodolsky, Golub and Cromwell, 2001) and is followed by reduced self-confidence;
- Negatively biased judgments which alter individuals' choices and make them a) see problems more threatening than they actually are or b) overemphasize negative information related to their experience (Lyubomirsky *et al.*, 1999);
- A need for more temporal resources in decision making situations (Nolen-Hoeksema, 2000)

Ruminative thoughts in consumer behavior

We believe that rumination theory offers great potential for the study of consumer behavior, and is particularly relevant to better understand perturbations in the decision making process because:

- Consumption is a goal-oriented activity which leads to problem-solving situations (related to information search on products and/or brands, to prices and promotion, *etc.*)
- Rumination may arise at two different stages of the purchasing decision process. At the pre-purchase stage, we suggest that rumination is likely to occur when consumers have difficulties to solve the problem they confront (e.g., being unable to choose an Internet provider, fearing the risk of a wrong choice). At the post-purchase stage, rumination may occur when the decision produces undesirable outcomes (e.g., regretting to have subscribed to a non user-friendly Internet service).

The central role played by goals and the temporal dimension of rumination (e.g., pre-choice, post-choice) presents a significant advantage to understand the perturbations which can occur during consumers' purchase process. In that framework, rumination may play two main roles in the decision making process. Rumination may interact with other variables and moderate some consequences of consumers' decision making process. It could also be a mediator: rumination could have a direct influence on some emotional states or behaviors. This effect however would occur only and to the extent that rumination takes place. Because it considerably affects consumers' cognition and affect, rumination could foster unexpected and/or exacerbated behaviors (e.g., revenge; systematic choice deferral; systematic removal of brands from the consideration set of alternatives...). It also allows for the adoption of a different point of view on classical relationships between consumer behavior variables (e.g., satisfaction and repurchase, for example when consumers favor simplified choice reasoning).

In previous research on rumination, data are typically based on self reports using questionnaires or on manipulations designed to influence individual's thoughts and/or to put them into situations in which higher order goals could be frustrated. We could devise qualitative works and experiments adapted to the context of consumption behavior that would address the following questions: which (unhappy) consumption episodes instigate rumination? To what extent can marketing actions trigger rumination? Will every frustrated consumption goals initiate rumination or only specific high order consumption goals (related to the self, or high involvement product categories)? What is positive rumination (to date there is no research about positive rumination), when does it occur, does it improve one's image and does it also imply counterintuitive implications (e.g., negative effects, such as choice deferral because consumers do not want the positive thoughts to end...)? At which stage of the purchase process is rumination more likely to occur? How can we prevent consumers from engaging into a rumination process? How can we help companies to reduce the likelihood that their products and/or services (sorting them by categories) will trigger ruminative thoughts? Eventually, are some consumers more likely to ruminate than others?

Ad Avoidance and Brand Devaluation: When What They Don't See Can Hurt You

Brittany Duff, University of Illinois at Urbana-Champaign, USA

Ron Faber, University of Minnesota, USA

Every day we see thousands of advertisements, yet consumers actively attend to only a small minority of the ads they are exposed to. Most advertising research looks only at what happens after attention to the ad has occurred. While this is obviously important, it may be equally important to understand what happens to the ads that are not attended to, or purposely ignored.

Several advertising researchers have used the mere exposure effect (MEE) to suggest that avoided ads can have positive outcomes for advertisers (Edwards, Li and Lee 2002; Baker 1999). Zajonc (1968) showed that "unreinforced" exposure to novel stimuli increases liking of that stimuli. This is what has been cited in the many applications of MEE to ignored or passively viewed advertising. Indeed, Bornstein (1989) pointed out that advertising, which may be conceptualized as repeated, unreinforced exposures designed to enhance attitude, represents an important application of MEE. However, "unreinforced" implies that no affective response is attached to the stimuli, something that may not be the case in all instances of ad avoidance.

Distracter Devaluation

In opposition to MEE, recent research has found that non-attended objects (distracters) can lead to negative, rather than positive ratings. Raymond, Fenske and Tavassoli (2003) had participants view stimuli and quickly indicate on which side of the page the target stimulus appeared. Participants later rated their affect toward the attended (target) stimulus, the ignored stimulus, or a previously unseen (novel) stimulus. The ignored stimuli were rated lower than either the novel stimuli or the attended stimuli. This shows that attentional state during initial exposure can influence affective response when the stimulus is encountered again. When the stimulus is actively ignored during exposure it can cause a subsequent negative rating. This is referred to as the distracter devaluation effect.

Further studies demonstrated that overtly knowing what not to look at caused an even stronger negative affective association. This shows that top-down processing may create an emotional response, and that attention and emotion may work together to prioritize the processing of stimuli in order to help people accomplish task related goals (Fenske, Raymond and Kunar 2004). When engaged in visual search, it is inefficient to re-search areas or re-attend to items once it has been determined that they are not what is being sought. Thus we tag items as inhibited or negative so as not to process them again. While this is functional for goal-oriented behaviors, it suggests that ads that interrupt or distract from search efforts may actually harm brand ratings.

Motivational relevance

Object-based inhibition is part of a top-down attentional process and is dependent on limited-capacity resources (Olivers and Humphreys 2002). Top-down processing occurs when there is already a goal in mind (e.g. finding that specific book) versus a bottom-up approach where something may gain attention by catching your eye. We are constantly engaged in some sort of bottom-up processing as we scan our environments, but inhibition primarily occurs in goal-directed searches.

Certain items have been shown to be generally prioritized for processing- such as fearful faces or food. These items can be said to elicit motivated attention (e.g. Schupp et al 2004; Lang, Bradley and Cuthbert 1998). Salience can also be related to physiological drive states with increased attention for items related to eating found for participants who abstain from eating compared to those who didn't (Mogg et al 1998).

Study 1

Study 1 was conducted to determine if a goal-directed (top down) task would create brand devaluation for distracting ads, and if a physiological need state (affecting bottom-up processing) would impact these results. Participants ($n=118$) viewed 19 webpages that contained food-related news articles and ads (experimenter created). Some ads were repeated while others were included just once. Participants were randomly assigned to one of three conditions. Two groups (Task groups) were asked to find specific information on each page. One of these groups had food related ads on each webpage that were later rated, while the Task-No Ad group had different ads on their webpages that weren't subsequently rated and therefore served as a baseline in ratings. The third group (Non-Task Group) saw pages with the food ads, but were not given any tasks. They were told to look at the pages like they would any webpage that they were seeing for the first time. Each webpage appeared on screen for 15 seconds so that the time exposed to the pages was the same for all groups. Hunger levels were assessed before viewing since this should affect motivational relevance and prioritize the processing of food-related stimuli. This allows for an examination of the impact of both bottom-up and top-down attentional strategies.

Findings supported the hypotheses. A significant difference ($p<.001$) between hungry vs. non-hungry participants emerged. Hungry participants showed no differences between groups on ad liking and trial intent (all p 's $>.15$, n.s.). However, as predicted, non-hungry participants showed significant differences (in the predicted directions, with the AdsTask group showing the lowest means) for ad liking (repeated ads $F(2,57)=3.25, p<.05$; non-repeated $F(2,57)=3.65, p<.05$) and trial intent (repeated $F(2,57)=3.90, p<.05$; non-repeated $F(2,57)=5.97, p<.005$). There were no differences between non-hungry groups on liking or trial for the unseen (novel) ads.

Study 2

Study 2 ($n=138$) was conducted to clarify and extend study one results. The same stimuli and method were used. Dependent variables focused on mood,¹ self-reported attention to ads (vs. ignoring them), and ad recognition. No mood effects were present for either the hungry ($F(2,69)=1.42, p>.2$) nor the non-hungry groups ($F(2,67)=1.56, p>.2$). As expected, for the non-hungry participants there were differences by viewing group with the task groups reporting significantly lower attention to ads ($F(2,68)=6.75, p<.005$). However, for hungry participants there was no difference in self-reported attention to the ads between groups ($F(2,69)=.043, p>.9$). This suggests that for hungry participants bottom-up processing may override the top-down goal. Recognition scores also confirm that the devaluation effect most likely occurs without any explicit recognition of ads.

Overall the studies show that the outcome (negative or positive) may depend on goal at time of exposure.

The Sweet Side of Sugar—The Influence of Raised Insulin Levels on Price Fairness and Willingness to Pay

Tim Eberhardt, Zeppelin University, Germany
 Thomas Fojcik, Zeppelin University, Germany
 Mirja Hubert, Zeppelin University, Germany
 Marc Linzmajer, Zeppelin University, Germany
 Peter Kenning, Zeppelin University, Germany

Psychologists Daniel Kahneman and Amos Tversky have influenced the research in consumer psychology and behavioral economics over the last thirty years (Tversky and Kahneman 1974). While their findings have been useful in many fields of marketing research, they were particularly useful for research in behavioral pricing (e.g., Conover 1986; Vanhuele and Drèze 2002). Pricing research has traditionally analyzed such concerns as consumer judgment of price fairness in terms of the consumers' relationship to retailers. However, Knutson et al. (2007) moved the research in a new direction when they used event-related fMRI to investigate which distinct brain areas are activated in purchasing decisions dealing with products and prices. They found activity associated with anticipating gains and losses at the nucleus accumbens (NAcc), the insula, and the mesial prefrontal cortex (MPFC). Findings of Knutson et al. (2001) and Kenning and Plassmann (2008) show a specific stimulation of the NAcc in anticipation of a reward, indicating the importance of the NAcc in consumer behavior studies. Further, the role of serotonin, which has long been implicated in social behavior (Kandel et al. 2000) and which is believed to play an important role in activating the NAcc (Purves et al. 2008) can be linked to raised levels of tryptophan in the NAcc (Crockett et al. 2008). If, therefore, raised levels of serotonin are associated with higher levels of tryptophan, and knowing that raised levels of insulin in the blood increase the supply of tryptophan (Daniel et al. 1981), the link between insulin level and social behaviors (particularly those associated with consumer behavior) suggests a valuable area of investigation.

Though the effects of e.g. dopamine levels in humans have increasingly been in the focus of academic scrutiny in the field of economics (Balleine et al. 2009), the effects of serotonin has, to date, received less attention. This investigation is one of the first to explore the biological correlates of raised insulin (and hence serotonin) levels on buying decision behavior in a price fairness task, with the goal of providing new findings for psychologists and marketing researchers.

Our study used a paper-based presentation of 48 convenience goods (24 premium brands, 24 store brands, colored pictures, prices in ¢), intending to activate a low-involvement situation for the participants of the study (Monroe and Lee 1999). Involvement was checked

¹Diffuse positive affect as shown by mood is posited to be a factor in MEE (Monahan, Murphy and Zajonc, 2000)

using the Purchase Decision Involvement (PDI) scale developed by Mittal (1989), consisting of a four-item measure on seven-point bipolar phrases. Participants had to decide whether or not they considered the given price of a product to be “fair” and, if not, what price they would be willing to pay with the option to adjust prices for each individual product. In the forced-choice-task, each subject had to evaluate six items for one product (288 decisions). A May 2008 pretest containing 10 subjects confirmed validation and distinctiveness of both the stimulus material and the translated items. The pretest also served as a first measure of the effects of different glucose manipulations on the subjects. In February 2009, 37 selected undergraduate students (21 male, 16 female) participated in the main study. We divided the participants into three groups. Subjects of the experimental group (14 subjects) were manipulated using 90 grams (recommended daily allowance for a healthy adult) of pharmaceutical glucose dissolved in 0.3 liter of sparkling water. Control group I (14 subjects) had to drink 0.3 liter sparkling water with no glucose added to the water. Control group II (nine subjects) drank no water and was not manipulated at all. Study design for every participant followed precisely the insulin release curve of a healthy adult metabolic subject (Suckale and Solimena 2008) to match the hypothetical insulin level of the subjects to their respective response behavior.

Statistical analyses were conducted with SPSS. For the analysis of our data we used a simple independent t-test, including “Levene’s Test” to explore equality of means and variances between our study groups. Normal distribution condition was examined with the Shapiro-Wilk-Test, which is generally used for small sample sizes ($n < 50$). The analysis of our data and the identified structures with significant changes between the experimental group and the two control groups revealed very interesting results, confirming our hypothesis that glucose levels change perception of price fairness and willingness to pay.

The experimental group evaluated all prices of our product-portfolio ($n=48$ products) to be more fair than did their counterparts in both control groups [*product-portfolio*: $M_{\text{experimental group}}=69.93$; $SD=5.98$ / $M_{\text{control group I}}=62.30$; $SD=5.77$; 69.93 vs. 62.30 ; $t=3.44$, $p < .01$; $M_{\text{experimental group}}/M_{\text{control group II}}=63.14$; $SD=6.00$; 69.93 vs. 63.14 ; $t=2.66$, $p < .05$]. Subjects in the experimental group were willing to pay much higher prices for the same products than were subjects in both control groups. This effect was also revealed by testing different prices of store brands ($n=24$ products, price-range between 0.29 - 2.55 ?; $M=0.79$?) and premium brands ($n=24$ products, price-range between 0.55 - 11.99 ?; $M=2.29$?). Overall, the experimental group accepted higher prices while subjects in both control groups rejected higher price-levels over total response time within the experiment [*store brands*: $M_{\text{experimental group}}=20.03$; $SD=2.21$ / $M_{\text{control group I}}=18.69$; $SD=.73$; 20.03 vs. 18.69 ; $t=2.16$, $p < .05$; $M_{\text{experimental group}}/M_{\text{control group II}}=18.00$; $SD=0.95$; 20.03 vs. 18.00 ; $t=3.03$, $p < .01$; *premium brands*: $M_{\text{experimental group}}=49.90$; $SD=4.36$ / $M_{\text{control group I}}=43.61$; $SD=5.66$; 49.90 vs. 43.61 , $t=3.29$; $p < .01$; $M_{\text{experimental group}}/M_{\text{control group II}}=45.14$; $SD=5.68$; 49.90 vs. 45.14 , $t=2.14$; $p < .05$].

Second, we tested differences between two levels of insulin at two intervals (within the first 10 minutes and after 40 minutes), following the insulin release curve of a healthy adult metabolic subject. The above-mentioned effect differential between the experimental group and the two control groups could be confirmed in the first range of our study over all products (within 10 minutes after glucose manipulation; first peak of insulin release curve). [The following figures indicate price variances of the total sum of the product-portfolio: *product-portfolio*: $M_{\text{experimental group}}=1.43$; $SD=2.51$ / $M_{\text{control group I}}=5.90$; $SD=3.93$, 1.43 vs. 5.90 ; $t=-3.60$, $p < .01$; $M_{\text{experimental group}}/M_{\text{control group II}}=5.37$; $SD=3.47$; 1.43 vs. 5.90 ; $t=-2.95$; $p < .01$.] The same effect was identified by testing premium brands with our study groups, but not for store brands. [The following figures indicate price variances of the total sum of the product-portfolio: *premium brands*: $M_{\text{experimental group}}=1.43$; $SD=2.14$ / $M_{\text{control group I}}=5.50$; $SD=3.83$; 1.43 vs. 5.50 ; $t=-3.46$; $p < .01$; $M_{\text{experimental group}}/M_{\text{control group II}}=4.86$; $SD=3.41$; 1.43 vs. 4.86 ; $t=-2.69$; $p < .05$; *store brands*: $M_{\text{experimental group}}=-.01$; $SD=.90$ / $M_{\text{control group I}}=.41$; $SD=.55$; $-.01$ vs. $.41$; $t=-1.48$; $p > .05$; $M_{\text{experimental group}}/M_{\text{control group II}}=.51$; $SD=.44$; $-.01$ vs. $.44$; $t=-1.83$; $p > .05$.] In the second range (40 minutes after glucose manipulation; second peak of insulin release curve) the existence of these effects could not be determined significantly.

Our study provided first insights about the biological correlates of raised insulin levels (through oral glucose manipulation) on price fairness perceptions. Statistical analysis showed that higher insulin levels indicate higher price acceptance. The estimated effects could support our assumption that glucose stimulates the monoamine serotonin, which results in neural activation. The effect is likely due to activation in neural areas of emotional regulation. Further research, including the use of fMRI, could determine more reliable insights into the hypothetical “glucose-insulin-tryptophan-serotonin” chain and its effects on distinctive brain areas and, thereby, on consumer behavior.

Power Dynamics in Immigrant Families in Britain and Its Effect on Consumption

Onyipreye Worlu, Manchester Business School, UK

Andrew Lindridge, Open University, UK

Research into family networks and how they are constructed and sustained through consumption can be criticised for being inherently western centric and White. Previous studies have tended to focus on key themes such as how individuals influence other family members (Cotte and Wood, 2004), how individuals represent family as aspects of their extended self in terms of consumption (Tian and Belk, 2005), and lastly family member's influence on consumption (Commuri and Gentry, 2005), to name but a few are often lacking in their focus on ethnic minorities. Despite calls for more research on gender differences in immigrant populations, relatively few studies have been conducted and those that have been studied have been product specific or based upon impulse buying behaviour (Mitchell and Walsh, 2004). This research argues that the current research into immigration, family and consumption practices are lacking in their discussion of idealised norms that govern gender relations in particular the construction of consumption behaviour and consequently power dynamics between husband and wife. The research will, therefore, address this research gap by providing an insight into how immigrant women, through consumption, use power dynamics to assert identities.

Inman et al. (2007) argued that women appear to hold the key to the familial structure amongst immigrant families. Cultural inhibitions, such as the belief that a woman's primary role is in the home or that women take second place to men is a widely held belief in most immigrant families (Inman et al., 1999); a belief that may lay in transactional gendered socialisation, and the immigrant and the host society's culture (Jayakar, 1994). However, when migrants' acculturation process is considered, immigrant women may produce a diverse and fluid range of identity (Üstüner and Holt, 2007). This in turn may cause them to begin to challenge their own, ethnic groups, patriarchal cultural values etc. This act of cultural resistance may exist in the miniature of simple, daily activities yet these acts appear to remain relatively unexplored.

One area where cultural resistance may exist is in the cultural inhibition of the woman's role in the family household, i.e. subservience behaviour to her husband. In particular how women, through engaging with the consumption process may have opportunities to express acts of cultural, consumption orientated resistance. It has been well documented that culture and self-identity plays a significant role in consumption; in particular how cultural values manifest through consumption of products (McCracken, 1986; Foxall and Goldsmith, 1994; Lindridge and Dibb, 2003). As a result, for example, cultural resistance may occur in modifying food choices which were once chosen in line of the husband's preference then changed in line of the wife's preference, and so forth. However, research that encompasses acculturation and cultural resistance, within a culturally determined family dynamic are lacking in consumer research.

Methodology

This research will focus on Black Nigerian immigrants living in Britain. The choice of Black Nigerians is partially one of convenience and also because the Black African population, living in the UK, is relatively understudied in comparison with other visible ethnic sub-groups (Daley, 1998).

This research used two sample groups consisting of ten first generation Nigerian couples (husband and wife) living in Britain and ten British White couples. Both the sample groups were matched for construct equivalence (in terms of age, religious background and socio-economic status) and recruited, using the snowball method of sampling, from London and Manchester.

Taking a Black feminist paradigm, the research was qualitative in nature and used semi-structured and in-depth interviews. The first stage of the fieldwork consisted of conducting preliminary interviews followed by further in-depth interviews with the wives of each couple. This two-stage interview process, conducted over a period of three months, aimed to explore the world of our female participants. It also allowed us to juxtapose the narratives shared with their husbands to the narratives of their individual interview, allowing us to highlight the antecedents of various acts of cultural resistance.

Complimenting the interviews, participating couples were asked to keep receipts of items consumed. These receipts provided points of discussions, for example items purchased that may have caused conflict or tension. This allowed us to explore wider aspects of our participants' decision-making and how power dynamics, based on gender roles, were acted out.

Preliminary analysis

Preliminary analysis of the data showed that acts of consumption-orientated resistance were evident for all our participants. British white women and Black Nigerian women tended to show similarity through their career path goals, work/ family conflict, gender based mistreatment, friendship and community. Both groups showed resistance through the purchase of items without approval from their

spouse; however they varied by the cost of the product purchased. For example British white women were at times more likely to purchase items that were viewed as capital intensive such as white goods. Whereas Black Nigerian women were more likely to purchase items that were less capital intensive such as food and were highly unlikely to purchase high capital intensive products without consultation with their spouse and their presence in the buying process e.g. the buying of electronics.

However, all our Black Nigerian participants demonstrated varying levels of resistance to what they perceived to be traditional Nigerian, patriarchal values. From a cultural values perspective this manifested through expressing a greater sense of individuality; reflective of their engagements with British White culture. For example, many of the participants exhibited this through personal fashion (e.g. clothes, jewellery, hairstyles and cosmetics) and in some cases spoken language (e.g. the use of British slang). Food purchase and food preparation for the family was also shown to be pivotal in individuality and provided a space in which these immigrant women were also able to exhibit forms of resistance of their traditional cultural and patriarchal values.

Consumer Response to Stereotype Threat Related to Dissociative Groups

Mohammed El Hazzouri, University of Manitoba, Canada

Sergio W Carvalho, University of Manitoba, Canada

Kelley Main, University of Manitoba, Canada

In everyday life, social identity and stereotypes influence how people behave. The literature on stereotype threat (e.g., Steele, Spencer, and Aronson 2002), for instance, argues that stereotype threat occurs whenever a person who highly identifies with a certain domain but belongs to a group that is stereotyped to be incompetent in that domain, becomes aware that he/she might engage in behavior that would confirm the stereotype. Previous research (e.g., Aronson et al. 1999) has shown that people's academic performance can be significantly impaired by the presence of a stereotype threat. Apparently, the psychological pressure of having to perform well in order to deny the stereotype leads to an opposite outcome—poor performance.

In the consumption setting, it has been found that consumers might be reluctant to use products that send negative cues about themselves (Banister and Hogg 2004) and avoid selecting products that are associated with negative reference groups (White and Dahl 2006). More specifically, recent research suggests that males require an excuse to get involved with female oriented consumption (Argo, Zhu and Dahl 2007).

However, to the best of our knowledge, neither the literature on stereotype threat nor the literature on consumer behaviour has investigated how people react to a stereotype threat when the stereotype domain is related to a dissociative group. The current research that draws on stereotype threat and dissociative groups, examines how consumers respond to situations in which demonstrating competence (ability) in using a product is not desirable since it might associate them with a dissociative group. More specifically, we evaluate how consumers' performance and enjoyment of using products, and their satisfaction with their own performance are affected when consuming products that are associated with a dissociative group.

Consumer response to stereotype threat related to a dissociative group was assessed in a pilot study and an experiment within the context of a gift-wrapping task—a context found to be a gender-related stereotype, which males would like to be dissociated with. Undergraduate business students at a major mid-western university participated in the study for course credit.

The results of a pilot study showed that participants who were told that the task was designed to test the wrapping materials (stereotype threat absent) were more satisfied with their own performance and felt more competent while wrapping the gift box than participants who were told that the gift wrapping task was designed to test their artistic ability (stereotype threat present).

An experiment was then designed to investigate the interactive effects of gender and stereotype threat on consumers' performance and enjoyment, and their satisfaction with their own performance in the gift-wrapping task. Seventy-eight students (50% males) participated in this study. The design was similar to that of the pilot study. With the exception of task performance that was evaluated by independent judges, all of the dependent variables of interest (task enjoyment and satisfaction with own performance) were self-reported measures.

Results revealed a significant two-way interaction of gender and stereotype threat on task performance ($F(1,74)=10.18, p<.01$), task enjoyment ($F(1,74)=6.79, p=.01$), and satisfaction with own performance ($F(1,74)=7.03, p=.01$). Simple effect tests revealed that there was a significant effect of stereotype threat on the performance of male participants ($M_{\text{absent}}=5.50$ vs. $M_{\text{present}}=4.84; F(1,74)=6.03, p<.05$), on how much they enjoyed the task ($M_{\text{absent}}=4.91$ vs. $M_{\text{present}}=4.03; F(1,74)=4.58, p<.05$), and on their satisfaction with their own performance ($M_{\text{absent}}=4.24$ vs. $M_{\text{present}}=3.24; F(1,74)=4.43, p<.05$). In addition, within the present stereotype threat condition, compared to female participants, males performed significantly worse ($M_{\text{Males}}=4.84$ vs. $M_{\text{females}}=6.21; F(1,74)=24.48, p<.001$), enjoyed the task much less ($M_{\text{Males}}=4.03$ vs. $M_{\text{females}}=5.75; F(1,74)=12.07, p<.001$), and evaluated their own performance much lower ($M_{\text{Males}}=3.24$ vs. $M_{\text{females}}=5.10; F(1,74)=10.21, p<.01$). Male and female participants performed and enjoyed the task equally well when they were told that the gift-wrapping task was designed to evaluate the wrapping materials ($p>.10$).

Conclusion

Overall, results suggest that male participants could perform well but needed an excuse to do so, a finding that is consistent with Argo, Zhu, and Dahl (2007) who demonstrated that males needed an excuse to get involved in an emotional melodramatic story. When we gave males the excuse that the gift-wrapping task was designed to evaluate the wrapping materials, they performed as well as females. Our findings contribute to the literature on stereotype threat by demonstrating that the threat can also take place even when the person is highly disidentified with the stereotype relevant domain. This research also adds to the consumer literature related to dissociative groups by showing that a product perceived to be associated with a dissociative group might not only reduce consumers' preference for that product but also negatively impact consumers' performance and enjoyment in using that product, and personal satisfaction with their performance. From a public policy standpoint, this research can also partly explain the effect of gender stereotypes on females' and males' performance in and enjoyment of domains that are stereotypically gender-related such as arts, and household work.

Transmodern Metaphors and Consumer Spirituality

Esi Abbam Elliot, University of Illinois at Chicago, USA
Benet DeBerry-Spence, University of Illinois at Chicago, USA

This study on transmodern metaphors is positioned at the nexus of consumer spirituality, where *transmodern* is defined as "a way of thinking that combines intuition and spirituality with rational brainwork" (Luyckx, 1999, 971). The term *metaphor* refers to associations that relate abstract concepts to physical things and are used to construct conceptual understandings (Lakoff 1987; Lakoff and Johnson, 1980). Existing consumer research has focused on the cognitive linguistic, psycholinguistic, literary and cultural views of metaphors (Dodd 2002; Lakoff and Johnson 1980; Denny and Sunderland 2005; Coulter and Zaltman 2000; McQuarrie and Mick, 1996; Hirshman 2000; Zaltman and Coulter 1995; Zaltman 1997); yet, limited attention has been given to spirituality and metaphors. This provides the basis for our research, which examines the use of transmodern metaphors associated with consumer spirituality. We contribute to theory by introducing 'meta-connections' as an important metaphorical connectivity relating to consumer spirituality.

Today's global contemporary society finds consumers increasingly interested in and influenced by their own spirituality. Spirituality concerns one's personal quest for understanding answers to ultimate questions about life, meaning, and relationships with the sacred or transcendent (Koenig et al. 2001). Spiritual awareness leads consumers to not only consider secular, rational and scientific approaches to understandings, but to incorporate transmodern considerations. The marketing literature has discussed metaphor and meanings

extensively, drawing on two traditions concerning what metaphor represents and how it may be used within a culture (Hirschman 2007). The first tradition is grounded in literary theory and linguistics, while the second draws from symbolic anthropology and is grounded in cultural images (Hirschman 2007). Although anthropological construal of metaphor is grounded in human experience, it is usually meant to reflect phenomena experienced in the natural or social world. The question then becomes, “What about phenomena experienced that fall outside the realm of the natural or social domain, such as the spiritual?” The current study builds on this question and explores metaphorical associations related to consumer spirituality.

To examine consumer use of transmodern metaphors, an initial study was conducted using visuals from advertisements featuring African kente cloth and targeted at African American consumers from the period of 1980 to 2000. The varied properties embedded in a textile (e.g., social, personal, spiritual, cultural, political, historical, etc.) make it potent symbol, enabling it to say things that words often cannot (Schneider and Weiner 1986). Further, the African kente cloth, in addition to being the most well known and commercially successful African fabric (Rabine 2002), often features woven patterns and symbols associated with spirituality (Ross 1998). Advertisements were compiled from a variety of businesses ranging from the food and beverage, fashion, insurance and communication industries. The intent was to incorporate a broad set of kente product and industry usage, thus yielding a diverse set of consumer interpretations.

Initial research indicates consumer interpretations of kente involve metaphorical spiritual associations, which we refer to as meta-connections. The term ‘meta’ captures those experiences that reflect the metaphysical; that is, those features of reality that exist beyond the physical world and our immediate senses, but nonetheless are part of the consumer’s everyday life. In this study, meta-connections are captured in consumer interpretations and spiritual sensing of the vivid colors, geometric symbols and proverbial messages embedded in the advertisement. An example is a Disneyworld advert featuring Mickey Mouse and Miss Collegiate African American 1993, wearing kente textiles with patterns that are interpreted with metaphorical associations of spiritual purity.

The introduction of ‘meta-connections’ offers a number of advancements. First, it extends the current literature to include metaphorical associations of spirituality that are interpreted and acted on by consumers in their everyday lives. It therefore throws light on transmodern approaches open to consumer spirituality and related belief systems. Second, spiritual aspects of traditional societies continue to be prevalent in many of contemporary ethnic communities. The inclusion of meta-connections as a type of consumer metaphorical association captures the ontological perspectives embedded within many ethnic cultures and acknowledges the importance of these perspectives in understanding consumer behavior.

Consumer Creativity During Unconstrained Consumption Tasks

Marit Gundersen Engeset, Buskerud University College, Norway
Sigurd V. Troye, Norwegian School of Economics, Norway

Abstract

Interest in consumer creativity reflects an emerging trend in consumer research to understand how consumers themselves construct meaning, create value, and participate actively in every part of the consumption process. Building on creativity theory, consumer researchers have focused on antecedents and consequences of consumer creativity in *constrained* consumption situations. The present research adds to the literature on consumer creativity by demonstrating high variability in creative processing and creative production

during a more realistic, *unconstrained* consumption task. The results suggest that creative abilities influence creative processing which in turn influences behavioral intentions towards the solutions.

Background

In marketing and consumer research consumers have traditionally been viewed as destroyers rather than creators of value. Recent research on consumer creativity (Moreau and Dahl 2005, Burroughs and Mick 2004), and on consumers' role as co-creators of value (Xie, Bagozzi and Troye 2008), challenges this view. Empirical and anecdotal evidence suggest that consumers do not always follow the least effortful avenue in their pursuit of goal attainment, but often enjoy exploring alternatives and thinking creatively during consumption tasks (Chernev 2006; Billings and Scherer 1988). The present research adds to the insight of how consumers act creatively in *constrained* consumption tasks (Moreau and Dahl 2005, Burroughs and Mick 2004) by exploring how consumers act creatively in *unconstrained* situations. We will also investigate antecedents and consequences of such creativity.

Creativity research conceptualizes the creative process as a mental process where different categories of knowledge are combined to constructively address an issue (Smith 1995). The process is typically described in terms of phases where the person searches for knowledge to understand and address a given problem (Ward, Smith and Finke 1999). Bottom up thinking, divergent thinking and convergent thinking are indicators of creative processing. Creative production refers to the solution itself. A solution is thought to be creative if it is a novel, appropriate and aesthetic solution to the problem (Burroughs, Moreau, and Mick 2008). Creative abilities are factors that enable the person to think more creatively and produce more creative solutions. Knowledge and motivation are considered critical for creativity (Amabile, 1996). Self efficacy and innovativeness are factors likely to influence creativity in a consumption setting. Consumer creativity has also been found to enhance consumers' positive affect (Burroughs and Mick, 2004); it is therefore likely that satisfaction and purchase intentions will be influenced by consumer creativity.

The Study

273 people participated in the study. A scenario was presented where participants were asked to imagine that they would cook dinner for friends at a dinner party, and write down what they would serve on such an occasion. Since no potential solutions or resources were limited in the scenario, no explicit constraints were imposed on the participants. This was important because the research is concerned with how consumers use creative processing in realistic decision situations. Four judges scored the usefulness of the solutions on a 6 item scale derived from Besemer and O'Quinn's (1986) CPSS scale. Novelty and aesthetics was assessed by measuring uniqueness and richness of the solutions. After creating solutions to the consumption scenarios, subjects were asked to explain in detail how they had been thinking during construction of each of the solutions, what came into mind first, what did they consider during the decision making task, and so on. Those reports were coded by independent judges with regards to three different measures of creative thinking: bottom up thinking, convergent thinking, and divergent thinking. Established scales were used to measure knowledge, motivation, self efficacy, and innovativeness. Three items measured purchase intentions.

Results

A total of 245 usable questionnaires (52% male) were returned. Analysis of creative process suggests that even when little constraints operate, consumers do vary to a great extent in their use of creative processing. Creativity in solutions varied from very low to high. There were significant correlations between creative process and purchase intentions ($r=.286$, $p<.01$), creative abilities and creative process ($r=.211$, $p<.001$), and creative abilities and creative product ($r=.197$, $p<.01$). To test the structural relationships between the constructs in this study, a model where creative abilities influenced creative processing and creative products, creative processing influenced creative production, and both creativity constructs influenced purchase intentions was estimated in LISREL 8.7. The composite reliability of the creative product scale was low (.51). As a result, creative production was removed, and a new model with creative abilities predicting creative processing which in turn predicted purchase intentions was estimated. Fit measures indicated acceptable representation of the data (K^2 square=72.52 with 33 df; RMSEA=.070, and AGFI .91). All the paths in the model were significant, and the composite reliability for all constructs was acceptable (0,66-0,83).

Discussion

The results presented in this paper suggest high variability in both creative processing and creative production during an unconstrained consumption task. This supports the assumption that creative and noncreative thinking can be conceptualized on a continuum rather than as a dichotomy (Moreau and Dahl 2005; Ward et al 1999). The research contributes with evidence of the existence of creative processes during unconstrained consumption tasks. Creative production correlated with creative abilities, but not with creative processing. This is puzzling, since creativity research typically assumes a strong link between process and production in many domains (Amabile, 1996). The paper discusses how measurement issues regarding creative production may be the reason for this finding, and how this must be addressed to fully understand the relationships tested in this study. Further, although no explicit constraints were imposed on the participants, they may have experienced implicit constraints by imagining a scenario where they would be impression managing (hosting dinner guests). This may have influenced their choices of final solutions more than their creative processing. Despite this weakness, the research reports interesting results regarding creative processing during a consumption task; creative abilities influence creative processing which in turn influence purchase intentions. The practical relevance of focusing on consumer creativity is underscored by the fact that creativity led to higher purchase intentions.

The hope is that this research will contribute to the consumer creativity literature by broadening its scope. By demonstrating that consumers do engage in creative processing and creative production when faced with less constrained consumption problems, new questions rise. What are the factors influencing such creativity? What are the consequences for brand loyalty? Will creative processing influence satisfaction with the product as well as satisfaction with the process and the decision? Some of these questions have been touched upon in this research, but more questions remain unanswered and represent opportunities for future work in this area.

Examining Immigrant Turkish Household Food Consumption: Consumer Insights for Food Acculturation Models

Elif Akagun Ergin, Cankaya University, Turkey

Carol Kaufman-Scarborough, Rutgers University-Camden, USA

This research examines the food consumption behaviors of Turkish immigrant consumers who migrate to the United States. This population has migrated steadily over many years and establishes stable populations in specific concentrated areas in the Northeastern United States. The families typically establish close relationships within Turkish communities and maintain the food customs of their culture-of-origin throughout numerous years. In the present manuscript, we report on a series of depth interviews with Turkish immigrant consumers regarding their typical food consumption practices and perceptions. This sample is part of a larger study focusing on Turkish immigrant behaviors.

Globalization has given rise to a multicultural society. Researchers have studied the food consumption practices, preferences, and realities of consumers as they emigrate to other cultures. Quite often, unique “hybrids” of their former cultures are created through partial assimilation into the host culture, in this case, the United States. Our study takes the perspective that does not place expectations on the subjects to conform to United States culture, i.e., how much progress they have made in assimilating to U.S. culture. Instead, we are interested in the reality that they have created as members of their own culture while living in the United States. Such realities differ in today’s information-rich world since immigrants to the US are likely to have international cell phones, surf the World Wide Web, and watch homeland programming via satellite television.

Researchers have described assimilation as a process in which an immigrant’s behavior becomes a mixture or blend of two cultures. The norms of the culture of origin become mixed with the norms of the culture of residence (Wallendorf and Reilly 1983). However, certain product constellations that are strongly linked with the home country culture are thought to be resistant to assimilation, and actually may give rise to a system of protected norms that form generally-accepted standards of consumption. Such is the case of food purchase, preparation, and consumption with Turkish immigrants.

Similar to the dense Mexican population in California, the Turkish immigrants seem to create enclaves that can inhibit the acculturation process as they form a “home away from home” in their local communities (Penaloza and Gilly 1999), with small retail stores and even Turkish elementary schools. Moreover, the longer the immigrants stay in the U.S., they appear to become more proficient at “culture switching.” That is, like the Haitian immigrants described in Oswald’s study (1999), the Turkish immigrants are adept at switching from Turkish culture to mainstream American culture based on their specific situation. More often than not, however, their food culture appears to be firmly grounded in Turkish customs, values, and practices, while their employment can be well-integrated into the U.S. labor force.

In order to establish a baseline for food behaviors, semi-structured interviews were conducted with seven Turkish immigrants regarding their reasons for immigration, their food-related practices, their shopping and food preparation patterns, and foods that they would like to have but cannot buy in the United States. Six females and one male participated in this phase of the study, with ages ranging from 33 to 50 (average age is 41.5). Participants were recruited and selected in order to include representation from various parts of Turkey: two from Istanbul, Espiye (Black Sea Coast), Bolu, Kayseri (Central Anatolia Region), Edirne, and Samsun (Black Sea Coast).

Like many other cultures, Turkey is rich in cultural variations across regions, with food skills, preferences, and local tastes combining to create a foodways culture that is representative of both regional and country customs. The stories of each person’s immigration were similar, although they grew up in different areas of Turkey. Participants were asked to describe how they shopped for food when living in Turkey. The open-ended questions attempted to draw each respondent back into the early formations of their food preferences as well as their present-day practices.

The verbatims were read and re-read to attempt to extract common themes without imposing any anticipated structure to the respondents’ comments following Strauss and Corbin (1988) and Miles and Huberman (1994). Interestingly, numerous comments reflected back to each respondent’s early childhood days spend with their parents, forming their shopping and food preferences. The data reveal that food consumption choices are more complex than suggested by assimilation models, but instead incorporate childhood sensory experiences, religious practices, taste preferences, the desire to maintain cultural food habits, availability of preferred products, and the desire to retain homeland food practices.

This initial phase of our research provided an insightful view to the complexity of Turkish immigrant food behaviors. It is simply not maintaining past food practices nor learning new ones. For instance, participants spoke to us with concerns regarding “hidden” meat by-products that violate religious customs, such as gelatins that are common ingredients in U.S. foods such as the marshmallows in children’s cereals. Additional research is needed to try to unfold how such concerns affect food purchases and practices.

Managerial implications also abound for retailers. Grocery stores, for example, may want to further study whether Turkish customers are able to fulfill their desired purchases within U.S. retail settings. If there is a large enough customer base, it might be in the store’s best interest to open an ethnic section for those ethnic groups that provide a large consumer base in the community.

It's Fake!? Consumers' Self Creation in a Market with Easy Access to Counterfeit Goods

Marcia Christina Ferreira, EBAPE / FGV, Brazil

Bill Pereira, EBAPE/FGV-RJ. FUCAPE Business School, Brazil

Consumption is a central practice in everyday life supplying meanings and value for the creation and maintenance of the consumer's personal and social world (Wattabasuwan 2005). Symbolic value and meanings are important for consumers not only because they help retain their former sense, but also because they help them to be categorized in society, communicate cultural meanings, traditions and group identity, as well as to shape and communicate their identity through the meanings attributed to their possessions (McCracken 1981; Slater 1997; Belk 1998). Consumption meanings emerge in a dialectical process between its owner and the object as the symbolism assigned to this object reflects both, the image of the subject and the image of the object (Wattabasuwan 2005). An argument well illustrated by Belk (1988: p. 141): "the more we believe we possess or are possessed by an object, the more a part of self it becomes". Therefore, the dialectical process would not be subject-object, but in fact subject-object-subject.

The present research chooses counterfeit consumption as base to explore the dynamic interaction between consumer actions, the marketplace and the cultural meanings (Arnould and Thompson 2005) and aim to better understand consumer's self creations via possessions of counterfeit goods. In a marketplace with abundant supply and easy access to counterfeits consumers can alter their behaviour looking for products "with brand" instead of originals giving uncountable justifications for their actions resulting in a consumption "socially acceptable" (Gentry et al 2001). Therefore a market "plentiful" of counterfeit goods was chosen as context for the present research as it allows exploring the phenomenon as relations between an existent culture and social resources as well as relations between possessions and meanings. A perspective not yet explored in the literature.

The majority of existing literature concentrates in profiling counterfeit consumers as well as investigating their consumption reasons (Penz and Stöttingner 2008) resulting in studies that search for rational answers driven by utilitarian principles. However, profound explanations need to be done beyond correlations between variables which would be better assessed by qualitative research (Eisend and Schuchert-Güler 2006). Counterfeit consumers present distinctive construction of meanings indicating they consider more personal and subjective value in choosing this product (Gentry, Putrevu and Shultz 2006). Since counterfeits are as closely related to the person's self image and identity as regular products, consumers are capable of transferring part of the meanings from the original to themselves and build their identity, depending on the counterfeit likeness (Hoe, Hogg and Hart 2003).

Looking at the context in question, the literature gives evidence that individuals rate counterfeit consumption as pleasant as regular shopping (Matos Ituassu and Rossi 2007). During their decision making counterfeit consumers might prefer product's meanings instead of quality or price, suggesting a choice based on product's usage (Ferreira, Botelho and Almeida 2008). Moreover counterfeits could contribute for consumer's legitimacy working as symbolic capital and yet becoming socially acceptable (Strehlau, Vasconcelos and Huertas 2006). Finally counterfeit consumer value seems to be ruled by experiences with individuals reacting to meanings existing in original products and then acting through counterfeits as a way to find authentic consumption value, since these goods were mostly consumed playfully and along with non aesthetic value (Ferreira, 2008).

The developing country Brazil was used as research context. In 2008 the turnover of counterfeit goods was between US\$ 30 billion and US\$ 40 billion, in a country where only 3 in 10 persons do not consume fake products (Bompan 2008). Additionally an anthropologic study shows an abrupt intensification of consumption as a result of economic expansion and political changes. To understand this new reality individuals developed conflicting views putting in one side desires and values and the frustration and political issues on the other (O'Dougherty 2002).

In this marketplace, counterfeit consumers were asked to reflect upon their lifetime experiences while shopping. Fourteen in-depth interviews were conducted using a semi-structured questionnaire with male and females, aged between 20 e 54 years, living in Rio de Janeiro. The sample, selected by convenience, was collected mainly through face-to-face interviews during 45 minutes on average, in locations chosen by the informants (excluding five phone interviews). The data collected were recorded, transcribed and analyzed individually by the researchers (Miles and Huberman 1994). Additionally, the largest trade centre for counterfeits in the country was used for field observations. Researchers talked with dealers and consumers seeking to better understand the consumptions' dynamics in that marketplace. As a working in progress, further investigations will be carried out.

When creating meaning counterfeit consumers appear to arbitrate a dialog between object's representation (counterfeit object) and signification (original object) through rituals of possession determined by distinct levels of self creation. Therefore it's possible to address this phenomenon in the chosen context as a three-way conversation (subject-object-subject) but with the object divided in two: original and counterfeit. Three levels of symbolic action emerge from the analysis of counterfeit consumer's self-extension: (a) controlling level; (b) creative level; (c) fulfilling level. On the first level the counterfeit object was possessed by consumers through strict control over their significance. In this case, such product was consumed mainly by their practical characteristics and justified by their utilitarian trade-off. Therefore, such practice has been allocated on the lowest level of self-extension with fewer presence of symbolic action.

On a second level, the consumers seek for symbolic actions that can be determined by their creativity with an objective to personify such possession. On this level the dialog between representation and significance was permanent and led the consumers to reveal [or remember] incessantly their counterfeit consumption to get closer each time to significance inspired by the original good. Extremely knowledgeable of both objects consumers in the third level of self-extension were capable of divestment of most of the counterfeit

representation in search for a fully significance prevailing through the idea of original product. And they did it believing that their personal features (such as beauty, success or wealth) work as a catalyst transferring to the counterfeit object most of the significance from the original item.

Doing Qualitative Research with Archival Data: Making Secondary Data a Primary Resource

Eileen Fischer, York University, Canada
Marie-Agnès Parmentier, HEC Montréal, Canada

Since consumer researchers began to publish studies grounded in qualitative data, many have collected archival or secondary data as a matter of course. However archival data has played what can only be regarded as a secondary role in most qualitative consumer research studies. Archival data comprises a wide array of empirical materials created by individuals for their own purposes (e.g. diaries, letters, photographs, weblogs, fan art and discussion list postings) or behalf of organizations (e.g. corporate annual reports, press releases, advertisements, magazine articles, restaurant reviews, ratings websites etcetera). With rare exceptions (notably Belk's (1992) study that relied on personal documents) common methodological practice has been to make use of interview and, less frequently, observational data as the main resource in developing interpretations and analyses of focal phenomena. Archival data has chiefly been used to help develop understandings of the research context, rather than to inform the development of concepts and theories. Evidence supporting this assertion is that virtually every scholar who has collected both interview or observational data *and* archival data offers quotes from interviews or field notes when reporting findings and developing theoretical contributions, but only a tiny minority refer to archival material for the same purposes. And although interviews and observations are fine materials with which to build contributions to consumer research, there are burgeoning opportunities for making greater use of archival data for this purpose. Indeed, in section one of the paper, we argue that there is also an increasing case to be made for the necessity of drawing on archival data as one primary resource.

The claim that archival data is an increasingly viable resource stems from the fact that an ever greater amount of archival verbal and visual material is becoming nearly universally available owing to the internet. Just as the growth of online communities has led to ever growing opportunities for netnography (Kozinets 2002, 2008), so has the proliferation, online, of archives of materials ranging from periodicals to blogs to corporate annual reports to product complaint websites made possible an ever widening scope of systematic,

archival research. And as museums and other repositories make portions of their holdings available electronically, this tsunami of available archival data will expand further.

The claim that we should consider archival data as a more primary source of insight stems from the increasingly sophisticated critiques emerging of interview data as a primary resource in qualitative research. Arnould and Wallendorf (1994) have vividly illustrated the disjunctions between what people say and what people do; they make a compelling case that we cannot rely primarily on interviews to provide insights into patterns of and motives for consumers' behaviors. More recently, insightful critiques of neopositivist, romantic and localist views of the qualitative interviews have raised significant challenges to our thinking about which research questions are possible or suitable to address based on interviews alone (Alvesson 2003).

Given this convergence of opportunity and need for greater use of archival data, we must consider how we can best gather and analyze such materials. Existing guidelines for gathering and analyzing "secondary data" are sparse, and typically assume that it will play a secondary role. Moreover, they overlook the fact that qualitative researchers today face challenges not of finding archival data, but rather of deciding how to put limits on what is collected and analyzed systematically. Thus, it is important to develop guidance on tractable and coherent strategies for collecting archival data when it will be used as a primary resource for theory building. And, as its role becomes more central, it is important that we give consideration to appropriate ways of interpreting such data.

The second section of this paper discusses how researchers can decide what archival data to collect when they must determine what to include and what to exclude from a data collection in progress. In initial stages of a research project, researchers benefit from creating an inventory of the sources of archival material they could access, and examining selections of data from each in order to familiarize themselves with their phenomenon of interest and with the contents of each potential archival data source. As the research question(s) of interest are identified it becomes useful for the researchers to consider three factors related to their question(s). The first is the "unit of analysis." While rarely explicitly considered in qualitative research, our paper makes the case that clarity regarding the unit of analysis can help the researcher make defensible decisions to include some archival sources and to exclude others. A second consideration in relation the research question is whether or not it concerns a process that is expected to span some duration. Understanding events in that duration that are of theoretical interest (e.g., emergence, transformation, or termination) can also help to identify which archival sources can be excluded and which are most likely to be usefully included. A third factor related to research question(s) is whether they are concerned with developing hermeneutic understanding of the perspective of some individuals or group of actors. Again, as we elaborate in the paper, clarity on this aspect of the research question can help to identify which sources of archival data are critical to consider as a primary resource and which can be regarded as secondary. Examples are developed to illustrate and elaborate upon these criteria.

In the third section of the paper, we detail a set of questions that researchers can pose about specific sets of archival data that will help them make appropriate choices when analyzing that particular data. Briefly, these questions prompt the researcher to consider the circumstances under which the data was created, the limitations on the perspectives of those who created it, and the possible motivations that shape what is included and omitted, and how the phenomenon of interest is portrayed. Examples are again discussed in this section.

In the concluding section we identify research topics that lend themselves well to investigation using archival data as a primary resource.

Reevaluating Disclaimers and the FTC's Clear and Conspicuous Standards

Kendra Fowler, Kent State University, USA
Veronica Thomas, Kent State University, USA
Richard Kolbe, Kent State University, USA

Disclaimers are "messages intended to fully disclose all information that could affect decision making and elucidate possibly misunderstood statements" (Herbst and Allan 2006, 213). The use of disclaimers in advertising is on the rise and has become almost commonplace in television commercials (Hoy and Andrews 2004; Kolbe and Muehling 1995; Muehling and Kolbe 1997). The Federal Trade Commission in an effort to promote competitive business practices, protect consumers, and regulate advertising (Hoy and Lwin 2007) developed, in 1970, Clear and Conspicuous standards (CCS) for advertising disclosures.

Research shows, however, that consumers are not always able to process the provided information (Morgan and Stoltman 2002). The majority of advertisers, ad agencies, broadcasters and regulatory agencies believe that consumers "do not read, cannot read, and do not attempt to read the fine print" (Muehling and Kolbe 1997, p. 4). Consequently, despite the increase in disclosures, there does not appear to be a corresponding increase in the informational value of the advertisements from the consumers' standpoint. The guidelines set forth to protect consumers from deception need to be revisited. Specifically, the effectiveness of the standards at enhancing consumers' recall of disclosures and the contribution they make to enhance overall understandability of advertising needs to be reanalyzed, a point echoed by the Current FCC Commissioner, Jonathan Edelman (Eggerton 2006) as well as academics (Hoy and Andrews 2004; Muehling and Kolbe 1997; Stewart and Martin 2004). In an effort to understand the impact of disclosure statements, we analyzed the FTC's current suggested disclosure practices and provide evidence as to the effectiveness of these methods in enhancing disclosure recall and perceptions of understanding.

A total of 327 undergraduate students from a large midwestern university participated in an online survey for extra credit. Sixteen conditions were created to observe how the stylistic elements associated with a disclosure impacts the recall of the disclosed information and perceived understandability of the advertisement. In all of the conditions, participants viewed a stimulus for a well known credit card. Conditions were created to study the effect of modes of delivery, font size, distraction, and technical language. Prevailing industry norms were followed and disclosures were placed at the bottom of the screen near the end of the commercial message and no other sounds aired during the disclosures presentation. The disclaimer in all of the stimuli appeared for only fifteen seconds and consisted of fifty words, requiring the participants to be able to read at a rate of 200 words per minute. This rate was chosen because it was within the range at which

an average person could be expected to read (Douglass and Douglass 1993) and was slightly less than the average rate used in most fine print disclosures (Kolbe and Muehling 1997). After viewing the appropriate stimulus for their condition, participants were asked to complete a survey that included measures of disclosure recall and perceived understandability of the advertisement.

In the case of disclosure recall, no significant ($p \leq .05$) interaction effects were found. Looking then at main effects, we find significant results for the effect of distraction ($F(2,255)=5.045, p \leq .01, \eta^2=.038$) and language ($F(1,255)=10.836, p \leq .001, \eta^2=.041$) on recall of the disclosure. The effect of audio ($F(1,255)=.588, p=.44, \eta^2=.002$) and size ($F(1,255)=2.089, p=.15, \eta^2=.008$), however, failed to reach significance.

As expected, increasing the level of background distraction decreased the recall of the disclosure. Tukey pairwise comparisons indicate no significant differences between conditions of no distraction ($M=2.875$) and low distraction ($M=2.725$), but recall under the condition of high distraction ($M=2.063$) was significantly reduced. Language also impacted recall of the disclosure in the predicted direction. Disclosures written in a nontechnical language scored higher ($M=2.992$) than did disclosures written in a more technical language ($M=2.248$).

In the case of perceived understandability of the advertisement, significant ($p \leq .05$) interaction effects were found for the audio x distraction interaction, ($F(2,354)=10.243, p \leq .001, \eta^2=.055$) and language x distraction interaction ($F(2,354)=3.338, p=.04, \eta^2=.019$), but all other interactions failed to reach statistical significance. Additionally, the main effect of size failed to meet standard levels of significance ($F(1,354)=3.196, p=.08, \eta^2=.009$).

Managerially, our results suggest that when recall of the content of the disclosure statement is important, marketers should focus on the background upon which the disclosure appears and the language in which the disclosure is written. However, if the marketer's goal is instead to enhance the overall understandability of the message, simplifying the language in which the disclosure statement is written becomes critical, as in conditions of both no distraction and low distraction, technical language has a significant negative effect on perceived understandability. The effect of the modality of the disclosure should also be considered in light of its effect on perceived understandability. In the case of low distraction, presenting the disclosure in both print and auditory formats has little to no effect on understandability of the advertisement; while in both the moderate and high levels of distraction, dual modality results in lower levels of perceived understandability.

From an academic viewpoint, this study extends previous work in disclosure research by examining the effect of differing conditions under which disclosures appear. We also suggest more concrete alternatives to the FTC's standards for clear and conspicuous disclosure. First, we recommend that visual presentation of the disclosure should have text that is at least 1/25 of the screen and be presented in a color that drastically contrasts with the background. We further propose that the disclosure be presented at a time when there is no music or scene change. Finally, the disclosure should not contain language that the average consumer could not comprehend. It is our belief that these three guidelines, when implemented simultaneously, will ensure that television disclosures are able to meet the challenge of fully divulging "all information that could affect decision making and elucidate possibly misunderstood statements" (Herbst and Allan 2006, p. 213).

Consumer Transformations: A Hero's Journey

Aubrey Fowler III, Valdosta State University, USA

Courtney Droms, Valdosta State University, USA

Consumers seek to transform themselves, moving from one state of being into another; however, much of the literature that touch upon consumer transformations appears to be concerned with identity projects (i.e., Arnould and Price; Belk and Costa 1998; Kozinets 2001) or with simple modification of the self (i.e., Gimlin 2002; Pitts 2003; Sanders 2008). We take a different approach to understanding consumer transformations by understanding it as something much more than simply modifying the body with a tattoo or plastic surgery or developing an identity that one can carry around like a costume one wears to a party. Instead, we view consumer transformations as a full-body experience where the individual transforms him or herself from one state of being into another. In the case of our research,

the consumers we investigate have undergone gastric bypass surgery which allows them to literally as well as figuratively transform themselves from an obese person into a much smaller.

For instance, Peter was, at one time, over three hundred pounds. For most of his life, he had tried, desperately at times, to lose weight using a variety of more traditional means such as dieting and exercise. Furthermore, he had often looked to the marketplace for help, engaging the services of Weight Watchers, doctor-regimented diet plans, and even so-called “diet camps.” As failure after failure mounted, Peter became more and more desperate to lose weight. Finally, after much deliberation, he decided to have gastric bypass surgery. Now, a little over a year after the surgery, Peter is over a hundred pounds lighter with more pounds expected to be shed in the coming months. For him, the experience of losing “a whole other person” has been a transformation along the lines of “becoming someone else.”

This transformation takes literal form in the shrinking body as well as in his relationships with the world around him. For instance, he has had to relearn how to navigate the world. In his previous life, he had to “squeeze into desk chairs at school or on airplanes in order to fit into a world made for skinny people.” Now, he can fit comfortably into desk chairs and no longer feels out of place when he sits them, but he still moves down the airplane aisle in a sideways fashion instead of walking with his body facing straight ahead even though he can do so without bumping passengers that are already seated. Furthermore, he has had to undergo a mental transformation as well, moving from a person who had difficulties with the self-discipline required to maintain various weight-loss programs, to an individual who absolutely needs to maintain self-discipline in order to live. “I slipped one time,” he says, “and had too much Gatorade with all that sugar and I was sick for almost a week. I simply can’t take in anything like I used to, and I have to be really careful.”

Through Peter’s story and the narratives of other individuals who have undergone gastric bypass surgery, we find that consumers who transform themselves do so in a pattern that appears to follow the hero’s journey as developed by Joseph Campbell (1968). The hero’s journey is a mythic structure inherent within the literature and mythologies of many, if not all, cultures where the hero “ventures forth from the world of common day into a region of supernatural wonder” where “fabulous forces are there encountered and a decisive victory won,” and then the hero returns to face a new status quo where he (or she) “bestow boons on his fellow man” (Campbell 1968, 30). The three stages of the journey that Campbell identifies are departure, initiation, and return.

Peter’s story follows this same series of stages. The separation stage begins with Peter’s navigation of the ordinary world of his obesity and ends with his entrance into “the belly of the whale” or the actual surgery itself. His Initiation stage involves the trials and victories that start upon waking up from the surgery and ends with the hero “seizing the sword” (Vogler 1992). In this moment, the hero essentially casts aside the remnants of the old self and takes firm possession of the new self. The return involves the reintegration of the hero into the ordinary world where, in Peter’s case, he not only learns to navigate a “new” world in a “new” body, but with a renewed sense of self. Furthermore, he then has the opportunity to provide guidance to others who are seeking to transform themselves.

Our research follows in the tradition of bringing mythological structure to the various activities that consumers engage in. Levy (1981) determined that consumer interviews can be read as mythological narratives much as one might read fairy tales, fables, and other tales. Stern (1995) used Frye’s taxonomy in an effort to better understand the various myths contained within both consumer narratives and advertisements dealing with Thanksgiving rituals. Holt and Thompson (2004) examine the various “heroic” myths related to masculinity within Western culture, finding that, in recent years, the “man-of-action” myth has risen as the celebrated cultural model of masculinity. Additional research from the psychology literature has used the hero’s journey as a framework for understanding in counseling situations (Lawson 2005) and even spiritual development (Feinstein 1997).

Our research intends to define a framework for understanding consumer transformations that take place in the market. We believe that such a framework will be useful for marketers seeking to understand such transformations as well as though attempting to support those transformations. Ultimately, we believe that the framework that we develop will also move beyond the case presented here and extend into such contexts as helping individuals escape various addictions; deal with the loss of health, property, or loved ones; or even to achieve new states of spirituality, consciousness, or awareness. As such, we believe that our research will contribute to the field of transformative consumer research in addition to our understanding of basic consumer research.

The Effects of Experience-Based Marketing Communication on Brand Relations and Hedonic Brand Attitudes: The Moderating Role of Affective Orientation

Marieke Fransen, University of Amsterdam, the Netherlands

Paulien Lodder, University of Amsterdam, the Netherlands

Introduction

Events such as the “Nike run London”, and theme stores such as “M&M’s World” and the “New World of Coca Cola” (i.e., experience-based marketing communications) are a growing phenomenon in the area of marketing communication. The emergence of this

new form of marketing communication appears to be due to several reasons. First, the overuse of traditional media seems to call for a different strategy to be able to stand out from competitors (e.g., Smit and Neijens 1999). Second, as a result of today's global marketplace where many companies are competing for the same often limited market share, it has become difficult to compete and differentiate on mere product or brand characteristics. Third, consumers are more and more looking for marketing communications that are relevant for them as an individual and recognizes their need for novelty and excitement (Schmitt 1999). Fourth, consumers' growing need for the experiential aspects of consumption (Holbrook 2000; Holbrook and Hirschman 1981) resulting in less rational decision making strategies, calls for a different marketing communication approach.

Despite the continuous attention of marketers to experience-based marketing communication, surprisingly little empirical attention has been paid to this phenomenon. One reason for this could be that there is not one clear term or definition available in the literature. Terms that are proposed include "experiential marketing" (Schmitt 1999), "event marketing" (Wood and Masterman 2008), and "experience marketing" (Pine and Gilmore 1998). Unfortunately, these terms are used interchangeably but do not always apply the same definition. However, there seems to be consensus on several components. First, experience-based marketing communication is initialized by the company. Hence, the event, experience, or theme store is staged by a company distinguishing it from, for example, "event sponsoring" (e.g., Cornwell and Maignan 1998). Moreover, the experience of the consumer, rather than the marketing message (as in traditional forms of marketing communication), is of focal attention in experience-based marketing communication strategies. Finally, it is generally assumed, but not empirically tested, that experience-based marketing communication enhances brand attitudes and brand relations.

The aim of the present research is to empirically examine the effects of experience-based marketing communication tools on consumer responses. It is hypothesized that a visit to a theme store (i.e., "Heineken the City") or an online co-creation task (designing a label for a Heineken beer bottle) can have a positive influence on brand attitude and brand relation (compared to a control condition). Furthermore, based on the assumption that experience-based marketing tools tap into consumers' emotions (rather than cognitions), it is expected that the effects of experience-based marketing tools on consumer responses is stronger for people with dispositional high (versus low) affective orientation (Booth-Butterfield and Booth-Butterfield 1990).

Method

We used a 3 (experience: visit to Heineken the city vs. designing a label for Heineken beer bottle vs. control) x 2 (affective orientation: high vs. low) between subjects design to test our hypotheses. Consumers (N=101) were randomly assigned to one of the experience conditions. Based on a median split, participants were classified as high or low in affective orientation. One week after visiting the theme store "Heineken the city" or performing the online design task participants received a questionnaire measuring consumer brand attitudes (Voss, Spangenberg, and Grohmann 2003) and brand relation (e.g., Chang and Chieng 2006). Note that participants in the control condition only received this latter questionnaire and were not exposed to any form of marketing communication.

Results and Discussion

A full factorial ANOVA revealed a main effect of experience demonstrating that participants who visited the theme store or designed a label online had a more positive attitude towards the brand (Heineken) and had a stronger brand relation than participants in the control condition. No differences were observed between the two different experience conditions. Moreover, we observed the expected interaction effect between experience and affective orientation showing that particularly participants with high dispositional affective orientation (compared with participants low in affective orientation) are affected by experience-based forms of marketing communications. Again, no differences between the two different forms of experiences (i.e., visit and design condition) were observed.

The present study shows initial evidence for a positive relation between experience-based marketing communication and consumer responses. Moreover, it reveals a boundary condition for these effects to occur, namely, the extent to which people have a dispositional affective orientation. These results provide promising evidence to support the growing field of experience-based marketing communication.

Does What Happens in Virtual Worlds Stay in Virtual Worlds? A Theory of Planned Behavior Approach to the Examination of Cognitive Transference in Virtual Marketing Channels

Jason Gabisch, University of Massachusetts, USA

Online virtual environments differ significantly from traditional e-commerce in that virtual worlds move beyond information search by allowing users to simulate behaviors before carrying them out in the traditional channel. Several global companies such as Adidas, BMW, Dell, IBM, Microsoft, Reebok, and Coca-Cola have, or have had, a presence in Second Life. These companies have developed a virtual presence in an attempt to create and increase brand awareness with the hope that these brand experiences will eventually influence real world purchase intentions and behavior (Arakji and Lang 2008). Research has shown that consumers are increasingly employing multiple marketing channels before purchasing products, for instance some consumers search online before making purchases in the store (Kumar and Venkatesan 2005).

The main objective of this paper is to investigate whether brand experiences in the online virtual environment affect purchase intentions and behaviors in the real world. Data is collected specifically from users of the popular 3D virtual world Second Life. A primary gap in the virtual reality literature concerns the lack of empirical data collected from real-time virtual environments. Empirical studies to date have collected data using lab experiments where buyers interact with 3D objects on corporate websites or with computer-operated sales avatars (Li et al 2002; Suh and Lee 2005; Jiang and Benbasat 2005; Wang et al 2007; Holzwarth et al 2006).

The Theory of Planned Behavior (TPB; Ajzen 1991), an established social psychology model for predicting behavior, is employed and extended in this paper in order to improve the model's predictive power for explaining how virtual world brand experience affects real world purchase intentions and behavior. An extended version of the TPB model is presented and tested that includes the additional constructs of virtual world behavior, self-image congruency, and perceived diagnosticity. This paper contributes to the consumer psychology and marketing literature by presenting a conceptual model for understanding the ability of online virtual environments to serve as viable marketing channels for influencing consumer cognitions and behavior, and extends and applies the TPB model across multiple marketing channels.

The literature and concepts reviewed in this article include extant work on extensions to the TPB model, self-image congruency, perceived diagnosticity, and the impact of past behavior on predicting future purchasing behaviors. A conceptual model is developed where virtual world brand experience has a direct effect on purchase intentions and behavior in the TPB. Self-image congruency and perceived diagnosticity are hypothesized to moderate these relationships.

Online virtual environments have been identified in the literature as emerging marketing channels where consumers engage in information search, trial, and purchasing. Behavior in virtual environments may impact real world behavior, and studies have shown that consumer interactions with products in the virtual environment have the potential to increase product knowledge, purchase intentions, and lead to more confident brand attitudes (Li et al. 2002, Suh and Lee 2005). It is hypothesized in this paper that virtual world behavior with the brand will have a significant impact on real world purchasing intentions and behavior.

The self-image congruency construct has been identified in the marketing literature as the degree to which a product or brand matches a consumer's self-concept (Kressmann et al 2006, Sirgy et al 1997). Consumers who perceive brand experiences in the online virtual environment to be consistent with their self-image are more likely to transfer their intentions and behaviors to the real world. Thus, it is hypothesized in this paper that higher self-image congruency strengthens the relationship between virtual world brand behavior and real world purchase intentions and behavior. The perceived diagnosticity construct is a key variable in the product trial and virtual reality literature, and has been defined as "the extent to which a consumer believes that a particular shopping experience was helpful for evaluating the product" (Jiang and Benbasat 2004). It is likely that the more helpful a virtual experience for evaluating a brand, the stronger influence the virtual experience will have on real world purchase intentions and behaviors. It is hypothesized that the higher a consumer's perceived diagnosticity while interacting with brands in the virtual world, the stronger the relationship between virtual world behavior and real world purchase intentions and behavior.

To test the proposed hypotheses, a questionnaire was administered to 209 registered users of the virtual world, Second Life. The survey was made possible by collaborating with a marketing research firm that specializes in data collection within virtual worlds, such as Second Life. A random sample of users was sent online invitations asking them to participate in the survey. Respondents answered questions using memorable experiences with real life brands in Second Life that they could recall from memory. Gender, age, and nationality statistics for the sample were similar to the average reported statistics for the overall population of registered users in Second Life. Multi-item scales were adapted from the literature and used to measure the constructs. All scale reliabilities were above .70. Four hierarchical multiple regression analyses were performed to test the main effects of virtual world behavior on real world purchase intentions and behavior, in addition to exploring the moderation effects of self-image congruency and perceived diagnosticity.

Overall, the findings from this study provide strong support for an extended version of the TPB that includes virtual world behavior, self-image congruency, and perceived diagnosticity. Virtual world behavior is found to explain unique variance in both real world purchase intentions and behavior, thus indicating that brand experiences in the virtual world may have a significant impact on consumer purchasing in the real world. Self-image congruency and perceived diagnosticity are found to moderate the relationship between virtual world behavior and real world purchase intentions. Respondents who perceived their virtual world brand experience as more consistent with their self-concept formed higher purchase intentions, suggesting that consumers may tend to behave in ways that are congruent with their self-image across various marketing channels. Also, the more realistic and helpful brand experiences in the virtual world are perceived to be by consumers, the more influence those virtual world brand experiences have on real world purchasing behavior.

When Avoidable Losses Are Perceived as Gains: Repair Costs and Their Effects in New Product Purchases

Andrew Gershoff, University of Michigan, USA

Beatriz Pereira, University of Michigan, USA

Consumers frequently consider money that they save as a gain, consistent with prospect theory (Kahneman and Tversky 1979). Studies have shown this phenomenon in different purchase situations, such as rebates (Thaler 1985) and trade-ins (Okada 2001). When presented with these savings, consumers show less price sensitivity in new purchases. In particular, saving money can be viewed as a gain by avoiding a loss (i.e. in trade-ins, waste is avoided by attributing a residual value to the used product).

But what about cases where a consumer finds herself facing a payment to repair a broken product or replace a lost item? Does framing the purchase of a better camera as a way to avoid paying to repair the old camera lead to decreased price sensitivity for the new one?

This paper provides evidence that other types of avoidable losses cause a reduction in the price sensitivity of consumers, in particular when a product is in need of repair. Repairing a broken product is painful since the repair cost is perceived as a loss. In order to return to the status quo, the consumer must sacrifice money. This makes a repair quite different from a purchase, where the money is intended to be spent and thus is not viewed as a loss (Novemsky and Kahneman 2005). A similar loss occurs in the case of a consumer losing a possession, and purchasing the same item again. The repurchase only returns the consumer to the status quo.

This research builds on the mental accounting literature (Thaler 1985). If a consumer seriously considers repairing a broken product, the repair cost is likely allocated to its own mental account. Actively searching for repair prices indicates a certain level of commitment to the repair option and also increases the rigor of budgeting (Heath and Soll 1996), as some amount of money is allocated to the repair account.

If the consumer then decides not to repair, the amount allocated to the repair account remains unspent. Hence, we hypothesize that a repair amount that was not spent is likely to be transferred from the repair account to the replacement account. This gain will therefore reduce price sensitivity in the purchase of the replacement. In other words, the higher the repair amount, the less price sensitive the consumer will be in the new purchase. According to prospect theory the perceived gains should increase as the repair costs increase, but at decreasing rates (Kahneman and Tversky 1979; Thaler 1980).

We conducted two experiments to test our hypothesis that repair cost influences repurchase price sensitivity. In the first study, we manipulated repair prices for washing machines and laptop computers, two common household durable goods. Participants were told to imagine that a washing machine they had bought seven years ago for \$500 was in need of repair (or a one year old laptop computer they had bought for \$1,600). The repair price manipulation had levels representing 40%, 80% or 110% of the original price (\$200, \$400 and \$550 for the washer and \$640, \$1,280 and \$1,760 for the laptop). Participants were asked to provide their willingness to pay for a new product using a scale with prices from \$250 to \$750 in \$50 increments for the washer and from \$500 to \$3,000 in \$250 increments for the laptop. As predicted, an ANOVA showed that the mean willingness to pay increased as the repair costs increased (washer: $F(1,81)=12.622, p<.001, M_{40\%}=4.61, M_{80\%}=7.12, M_{110\%}=7.83$; laptop: $F(1,88)=5.590, p<.005, M_{40\%}=4.49, M_{80\%}=5.83, M_{110\%}=6.16$).

In the second study we told participants that they had a 4 megapixels digital camera that recently broke. The choice task was to select a price for a new camera (\$200, \$250 or \$300 for a 4, 5 or 6 megapixels camera, respectively). Half of the participants were asked first whether they would repair the broken camera, and then chose between the three price/feature levels. The others had just one decision task: repair the broken camera or purchase one of the three new alternatives. This manipulation was intended to force participants to broadly or narrowly bracket the decisions (Read, Loewenstein and Rabin 1999), and to support the hypothesis that the repair cost needs to be considered as a separate option to effectively reduce price sensitivity. In this case, setting the decision stages together (broad bracketing) would allow participants to see that the repair was just one of several possibilities, which would not allow them to feel the pain of spending

money to return to the status quo. The narrow (sequential) versus broad (one stage) decision making was also included to rule out alternative explanations, such as participants inferring that a higher repair price meant that their original camera was more expensive.

An ANOVA revealed a main effect of repair cost ($F(2,98)=4.546, p<.025$) and an interaction between repair cost level and decision format ($F(2,98)=5.267, p<.01$). As repair prices increase, participants move from the cheapest camera model to the more expensive ones, but only in the sequential decision condition. The mean willingness to pay for each repair level in the sequential decision was $M_{\$100}=221.88$; $M_{\$150}=255.56$; $M_{\$200}=275$. The willingness to pay means for each repair level in the non-sequential decision was $M_{\$100}=244.12$; $M_{\$150}=235.56$; $M_{\$200}=243.75$. Although we expected that all means in the sequential decision condition would be greater than the means in no non-sequential decision, the mean difference found in the two conditions where the repair price was \$100 is not significant. These results support our proposition that the avoided loss—the repair amount—takes the form of a gain by being transferred to the product account.

This research provides support for the hypothesis that repair costs can be perceived as a gain towards the product account when the consumer decides not to do the repair, thus reducing the price sensitivity towards the replacement good. Our findings seem to be relevant both to consumers—that should be aware that money saved is not a gain—and to marketers—that could try to create strategies to sell more expensive products by framing repairs as perceived gains.

Anonymous and Unanimous: The Impact of Anonymity on Judgments of Opinion Representativeness

Dilney Goncalves, INSEAD, France
Amitava Chattopadhyay, INSEAD, Singapore

John is about to write an online review about a digital camera that he just purchased. He wants his opinion to have the greatest impact possible. Should he provide an anonymous opinion or should he identify himself? Common sense and research on communication suggest that identified sources make messages more trustworthy (Rains 2007). The decision to act on an opinion, however, depends not only on its perceived trustworthiness, but also on its perceived *representativeness*: is the opinion representative of the population of customers or just an isolated case? The question we address is: "Are people more likely to infer a more representative (versus more idiosyncratic) opinion when the source is anonymous or identified?" Building on attribution theories, we propose that it is easier to attribute an opinion to idiosyncratic preferences when the opinion is associated with a name than when it is anonymous.

Attribution theories suggest that behaviors result from the summation of dispositions and situational factors (Jones & Davis 1965, Kelley 1967). In our research, the behavior of interest is writing the opinion or review. Thus, a product review reveals the summation of the reviewer's dispositions and situational factors, one of which is the product's actual performance. If a consumer who reads the review wants to infer how good the product is, he or she has to discount the reviewer's dispositions. If the consumer can easily attribute the review to the reviewer's dispositions, he or she will infer that the review does not say much about the product. Consequently, this consumer will think that this is an isolated opinion and not a consensus. When a person expresses an opinion that is known to be a consensus, it is difficult to attribute it to that person's idiosyncratic dispositions. Conversely, if the opinion is known not to be a consensus, it is easy to attribute it to the person who produced it (Jones and Davis 1965).

We hypothesize that people have learned from experience that idiosyncratic opinions are strongly associated to a person's identity whereas consensus are weakly associated with any one person. Moreover, people use this knowledge to make the reverse causal inferences: if an opinion is difficult to link to one particular person, it is probably a consensus. Thus, we predict that if an opinion is identified (as opposed to anonymous), it is easier to make a dispositional attribution, and therefore the identified opinion is less likely to be perceived as representative than the anonymous one.

Study 1

The first study was a 2 (anonymity: anonymous vs. identified) X 2 (opinion valence: positive vs. negative) between-subjects factorial. Participants ($n=251$) read a scenario where they took the role of a restaurant manager. They were told that they had received some customer feedback. Then they read the feedback which was either positive or negative. In the identified condition, the last line of the feedback form displayed a name—purportedly of the customer who wrote the feedback. Participants in the anonymous condition did not see any name.

Two names were used: one common and one uncommon. After reading the feedback, all participants were asked to estimate the percentage of the restaurant's customers that shared the same opinion as presented in the form.

We obtained a significant interaction between opinion valence and anonymity. People in the negative condition estimated the opinion to be less general in the identified condition (43% of the population of customers) than in the anonymous condition (53%; $F(1,109)=4.16$, $p<0.05$). In the positive condition, there was no significant difference between estimates based on identified and anonymous opinions (55% vs. 53% respectively). The significant difference found in the negative conditions is consistent with more dispositional attributions being made when the name was presented than when it was absent. The lack of a significant difference in the positive conditions might have happened because people did not generate causal attributions. This finding is consistent with research suggesting that negative events generate more spontaneous causal attributions than positive events (Gilbert & Malone 1995). This happens because negative events are usually unexpected, especially given our scenario where participants acted as the restaurant manager. Positive events can lead to spontaneous causal attributions, however, if they are unexpected (Kanazawa 1992). In study 2 we lead participants to engage in causal attributions by using expected versus unexpected reviews. In addition, we measure Need for Cognitive Closure (NFCC), an individual characteristic that should influence the extent to which people make causal attributions (Kruglanski, Webster, & Klem 1993; Webster & Kruglanski 1994).

Study 2

The second study was a 2 (reviews: expected vs. unexpected) x 2 (anonymity: anonymous vs. identified) between-subjects factorial. Participants ($n=144$) were told they would read a product review purportedly picked at random from Amazon.com. Participants read a review confirming or disconfirming prior—experimentally manipulated—expectations. Anonymity was manipulated just like in study 1. In addition to percentage estimates, we measured the predictability and need for order and structure subscales of the NFCC Scale. We predicted that individuals high in these scales will make more dispositional attributions because dispositional attributions make the world seem more predictable.

We obtained a 3-way interaction between NFCC, expectedness, and anonymity. There was no effect of anonymity among individuals low in NFCC. Among individuals high in NFCC, there was a significant interaction between expectedness and anonymity ($F(1,63)=8.17$, $p=.006$): unexpected anonymous reviews were estimated to represent 59.8% of consumers who had used the product whereas unexpected identified reviews were estimated to represent 43.9% of consumers ($F(1,34)=3.08$, $p=.058$). Expected reviews showed the opposite pattern: identified reviews were estimated to represent 82.5% of consumers whereas anonymous reviews were estimated to represent 64.6% of consumers ($F(1,29)=4.9$, $p=.035$). Whereas the results for unexpected reviews are in accordance with our predictions, those of expected reviews were not predicted.

We showed that anonymity increases perceived representativeness of opinions. Our results suggest that causal attributions underlie the effect. In future studies we will test the process by directly manipulating ease of attribution and how these inferences influence attitudes and choice. This research contributes to the literature in representativeness judgments and word-of-mouth.

Developing Positive Attitudes and Strong Goals to Purchase Products of Fantasy

R. Justin Goss, University of Texas at San Antonio, USA

Ian M. Handley, Montana State University, USA

Brett M. Rynnion, Montana State University, USA

Individuals often fantasize about obtaining better products such as a better car, a new HDTV, or a dream vacation. Yet, as ubiquitous as such fantasies are, they are often times not realized. Oettingen (1996) has suggested that how individuals think about the future may be important in understanding how they come to set, and commit to, goals to achieve fantasies. In her Fantasy Realization Theory (FRT), Oettingen (1996) offers three ways an individual might deal with fantasies about the future, ultimately influencing goal formation and commitment. Two of the possibilities create a readiness to act that is independent of individuals' expectations, whereas the third entails an expectancy-based readiness to act.

First, individuals may largely disregard positive fantasies about the future and instead dwell on a negative reality that blocks a desired future. In this case, individuals experience no need or direction in which to act. Therefore, their expectations about achieving the fantasy do not heavily influence goal formation or strength.

Second, individuals can think about positive fantasies without considering current situations that may impede their fantasy-realization. As a result, they experience no need to act (i.e., overcome impediments), and therefore their expectations about achieving the fantasy do not heavily influence goal formation or strength.

Third, individuals may contrast a positive fantasy with a negative reality that blocks the potential realization of that fantasy. In doing so, the desired future becomes something that is to be attained, and the negative reality becomes something that must be altered. In this case, a necessity to act is produced. If individuals' expectations for attaining the fantasy are high (low), then a goal will (will not) be formed.

Prior FRT research has investigated pre-existing expectations for fantasy realization (Oettingen et al. 2001). In the current research, expectations for fantasy realization were manipulated by presenting participants an advertisement in which strong arguments made electronic products seem easily attainable or weak arguments made electronic products seem less attainable. That is, we took advantage of the idea that strong, persuasive arguments are those that communicate a highly desired (or undesired) outcome is likely (expected) if one adopts what is advocated within the message (Fishbein and Ajzen 1975). Based on FRT, we reasoned that participants who mentally contrast product fantasies and negative realities should consider the expectations within arguments, and form stronger goals to, and more favorable attitudes toward, purchasing an electronics product when doing so is supported by strong versus weak arguments. Further, argument strength will not affect the positive- or negative-only conditions. In the present experiment, goals strength was operationalized as expectations, plans, motivation, and attitudes regarding purchasing a fantasy electronic product.

To test our hypotheses, undergraduate participants were randomly assigned to the conditions of a 3 (Mindset Type: Positive Fantasy vs. Negative Reality vs. Mental Contrast) X 2 (Advertisement Quality: Strong vs. Weak) factorial design. Following Oettingen et al. (2001), participants first listed 4 positive fantasies about owning a desired electronics product and 4 negative realities standing in the way of that fantasy. Participants were then induced to either consider only *positive fantasies* about buying a desired electronics product, dwell on *negative realities* that stand in the way of buying the product, or *mentally contrasting* both. Participants were then presented with an advertisement that offered either excellent incentives (*strong arguments*) or lackluster incentives (*weak arguments*) for buying the electronic product from an advertised store. We then administered a questionnaire measuring participants' expectations, plans, motivation, and attitudes regarding purchasing a fantasy electronic product.

For all dependent measures, planned comparison confirmed significant differences between participants who received the strong versus weak advertisement, but only for the mental-contrast conditions. Therefore, for ease of presentation, the fantasy and negative-reality conditions were combined and compared to the mental-contrast condition. As predicted, participants in the mental contrast condition who received a strong versus weak advertisement demonstrated more positive attitudes, higher expectations, and stronger motivation and plans (goals) about buying a fantasy electronics product. Further, participants in the positive-fantasy only and negative-reality only conditions did not differ on these measures, regardless of which persuasive advertisement they received.

These results demonstrate that Fantasy Realization Theory can be used to predict consumer attitudes, expectations, and motivations. Specifically, by prompting consumers to contrast their present reality against a positive consumer fantasy, marketing managers can more successfully create positive consumer attitudes, expectations, and motivations by presenting strong arguments for purchasing a product.

We predict that individuals in the mental-contrast conditions will generate more positive thoughts in response to the strong versus weak advertisement, whereas individuals in the other conditions will not. This idea follows from FRT which suggests that only individuals who mentally contrast reality and fantasy consult their expectations (in this case provided by advertisement arguments) to determine goal commitment. Further, as is commonly observed in persuasion research (Petty and Wegener 1998), these thoughts should mediate the relationship between mental set and ultimate consumer attitudes. We also predict that only individuals in the mental-contrast conditions will indicate in their thought listings more plans and reports of intentions to purchase a fantasy product after reading strong versus weak advertisements. Importantly, this would provide evidence that individuals in this condition spontaneously devise plans and intentions in response to expectations, an effect not yet observed but consistent with FRT.

Celebrity Endorsements and Advertising Effectiveness: The Importance of Value Congruence

Eda Gurel-Atay, University of Oregon, USA

Lynn Kahle, University of Oregon, USA

A number of companies use celebrities in advertisements to promote different kinds of products. Indeed, millions of dollars are spent on celebrity contracts each year by assuming that the benefits of using celebrities will exceed the costs. Given the popularity and importance

of celebrity endorsements, the impact of celebrity endorsements on advertising effectiveness has been studied extensively over the last 30 years. Source variables, i.e., credibility (which includes expertise and trustworthiness) and attractiveness (which includes familiarity, similarity, and likeability), have been used by many researchers to understand the impact of celebrity endorsements. However, the underlying mechanisms used to explain the impact of these source variables on the relationship between celebrity endorsement and advertising effectiveness fail to converge.

One of the theories used frequently by researchers to explain the impact of celebrity endorsements is the match-up hypothesis. It suggests that there should be a good fit between the celebrity and the product; however, it is not clear what constitutes a good fit. Some researchers have focused on the attractiveness dimension and suggested that attractive celebrities will be more effective if they are used to promote attractiveness-related products, such as razors (e.g., Kahle and Homer 1985; Kamins 1990). Other researchers focused on the expertise, or product relatedness, dimension. They claimed that when there is congruency between the product type and the celebrity (as in the case of a sports athlete promoting sports shoes), advertising effectiveness will be enhanced (e.g., Till and Busler 2000). The congruency between celebrities and consumers has also been studied. For instance, Boyd and Shank (2004) showed that when there is a fit between the celebrity and consumer in terms of gender, consumers perceive the celebrity as more trustworthy, regardless of the product type endorsed by the celebrity.

The purpose of this study is to introduce another dimension for the match-up hypothesis: values. Because values are higher-order constructs that can affect other consumer-related constructs, such as consumer attitudes and behaviors, it is important to consider them when examining the impacts of celebrity-product congruence on advertising effectiveness. In other words, the congruency between consumers' perceptions of celebrities' values and product values might play an important role in determining the effectiveness of celebrity endorsements. Specifically, it is posited in this study that when there is a high level of value congruence between celebrities and products, advertisements will be more effective. The fit between celebrities and consumers is also important. As suggested by similarity studies (e.g., Feick and Higie 1992), the values of celebrities should be similar to the values of target consumers for effective celebrity endorsement.

To test the effects of congruency between celebrity's values, product values, and consumer values on advertising effectiveness, an experiment was designed. Several pilot tests were conducted to determine the value that would be used in the experimental ad (an internal value: a sense of accomplishment, cf. Homer and Kahle 1988), select the celebrity that was perceived as endorsing that value (Michael Jordan, $M=8.19/9.00$), and choose product categories that were perceived as high (congruent: fitness machine, $M=5.39/9.00$) or low (incongruent: beer, $M=2.98/9.00$) on that value. In other words, based on pilot tests, it was decided that fitness machine was congruent with Michael Jordan and beer was incongruent with Michael Jordan in terms of "a sense of accomplishment" value.

A 2 (product value: congruent vs. incongruent) X 3 (consumer values: internal vs. external vs. fun/excitement) between-subjects design was used to examine the impact of value congruence on two key dependent variables: attitude toward brand, and purchase intention. Based on Homer and Kahle's suggestion, consumer values were categorized into three dimensions. Internal values reflect the belief that people can fulfill their values by themselves and include self-fulfilling, a sense of accomplishment, and self-respect. External values reflect the belief that people are dependent on others to fulfill their values and include being well-respected, sense of belonging, security, and warm relationships with others. The last dimension includes fun and enjoyment and excitement values and can be fulfilled either internally or externally. Two magazine ads were designed to manipulate the congruence between the celebrity and product categories. In one ad, Michael Jordan was endorsing a treadmill, and in the other ad, he was endorsing beer. Participants first ($N=98$ college students) were exposed to one of these experimental ads and several real magazine ads. Then, they completed the measures for consumer values (i.e., List of Values, cf. Kahle 1996), attitude toward brand, purchase intention, celebrity characteristics (e.g., likeability, attractiveness, expertise, and familiarity), and manipulation check.

A MANCOVA was conducted on two dependent variables (i.e., attitude toward brand and purchase intention) by using product congruence and consumer values as independent variables, and celebrity characteristics and attitude toward ad as covariates. With the use of Wilks' criterion, the combined DVs were significantly related to one of the covariates, namely attitude toward ad ($F(2, 89)=8.815$, $p<.001$). After adjusting for this covariate, product value congruence had a significant main effect on the combined DVs ($F(2, 89)=10.05$, $p<.001$), consumer values had a marginal effect on the combined DVs ($F(4, 178)=2.152$, $p<.076$), and the interaction between product value congruence and consumer values had a marginal effect on the combined DVs ($F(4, 178)=2.053$, $p<.092$). Univariate analysis revealed that product value congruence and consumer values had significant main effects on attitude toward brand but not on purchase intention. Moreover, planned t-tests showed that attitude toward brand was more favorable when participants were exposed to a congruent experimental ad (i.e., when the product value was congruent with the celebrity's value; $M=5.69$) than when participants were exposed to an incongruent ad ($M=4.59$; $t=4.513$, $p<.001$). Attitude toward brand was also more favorable for participants who endorsed external values ($M=5.42$) than for participants who endorsed internal values ($M=4.69$; $t=-2.118$, $p<.038$). Univariate analysis also showed that the interaction between product value congruence and consumer values had significant effects on both DVs. Further analyses indicated that when the product value was congruent with the celebrity's value, consumers with external values had more favorable attitudes toward the brand ($M=6.41$) than consumers with internal values ($M=4.93$, $t=-3.145$, $p<.005$) and consumers with fun/excitement values ($M=5.48$, $t=2.620$, $p<.015$). Similarly, when the product value was congruent with the celebrity's value, consumers with external values had higher intentions to buy the brand ($M=4.59$) than consumers with internal values ($M=2.52$, $t=-3.288$, $p<.005$) and consumers with fun/excitement values ($M=3.34$, $t=1.767$, $p<.087$).

The present research shows that even a single ad based on value congruence is capable of affecting attitude toward brand and purchase intention. Specifically, this study provides evidence that the congruence between celebrity values and product values has positive impacts on key DVs. Interestingly; more favorable results were obtained when consumers' values were incongruent with the celebrity values and product values. This finding supports the idea that moderate incongruity might be more persuasive through creating some curiosity (e.g., Lee and Thorson 2008).

Overall, this study provides some insights that value congruence adds to the variance explained in advertising effectiveness, beyond and above attractiveness and expertise dimensions of the match-up hypothesis. Moreover, considering consumer values will help researchers and practitioners to measure the effectiveness of celebrity endorsements more reliably.

Self-Brand Attraction: An Interpersonal Attraction Approach to Brand Relationships

Lora M. Harding, Northwestern University, USA
Ashlee Humphreys, Northwestern University, USA

Are brand-consumer relationships the same as interpersonal relationships? For almost a decade, brands have been theorized as parasocial entities with which consumers can form personal attachments (Aaker 1997; Fournier 1998). But what is the nature of this relationship? Further, can the interpersonal metaphor truly be extended to the person-brand context? If brands do have personalities, is it enough to simply like the "person"? Or, might a feeling of reciprocated affection from the brand itself also play a role, as human interpersonal attraction theory might predict?

In this research, we build from previous research in marketing that has accounted for brand-consumer connections as relationships (Fournier 1998) and theorized that brands have personalities (Aaker 1997). Specifically, we take both of these ideas seriously by using the interpersonal attraction paradigm from relationship research (Byrne 1961) to better understand brand relationships and to predict self-brand attraction better than competing theorizations (e.g., Keller 1993). Our findings show that felt similarity toward the brand and its associations is necessary, but does not sufficiently account for consumers' opinions toward, connections with, and felt closeness to brands (i.e., the brand relationship). We further specify Fournier's insight by showing that relationships aren't simply about felt kinship with brands; they're dyadic in the sense that one must also consider the reciprocal liking of the brand for the person.

Thus, in accordance with Byrne's theory of interpersonal attraction (Byrne 1971), we predicted participants would convey a closer relationship to the brand the more similar they felt they were to the brand. Also in accordance with Byrne's findings, we predicted the brand's attitude toward the participant would play a role. Specifically, we predicted that the positive relationship between self-brand similarity and brand relationship closeness would only hold when participants felt that the brand did not like them more than they liked the brand. This prediction stems from research in the reciprocity literature, which suggests that excessive liking can convey unselectivity and even desperation (Eastwick, Finkel, Mochon, and Ariely 2007). To test these predictions, we adapted Byrne's interpersonal attraction paradigm to a consumer-brand setting. Whereas Byrne manipulated self-other similarity by varying the extent to which the parties expressed like attitudes toward a variety of topics, we assessed self-brand similarity by measuring these attitudes. Furthermore, whereas Byrne manipulated others' attitudes toward the self by supplying contrived responses to an interpersonal judgment scale, we measured both participants' liking for the target brand and the felt reciprocal liking of the brand for the participant. The details of our survey methodology are described below.

In the first part of the survey, participants were asked to indicate their attitudes toward several topics (e.g., musical tastes; Byrne 1971). After several unrelated filler tasks, participants then took part in the second part of the survey which assessed their relationship with Chevrolet, an automotive brand we anticipated would elicit varied similarity and feeling reciprocation assessments. First, we asked participants to imagine Chevrolet as a person (Aaker 1997) and to write a brief description of that person. Next, they were asked to project the brand's attitudes toward the same topics assessed earlier. Self-brand attitude discrepancies that fell within one standard deviation were considered similar attitudes, the sum of which comprised our self-brand similarity index. We then elicited participants' liking for the brand as a person and the felt reciprocal liking of the brand for the participant (Byrne 1961, 1971). The difference between these ratings was used as our measure of self-brand reciprocation, with higher scores representing over-reciprocation by the participant and lower scores representing over-reciprocation by the brand. Finally, we assessed participants' connection with the brand (Moore and Homer 2008), self-brand overlap (Aron, Aron, and Smollan 1992), and their overall opinion of the brand (four 7-point semantic differentials)—dependent measures selected to capture brand relationship closeness.

Regression analyses were conducted in which each of the dependent measures was regressed on self-brand similarity, self-brand reciprocation, and the product of the two. Results revealed the predicted main effect of similarity. For all three measures of brand relationship closeness, participants expressed a stronger connection to, a greater overlap with, and a more favorable opinion of Chevrolet when they felt they shared attitudes with the brand. Results also revealed the predicted interaction between self-brand similarity and feeling

reciprocation for two of the three dependent variables—self-brand overlap and brand attitude. To explore the nature of this interaction, we conducted a 2 x 2 between-participants ANOVA, separating those above and below the median for both independent variables. As predicted, there was a positive relationship between self-brand similarity and brand relationship closeness that held only when the brand is perceived to equally- or under-reciprocate affection.

These findings have several implications for consumer research. First, they prompt a reappraisal of our understanding of brands from a purely cognitive perspective, where brand equity is a product of brand association and valance (Keller 1993). Our findings suggest that brand liking is the product of a complex parasocial interplay that requires both projection of attitudes and reciprocated liking, at least for high-involvement products such as automobiles. Secondly, our work further specifies the nature of the consumer-brand relationship explored in previous research. We find that similarity of attitudes between the consumer and the brand is one important component of the brand relationship. However, we also find that consumers consider the extent to which their feelings toward the brand are reciprocated. In particular, our findings suggest that self-brand similarity exerts a positive influence on brand relationship closeness, but only when consumers feel that the brand does not like them more than they like the brand. In other words, when consumers feel that the brand over-reciprocates their affections, it seems they are “turned off,” thereby nullifying the effect of self-brand similarity on relationship closeness. In contrast, when consumers feel that the brand equally or even under-reciprocates their affections, our results suggest they are “turned on,” in which case self-brand similarity comes into play. Therefore, when it comes to brand relationships, it is not necessarily the case that consumers and brands of a feather flock together. Consumers must also feel that the brand is a catch, and that a relationship with that brand is not easy to come by.

Unconscious Brand Reactions Influence Financial Decision-Making

Philip Harris, University of Melbourne, Australia

Carsten Murawski, University of Melbourne, Australia

Abstract

Recent neuroimaging insights indicate that the reward value associated with brands may impact on affective processes underlying choice. In this research, we explore the possibility that brands with affective value can impact on behaviour by influencing affective systems underlying decision-making. Our results indicate that brand images with affective value can shift decision-making towards affectively-driven choices. Furthermore, these effects occur without conscious awareness of the identity of the brand stimuli. These findings provide initial evidence that brands may impact on behaviour outside of the consumer context by modulating affective systems underlying decision-making.

Introduction

Recent research indicates that exposure to goal-relevant brands automatically primes goal-directed behaviour, even without conscious awareness of the stimulus (Fitzsimons, Chartrand, & Fitzsimons, 2008; Chartrand, Huber, Shiv, and Tanner, 2008). An Apple logo may prime creative behaviour, or a Disney logo may prime honesty. These data indicate that brand exposure can moderate the salience of pre-existing behavioural goals, and may operate via mechanisms that are at least partially inaccessible to conscious introspection.

Increasingly, research drawing on neuroscientific techniques supports the idea that favoured brands may act as reward cues that moderate decision-making. Brand or product preference preferentially engages neural regions associated with reward processing (Plassmann, Kenning, Deppe, Kugel, & Schwindt, 2008; Schaefer & Rotte, 2007); and neural regions that mediate the influence of affect in decision-making (e.g. Deppe et al., 2005; Erk, Spitzer, Wunderlich, Galley, & Walter, 2002; Plassmann et al., 2008; Schaefer, Berens, Heinze, & Rotte, 2006). Further, the reward value associated with stimuli may bias decision-making in the absence of conscious processing (Pessiglioni, Petrovic, Daunizeau et al., 2008). These findings may have important consequences for brand theory. Affective brand responses may impact on behaviour via the modulation of affective processes in parallel with activation of brand-related schema in the absence of conscious processing. In this research we sought to examine these processes. We posed the question: Would unconscious presentation of a brand with affective value impact on decision-making behaviour that is susceptible to the influence of affective motivational states?

Brands and affective bases of decision-making

To consider these effects, we examined a scenario in which an individual is faced with a decision that is susceptible to the influence of affective motivational states—a choice between an immediately available monetary reward and another that is available only after a delay. This scenario pits the emotionally-driven drive for impulsive gratification against more reasoned and less impulsive choice behaviour (Hoch and Lowenstein, 1991). Crucially, incidental affective states impact on the extent that delayed rewards are valuable. For example, males devalue delayed financial rewards more heavily after exposure to images of attractive females (Wilson & Daly, 2004). Furthermore, decisions that favour immediate rewards have been shown to engage neural regions linked with affective processing, particularly those associated with reward processing (McClure, Ericson, Laibson, Loewenstein, & Cohen, 2007; McClure, Laibson, & Cohen, 2004).

Hypothesis Development

We believe that favoured brands may act on such decision-making processes. By acting as reward cues, we propose that brands with affective value may directly prime affective processes underlying decision-making mechanisms, and will bias decisions between earlier and later monetary rewards towards earlier reward options. We predict that subliminal presentation of a brand with affective value will prime significant devaluing of delayed financial rewards than other priming stimuli with lesser affective value.

Method

One hundred and thirteen undergraduate college students participated in a computer-based temporal discounting task which offered a series of choices between an immediate reward of \$20 and a reward of higher value to be paid at one of six possible delays (1, 10, 21, 55, 90, 180 days). Each choice was preceded by the subliminal presentation (16 ms pre- and post-masked) of one of four priming image types: a brand logo (Apple or Windows); a smiling face, or a household object. Participants completed the discounting task four times, once for each of the priming image types. The principal dependent variable was the subjective value assigned to delayed rewards when subliminally primed by each of the four image types. Following the discounting task, participants completed a five-item brand affect scale which incorporated seven-point ratings of brand salience, brand affective value, brand ownership, desire to own brand products, and intention to purchase branded products within the next six months.

Results

Seven participants with discounting rates greater than three standard deviations above the median discounting rate were removed from the data set. Paired t-tests examining brand affect scale ratings indicated that ratings for Apple were significantly higher than for Windows overall, $t(103)=3.40$, $p=.001$, and on individual scale item ratings of affective value, $t(103)=2.20$, $p<.05$, desire to own, $t(103)=5.26$, $p<.001$, and intention to purchase, $t(103)=5.40$, $p<.001$. Responses to the smiles priming condition are not examined in this paper. A repeated measures analysis of variance examined the impact of priming condition (3-Apple, Windows, Neutral) and reward delay time (6) on subjective value of delayed rewards for the remaining 106 participants. Main effects of image priming condition, $F(2,10)=4.10$, $p<.05$, and delay time, $F(5,525)=495.69$, $p<.001$, were observed, whereas an interaction between priming condition and delay time, $F(10,1050)=.41$, $p=NS$, was not observed. Delayed rewards were significantly less valuable when preceded by an Apple logo than when preceded by a Windows logo, $t(105)=1.92$, $p<.05$, one-tailed, or a neutral image type, $t(105)=2.62$, $p=.005$, one-tailed. Thus, the experimental hypothesis was supported.

Discussion

Our results indicate that the affective value associated with a brand may impact on unrelated decision-making processes. Following presentation of the Apple logo, participants were more likely to choose an immediate reward than when primed by other image types. Further, the impact of this affective value on behaviour occurred without conscious awareness of the priming images. Thus, our findings support a proposal that brand images can impact on behaviour by communicating affective value in the absence of conscious awareness of the stimulus. These findings provide initial evidence that brands may impact on behaviour outside of the consumer context by modulating affective systems underlying decision-making. In addition, an initial analysis indicates that when primed by a favoured brand, preference for immediate rewards is linked with faster response times than preference for delayed rewards, and is insensitive to decision-difficulty. Further analysis of these data will examine the role of heuristic decision-making processes associated with choices for immediate rewards and may provide further support for an affective mechanism evoked by unconscious brand presentation with impact on decision-making processes.

Insights into the Concept of Underconsumption and the Internal and External Mechanisms Consumers Utilize to Underconsume

Jonathan Hasford, University of Kentucky, USA

Abstract

While prior research has used the term underconsumption to characterize certain behavior patterns in consumers (e.g. Heath and Soll 1996), research is currently lacking an understanding of the phenomena of underconsumption. The current research aims to define the construct of underconsumption based on previous consumer research, including research on topics such as frugality (Lastovicka et al. 1999), tightwadism (Rick, Cryder, and Loewenstein 2007), and hyperopia (Haws and Poynor 2008). Furthermore, this research also provides an understanding of the external and internal mechanisms that consumers utilize to maintain lower amounts of consumption. An exploratory study is conducted to delineate the construct of underconsumption and investigate the mechanisms that consumers utilize.

Prior research has used the term underconsumption to describe patterns in consumer behavior (e.g. Heath and Soll 1996), but an understanding of the concept itself and the mechanisms that consumers utilize to maintain underconsumption behaviors are still unknown (Lee, Fernandez, and Hyman, 2009). In the current research, literature related to frugality (Lastovicka et al., 1999), tightwadism (Rick, Cryder, and Loewenstein, 2007), and hyperopia (Haws and Poynor, 2008) are used to provide an understanding of underconsumption. Additionally, this research also attempts to understand the mechanisms that consumers utilize in order to underconsume. The ultimate goal of this research is to generate a comprehensive model which explains the antecedents to consumer underconsumption.

Defining Underconsumption

Three related topics of research provide a framework for defining underconsumption. Lastovicka et al. (1999) define frugality as a consumer lifestyle trait in which individuals are restrained in acquiring and resourcefully using economic goods and services to achieve longer-term goals. Tightwads are classified as those whose affective reaction to spending leads to less consumption than the individual's more deliberate self would prefer (Rick et al., 2007). Lastly, hyperopia is defined as the deprivation of hedonic experiences due to excessive overwork and the need for control at one's job (Kivetz and Simonson 2002). While each of these classifications is unique, they all involve lesser amounts of consumption relative to others of similar background and status. Therefore, using these three types of underconsumption, overall underconsumption is defined as consuming fewer goods, services, and experiences than others of similar demographic and socioeconomic status. Since underconsumption consists of frugality, tightwadism, and hyperopia, these concepts should be empirically related to one another.

Mechanisms that Influence Underconsumption

In addition to developing the concept of underconsumption, the current research also investigates the mechanisms consumers utilize to underconsume. Frugal consumers and tightwads experience affective reactions during consumption decisions, while hyperopic consumers do not. Frugal consumers derive pleasure from saving to meet long-term goals, while tightwads experience anticipatory pain and anxiety toward spending (Rick et al. 2007). Since these forms of underconsumption involve the recognition of future affect, self-control and willpower should help consumers avoid the perceived negative affect that is related to present consumption. Self-control refers to the general strategies that one imposes individually in order to maintain consistency in behavior, while willpower relates to the tactics such as precommitment, economic cost assessment, and regret and guilt that allow people to overcome their desires (Hoch and Loewenstein 1991). A greater presence of these internal mechanisms should lead to increased levels of tightwadism and frugality as consumers will manage and control their desires in order to meet their affect-laden consumption decisions.

Since individuals are inherently different in their ability to regulate their own consumption levels (Tangney, Baumeister, and Boone 2004), the hyperopic consumer is expected to use different mechanisms. Recall that a hyperopic consumes less due to overwork and the need for control. This very imbalance is the mechanism that the hyperopic consumer utilizes. Desire control, which consists of avoidance, postponement, and distraction, involves the manipulation of one's own reference points in order to reduce the frustration they experience in consumption decisions (Hoch and Loewenstein 1991). Therefore, hyperopic consumers use work and other precommitments as external mechanisms to avoid consumption situations instead of relying on the internal mechanisms of self control and willpower that tightwads and frugal consumers utilize.

Method

Sixty-three undergraduate students completed a questionnaire related to underconsumption and the internal control mechanisms discussed earlier. First, the participants filled out each set of items for frugality (Lastovicka et al. 1999), tightwaddism (Rick et al. 2007), and hyperopia (Haws and Poynor 2008). Then, participants were provided with a scenario in which they were to imagine saving for a spring break trip. The participants were asked to assess their ability to budget themselves and save money for the trip (i.e. willpower). After completing the scenario, participants concluded the study by filling out two self-control scales from Tangney et al. (2004) and Haws and Bearden (2006).

Results

In order to determine whether the concepts of frugality, tightwaddism, and hyperopia fit within the overarching construct of underconsumption, a correlation analysis of the data was conducted. Results showed that hyperopia significantly correlated with frugality ($r=.33, p<.01$) and with tightwaddism ($r=.31, p=.01$). Frugality was also significantly correlated with tightwaddism ($r=.50, p<.01$). Given that all three of these concepts are related to one another, these findings suggest that each classification shares a common underlying concept, in this case underconsumption.

To analyze the concept of self-control and its relationship to the types of underconsumption, a regression analysis was conducted between the total score on the self control items and the total scores of each measure of underconsumption. Findings revealed that increased levels of self control predicted increases in both frugality ($\alpha=.63, p<.01$) and tightwaddism ($\alpha=.55, p<.01$). Conversely, self control was not predictive of hyperopia ($\alpha=.09, p>.47$).

The consumption scenario was also analyzed to provide further insight on the processes that consumers utilize to promote underconsumption. Results demonstrated that greater willpower in the scenario was predictive of increased levels of frugality ($\alpha=.30, p<.05$) and tightwaddism ($\alpha=.28, p<.05$), and was unrelated to hyperopia ($\alpha=.08, p>.53$). The self control and willpower findings together provide support for internal mechanisms of control promoting underconsumption behavior within tightwads and frugal consumers. Furthermore, the lack of self control and willpower in hyperopic consumers suggests that external mechanisms of desire control need to be investigated. A follow-up study will be conducted to determine the influence of avoidance, postponement, and distraction in hyperopic consumers. Ultimately, a comprehensive model of the antecedents to underconsumption will be created.

Conveying an Impression: Effects of the Consumer Review Process on Attitude Communication and Persistence

Stephen Xihao He, Georgia Institute of Technology, USA

Samuel Bond, Georgia Institute of Technology, USA

Abstract

This research examines the long-term impact of review writing on the evaluation of a consumption experience. Relevant theories offer conflicting predictions regarding the extent to which writing a product review will stabilize attitude towards the product. We investigate this question in an experimental setting using short movie clips as target stimuli. Our results indicate that the timing and format of the review task systematically influence attitude persistence over time, as well as readers' inferences regarding that attitude. Implications and extensions of these results are discussed.

Introduction

Increasingly, consumers are involved in reading as well as writing reviews about consumption experiences. Many studies have explored the influence of consumer-created content on attitudes and behaviors of the audience (Chen and Xie 2008; Chevalier and Mayzlin 2006), but research that examines the influence of the creation process on creators themselves has been rare. An exception is recent evidence that writing a product review can change one's attitude toward the product (He and Bond 2009). However, it remains unclear whether any influence of review writing will endure over time. More generally, the intersection of review writing and attitude persistence is a neglected but important topic.

Different research streams imply contradictory predictions for the impact of review writing on attitude persistence. On the one hand, classic models of elaboration such as the ELM and HSM (Chaiken 1980; Petty and Cacioppo 1986) suggest that greater cognitive processing of attitude-relevant information should increase attitude strength and persistence. However, another approach has focused on the effect of reasoning about attitudes on attitude change over time and attitude-behavior consistency (Sengupta and Fitzsimons 2000; Wilson and Schooler 1991). Findings from this stream reveal that analyzing reasons before attitude measurement generally reduces attitude persistence, while analyzing reasons after measurement increases persistence.

In order to reconcile this conflict and make predictions, we consider two cases, in which consumers review a product either *before* or *after* reporting their attitudes. In the first case, we note that review writing is different from typical reasoning manipulations, which force participants to justify their views with reasons and therefore focus on aspects of the experience that are verbalizable and accessible but may not contribute meaningfully to attitudes. Review writers, on the other hand, are instead free to list both positive and negative aspects of their experience without needing to defend or justify their views. Because review writers are not bound to an attitude derived from available reasons, we suggest that their attitudes are likely to cohere with the content of reviews and persist over time (a reinforcement effect). In the case of writing a review after providing one's attitude, both streams of research cited above agree on a reinforcement effect. Therefore, the act of writing about a consumption experience will make initial attitudes more persistent, whether or not the review precedes or follows attitude assessment.

Hypothesis 1: Writing a product review prior to stating one's attitude will increase the stability of that attitude over time.

Hypothesis 2: Writing a product review after stating one's attitude will increase the stability of that attitude over time.

Although some review forums (e.g., *car.com*) request piece-meal, *guided* reviews that discuss specific attributes of the product, others (e.g., *imdb.com*) request open-ended, *unguided* reviews that encompass the whole product experience. We expect that guiding consumers to focus on specific attributes should especially enhance elaboration and encoding of thoughts during the review process, strengthening attitudes and increasing attitude persistence.

Hypothesis 3: The enhancement effect of review writing on attitude persistence will be stronger for reviews that are guided rather than unguided.

Design/Procedure

The study was conducted in a lab with 118 student participants. A mixed design included two between-subjects factors (order: *review-first* vs. *attitude-first*; review type: *guided* vs. *unguided* vs. *filler*) and one within-subjects factor (time: *immediate* vs. *one month later*). At t1, all participants watched the target stimulus, a short animated movie clip portraying an origami artist performing his craft. After viewing the movie, participants were given different instructions according to condition. The *review-first* conditions were asked to generate written reviews: the *guided review* group answered a series of questions focusing on attributes of the clip and the *unguided review* group was instructed to write an integrated, open-ended review. The *filler group* wrote 10-15 sentences summarizing events of the previous day. Next, these participants rated the clip on four 7-point attitude scales; they also answered various follow-up questions and demographic measures. Participants in the *attitude-first* conditions completed the steps above in opposite order. One month later, all participants took part in a second session where identical attitude measures were collected.

Results and Conclusions

Composite attitude measures were formed by averaging the four attitude questions at both t1 and t2. The absolute attitude difference between t1 and t2 was used to represent attitude persistence. For the following analyses, the condition in which attitudes were reported immediately and followed by the filler task serves as an omnibus control.

Data for the control condition showed an average absolute attitude change of .69 over the one-month delay. This change is both surprisingly large and significantly different from zero ($t=4.16, p<.001$), suggesting participants were generally poor at retrieving their prior attitudes. The main effect of order was marginally significant ($F(1, 111)=3.54, p=.06$), indicating that whether the attitude was measured before or after review writing influenced the stability of that attitude over time. In support of Hypothesis 1, attitude persistence was increased by the provision of a review before attitude assessment. Planned contrasts revealed that participants who provided guided reviews before reporting their attitudes exhibited marginally less attitude change ($M=.42$) than those in the control condition ($M=.69, F(1, 35)=2.74, p=.11$), while participants who provided unguided reviews before reporting their attitudes exhibited attitude change that was directionally less than controls ($M=.57, ns$). The difference between the two review conditions was only directional, lending weak support to Hypothesis 3.

In order to test Hypothesis 2, we compared the attitude change of participants who provided guided reviews after reporting their attitudes ($M=.60$) to that of participants who provided unguided reviews after reporting their attitudes ($M=.71$) and the omnibus control condition ($M=.69$). No reliable differences were observed; therefore, H2 was not supported.

Analysis of within-cell attitude variance at t1 revealed one potential means by which reviews may affect attitude persistence. Specifically, the variance within the *rate-first* conditions ($V=.96$) was considerably smaller than that of participants who had written

reviews ($V=2.19$, Leven's test $F(1, 91)=3.53, p=.06$). This suggests that that as a result of cognitive reflection, initial attitudes in the review condition were more well-formed and less subject to fluctuation over time.

Overall, these results provide initial evidence that the act of writing a review can influence consumers' attitude persistence. In subsequent research, we plan to explore the robustness of this finding to consumption experiences that differ in product category, valence, or intensity, and also to analyze the content of reviews themselves for differences that may affect long-term memory and retrieval of the consumption experience.

Players' Attitudes Toward Preorders and Adoption Intention of New Videogames: A Qualitative Approach

Monica D. Hernandez, Texas A&M University-Corpus Christi, USA

Handan Vicdan, Eastern Kentuck University, USA

Launching of new products connotes high costs and high probability of risk for manufacturers. Marketers of video games, books, music CD, DVD movies, and telecommunication gadgets usually promote new products months ahead of introducing them to the market. Consumers can preorder these products and receive them as soon as they become available. Despite the economic importance of worldwide videogame sales (Magiera 2009), the motives of players relying on preorders have not been explored. Why are consumers willing to pay in advance when they have other readily available alternatives? Why do some consumers buy products when they do not know about their features? How do they choose between a promised superior functionality versus a trialable alternative? We seek to bring insights into these issues. The contribution of this research is threefold: (1) explore the motives of videogame players in preordering, (2) highlight the unique pattern of the phenomenon in the early adoption of new videogames, and (3) adopt a qualitative approach to explore preorder decisions rather than an experimental approach to provide richer and broader coverage of the likely factors associated with the topic of interest.

In the case of videogames, preorders display two patterns: (1) Continuous innovation or an updated and enhanced version of a pre-existing game (e.g. Guitar Hero III, Rock Band), (2) discontinuous innovation or a totally new product including new features and qualities (consider the game Guitar Hero introduced for the very first time). In the former situation, consumers preorder video games when they have had certain experience with an earlier version of the game or at least with the game developer. For instance, players who have been satisfied with the videogame FIFA 2008 are potential buyers of FIFA 2009. We can extend this situation when new video game consoles are introduced. The second situation occurs when some videogames—similar to new telecommunication devices—usually come with totally new features that the consumer has never experienced before.

We conducted focus group interviews with videogame players to obtain insights about preordering behavior. Each session was videotaped and lasted about 70 minutes. We followed a grounded theory approach (Glaser and Strauss 1967) to formulate a theory about the phenomenon of interest. The interviewees were asked to describe their thoughts and experiences regarding the preorder and gaming process. We identified common emerging themes and discussed the implications of these themes on preorder intentions. We classified emerging themes into two groups: purchase and adoption (psychological and product related elements).

Purchase: (1) Securing the purchase: Players expressed their concern about the risk of the unavailability of the videogame. Hui et al. (2008) concluded that the highest point of sales of new products occurs in the preorder stage. After launching the product, sales decline. A plausible explanation is that players rush to preorder a game to secure its acquisition rather than waiting and find it unavailable due to high demand and/or low supply. This situation is akin to Belk et al.'s (2003) description of desire: players' intent on acquiring the symbolic benefits of a desired game rather than the game itself is fulfilled through preordering. True thrill is kept alive through preordering until the actual game is acquired. Once acquired, players undergo exploration of new features stage. Subsequently, players' thrill ends if they no longer have anything to discover or learn about the game, and if perceived challenge or competition is over. (2) *Risk absence:* New technologies derive new tasks for consumers and generate uncertainty (Ziamou 2002). Despite the absence of trialability, consumers expressed no functional (performance) risk involved in the preorder, confirming the claim that a continuous innovation has lower levels of perceived risks. Similarly, they do not perceive any risk of making a poor purchase decision. Players expressed that they never

“regretted” a preorder. They also feel confident, as they have the option to opt-out of preorder. (3) *Main sources of information*: For continuous innovations, familiarity with game increases the desire for preordering. For discontinuous innovations, advertising and early reviews increase expectations. High involvement players desire to acquire both discontinuous and continuous innovations.

Adoption: (1) Trialability versus discovery: Rogers (1983) viewed trialability as a dimension of adoption of new products, which relates to the opportunity to be exposed to the innovation. However, this opportunity is inexistent in the case of preorders. Accordingly, lack of trialability may have a negative impact on perceived risk. We found that discovery stage substitutes the lack of trialability. (2) *Desire for status versus desire for process*: High involvement players have a high desire for status (“to win”), focusing on the “outcome.” In contrast, low involvement players have a desire for fun and focus on the “process” (“to play”). (3) *Curiosity versus defined expectations*: Players reported their defined expectations from a new videogame to include advanced features that make it more realistic (little discrepancy between the videogame and its actual manifestations in real life) and interactive, and increase sensation. Curiosity or interest in novelty also emerged as a common category. Players perceive new products as providing continuity of a known story, yet with novel features and challenges that create excitement and room for discovery. They seem to be curious about the features to accomplish this goal. Although familiarity with the game increases the desire to preorder, consumers still seek room for discovery (discover added features), which also creates allure and increases the desire to preorder.

Choice Behavior of Maximizers and Satisficers When Alternatives Are Priced Using Non-monetary Points

Meng-Hua Hsieh, University of Washington, USA
 Richard Yalch, University of Washington, USA
 Edwin Love, Western Washington University, USA

Abstract

Schwartz et al. (2002) suggested that Herbert Simon’s concept of satisficing could be considered an individual difference and developed a scale to measure maximizing-satisficing tendencies. Satisficers settle for non-optimal choices by restricting their information seeking and analysis, whereas maximizers persist and evaluate all or most options. Although clearly relevant to consumer decision-making, little consumer research using this concept has been reported.

A potential application is found in Hsee et al.’s (2003) research demonstrating how making an optimal choice among alternatives varying in effort and reward is complicated when the decision involves a medium such as airline mileage or reward points. Consumers sometimes choose a higher effort alternative to acquire more points even though these points cannot be used to acquire anything of additional value. This phenomenon is explained by the decision being determined by whether the ratio of the relevant medium levels is greater than the ratio of the resultant outcomes. Thus, in their first study, 50% of the subjects selected the option to work for 7 minutes to earn 100 points that could be exchanged for a gallon of pistachio ice cream compared to only 22% when the choice did not involve points (i.e., work for 7 minutes to earn a gallon of pistachio ice cream).

Although many consumers exhibited a myopic reliance on medium differences in making choices, others did not. A possible reason is found in Schwartz et al.’s (2002) suggestion that some individuals accept non-optimal choices rather than exert the extra effort required to identify the best alternative. We propose that Maximizers are more likely than Satisficers to use only the ratios of effort and medium and ignore the exchange rates and the resulting outcome ratios when making their decision.

Research Study

We conducted an experiment based on Hsee et al. (2003) Study 1, with several changes, such as adding a 30/35 minutes effort condition to the original 6/7 minutes effort (equal ratios but increasing the incremental time from 1 to 5 minutes), having individuals rank five ice cream flavors and then presenting them with choices between either their 1st and 2nd most preferred flavors or their 1st and 5th most preferred. Also, to better quantify the effect of the medium on decision making, individuals were asked to state their strength of preference as well as make a discrete choice.

The experimental design was thus a 2 (effort levels: 6/7 or 30/35 minutes) by 2 (outcome equivalence: 1st versus 2nd or 1st versus 5th most preferred flavors) by 2 (medium: no points or 60/100 points) full factorial design. After making a choice (e.g., 6 minutes-60 points-1st preferred or 7 minutes-100 points-2nd most preferred), 203 undergraduate student subjects indicated their strength of preference by dragging a pointer on an on-screen line with end points labeled 1 (strongly preferred Task 1) and 100 (strongly preferred Task 2). Next,

subjects responded to an open-ended inquiry about their reasons for making their choice. Response times for the discrete choice and strength-of-preference tasks were recorded. Lastly, subjects responded to the Maximizing-Satisficing scale.

Results

Analysis revealed that we were able to replicate the medium maximization effect in the conditions most similar to Hsee et al.'s Study 1. Forty-two percent of subjects selected the more effortful Task 2 (7 minutes to receive the 2nd flavor) over task 1 (6 minutes to receive the 1st flavor) when points (100 versus 60 points) were involved while only 11% did so when no points were involved. Counter to expectations, the medium maximization effect slightly increased with greater effort time, despite equal ratios, when the flavor choices remained between 1st and 2nd. Forty-six percent of subjects selected Task 2 with points versus only 5% with no points. Although greater outcome disparity did not eliminate the Medium Maximization effect, the effect decreased with more effort despite equal ratios, as predicted. When the effort ratio was 6/7 minutes and the choice was between 1st and 5th most preferred flavors, 35% selected Task 2 with points while no one did so without points. However, when Task 1 was 30 minutes to receive the 1st preferred flavor and Task 2 was 35 minutes to receive the 5th most preferred flavor, no one selected Task 2 when no points were involved and only 22% did so when points were involved.

A logistic regression revealed a significantly positive main effect of including a medium ($p < 0.05$) and a significant effect of outcome equivalence ($p < 0.05$). The main effect of effort level and all the interactions were not significant. ANOVA analysis using slider preference yielded the same pattern of significance.

Analysis using Maximizing-Satisficing scores found little support for it as a moderator. Further, other analyses (e.g., response time and reasons for choosing Task 2) were not consistent with the notion that Maximizers exert extra effort to optimize their choices. Other researchers (e.g., Diab et al. 2008; Nenkov et al. 2008) have recently questioned the original Maximizing-Satisficing scale's validity while acknowledging the concept's usefulness.

Discussion

This research supports the notion that medium maximization may undermine consumer's ability to select the best alternative in terms of effort and outcome ratios. However, it also demonstrates that medium maximization is less of an issue when outcomes are more easily compared and effort levels differ more at an absolute level. Individual differences in susceptibility to medium maximization could not be clearly predicted from scores on the original Maximizing-Satisficing scale. In order to handle the issues with Schwartz et al.'s scale, a follow-up study was conducted using revised Maximizing-Satisficing scales (e.g., Diab et al. 2008) as well as need for cognition and involvement measures. The results demonstrate that Maximizing-Satisficing is a distinct concept worthy of future research in a consumer context.

Carrying the Torch: Determinants of Intergeneration Influences as Sources of Brand Loyalty

Kyle Huggins, James Madison University, USA

Kenneth Bates, University of San Diego, USA

Darin White, Samford University, USA

Much of consumer behavior becomes engrained at a very young age. From the time we are born, we consume; and as this process is replicated, we begin to develop preferences for certain products and brands of products. One key relationship that is instrumental in the forming of these preferences is the relationship that a child develops with his or her parents. As a family grows and develops, the purchasing decisions that reflect a family's lifestyle become internalized allowing children to learn to accept them as the norm (Sears 1983). Hence, this socialization process has become an area of particular interest for consumer researchers studying the effect of intergenerational (IG) influences on brand loyalty.

Moore, Wilkie, and Lutz (2002) performed one of the most methodologically challenging studies demonstrating the effects of intergeneration influences on brand equity. They concluded that "intergenerational influences are a real marketplace phenomenon and a factor that merits much closer attention." Even so, little research has since been conducted to provide answers to which specific family factors contribute to this phenomenon. Therefore, this paper seeks to fill that gap by researching the effects of several predictor variables including mother involvement, sibling influence, and family structure on IG influences.

Consistent with Moore et al. (2002), we conducted parallel surveys of 121 mother-daughter dyads. We recruited the daughters from an introductory marketing course from a Southeastern university with the proviso that they must currently live off-campus and shop for groceries. We developed two similar questionnaires where each dyadic member was asked to indicate whether she used each of the twenty-four product categories listed. Respondents then listed their preferred brands as well as listing any additional brands that were "seriously

considered.” Then we asked participants to report independently their perceived dyadic partner’s product usage and brand preference in each category. Students completed their questionnaires first and provided their mother’s name and address for the mailing of the parallel survey and cover letter that explained the project. Both dyadic partners were alerted not to communicate about survey responses until all forms were returned.

While data collection was identical, our assessment of the scope of intergeneration influence is different than Moore et al. (2002). The aforementioned authors’ measurement of IG brand loyalty consists if, and only if, there is a direct match between the actual choice of the most preferred brand of both mother and daughter. However, exact matches do not take into account the probability of chance or bidirectionality, which the authors admit is a limitation of their research. Therefore, we chose to combine both the dyadic analysis of Moore et al. (2002) with the perceived single-member approach of their earlier predecessors (Childers and Rao 1992; Heckler, Childers, and Arunachalam 1989). Using the exact survey distributed by the Moore et al. (2002), a combination of answers allows for an alternate way to analyze intergenerational brand loyalty. Using a combination of survey items such as acknowledgement of mom’s consideration set, whether the daughter chooses from her mom’s consideration set, and actual brand preference match, we were able to conceptualize at the individual level different categorizations that account for intentional IG brand loyalty, perceived IG brand loyalty, deliberate avoidance, chance matches, and complete unfamiliarity. These new categorizations of choice data have allowed us to conceptualize IG brand loyalty as the combination of both intentional and perceived IG brand loyalty. Theoretically, we argue that even though the survey data for some mother-daughter dyads do not match in brand preference, there is still an effect of IG influence. For example, we contend that when a daughter knows her mom’s consideration set and actually chooses the brand she perceives as her mother’s preferred choice, then there is perceived brand loyalty. We contend this data should be considered in the dyadic analysis even though the dyad does not “match” in brand preference. Likewise, these new categorizations allow us to remove matches that are considered to be a product of chance and bidirectionality. We believe the removal of these chance matches along with the addition of perceived IG brand loyalty is one initial contribution to this literature stream as it adds validity to the construct.

Finally, in addition to collecting product and brand preference information, we collected information on a number of independent variables as they relate to predicting IG brand loyalty. We hypothesize that there are direct and interaction effects of the relationships between IG brand loyalty and a number of family related variables such as mother involvement, number of siblings, and household family structure (traditional vs. non-traditional). Here, mother involvement specifically measures post hoc a daughter’s perception of actual versus desired level of involvement during the daughters’ formative years. The key to this measure is not just the amount of time that daughter and mother spend together, but also the quality of time that will have a profound impact on the nature of the mother-daughter relationship and the daughter’s desire to adopt intergenerational brands. Early results indicate that intergenerational influences increase ten percent across all product categories and brands when both intentional and perceived brand matches are included in the analysis. This suggests that IG brand loyalty is even more prevalent than originally expected. Additionally, regression analysis demonstrates that predictor variables are significant and account for a reasonable amount of variance ($r^2=.169$). We believe that these results are interesting and adequately respond to the call by Moore et al. (2002) for discovering predictors of intergenerational influence. This is by no means an exhaustive list of determinants, but it is an important step in the understanding of the interactions of the familial socialization process.

The Effects of Self-Construal and Moral Identity on Company Evaluations: The Moderating Roles of Social and Personal Relevance of Corporate Social Responsibility Activities

Elif Isikman, University of Southern California, USA

Zeynep Gurhan-Canli, Koc University, Turkey

Vanitha Swaminathan, University of Pittsburgh, USA

In this research, we examine the effects of self-construal and moral identity on company evaluations as a function of social and personal relevance of CSR activities. In a set of two studies, we find that when self construal is independent (vs. interdependent), company evaluations do not vary as a function of social (vs. personal) relevance of the CSR activity. In contrast, when self-construal is independent (vs. interdependent), high personal (vs. social) relevance of CSR activity, leads to more favorable company evaluations. In a third study, we demonstrate that social relevance interacts with symbolization dimension of moral identity to predict company evaluations.

An important objective of corporate social responsibility (CSR) activities is to improve consumers’ evaluations of a company or its brands. Extant research examined the effects of CSR activity-company fit (Becker-Olsen, Cudmore and Hill 2006; Lafferty, Goldsmith, and Hult 2004; Simmons and Becker-Olson 2006), fit between CSR efforts and consumer characteristics (Sen and Battacharya 2001), and consumer attributions (Ellen, Webb, and Mohr 2006; Forehand and Grier 2003; Yoon, Gurhan-Canli, and Schwarz 2006) on company

evaluations. While previous research (e.g., Sen and Bhattacharya 2001) examined personal relevance of CSR activities on company evaluations, relatively little research investigated the extent to which consumers perceive social benefits from CSR activities and how such perceptions influence company evaluations. In this research, we contribute to this growing body of literature by distinguishing between perceived social and personal relevance of CSR activities and investigating their moderating effects when self-construal and moral identity are present.

Consumers may evaluate CSR activities both from personal and social perspectives. For example, college students may perceive contributions to college (vs. primary school) education personally more relevant although both of these contributions may be evaluated equally high in terms of their social impact. A person may deeply care about arts education but may perceive efforts to address illiteracy more relevant from a social perspective.

Two key concepts that are examined in relation to perceived personal and social relevance are self-construal and moral identity. Self-construal refers to perception of one's self either as an individual entity or in relation to others. Markus and Kitayama (1991) examined individual self-perceptions in relation to cultural identity and divided this construct into two variables, independent and interdependent. Independent individuals see themselves as stable and separate from the interpersonal context and value autonomy and uniqueness. On the other hand, interdependent individuals consider themselves more flexible and interlaced within the social context, and value maintaining group harmony. Arnocky, Stroink, and Decicco (2007) suggested that self-construal has an important role for individuals to determine what types of environmental problems concerns them. Thus, it may also affect the company evaluations based on the adopted CSR activity. We argue that self-construal has different effects on the company evaluations when the level of personal and social relevance to CSR activities changes. Because independent individuals value satisfying their own personal goals and interests, they may respond favorably to CSR activities that match their personal values. Nevertheless, independent individuals may evaluate companies similarly in terms of social relevance of CSR activities as they prioritize the conformity of CSR activities with their self interests. As interdependent individuals value group goals and interests, they may appreciate activities that have high perceived benefits to the society. On the other hand, their company evaluations may not change significantly with respect to the personal relevance of CSR activities as satisfying group interests, as opposed to their own, is more important for them. In sum, we hypothesize that

- $H1_a$: When self-construal is independent (vs. interdependent), high personal (vs. social) relevance of CSR activity, leads to higher company evaluations.
- $H1_b$: When self construal is independent (vs. interdependent), company evaluations should not vary as a function of social (vs. personal) relevance of the CSR activity.

Blasi (1984) and Hart (1998) described moral identity as one kind of self-regulatory mechanism which motivates moral actions. Aquino and Reed (2002) examined moral identity from two different dimensions; internalization and symbolization. Internalization is the long-term process of consolidating and embedding one's private self-concept, one's own beliefs, attitudes, and values. On the other hand, symbolization is the process of reflecting moral values in one's public actions. As moral identity has a role in determining moral actions, individuals with differences in their moral identity may have variances in their company evaluations based on their CSR activities. We propose that moral identity interacts with social and personal relevance of CSR activities in different ways. Internalization represents self-importance of the moral behavior. Therefore, high internalizers may have more favorably attitudes towards companies with CSR activities that match with their personal values. Nevertheless, low internalizers have weaker associations of moral traits with their self-concept. Thus, perceived personal relevance of CSR activities may not alter their company evaluations. Symbolization captures the extent to which individuals are concerned about reflecting their moral values with their actions. As high symbolizers want to convey their moral traits with their behavior, they may have more favorable evaluations towards moral activities that are perceived highly relevant to the society. On the other hand, low symbolizers care less for showing their moral characteristics. Regardless of the social relevance of CSR activities, they may value companies equally. Thus, we hypothesize that

- $H2_a$: When internalization (vs. symbolization) is high, high personal (vs. social) relevance of the CSR activity should lead to more favorable company evaluations.
- $H2_b$: When internalization (vs. symbolization) is low, company evaluations should not vary as a function of personal (vs. social) relevance of the CSR activity.

We ran three experiments among undergraduate students. In these studies, participants read information about the target company and its ongoing CSR activity. In the first study, we measured personal and social relevance; independent and interdependent self-construal. In our second study, we manipulated all our variables and employed a 2 (self construal: independent vs. interdependent) x 2 (social relevance: high vs. low) x 2 (personal relevance: high vs. low) between subjects design. In both studies, findings are consistent with our hypothesis (i.e., $H1_a$ and $H1_b$). In our third study, we measured moral identity, social and personal relevance. Preliminary analyses indicate that our results regarding symbolization dimension are consistent with our predictions. However, we found weak support for the significance of internalization.

Aliterate Consumers in the Marketplace

Haeran Jae, Virginia Commonwealth University, USA
Jodie L. Ferguson, Virginia Commonwealth University, USA

The past few decades have seen "increasing numbers of capable readers who are regularly choosing not to read" (Mikulecky, 1978, p. 3), leading to what has been called an aliteracy phenomenon. Consumers are overloaded with product information in the marketplace. Unfortunately, aliterate consumers avoid much of the available information. Instead of reading the instructions for using products, they rely on trial and error (Wallendorf, 2001).

In this research, the consumer aliteracy construct is developed, including a five-item measure of consumer aliteracy. This research also explores consumer aliteracy relationships with similar consumer behavior constructs. Finally, research questions for examining the effects of consumer aliteracy in the marketplace are offered, including the effects on advertising liking and comprehension.

The Consumer Aliteracy Construct

We define *consumer aliteracy* as the lack of reading habit in a capable reader participating in consumer behavior activities. We conducted a focus group of twelve consumers and we conducted eight in-depth consumer interviews to investigate the domain of the consumer aliteracy construct and to generate an initial pool of 67 scale items. Fifteen expert judges (i.e., marketing faculty and doctoral students at a Midwestern university) were consulted to critique the items. Items were removed that did not demonstrate face or content validity, resulting in a reduced set of 34 scale items. The 34 items were then presented in a survey to 301 consumers, where exploratory factor analysis revealed multiple factors with which the 34 items loaded. More consultations with expert judges resulted in reducing the scale to ten by eliminating items that were context specific or that were not related to consumer behaviors.

One hundred eleven consumers completed a survey that included the ten-item scale. Exploratory factor analysis revealed two factors ($\Lambda_1=4.01$ and $\Lambda_2=2.39$), however after further consideration, one factor was deemed situation-specific (e.g., reading *nutritional* information on packages, and taking *products* off shelves to read). After the situation-specific items were removed, the remaining five items accounted for 66.36% explained variance, had inter-item correlations ranging from .399-.676, and had Cronbach's alpha of .870. Another survey of 33 consumers confirmed the convergence of the five-items (i.e., Cronbach's alpha=.822). The final five-items to measure consumer aliteracy are: (1) I carefully read a document before I sign it, (2) I read the terms and conditions of a sale before I buy a product, (3) I am the kind of person who reads fine print in shopping, (4) When making a purchase, I read details word for word, and (5) I carefully read all transaction information before purchasing.

The Typical Aliterate Consumer

A survey of 111 respondents (i.e., where 54% were female and 62% were white/Caucasian) at a Southeastern university revealed some insights into the consumer aliteracy construct. Specifically, consumer aliteracy correlations with need for cognition and with consumer assertiveness were examined. Also, reading behaviors were examined to describe differences in aliteracy levels.

Aliterate consumers are not necessarily non-intellecuals, nor are consumer aliteracy synonymic with low need for cognition. In fact, consumer aliteracy did not significantly correlate with need for cognition² (i.e., $r=-.135$, $p=.163$). Respondents were also measured on consumer assertiveness,³ the tendency for an individual to request information or assistance (Richins 1983). Consumer aliteracy significantly correlated with assertiveness (i.e., $r=.227$, $p=.017$). Consumers who were highly aliterate were also highly assertive, perhaps because they would rather ask for information instead of reading the information for themselves.

²Need for cognition scale adapted from Wood and Swait (2002)

³Assertiveness scale adapted from Richins (1983).

Consumers who had subscriptions to newspapers (i.e., including local or national newspapers such as *USA Today*) or to economic/political/academic periodicals (e.g., *Fortune*) were lower in consumer aliteracy than those who did not have these types of subscriptions (i.e., $\text{mean}_{\text{news}}=2.39$, $\text{mean}_{\text{no news}}=3.10$, $p=.027$, and $\text{mean}_{\text{periodical}}=2.53$, $\text{mean}_{\text{no periodical}}=3.18$, $p=.015$). Consumers who admitted to not holding any print subscriptions were more aliterate than those who did have some kind of print subscription (i.e., $\text{mean}_{\text{no print}}=3.49$, $\text{mean}_{\text{print}}=2.71$, $p=.003$).

Interestingly, consumers who held subscriptions to either magazines (e.g., *Cosmopolitan* or *Sports Illustrated*) or to hobby periodicals (e.g., *Golf*) did not significantly differ on consumer aliteracy (i.e., $p=.181$ and $p=.236$, respectively). Also, consumer aliteracy did not significantly correlate with number of books read in the past 30 days (i.e., $r=.158$, $p=.10$), nor did it significantly correlate with print or online newspaper readership ($r=-.160$, $p=.09$). This may be evidence that reading strictly for pleasure is not related to consumer aliteracy in the marketplace.

Consumer Aliteracy Research Questions

Additional research is necessary to understand the effects of consumer aliteracy on consumer behaviors. The current research will continue with two additional studies, focusing on the following research questions.

(1) *Does consumer aliteracy bring about lower ad comprehension/ad liking?* Research on levels of processing effect (e.g., Craik & Lockhart, 1972), holds that there are several factors that affect processing depth. Because they lack the motivation to read, aliterate consumers may not engage in deeper processing levels. In turn, failure to use their processing abilities may cause aliterate consumers to poorly comprehend written materials (Guthrie & Wigfield, 1999).

(2) *Does ad complexity moderate the relationship between consumer aliteracy and ad comprehension/ad liking?* When message readability gets more complicated, individuals' ability to assess message arguments tends to be reduced because their working memory capacity is reduced (Chebat et al., 2003). Thus, although both literate and aliterate consumers will display a drop in comprehension and subsequent ad liking as text difficulty increases, the drop should be more pronounced among highly aliterate consumers.

(3) *Do visual aids in advertisements moderate the relationship between consumer aliteracy and ad comprehension/ad liking?* In information processing, aliterate individuals have been shown to rely more on pictorial information than on detailed written information (Kylene, 1996, 110-113). Thus, pictures used as a form of visual aid in product advertisements will benefit aliterate consumers more than such aids will help literate consumers.

Conclusion

The aliteracy social phenomenon is growing but is difficult to detect and thus difficult to counter. An investigation of consumer aliteracy may enable managers to either try to influence the consumer aliteracy tendencies, or use non-word message strategies in order to better communicate with highly aliterate consumers.

Too Many Cooks Spoil the Broth: How Conflicting Nonconscious Goals Influence Consumer Choice

Ji-Hoon Jhang, University of Colorado at Boulder, USA

Consumers are surrounded by a seemingly infinite number of brand images. Since Bargh (1990) proposed powerful effects of environmental cues on behavior, a burgeoning set of research in marketing has demonstrated that 1) environmental cues (e.g., brand images) can activate a consumer goal outside of awareness and 2) consumer choices are affected by this incidentally activated goal (e.g., Chartrand, Huber, Shiv, and Tanner, 2008).

These earlier works, however, leave two important questions unanswered regarding nonconscious goals. First, can various environmental cues encountered in everyday life (e.g., Nordstrom vs. Wal-Mart) activate multiple conflicting goals (e.g., prestige-related vs. thrift-related goals) outside of individuals' awareness? Second, if multiple (conflicting) nonconscious goals can be activated, how can those conflicting nonconscious goals shape consumer behavior? Despite a body of research in which multiple (conscious) goal pursuit

has been examined (e.g., Fishbach and Dhar, 2005), no research has yet explored multiple nonconscious goal pursuit (for exception, see Laran and Janiszewski 2009 JCR). This study aims to address these two questions.

The objective of the current study is to examine 1) whether or not conflicting nonconscious goals can be activated and 2) how conflicting nonconscious goals, once activated, influence consumer behavior. I tested three competing hypotheses regarding the pursuit of conflicting nonconscious goals (i.e. inhibition, overriding, and conflicting) using product choice task.

Arguments for each hypothesis

Three competing hypotheses are as follows. The first is *the inhibition hypothesis*; the focal goal pursuit may inhibit the alternative goal pursuit. Both goal shielding theory (Shah et al. 2002) and conflicting goal pursuit literature (Fishbach and Dhar 2005) lend their supports to this hypothesis. The second is *the overriding hypothesis*; the alternative goal pursuit may undermine the focal goal pursuit. This overriding effect is hypothesized by goal pull theory (Shah and Kruglanski 2002) as well as associative network model (Anderson et al. 2004). Finally, the third is *the conflicting hypothesis*; both the focal goal and the alternative goal may be pursued simultaneously so that they compete. Atkinson and Birch (1970)'s *temporal escalation criterion* combined with goal pull theory (Shah and Kruglanski 2002) lends its support to this conflicting hypothesis. In summary, three competing hypotheses will be formally stated as,

H1a (The inhibiting hypothesis): The nonconscious pursuit of the focal goal would inhibit the nonconscious pursuit of the alternative goal.

H1b (The overriding hypothesis): The nonconscious pursuit of the alternative goal would override the nonconscious pursuit of the focal goal.

H1c (The conflicting hypothesis): Both the focal goal and the alternative goal would be nonconsciously pursued simultaneously.

The following experiment was designed to test three competing hypotheses proposed above. By looking at individuals' choice deferral tendencies, I examined which hypothesis is the most viable.

Study

Dhar (1997) showed that people who have to make a choice among equally attractive alternatives often opt not to choose or choose the no-choice option. This no-choice option task provides an experimental circumstance in which proposed three competing hypotheses can be tested.

The experimental design was a 4 (nonconscious goal priming:⁴ prestige vs. thrift vs. vs. mingle (prestige-thrift or thrift-prestige) vs. control) between-subjects design. Since the prestige, thrift, and control conditions served as control conditions for each hypothesis, the three competing hypotheses were tested by comparisons between each goal priming condition. For instance, if *the inhibition hypothesis* is correct, the choice pattern between the prestige-thrift condition and the prestige condition would show no difference, and the same result should appear in the comparison between the thrift-prestige condition and the thrift condition. If *the overriding hypothesis* is correct, the choice pattern between the prestige-thrift condition and the thrift condition should be the same, and we should expect no differences between the thrift-prestige condition and the prestige condition as well. If *the conflicting hypothesis* is right, the proportion of the no-choice option should be greater in the mingle conditions than in other conditions.

Method

78 undergraduate students participated in the study for partial course credit. Following the introductory instruction, participants engaged in a scrambled-sentence task. Each participant conducted twenty sets of scrambled-sentence task. For participants in the 'one-goal' conditions (i.e. the prestige goal, the thrift goal), only the first ten sets of words will include goal-relevant words (e.g. "what, did, luxury, want, she") while the goal-relevant words will be replaced with goal-irrelevant words for the following ten sets of words (e.g. "what, did, can, want, she"). For participants in the 'conflicting goals' conditions (i.e., the prestige-thrift goal, the thrift-prestige goal, i.e., the mingle goal), each ten set included either prestige-relevant words or thrift-relevant words. Finally, all twenty sets of words included goal-irrelevant words for the control condition. After completing the sentence-scrambled task, each participant was asked to make a hypothetical choice between two sock options and the no-choice option. The choice task used in Chartrand et al.(2008) was modified and used; a) Nike at \$5.25 a pair, b) Hanes at \$6 for two pairs, and c) no-choice.

Results

The results supported *the competing hypothesis*. A greater proportion of participants chose the no-choice option in the mingle condition than the other three conditions (Choice_{mingle}⁵=42.1%, Choice_{prestige}=20% , Choice_{thrift}=23.8% , Choice_{control}=16.7%, $\chi^2[6]=16.11, p=.013$). There was no difference among the prestige, thrift, and control conditions. Also, the other choice proportions reflected the similar pattern found in Chartrand et al. (2008).

Discussion

Above result suggests that participants' choice pattern can be explained by *the competing hypothesis*. Neither the inhibition hypothesis nor the overriding hypothesis explains the choice pattern observed in the above study. Therefore, it is initially demonstrated that conflicting nonconscious goals are pursued simultaneously, rather than being inhibited or overridden. It should be noted, however,

⁴The prestige and thrift goals are chosen because 1) both goals are basic motivations every consumer would already have in their associative networks so that both goals can be activated outside of awareness, 2) both goals are perfectly conflicting and cannot be resolved, and 3) both goals are at similar level of specificity.

⁵There was no differences between the prestige-thrift and thrift-prestige condition, thus two conditions were collapsed and analyzed as the mingle condition.

that these results are just the initial evidence for conflicting nonconscious goal pursuit hypothesis. Thus, further tests should be done to clearly rule out the other two hypotheses.

When Does Halo Prevail against Animosity? Country-of-Origin Effects Contingent on Regulatory Focus

He Jia, Nanjing University, China

Yonggui Wang, University of International Business and Economics, China

Yiren Dong, Nanjing University, China

Guocai Wang, Nanjing University, China

Prior research has demonstrated that country-of-origin-related associations with a foreign product play a significant role in consumers' evaluation (Maheswaran and Chen 2006). Two general types of association are identified as halo and animosity, which influence consumers' product attitude in opposite directions (Hong and Kang 2006). For some foreign products marketed in certain regions, the halo effect and the animosity effect could co-exist when consumers' attention are drawn to the country of origin. Examples abound from Chinese consumers' evaluation of Japanese products to Australian consumers' attitude towards French products (Klein, Ettenson, and Morris 1998).

An important question going unheeded by prior research is: When does the halo dominate over the animosity in determining consumers' evaluation when a product's country of origin could stimulate both the halo effect regarding the association with superior quality and the animosity effect concerned with the persistent or temporary antipathy? This research addresses the aforementioned issue by drawing on regulatory focus theory (Higgins 1997). We propose the dual roles of regulatory focus in influencing consumers' attitude towards foreign products, whose country of origin could make both halo- and animosity-related associations simultaneously accessible to consumers in certain regions (referred to hereinafter as foreign products). Chinese consumers are investigated as a typical group who are susceptible to both the halo effect and the animosity effect when evaluating Japanese products.

Hypothesis Development

Extant country-of-origin literature suggests that consumers are susceptible to halo effect or animosity effect when they rely on the country-of-origin information rather than the attribute information for evaluation. Consumers use the country-of-origin information as a heuristic, whereas they rely on the substantive attribute information when they adopt systematic processing (Gürhan-Canli and Maheswaran 2000). Furthermore, halo and animosity differ in valence. The halo concerning the country-of-origin-related reputation in advanced techniques is positively valenced, whereas the activated animosity toward the country from which the product originates is negatively valenced.

Regulatory focus theory (Higgins 1997) suggests that people can pursue a goal with either a promotion or prevention focus. Promotion focus is oriented at accomplishment, whereas prevention focus is oriented at security. Friedman and Förster (2001) find that promotion-focused people tend to adopt a heuristic style of processing, whereas prevention-focused people are inclined to base their evaluation on a systematic style of processing. Besides, promotion-focused consumers are more sensitive to the presence and absence of positive outcomes, whereas prevention-focused consumers are more sensitive to the presence and absence of negative outcomes (Higgins 1997). As a consequence, the positive component of the focal object is more diagnostic to consumers with a promotion focus than the negative component, whereas the negative component of the focal object is more diagnostic to consumers with a prevention focus than the positive component (Shine, Park, and Wyer 2007).

Based on those findings of country-of-origin research and regulatory focus research, we posit that regulatory focus has dual effects during the process in which consumers evaluate foreign products. In the first stage, a promotion focus should propel consumers to adopt heuristic processing and rely on the country-of-origin information, whereas a prevention focus should propel consumers to adopt systematic processing and rely on the attribute information. In the second stage, a promotion focus makes the positively-valenced country-of-origin-related halo more diagnostic to consumers than the negatively-valenced country-of-origin-related animosity, whereas neither

the halo nor the animosity influences prevention-focused consumers' product attitude since their attention are directed to the attribute information instead of the country-of-origin information.

Hence, we hypothesize that for promotion-focused consumers, the country-of-origin-related halo effect on product attitude is greater than the country-of-origin-related animosity effect; for prevention-focused consumers, neither the halo effect nor the animosity effect on product attitude is significant.

Study 1

Ninety-one Chinese students participated in an experiment with a one-factor (regulatory focus: promotion versus prevention) between-subject design. The first part of the study was to prime participants' regulatory focus with the similar tasks employed in Wan, Hong, and Sternthal (2009). In the ostensibly unrelated second part of the study, participants read a description of a LCD flat television. In the description, the television was highlighted as manufactured by a famous Japanese electronic company. Nine attributes were displayed along with a picture. Then, participants completed the measures of product attitude (Russell and Russell 2006), country-of-origin-related halo (Kaynak and Kara 2002), and country-of-origin-related animosity (Russell and Russell 2006).

The influence of regulatory focus on consumers' attitude towards the television ($\alpha=0.83$) was significant ($F(1, 89)=4.67, p<0.05$). Participants with a promotion focus ($M=5.39$) evaluated the television more favorably than those with a prevention focus ($M=4.92$). Furthermore, product attitude was regressed on halo ($\alpha=0.93$) and animosity ($\alpha=0.75$) in the two groups of participants. For promotion-focused participants, the halo effect was significantly positive ($\beta=0.33, p<0.05$), whereas the animosity effect was negative but not significant ($\beta=-0.11, NS$). For prevention-focused participants, neither the halo effect ($\beta=0.22, NS$) nor the animosity effect ($\beta=0.20, NS$) was significant. This result provides initial evidence for the hypothesis.

Study 2

Although Study 1 demonstrated that prevention-focused consumers were not subject to country-of-origin-related halo or animosity effect, this study was inadequate to justify that prevention-focused consumers indeed rely on the attribute information for evaluation. Study 2 will solve this limitation. According to our theorizing, promotion-focused consumers' product attitude should remain unchanged no matter whether the attribute strength is strong or weak, for they focus on the country-of-origin information. In contrast, prevention-focused consumers' attitude towards foreign products should vary according to the attribute strength. Therefore, we predict an interaction effect between regulatory focus and attribute strength on consumers' attitude towards foreign products, which will be tested in Study 2.

Discussion

Based on regulatory focus theory, this research is among the initial efforts to investigate when the country-of-origin-related halo dominates over the country-of-origin-related animosity in determining consumers' attitude towards foreign products, which has rarely been explicated in the country-of-origin literature. In addition, the current research synthesizes and examines the dual roles of regulatory focus in shaping consumers' attitude.

Customization Mode, Decision Outcome, and Task Enjoyment: The Role of Regulatory Focus

He Jia, Nanjing University, China

Yonggui Wang, University of International Business and Economics, China

Mass-customization successfully balances between personalized products demanded by consumers and cost-efficiency pursued by firms (Franke and Schreier 2008). In particular, two customization modes are available for marketers and identified by consumer researchers from a perspective of option screening strategy (Levin et al. 2002; Park, Jun, and Macinnis 2000). Additive customization is to present consumers with a basic product and then invite them to add options to the product, which reflects a screening-in strategy. On the contrary, subtractive customization is to present a fully-loaded product and then invite consumers to delete options from the product, which reflects a screening-out strategy. The purpose of the current research is to investigate how the interplay between customization mode and regulatory focus (Higgins 1997) impacts decision outcome and task enjoyment when consumers participate in customization service.

Conceptual Framework

Customization Decision Outcome. This research examines how customization mode and regulatory focus interactively influence customization decision outcome by drawing on the accessibility-diagnostics model (Feldman and Lynch 1988), which implies persuasiveness of information is determined by both accessibility and diagnosticity, and accessibility is a precondition for diagnosticity to influence people (Zhao and Pechmann 2007).

Consumers in additive customization regard the basic product as a reference point and perceive the added options as gains in utility, whereas those in subtractive customization take the fully-loaded product as a reference point and perceive the deleted options as losses in utility (Park, Jun, and Macinnis 2000). The loss aversion principle (Tversky and Kahneman 1991) points that a loss is perceived as more intense than a gain of the same objective magnitude (Park, Jun, and Macinnis 2000). This suggests that in subtractive customization the losses of utility due to option deletion are accessible to consumers, whereas in additive customization the gains of utility due to option addition may be not so much accessible to consumers.

Regulatory focus theory distinguishes two motivational orientations during goal pursuit: a promotion focus is oriented at accomplishing aspiration, which makes people assign more value to gains and nongains; a prevention focus is oriented at fulfilling responsibility, which makes people assign more value to losses and nonlosses (Higgins 1997). This implies that potential gains are more diagnostic to consumers with a promotion focus than those with a prevention focus, whereas potential losses are more diagnostic to consumers with a prevention focus than those with a promotion focus.

In subtractive customization, the loss of utility is accessible to both consumers with a prevention focus and those with a promotion focus, but more diagnostic to prevention-focused consumers. In contrast, the gain of utility in additive customization is not so much accessible as the loss in subtractive customization. Consequently, in additive customization the minimal level of accessibility of potential gains inhibits diagnosticity from influencing consumers' choice although potential gains are more diagnostic to promotion-focused consumers. Therefore, we hypothesize that in subtractive customization a prevention focus should propel consumers to delete fewer options and as a result retain more options in the final customized offering than a promotion focus, whereas in additive customization the effect of regulatory focus should disappear.

Customization Task Enjoyment. Based on regulatory fit theory (Higgins 2000), this research also addresses consumers' task enjoyment, another important aspect of customization performance. Regulatory fit is a condition when the strategic means people use to pursue goals fit their regulatory focus (Higgins 2000). An approach strategy (approaching positive outcomes) sustains a promotion focus, whereas an avoidance strategy (avoiding negative outcomes) sustains a prevention focus. When the strategic means for goal pursuit fits one's regulatory focus, people just "feel right" and then unconsciously attribute their feeling to the stimulus they focus on, leading to an even more favorable evaluation (Avent and Higgins 2006).

From a perspective of option screening strategy (Levin et al. 2002), additive customization makes consumers naturally screen in options with desirable attributes, whereas subtractive customization makes consumers naturally screen out options with undesirable attributes. Therefore, additive customization is consistent with an approach strategy, whereas subtractive customization is similar to an avoidance strategy. In correspondence with regulatory fit theory, we hypothesize that promotion-focused consumers should more enjoy additive customization than prevention-focused consumers, whereas prevention-focused consumers should more enjoy subtractive customization than promotion-focused consumers.

Study 1

A group of Chinese students participated in a 2 X 2 between-subject experiment with both regulatory focus and customization mode manipulated, generating 92 valid responses. Participants in the additive customization condition were told that they could add ingredients to a basic pizza, whereas those in the subtractive customization condition were told that they could delete ingredients from a fully-loaded pizza (Levin et al. 2002). The number of options retained in the final customized offering was calculated to measure customization decision outcome. Participants also completed a scale of customization task enjoyment (Park, Jun, and Macinnis 2000).

The interaction effect between regulatory focus and customization mode on decision outcome was found significant ($F(1, 88)=4.86, p<0.05$) and mainly driven by the effect of regulatory focus in subtractive customization. Moreover, there was a marginally significant interaction effect between those two factors on task enjoyment ($F(1, 88)=3.77, p=0.055$). Further simple contrasts were also consistent with our predictions (detailed statistics provided upon request).

Study 2

The characteristics of options retained in the final customized offering might influence consumers' task enjoyment. Study 2 will control the quantity and price of options retained in the final product to exclude this possibility and further test the robustness of the findings

of Study 1 in another scenario. Besides, the boundary condition for the interaction effect on consumers' customization evaluation will be addressed.

Discussion

Theoretically, this research finds that the effect of regulatory focus on the number of options retained in the final customized offering is contingent on customization mode, which adds knowledge to the multi-option screening literature. Another contribution of the current research is to extend regulatory fit theory into a customization service context. Managerially, this research answers how to match customization mode with regulatory focus in order to accomplish superior customer value in customization service.

Becoming a Responsible Consumer: Using Narratives to Study the Development Paths and Goals

Suvi Joronen, University of Vaasa, Finland

The concept of a new consumer type, an alternative consumer, appeared as far back as the 1970's so the phenomenon itself is not very new. Characteristics like ethicality, green, fair trade and the concern toward developing countries became to define this new consumer type (Gabriel & Lang, 1995). This paper explores how the responsibility is constructed as a part of a consumer's life.

The theory is drawn here not only through the attitudinal dimensions, but especially through the personality indicators and the influence of the overall social structure. As Degevos (2005) states, the importance of socio-cultural and socio-psychological determinants should not be underestimated in the consumer studies.

The responsibility can be seen as a consequence led by the particular personality variables and the specific events in the socio-cultural environment. These personality variables include such inner entities as values, motives, moral conceptions and subjective norms. Especially the existence of certain nature related values have been found to have an influence to the responsible consumption behavior (e.g., Grunert & Juhl, 1995). Also, the change in a value system (e.g. anthropocentric values ? ecocentric values) is assumed to precede the behavioral change (see Rokeach, 1973). Besides the normative nature of subjective norms, the social norms often advise consumers to behave in a certain way. It depends on the nature of cultural and political environment how the sustainable consumption is adopted in a certain country. Both the person's subjective development processes as well as the influences outside are here assumed to be the principal factors explaining the process of growing as a responsible consumer.

Qualitative research was conducted to study respondents' subjective experiences about responsible consumption. Written biographies were chosen as a narrative research method (see Riessman, 1993). The written biographies are found to be appropriate in the identity development studies (e.g., Hole, 2007). Therefore, in this study, I used written truth based stories for finding out how responsibility has become an integral part of respondent's self-identity. The study was based on a sample of Finnish and French consumers at the age range from 24 to 63, with a bias toward the lower ages. There were a total of seventeen informants; four males and fourteen females. Four of the informants were French including two of them living in an autonomic eco-village. The sample choice was a convenience sample followed a snow-ball sampling. It was considered as crucial that the sample members were responsible consumers. In order to assure this, the respondents needed to meet at least one of the following criterions: 1) *Buying fair trade and/or organic products regularly* 2) *Boycotting products found being unethical* 3) *Collective activity, as a membership in associations*.

A postal questionnaire was developed and which was similar to all informants. In the first part of the questionnaire, the respondents were asked to write a truth based story of a following topic: “*Me as a responsible consumer*”. They were asked to describe the events from childhood until the present day. In the second part of the questionnaire, the respondents were asked about socio-demographic characteristics including age, gender, education and the nature of being a responsible consumer (the frequency of buying fair trade/organic products, participation in associations, boycotts).

The analysis was made at two levels. At the first level, the differences in the thematic structures of stories indicated how the responsible consumption appears mostly as a specific goal for the respondents. Each of these four goals included two main themes which were found through the content analysis. These goals vary particularly according to the motives, the level of commitment and the actualized responsible actions. The goals I nominated as follows: 1) *Responsibility as a way to rational consumption* 2) *Responsibility as a way to healthiness* 3) *Responsibility as a way to save the nature* 4) *Being comprehensively responsible*. These goals are not absolute in the sense that the same respondent can have more than just one goal. Moreover, the changes in goals over time became apparent in the stories. For example, the responsibility starts to have more meanings in respondent’s life and this lead adopting new goals and perhaps also new behavioral patterns.

At the second level of analysis, the plot structure of stories was used to identify whether there are differences in the developing paths. Through that I noticed that each story can be divided into three life stages: childhood, youth, and maturity. Three distinctive developing paths were nominated as follows: 1) *From childhood landscape into eco-consumerism* 2) *Through teenage rebel into savior of earth* 3) *Through slowly changing into a critical consumer*. This life stage separation allowed recognizing not the particular stage of life in which the identity as a responsible consumer started to develop but also the possible changes in time concerning the personal commitment and goals. For example, the changes in the subjective values and motives or in social environment seemed to have an influence on the process of growing into a responsible consumer.

The study indicates firstly the different positions of responsible consumption in respondent’s life. For example, for one the responsible consumption appears as a goal to be healthy while for another it appears as an intention to change the “bad capitalistic world”. For most of the respondents, the commitment appears as daily routines including such actions as recycling, giving donations, buying fair trade/organic products and boycotting unethical business. On the other hand, the goal of being comprehensively responsible indicates more radical form of responsibility (c.f. The Simple Living Movement). Secondly, the life stage division helped to recognize the special events and changes in timeline. This permitted again finding out the specific life period which was significant in terms of growing into a responsible consumer. Worth noting is also the changes in the level of personal commitment and goals which can lead someone to move from modest behavioral patterns toward more extreme or vice versa.

The Role of Quality-of-Experience and Affect in Maladaptive Food Consumption

Luke Kachersky, Fordham University, USA

Sylvia Clark, St. John’s University, USA

“Hungry? Why wait,” asks a popular advertisement for a candy bar. Perhaps more curious is the inverse, “Waiting? Why hunger?” In a recent survey, 47% of 16-24 year-olds and 40% of 35-44 year-olds reported that they had eaten because they had nothing better to do (BBC News, 2004). This is an important issue since such maladaptive behavior undermines long-term life satisfaction (Kushner and Foster 2000).

The accepted knowledge of consumer behavior posits that consumers exhaust resources in order to satisfy needs. In eating, consumers use up natural resources—animals and plants—to sustain themselves. Yet, as the BBC survey indicates, eating that is not motivated by sustenance is a common occurrence. So which need is satisfied in such consumption? In addition to sustenance needs, people have experiential needs to “keep consciousness in an organized state, focused on some activity that requires attention” (Csikszentmihalyi 2000, p. 270). When people satisfy such needs with high-quality experiences, they also satisfy the ultimate goal of feeling good (Csikszentmihalyi 1993, 1997). The present research proposes that people eat when they are deficient in QOE to improve their experiential and affective states.

There are other options besides eating to satisfy experiential needs; one could engage oneself in work or hobbies, for example. However, humans often use shortcuts to satisfy psychological needs. Eating both immediately engages attention and, as many studies have shown, provides a psychophysical response that improves one’s affective state (e.g. Christensen 2001, Van der Does 2001). While this sounds like a promising solution, studies have shown that consumers are happier when they are having high-quality experiences than when they are consuming (Csikszentmihalyi 1997, 1999). As a result, the following relationships among quality-of-experience (QOE), eating, and affect are proposed:

- H1: Consumers having high-quality experiences will eat less than those having low-quality experiences.
 H2: Consumers having high quality experiences will feel more positive affect than those having low-quality experiences.
 H3: Amount of food eaten will be positively correlated to positive affect for consumers having low-quality experiences, but will have no impact on positive affect for those having high-quality experiences.

Our first study was conducted with 34 participants recruited from introductory marketing classes at a large northeastern university. Students were offered extra course credit in exchange for their participation. Participants were first asked to work on a task in which they were given ten minutes to unscramble as many words as possible from a list of 75 scrambled five-letter words. A bag of 60 Skittles candies was placed on each participant's desk, and they were free to partake. At the conclusion of this task, participants were asked to stop working and to place their bag of Skittles underneath their chairs. The number of Skittles eaten served as our measure of food consumption. They then completed a questionnaire measuring positive and negative affect (PANAS; Watson, Clark, and Tellegen 1988); perceived skill and challenge of the word task (Novak 1997; to measure QOE); the last time they ate, and liking for Skittles. Finally, at dismissal participants were told the true purpose of the study and given the option to have their data discarded. No participants chose this option.

Low QOE denotes a person of low-to-moderate skills whose skills are mismatched with the perceived challenge of the experience. High QOE means skills are high and commensurate with the challenge of the experience (Csikszentmihalyi 1990). Participants' responses to the perceived skill and perceived challenge scales were placed on a "map of everyday experience" (Csikszentmihalyi 2003), which is a Cartesian plane with axes defined for challenge and skill. The plane is divided into low-quality experiences (e.g., apathy) and high-quality experiences (e.g., arousal). The resulting classification matched the underlying construct. High QOE participants (N=14) saw themselves as skilled at the word task and perceived the task as offering a similarly high level of challenge ($M_{skill}=4.71$ vs. $M_{challenge}=5.11$, $p=.32$). Low QOE participants (N=20) saw themselves as less skilled, and overmatched by the challenge ($M_{skill}=2.70$ vs. $M_{challenge}=3.77$, $p<.01$). Across the QOE groups, participants did not differ in their liking for Skittles, the last time they ate, or the number of words they correctly solved ($p's>.20$).

In keeping with hypothesis 1, high QOE participants ate fewer Skittles than did low QOE participants ($M_{high}=7.79$ vs. $M_{low}=17.65$, $p<.03$). Further, consistent with hypothesis 2, high QOE participants felt more positive affect than low QOE participants ($M_{high}=3.44$ vs. $M_{low}=2.82$, $p<.03$). However, as predicted in hypothesis 3, as low QOE participants ate more Skittles, they also felt more positive affect ($r=.55$, $p<.02$), but the same was not true for high QOE participants ($r=-.025$, $p=.93$).

Together, these results suggest that a deficiency in QOE can drive people to eat more (hypothesis 1), which improves one's affective state (hypothesis 3), but not to the extent of a high-quality experience (hypothesis 2). This study represents a first step in explaining the causes and consequences of eating to satisfy experiential but not sustenance needs. Follow-up studies will explore ways in which consumers and marketers can cure this maladaptive behavior.

Mine Versus Ours: Does It Matter?

Bernadette Kamleitner, Queen Mary, University of London, UK
 Anna Rabinovich, University of Exeter, UK

In particular when it comes to high-involvement acquisitions consumers often jointly buy and own objects such as cars, computers, and houses. Whereas there is extensive literature on how these joint decisions come about (e.g., Davis 1976; Su et al. 2008), there is paucity in research on how joint ownership affects consumer behavior after an acquisition has been made. The question of whether joint ownership leads to differences in consumer behavior has yet to be addressed. Theoretically there are three possibilities. First, there may be no behavioral differences between joint and individual owners as both cases involve factual ownership. For the most part existing consumer literature on ownership effects does not address the issue of different ownership modes (e.g., Beggan 1992; Kahneman, Knetsch, and Thaler 1991); possibly because no differences are to be expected.

Second, joint ownership may have a positive impact on consumer behavior. It has been argued that ownership creates a sense of responsibility for an object (e.g., Furby 1978) which instigates behaviors towards protecting and enhancing the owned object (e.g., Van Dyne and Pierce 2004). Joint ownership signifies that at least two consumers are entitled to use an object and can hence be held responsible

to each other. As a consequence joint owners may feel even more responsible towards the owned object than individual owners and may hence take more care of the object.

Third, joint ownership may have a negative impact on consumer behavior. On the one hand joint ownership and the resulting joint responsibility may lead to a decrease in experienced responsibility (Latane 1981) and lead to less behavioral care for the object. On the other hand, there is evidence that effects of ownership are mainly due to the degree to which ownership is perceived as such (e.g., Reb and Connolly 2007). It seems plausible to assume that joint ownership decreases the sense of ownership experienced and hence reduces a consumer's willingness to care for an object.

In two studies we gather initial information on whether joint ownership leads consumers to behave differently towards an object than individual ownership.

Study 1 assessed whether consumers intuitively believe that the mere fact of joint ownership leads to differences in consumer behavior. Participants (53 students) read a scenario about two students who each got a car from their parents. The only difference between the two students is the actual ownership mode. One student is sole owner of the car, one student shares ownership with the mother. Actual usage by other people and expenses are kept constant. After reading the scenario participants indicated which student was more likely to engage in four different acts of caring for the car (e.g., checking it for scratches; $\alpha=.76$), who felt more responsible for the car and who experienced a stronger sense of ownership.

Mean values of all items were compared to the scale midpoint (4=both equally likely). Results show that participants thought that joint ownership decreases the care taken for the car, decreases the responsibility felt for the car, and decreases perceived ownership of the car. In a regression, responsibility and perceived ownership significantly predict the likelihood of caring for the car.

Study 2 assessed whether lay intuitions observed in study 1 are in line with actual consumer behavior. Participants (61 students) were asked to answer questions about the computer or laptop they use most frequently. To assess actual ownership status participants were asked to report the number of regular users as well as the legal ownership situation. In addition, participants were asked to report on perceived ownership, perceived responsibility, and their behavior towards the computer (all alphas $>.60$). The eight items assessing behavior loaded on two different factors: behavior that prevents the computer from being damaged (e.g., not drinking at the keyboard) and behavior that promotes the computer (e.g., buying add-ons).

In separate regressions, the number of users had no effect on perceived responsibility and prevention behaviors. However, the larger the number of regular users, the less participants engage in behaviors that promote the computer and the lower is their perceived sense of ownership. Perceived sense of ownership predicts promotion behavior. Results were replicated with regard to legal ownership status. Controlling for the time spent with the computer did not alter the results.

To conclude, it seems that compared to individual ownership joint ownership has a detrimental effect on behavior towards an owned object. This effect is reflected in consumers' lay intuition. However, whereas lay intuition seems to relate this finding to both decreased perceived responsibility and decreased perceived ownership, actual behavior was only affected by perceived ownership. In addition, whereas lay intuition seems to assume an effect of joint ownership on all forms of caring behavior, the actual effect was restricted to behaviors that promote the owned object.

A Meta-Analytic Review of Racial Similarity Effects in Advertising

Ioannis Kareklas, University of Connecticut, USA

Maxim Polonsky, University of Connecticut, USA

The ideological struggle of African Americans during the early 1960s and throughout the 1970s was instrumental in elevating concern for ethnic minorities in American society. Marketing academicians and practitioners alike took note of the social advances which emerged from the civil rights movement. Advertisers started targeting African American consumers more systematically, and begun to feature more African American models in their advertisements (DeVecchio and Goodstein 2004). Academic researchers responded by investigating how majority and minority consumers evaluate racially integrated advertisements.

Underlying this newly found interest in ethnic consumers has been the desire on the part of the advertising community to respond to the moral criticism, which was increasingly directed towards advertisers, summarized by Barban and Cundiff as "You must "integrate"

your advertising because it is morally reprehensible to do otherwise” (Barban and Cundiff 1964). Specifically, both the NAACP (National Association for the Advancement of Colored People) and CORE (Congress of Racial Equality) urged national advertisers to feature more African American models in their ads (Block 1972). At least partially in reaction to these pressures, the representation of ethnic minorities in magazine advertisements doubled between 1965 and 1969 (Kassarjian 1969), and there was a proliferation of research examining the effects associated with featuring ethnic minorities in advertisements, with particular attention to assessing reactions by White and Black consumers to ads featuring Black models.

Some studies investigated how White American consumers respond to advertisements featuring minority models (e.g., Bush, Gwinner, and Solomon 1974; Bush, Hair, Jr., and Solomon 1979; Hoon and Ramaprasad 2006; Whittler and DiMeo 1991), whereas others focused on the advertising evaluations of African American consumers in response to ads featuring minority models (e.g., Green 1999; Simpson et al. 2000; Whittler and Spira 2002). Studies also examined the advertising evaluations of both majority and minority consumers in response to advertisements, featuring both White American and African American models in the same ad (e.g., Barban 1969; Cagley and Cardozo 1970; Schmid 2000; Stafford, Birdwell, and Van Tassel 1970). A smaller subset of studies in this domain investigated the advertising evaluations of Asian American consumers (e.g., Brumbaugh and Grier 2006; Forehand and Deshpande 2001; Schumann, Lee, and Watchravesringkan 2004), and Hispanic consumers (e.g., Appiah 2001; Avery, Hernandez, and Hebl 2004; Deshpande and Stayman 1994) in response to ads featuring similar versus different-race models.

As minorities were increasingly being portrayed in media advertisements, a mounting body of research examined the potential for an adverse reaction to this growing practice by White consumers. The basic premise of this argument, which has been termed “White backlash,” is that attempts to appear more socially responsible and appeal to minority consumers by featuring Black models in ads may lead to alienating White consumers (Barban 1969; Barban and Cundiff 1964; Block 1972; Stafford, Birdwell, and Van Tassel 1970). Backlash may take the form of a negative attitude towards the ad, the spokesperson, the company, the product, or the brand being advertised (Schmid 2000). If true, this is a justifiable concern given that the purchasing power of White consumers greatly exceeds that of all of the other racial groups in the U.S. (Humphreys 2008). However, early empirical investigations tended to disconfirm the existence of White backlash, finding instead that White consumers did not react adversely to integrated commercials, or commercials featuring all-Black models (e.g., Barban 1969; Barban and Cundiff 1964; Block 1972; Stafford, Birdwell, and Van Tassel 1970).

Some research in this domain has yielded opposite than expected results, with participants preferring racially dissimilar endorsers. For example, David et al. (2002) report that White participants rated Black models as more attractive than White models, and even considered themselves more similar to the Black than the White models. Similarly, a recent study by Wang and Arpan (2008) found that White participants rated Black (as compared to White) spokespersons as more credible, and evaluated Public Service Announcements (PSAs) more favorably when the spokespersons were Black as opposed to when they were White.

The Current Review

The aforementioned studies offer often confounding results. Some researchers suggest that both majority and minority consumers provide favorable advertising evaluations when ads feature similar race (vs. different-race) models (for a review, see Whittler 1991), while others report participants preferring racially dissimilar endorsers (e.g., David et al. 2002; Wang and Arpan 2008). The purpose of this paper is to report the findings of a meta-analysis which was conducted to summarize extant findings related to the effects of racial similarity (vs. dissimilarity) between source and participants on the advertising evaluations of Black, White, Hispanic, and Asian consumers. In total, forty one independent papers spanning forty years of publications (from 1969 to 2009) are included in the meta-analysis, which include responses from a total of 10,056 participants (3,232 Black, 6,263 White, 419 Asian, and 142 Hispanic).

Inclusion Criteria

Studies were deemed eligible for inclusion if they met all of the following criteria: (a) used Black and/or White, and/or Hispanic, and/or Asian participants, (b) exposed participants to advertisements featuring both similar-race and different-race models, (c) provided a measure of participants’ advertising evaluations (such as attitude towards the ad, attitude toward the brand, or purchase intention), (d) reported data that came from independent samples, which were not published in any other study already included in the meta-analysis, and (e) provided sufficient quantitative empirical results that allowed calculation of an effect size.

Preliminary Results

A priori moderator analyses revealed that source-participant racial similarity is most important for Hispanic participants ($d=.67$, 95% CI=.39, .96, $p<.001$), followed by Black participants ($d=.56$, 95% CI=.51, .61, $p<.001$), then by Asian participants ($d=.16$, 95% CI=.03, .30, $p<.05$), and finally by White participants ($d=.15$, 95% CI=.11, .18, $p<.001$). Additionally, the effect of racial similarity on participants’ advertising evaluations for papers published in Psychology journals ($d=.57$, $p<.001$) far exceeded effect sizes published in Communication ($d=.06$, $p<.05$) and Marketing journals ($d=.05$, $p<.001$).

Why Do We Find It Hard to Choose? Maximizers' Expectations and Their Effect on Choice Strategy

Jonas Kiesekoms, Ghent University, Belgium
 Maarten Elen, Ghent University, Belgium
 Maggie Geuens, Ghent University, Belgium
 Mario Pandelaere, Ghent University, Belgium

Generally, it is assumed that people strive for the best option when confronted with a choice set (i.e. 'maximizing') (Von Neumann & Morgenstern, 1964). However, due to the increased complexity that characterizes our society, maximizing is not always possible. Indeed, people often have a satisficing goal. In other words, people often search for an appropriate choice option which passes a certain acceptance-threshold (i.e. satisficing). (Simon, 1955). Maximizers, on the other hand, spend more effort analyzing each option until they have found the best possible one (Iyengar, Wells & Schwartz 2006). Research links the tendency to maximize with less happiness, less optimism, less confidence and less satisfaction with life. (Schwartz, 2002). Therefore it is important to identify variables that cause people to maximize. The current study examines a possible cause of maximizing, namely impact expectations. It is possible that maximizers strive to optimize choice outcomes, because they have higher expectations concerning the impact of proximate events on their subjective well-being. In other words, maximizers may believe that the choice they make has more impact on their happiness than satisficers do. This might cause maximizers to allocate more effort in choices than satisficers, hence making sure they choose the best.

H1: Maximizers will have higher expectations concerning the impact of proximate events than satisficers.

However, maximizers' impact expectations of delayed events might be lower. Contrary to satisficers, maximizers might take waiting time into account as a cost. Thus, while satisficers might overlook delay costs, maximizers might consider waiting time to be a cost when evaluating the impact of a delayed, (positive) event. In other words, when evaluating the impact of a delayed, (positive) event, maximizers do not simply assess the reward outcome, but evaluate the event-delay outcome.

H2: Maximizers are more sensitive to waiting costs than satisficers.

The current study examines whether maximizers and satisficers differ in intertemporal choices. Such an intertemporal choice implies a choice between an option that is attractive on short term versus an option that is beneficial on long term. A preference for the more immediate reward is called a time-inconsistent choice (Hoch & Loewenstein, 1991). As maximizers might be more sensitive to waiting costs, this may cause them to make more time-inconsistent choices than satisficers.

H3: Maximizers make more time-inconsistent choices than satisficers.

An online survey was set up to provide a first idea of the strength of the hypotheses.

121 subjects participated in an online survey. During the experiment, a control question was asked to determine whether the respondent was sufficiently involved to take part in the experiment. This was the following scale question: "Do not answer this question". Ten respondents who did answer the control question were deleted from the sample. As a result, all analyses were performed on 111 test subjects.

Respondents first answered the maximizing-satisficing scale as taken from Nenkov et al. (2008). This 13 item 7-point likert scale consists of statements of the following type: "Renting videos is really difficult. I'm always struggling to pick the best one". Secondly, *the impact expectations* of "winning 100 euros" and "receiving a favourite cd as a gift" were measured. Each time respondents were asked to indicate how much happier they would be (tomorrow vs today) if this event would occur.

Thirdly, delay discounting was measured. Respondents were given four choices between an immediate, smaller reward or a delayed, larger reward. The four reward pairs were taken from Kirby & Herrnstein (1995): 12€-16€, 21€-25€, 30€-34€, 45€-52€. A typical delay discounting question was as follows: "Which reward would you prefer: 12€ in two days or 16€ in ten days".

First, a mean split on the scores of the maximizing-satisficing scale was performed to categorize respondents as maximizer (n=46) or satisficer (n=65). Secondly we performed ANOVA tests on the impact expectations. Maximizers had bigger expectations concerning the impact of "winning 100 euros" ($F(1,109)=5.087, p<.05$) or "receiving a favourite cd as a gift" ($F(1,109)=6.056, p<.05$) on their happiness, thus providing support for the first hypothesis.

Next, Pearson chi-square analyses were performed for each of the four choice pairs. Maximizers and satisficers appeared to differ significantly for two out of the four pairs, namely the 21€-25€ and 30€-34€ choice pairs. Satisficers chose more than expected the larger,

delayed reward than maximizers (respectively $\chi^2(1)=2.729$, $p=.099$ and $\chi^2(1)=5.447$, $p<.05$). While results for the other two choice options did not prove to be significant, they showed a similar pattern. This provides partial support for the third hypothesis.

Data concerning the second hypothesis, as well as more support for hypothesis 1 and 3 are being collected. Also, the impact of maximizers' and satisficers' choices on experienced regret is being examined. When 'going for the best' implies 'choosing the immediate', maximizing might be regretful in the long term.

Do Easterners Feel More Discomfort in Response to Positive Information than Westerners?

Chang Soo Kim, McGill University, Canada

Tai Hoon Cha, Hankuk University of Foreign Studies, Korea

Myung-Soo Jo, McGill University, Canada

Do people respond favorably when they perceive positive, favorable information? For example, when frequent consumers of coffee lattes read an article that argues coffee latte is the most delicious form of coffee, they should feel reinforced and comforted, because the information is consistent with their own attitudes and preferences. Yet some people may sense less positive feelings due to their information processing method. In particular, these differences likely are greater across cultures, especially between Eastern and Western cultures. People from Eastern cultures tend to use more situational inferences, experiential knowledge, dialectics, and relationships to process information, whereas Westerners rely more on dispositional inferences, logical thinking, a lack of contradiction, and categorization (Choi, Nisbett, and Norenzayan 1999; Nisbett 2003; Nisbett et al. 2001; Norenzayan, Choi, and Nisbett 2002). Thus, Easterners may respond differently than Westerners to the same favorable product or service information, such that Westerners feel less discomfort when confronted with the same information.

Because they display greater hindsight bias than Westerners, Easterners may be more likely to process positive information as inconsistent (Choi and Nisbett 2000). Hindsight bias involves the tendency to overestimate in hindsight what is known in foresight (Choi and Nisbett 2000; Fischhoff 1975). According to previous research (Choi, Dalai, and Kim-Prieto 1999), Asians engage in more complex information processing than do Americans. If Easterners think more deeply about alternative perceptions of an object (e.g., the dark side), positive information may appear more inconsistent. For example, Easterners reading the positive coffee latte story might ponder it further and realize that coffee latte contains more fat and calories, which may help make it the most delicious coffee. Thus, Easterners would display more discomfort than Westerners when they receive such positive information. In contrast, Westerners likely process the positive information as consistent and focus more specifically on the positive aspects, because they rely on object focusing and categorization processing (Nisbett 2003), which means they do not consider category overlaps (i.e., non-contradiction processing; Nisbett 2003). In turn, Easterners should feel more discomfort than Westerners when they consider the same positive information.

Higher discomfort then may result in greater motivation to reduce the discomfort. That is, Easterners should experience a greater motivation to resolve their discomfort by perhaps ignoring or discarding the information. In contrast, Westerners, with their lower sense of discomfort, likely feel less motivation to resolve what they already perceive as positive and consistent information. Again, Westerners use more focusing and non-contradictory information processing, such that they consider the positive information as nonsituated (Nisbett 2003). Therefore, Easterners should experience more motivation to reduce discomfort than do Westerners for the same positive information.

These varying levels of motivation may in turn affect information processing, especially systematic and counterargument processing. Higher discomfort and motivation should cause Easterners to follow more detailed and counterargument-based processing, because people employ more systematic processing to deal with inconsistent information (Jain and Maheswaran 2000). In contrast, Westerners likely employ less systematic processing and fewer counterarguments to positive information, focusing instead on the presented information (i.e., focal focusing; Nisbett 2003). They believe, "Coffee latte is the best coffee," and thus, they forego systematic or counterargument-based processing. That is, Easterners should display more systematic and counterargument processing than Westerners with regard to the same positive information.

The tests of these hypotheses include both Koreans and Americans who prefer coffee latte over Espresso; that is, only Koreans and Americans who like coffee latte participated in this study. The studies took place in a metropolitan Korean city and a Midwestern U.S. town with subjects from similar demographic backgrounds (i.e., young college students). The same stimuli appear in both the Korean and U.S. studies. The positive information stimulus reads: "The Health & Culture Center (HCC) at Harvard University reports that coffee latte is

most preferred coffee by students. HCC also reports that people evaluate caffè latte as the most polished, mildest, and most delicious coffee.” Subjects responded to several discomfort and motivation to reduce discomfort items on seven-point scales (discomfort: uneasy, uncomfortable, bothered by the information; motivation: discard, ignore, skip over the information). To measure systematic and counterargument processing, the study used open-ended questions that asked the subjects to describe their thoughts about the presented information.

The findings provide strong support for the hypotheses. Korean subjects exhibited much higher levels of discomfort than did the U.S. subjects in response to the same positive caffè latte information ($p < .01$). Furthermore, the Korean subjects were more motivated to reduce their discomfort than the Americans with the same positive information ($p < .05$). Finally, the subjects’ remarks and comments matched the hypotheses: Koreans noted more systematic processing and counterarguments than did the Americans.

Thus, as hypothesized, Easterners experience more discomfort and greater motivation to reduce their discomfort than do Westerners when it comes to positive information. These findings suggest that marketers should employ different methods to present positive information in Eastern countries to elicit the most favorable reactions. For example, claims that “we are the best” may not be well-received in Eastern cultures, because they would elicit higher levels of discomfort and evoke greater motivation to reject the information and create counterarguments.

The Effects of Corporate Commitment and Cause Commercialization in Cause-Related Marketing

Yoojung Kim, University of Texas at Austin, USA

Jung Lim, University of Texas at Austin, USA

Sejung Marina Choi, University of Texas at Austin, USA

In Cause-Related Marketing (CRM), one of the major Corporate Social Responsibility (CSR) strategies, a participating company makes a donation to a charity or cause each time a consumer purchases an item from that company. According to the IEG Sponsorship Report, U.S. corporate spending on CRM was \$1.50 billion in 2008—a dramatic increase from \$120 million in 1990. CRM has been widely recognized as an effective marketing strategy that enhances corporate image and boosts sales. As today’s consumers become increasingly savvy, consumer responses to CRM may not be uniformly positive, however. Attribution theory suggests that consumers will not evaluate a company’s CRM positively if consumers become suspicious of the motives underlying the activity (Webb and Mohr 1998). When consumers become doubtful and attribute the company’s motive for CRM efforts mostly to its self-serving benefits, CRM becomes ineffective and may even backfire (Yoon, Gürhan-Canli and Schwarz 2006).

A significant factor leading to positive CRM outcomes is a company’s commitment to CSR. Past research suggests that the amount of resources invested by a company in its CRM program, including the duration of the CRM activity, influences consumer perceptions of the company’s overall commitment to a social cause. For example, Varadarajan and Menon (1988) proposed that long- versus short-term CRM campaigns have greater potential to enhance a corporate image. Likewise, advertising campaigns with a social dimension are more likely to be successful when accompanied by a long-term commitment (Drumwright 1996). Other investments, such as monetary donations, employee expertise, and volunteer work, also enhance perceived corporate commitment (Brink et al. 2006).

Another factor that may influence the effectiveness of CRM is the cause’s level of commercialization. As more and more causes have engaged in CRM, there has been growing concern about cause exploitation and over-commercialization (Varadarajan and Menon 1988). As Gurin (1987) noted, for example, companies generally wish to be associated with popular, risk-free, and highly visible causes to maximize their benefits from CRM programs. As a result, less popular, relatively risky, and less visible causes that are often in greater need of support tend to be neglected and receive little corporate support. Further, over-commercialization of a nonprofit organization could endanger the value of the cause and thus erode its appeal to individual supporters (Gurin 1987). Yet this dimension of CRM has been overlooked in previous research on consumer response to various CRM acts and deserves careful research attention.

Therefore, this study investigated the effects of two variables on CRM effectiveness: a company's commitment to CSR, and the level of commercialization of the cause. As drawn from attribution theory, it was predicted that when a company demonstrates strong commitment to CSR in general by having engaged in various CSR activities over the long term, consumers will infer more altruistic and less self-serving motives from the company's CRM and hold more credible perceptions of and favorable attitudes toward the company than is the case when the company shows little commitment or has no history of CSR activities. Similarly, when the company is aligned with a less commercialized cause that receives little corporate support, consumers will perceive more altruistic and less profit-oriented motives from engaging in CRM and show greater corporate credibility and attitude than would be the case when associated with a more commercialized cause that enjoys a larger roster of corporate sponsors.

To examine how CRM programs with different degrees of corporate commitment to CSR and cause commercialization influence consumers' attribution of corporate motives, credibility, and attitude, this experimental study employed a 2 (CSR commitment: strong vs. weak) X 2 (commercialization of the cause: high vs. low) between-subjects, factorial design. A fictitious beauty care company was used in this study; the subjects were instructed to read the description of the company and its recent activity in supporting a social cause. Specifically, stronger corporate CSR commitment was manipulated by focusing on a long history of corporate involvement in CSR activities and support of various socially worthy causes while weaker corporate commitment was manipulated by stating that the company had no record of CSR engagement until recently. For the commercialization level of the cause, the Susan G. Komen Breast Cancer Foundation (Komen) was chosen as the more commercialized cause based on its popularity and sufficient number of corporate sponsors, while Breast Cancer Action (BCA) was selected for the less commercialized cause that has low visibility and little corporate support. Congruence between cause, company, and cause importance were pretested—no significant differences were found across the four conditions.

As predicted, the results suggest that stronger corporate CSR commitment leads consumers to ascribe more altruistic and less self-serving motives to a company's CRM, and to hold more credible perceptions of and favorable attitudes toward it than does weaker corporate CSR commitment. On the other hand, the level of cause commercialization produced no significant effects on the dependent measures. Study findings expand our theoretical knowledge of the effects of corporate CSR commitment and cause commercialization on consumer attributions of corporate motives in the CRM context that subsequently influence corporate credibility and attitude. This study also has useful implications for managers who seek to optimize the effectiveness of CRM campaigns by indicating the benefits of establishing long-lasting CRM programs and points to the importance of carefully selecting a socially worthy cause.

Do Opposites Attract? Understanding How Oppositional Advertisements Work

Anjala Krishen, University of Nevada at Las Vegas, USA

Pamela Miles Homer, California State University, Long Beach, USA

Introduction

In their discussion of advertising language, McQuarrie and Mick (1996) identify schemes and tropes as two key forms of figurative rhetoric. Tropes are theorized to increase destabilization in several forms, one of which is opposition. Recently, scholars distinguish Janusian thinking, a process which involves bringing opposites to mind and creating meaning out of them (Rothenberg 1971; Blasko and Mokwa 1986), as an important form of advertising creativity (Sasser and Koslow 2008; Goldenberg and Mazursky 2008). We hence define opposition in advertising as the practice of pitting two seemingly opposing views in one ad. Oppositional ads can feature either literal or metaphorical opposition, often originating from consumer mythology (Levy 1981). An example of literal binary opposition is one such as inside/outside or weak/strong. On the other hand, a metaphorical opposition may be one such as heart/mind or beauty/power. In this paper, we extend extant research to explore when and why oppositional ads are effective/persuasive. We propose that opposition is a visual tool that simplifies decision-making and perceptual cognition. In a series of two experiments, we demonstrate that the underlying mechanism for opposition is reduction of visual complexity. In our first study that utilizes actual print advertisements, we show that perceived complexity is consistently lower for those ads defined as oppositional. The second experiment connects the lower perceived complexity in an oppositional advertisement to higher ad meaning and ad creativity.

Study 1: Opposition and Perceived Complexity

Due to the sparse academic research on consumer's perceptions of oppositional advertisements, an initial understanding of the role of visual complexity is warranted. The aim of Study 1 (S1) is to determine consumers' perceptions of the complexity level of an

oppositional versus a non-oppositional ad across two different product categories (i.e., undergarments and candy). Thus, a 2 (*product category*: undergarments versus candy) x 2 (*ad type*: oppositional versus non-oppositional) mixed-design is used to test the guiding hypotheses: opposition format (*ad type*) serves as the within-subjects factor and *product category* serves as the between-subjects factor ($N=60$). *Perceived complexity*, the primary dependent variable, is measured with a seven-item (7-point) semantic differential scale (Geissler, Zinkhan, and Watson 2001). Items range as follows: not complex/complex, not dense/dense, not crowded/crowded, no variety/variety, inefficient/efficient, not overwhelming/overwhelming, and simple/complicated.

Results

Analysis of variance (ANOVA) identifies a main effect for *ad type* ($F(1, 60)=56.93, p<.01, M=2.84$ versus $M=4.49$) and an *ad type* x *product category* interaction ($F(1, 60)=12.85, p<.01$) for *perceived complexity*. Planned comparisons reveal that perceived complexity remains relatively constant across the two product categories for oppositional type ads ($M=3.03$ for the undergarment ads and $M=2.54$ for the candy ads; $t(60)=1.27, ns$). However, for the non-oppositional advertisements, perceived complexity is greater for the candy ads ($M=5.09$) compared to the undergarment ads ($M=3.89$; $t(60)=3.0, p<.01$).

Discussion

S1 data show that individuals perceive that ads that are oppositional in nature are less complex, and this finding is robust across two different product categories. Next, a second study (S2) connects lower perceived ad complexity, shown in S1, to mechanistic explanations for opposition itself.

Study 2: Oppositional Versus Its Half

To better understand how opposition in advertising works, S2 uses one particular advertisement. The idea is to have one set of respondents view the oppositional advertisement while the others view only the half of the ad that “sells” the product. The complexity level for these two ads is hypothesized to be significantly different, with the oppositional format being perceived as less complex (though it has more physical information). Thus, this experiment ($N=54$) is a single factor between-subjects design (*ad type*: oppositional versus non-oppositional). *Perceived complexity*, *ad meaning*, and *ad creativity* are the dependent measures of interest. The *ad meaning* construct is the average of three (9-point) scales: meaningless/meaningful, not believable/very believable, and not credible/very credible ($\alpha=.62$). Similarly, *ad creativity* averages three 9-point items: not creative/creative, not eye-catching/eye-catching, and not clear/clear ($\alpha=.70$).

Results

The print advertisement features a popular children’s drink and thus, familiarity is treated as a covariate (in all hypothesis tests) to account for prior knowledge and experience with the brand. The two ads are rated as being similar in terms of *uniqueness*, which serves to refute a “novelty” explanation ($F(1,53)=2.02, ns$). For *perceived complexity*, analyses reveal an *ad type* main effect, supporting that the oppositional ad is perceived to be less complex than the non-oppositional ad ($F(1,52)=8.84, p<.01, M=3.03$ versus $M=4.11$). In addition, the oppositional advertisement displays higher *ad meaning* than the non-oppositional ad ($F(1,51)=4.73, p<.05, M=6.23$ versus $M=5.52$), and is perceived to be more *creative* than the non-oppositional version ($F(1,52)=3.86, p=.05, M=6.69$ versus $M=5.98$).

Discussion

S2 extends the previous study by showing that not only is there lower perceived complexity in the oppositional advertisement (which has physically more information than its non-oppositional counterpart), there are also significant differences in terms of ad meaning and ad creativity. The oppositional ad is perceived to have higher ad meaning and creativity, thus providing an explanation for why individuals prefer opposition.

Concluding Remarks

In summary, these studies extend the concept of opposition in choice sets (Krishen, Nakamoto, and Herr 2008) to advertisements, showing that it is a visual perception phenomenon that cuts across multiple human tasks. As such, we show that opposition not only allows individuals to make easier decisions, but it can also enable more simplistic perceptual processes. Thus, even though opposition does not appear to reduce information load, it is a creative technique that can reduce visual complexity. We plan to share more data at the ACR conference: e.g., a third study is currently underway.

US Consumers and Disaster: Observing “Panic Buying” During the Winter Storm and Hurricane Seasons

Owen Kulemeka, University of Illinois at Urbana-Champaign, USA

In the US, consuming is an integral part of preparing for disasters. In Hurricane Katrina’s aftermath, government officials have stressed that US residents should not plan on solely relying on charity or government aid after a disaster. Residents are encouraged to purchase emergency supplies prior to a disaster because past disasters have shown that it can take weeks before outside aid arrives (FEMA, 2009).

Despite the emphasis on pre-disaster buying, little academic research has been done on how people purchase emergency supplies. Much of what has been written about purchasing emergency supplies is primarily in the popular press and focuses on what is called “panic buying.” Each year before seasonal disasters, government officials and journalists admonish consumers to avoid panic buying. Consumers are criticized for buying supplies too early thus driving prices up or for waiting until the last minute which is seen as neglecting emergency planning (Mitchell, 2008; Perry, 2008).

These criticisms provide little insight into how consumers purchase emergency supplies. Dismissing pre-disaster behavior as “panic buying” provides no answers regarding why some consumers purchase in advance and others wait. To gain insight into consumers’ pre-disaster behavior, I am studying how US consumers in areas prone to seasonal disasters make decisions about purchasing emergency supplies.

The study is divided into two parts. In the first part, I have developed a model that describes how consumers make purchasing decisions regarding emergency supplies. To develop this model, I have drawn from research findings regarding the issue of panic in disasters and how people seek information or help on critical needs.

Past research on disasters has shown that contrary to popular views, people rarely panic prior to a disaster or when a disaster is occurring (Drabek, 1986). Helsloot and Ruitenbergs (2004) review of research on panic points out that in a disaster situation (e.g. during an earthquake), the initial fear that occurs due to uncertainty quickly diminishes and people start to look for ways to provide security for themselves and others. Instead of panicking, most people turn to help others and leave an insecure area in an orderly fashion.

When panic does occur, it impacts only a small number of people and lasts a short time (Perry & Lindell, 2003; Quarantelli, 1999; Dynes, 1994). The panic myth has emerged primarily because disaster victims inaccurately describe their response to disasters as panic. Journalists also describe unsuccessful attempts to deal with a disaster (e.g. failing to leave a burning building) as instances of panic. Helsloot and Ruitenbergs noted that in many cases, failure to escape a fire is due to disorientation or smoke inhalation rather than panic.

Panic does occur in very limited situations when the following factors are present. First, people perceive an immediate, serious danger. Second, only a few escape routes are present. Third, they feel that escape routes are closing making immediate escape necessary. Fourth, there is a lack of communication about a situation (Helsloot and Ruitenbergs, 2004).

In my model, I argue that since panic is rare except in extreme situations when the threat of death is imminent, consumer purchasing before a disaster is rational. In most pre-disaster shopping contexts, people are not facing a life or death situation. Hence, people shop in a manner that is not panicky but instead is aimed at meeting their needs rationally.

The second part of my model focuses on how people seek information and help on critical needs. Research on information seeking has revealed three key findings regarding help and information seeking. First, people (depending on their social status) exist in different levels of information poverty. Individuals who are marginalized (e.g. the poor) often lack information on how to obtain critical help because they cannot easily access information networks (Chatman, 1996).

Second, how people seek information and help is often shaped by the group in which they belong. In a marginalized group (e.g. a minority community), an intense information environment can develop. In these information rounds, individuals share a world view which dictates what outside information and help is accepted (Chatman, 1999). Members of a marginalized round can purposely block out information or help from the outside if it emerges from contexts they cannot control and knowledge could cause distress. Marginalized individuals will seek external information or help when their group agrees that help is needed and life in the round is no longer functioning (Chatman, 1999).

A third finding is that how people act to address critical needs is shaped by the constraints they feel (e.g. How much money do I have?), whether they recognize the situation as a problem (e.g. Is this storm going to be as big as they predict?), and whether they feel personally involved (e.g. Is the storm going to strike my neighborhood?) (Grünig, 1997).

In my model, I argue that consumers’ purchasing decisions prior to a disaster are shaped by their level of information poverty (how well connected they are to information networks) and whether their community values preparedness. In addition, how constrained they feel, their level of involvement, and problem recognition influence their decisions.

In the second part of my study, I am observing behavior in supermarkets to see whether it supports my model. In Winter 2009, I travelled to areas under storm watches and observed purchasing behavior. In Fall 2009, I will observe pre-hurricane buying. Preliminary findings from observations reveal that panic, hoarding, and other anti-social behaviors do not characterize pre-disaster shopping. Instead, most pre-disaster shoppers are organized and willing to assist others. Those who delay purchasing cite conflicting information from forecasters and a lack of resources (they fear buying supplies that will be wasted if a storm does not occur) as reasons for waiting until the last minute.

Effects of Color on Consumers' Perceptions of Package Volumes

Joseph Lajos, HEC Paris, France
Amitava Chattopadhyay, INSEAD, Singapore

A body of research in marketing has examined the effects of visual biases on consumers' judgments of product volumes (see Krishna 2007 and Raghubir 2007 for reviews). Although the potential influences of a package's proportions and shape on consumers' judgments of product volumes have been studied extensively, marketing research has not examined the potential of package color to bias consumers' product volume judgments.

Folkes and Matta (2004) observed that attention and size often covary, and provided evidence that attentional differences contaminate people's judgments of relative size such that objects that attract more attention are judged as larger. Their logic is essentially based on reversing the argument that large sizes attract more attention.

Fashion consultants often suggest that if you want to attract attention, you should wear red (Manji 2009). Research in psychology confirms the common notion that reds (and other high wavelength colors) attract more attention than blues and purples (and other low wavelength colors). Using a variety of methods this research finds that high wavelength colors stand out, "advance," and are more noticeable, whereas low wavelength colors fade away, "retreat," or go unnoticed (e.g., Johns and Sumner 1948; Luckiesh 1918; Pillsbury and Schaefer 1937; Taylor and Sumner 1945).

Combining research suggesting that high wavelength colors attract more attention than low wavelength colors with research suggesting that objects that attract more attention appear larger leads us to hypothesize that consumers judge products to have greater volumes when their packages are colored with a high wavelength hue (e.g., red) versus a low wavelength hue (e.g., purple).

Consistent with our hypothesis, research in psychology that has examined the effect of color on people's size judgments has often found that red objects appear larger than equally-sized purple or blue objects (e.g., Bevan and Dukes 1953; Claessen, Overbeeke, and Smets 1995; Gundlach and Macoubrey 1931; Wallis 1935; Warden and Flynn 1926). It is also notable that differences in the perceived size of the red and blue areas of the French flag (which are actually equally sized) resulted in an official recommendation to reduce the size of the red area compared to that of the blue (Helson 1951).

A weakness of past research on the effect of color on size judgments is that most of this research did not utilize a standardized color system that differentiates between the various shades of colors. Another weakness of past research in this domain is that it is solely empirical, and does not advance a theory to explain the demonstrated results. We report results from three studies that support our hypothesis.

In study 1, we asked 118 participants to view 30 slides, each of which displayed a pair of shapes arranged vertically that differed in color, and to report which of the two shapes appeared larger. On two of the slides, the shapes were actually of an identical size and differed only in color (red vs. purple and green vs. yellow). Consistent with our hypothesis, significantly more participants judged the red shape to be larger than the purple shape ($N=55$ vs. $N=25$), ($\chi^2(1)=11.25, p<.01$). We also obtained this effect with colors that were closer in wavelength, as significantly more participants judged the yellow shape to be larger than the green shape than vice versa ($N=58$ vs. $N=22$), ($\chi^2(1)=16.20, p<.01$).

In study 2, we asked 11 participants to view pictures of 12 product packages, to estimate the volume of each package in fluid ounces, and to answer a series of distracter questions about each product. We photographed the products next to a can of soda that served as a volume reference and used professional software to re-color the products' packages. One package, a bucket of fish food, appeared twice in the series, once colored red and once colored purple. Consistent with our hypothesis, a within-subjects ANOVA revealed that participants' estimates of the volume of the fish food bucket were significantly higher in the red condition ($M=199.09$ fl. oz.) than in the purple condition ($M=109.27$ fl. oz.), ($F(1, 10)=5.21, p<.05$).

In study 3, we asked 16 participants to complete the same procedure as in study 2, but with different product packages, and the addition questions about willingness to pay and liking of the package colors. We implemented the red vs. purple color manipulation using a box of detergent. Consistent with our hypothesis a within-subjects ANOVA revealed that participants' estimates of the volume of the detergent box were significantly higher in the red condition ($M=3083.33$ mL) than in the purple condition ($M=2262.67$ mL), ($F(1, 14)=4.64, p<.05$). The color manipulation also affected participants' willingness to pay for the detergent, which was significantly higher in the red condition

($M = \$5.36$) than in the purple condition ($M = \$3.50$), ($F(1, 14) = 6.05, p < .05$). Participants reported liking packaging of both colors statistically equally ($M_{\text{red}} = -1.87$ vs. $M_{\text{purple}} = -.73$), ($F(1, 14) = 1.32, p > .2$). Furthermore, the aforementioned effect of color on willingness to pay became non-significant when participants' volume estimates of the red and purple packages were included in the ANOVA as covariates ($F(1, 12) = 0.78, p = .4$). In contrast, when participants' liking of the red and purple colors were included in the ANOVA as covariates, the effect of color on willingness to pay strengthened ($F(1, 12) = 14.98, p < .005$). Together, these results suggest that color influences willingness to pay via an intermediary influence on volume estimates as opposed to an intermediary influence on attitude toward the packaging.

Do We Really Want to Keep Up with the Joneses? A Closer Look at Luxury, Concealment, Social Interaction, and Justification

Jannine D Lasaleta, University of Minnesota, USA

Jane Ebert, University of Minnesota, USA

Christine Bennett, University of St. Thomas, USA

Several theories have offered insight as on why people consume luxury items. For example, McCormick (1983) suggests people may “keep up with the Joneses” by buying expensive items to maintain self-esteem. Veblen (1912) proposed that people purchase luxury items to signal wealth and status to others. In contrast to this, recent research (Kivetz and Simonson 2003, Kivetz and Zheng 2006) finds that consumers are often reluctant to purchase luxury items, and they expect to feel guilty if they do. People feel they must earn the right to indulge (e.g., by justifying luxury purchases through effort or good performance) perhaps driven by pervasive cultural norms emphasizing the puritan work ethic. However, a recent intriguing study by Schwarz and Xu (2009) suggests that, while people may expect feelings of guilt for purchasing luxury items, they actually do not feel as guilty as they anticipated.

Building on this research, the current work examines consumers’ thoughts and behavior with luxury purchases when interacting with others. Word-of-mouth communication is considered a key channel for luxury marketing, so how people present their luxury purchases to others is likely to be of considerable interest to marketers.

While a consumer’s guilt after buying a luxury item may lessen, potentially reducing the consumer’s need to justify to one’s self, we suspect that the consumer may continue to feel a need to justify purchases to others. Cultural norms or theories that guide a consumer’s expectations of own thoughts and feelings following a luxury purchase are likely to guide expectations about others’ thoughts and feelings about the purchase. So, just as a consumer expects to feel guilty and judge himself negatively following a luxury purchase, he is likely to expect others will judge him negatively. One way a consumer may deal with this, not previously explored in consumer research, is to *conceal* the luxury purchase from others or to present the purchase in ways that will likely minimize negative judgment by others.

We investigate these ideas in four studies. First, we examine whether people sometimes conceal luxury or indulgent purchases from others (study 1), and whether they prefer to conceal information that might lead to negative judgments by others, in particular information about the cost of the luxury or indulgent item (studies 1 and 2). Next (studies 3 and 4), we examine the effect that describing a past luxury or indulgent purchase to others has on consumers’ thoughts and descriptions about the item. Specifically, we propose that when people are asked about their thoughts privately versus when interacting (or expecting interaction) with others, they will naturally present information in ways that are likely to minimize negative judgment by others.

In study 1, participants were asked to think of and describe a situation where they had bought something for themselves and had chosen “to conceal the purchase and/or information about the purchase from someone.” They listed the item, its cost, reason for purchase, whom they did and did not tell about the purchase, and why. Participants commonly chose to conceal three types of items: illicit, embarrassing, and (as predicted) luxury or indulgent items. For luxury items, consumers most commonly concealed the item or its cost, and claimed their behavior stemmed from fear of negative judgment by others.

In study 2 we examined what information about a luxury purchase (including cost) people prefer to withhold from friends. Participants imagined they purchased an item from an online luxury retailer, and were asked to give the name and email of a friend who would receive free shipping on his/her next purchase. Participants indicated which of three email options they preferred that varied on information disclosed to their friend about their purchase, and explained why. Option A mentioned the participant’s purchase, providing a picture, description, and price; option B mentioned the participant’s purchase, providing only the general category of the purchase; option C did not mention the participant’s purchase. Participants preferred option B over option A, most commonly explaining their preference as a reluctance to purchase details with their friends. (Option C was disliked for reasons unrelated to the purchase).

In studies 3 and 4, we directly test the effects of presenting luxury purchases to others on what consumers say and think. In study 3, participants brought to mind a luxury item they had bought either in the recent or distant past (manipulated between subjects) and imagined they were using or wearing it. They completed a thought listing about the item or they first imagined a friend complimenting them on the item before completing a thought listing (manipulated between subjects). Finally, they rated their purchased item on scales, including happiness with the item and value for money. Overall, most thoughts consisted of positive descriptors of the item, however when thinking about responding to a friend, participants more frequently also mentioned the cost of the item, presenting this information in ways likely to reduce negative judgment (e.g., emphasizing value for money or low price). This difference was reduced for purchases from the distant past, perhaps reflecting less need for purchase justification. Consistent with this idea, participants rated items purchased in the distant past as better value for money than those bought more recently, even when controlling for item cost.

In study 4, we show that these changes to thoughts only occur with the expectation of interaction with others, not simply when others are present, suggesting that self-presentation concerns drive this effect. Participants were asked to think about a luxury item they had purchased recently and completed a thought listing. Participants did this alone, in the mere presence of others, or in the presence of others with the expectation of discussing their purchases. As in study 3, all participants most commonly listed positive descriptors about the item. However, participants in the expected discussion condition also listed cost related thoughts significantly more often than did participants in the other conditions. As before, they presented this cost information in positive ways likely to minimize negative judgment by others. There were no differences by condition on cost of item.

Instant Wins versus Sweepstakes: Attitudes toward Delayed Promotions

Gilles Laurent, HEC Paris, France

Ayse Onculer, ESSEC Business School, France

Sonja Prokopec, ESSEC Business School, France

Retailers frequently use sales promotion tools as a part of their marketing effort. The market for consumer-oriented activities, such as sweepstakes, discount coupons and free samples, has grown substantially in the last decade, reaching approximately \$300 billion in the United States alone (*Promo Trends Report*, 2004). Given this huge volume, it is essential for companies and policy-makers to understand how individuals respond to different types of reward mechanisms.

To our knowledge, experimental studies focusing on consumer response for promotional activities are quite scarce (see Ward and Hill, 1991; Prendergast et al, 2005; Chandran and Morwitz, 2006). The current study investigates the impact of time preferences on attitudes towards sales promotion tools. Our conjecture is that delayed promotions do not always induce the same kind of purchase behavior and that risk attitudes, time preferences and affective responses contribute to differences in consumer reactions.

Sales promotion activities can take various forms with respect to the reward structure. A possible taxonomy is as follows:

1. Risky versus certain: The promotional campaign can offer a risky prize (through a lottery or contest) or a certain one (discount coupons).
2. Immediate versus delayed: The prize can be redeemed immediately (checkout coupons, instant-wins) or in the future (mail-in rebates, sweepstakes).
3. Hedonic versus utilitarian: The prize can be more pleasure-oriented (vacation, perfume, etc) or more functional (monetary reward, gasoline, etc).

Past experimental findings have shown that individuals prefer more hedonic alternatives in a probabilistic setting and hedonic options are more popular as prizes than purchases (O'Curry and Strahilevitz, 2001). There is also evidence that even though individuals are generally risk-averse for immediate lotteries, this aversion decreases over time (Shelley, 1994; Sagristano et al, 2002). Anticipated feelings such as hope and savoring can be one possible reason for this declining risk aversion (Loewenstein 1987, Chew and Ho, 1994). Individuals are also found to be less sensitive to changes in probabilities for affect-rich rewards (Rottenstreich and Hsee, 2001).

Taking these findings as a starting point, we propose that individuals prefer a certain prize to be obtained immediately to an immediate risky prize but this preference for a certain prize over a risky one decreases over time. In addition, the preference for lotteries with hedonic prizes over utilitarian prizes increases with delay.

An experiment is conducted to test these hypotheses. The experiment consists of a ranking task, where subjects (31 MBA students) are asked to rank 8 different promotion packages from the most attractive to the least attractive option. The options are generated in a 2x2x2 design, where we manipulated the type of the reward (perfume or gasoline), the temporal dimension (immediate or in two weeks) and the riskiness (certain or with 10% probability). The preliminary results provide evidence for our hypotheses. On average, the most attractive option was a future hedonic prize: 48% of the subjects ranked "10% chance of winning a $\text{€}100$ voucher for a bottle of perfume, to be determined and given in two weeks" as their first option; followed by 32% who ranked "a $\text{€}10$ voucher for a bottle of perfume, to be given in two weeks" as their first option ($\chi^2=33.10, p<.01$). The least preferred option was "10 chance of winning a $\text{€}100$ voucher for gasoline, to be determined and given immediately", chosen by 45% of the subjects as the least attractive option. Further analysis will examine the interactions between the type of the reward, its temporal distance and its riskiness.

These preliminary results have interesting implications. If a marketer has to choose one single promotional tool, the most attractive option for the average consumer would be a lottery drawing in the future, involving hedonic prizes. In a following experiment, we plan to explore whether preference for promotional tools varies depending on the price of the product. We believe that exploring the behavioral response to different sales promotion activities is a rich vein for future research.

Transumers: Motivations of Non-ownership Consumption

Stephanie Lawson, Florida State University, USA

Transumers engage in fractional ownership to enjoy products and experiences without the hassles or risks of permanent ownership. The dynamic changes taking place in the global marketplace related to economic, social, and cultural forces have created an environment ripe for fractional ownership. Previous studies forecast the rapid pace of technological innovation will result in a shift toward shared ownership. There is an absence of research on the motivations of fractional ownership. Based on exploratory consumer interviews, a survey instrument was developed and tested. Findings suggest consumers engage in fractional ownership for reasons ranging from environmental consciousness to status seeking.

Imagine having access to the latest luxury handbags or golf clubs whenever you desired or using a car share service and never having to worry about the costs of automobile ownership. This is reality for a growing consumer segment participating in fractional ownership consumption experiences. These individuals, known as Transumers, are defined as, "consumers driven by experience instead of the fixed, by entertainment, by discovery, by fighting boredom, who increasingly live a transient lifestyle, freeing themselves from the hassles of permanent ownership and possessions" (Trendwatching.com 2006). The term Transumer was coined in 2003 by, global design and business consultancy firm, Fitch and originated from the marriage of the words transient and consumer (Trendwatching.com 2006). While the popular press is replete with research related to transumption behaviors, Transumers have not been specifically studied in the consumer behavior literature. Transumers are thought to be motivated by experiences instead of possessions, by entertainment, by discovery, and environmental consciousness. The primary purpose of this research is to understand the motivations and individual difference variables influencing transumption behavior.

The dynamic and unique changes currently taking place in the global marketplace related to economic, social, and cultural forces have created an environment ripe for shared or fractional ownership. According to Zukin and Maguire (2004), consumption is an economic, social, and cultural process of selecting goods reflecting the opportunity and limitations of modern life. As interest in sustainability and green marketing increases, these consumers are of particular interest to businesses seeking to capitalize on the growing interest in protecting the environment by offering alternative consumption experiences. Previous studies have forecasted the increasingly rapid pace of technology change will result in a shift toward shared ownership. By engaging in fractional ownership, consumers have access to the latest and greatest and increased social status with less cost. Nissanoff (2006) believes we will evolve into a society where we view the ownership of most things as temporary—like the perception of leased vehicles. The concept of fractional ownership is not new. For example, car leasing introduced consumers to the idea of temporary ownership of vehicles that were above their ownership threshold (Nissanoff 2006). However, the key characteristic that differentiates Transumers from simply leasing a car or owning a timeshare is their pursuit of experiences *across* consumption categories (Levenson 2007). Consumers do not permanently acquire products, but rather an experience. Bag, Borrow, or Steal; ZipCar; and NetFlix are examples of firms that allow consumers to "own" a product for a flexible amount of time for a usage fee.

A two-part study was conducted to first illuminate common themes among individuals and then to investigate how these individual difference variables influence attitudes and behavioral intentions toward fractional ownership. First, an exploratory qualitative study consisting of semi-structured interviews was conducted with individuals engaging in non-ownership consumption. Coding of interviews revealed five themes which illuminate motivations to participate in non-ownership consumption. Although not exhaustive these themes provide insight into the reasons consumers seek non-ownership consumption opportunities.

Based on the emerging themes and the popular description of Transumers, a survey instrument was developed and tested using PLS. Data were collected with the use of 161 self-report questionnaires from adults in the southeastern United States. The hypothesized model describes the individual difference variables including possessiveness, materialism, variety seeking, status consciousness, frugality, and environmental consciousness and their relationships with attitude toward fractional ownership and behavioral intentions to participate in fractional ownership. The hypothesized model was supported by the data. The findings reveal the strongest motivators of positive attitudes and intentions towards fractional ownership were environmental consciousness and status consciousness.

The primary contribution of this research is the conceptual understanding of a unique and growing consumer segment previously absent from the marketing literature. The purpose of this study was to develop the concept of a consumer that engages in fractional ownership across product categories in an effort to collect new experiences while freeing themselves from the responsibilities of permanent ownership. Findings suggest Transumers are both status seeking and environmentally consciousness which at first appears counterintuitive. However, research suggests that while consumers use luxury goods to symbolize success, their definition of success is changing. Many consumers want the brands they buy to reflect their concern for the environment and social issues. At least 1 in 4 American adults hold environmentalism, global issues, and spiritual searching as personal values (Bendell and Kleanthous 2007).

Further, past research on duration of use and acquisition mode suggests consumers expecting to use a product for a short amount of time, all other variables being equal, would rather rent than own (Moore and Taylor 2008). This counterintuitive finding lends a clue as

to why consumers are motivated to participate in a leasing lifestyle. Specifically, the fashion industry is naturally aligned with the trend towards transumption due to the seasonality and temporary nature of style. If consumers are aware that trends change with the seasons, they may expect to use product for a shorter duration resulting in a greater motivation to rent rather than purchase. Luxury consumption has been impacted by a weakening economy; however, several luxury fractional ownership firms have recently experienced an increase in transactions. Michele Krause, the founder of Bling Yourself, an online fractional ownership accessory retailer, says that the economic downturn has not impacted their number of new customers or rentals (Roane 2008). Is fractional ownership not only a way to reduce environmental impact but also the answer to a sustainable economy?

In conclusion, the availability of fractional ownership options means less commitment, enabling consumers to enjoy a product temporarily before moving on to the next experience (Winsper 2007). Future research seeks to create a typology of transuming consumers by conducting interviews across industries and clustering based on theme. Investigating this new consumption trend provides marketers with insight into the motivations of these consumers and further seeks to illuminate the question set forth by Belk (2007), "Why share rather than own?"

Is a Gift Always a Gift? An Ethnographic Inquiry into the Diversity of Giving Experiences

Marine Le Gall-Ely, ICI, Université de Bretagne Occidentale, France

Christine Gonzalez, LEMNA, Université de Nantes, France

Caroline Urbain, LEMNA, Université de Nantes, France

In January 2005, after the Asian tsunami, the French Croix-Rouge collected more money in one week than usually collected in an entire year of fundraising (41 millions Euros). Médecins Sans Frontières was approached by 411 volunteers ready to fly to Indonesia, a number usually taking five months to reach. The total amount of giving actually reached far beyond the needs of these associations to face up to this disaster. Why did people give to meet the tsunami disaster? Maybe because of the situation (Christmas period, death saliency, social influence of children and grand-children...) generating affective reactions (surprise, anxiety, fear...) and resulting in taking giving behaviors in action.

We assume that situations may have a great impact on giving behaviors just as it does on consumption behaviors in general. Situations are defined by Belk (1975) as "momentary encounters with those elements of the total environment which are available to the individual at a particular time". Situational characteristics are physical and social surroundings, temporal perspective, task definition features and antecedent states.

The aim of the present research⁶ is to answer the following questions:

Do situations influence giving behaviors?

If they do, how does the situation have an impact on giving?

By focusing on the physical and social surroundings, on the affective and experiential aspects of giving behaviors, we lie within the scope of consumer culture theory (CCT, Arnould and Thompson, 2005). Although givers do not actually consume physical goods or

⁶This research is a part of a larger one, financed by the ANR (the French National Research Agency), aiming at tackling problems encountered by associations by a better understanding of giving behaviors. The research is limited to individual giving behaviors, excluding firms or foundations donations.

services, we believe that they do indeed undergo a consumption experience with persons or associations who benefit from their giving behaviors.

As we cannot assume that the different types of giving behaviors (gifting, donation, volunteering...) are not related, we will study how people imagine and experience giving:

- of money, of time, of gift, but also of blood, of organs,
- to other persons, known (members of the family, friends) or unknown (beggar),
- or to associations (local or international, public or civil, whereas aiming at social tasks, health promotion and risk prevention, education and research, culture, sports and leisure...).

A lot of research in an anthropological (Malinowski, 1922 ; Mauss, 1923-1924 ; Weiner, 1992 ; Godelier, 2002), sociological (Levi-Strauss, 1971 ; Godbout and Caillé, 2001), philosophical (Derrida, 1991) or economical (Cheal, 1988) perspectives pays attention to giving behaviors.

In consumer research, an important research stream has focused on giving since the seminal works of Belk (1979 ; 1993) and Sherry (1983). Most of them have dealt with gift giving (Otnes, Lowrey and Kim, 1993 ; Sherry, McGrath and Levy, 1993 ; McGrath, 1995 ; Otnes, 1996 ; Ruth, Otnes and Brunel, 1999).

When raising the issue of fundraising by associations, the research has concentrated on the influence of socio-demographic and psychological features of givers and volunteers on their behaviors (Guy and Patton, 1988 ; Burnett and Lunsford, 1994 ; Wymer, 1997 ; Wooten, 2000 ; Bennett, 2003 ; Sargeant and Woodliffe, 2007), or less often, on the influence of appeal techniques on giving behaviors (Rothschild, 1979 ; Bendapudi, Singh and Bendapudi, 1996 ; Desmet and Feinberg, 2003 ; Venable *et alii*, 2005 ; Goatman and Lewis, 2007).

Few studies have adressed the question of situational characteristics on giving behaviors, some focusing on social surroundings (Fisher and Ackerman, 1998 ; Bryant and Test, 1967 ; Gillath *et al.*, 2005), on temporal perspective (Fisher, Vandenbosch and Antia, 2008) or on task definition features (Bryant, Slaughter, Kang and Tax, 2003).

To our knowledge, some situational influences, as physical surroundings or antecedent states have not been studied, and, moreover, no comprehensive and integrative study of situational influences on giving behaviors has been conducted, what could be of great interest for associations' marketing.

So, we have designed an ethnographic study aiming at studying behaviors in social and cultural context (Arnould and Wallendorf, 1994 ; Sherry, 1995 ; Sunderland and Denny, 2007). As a first stage, we have conducted depth interviews with 15 persons from January to February 2009. We employed snowball sampling, recruiting informants from among family and acquaintance networks. We have interviewed 8 women and 7 men, from 26 to 65 years-old, living in Paris or west regions of France. They are either workers, retired or housewife, single, married or widow, with or without children in care, with diverse levels of education, of income, practising or not diverse religions (Christianity, Judaism, Muslim religion). We followed Bertaux and Kohli's (2001) and Bertaux (2009) recommendations on life stories questions to elicit holistic descriptions of our informants' representations and experiences of giving. Interviews ranged from 55 to 85 minutes, were audiotaped, transcribed, and yielded to more than 300 pages single-spaced pages of text.

We are in the process of interpreting the text using dialectical tacking (Strauss and Corbin, 1998), immersing ourselves in the interdisciplinary literature on giving behaviors, to seek out consistencies and/or inconsistencies with our text.

Some preliminary results emerge about the situations:

- the existence of different types of experiences (Holbrook and Hirschman, 1982 ; Caru and Cova, 2003) of giving: ordinary as giving a coin to a beggar in the street or old clothes to an association *versus* extraordinary as TV shows or sports events aiming at fundraising, definitions of ordinary and extraordinary experiences being diverse among participants ;
- the physical surroundings, often described as "disappointing", especially in small charity organizations;
- the influence of emotions: for example, the death saliency seems to be important in acting the giving behavior in extraordinary experience, the mood seems to influence more ordinary experiences ; disappointment is also salient in discourse;
- the social aspects of giving: it may be an individual *versus* a social experience.

Life stories also have shed light on the importance of the life path, especially childhood, in framing giving representations and learning to give.

From these preliminary results, we conclude that associations should evolve from a person-association/cause relationship to a person-association/cause-situation relationship as giving decisions are also contingent on situational variables.

Further depth interviews and diaries will be collected and analyzed until the end of 2009. Observations will also be organized.

The Effect of Emotion on Color Preferences

Chan Jean Lee, University of California at Berkeley, USA
 Eduardo Andrade, University of California at Berkeley, USA

Can mood change our color preferences? Would people be attracted to different colors depending on their mood? Even though emotional influence on judgment and decision making has been well established (Schwarz and Clore 1983), little is known how a perceiver's emotion affects his or her aesthetic judgments including color preferences. On the other hand, it is well established that people feel various emotions from colors (Crozier 1996; Guilford and Smith 1959; Ou et al. 2004; Valdez and Mehrabian 1994). For example, people feel calmness or low arousal from short-wavelength colors, such as blue and green. People feel excitement, happiness, or high arousal from long-wavelength colors, such as red and yellow. People feel relaxation and softness from light or pastel tone colors, while tension and hardness from dark colors. Given the strong associations of colors and emotions, we examine if an individual's color preferences are contingent on his emotion.

Specifically, we contrast three potential hypotheses from emotion literature: affective evaluation (Andrade 2005; Schwarz and Clore 1983; Isen et al. 1978), affect regulation (Andrade 2005; Gross 1998), and affective fit. These three hypotheses predict a perceiver's emotional influence on color preference differently.

We used within-subject design to measure color preferences, since individual differences in color preference are rather significant (Schloss and Palmer 2007). Thus, the changes between two color preferences were used as the main dependent variables of the study. We used emotionally laden movies to induce happiness, sadness, and neutral emotion. The movies were edited into black and white films to eliminate color exposure confounding during video watching. We asked participants to evaluate the colors before and after watching emotionally laden movies. As a cover story, participants were told to take part in two unrelated studies, color preference study and video evaluation study. They heard that to avoid their eyes from being tired from evaluating subtly different colors, color preference study would be split into part I and part II and videos study would take part in between the two parts.

Colors were chosen based on Hue-Saturation-Light (HSL) color scheme, which is widely accepted by color theorists as describing three independent properties of colors (Valdez and Mehrabian 1994). To identify which aspect of colors is influenced by emotions, hue (red, blue, yellow, and green), saturation (saturated vs., muted), and lightness (light, middle, dark) dimensions of colors were fully

factorized. Therefore, we used a mixed ANOVA design: 3 emotion (happy, sad, and neutral: between-subjects) x 4 hue x 2 saturation x 3 lightness ANOVA.

One hundred fifty nine undergraduate students from a large western university participated in a study. Emotions were induced successfully as intended. The three hypotheses predicted emotional effect on color preferences in different direction. To test these hypotheses, we conducted a mixed ANOVA examining the effects of a perceiver's emotion (happy, sad, and neutral: between-subjects) on preferences for colors' dimensions (hue x saturation x light). A full factorial ANOVA did not reveal significant effects. However, after grouping hues by wavelength we found a significant interaction among wavelength, lightness, and emotion. In the light and middle lightness levels, the happy group's preferences for long wavelength colors significantly increased. However, the happy group's preferences for dark colors were not different from other groups.

In summary, a perceiver's emotion affects his color preferences. More specifically, when people are happy (vs. neutral), happiness associated colors, that is, highly arousing colors such as light red and yellow, are more preferred.

Social Attributions of Obesity and Attitudes toward Food Marketing: Implications on Framing Strategy

Jung-Sook Lee, Towson University, USA

Using attribution theory, the study investigates the relationships between social attributions of obesity and consumers' attitudes toward food-marketing policy. Findings from a survey of 316 college students indicate that differences in social attributions, causes of and responsibilities to obesity, are significantly related to consumers' attitudes toward food-marketing policy. Attitudes toward food advertising and beliefs on the importance of obesity are also important in predicting consumers' attitudes toward food-marketing policies, both directly and indirectly through social attributions about obesity. A synergetic framing, instead of a competitive framing, between personal and social attributions is recommended as a message framing strategy to build consumers' support for policies on food marketing.

Antecedents of Attitudes towards Counterfeits of Luxury Brands: A Consumer Misbehavior Model Perspective

Seung-Hee Lee, Ewha Womans University, Seoul, Korea
Boonghee Yoo, Hofstra University, USA

Conceptualization: Counterfeiting is a global phenomenon with a growth rate of 1700% over the past decade (U.S. Department of State, 2006). Estimates of global sales for counterfeit products are about \$600 billion per year, accounting for 9% of world trade (Cordeiro 2007). Much research can be found in the literature that deals with anti-counterfeit strategies from the supply side to protect counterfeiting (e.g., Chaudhry et al 2005; Shultz and Nill 2002). However, the counterfeiting problem is not related only to the manufacturers of counterfeit products, but also the demand for these counterfeit products. For better understanding consumer behavior about counterfeit products, the consumer misbehavior model was used for this study. Consumer misbehavior is defined as 'behavioral acts by consumers which violate the generally accepted norms of conduct in consumption situations' (Fullerton & Punj 1997, p.336). This consumer misbehavior has been accepted as a component of consumer experience. More than thirty-five types of consumer misbehavior such as shoplifting, financial fraud, and purchase of counterfeit products have been explained. Based on the literature review, this research involves three elements: 1) product variables such as price and quality, 2) individual variables such as materialism and consumer ethics, and 3) social variables such as subjective norms.

Purpose of this study: Therefore, the purpose of this study was to examine the determinants that influence consumers to purchase counterfeit products, and to propose and test a model that deals with the main antecedents of consumer attitudes toward counterfeits of luxury brands. Six hypotheses were developed. H1: The perceived price-advantage of counterfeits has a positive effect on the attitude toward counterfeit products. H2: The perceived quality of counterfeits has a positive effect on the attitude toward counterfeit products. H3: Materialism has a positive effect on the attitude toward counterfeit products. H4: Consumer ethics has a negative effect on the attitude

toward counterfeit products. H5: Subjective norm has a positive effect on the attitude toward counterfeit products. H6: Attitude toward counterfeit products has a positive effect on purchase intention of counterfeits.

Method: Three hundred and sixty-nine undergraduate female students ($M=21.4$) at a large university in Seoul, Korea took part in this study. Korea is one of the top five biggest manufacturers in counterfeit production worldwide along with China, Taiwan, India and Hong Kong (Casabona 2009). Approximately 70% of the respondents were marketing and fashion majors. Their monthly personal disposable income ranged from \$70 to \$900 ($M=\$318$). The questionnaire included demographic items and questions as to whether or not participants had purchased counterfeit products. The purchasers of counterfeits 'knowingly' purchased a counterfeit as non-deceptive counterfeits. For measurement, perceived price-advantage, quality of counterfeits, and subjective norms items were adopted from Tom et al (1998)'s scale. Richins and Dawson (1992)'s materialism scale and Muncy and Vitell (1992)'s consumer ethics scale were also used for this study. Each item was accompanied by a 7-point scale (7=strongly agree; 1=strongly disagree). Descriptive statistics and structural equation modeling using AMOS program were conducted for data analyses.

Major Findings: Approximately 67% of respondents had purchased counterfeit fashion products such as clothing, handbags, accessories and shoes. To ensure data validity and reliability in this study, internal consistency, convergent validity, and discriminate validity were examined. As the results, strong evidence demonstrated satisfactory data validity and reliability. As the next step, the subsequent process of identifying the structural model that best fits the data was conducted. The findings indicated the structural model presented in this study showed adequate overall goodness-of-fit with observed data (Chi-square =15.85, d.f. =5, $p=.05$; GFI=.99; AGFI=.98; CFI=.99; RMSEA=.001, RMR=.028). The results of hypothesis testing showed four hypotheses out of six supported at the significant level of lower than 0.05. That is, the perceived price-advantage of counterfeits (H1: Estimate= .126, $p<.05$), and perceived quality of counterfeits (H2: Estimate= .373, $p<.0001$) had a positive effect on the attitude toward counterfeit products. Also materialism (H4: Estimate= -.175, $p<.0001$) had a negative effect on the attitude toward counterfeit products. Finally, attitude toward counterfeit products (H6: Estimate= .446, $p<.0001$) had a positive effect on purchase intention of counterfeits. However, H2 and H4 were not supported.

Managerial Implications: Based on these results, consumer's attitudes toward counterfeits is an important predictor of counterfeits of luxury brands. Purchasing counterfeit products is illegal globally and is considered consumer misbehavior. This study will provide practical and useful information for educators, global marketers and policy makers that will be beneficial in the protection of counterfeit misbehavior. Results of this study are only partially conclusive, and further research is necessary to better understand this phenomena.

The Effects of Values-Affirmation on Charity Support Behavior: The Mediating Role of Positive Other-Directed Feelings

Yun Lee, University of Iowa, USA

Jing Wang, University of Iowa, USA

Despite charitable organizations' enormous social and economic impacts in our society (Bendapud et al. 1996), charitable giving has stagnated in the U.S over the last 30 years, and philanthropic institutions have found it increasingly difficult to raise needed funds from givers (Merchant and Ford 2008). Given today's daunting situations charities are faced with, in this article, we suggest that affirming important personal values motivate charity support behavior.

This argument follows from self-affirmation theory. Self-affirmation refers to behavioral or cognitive events that bolster the 'perceived integrity of the self' (Steel 1988, p.291). Social psychologists have documented that self-affirmation encourages people to see themselves objectively (Harris and Napper 2005), and helps them buffer against self-threatening information (Armitage et al. 2008; Harris et al. 2007; Koole et al. 1999) and decrease biased information processing of a persuasive message (Cohen et al. 2000; Harris and Napper 2005; Reed et al. 1998). It has also been linked with less motivational processing of dissonance provoking situations (Steele and Liu 1983), increased open-mindedness (Correll et al. 2004; Sherman and Cohen 2006), and decreased closed-mindedness and inflexibility in negotiation (Cohen et al. 2007). Taken these together, we argue that the process of values-affirmation may increase the persuasiveness of a message about charity support.

H1: Participants in values-affirmation conditions are more likely to support charity than those in control conditions.

Recent studies (Koole et al. 1999; Steele and Liu 1983; Tesser 2000) have argued that values-affirmation increases positive feelings. Along the same line with this argument, Crocker et al. (2008) demonstrated that affirming important personal values induced greater positive other-directed emotions, by enabling people to diminish concern for themselves (Correll et al. 2004) and transcend the self (Crocker et al. 2008). As for the linkage between positive mood and enhanced helping behavior, Weyant (1978) found that when people were on positive mood, they volunteered more than those on neutral mood. This leads us to theorize that values-affirmation increases positive other-directed feelings, and thereby enhance helping behavior.

H2: The enhanced charity support behavior through the process of values-affirmation is mediated by positive other-directed feelings.

In three studies, we investigate whether this is the case. We begin by demonstrating the effects of values-affirmation on donation intent to the Red Cross (Study 1), willingness to help people in crisis (Study 2), and willingness to help patients coping with end-stage diseases (Study 3). We then demonstrate that participants in values-affirmation conditions are more likely to help charity on the greater positive other-directed feelings than those in control conditions (Study 2). Finally, we demonstrate that the effect of values-affirmation on willingness to help others is mediated by positive other-directed feelings (Study 3).

Study 1

Method

Participants were asked to rank six values (i.e., business, art-music-theater, social life-relationships, science-pursuit of knowledge, religion-mortality, government-politics) in order of their personal importance (Sherman et al. 2000). Participants were then assigned to either the values-affirmation versus the control condition. In the values affirmation condition, participants were instructed to think about their most important value and write a short essay about why the value was important and meaningful to them. In the control condition, participants were asked to write about their least important value and why it might be important and meaningful to other people (Schmeichel and Vohs 2009). Then participants were presented with the message from the Red Cross and asked whether they would like to make monthly donation to the Red Cross Champions Program (0= do not want to make monthly donation, 1= want to make monthly donation).

Results

Monthly Donation Intention. We measured monthly donation intention as dichotomous and analyzed the data by using Chi-Square test. The results showed that participants (59.4%) in the values-affirmation conditions were more likely to make monthly donation to charity than those (40.6%) in the control conditions ($\chi^2(1)=3.574, p=.06$).

Study 2

Method

Participants were asked to rank twelve values (i.e., relations with family and friends, social skills, romantic values, athletics, sense of humor, creativity, managerial skills, spontaneity, neatness or tidiness, aesthetic appreciation, physical attractiveness, and music ability or appreciation) in order of their personal importance (Harris and Napper 2005). As Study 1, participants were then assigned to either the values-affirmation versus the control condition. And we measured their positive other-directed feelings (loving, connected, and grateful; Crocker et al. 2008) using a three-item five-point scale (1= not at all, 5= extremely). Then participants were presented with the message of the Red Cross Champions Program and asked to leave their email addresses, if they were willing to help people in crisis, so that the program coordinator could contact them.

Results

Willingness to help people in crisis. We coded the data of willingness to help as binary (0= did not leave email address, 1=left email address) and analyzed them using Chi-Square test. The results showed that participants (60.4%) in the values-affirmation conditions were more likely to help others in crisis than those (39.6%) in the control conditions ($\chi^2(1)=3.333, p=.06$).

Positive Other-directed feelings. The results of a 2 (values-affirmation vs. control) \times 2 (email left: yes vs. no) between-subjects ANOVA revealed a significant interaction ($F(1,74)=4.926, p=.03$). Participants in the values-affirmation conditions were more likely to help people in crisis on the greater positive other-directed feelings ($\alpha=.79$) than those in the control conditions ($M_{\text{values}}=2.86, M_{\text{control}}=2.17, t(46)=3.347, p=.002$). Furthermore, in the values-affirmation conditions, participants who wanted to help people in crisis showed greater positive other-directed feelings than those who did not want to help ($M_{\text{yes}}=2.86, M_{\text{no}}=2.17, t(37)=-1.81, p=.07$). However participants in the control conditions did not differ on positive other-directed feelings regardless of participants' willingness to help ($M_{\text{no}}=2.35, M_{\text{yes}}=1.93, t(37)=1.29, p>.20$).

Study 3

Method

As previous studies, participants were asked to work on ranking and writing tasks. Then participants' positive other-directed feelings (loving, connected, and grateful) and positive self-directed feelings (powerful, strong, and admirable) were measured using a six-item five-point scale (1= not at all, 5= extremely; Crocker et al. 2008). Then they were told that a charity organization needed volunteers to help patients coping with end-stage diseases and asked to indicate their willingness to help (1= not at all, 5= very much). They were also asked to leave their email addresses, if they want to help patients, so that the program director could contact them.

Results

Email Left. The results demonstrated that participants (62.3%) in the values-affirmation conditions were more likely to help patients than those (37.7%) in the control conditions ($\chi^2(1)=3.689, p=.05$).

Willingness to help. The results of a one-way ANOVA revealed a significant effect for values-affirmation ($F(1, 86)=5.475, p=.02$). Participants in the values-affirmation conditions were more likely to help patients than those in the control conditions ($M_{\text{values}}=2.9, M_{\text{control}}=2.13$).

Mediation analyses. The positive other-directed feelings ($\alpha=.82$) explained the relationship between values-affirmation and willingness to help charity. Values-affirmation significantly enhanced positive other-directed feelings ($\beta=-.703, p<.01$; most=0, least=1), which in turn predicted an increase in willingness to help ($\beta=.384, p<.05$). When the positive other-directed feelings was included in the regression analysis predicting willingness to help, however, the effect of values-affirmation on willingness to help ($\beta=-.768, p<.05$) was no longer significant ($\beta=-.504, p>.10$, NS), and only the effect of positive other-directed feelings was observed ($\beta=.353, p<.05$; Sobel $z=1.66, p<.10$). The positive self-directed feelings ($\alpha=.86$), however, didn't mediate the effect of values-affirmation on charity support behavior.

Across three studies, we demonstrated that affirming important personal values increased charity support behavior and the effect of values-affirmation on charity support behavior was mediated by positive other-directed feelings. This research suggests that when people are encouraged to affirm important values, they experience greater positive other-directed feelings, and thereby transcend concerns about the self and overcome motivational conflicts between prosocial and selfish impulses.

Effects of Advertising Exposure on Materialism and Self-Esteem: Advertised Luxuries as a Feel-Good Strategy?

Inge Lens, K.U. Leuven, Belgium
 Mario Pandelaere, Ghent University, Belgium
 Luk Warlop, K.U. Leuven, Belgium

Advertisements communicate that any aspiration can be fulfilled if one possesses the right products and brands (Kasser 2002; Pollay 1986). However, little experimental research has shown this presumed effect of advertising exposure on materialism (e.g., Brand and Greenberg 1994; Han and Shavitt 2005; Zhang and Shavitt 2003). Even less research attempted to disentangle the role of self-esteem in

this effect. Given that materialists derive a sense of worth and happiness from the acquisition of possessions (Richins and Dawson 1992), feeling unable to afford advertised products might be problematic for the self-esteem of consumers who repeatedly fail to meet their culturally imposed, materialistic standards (Kasser et al. 2007). In contrast, the pleasant experience of feeling able to afford advertised products may motivate consumers to strive even more for wealth (cf. Vohs and Baumeister 2008). However, this might be less problematic for their self-esteem as these consumers probably feel confident that they will achieve their (material) aspirations (cf. Nickerson et al. 2003). The aim of this research is to investigate these relations between advertising exposure, self-esteem and materialism. We predict that consumers' perceived ability to afford advertised products moderates the effect of advertising exposure on self-esteem and materialism.

In a first experiment, 189 participants were divided over two conditions. Participants in the advertising condition were exposed to five ads for luxurious products. For each ad they indicated to what extent they felt able to afford the product. Participants in the control condition saw no ads. Next, levels of self-esteem (Rosenberg, 1965), chronic materialism (Richins and Dawson, 1992) and momentary importance attached to materialism related goals, e.g., financial success or social status (Aspiration Index, extrinsic subscales; Kasser and Ryan 1993, 1996), were measured. A significant momentary increase in materialism is found in the advertising condition relative to the control condition. Additionally, advertising exposure significantly enhances the self-esteem of consumers who believe they can afford the promoted luxuries, compared to consumers who cannot afford them. However, it is possible that perceived affordability is a consequence rather than an antecedent of self-esteem. Consumers with high self-esteem may be more optimistic about their ability to buy advertised items. In that case, self-esteem measured prior to advertising exposure should predict perceived affordability. To test this hypothesis, participants in the control condition judged the same ads at the end of the study. Their self-esteem scores do not predict affordability, which rules out this alternative interpretation.

Study two aims to replicate these findings and tests whether the effect of affordability concerns is altered if participants are encouraged to imagine themselves owning the advertised products. Forty-seven participants were exposed to six ads for luxury products. After the exposure, 23 participants recalled one ad/product and imagined how they would feel if they would own the product. The other half of the participants did not engage in this mental simulation task. Seventeen participants did not see any ads (control condition). Next, self-esteem (Rosenberg 1965) and temporal materialism (Aspiration Index; Kasser and Ryan 1993, 1996) were measured. Affordability was measured after a number of unrelated tasks to assess whether these concerns affect self-esteem without being actively cued during the advertising exposure (as in study 1). No effect of advertising condition (ad vs. no ads) on materialism is found, yet a significant interaction effect of simulation condition (no imagination vs. imagination) and perceived affordability is found on temporal materialism. In the *no imagination condition*, the regression slope is significant, suggesting that the more one feels able to afford the products, the higher the increase in materialism after the exposure (in comparison to mean materialism in the control condition). In the *imagination condition*, the regression slope is not significant. Also for self-esteem a significant interaction effect of simulation condition and affordability is found. In the *no imagination condition*, the slope is significant, suggesting that the more one feels able to afford the products, the higher the increase in self-esteem after the exposure and vice versa. In the *imagination condition*, the regression slope is not significant.

Both experiments provide preliminary evidence that advertising exposure might induce materialism, most likely in consumers who feel able to afford the advertised products. For consumers who claim being able to buy luxuries, increased levels of materialism after the exposure seem to be less problematic than is usually expected, as they tend to express higher levels of self-esteem. Interestingly, the effects of ad exposure disappear when consumers imagine themselves owning the products. Such outcome-focused thoughts, as opposed to process-focus thoughts, may draw consumers' attention away from actions needed to be taken in order to obtain the product (Escalas and Luce 2004), e.g., being able to buy it. Spending cognitive effort on this imagination process might thus reduce the impact of prior affordability concerns. Interesting would be to assess whether these findings are restricted to luxury advertising or apply to a broader advertising context.

Finally, these results do not necessarily imply that ad exposure is constructive for consumers' self-esteem. Even though the expected inverse relation between materialism and self-esteem (Chaplin and John 2007) was not found, a self-esteem boost resulting from feeling able to afford luxuries seems contingent on social approval. And such extrinsically oriented feelings of self-worth are unlikely to ensure a healthy psychological life in the long run (Kasser, Koestner, and Leks 2002; Ryan and Deci, 2000).

The Effect of Physical Enclosing on Negative Emotion Regulation

Xiuping Li, National University of Singapore, Singapore
Liyuan Wei, City University of Hong Kong, Hong Kong, China

In three studies, we had shown that people attained certain closure over negative events by putting materials relating to the event into the envelope. In study 1, we showed that people felt less bad about a decision that they regretted a lot in study 1A (a strong desire that they could not satisfy in study 1B) if they put the recalled event (desire) into an envelope. Experiment 2 found that people felt less negative after reading a sad story print on a paper after putting the paper into the envelope. However enclosing an unrelated task did not soothe the emotional reaction.

Despite wishes to feel happy and positive, negative emotions—often triggered by the memory of past experiences—come back to haunt us. How can we stop our mind from being distracted by intrusive memories of negative experiences and get closure?

Memory researchers have discussed the concept of cognitive inhibition and found that an explicit instruction to inhibit an unwanted thought may actually increase the accessibility (and hence recall) of the concept (Wegner et al., 1987). Similarly, literature on emotion regulation has suggested that suppression of negative emotional reactions can backfire (Gross, 1998; Wegner, Erber & Zanakos, 1993). However, other than deliberately trying hard to forget, lay people do seek remedies by physically locking things up. For instance, a self-help website on how to deal with a broken relationship advises readers to "put everything that reminds you of your ex in a box and seal it..." (Pant, 2007). Do these behavioral strategies to put physical closure on objects work? The premise that physically enclosing and sealing emotion-related items will help people attain psychological closure over emotional experience stems from recent research on embodied cognition and metaphors. We report the results of three experiments which showed that sealing an emotional laden object into an envelope could relieve the related negative emotions people experienced as a result.

In study 1A, eighty students were randomly assigned to the two conditions. In both conditions, participants were first asked to recall a recent decision that they felt greatly regretful. In one condition, after participants recalled the event, they were instructed to put the questionnaire into an envelope before they handed back the questionnaires; in the other condition, participants were simply asked to hand back the questionnaires. In the second task, participants reported how they felt about the event along four negative emotion scales: regretful, guilty, sad, and worried, all anchored from 1, not at all, to 5 extremely. The four negative emotions were averaged to indicate how negative participants felt about the event at the moment the measurement was taken (cronbach alpha=.79). A simple t test of the treatment factor revealed that participants who put the recalled event into the envelope felt less negatively ($M=2.00$) about the event than those who just handed back the recall task without an envelope ($M=2.52$, $t(1, 78)=2.42$).

Study 1B was different from 1A along the two aspects. Rather than recalling a regrettable experience, participants were instead asked to report something they wanted to do very badly but could not do it. Second, the study was conducted in the dorms on campus. On specific emotional reactions towards the strong desires, people who were given an envelope to put their questionnaire into felt much less negative on almost all single items that were measured (Sad, disappointed, unsatisfied, anxious $t(1, 37)>2.33$, $ps<.05$). In addition, in terms of mental disturbance they felt over their strong desire, those people who experienced the physical closure did feel less distracted or unsettled towards it ($t(1, 37) s>2.25$, $ps<.05$).

Study 2 tested whether the difference was driven by the action of putting things into envelope (in the similar fashion as how catharsis works for some negative emotions) or due to the fact that the specific emotion laden material was put to a symbolic closure. The main test had three conditions, and all conditions needed to complete three tasks in the same sequence and at the same pace. In the first task participants were asked to read a recent news report on the death of a baby. The second task, which was totally irrelevant to the news, measured how college students made a few daily hypothetical decisions. In the last task participants were asked to report how they felt at the moment.

In the first condition, every completed questionnaire was collected back by the experimenter before the next questionnaire was handed out (i.e., control condition). In the second condition, after participants completed the first task, they were given a small envelope and instructed to put the task completed into the envelope. After experimenter collected all envelopes, the second questionnaire would be handed out, followed by the third task (i.e., the condition where physical closure was specified at the emotional event). In the third condition, participants they were given a small envelope to put the second task in and handed it back before they were given the last questionnaire (i.e., the condition where physical closure was acted on unrelated task).

The three negative emotions measured have a relatively high correlation (Cronbach's $\alpha=.90$), and were averaged to indicate how negative the sad story made participants felt. Helmer contrasts were conducted first and showed that after participants put the emotional laden materials into the envelope ($M=2.90$), the negative emotions they felt were significantly less than the rest two conditions ($F(1, 77)=3.89, p<.05$). However, the difference between the control condition and the experimental condition where participants were asked to put an unrelated task to the envelope did not differ on the reported emotional states ($M_{\text{control}}=4.28; M_{\text{unrelated}}=4.12, F(1, 77)=.32, p>.80$).

It is known that the body is closely tied to the processing of emotional information (Niedenthal et al., 2009). Therefore, it is reasonable to expect that bodily experience may also be pivotal in the regulation of emotions. While supporting theories on embodied cognition and embodied emotion, our results took one step further to show that people's emotion regulation process can indeed be facilitated by taking a physical action on the emotional laden materials. The experiments demonstrated that the abstract mental state such as psychological closure over an event appeared to rely on the sensory-motor experiences brought by the simple act of enclosing.

Influence of Self-Relevant Base-Rate Information on Risk Perception of Getting Depression

Ying-Ching Lin, National Dong Hwa University, Taiwan

The aim of this current research is to examine the influence of base-rate information on risk perception in the context of depression. The issue of depression has gained the attention of social marketers and researchers all over the world (e.g., Fontaine & Jones, 1997, Nelson & Craighead, 1977, Tennen & Herzberger, 1987), and has a high incidence in the population studied. The question is whether or not providing this population with the base-rate information on the incidence of depression will be effective to get them to seek help. Therefore, this question is the focus of this paper.

The theoretical framework of this study is based on the impersonal impact hypothesis, which proposes that people's general risk perception may be heightened by the relative information provided, but their personal risk judgments are not (Weinstein, 1989; Tyler & Cook, 1984). Therefore, the purpose of study 1 is to demonstrate that offering social level information such as base-rate information doesn't influence an individual's risk perception, but the personal level information such as the level of depression can indeed influence the risk perception of getting depression and decrease the level of self-positivity bias. Study 2 will examine the individual's perception of the relevance of the base-rate information to see if different levels of self-relevant perception affect their estimations of own risk and other risk of getting depression. While study 2 examines the perception of the relevance to the base-rate information, Study 3 directly manipulates the level of base-rate relevance to see if more self-relevant base-rate information draws the attention of participants to their risk of getting depression and so decrease the difference between their own risk and other's risk of getting depression.

Method

Study 1 examined the effect of social level risk information and personal level risk information on self-risk perception, the updating of self-risk estimates and on the level of self-positivity bias for getting depression. We predict that base-rate information serves as social level risk information and will not change self-risk perception of getting depression, and will remain at the same level of self-positivity bias. However, the result of self-diagnosis inventory serves as a personal level risk judgment and will increase an individual's risk perceptions, and will help to reduce the level of self-positivity bias. At the same time, Study 1 also examines the effect of social level risk information and personal level risk information on an individual's willingness to update his/her self-risk estimates. A 3 (estimate: self initial / other/ self updated) x 2 (social level risk information—base-rate: present vs. absent) x 2 (personal level risk information—level of depression from self-diagnosis inventory: low vs. high) mixed design was used in this study. Seventy-eight undergraduate students participated in this study.

Study 2 proposes that self-relevant perception of the base-rate information will affect people's risk perception and the updating of their self-risk as well as the level of self-positivity bias. We predict that if people think that base-rate information is not relevant to them, they will continue to hold their self-positivity bias, and they will not update their self-risk estimation after they know the BR information for depression. On the other hand, if they think that the base-rate is related to them, then they will pay more attention to this information and will be prepared to update their self-risk estimation and their self-positivity bias will decrease as well. Study 1 showed that the level of depression plays an important role in risk perception and self-positivity bias. Therefore, study 2 will examine the effect of self-relevant perception of the base-rate information on the risk estimations between depressed and non-depressed groups. A 3 (estimate: self initial / other/ self updated) x 2 (self-relevant perception: low vs. high) x 2 (level of depression: high vs. low) mixed design was used in study 2, with the estimating factor manipulated within-subjects, and the remaining factors measured between subjects. One hundred and seventeen undergraduate university students participated in study 2.

Study 3 examines the robustness of these results by directly manipulating the level of base-rate relevance. A 3 (estimate: self initial / other/ self updated) x 2 (self-relevance to base-rate information: low / high) x 2 (level of depression: high / low) mixed design was used in this study, with the estimating factor manipulated within-subjects, base-rate relevant manipulated and level of depression measured between subjects. One hundred and seven undergraduate students participated study 3.

Conclusion

The present study examined the effect of base-rate information on risk judgments about depression. In practice, social marketers provide different risk information to influence the risk perception of their target audiences. However, recent studies on information processing show a different view of the effects of base-rate information on self-positivity bias (e.g. Lin, et al., 2003; Lin & Raghuram, 2005). The present research echoes the findings of previous researches. Study 1 showed that since base-rate information serves as a social level risk information, providing this base-rate information does not change self-risk perception of getting depression, nor the level of self-

positivity bias. However, more personal information such as the result of self-diagnosis inventory increased individuals' risk perceptions and helped to reduce the self-positivity bias. That is to say, non-depressed individuals showed self-positivity but depressed individuals showed realism on the risk perception of getting depression (*i.e.*, "depressive realism," Tennen & Herzberger, 1987). Built on the findings of study 1 and the impersonal impact hypothesis (Tyler & Cook, 1984), study 2 and study 3 showed that if people believe that the base-rate information is highly relevant to them, then this more self-relevant base-rate information can work the same as personal level information. For depressed individuals, providing higher relevant base-rate information increased their risk estimations for getting depression and they showed realism regarding their own chances and those of others of getting depression. For non-depressed individuals, even when they did not show a significant difference for their self-risk between low and high base-rate relevant conditions, they did lower their self-positivity bias when they thought that the base-rate information was more relevant to them. At the same time, the results also showed that relevant perception of base-rate information served as a mediator between base-rate information and risk perception, especially for non-depressed individuals, which provides further evidence that more relevant base-rate information affects an individual's risk perception.

The results of our study also showed that base-rate information affects an individual's self-risk updating. Depressives, who typically have a pessimistic outlook on life, have been shown to be realistic about accepting their likelihood of risk ("depressive realism"; *cf.* Alloy & Abramson, 1979; see Ackermann & DeRubeis, 1991 for a review). They view their life and future in negative terms (Beck, 1967, 1976). Their absolute estimates reflect pessimism, and their relative estimates reflect self-negativity or realism rather than self-positivity (Keller, Lipkus & Rimer, 2002). The results of the present research reflect this pattern. Depressed individuals were realistic once they knew their chances of getting depression, therefore they did not update their risk perception according to the base-rate information (study 3). Even if they did update, their self-risk estimations would be based on their judgments of the base-rate. With other words, if they thought that the base-rate information was not relevant to them, then they decreased their self-risk estimations, but they increased their self-risk estimation if they thought that the base-rate information was more relevant to them (study 2).

Non-depressed individuals, on the other hand, are defined as those whose estimates reflect an absolute level of positivity (*i.e.*, they believe that they are less at risk for a negative event and are more likely to experience a positive event, than they actually are). In the meantime, they tend to have a high self-esteem (Lin et al., 2003; Lin & Raghurir, 2005). Therefore, when they were told the base-rate information, they tended to lower their risk estimations (study 3). More specifically, when they thought that the base-rate information was related to them, they tended to lower their self-risk estimation of getting depression (study 2) in order to maintain their self-esteem (Lin et al., 2003; Lin et al., 2004; Lin & Raghurir, 2005). Although, they would not admit that their risk of getting depression would be higher than they expected once they were given the base-rate information, they tended to lower their self-positivity bias. The base-rate information made the non-depressed individuals notice their risk of getting depression in relative level.

What You Buy Affects How Old You Feel

Yu-Tse Lin, Fu Jen Catholic University, Taiwan
Kang-Ning Xia, Yuan Ze University, Taiwan

Fashion consumption is a means for consumers to express and display themselves. Personal possession of fashion clothes or accessories could be considered as an extension of the self (Belk 1988). Therefore, fashion consumption is closely related to a consumer's self concept, and many researches have discussed this issue (e.g., Banister and Hogg 2004; Grant and Stephen 2005; Phau and Lo 2004). However, in the past, the researches regarding to self concept and fashion consumption were seldom involved with cognitive age. Actually, the perception of one's age is indeed part of self image (Guptill 1969). Consumer will behave based on their cognitive ages (Kastenbaum, Derbin, Sabatini, and Artt 1972; Stephens 1991; Wilkes 1992), and accordingly, they have their thoughts about what fashion is and what

suitable to them is. Correspondingly, although not all of the fashion brands are positioned completely according to age, their positions still are related to age. Hence, for consumers, they will choose the brands or products that they thought are suitable to their age, and what really determinant in their consumption is their cognitive age rather than the chronological age.

Literature

Cognitive age is defined as the age one perceives one's self to be (Barak and Schiffman 1980; Blau 1956; Guptill 1969) and often expressed in terms of how old one feels, thinks, and looks, as well as the things one does (Kastenbaum, Derbin, Sabatini, and Artt 1972; Stephens 1991). Most researches about cognitive age were focused on the relationship between cognitive age and demographic variables with aged people (e.g., Stephens 1991; Markides and Boldt 1983; Bultena and Powers 1978; George, Mutran, and Pennybacker 1980), and seldom researches concerned the effect of cognitive age on general consumer behaviors, such as fashion consumption. Therefore, this study is aimed to probe the relationship between cognitive age and fashion consumption.

Most of the previous researches indicated that fashion attitudes influence fashion consumption behaviors (e.g., Grant and Stephen 2005; Joergens 2006; Park and Burns 2005; Park, Kim, and Forney 2006; Workman and Studak 2006). When further discussing the above relationship, it may be inferred that cognitive age could be the mediator of the fashion attitudes and fashion consumption behaviors. The related evidence is that previous researches showed that fashion attitudes influence the consumer's cognitive age (Barak 1998; Fenigstein, Scheier, and Buss 1975); in other words, when people are more willing toward fashion, more glad to try the new, and more ready to not rely on safe and well-established routines, they will perceived themselves to be younger, and vice versa.

Methods

This study used the two-step structural equations modeling (SEM) to explore the relationship. First, the confirmatory factor analysis (CFA) was performed to evaluate the construct validity. Then a structural analysis was performed to test whether the structural coefficients were significant. In addition, in order to further demonstrate the full or partial mediatory role of cognitive age in each antecedent, three nested competing models were compared with the base model to determine which the better one is. The data come from the 2006 Eastern Integrated Consumer Profile (E-ICP) database, which is a powerful survey of consumers in Taiwan. A self-report questionnaire was completed by 1344 persons aged 13-64 in Taiwan.

In this study, the construct of fashion behavior had three variables: fashion information seeking behavior, purchasing a fashion product, and the new fashion product trial (Raju 1980; Stephens 1991). The fashion attitude also had three variables: high vogue, mature taste, and utilitarian orientation.

The models

The base model is described that the cognitive age plays a mediatory role between fashion attitude and fashion behavior. It fully mediates between high vogue and fashion behaviors. Similarly, it fully mediates between utilitarian orientation and fashion behaviors. However, mature taste has a direct effect on fashion behaviors. In other words, there is only partial mediation between individual taste and fashion behaviors.

Competing model 1 indicates that the cognitive age mediates the impact of fashion attitude on fashion behavior. Especially, that each antecedent is fully mediated, not partially mediated. Competing model 2 indicates that the cognitive age fully mediates between utilitarian orientation and fashion behaviors. However, for the relationship between the mature taste and fashion behaviors, and high vogue and fashion behaviors, the mediation is partial. Competing model 3 indicates that the cognitive age is fully mediated between high vogue and the fashion behaviors. However, it is partially mediated between mature taste and fashion behaviors; it is also partially mediated between utilitarian orientation and fashion behaviors. In addition, some researches indicated that cognitive age may have a direct impact on fashion attitude, rather than the mediatory role between fashion attitude and fashion behaviors (Lumpkin 1985; Tongren 1988). Thus the non-nested competing model 4 was compared with the base model.

Results

The results showed the base model is better than other competing models. First, the chi-square difference between the base model and the competing model 1 is significant ($\Delta\chi^2=-288.82$, d.f.=3, $p<.05$). This finding indicates the failure of competing model 1 to reduce three paths from the mature taste to fashion behaviors. Second, the chi-square difference between the base model and the competing model 2 is not significant ($\Delta\chi^2=4.03$, d.f.=3, $p>.05$). This finding indicates the failure of competing model 2 to increase three paths from high vogue to fashion behaviors. Third, the chi-square differences between the base model and the competing model 3 is not significant ($\Delta\chi^2=4.2$, d.f.=3, $p>.05$). This result indicates the failure of the competing model 3 to increase three paths from the utilitarian orientation to fashion behaviors. The results also showed a good model fit of the base model: the goodness of fit index (GFI) was 0.96; the adjusted goodness-of-fit index (AGFI) was 0.94; the comparative fit index (CFI) was 0.97.

Conclusion

In summary, the results of this study added to the body of knowledge regarding the fashion consumption. This study indicated that cognitive age plays a mediatory role between the fashion attitudes and fashion consumption behaviors. While previous researches ignored the effect of cognitive age, the present study delineated the influence of cognitive age. In addition, this study enriched the researches regarding self-concept and consumption behaviors; this study indicates that cognitive age is also a significant self related factor that can predict the consumption behaviors. Finally, for marketers, as to fashion behavior and its causes, cognitive age is a simple concept that can be easily used to understand and segment consumers, and for the marketing practice, it is believed that cognitive age is more applicable than chronological age.

The Evil Eye on Mimicry: The Influence of Money Primes on Mimicry

Jia (Elke) Liu, University of Groningen, the Netherlands

Dirk Smeesters, Erasmus University Rotterdam, the Netherlands

Social interactions are a central aspect of human existence. Individuals have a constant drive to get along with others. One of the forces that help us connect to others is nonconscious mimicry, the tendency to mimic other individuals' behavior without awareness or intention

(Chartrand and van Baaren, forthcoming). Mimicry serves as a social glue to bond people together (Chartrand and Bargh 1999), and it can even influence consumers' product preference (Tanner et al. 2008). Being mimicked by others makes individuals feel close to these others and more likely to offer them help (van Baaren et al. 2004). However, there are also counter forces in humans' lives that may lead to opposite effects. Money is one of them. Thoughts of money drive people to keep distance from others and offer less help to people in need (Vohs, Mead and Goode 2006, 2008). Which of these forces is stronger in regulating social orientations and shaping consumers' product preference? We will address this question in this paper.

Thoughts of money can influence interpersonal behavior. Vohs et al. (2006) demonstrated that participants who were subtly reminded of money were less likely to offer help and sat further away from a confederate compared to control participants. Furthermore, other literature suggests that the concept of money can induce a business norm (Heyman and Ariely 2004), which might activate a competition orientation and avoidance reaction to interaction others (Kay et al. 2004; Orbell and Dawes 1993). Hence, participants who are reminded of money are expected to mimic another person less compared to control participants.

Mimicry is also a tool to create interpersonal rapport (Lakin et al. 2003). Chartrand and Bargh (1999) found that participants who were mimicked reported liking the other more compared to those who were not mimicked. Then, the question is whether this powerful effect of being mimicked on the creation of liking will still hold when individuals are reminded of money. We think not. We rather expect that when the concept of money is primed, being mimicked will *reduce* the liking of the mimicking other. As people primed with the construct of money strive to avoid connectedness and affiliation with others, they might resist the affiliation attempt executed by the mimicking other. Hence, they might like the other who tried to affiliate even less than when the other did not intend to affiliate.

Experiment 1

Forty-one undergraduates were randomly assigned to either the money or control prime condition. First, participants filled out a battery of questionnaires on a computer. The screen background of the questions was either Euro currency (money condition) or coral (control condition). The money manipulation did not elicit different affect states than the control condition ($t < 1$, *ns*) (also in Experiment 2). Then, participants were left alone in the room and taped for one minute. The number of times participants rubbed their face or shook their foot was measured as a baseline, which did not differ between the money and control conditions ($t < 1$, *ns*). Participants were then asked to discuss four advertisements together with the confederate. For each of the four ad discussions, we taped the first minute of the interaction. During this minute, the confederate was instructed to shake his foot twice and to rub his face twice.

Two judges blind to the experimental conditions coded the videotapes. The mimicry scores were subject to a 2 (prime: money vs. control) \times 4 (measure: measure 1 vs. measure 2 vs. measure 3 vs. measure 4) mixed ANOVA with prime as a between-participants variable and measure as a repeated-measures factor. This analysis only revealed a main effect of prime ($F(1, 39) = 6.77$, $p < .02$). Participants mimicked the confederate less when they were primed with money ($M = 0.61$) compared to the control condition ($M = 0.93$).

Experiment 2

Fifty-seven undergraduates were randomly assigned to the conditions of a 2 (prime: money vs. control) \times 2 (behavior: mimicry vs. non-mimicry) between-participants design. The prime manipulation was the same as in Experiment 1. Then, participants were asked to discuss a set of four ads with a confederate. The confederate was trained to mimic only those behaviors that people do nonconsciously, such as foot shaking and leg crossing. In the non-mimicry condition, the confederate was trained to refrain actively from mimicking any of the participants' gestures and postures. After the discussion, participants received a short questionnaire to evaluate the discussion they just had. Measures of liking for the confederate were also included.

A 2 (prime: money vs. control) \times 2 (behavior: mimicry vs. non-mimicry) between-participants ANOVA was conducted on the composite index of participants' liking of the confederate. There was a significant main effect of money ($F(1, 57) = 19.09$, $p < .001$), which was qualified by a significant interaction between the prime and mimicry behavior ($F(1, 57) = 8.23$, $p < .01$). In the control condition, participants liked the other more when being mimicked by the other ($M = 5.33$) compared to not being mimicked by the other ($M = 4.35$, $F(1, 57) = 4.08$, $p < .05$). However, in the money prime condition, participants liked the other less when being mimicked by the other ($M = 2.86$) compared to not being mimicked by the other ($M = 3.83$, $F(1, 57) = 4.15$, $p < .05$).

General Discussion

Two experiments demonstrated that thoughts of money inhibited the tendency to mimic. Further, the effectiveness of mimicry as a social glue was also impaired by the concept of money. Specifically, instead of liking the interaction partner more, participants primed with money liked the interaction partner less after being mimicked compared to not being mimicked. These results may have implications for consumer behavior. Specifically, the concept of money may inhibit consumers from mimicking the consumption behaviors of other people. Further, whereas being mimicked by another consumer leads to more liking of a product that is introduced in a dyad (Tanner et al. 2008), priming money may actually reverse that effect.

The Effect of General Action Goals on Evaluations of Innovative Products

Xuefeng Liu, University of Illinois at Urbana-Champaign, USA
Dolores Albarracín, University of Illinois at Urbana-Champaign, USA

As goal systems are hierarchical in nature, some goals are more general than others. But so far no work has investigated the effects of general goals on product evaluations. General action goals are among the broadest possible goals and can direct amount of cognitive and motor output resulting in a variety of behaviors such as learning and eating. In the present study, participants evaluated an incrementally new product more favorably when they were primed with general action than inaction goals. In contrast, participants evaluated a radically new product similarly whether they were primed with general action or inaction goals.

According to Kruglanski et al (2002) and Bandura (1989), goal systems are hierarchical networks wherein some goals are more general than others. A general goal may connect with many sub-goals and means of attainment. Up to now, the most general set of identified goals concern general action and inaction, which are both ends of a continuum of cognitive and motor output (Albarracín et al. 2008). General action goals produce behavior with high cognitive and/or motor output (such as learning or eating), whereas general inaction goals produce behavior with low cognitive and/or motor output (such as low learning or resting).

Previous studies found that specific goals can significantly influence product evaluations. That is, products are perceived as positive or negative to the extent that they support or hinder the specific goals that individuals happen to be considering at the time (Brendl and Higgins 1996; Markman and Brendl 2000; Brendl, Markman, and Messner 2003). Thus, for example, calling people's attention to the goal of losing weight may lead them to evaluate ice creams less favorably than they otherwise would. However, few studies have been conducted to investigate the effect of general goals on product evaluations. And more importantly, the effect of general goals on product evaluations cannot be easily inferred from the effects of specific goals. The reason is that when a general goal is activated, their sub-goals are probably activated as well. Under this situation, a product (e.g., an ice cream) satisfying one specific goal (e.g., being hedonic) may at the same time hinder the satisfaction of another specific goal (e.g., being healthy) which belongs to the same general goal (e.g., being happy) as the former does. Thus, the effect of general goals should be studied separately.

The purpose of the present study was to investigate the effect of general action goals on evaluations of new products. In prior studies, Albarracín and Handley (2009) found that action goals increase the accessibility and hence resistance of prior attitudes to persuasive message. Correspondingly, inaction goals decrease the accessibility of prior attitudes and the need to adhere to known routines or objects. In other words, relative to inaction goals, action goals make people more likely to resort to their prior attitudes in processing subsequent information and thus to evaluate products basing on their prior attitudes. From this point of view, given consumers generally have a positive attitude towards incrementally new products which are usually new versions of existing products, action goals may facilitate liking of this type of products. Therefore, after reading an ad about the focal incrementally new product, consumers with activated action goals will evaluate it more favorably than those with activated inaction goals. However, if no prior attitude towards an object exists, action goals and inaction goals would not make a difference in terms of subsequent information processing. As a result, action goals and inaction goals may not influence consumers' evaluation towards radically new products which are not strongly associated with any prior attitudes. To sum up, general action goals may produce liking for the incrementally new products whereas it may not influence produce liking for radically new products.

We conducted an experiment with 109 participants randomly assigned to one of the four conditions of a 2 (general goals: action vs. inaction) x 2 (product type: incrementally new product vs. radically new product) between-subject factorial design. The action and inaction goals were primed in a word completion task. Specifically, participants in the action condition were asked to complete 23 incomplete words, 8 of which were action-related such as "go" and "active". Participants in the inaction condition were asked to complete 23 incomplete words, 8 of which were inaction-related such as "relax" and "rest". Upon completion of this task, participants read information about a radically new product (a nap alarm which keeps drivers from falling in sleep when driving) or an incrementally new product (a computer mouse). Both products were described by attribute information and a picture. After reading the product information, participants responded to three product evaluation measures such as "The nap alarm (mouse) in the ad is" ("-5"="very bad" and "5"="very good"), "The nap alarm (mouse) in the ad is" ("-5"="very undesirable" and "5"="very desirable"), and "The nap alarm (mouse) in the ad is something I" ("-5"="dislike very much" and "5"="like very much"). As a manipulation check, all participants reported their attitude towards the statement that "The nap alarm (mouse) in the ad is innovative" ("0"="not at all" and "10"="extremely").

Participants rated the nap alarm ($M=4.97$) as being more innovative than the computer mouse ($M=3.84$), $t(107)=2.25$, $p<.03$, which indicated that our product-type manipulation was successful. Responses to three product evaluation questions were averaged to form a single measure (Cronbach's $\alpha=.90$). The interactive effect of prime and product type on product evaluation was significant,

$F(1,105)=4.60, p=.03$. As predicted, the computer mouse was liked better when action goals were primed than when inaction goals were primed ($M=.29$ vs. $M=-.90, F(1,105)=3.89, p=.05$). However the nap alarm was evaluated similarly in each of the goal priming conditions ($M=-.40$ vs. $M=-.99, F(1,105)=1.10, p>.10$).

To verify our assumption that consumers generally have a positive attitude towards incrementally new products but do not have clear attitudes towards radically new products, 21 participants who did not take part in the main study were asked to rate “what is your general attitude towards radically new products” (“-5”=“very negative” and “5”=“very positive”) and “what is your general attitude towards incrementally new products” (“-5”=“very negative” and “5”=“very positive”). The results supported our assumptions that consumers have a positive attitude towards incrementally new products ($M=2.62, t(20)=8.60, p<.001$) and a slightly but non-significantly positive attitude towards radically new products ($M=.81, t(20)=1.72, p>.10$).

Marketers spend a large amount of money on advertising their new products. Our findings suggested that adding action-related words and images into the ads of incrementally new products may activate general action goals in consumers’ mind, and thus increase their liking for incrementally new products. In future research, we will use different manipulations of general action and inaction goals and test their influence on consumer judgments in various consumption contexts.

Brand Dilution: The Impact of the User of Counterfeits on Original Brand Perception

Barbara Loken, University of Minnesota, USA

Nelson Amaral, University of Minnesota, USA

The costs associated with counterfeit goods world-wide has been estimated at about \$550 billion, or 5-7% of world trade (Underwriters Laboratories, 2007). However, these costs do not begin to account for the reduction in perceived quality, prestige, and other core brand associations that may result and are difficult to account for on a balance sheet. Despite the magnitude of the problem very little attention has been given to the issue of counterfeits in the marketing literature. Specifically, research on the effects of counterfeit goods on dilution of the brands they imitate is lacking (Loken and John, 2009). Our research addresses this gap directly while also looking at the impact that the user of the counterfeit products might have on the original parent brand.

We suggest that counterfeit products of high-prestige brands dilute the original brands through a weakening of the symbolism of those brands to specific (*i.e.* target) social groups. Research on dissociative reference groups suggests that people avoid brands that are associated with disliked groups (White and Dahl 2006). Furthermore, consumers may abandon brands when out-groups adopt them and the brands stop being distinctive (Berger and Heath 2007). With respect to prestigious brands in particular, there is evidence that an individual’s consumption pattern could symbolize his or her social class position (Martineau, 1968). As a result, the consumer’s use of a counterfeit product, such as a counterfeit “Louis Vuitton” bag, could have specific effects on the symbolism of that brand for other consumers, depending on the social class of the counterfeit user. We investigate this proposition directly by manipulating the social class of the user of both real and counterfeit products.

The extant literature above results in two hypotheses that are tested by our research:

H1: For participants who are exposed to counterfeit products, the overall beliefs about the prestige of the real brand will be lower than the comparable beliefs of participants exposed to the real brand.

H2: For prestige brands, the impact of counterfeit brands on the original brand will be moderated by the social class of the user of the product such that a user from a lower social class will have a greater effect on the symbolism and therefore ratings of the prestige of the real brand.

Our design results in two between subject factors: product (real vs. counterfeit) and social class of the user (“low” class vs. “high” class). Undergraduates entered the lab and were seated at individual cubicles or rooms. Participants were shown a photograph of a young woman (for females) or a young man (for males) using a prestigious product (males=Rolex watch; females=Prada handbag) and were told that the product in the picture was either a real product or a counterfeit product. A brief description of the individual was used to convey the user’s social class. For example, for female participants, the higher class user was described as a 25-year-old recent MBA graduate who bought the product while on a trip to Milan. The lower class user was described as a 25-year-old Applebee’s waitress who bought the bag online.

After looking at the picture and reading the description of the user, participants (drawn from a relatively high class pool of subjects—undergraduate students at a large mid-western university) answered a series of questions that were analyzed as manipulation checks and measures of the dependent variables. The key measures were participants’ beliefs about (a) the prestige of the original brand and (b) whether the brand was a high class brand, each assessed, on 7-point agree-disagree and likely-unlikely scales (the two scales for each, prestige belief and high-class belief, were highly correlated (both $r=0.78$) and were averaged as a measure of each). We also measured overall attitudes toward the brand on four 7-point rating scales, with end points: *excellent-poor*, *better-worse than other brands*, *a good-bad value*, *extremely favorable-unfavorable* (these latter four scales were averaged ($\alpha=0.83$)). Manipulation checks about the product and “user” (the person depicted in the photo and descriptive stimuli) were also collected as well as a few covariates (e.g. the number of designer products and counterfeit products the individual owns).

Consistent with our expectations, a simple comparison of means provided strong evidence for the first hypothesis. Specifically, participants who were exposed to counterfeit goods provided lower ratings on both the prestige and high-class beliefs about the brand. We also found lower overall attitudes toward the brand (4-item index) for the original product. More interestingly, an analysis of variance with covariates provided evidence for a significant two way interaction between the two factors in the study such that the social class of the user had a significant impact on the participants’ evaluations of the original brand. Specifically, the social class of the user had a significant effect on both the belief (prestige and high-class) and attitude ratings when the user in the photo was seen using a *counterfeit* prestige product, but the same effect did not occur when the user was seen using a real product. When a lower-class individual was seen using a counterfeit product it resulted in significantly lower evaluations than when the same counterfeit product was seen being used by a high-class individual.

Overall, our findings indicate that, for prestige products, the use of counterfeit products can dilute people’s perceptions of the original brand. These are the first findings that document these dilution effects on beliefs about the original brand’s prestige, beliefs about whether the original brand is high-class, and overall attitudes toward the original brand. These effects of brand dilution of counterfeits on the original brands are not the same for all users. Because of the symbolism of prestige brands for different social classes, the social class of the users of these counterfeits plays an important role in understanding the effects of these counterfeit products on the original products. The contribution of this research to the literature is twofold. First, we demonstrate through experimental evidence the problem posed by counterfeits on beliefs about the original brands and attitudes toward the original brand. Counterfeiting is a costly problem for brands, not only in terms of the reduced sales of the original brands, but dilution to the original brand beliefs and attitudes. Second, we use a social psychological theoretical framework to provide evidence for the importance of understanding how specific consumer groups differ in their response to counterfeit use and how this factor impacts consumer perceptions and attitudes of the original prestige brands.

Google or Googol? How Meanings of Sound and Spelling Processes Influence Evaluations for Brand Names

David Luna, Baruch College, CUNY, USA
 Marina Carnevale, Baruch College, CUNY, USA
 Dawn Lerman, Fordham University, USA

Despite the heavy reliance of consumers on brand names they are exposed to auditorily (i.e., via word of mouth; Hein, 2007), the majority of studies on brand naming typically examine consumers’ responses to names they are exposed to visually. Consequently, little is known about how consumers process and later use sounds.

In two studies we explore how brand names are auditorily processed and how transcribing the auditory stimuli affects brand evaluations, given the associations that sounds solicit. Accurate spelling of a brand name presented auditorily is relevant because of the potential influence of correct spelling on the ability to find the brand (e.g., online).

The spelling of a word (e.g., *c-l-o-c-k*) is stored in a sort of mental dictionary that individuals possess and fed by phonetically associated words (i.e., with a similar spelling pattern, such as *lock*) and/or semantically related ones (i.e., associated to the meaning of the word, e.g., *time*). Research suggests that frequency of exposure to a stimuli increases the number of semantic associations solicited (Chaffin, 1997). However, the way sounds are translated into writing might reverse these effects.

Over 72% of the sounds in English can be written in more than one way (Ziegler, Stone, and Jacobs 1997). The brand name “Google”, for example, originated from a common misspelling by one of its co-founders of the word “googol”. In this case the sound *gól* can be transcribed into a variety of strings of letters, such as *-gol*, *-gle*. The two spelling alternatives, however, differ with respect to their frequency of occurrence within the English lexical system (frequent and non frequent, respectively). This is important because it affects the spelling process of unfamiliar words, such as brand names. When attempting to spell a brand name that contains a frequent sound-to-spelling pattern, individuals will translate each sound into a string of letters by recurring to words that are phonetically associated. The same will happen when a word that sounds like the non-word is presented before the non-word (i.e., lexical priming; Seymour and Dargie 1990). In the case of non-frequent spelling patterns, however, individuals will recur to words that are semantically related (Houghton and Zorzi, 2003). We thus expect brand names with non-frequent spelling patterns to be processed semantically (rather than phonetically). Increased semantic elaboration should lead to greater spelling accuracy and influence brand evaluations.

One way to classify the effects of meanings conveyed by sounds is based on distinctions within vowel (i.e., front vs. back). Brand names containing front (back) vowels may solicit perceptions such as smallness (largeness), lightness (heaviness; Klink, 2000). Lowrey and Shrum (2007) show that the congruency between the meanings conveyed by the sound and the attributes positively valenced for the product category may positively influence brand evaluations. However, such effects should only happen for those brand names that are semantically processed (i.e., with non frequent spelling patterns).

In this research, we examine how increased semantic elaboration can lead to greater spelling accuracy and higher evaluations. We expect that semantic elaboration will enhance brand evaluations only when spelling accuracy is facilitated by spelling prime (Study 1). In Study 2 we explore whether different spelling patterns of brand names may solicit semantically versus phonetically related words and how this affects evaluations.

Study 1

Method. Seventy-five undergraduate students participated in a 2 (Semantic elaboration) x 2 (spelling prime) between-subjects experiment. Each participant was exposed to eight audio clips, and, after each of them, had up to three trials to spell the brand name correctly. The sum of the number of trials left unused by each participant was utilized to assess one of the dependent variables: accuracy of spelling. Following the spelling task, brand evaluation was measured through a seven-item scale.

Each audio clip provided information about: product category, last words in the ad, and brand name. The priming condition consisted of having the last word in the ad either prime (e.g., thinking of the *staff*) or not prime (e.g., thinking of notes) the intended spelling for the target brand name that immediately followed (e.g., *Paff.com*). Semantic elaboration was operationalized by changing the word used in the priming sentence to be congruent (e.g., *fuel*) or incongruent (e.g., *staff*) with the product category (e.g., cars).

Results. Results showed that elaboration and spelling prime each had a significant main effect on spelling accuracy ($F(1, 74)=4.54, p<0.05$ and $F(1, 74)=18.45, p<0.01$, respectively). Those effects were qualified by a significant interaction of priming and elaboration on brand evaluations ($F(1, 74)=5.75, p<0.05$). As expected, when primed, participants in the elaboration condition had higher brand evaluations than those in the no-elaboration condition ($F(1, 74)=4.10, p<0.05$). In the no-prime condition, however, there was no effect of elaboration on brand evaluations ($F(1, 74)=1.816, p=.18$). Finally, spelling accuracy proved to be a significant predictor of brand evaluations ($F(1, 74)=5.99, p<0.05$).

Study 2

Method. Eighty-nine undergraduate business students participated in a 2 (Phonetic symbolism: congruent or incongruent) x 2 (Frequency: frequent or non frequent) between-subjects experiment. The procedure and measures were the same as in study 1 except for the association task. For the latter, we adapted Chaffin's (1997) procedure. To manipulate frequency, while hearing the audio clip, subjects could read the ad phrase that contained a word with the same frequent (vs. non frequent) spelling pattern of the target name. We referred to the frequency norms provided by Ziegler et al.'s (1997). Following Lowrey and Shrum (2007), we manipulated congruency by varying front versus back vowel to convey meanings that had a positive valence (or not) for the product category in the congruent (or incongruent) condition. The frequency manipulation only changed the target spelling pattern (not the sound).

Results. Results showed a main effect of frequency on semantic associations ($F(1, 85)=5.06, p<0.05$); as expected, brand names with non frequent spelling patterns tended to be semantically rather than phonetically processed. Analysis of variance revealed no significant interaction for the factors (congruency/frequency) on brand evaluations. However, semantic associations had a significant impact on evaluations ($F(2,85)=3.29, p<0.05$).

Conclusion

Our results support a greater understanding of how consumers process brand names auditorily and of the effects of phonetic symbolism on brand evaluations.

Product Placement Effects over Time: The Effects of Brand and Design Attributes in a Dynamic On-Line Choice Task

Ah-reum Maeng, University of Wisconsin-Madison, USA
 David Schweidel, University of Wisconsin-Madison, USA
 Thomas C. O'Guinn, University of Wisconsin-Madison, USA

Product placement, including branded entertainment continues to gain in popularity as a way of reaching consumers. As television viewers are better able to skip traditional commercials, branded entertainment provides advertisers with a way to reach consumers with their brands in a constructed setting. They can do this whether they are watching television online or engaging in time-shifted viewing. In 2007, among just 10 broadcast television programs, there were more than 25,000 product placements; on cable programs, there were more than 150,000 product placements (Kang, 2009).

Two reasons cited for the increased use of product placement is that it can result in a "stronger emotional connection" with viewers, and allow marketers to target specific groups (Eggerton, 2006). There has also been the widespread belief that branded entertainment benefits from what it is not: highly involving advertising.

Belch (2005) provides a review of the product placement literature. Belch notes that much of the research has focused on the impact of product placement on respondents' memory, attitudes, and occasionally behavior: the usual suspects. In examining the role that product placement plays in consumers' actions, Auty and Lewis (2004) find that exposure to product placement can increase the choice of the featured product among children, with previous exposure to the product placement (such as repeatedly watching the same movie) affecting the choice. Russell and Puto (1999) discuss how product placement may affect viewers based on their connectedness to a program. In sum, these theoretical assertions are diverse and could be said to be "all over the map." No single strong theoretical basis for branded entertainment has yet emerged and been recognized as such by the field.

We contribute to the growing body of research into the impact of product placement by studying how it affects the actual dynamic choice process. While previous studies have supported the notion that product placement can influence choice, it has not considered how consumers who are exposed to product placement may differ in how they progress through a choice task compared to those who have not been exposed to product placement, and certainly not dynamically.

Data were collected from 170 respondents who were told that they were watching a rough cut of a television program and we were interested in their perception of the program and characters. The research was conducted at a large university in the Midwest with a Canadian television program to minimize respondents' familiarity. A professional video editor inserted a featured product (an LG cell phone with a slide design) at three occasions in the episode. The cell phone was originally depicted in a cutaway shot. The control condition featured no product placement, and three other conditions were tested in which the length of cut-away shots were manipulated. After watching the episode, respondents were asked to complete a survey about how much they liked the program and characters in the program. Upon completing this task, they were told that they were also going to participate in a brief study to understand students' preferences for different consumer products. This study contained three different product categories: cell phones and two categories for distraction (coffee machines and computers). In each product category, respondents were first asked how they would like to arrange the choice alternatives, whether by brand or by design. We felt this was a useful choice in its correspondence to how actual on-line shoppers are asked to structure their choice task. They then chose the first choice alternative that they were interested in viewing, based on its attributes. Respondents could then end the choice task by selecting the current product, or view another choice alternative. The sequence of decisions made by the respondent was recorded, as well as the amount of time spent viewing each page.

The data were analyzed using a path model (e.g., Hui, Bradlow and Fader, 2009) that allowed respondents' utilities for each of the alternatives to be updated based on the sequence of choices that were viewed and the duration for which each was viewed. Two different updating processes were considered: one in which only the utility of the current product may be updated, and one in which the utility of all choice-alternatives may be updated based on the attributes that they have in common with the product being viewed currently. For example, if a respondent was viewing an LG flip phone, the utility associated with the LG brand and the utility associated with flip phones may be updated. Thus, in addition to updating the utility of the LG flip phone, the utility of the LG slide phone would be updated (the same brand), as well the utility of the Samsung flip phone (the same design but a competing brand).

Our data show that respondents update the utilities based on the attributes of the product that they are viewing. Though we do not find support for exposure to product placement affecting the preference for the featured design, our results indicate that there are two distinct ways in which exposure to product placement affects preference for the featured brand. First, it increases the initial preference for the brand, resulting in respondents being more likely to choose one of the featured brand's choice alternatives initially. As respondents

continued through the choice task, however, they were expected to revise their utility for the featured brand's products downward by a greater magnitude compared to those respondents who were not exposed to product placement. This is what occurred.

Thus, though product placement may spark initial interest in the featured product, suggesting a probably accessibility effect. However, once a realistic on-line choice task is commenced, with different ways of sorting, accessibility is swamped by much more involved on-line (in the cognitive sensed) choice. Simply put, branded entertainment or placement yields a first preference, but is a weak and ephemeral effect once actual choice comes into play. This suggests that product placement is best for low-involvement products for which accessibility and quick decisions are the norm.

The Role of Consumers' Attributions during Price Promotions

Igor Makienko, University of Nevada at Reno, USA

Prior research provided strong evidence that attributions play an important role in the price-promotion context (c.f. Kardes, Posavac, and Cronley, 2004). Consumers, however, are not likely to engage in attributional thinking unless they are motivated to expend their effort to process incoming information systematically (Maheswaran and Chaiken, 1991).

Typical price promotions offering typical benefits may not raise any questions. When incoming information is in line with individual's established beliefs, its cognition may proceed almost automatically—through activation of well-developed schemata (Olson, 1977). On the other hand, when observed retailer's behavior deviates from regular business practice it can 'create enough cognitive unrest' (Lichtenstein and Bearden, 1986, p.295) to motivate consumers to find plausible explanation behind such behavior (Brown and Krishna, 2004; Main, Dahl and Darke, 2007).

In price promotion context offering excessive value may be perceived as a violation of the common sense of selling. Consumers know that marketers cannot cross the point after which they will experience losses (Raghubir, 2004). Therefore, they will try to find alternative explanation for such generosity. Prior research shows that bigger discounts may not always be associated with greater value because they may signal low quality (Bagwell and Riordan, 1991; Friestad and Wright, 1994). Consumers' attributions about inferior product quality in such situations will 'restore' the common sense of selling.

Discount is not the only element of price promotion that may be questioned by consumers. Reference price shows original 'pre-sale' price of a product and may also be manipulated by a retailer. Urbany et al. (1988) found that exaggerated reference prices increased consumers' deal evaluations, estimates of regular product price and decreased search intentions. The authors concluded that consumers may be skeptical of reference prices and at the same time be influenced by them.

In our research we develop a model of consumers' attributions during price promotions offering excessive value and suggest that the type of attributions depends on a reference price level. When suspiciously high discount is presented along with a plausible reference price consumers are likely to generate attributions about inferior product quality. Alternatively, when identical discount is presented along with implausibly high reference price consumers are likely to generate attributions about the manipulative intent to enhance perceived value of the deal (by first inflating regular price and then offering an attractive discount). In the latter situation product quality will not be a concern because high discount will push sales price down into the expected sales price range. At the same time, in both situations consumers will generate negative attributions about retailer's manipulative tactics.

Methodology

A 2 (implausibly high discount vs. typical discount) by 2 (implausibly high reference price vs. plausible reference price) incomplete factorial design was employed to investigate the effects of discount and the reference price on consumers' perceptions of price promotions. Implausibly high reference price in the context of regular discount was excluded from the experiment because it did not reflect price promotion practice. Eighty four respondents were exposed to mock print advertising of a digital camera with a blocked out brand name and were asked to answer questions that followed. Combinations of discount and reference price used in the experiment were as follows: \$150/30% off regular price, \$150/80% off regular price and \$600/80% off regular price.

Preliminary Data Analysis

Manipulation check showed that respondents perceived 30% discount as significantly lower than 80% discount regardless of the level of reference price. "\$150/30%" price promotion was evaluated as significantly more believable than two other conditions that were not perceived as significantly different. However, the mean in the 'least believable' conditions were still higher than 3.6 points on a 7 point scale. Means of respondents' product knowledge, usage level and their involvement with a stimulus were higher than 4 points on a 7 point

scale and were not significantly different across all three conditions. Additionally, respondents did not question the typicality of the advertised digital camera. Overall, preliminary findings indicate that respondents perceived stimuli as intended, were familiar with digital cameras and exhibited higher than average level of involvement during evaluation process.

Major Findings

Results of a one-way ANOVA showed significant differences among groups in terms of retailer credibility ($F=4.14$, $p=0.019$), brand attitude ($F=4.70$, $p=0.012$), product quality ($F=5.6$, $p=0.005$) and deal evaluations ($F=4.55$, $p=0.013$). At the same time respondents' purchase intentions were not different across the three conditions ($p=0.301$).

Our results provide additional support to findings by Urbany et al. (1988). When exposed to exaggerated reference price respondents did not believe that the amount of advertised price reduction was a truthful claim. However, their deal evaluations were significantly higher than those in a typical "\$150/30%" price promotion condition.

In line with our hypotheses respondents' quality perceptions in a "\$150/80%" condition were significantly lower than those in two other conditions. However, neutral assessment of product quality in a "\$600/80%" condition did not improve respondents' perceptions of retailer credibility. Retailer credibility in this condition was not significantly different from that in a "\$150/80%" condition and both were significantly lower than retailer credibility in a typical price promotion condition (\$150/30%).

Additionally, brand evaluations in both atypical price promotion conditions were significantly lower than those in a typical price promotion condition.

Overall, our results support our suggestion that consumers will generate different attributions during price promotions offering excessive value. The type of attributions depends on a reference price level. Price promotions with plausible reference prices will be attributed to inferior product quality, while price promotions with implausibly high reference prices will be attributed to the desire of a retailer to enhance perceived value of the deal. Despite respondents' high evaluations of the monetary value of a deal in atypical price promotion conditions, consumers' attributions about retailer's motives adversely affected consumers' brand perceptions in both atypical price promotion conditions. Absence of significant differences in purchase intentions may be explained by the fact that almost 97% of respondents already owned digital cameras and were not going to purchase it in the next six months.

Artisan Cheese: Pursuing Authentic Consumables in a Mass-Production World

Kathleen Micken, Roger Williams University, USA

Scott Roberts, St Edwards University, USA

W. Brett McKenzie, Roger Williams University, USA

Writers have recently focused on consumers seeking authenticity in their choices. Specific to the consumables area, some have studied tea (Gould 1998) and high-end wine (Beverland 2006). To better understand the complex concept of authenticity, we surveyed knowledgeable consumers about the characteristics of artisan cheese using Beverland's authenticity attributes as a framework. Statistical analysis of our highly involved consumers' responses revealed two overarching dimensions: seeking an authentic product (e.g., inputs are hormone and cruelty free) and preferring an authentic production process (e.g., made by hand, with passion and expertise).

Conceptualization

Recently, many writers (c.f., Chalmers and Price 2009) have focused on consumers seeking authenticity in their choices. Researchers have examined authenticity in a diversity of areas, such as promotion and branding (Gustafsson 2006; Kozinets, et al. 2008), tourism and

place consumption (Costa and Bamossey 2001), music (Arthur 2006; Peterson 2005), antiques (Ger and Csaba 2000; Parsons 2008), and the performing arts (Derbaix and Decrop 2007). Specific to the consumables area, some have studied tea (Gould 1998), beer (Beverland, Lindgreen and Vink, 2008), and high-end wine (Beverland 2006).

Beverland proposed six dimensions of authenticity related to wines: heritage and pedigree; stylistic consistency; quality commitment; relationship to place; method of production; and, downplaying commercial motives. While his work is qualitative, its promise encouraged us to develop quantitative measures along similar dimensions. This type of exercise is potentially fraught with imprecision and the possibility of only further muddying an already opaque concept (Grayson 2002) particularly as our reading suggests that authenticity is negotiated between audience and creator (c.f., Peterson 1997). Furthermore, Leigh, et al. (2006), address the challenge even more strongly by noting, “few consumer researchers have explicitly defined *authenticity*” (p. 482).

Both wine and beer have been studied; yet, to our knowledge, the authenticity of artisan cheese has not been addressed. Accordingly, we first read widely and deeply about artisan cheese, understanding what others have said about its defining characteristics. We also interviewed cheese experts, cheese makers, cheese retailers and cheese consumers. We subsequently designed a survey, informed by Beverland’s authenticity attributes, for attendees at the Second Annual California’s Artisan Cheese Festival. This venue was selected because it provided entree to consumers interested in artisan cheese.

Method

Developing the survey instrument was challenging. Beverland’s conceptual work has established guidelines for thinking about the attributes of authenticity. Additionally, while there is some agreement among researchers about what comprises authenticity, no specific measures have been developed. As Chronis and Hampton (2006) explain, “Academic work . . . remains vague both in terms of its definition and in its marketing relevance” (p. 367). We therefore considered the characteristics of artisan cheese derived from our readings and our informants in comparison with Beverland’s six attributes. We then created statements about cheese to reflect each attribute. The initial effort resulted in 49 items. For the final survey, we reduced the list to twenty, each with a rating scale. Some items directly asked about characteristics of cheese and its making that would reflect the Beverland authenticity attributes. Others focused on the respondents’ relationships to food, experiences, and a self-evaluation on their level of expertise with cheese.

Findings

The findings from this study contribute to our understanding of authenticity by considering the consumer’s perspective. Data were initially analyzed by factor analysis, to determine if the responses could be explained by the six underlying authenticity attributes. After applying both orthogonal and oblique rotations, the result was that four factors best describe the data. Items from several of the six Beverland authenticity attributes loaded (at more than .3) on each factor. Nevertheless, the factor structure was quite interpretable. Responses seem to focus in two areas: seeking an authentic product (what it is made of, with milk from what animals, how the milk is or is not processed, how the animals are treated, who makes the cheese, and where) and seeking an authentic process (made with passion and skill, by hand, by a cheesemaker who raises his/her own animals).

Interestingly, attributes (from Beverland) of stylistic consistency, heritage and pedigree, and downplaying of commercialization were not important elements of the factor structure (low factor loadings). All three are explained to some extent by recognizing that artisan cheese is a relatively new development in the United States. The stylistic consistency results are reinforced by knowing that artisan cheese inherently varies from season to season and from animal to animal—an attribute more recognized by cheese experts than cheese novices in this study. There is no long history of craft cheese production nor established brand appellation (DOC or AOC designation) to provide heritage and pedigree. And while our participants may not like industrialization, the artisan cheese market is currently highly individualized and has yet to confront consolidation or cooption by conglomerates.

We also analyzed the data with multidimensional scaling (Prefscal) to develop a perceptual map of the authenticity attributes. These results yielded a plot with two dimensions that can be interpreted as “Authentic Product”—“Authentic Process” and as “Maker”—“Cheese.” Two clusters, suggested by the factor analysis comprised the Product?Process dimension, again indicating that our respondents focused on the product and process as carriers of authenticity. The contribution of the multidimensional scaling is the attribute clustering in the second dimension (which combines product and process attributes together). This dimension appears to discriminate between the maker—combining “product” attributes of who and where with “process” attributes of skill and passion, of dedication, and of using one’s own animals—and the cheese—combining “product” attributes of type of animal and milk, type of milk processing, with “process” attributes of production by hand. External factors, such as awards, pairing with other artisan products (such as bread), purchases at farmer’s markets, and the evaluation of the marketing, were of less importance.

Conclusion

As noted in the introduction, authenticity is a complex and problematic concept. The referenced articles base their conclusions primarily on qualitative, ethnographic, historical, and observational analyses. This study broached a more quantitative examination of authenticity from the consumer perspective. Artisan cheese is an especially complex good because the origins of its raw materials (type of milk, season of milking, local of livestock), production (inherited recipe, adapted recipe, new recipe), and regulation (food product safety, processing, labeling) all affect its final form. Our consumers’ responses are similarly complex. The responses to the self-evaluation questions show consumers are in some ways self-reflective, in that being able to discern authentic products accrues to their own status as authentic. Examining this confounding may be the key to a clearer definition of authenticity.

Consumer Strategies for Regaining Optimal Distinctiveness

Melissa Minor, University of Florida, USA

Optimal Distinctiveness Theory (ODT) posits that assimilation and differentiation are opposing forces whose equilibrium is optimal distinctiveness (Brewer 1991). The need for assimilation refers to an individual's desire for group membership and inclusion. Differentiation, on the other hand, refers to the need to feel distinct (Pickett & Brewer 2001). When an individual feels that these forces are in balance, the individual is said to have reached optimal distinctiveness, and deviations from optimal distinctiveness should motivate individuals to assimilate or differentiate themselves to regain equilibrium. Research on ODT has found a myriad of effects of heightening either the need for differentiation or assimilation. Individuals primed to feel overly different from (similar to) their peers overestimate (underestimate) the social consensus of their attitudes (Simon et al. 1990) and exaggerate (minimize) perceptions of in-group homogeneity (Pickett & Brewer 2001), importance, and size (Pickett, Silver & Brewer 2002).

The implications of ODT for consumer behavior have not been extensively researched. Because consuming a product places the individual into a group consisting of users of that product or products like it, two differentiation strategies seem particularly applicable to consumerism: identifying with numerically distinct in-groups and identifying with a group that positions itself against the mainstream (Hornsey & Jetten 2004). Indeed, recent work by Timmor and Katz-Navon (2008) suggests that individuals with a heightened need for differentiation will identify with a numerically distinct in-group in a consumption setting: Individuals predisposed to a high need for differentiation (assimilation) were more likely to adopt a new product when they perceived the current group of adopters to be small (large).

However, estimating the size of the in-group associated with a product may not always be easy. Some brands carry with them a cult-like group of consumers (e.g., Apple, Harley Davidson), easily defining the in-group and out-groups for the consumer. However, in other cases, consumption groups are less well-defined. In those situations, consumers' needs for assimilation and differentiation may be more easily met by selecting seemingly "typical" and "atypical" offerings.

Because atypical products or product styles are less frequently instantiated and generally less popular than more typical products or product styles (Loken & Ward 1990), I hypothesize that they will be chosen more often by individuals with a heightened need for differentiation because consumers assume that doing so places the consumer into a numerically distinct in-group and/or a group that positions itself against the mainstream. Alternatively, I hypothesize that individuals with a heightened need for assimilation will select more typical products or product styles because they assume that doing so places them into a numerically larger and/or more mainstream consumption group.

These hypotheses were tested in two studies that investigated consumer choices after their optimal distinctiveness levels were threatened. In both studies, the needs for assimilation and differentiation were manipulated by informing consumers that they were similar to or dissimilar to a large majority of their peers. This information came in the form of feedback from a task where consumers were asked to provide their attitudes toward a variety of well-known brands: After providing their attitudes, consumers either learned that they were similar to 20% of their peers (heightened-need-for-assimilation condition) or 80% of their peers (heightened-need-for-differentiation condition).

In Study 1, after receiving this feedback, consumers were asked to choose between 13 University of Florida t-shirts differing in how typical they were (i.e., in how commonly they were worn by members of the student body). As predicted, individuals who were told that their tastes were very similar to their peers chose less typical t-shirt styles than individuals who were told that their tastes were very different from their peers, $F(1,135)=4.893, p<.05$. Open-ended responses also supported the hypotheses: Some consumers explained their atypical choices by saying that the t-shirt was not worn by thousands of students on campus. Alternatively, other consumers explained their typical choice by saying it was the t-shirt they felt best represented the University.

In Study 1, choices among t-shirts apparently allowed consumers to regain optimal distinctiveness, but are all products equally suited to help consumers regain their optimal distinctiveness? Past research suggests that consumers express themselves through classically "symbolic" goods such as cars and clothing (Belk 1988), whereas recent research suggests that consumers express themselves through personally important products such as music preferences or hairstyles (Berger and Heath 2007). Study 2 examined two dimensions: product symbolism and consumption conspicuousness. Specifically, this study explored whether threatening optimal distinctiveness would affect product choices for all product types, or whether only choices among highly conspicuous or symbolic products would be affected by such a threat. Thus, the study featured a 2(feedback: similar to or different from peers) X 2(target product consumed conspicuously or inconspicuously) X 2(target product symbolic or unsymbolic) between-subjects design.

After receiving feedback about their similarity to their peers (as in Study 1), consumers chose between browsing two special collections on two mock websites: "unique, one-of-a-kind offerings" and products with "more mass appeal". Product conspicuousness and symbolism were manipulated by changing the website's name (e.g., www.tshirts.com vs. www.movies.com).

When choosing among products consumed conspicuously, consumers who were told that they were very similar (very different) from their peers chose to browse the "unique" ("mass appeal") offerings ($p < .05$), as in Study 1. However, when choosing among less conspicuously consumed products, there was no effect of similarity/distinctiveness feedback ($p > .15$). Thus, consumers seem to perceive conspicuously consumed products to be more useful for regaining optimal distinctiveness than inconspicuously consumed products [Feedback X Conspicuous Interaction: $F(1,99)=4.29, p<.05$].

The results of these two studies suggest that consumption-based coping strategies exist for helping consumers regain their threatened optimal distinctiveness. Further, Study 2 suggests threatened optimal distinctiveness is best regained publicly. Future studies will examine whether a non-consumption-based affirmation of optimal distinctiveness eliminates this effect, and, if so, whether this affirmation must be made publicly.

Jack of all Trades, Master of None: The Impact of Assortment Inferences on Choice

Chrissy Mitakakis, Baruch College, CUNY, USA

Thomas Kramer, Baruch College, CUNY, USA

Imagine that Sue and Bob would like to purchase a notebook for school. Sue is shopping for the notebook in a store that has a great assortment variety (i.e., in addition to paper products it also sells household cleaners, fruits, among many others). Bob is shopping in an equally well-known store, which sells only a few different types of items besides notebooks (i.e., only paper products, household cleaners, and fruits). Would the size of the assortment available at the store, which is de facto irrelevant to the choice of the notebook, nonetheless differentially impact Sue and Bob? The current research examines this question. We propose that the number of noncomparable items in an assortment can indeed affect consumers' perceptions and choice of a target product. Although prior studies have investigated the impact of the number of options under consideration (i.e., Chernev 2001, 2003; Lancaster 1990; Broniarczyk, Hoyer, and McAlister 1998; Chernev 2003; Greenleaf and Lehmann 1995; Huffman and Kahn 1998; Kahn and Wansink 2004; Lin and Wu 2006; Menon and Kahn 1995), such research was focused on the number of alternatives from the same product category. However, the literature is lacking an investigation into the effect of assortment size of unrelated options on consumer responses to a particular product. This lack is even more surprising considering the growth of retailing formats such as supercenters or hypermarkets, which sell a seemingly endless variety of products.

In particular, we argue that consumer responses to a product will be less favorable when it is sold in a store with a greater assortment of unrelated products. We further posit that these effects are driven by a lay theory that consumers hold about the marketplace, such that stores that offer products in too many categories cannot offer quality products in all ("jack-of-all-trades-master-of-none"). Thus, we propose that consumers perceive a product that is found in a large assortment of noncomparable products as worse in quality than one that is found in a small assortment of noncomparable products. We define noncomparable products as "those that have few attributes in common" (Bettman and Sujian 1987, p.142), and are generally considered to come from different product categories (Johnson 1984). According to our proposed theory, a large number of noncomparable products can signal the notion that the store's attempt to carry many different types of products detracts from its knowledge about any one product. Consequently, the product will be perceived as having lower quality, compared to the identical one found in an assortment consisting of only a few noncomparable products. Additionally, since these judgments involve conscious, cognitive components, it is also argued that the proposed effects will occur only under full cognitive capacity.

In this research, we propose a new lay theory that consumers hold during the decision making process. Consistent with previous research that has found that people act as intuitive scientists and develop naïve theories about the world around them (Hong, Levy, and Chiu 2001; Kruglanski 1990), research in consumer behavior has been able to identify several different beliefs that consumers may have about the marketplace (Pratap, Mathur, and Maheswaran 2009). For example, consumers have been found to hold lay theories about the relationship between price and quality (Cronley et al. 2005; Kardes, Posavac, and Cronley 2004), ease of accessibility of information (Menon and Raghuram 2005; Schwarz 2004), and hedonic contrast effects (Novemsky and Ratner 2003). Our research proposes that consumers hold a lay theory based on the lack of comparability of surrounding products that are found in an assortment, and thus use this information in making judgments about a single product.

To examine the proposed lay theory consumers have regarding the presence of noncomparable products, we investigated the effects of the size of the assortment of noncomparable products in the purchase environment on consumers' evaluations of a target product (a notebook). In order to assess consumers' utilization of the proposed lay theory, we told participants that the notebook was found in an assortment with either three or twenty noncomparable products (such as household cleaners, food items, etc.), as well varied some participants' cognitive resources with a cognitive load task. After the presentation of the hypothetical shopping scenario, we assessed participants' attitudes toward the product as well as their likelihood of purchasing that product. Our results support the hypothesis that consumers perceive a target product to be of significantly lower quality, and are significantly less likely to purchase it, when it is found in an assortment with several noncomparable products, as opposed to when it is found in an assortment with only a few other

noncomparable products. However, as hypothesized, this effect occurs only with participants who have the cognitive resources available for the “jack-of-all-trades-master-of-none” inference.

We contribute to the literature by proposing a new type of lay theory that consumers use when perceiving product assortments containing different, noncomparable products. This paper demonstrates that consumers use a specific lay theory based on the context of the product assortment to render judgments about a target product. In addition to our theoretical contribution, our findings can also help contribute important managerial implications about retailers’ assortments. Thus, we offer new insight about consumers’ perceptions about a product when the variety of noncomparable products in an assortment increases. Based on our findings, our second study (currently in progress) examines the moderating role of the extent of comparability of other products in an assortment. Future research might also examine whether consumers use this lay theory for all types of products, or whether the product type (i.e., necessity versus luxury) would make a difference.

Ethnic Chinese Representations in Indonesian Advertising

Angeline Nariswari, University of Hawaii at Manoa, USA

Xin Zhao, University of Hawaii at Manoa, USA

This paper moves beyond the primary discourse of advertising as a promotional tool and views advertising as a cultural system (Lears 1994; Leiss 2006; Sherry 1987) that distortedly reflects the social aspirations of consumers, the ideals of its creators (Marchand 1986) and the views of the power dominant (Hall 1997). We take advertising as a cultural text to examine how particular social groups and ethnic minorities are represented.

Existing research shows that images created during slavery period emphasized the subordinate status of black people, deducing them to particular physical characteristics and portraying them as inherently lazy and uncultured (Hall 1997). More recent portrayals present African Americans among others in lower-status roles, perpetuating class distinctions with the White majority (Bristor, Lee and Hunt 1995). On the other hand, Asian Americans are persistently represented as the “model minority,” and are strongly associated with

technology related products. They are commonly portrayed in business settings but less in social or family settings and relationships (Taylor, Landreth, and Bang 2005; Taylor and Lee 1994; Taylor and Stern 1997). This stream of research is constrained within Western societies and it is unclear how ethnic minorities are represented in other countries.

We focus on the portrayals of ethnic Chinese in Indonesian advertising. Much of the local resentment against the Chinese minority stems from the fact that despite comprising of only 1.45% to 2.04% of the population (Suryadinata, Arifin, and Ananta, 2003), they are perceived to play a dominant role in the Indonesian economy (Tan 2008). Historically, tension between the ethnic Chinese and indigenous Indonesians can be traced back to the time of Dutch colonization. The Dutch “divide and rule” policy positioned the Chinese as being a class higher than indigenous Indonesians (Nanjing 2006). Ethnic Chinese were provided with separate schools (Suryadinata 2005; Tan 2008) but were restricted in access to land ownership and the areas in which they are allowed to reside (Nanjing 2006). These policies contribute to Chinese expertise in trade but also separate them from indigenous Indonesians.

Recent changes towards democracy have introduced Indonesian people to values of freedom, democracy, and tolerance towards diversity. Nevertheless, as prejudice, resentment, and suspicion against the Chinese have never been fully resolved, such sentiments may still loom below the surface. The Indonesian setting provides us with a rich historical context to explore the boundaries of foreignness and localness through texts of consumer culture. We aim to examine how advertising appropriates existing social tensions to promote consumption.

Public display of Chinese tradition and culture is a recent phenomenon that was only reinstated by President Abdurrahman Wahid in 2000. Before the reform era, under Suharto’s rule, the three pillars of Chinese culture: language and schooling, press, as well as organizations were banned as part of an assimilation policy (Suryadinata 2005). Expression of Chinese culture and belief, including public celebrations of Chinese holidays, were not permitted (Fang and Wendyartaka 2008). Citizens of Chinese descent were encouraged to forgo their Chinese names and take up Indonesian sounding names (Suryadinata 2004). The government utilized media to demonize the Chinese as being “unpatriotic, exclusive, speculative, pro-China (or Taiwan), indifferent to society, greedy, filthy (eating pork), pertinent to bribery, and controlling Indonesian economy.” (Nanjing 2006, 199). Over the course of the reform era, a series of new policies encourage a move towards a more democratic and tolerant society. This study explores whether or not and how such changes in values are reflected and appropriated in advertising.

While most studies explore representations of ethnic minorities through content analysis, this study employs a semiotic approach (Barthes, 1972; Mick, 1986; Rose 2006) to identify the strategies used to represent ethnic Chinese. We gathered advertisements in *Kompas* newspaper and *Femina* magazine during the Chinese New Year season from 2000-2009. These media were chosen for their leading national circulation. While *Kompas* targets a general audience, *Femina* targets the middle-upper female class. Chinese New Year was selected to gain efficient access to commercial texts concentrated around and targeted towards Chinese culture and consumers. The advertisements were chosen based on how conceptually significant each text is in representing ethnic Chinese in Indonesia (Mick 1986; Rose 2006; Zhao and Belk 2008). Interpretations are made based on a semiotics approach, in which denotative as well as connotative meanings of images are explored (Leeuwen 2008).

Our initial exploration generates a number of findings: appearance of stereotypical characters, gender reversal, and arbitrary reinterpretation of Chinese culture. Among the stereotypical characters found are those of the chubby Chinese male or children and the loony elderly figure. Chubbiness becomes a symbol of greed, ugliness, and inability to control one’s appetite. It represents excessive wealth and insensitivity towards people in a poor society. An advertisement for a real estate developer depicts an elderly man in traditional Chinese clothing holding an *angpao* (red envelope containing money, normally given out to children during Chinese New Year) with uncontrollable glee. His expression of overwhelming joy represents an obsession with money and a childlike inability to control emotions.

Another theme found is of gender reversals, where men are “demasculinized” and women take leading roles commonly portrayed by males. An ad for a national bank presents a chubby male comically attempting to make kung fu moves. He wears flower-patterned shorts indicative of feminine taste. His lack of kung fu skills and manliness allows him to be laughed at. In contrast, an advertisement for a brand of high-calcium milk presents two women performing the *barongsai* (dragon) dance. One woman stands firmly on the shoulders of the other, while three men play music in the background. Considering that the *barongsai* dance is traditionally performed by males, this ad presents an opposite picture of females taking over a male-dominant role.

One final example reflects how arbitrary interpretation of Chinese culture is made. An advertisement for a telecommunications service provider shows a man holding burning incense in front of a Chinese temple. The incense smoke forms the image of a goat; in line with the celebration of the Year of the Goat. However, such image presents the idea that the Chinese worship the goat rather than their Gods, reflecting a backward pagan culture that lag behind the Muslim majority who worship one God.

While in reality it is the male Chinese businessmen who play the dominant role in the society, they appear to be the dominant target of ridicule or the ones to take on background roles. Interestingly, some of the brands who present such roles are Chinese owned. Putting the ethnic Chinese in such vulnerable roles allows them to appear in a less-threatening and humbling manner. We find Indonesian ads to acknowledge and make use of existing stereotypes to present a safe opportunity for laughter as well as self-humiliation as a temporary mechanism to release tension. As such, we conclude that advertising not only provides a distorted mirror of society (Pollay 1986), but can also function to hide and reverse reality.

Is a "Premium" Private Label Brand for a Marketer Seen as a "Premium" By a Consumer? The Perceptual Categorization of Private Labels Tiers

Magda Nenycz-Thiel, Ehrenberg-Bass Institute for Marketing Science, Australia
Jenni Romaniuk, University of South Australia, Australia

Private labels are now a permanent feature of competitive retail landscapes all around the world. The category is strongest in the UK and Western Europe, where its market share accounts for 20-40% of grocery sales (De Wulf et al. 2005). Although, private label share in the US lags behind the UK and other Western European countries, it is growing at a rate far outpacing the growth of manufacturers' brands (Baltas and Argouslidis 2007). In 2002, US sales of private labels exceeded 50 billion dollars and their share in grocery retailing reached 15% (Sprott and Shimp 2004). Given the current economic conditions it is likely that this growth trend will continue.

Traditionally, private labels have been positioned as low price / good value for money offerings. Their major selling point has been their price advantage and as such private labels themselves can act as a cue to trigger a perception of value (Zeithaml 1988).

However, the rationale for introducing premium private labels is not under the guise of offering something that is cheaper than manufacturer brands, but to create a point of differentiation from other retailers (Corstjens and Lal 2000). In order to achieve this premium positioning the retailers invest in attractive packaging and include words that imply premium, such as *Finest*, in the brands names. Many premium private labels lines are now advertised and have samples inserted into food magazines and distributed in retailing outlets (Lincoln and Thomassen 2008).

Nevertheless, those positioning strategies can only be considered successful if consumers notice them. Drawing from categorization research, consumers' knowledge forms schema-like structures in memory, which enhances information processing efficiency (e.g. Cohen and Basu 1987). If two brands possess similar specifications that differ from other brands, they will be grouped together in consumers' memory, forming a sub-category. The categories or schemas are described by Bettman (1979 pp. 455) as 'cognitive structures representing one's expectations about a domain'. Those expectations may be about typical values on some attributes, importance of those attributes, and finally about how the value of an attribute varies across brands in the category (Sujan and Bettman 1989). If those expectations are strong and well anchored it is difficult to exert any influence on them. Since the schemas reflecting the traditional positioning of private labels have not changed for years, the question arises whether consumers perceive differences between different tiers of private labels? In this paper, we build on categorization theory and examine whether, and based on which cues, such categorization happens for different tiers of private labels.

Research Method

We draw on data from three food categories in the United Kingdom, including tea (N=2,000), instant coffee (N=2,000) and roast coffee (N=2,000). Different respondents were interviewed for each category. The respondent pool was drawn from the Tesco Club Card panel data and past panel buying behaviour was used to confirm that each respondent had bought from the category they were questioned about in the last six months. Each category includes one value and one premium private label, for the purpose of comparison. National brands were also included in the study, but are not the focus of the first stage of analysis.

The data was collected via phone using a free choice, pick-any approach (Barnard and Ehrenberg 1990). Respondents were given a list of brands and then a list of attributes. They were asked which, if any, brands they linked to each attribute. Marketers and researchers who are experts within the industry developed the attribute list. The attributes were chosen based on them being important to consumers when buying from the category. Although the attribute lists varied across categories, there was some overlap. Attributes relating to *value, trust, good quality* were common across categories, with the remainder reflecting the category specific core performance and benefit attributes, such as *when I want to relax* and *is natural* for the tea category, and *smooth, strong flavour* and *to indulge myself* in the coffee categories.

Analysis approach

Based on the actual status of the brand, we coded value private labels as 0 and premium private labels as 1 to create the dependent variable. The independent variables for each category were the attribute responses (also coded as 1: linked the brand to the attribute and 0: did not link the brand to the attribute).

We used binary logistic regression to examine how people categorize private label brands and what (if any) informational cues they use to discriminate between premium and value private labels.

Results

We find that consumers do differ in the attributes they link to premium private labels compared to the more traditional value private labels. The logistic regression models are statistically significant in each category and explain high levels of variance, Nagelkerke R^2 's ranging from 36% in the instant coffee category to 43% in the roast coffee category. Consistent across all categories, link to attributes *high quality ingredients, would taste good* and *to indulge* increase the probability that a brand was a premium private label. This suggests that enhancement of the extrinsic product cues, such as improved packaging or a distinctive brand name can influence consumers' quality perceptions. Conversely, associations with *good value* and *down to earth* decrease the probability of a private label brand being a premium brand.

After this, there was a succession of category specific attributes that contributed positively or negatively to the categorization into premium private labels. In both coffee categories, associations with *smooth, after dinner* and *full bodied* increased the probability that the brand was the premium brand. In the tea category the attribute *has a strong flavour*, also featured significantly in the same way. Conversely, the attributes *mild taste* in the roast coffee category, *when I want to relax* and *natural* in the tea category and a group of attributes in the instant coffee category (*traditional, when I want to relax* and *mild taste*) featured as the negative drivers of categorization.

We find that consumers do see premium private labels as a different group of brands compared to the value private labels. Our findings suggest that although the perceptual schemas reflecting traditional positioning of private labels have been reinforced over many years, marketing activities that improve the extrinsic product cues are able to influence consumers' perceptions. Therefore, the consumer perceptions of what a premium private label represents can, by investment in marketing support, be matched with marketers' perceptions. The next step of this research is to see whether the same categorization into premium and non-premium brands is evident for national brands and if the same informational cues are utilized to differentiate between national brands.

Finger Length Ratio and Attitudes toward Several Product Categories

Marcelo V. Nepomuceno, John Molson School of Business, Canada

Gad Saad, John Molson School of Business, Canada

Eric Stenstrom, John Molson School of Business, Canada

Zack Mendenhall, John Molson School of Business, Canada

Recent studies have highlighted the relevance of physiology in understanding human behavior. For instance, Coates and Herbert (2008) have shown that higher levels of testosterone are correlated to male traders' profitability. Similarly, Saad and Vongas (2009) showed that men's testosterone levels increased while driving a luxurious sports car, suggesting a relationship between hormones and conspicuous consumption. Finger length ratio, a sexually dimorphic trait, is a marker of prenatal testosterone (Manning et al. 1998). The second-to-fourth finger length ratio (2D:4D) has been consistently correlated to a wide range of sexually differentiated phenomena, such as athletic ability (Manning and Taylor 2001), spatial ability (Loehlin, Medland, and Martin 2009), risk-taking behavior (Coates and Page 2009), sexual orientation (Manning, Churchill and Peters 2007) and aggression (McIntyre et al. 2007). Yet, little is known about the relationship between 2D:4D and consumption phenomena possessing a strong sex-specificity. One exception is the research conducted by Millet, Kobe (2007) wherein males with low 2D:4D placed in a subordinate condition exhibited greater future discounting rates than high 2D:4D individuals put in the same condition. Moreover, he found that 2D:4D moderates one's susceptibility to media violence. Specifically, individuals with lower digit ratios responded more aggressively and less cooperatively to aggressive music video than those with higher ratios. In the current research, we focus on the relationship between digit ratio and the attitudes that individuals hold toward specific products.

Using a sample of 240 university students, we tested the hypothesis that lower finger length ratio would correlate with attitudes towards product categories that have a strong male penchant. In addition, given that $rel2$, the length of the index finger relative to the sum of the lengths of all four fingers, has recently been shown to be more accurate than 2D:4D in discriminating between males and females (Loehlin, Medland, and Martin 2009), we propose that $rel2$ will be more strongly correlated to individuals' product attitudes than will 2D:4D. Trained experimenters measured the lengths of right-hand fingers using digital callipers. Participants responded to several items, which assessed their attitude towards several product categories, namely cosmetics, electronics, pornography, clothing, movies genres (drama, action, science fiction, romance, animation and war), sports (hockey, boxing, synchronized swimming and gymnastics), and video-games genres (First-person Shooter, Real-time Strategy, Party-game, Platformer, and Life Simulator). Each product category possessed a valenced sex-specificity, namely male, female, or neutral. One-way ANOVAs revealed that nine product categories were significantly preferred by males (hockey, boxing, electronics, pornography, action movies, science fiction movies, war movies, First-person Shooter games and Real-time Strategy games), eight by females (drama movies, romance movies, party games, life simulator games, synchronized swimming, gymnastics, cosmetics, and clothing), and two were neutral (animation movies and platformer games). For example, pornography was deemed a male product category given that men held a more positive attitude toward it than did women ($F=54.07$, $p<.001$). All attitudinal items possessed reliability alphas above .80.

Regression analyses were conducted on both ethnically homogeneous (Caucasians only, $n=132$) and heterogeneous samples (all ethnicities, $n=133$). Two major findings were obtained. First, $rel2$ was generally a better predictor of the collected product attitudes than 2D:4D. Second, we found significant ($p<.05$) or marginally significant ($p<.10$) correlations between $rel2$ and product attitudes held by Caucasians for four out of the nine product categories preferred by males. For example, low $rel2$ (i.e., indicative of higher exposure in uterus to testosterone) was associated with more positive attitudes towards electronics in the Caucasian sample ($p=.006$, Adjusted $R^2=.055$). Similarly, low $rel2$ was negatively correlated with attitudes towards pornography in Caucasians ($p=.064$, Adjusted $R^2=.02$). Given that the relations were stronger with an ethnically homogeneous sample (Caucasians only), our results are in accordance with previous finger length ratio studies (Manning, Churchill, and Peters 2007), and reinforce the importance of controlling for ethnicity in future research on digit ratio. Moreover, this study suggests that finger length ratios may be predictive of attitudes toward products possessing a strong sex-specificity.

Online Consumer Privacy 2.0

Thuc-Doan Nguyen, California State University, Long Beach, USA
Eric P. H. Li, York University, Canada

The surge of social networking sites (e.g., *Facebook*) and video/photo sharing sites (e.g. *Youtube/Flickr*) generates new issues on consumer privacy in the Web 2.0 era. Moving beyond the concern about the disclosure of personal data such as real name, home address, social security number, credit number, and phone number to advertising agencies or marketers, the current research demonstrates the need for re-visiting the content and concept of "privacy." The study highlights the urgency to develop new policies to mitigate uprising issues related to the disclosure of personal stories and images.

Recently, consumer researchers are interested in understanding the relationship between consumer social interactions and community building in online world from a socio-cultural perspective (e.g., Kozinets 1999; Schau and Gilly 2003). With the improvement and popularization of Internet technology, consumers are actively engaging in different creative activities such as developing personal Web sites (Schau and Gilly 2003) and consumer-created advertisements (Muniz and Schau 2007), and forming different virtual communities (Muniz and Schau 2005). Those research has enriched our knowledge of consumer online behavior. However, an important aspect of virtual world, the concern of privacy, is under-researched in this paradigm. This study is designed to bridge the gap to enhance our understanding of the experience of consumers with web services such as *Facebook*, *MySpace*, *Youtube*, and *Flickr*. Consumers, on one hand, feel empowered in posting and sharing the moments and images of their lives in cyberspace. On the other hand, they feel uncertain about potential misuses of their personal images and stories by unknown audiences. They have limited knowledge on privacy-related issue and under-estimated the impact and potential risk of sharing personal images and stories. With the advancement of online searching technology it is not difficult for Internet users to trace someone's Internet footprint with simple information such as an email address. This challenges the notion of privacy protection in the virtual world as consumers are vulnerable in controlling the dissemination of information they posted on web sites.

Prior research on consumer privacy and Internet security are predominantly focused on the protection of consumers' personal information and the development of a safe environment for online shopping and transactions as well as the use of information/cookies gathered from the websites (Caudill and Murphy 2000; Sheehan and Hoy 2000; Milne and Culnan 2002; Miyazaki 2008). Edwards (2004) argues that the existing protection law did not provide enough protection for consumers in cyberspace, especially issues that related to disclosure and invasion. Recently, marketer researchers considered privacy as one of the key drivers of online trust (Hoffman, Novak, and Peralta 1999; Bart et al. 2005; Baker, Tedesco, and Baker 2006; Miyazaki 2008). However, the increasing popularity of social networking sites and video/photo sharing web sites shifted the context of online privacy from transaction-oriented activities to social-oriented interactions. Consumers' engaging in social networking activities is based on the desire for group belongingness and the emphasis of self-existence. The more they contribute to the social networking sites or video/photo sharing sites, the more social capital they possessed within their social group(s). The more mundane events or activities they posted, the more they affirm their existence. These initial impetus and evolving motivations often force consumers play down their privacy concern. Furthermore, what consumers perceive as privacy concerns in transactions with marketers might not be applicable to their interactions with relatives and friends in the social networking sites. Moreover, consumers sometimes seem to be lack of knowledge about newly developed technologies that challenge to the existing concept of privacy.

In the current study we adopt a phenomenological approach to explore how consumers construct and interpret the concept of privacy in their everyday interaction in the virtual world. We seek to understand how consumers determine which items or information to share (and not to share) and with whom they want to share (or not to share). Our preliminary findings are organized around a series of themes emerging in the data including: the role of social networking activities in consumers' life, the dilemmas that the digitalization of everyday life, including its most private moments, pose for consumers, the personal responsibility and morality of users when they post things on social networking sites, and personal experience related to privacy. Finally, we also trace the development of consumers' idea about online privacy overtime. Our findings note that consumer learning about online privacy varies widely. The meanings consumers ascribed to online privacy reflect the role of virtual world to them and their experience with social networks.

In conclusion, our research aims to contribute to the existing consumer privacy literature by highlighting the multi-dimensionality of the concept of privacy in the new context. Our preliminary findings demonstrate the vulnerability of consumers in latest social networking activities and the challenges to privacy protection in cyberspace. Finally, we emphasize the urgency of renewing policy on consumer privacy and consumer education in the Web 2.0 era.

Fighting with Feathers and Bubbles: Consumer Resistance and the Urban Playground Movement

Yesim Ozalp, York University, Canada
 Daiane Scaraboto, York University, Canada
 Mei-Ling Wei, Saint Mary's University, Canada

Current perspectives on consumer movements define them as ideologically laden, organization-centered and well structured actions focused on fighting particular market and industry practices. However, as markets become increasingly politicized and public spaces increasingly commercialized, less structured forms of consumer resistance emerge. By looking at a series of diverse, fluid and sporadic actions undertaken by consumers in metropolitan cities, we attempt to enrich our understanding of political consumerism. Through an ethnographic investigation of the urban playground movement, we examine how consumers engage in playful interventions while subverting the norms and rules that structure public and market spaces.

A Brand in Hand: Symbolic Props in Self-Presentation

Grant Packard, University of Michigan, USA
 Andrew Gershoff, University of Michigan, USA

Considerable evidence exists that people tactically manage verbal communication and bodily expressions to convey a desired impression of the self—and sometimes deceive others in the process (e.g. Argo, White and Dahl 2006; Feldman, Forrest and Happ 2002; Jones and Pittman 1982). Research building on symbolic self-completion (Wicklund and Gollwitzer 1981) finds that individuals who feel under-endowed in signals of a salient self-concept strive to find alternative means to influence others' opinions of them in subsequent verbal interactions.

This paper contributes evidence supporting the use of brands as "props" (Goffman 1959) in such acts. We expect that individuals who feel situationally under-endowed on a desirable personality trait will be more likely than well-endowed individuals to socially display (obscure) a brand that is congruent (incongruent) with positive identity on that trait. This prediction is consistent with recent findings that a "shaken self" motivates choice preference for products that possess self-enhancing trait symbolism (Gao, Wheeler and Shiv 2009). Interaction of trait features with the situation may play a role in moderating the actual use of such products in self-presentation. For example, when one's real abilities are perceived to be difficult to defend in verbal presentation, people may prefer to "tell the truth" or be protective in signaling traits with a brand possession rather than risk being caught in an act of acquisitive or self-enhancing impression management (Arkin 1981; DePaulo 1992; Swann, Pelham and Krull 1989).

Study 1

The first study entailed a 2 (*Brand*: high vs. low symbolic meaning on a specific personality trait) x 2 (*Self*: high vs. low self-evaluation on the same trait) design. Pretests identified brand pairs for which differences existed in selected personality traits for individuals possessing the brands and for the brands themselves. Two magazine brands were selected that measured high vs. low in the trait of "amiability" (*In Touch Weekly* and *The Economist*, respectively), similar in selected other traits, and not different on measures supporting posited alternatives (e.g. awareness, likeability, purchase intent).

A cover story delivered a branded object into participants' possession in a manner meeting Schlenker and Weigold's (1992) criteria for actor, audience and situational factors in self-presentation. Participants were individually told that they would be entering a room to be judged in an interview. Through a ruse regarding "additional studies" to take home with them, participants found themselves in

possession of two file folders (delivery order was counterbalanced). One folder had a blank cover. The second had one of the two target brands printed prominently on the cover. Participants completed a bogus test and self-evaluation of their own amiability and then entered the interview room carrying the folders with them. The observed dependent variable was whether the brand printed on one of the folders was displayed or obscured (for example, by placing it beneath the blank folder) by the “interviewee” when it was set down on a table in front of the “interviewer”. The observer of the DV was blind to condition and specific hypotheses.

We found the predicted interaction of amiability self-evaluation and brand ($\beta=.06$, Wald(138)=6.00, $p=.01$) and a main effect for brand ($\beta=-.90$, Wald(138)=6.19, $p=.01$) driven by differences within the low amiability condition only. Spotlight analysis (Aiken and West 1991) produces comparable results (+1SD amiability: $\beta=.009$, $t=.145$, $p=.89$; -1SD amiability: $\beta=-.411$, $t=-3.51$, $p<.001$). To enhance interpretability, we report the rate of display behavior by amiability self-evaluation median split versus a mean chance expectation ((MCE) 50% display / 50% obscure as “chance”) as a conservative test for the behavior. Individuals with low amiability self-evaluations displayed the high amiability brand (*In Touch Weekly*) (72.2% vs MCE; $\chi^2(1,36)=13.69$, $p<.001$) and obscured the low amiability brand (*The Economist*) (28.1% vs MCE; $\chi^2(1,32)=8.92$, $p<.001$) from social view. In summary, the brand was displayed (obscured) when it enhanced (detracted from) a desirable self-presentation for those under-endowed in the salient trait. In contrast, individuals with high amiability self-evaluations did not display or obscure either brand at a rate different from chance ($M_{\text{Low Amiability Brand}}=59.5\%$, $M_{\text{High Amiability Brand}}=58.8\%$, $p's>.25$). This pattern is consistent with a symbolic self-completion account of brands as alternative symbols for their possessor’s traits or abilities.

Study 2

We subsequently sought a preliminary moderator test regarding enhanced social risk of being “caught in a lie” of acquisitive or self-enhancing impression management. A pretest identified intelligence as a socially desirable trait for which a person’s ability to verbally convince others of high ability in the interview situation was more difficult than amiability, and highly difficult overall. The design of Study 2 was similar to Study 1 except participants were assigned to either hard or easy intelligence test manipulations, and were told they would be judged by a group rather than a single interviewer.

We again found a significant interaction between the trait manipulation conditions and brand on the rate of display/obscure behavior observed ($\beta=-2.20$, Wald(120)=8.36, $p<.01$), but in the opposite direction. As predicted and in contrast with Study 1, participants in the low intelligence condition were now more likely to display the low vs. high intelligence brand (66.7% vs. 33.3%; $\chi^2(1,60)=6.67$, $p<.01$). Again, individuals with high self-evaluations on the salient trait did not display or obscure either brand at a rate greater than chance ($M_{\text{Low Intelligence Brand}}=36.7\%$, $M_{\text{High Intelligence Brand}}=56.7\%$, $p's >.10$). The second study’s findings provide preliminary support for the argument that contextual perceptions of risk in delivering a believable impression may moderate acquisitive self-presentation using symbolic props (such as brands), motivating more protective and/or self-concept congruent impression management behavior. We are currently planning a third study to better isolate this moderator between subjects within a single experiment and to replicate current findings with different brands.

Preliminary Conclusions

These studies provide evidence that individuals with low self-evaluations on situationally salient trait dimensions may tactically manage the social visibility of brands in their possession. We find that people display (obscure) a brand possessing positive symbolic trait meaning when they feel relatively under-endowed in that trait, but only when abilities on that trait are perceived to be relatively easy to support in verbal self-presentation. To our knowledge, this paper provides the first direct experimental support regarding the use of objects in self-presentation.

Between Two Worlds: The World of Goods and the Management of Gay Identity

Bill Pereira, EBAPE/FGV-RJ. FUCAPE Business School, Brazil

Eduardo Ayrosa, EBAPE/FGV-RJ, Brazil⁷

Brazilian culture is often described by sociologists as full of contrasts and dualisms, where opposites concepts cohabitate in soft and constant struggle (Da Matta, 1991, Barbosa 2006, Fry 1982). Despite cultivating symbols and behavior related to freedom and sensuality, Brazilians still hold some strict and conservatory standards of morality. An instance where such dispositions arise is on attitudes towards homosexuality and gays. In a recent survey from the Brazilian Institute of Social Social Research, results from interviews with 2.014 citizens from 150 Brazilian cities show a high level of rejection of homosexuality. On this survey, informants said that they would not feel at ease with public displays of affection between homosexual couples (INSTITUTO BRASILEIRO DE PESQUISA SOCIAL, 2008). Therefore, homosexuality still seems to be a stigmatized behavior in Brazil.

On the other hand, goods, services and marketing activities directed to the gay public-or, using the words of Peñaloza (1996), the *dream market*-have seen a steep growth in Brazil. Gay pride parades in Brazil have attracted more than three million people, and the São Paulo parade is deemed as the world's largest (Silva 2006). Such duality, peculiar to the Brazilian culture, is present even inside the gay culture of Rio de Janeiro, where homosexuals describe their reality as built upon two opposite but complimentary worlds: the gay and the heterosexual.

The present work aims to explore how gay men use consumption to build and manage symbolic barriers and bridges between the gay and the heterosexual worlds they live in. We seek not only to observe the way the informants manage to cross the boundaries between these two worlds, but also, and more important, how these two worlds are described in their life history, and how social interactions with goods and consumption environments help to build the barriers and bridges between the two worlds.

This work is based on data from ethnographic observation that has been taking place in the city of Rio de Janeiro since 2005. Data collection is based on field notes prepared by one of the authors, as well as long in-depth interviews with 19 gay men that currently live in this city. Informants are openly gay men, with gender identity fully established, that frequently go to gay venues, shops, bars, nightclubs, and all sorts of and consumption environments. Interviews were transcribed and analyzed along with ethnographic field notes. Data analysis involved careful reading and codification of all data, in a process that has been repeated several times upon the same set of data in order to have a full grasp of the narratives. As suggested by Belk *et alii* (1988), we adopted techniques for interpretive studies that included member checks, use of photographs, and analysis of secondary data such as magazines and advertising directed to the gay public (Kates 2002, Belk *et alii* 1988).

Stigma is related to a mark of social inferiority that, apparently or not, a dominant group imposes another. Goffman's (1986) approach about stigma is strongly related to the question concerning identity. According to him, the stigmatized person carries a "spoiled identity", since such identity is seen by the dominant group as shameful and depreciative to its bearer (Crocker *at. Al.*, 1998; Hogg, Hilbert e Piancentini, 2008). It is important to stress that the stigmatized attributes are culture- and context-dependent. What is seen as a stigma in one culture or context may not be seen the same way in another situation. After all, what is stigmatized is, in fact, not the stigma attribute, but what it represents. For instance, markings of the homosexual condition may be seen as a stigma in smaller cities, where social control over the conduct of the citizen is stronger, than on great metropolitan areas, where the social grids are looser (see Douglas & Isherwood, 1979).

Homosexuality, the homosexual subject, and the "gay man", are inventions dated on the 19th century. Since the second half of the 19th century, the homosexual practice became to define a special kind of person, and consequently, a new social category, namely the homosexual, which came to be marked as a deviant. Persons who, voluntarily or not, were framed in this category, began to live a secret life, marked by segregation (Kates, 1998, Silva, 2006, Trevisan, 2002; Foucault, 1988). Such a "secret life" provided the fertile ground for the development of a whole subculture, the gay culture, with its own behavioral codes, discourse, norms, values, and its own set of social identities. When forming a gay identity, during the process of "getting out of the closet", individuals in this condition use profusely the social meanings attached to goods and services in order to reach the new homosexual identity (Kates, 1998, 2002).

First conclusions of this study show that gay men's culture actually involve an active symbolic construction of both a gay and a straight world. What seems to be a simplistic division is, in fact, the representation of two separate and complimentary symbolic domains in which gay men live and, depending on the context, manage their social identities. The division of these two worlds lies not only in gay men's imagination, but also in their choices of clothing, accessories, and places like clubs, restaurants, or the beach. Nevertheless, it is through ritualistic activities that the gay men symbolically incorporate these goods, services and places in their culture (McCracken, 2002). This way, through consumption, they attribute meaning to the world. Consumption goods and rituals, then, become instruments of the gay culture to build and manage the gay identity throughout the gay and straight worlds.

Emotional Intelligence, Impulse Buying and Self-Esteem: The Predictive Validity of Two Ability Measures of Emotional Intelligence

Paula Peter, San Diego State University, USA
Sukumarakurup Krishnakumar, North Dakota State University, USA

Abstract

The present study tests for reliable measurement and criterion validity of two ability measures of emotional intelligence: the Consumer Emotional Intelligence Scale (CEIS, 2008) and the Mayer Salovey Caruso Emotional Intelligence Test (MSCEIT, 2002). In specific, we examine EI's influence on impulse buying and self-esteem and how different functional areas of EI uniquely affect these two constructs. The results provide new empirical insights regarding the criterion validity of different measures of EI in the context of consumer research.

Emotional Intelligence (EI) is a set of four broad categories of abilities that together enable individuals to perceive, use, understand, and manage emotions in themselves and others to achieve productive and/or positive ends (Mayer, Roberts, & Barsade, 2008; Mayer and Salovey 1997).

Kidwell, Hardesty, and Childers (2008) have developed the Consumer Emotional Intelligence Scale (CEIS) based on the classic measure of emotional intelligence, the Mayer, Salovey, Caruso Emotional Intelligence Test (MSCEIT; Mayer, Salovey, and Caruso, 2002). The CEIS differs from MSCEIT, in that it is shorter (18 items) and domain specific (marketing), whereas the MSCEIT is longer (141 items) and domain-generic.

Kidwell, Hardesty and Childers (2008) empirically showed that the CEIS is a better predictor of consumer decision making than MSCEIT. The present study aims to provide new and additional empirical insights regarding the criterion and predictive validity of CEIS vs. MSCEIT. We select impulsive buying and self-esteem as important consumer behavior constructs in which the ability to reason about emotions could impact decision quality. Additionally, we also included personality to test incremental predictive validity of EI.

Impulse buying and EI

Impulse buying could be described as unplanned and often uncontrolled urge to buy products. Recent research on impulse buying (e.g. Verplanken et al 2005) suggests that people engage in quick buying mostly due to affective reasons. Therefore, it is important to understand the ability of a consumer to: (a) differentiate between emotions; (b) use emotions to guide thoughts and behavior.

The perceiving emotions branch helps individuals to accurately identify the different emotions that could be elicited as a result of a purchase decision. The cognitive facilitation branch helps individuals to prioritize, think, and act in judiciously based on how they feel.

Because impulsive purchases are made quickly and often driven by hedonic or emotional considerations, we hypothesize that each of these branches and the overall EI will negatively influence impulsive buying behavior.

Self-Esteem and EI

Self-esteem is defined as "how much value people place on themselves" (Baumeister et al. 2003). The interaction between the cognitive and affective components that underlines the construct highlights the fact that affective information is being used to form attitudes of oneself over the long term. Therefore, an individual with higher levels of EI-abilities should be able to reason with and modify emotional information so that over the long term, a positive overall self-evaluation is formed.

The understanding emotions-branch helps individuals to understand the complexities of emotions that are felt. The management branch helps individuals modify the possible negative emotions in frustration into positive emotions, thereby potentially producing a

positive self-evaluation or higher self-esteem. Therefore, we hypothesize that each of these branches and the overall EI will positively influence self-esteem.

Method

A total of 152 students (68 females and 79 males) from a southwestern university completed an online study in a controlled environment (lab) for extra credit. The online study included ability measures of EI (MSCEIT 2003 and CEIS 2008), impulse buying (Rook and Fisher 1995), self-esteem (Rosenberg 1965), personality (TIPI) and general demographics. The subjects had 50 minutes to complete the survey and the order of the questions was randomized.

Results and Analysis

To compare the CEIS's and MSCEIT's effects on impulse buying and self-esteem, we compared bivariate correlations between EI scores computed by each of those scales, impulse buying and self-esteem. Both EI scales significantly predicted impulse buying and self-esteem and the correlations weren't statistically different. We also used separate hierarchical regression analyses with personality added at step 1 and CEIS (regression 1) or MSCEIT (regression 2) in step 2. When this was used to predict impulse buying, CEIS significantly added variance over and above personality ($\beta = -.18$, $\Delta R^2 = .03$, both $p < .05$), whereas MSCEIT did not. Both CEIS and MSCEIT added significant variance over personality when used to predict self-esteem.

In order to look at the relationship between impulse buying and EI, and self-esteem and EI, we created a combined EI-index created by the mean of normal scores from CEIS and MSCEIT. A hierarchical regression analysis was done with impulse buying or self-esteem as the dependent variable. EI negatively and significantly predicted impulse buying behavior ($\beta = -.21$, $\Delta R^2 = .04$, both $p < .05$) and self-esteem ($\beta = .25$, $\Delta R^2 = .06$, both $p < .01$) over and above the influence of personality variables.

To test our hypotheses related to the branches of EI, experience and reasoning area-scores obtained from MSCEIT and CEIS were normalized and averaged to form a combined index. Then, those experiential and reasoning area scores were used as independent variables in the regression equation to predict the impulse buying and self-esteem. The experiential area predicted impulse buying ($\beta = -.21$, $p < .05$), whereas the reasoning area did not ($\beta = -.08$, ns). The reasoning area predicted self-esteem ($\beta = .27$, $p < .01$), whereas the experiential area did not ($\beta = .09$, ns). The results support our hypotheses.

Conclusion

This study was the first attempt to examine incremental, measurement and criterion validity for emotional intelligence in consumer research. Our results suggest that CEIS predicted impulse buying slightly better than MSCEIT over and above the effects of personality.

EI, as a construct, significantly and incrementally predicted both impulse buying (negatively) and self-esteem (positively) over personality. At the branch level, the experiential area of EI was significant in predicting impulse buying and the reasoning area of EI was significant in predicting self-esteem. Our results suggest that consumers might activate different functional areas of emotional intelligence while engaging in consumer behaviors or decisions particularly those in which emotions play an important role.

The Role of Innovativeness in Environmentally Conscious Consumer Behavior

Diane M. Phillips, Saint Joseph's University, USA

Basil G. Englis, Berry College, USA

Michael R. Solomon, Saint Joseph's University, USA

Abstract

This study seeks to improve the predictive utility of the attitude-behavior link within the realm of environmentally responsible consumption. Using a sample of over 1400 American consumers, we collected data on attitudes about the environment, proclivity for new

and innovative ideas, and a wide variety of behaviors with respect to the environment. We find ample evidence to suggest that consumer innovativeness may help bridge the attitude-behavior disconnect by providing an important mediating effect between environmentally conscious attitudes and behaviors.

Why is Predicting Behavior so Difficult?

There is currently a disconnect between consumers' environmental attitudes and behaviors. Marketing decision-makers need evidence that a distinct segment of consumers, making up a substantial number of individuals, will act on their pro-environmental attitudes. Executives understand that it's not enough for customers to say they want green products; they need to "walk the walk" and actually choose these options over other alternatives. The primary purpose of this study is to take a step toward closing this disconnect; we find that innovativeness may be the vehicle by which we can do this.

Why does this disconnect occur at all? Perhaps we should not be surprised. Years of attitude research demonstrate that attitudes don't necessarily align with behavior. With regard to the environmental attitude-behavior link, there are a few additional barriers to behavior. One impediment is of our own making. Consumers may counterargue against green claims because of reports of widespread green-washing. Almost one-fourth of American consumers say they have "no way of knowing" if a product is green or actually does what it claims (Center for Media Research 2009). Because of this, some consumers rely increasingly on third party certifications to determine if a company actually lives up to its green claims (Zmuda and Parekh 2008).

If we assume that green-washing is not the sole culprit, what other impediments make it sometimes difficult for consumers to translate their pro-environmental attitudes into action? Some consumers cite factors in the immediate purchase environment, such as cost and availability (Mintel 2006). Consumer researchers have found a myriad of other constructs that have impacted pro-environmental behavior, such as feelings of empathy (Lee and Holden 1999), perceptions of morality (Borgmann 2000; Caruana 2007), lifestyles (Gilg, Barr, and Ford 2005), gender identity (Dobscha and Ozanne 2001), perceptions of risk (Böhm and Pfister 2008; Lee and Holden 1999), social connectedness (Dolan 2002), demographics (Im, et al. 2003, Hough 2007) and, not surprisingly, price (cf., Anonymous 2008).

Why Innovativeness?

While the issue of environmentalism is not new, for many consumers the specific actions available to them should they wish to ameliorate ecological problems are. Thus, we believe a focus on how consumers come to terms with new and innovative ideas and behaviors will provide greater predictive utility, above and beyond attitudes alone, to our model. Generally speaking, consumer innovativeness is a consumer's predisposition to seek out and be accepting of "new products and brands rather than remain with previous choices and consumption patterns" (Steenkamp, Hofstede, and Wedel 1999). Innovativeness is derived from a consumer's own personality and cognitive style (cf., Goldsmith and Hoffacker 1991, Midgley and Dowling 1993). Researchers propose that we can best describe innovativeness as a generalized predisposition to try new products (Im, Bayus, and Mason 2003). These researchers suggest that innovative consumers are generally more accepting of risk, are eager to try new things, and like to share their discoveries with others (Im, et al. 2003). For most consumers, environmentally responsible behaviors and green products are new. Therefore, within this scope, a willingness to enact these new behaviors and try these new products are innovative actions for these consumers.

Consumers can express their concern for the environment with a wide variety of different behaviors, from recycling their newspapers to riding a bike to work. We also believe that a more generalized characteristic of acceptance of risk and willingness to try new things is in sync with a broad inventory of pro-environmental behaviors. Therefore, when we provide consumers with a variety of behavioral choices (rather than a fixed set of choices), we believe that global consumer innovativeness will provide a useful vehicle by which we can better understand how consumers might proceed through the process of turning their pro-environmental attitudes into pro-environmental behaviors.

In brief:

H1: environmentally relevant attitudes will positively impact environmentally relevant behaviors

H2: global consumer innovativeness will positively impact environmentally relevant behaviors

H3: environmentally relevant attitudes will positively impact global consumer innovativeness

Taken together, we predict that environmentally relevant attitudes will impact global innovativeness which will in turn impact environmentally relevant behaviors. This suggests a meditational impact of global innovativeness on environmentally relevant behaviors.

Method

1443 adult consumers from an online consumer panel filled out a series of measures, including environmental attitudes (Dunlap, et al. 2000), global innovativeness (Tellis, et al. 2003), and behaviors (MacDonald and Oates 2006). All measures achieved high levels of reliability.

Results

Attitudes Impact Behaviors (H1). The attitudes measure that we used had three primary dimensions: Affinity for New Ideas, Nature Rules, and Humans Rule. We regressed environmentally relevant behaviors on the three environmental attitudes. The overall model was significant ($F_{(3, 1439)}=53.933, p<.0001$) as was the effect of Nature Rules ($t=6.732, p<.0001$) and Humans Rule ($t=-5.555, p<.0001$). H1 largely supported.

Global Innovativeness Impacts Behaviors (H2). The innovativeness measure we used also had three primary dimensions: Affinity for New Ideas, Early Adopter, and Distrust of New Products. We regressed environmental behaviors on global consumer innovativeness and found that the overall model was significant ($F_{(3,1439)}=73.071, p<.0001$) as were two of the three innovation dimensions. Affinity

for New Ideas was strong and positive ($t=13.843$, $p<.0001$) and Early Adopter was significant and negative ($t=-3.268$, $p<.001$). Further analyses revealed a strong correlation between these two constructs and that most of the impact was due to Affinity for New Ideas. H2 partially supported.

Attitudes Impact Innovativeness(H3). We regressed Affinity for New Ideas dimension on the three dimensions of the NEP scale. The overall model was significant ($F_{(3,1439)}=77.937$, $p<.0001$) and each of the dimensions was significant. Specifically, Nature Rules was significant and positive ($t=15.060$, $p<.0001$), Humans Rule was significant and positive ($t=8.326$, $p<.000$), and Growth Limits was significant and negative ($t=-4.661$, $p<.0001$). H3 largely supported.

Innovativeness Plays a Mediation Role. We performed a 3-part test of mediation (Baron & Kenney 1986). The first two steps are described above. In the third step, we regressed pro-environmental behaviors on Nature Rules, Humans Rule, Growth Limits, and Affinity for New Ideas. In order for mediation to occur, the effects of the other variables must be significantly reduced and the effect of Affinity for New Ideas has to be strong. This is exactly what occurred. Specifically, the overall model was strong and significant ($F_{(4,1438)}=96.697$, $p<.0001$), the only significant effect of attitudes was Humans Rule ($t=-8.843$, $p<.0001$), and importantly, the strength of Affinity for New Ideas increased ($t=14.225$, $p<.0001$).

Conclusion

Innovativeness plays an important role in helping to bridge the divide between environmental attitudes and environmental behaviors. Indeed, the primary driver of the process is the concept of Affinity for New Ideas. This indicates that it is this consumer who is most open to and accepting of new ideas that will be at the forefront of this new consumer movement.

Effects of Model Body Size and Product Price on Advertising Effectiveness, Purchase Intention, and Body-Related Behaviors

Maxim Polonsky, University of Connecticut, USA

Ioannis Kareklas, University of Connecticut, USA

Marketers claim that thin models are very efficient in selling products (Gillian 2000). Although women generally feel thin fashion models are more elegant and interesting (Martin et al., 2007), research findings on exposure to thin models and advertising effectiveness are mixed. Dittmar and Howard (2004) have shown that while the exposure to thin ideals in ads may harm an individual's body esteem, there is no difference between thin and average-size models in terms of advertising effectiveness (i.e. product and ad evaluation, and purchase intention). On the other hand, it can be argued that after exposure to ads featuring thin models, women may feel worse about themselves, while actually feeling better about the brands and products advertised. In addition, research findings show that consumers generally associate thin with happiness, desirability, and status (Tiggemann 2003).

When asked about the most important aspects in women's life, approximately fifty percent of American females indicate their shape and weight (The Downing Street Group, LLC 2007). Especially for young women, pressures to be thin contribute to lower self-esteem, body image disturbances, and eating disorders, with as many as fifty percent of undergraduate females expressing body dissatisfaction (Bearman et al., 2006). Media exposure has been shown to affect women's body esteem by a "thin is in" message.

Research shows that between 1970–1990, the emphasis on fitness increased, and the body shape of models tended to become thinner (Guillen and Barr 1994). A content analysis of popular fashion magazines from 1959 to 1999 found a significant decrease in models' body sizes during the 80s and 90s (Sypeck et al., 2004). For example, Botta (1999), found that exposure to thin body sizes had an influence on

young female's endorsement of the ideal thin body and the likelihood to use media models to define what their own bodies should look like. The relationship between exposure to thin-ideal and body image disturbances was also demonstrated in experimental research (Bessenoff 2006; Dittmar and Howard 2004) and supported by two meta-analytic reviews (Grabe et al., 2008; Groesz et al., 2002).

Two important moderators of the relationship between exposure to thin ideals in the media and body-related disturbances are social comparison tendency and thin-ideal internalization. Internalization of a thin-ideal has been viewed as an important risk factor that contributes to the development of eating disorders. Thin-ideal internalization refers to the extent to which an individual accepts the thin-ideal standard of beauty and attractiveness as her own and engages in behaviors that purportedly help to approximate these standards (Thompson et al., 1999).

As a theory, social comparison posits that individuals compare themselves to others to determine their own relative levels of abilities (Festinger 1954). There are two directions for social comparison: an upward comparison that is made when comparison others are perceived to be more fortunate; and a downward comparison that refers to less fortunate comparison others.

Research suggests that when discrepancies between the self and the comparison standard arise, people are motivated to change the self to be more like the comparison standard. Upward comparisons in particular lead to negative moods and lower self-esteem (Gibbons and Gerard, 1989). Social comparison processes may be unintentional, environmentally imposed, and even unwanted (Lyubomirsky and Ross, 1997). Richins (1991) pointed out that that social comparison with media models has unfavorable consequences for female body esteem, since the media body ideal is unattainable. That is why women who are more likely to compare their body to media models have higher levels of body dissatisfaction and lower levels of self-esteem (Stormer and Thompson 1996).

The aforementioned literature illustrates a potential marketing dilemma: images that are most effective in selling products may also harm consumers the most. In our experiment we employ a between-subject 3 x 2 factorial design, investigating the effect of exposure condition (ads featuring thin models, plus-size models, and average models) and price (low and high) on the following outcome variables: 1) advertising effectiveness (attitude toward the ad, purchase intention); 2) body-related behavioral intentions (to get cosmetic surgery, to exercise or diet excessively); and 3) willingness to eat an offered cookie. We introduce a price variable because, as mentioned above, a thin ideal is associated with status. We manipulate price and attempt to investigate whether price interacts with model body size to create the perception of quality and to elicit generally more favorable attitudes toward advertisements.

The location for the online experiment was a computer lab with a sitting capacity of 20 people. Participants had to come to the lab because we were interested in observing direct behavior of taking an offered cookie. Upon login onto the website, participants were randomized into one of the five conditions and told that they are participating in a marketing research study that explores different communication and appeal strategies (print vs. video, reading detailed information versus watching a short ad, sex appeal vs. humor, etc.) for two product categories—computers and women shoes. After completing a pre-test, participants in each condition were referred to CNET.com page “Best 5 desktops” (<http://reviews.cnet.com/best-desktops/?tag=leftColumnArea1.0>) or a similar updated page, and asked to read a short one-paragraph review for each of the five computers. Next, participants were asked to answer filler questions about their liking, preference, and purchase intention for any of the reviewed computers. Upon completion, study participants were exposed to the experimental ad and filled out a post-test questionnaire that consisted of: a) questions about advertising effectiveness (e.g. ad evaluation, purchase intention), and b) questions about attitudes toward and behavioral intentions to engage in such behaviors as cosmetic surgery, excessive exercise, and dieting. Participants were deceived that the later part of the post-test was an unrelated small scale survey study that was to be used in designing health interventions.

Our preliminary results suggest that thin body size paired with high price effectively signaled product quality and generated more favorable attitudes toward the ad among study participants. The same experimental condition however, had a positive effect on body-related disturbances. We focus our discussion on these controversial findings as well as on the influence of individual difference moderators.

"Please Drink Responsibly!" The Effectiveness of Responsibility Messages in Alcohol Product Advertising

Maxim Polonsky, University of Connecticut, USA

Ioannis Kareklas, University of Connecticut, USA

Among important factors influencing national alcohol consumption is alcohol advertising. Longitudinal studies have shown that exposure to alcohol advertising leads to drinking initiation, and to an increase in drinking rates (Snyder et al., 2006). Alcohol advertising on television keeps growing, especially alcohol advertising toward American youth (Center on Alcohol Marketing and Youth (CAMY) 2007), while alcohol responsibility advertising remains low.

CAMY defines responsibility advertising as alcohol industry-sponsored ads (corporate PSAs) in which responsibility (drinking responsibly, avoiding drunk driving, and addressing underage drinking) is the primary focus of the message. Content analysis using Nielsen data found that corporate PSAs make up less than three percent of the nearly 1.5 million alcohol televised advertising from 2001 to 2005 (CAMY 2007).

CAMY report (2007) dismisses brief warning messages within product ads as "ineffective" and cites Fox et al.'s (1998) study as the evidence. Such dismissal however is puzzling and unfortunate because: a) Fox's study actually concluded that responsibility messages had warning value, albeit a limited one (p. 57), and b) the investigated warnings were all print-based and thusly differed from video messages that last several seconds. The aim of the current study is to address the shortcomings in the literature and to investigate the effectiveness of brief warning messages as it relates to presentation modality.

There is no general consensus on the effectiveness of responsibility messages in alcohol advertisements. Snyder and Blood (1992) as well as Ringold (2002) found support for a boomerang effect under which the exposure to alcohol warnings actually created more favorable attitudes toward alcohol among viewers; however, MacKinnon and Lapin (1998) were not able to find a similar effect in two replication experiments. Just as Fox et al. (1998), these studies investigated print ads. Studies investigating TV ads specifically focused on the effectiveness of corporate PSAs. These studies concluded that responsibility messages sponsored by alcohol companies are ambiguous, and are never dissociated from the actual alcohol consumption and product promotion (Agostinelli and Grube, 2002; CAMY, 2007; Dejong et al., 1992).

The Wine Institute and the Distilled Spirits Council of the United States self-regulate their advertising practices using self-initiated marketing and advertising guidelines. Interestingly, the guidelines do not address either corporate PSA or on responsibility messages within the product ads (ICAP, 2001).

In study 1, we content analyzed brief responsibility messages within the product ads (N=596) of companies promoting alcohol in 2007 on national network and cable television. We found that the most common channel for the responsibility message was through text on the screen (93% of the total advertisements); a small percentage used a voice over only (5%); and 16% used both text and voice messages. Responsibility messages lasted 3 seconds on average for 15 and 30 second spots, and appeared closer to the end of a spot. In addition, 58% of text messages were combined with other textual information in a way that was very difficult to read.

Such numbers are in conflict with existing evidence that: a) messages using both video and textual information are more likely to be remembered compared to one channel alone (Krugman et al., 1994), b) when video and text are shown simultaneously, individuals pay more attention to video (Kallenbach et al., 2007), c) verbal information leads to greater learning relative to textual information (Mcneil, 2005), and d) primacy effect elicits higher recall and elaboration relative to recency placement (Brunel and Nelson 2003; Haugtvedt and Wegener 1994). In other words, if there was a formula on how to strategically place a warning message within an ad it would have to be a complete opposite of what was found. This is ironic, because effective placement and modality of responsibility messages may actually be more important and beneficial to manufacturers and not consumers. Arguably, consumers' attention during and recall after the message presentation may lead to positive evaluations of a product manufacturer as socially responsible. It is relevant to mention that the portrayal of responsibility by alcohol companies was found to be directly correlated to increases in market share, which is a major goal for the industry (Dejong et al., 1992).

The arguments presented above indicate that research on modality of responsibility messages in advertising is long overdue. How long should the warnings last in order to be noticed? How should the warning messages be presented? Our second study employs a 4 x 2 between-subjects factorial design, investigating the effect of responsibility message presentation mode (no message, text only, voice only, text + voice) and advertising length (15-second ads and 30-second ads) on the dependent variables of effectiveness: attention and recall, short-term drinking intention, attitudes toward manufacturer. Current drinking behaviors and tendency to enjoy advertising will

be tested as moderators. We use industry-manufactured ads as our stimuli. Following our review, we first propose the following hypotheses and research questions regarding message presentation.

- H1: Combined text and voice message presentation mode will be more effective than text or voice only.
 H2: Voice only message presentation will be more effective than text only message presentation.
 RQ1: Is text only presentation mode more effective than no presentation mode?

Because it is not clear whether responsibility messages in 15-second ads will differ in effectiveness from those in 30-second ads, we ask the following:

- RQ2: Is there a difference in message effectiveness between 30-second ads and 15-second ads?

Responsibility messages last for approximately three seconds for both length formats, and make up 10 percent and 20 percent of the total length respectively for 30 and 15-second ads. It is possible that higher percentage of the total length will be more effective.

It is important to note that in the current experiment, message effectiveness will be measured in more than one way (i.e. message recall as well as drinking intentions). Hence it is possible that even coherently and effectively presented message might actually not have any impact on individual's responsible drinking behavior. Quite the contrary, exposure to alcohol advertising may overweight the warning message and lead to higher degrees of drinking intentions.

Since there is a potential for responsibility message effectiveness to have a positive effect on manufacturer's perceived social responsibility and good will, we ask:

- RQ3: Is there a relationship between message effectiveness and perceived corporate responsibility?

The follow-up experiments will use similar 4 x 2 designs to specifically investigate the effectiveness of primacy and recency placement strategies.

Short-Term and Long-Term Affective Responses: A Comparison between Emotions and Sentiments

Paulo H M Prado, Federal University of Parana, Brazil

Affective responses have been presented in academic literature as important elements in the study of consumer behavior as they influence the evaluation, memory and judgment processes (Gardner, 1985). Some studies have sought to demonstrate that affective

responses have a significant impact on the assessment of consumer satisfaction, revising the theories that are restricted only to cognitive responses (Oliver, 1997; Fournier, 1998). The aim of this study is to compare the difference between affective responses of the consumer in the long and short term concerning consumption, contributing towards providing a more accurate definition of them. As shown in the consumer behavior literature, studies that have been done in this respect treat the different affective responses as just “emotions” in an indistinct and limited way, as they believe that the differences between each of the constructs are very subtle (Oliver, 1989; Prado, 2004). According to the authors of cognitive theories, such as Ortony et al (1988), an emotion can be defined as a short-term affective reaction to a specific object. For Lazarus (1991), emotions reflect a constant change in the environment-person relationship and their origin stems from evaluating a subject according to the level of importance of a particular event to a person’s well-being. Bagozzi et al. (1999) define emotions as a mental state of readiness that comes from the cognitive assessments or thoughts about an event. A sentiment represents a disposition to respond emotionally to a specific object in the long term; it is a disposition that transforms non-emotional events into emotionally loaded ones (Frijda; Mesquita, Sonnemans; Van Goozen, 1991). Thus, it consists of an evaluation framework that includes relevant concern with the object. Sentiments are dispositional emotions (Shand, 1922, Arnold, 1960). They are affective schemes, with the same structure as emotions (Fiske, 1922).

In the data collection procedure, the respondents were initially asked to indicate their main webmail provider. They were then asked to indicate their Sentiments about it, in a reduced version of the CES (Higgins, 1997) with 24 items on a 10-point scale (from Nothing to Extremely). They were asked about what happened when they last accessed their webmail provider (in a two line sentence), and then they indicated their emotional state at that moment, using the same scale. Both scales are the same based on the premise of Frijda & Mesquita (2000), in which the dimensionality of the two constructs is the same. Having answered the first part of the questionnaire, the participants were randomly exposed to a stimulus related to their webmail provider, one of low intensity (You must re-enter your personal information because it has been lost. Please re-enter it to continue using our services) and another of strong intensity (All your information has been lost, both your personal information and your stored e-mail messages. Please re-enter your personal information to continue using our services). The stimuli were tested to verify their discrimination power. Once again, the respondents were asked to indicate their emotions and their sentiments, using the same scales. The total sample involved 378 respondents, a suitable number for the necessary tests for the purposes of the study.

The constructs were analyzed initially to examine their dimensionality with an EFA, and their validity with a CFA. The results showed the grouping of positive and negative dimensions for sentiments before and after, with adequate internal consistence in both cases. For emotions, the dimensionality was a little diverse, despite positive and negative being separated. A similar result was found for the emotions reported after the introduction of the stimulus.

The strongest stimulus caused an increase of negative affections and a decrease in positive affections, as expected. In the case of Positive Sentiments, there was a significant fall in the average ($X_{\text{before}}=4.81$ for $X_{\text{after}}=3.31$; $t=12.882$; $p<0.0001$). For Negative Sentiments, there was a significant increase on average ($X_{\text{before}}=2.11$ for $X_{\text{after}}=4.28$; $t=-15.114$; $p<0.0001$). For Positive Emotions, there was a significant fall in the average ($X_{\text{before}}=4.04$ for $X_{\text{after}}=2.51$; $t=13.642$; $p<0.0001$). For Negative Emotions, there was a significant increase in the average ($X_{\text{before}}=1.99$ for $X_{\text{after}}=6.15$; $t=-32.832$; $p<0.0001$). The results showed that the variation of the responses for emotions before and after were greater than for sentiments.

For the evaluation of the variation of Negative Sentiments, we saw that the before-after effect was significant ($F=92.72$, $p<0.001$). But the relationship between the weak and strong stimuli did not produce statistically different results ($F=1.92$, $p=0.166$), as well as the interaction between the two factors ($F=2.015$, $p=0.156$).

Considering the variation of negative emotions, we found that the before-after effect was significant ($F=910.90$, $p<0.001$). Furthermore, the relationship of the weak and strong stimuli was ($F=37.21$, $0<0.001$). The interaction between them was also significant ($F=28.58$, $0<0.001$).

For the evaluation of the variation of Positive Sentiments, we saw that the before-after effect was significant ($F=92.72$, $p<0.001$). But the relationship between the weak and strong stimuli did not produce statistically different results ($F=1.92$, $p=0.166$), as well as the interaction between the two factors ($F=2.015$, $p=0.156$).

Considering the variation of Positive Emotions, we saw that the before-after effect was significant ($F=122.16$, $p<0.001$). Meanwhile, the relationship between the strong and weak stimuli was not shown to be statistically significant ($F=0.035$, $p=0.852$), like the interaction between the two factors ($F=0.121$, $p=0.728$).

In conclusion, the results showed discrimination in the measurement of emotions and sentiments, as well as variations of these affective responses to applied stimuli. This difference suggested that they are different concepts, although they are grouped under one large category in literature. The results also indicated that sentiments tend to suffer less influence from situational aspects. The variations in negative emotions were more intense than those of negative sentiments. This result was not repeated for the modifications of the positive affective responses. In part, this result may be explained by the nature of the stimulus (mostly negative), and by the asymmetric effect of the losses and gains on the responses of consumers.

Will Dangling the Carrot Make them Eat it? An Exploration of Children's Perceptions Towards Rewards for Healthy Food

Katherine Prater-Racicot, University of Sydney, Australia
Teresa Davis, University of Sydney, Australia
Catherine Sutton-Brady, University of Sydney, Australia

This study explored children's experiences with and perceptions towards rewards for food. This study explores how children perceived rewards for healthy food. A Consumer Socialization framework (Roedder-John, 1999) was applied to understand how a child's consumer socialization stage influences their perceptions towards the attributes of concrete and abstract rewards. Phenomenological interviews were used to gain understanding of children's perspectives and enabled the identification of the attributes of rewards which are most persuasive in influencing children's healthy food choices.

The Impact of Mood on Consumer Choice: Compromise or Not?

Cheng Qiu, University of Hong Kong, Hong Kong, China

This research investigates how mood influences consumer choice among a low-end option, a middle (compromise) option, and a high-end option. Previous research suggests that mood may affect consumer judgment through different mechanisms (Schwarz and Clore 2007) which bear different implications for the present research. One possibility is that mood may have motivational impact which drives consumer choice. Happy consumers may wish to maintain their pleasant feelings whereas unhappy consumers may seek mood-lifting opportunities (Isen 1984). In this case, consumers are more likely to choose the compromise option if they are in a good mood than if they are in a bad mood (Lin, Yen, and Chuang 2006). This is because the compromise option is perceived to be a safe choice (Simonson 1989). Such a low-risk choice may contribute to maintaining a good mood while at the same time entail less mood-lifting potential than a high-risk one (Nygren et al. 1996; Raghunathan and Pham 1999).

A second possibility is that mood may signal how benign or problematic the environment is and influence information processing (Schwarz and Clore 2007). Happy consumers tend to process information in a top-down manner, which may facilitate seeing the relationship among the options and their respective mood-management property. Happy consumers may therefore be more attracted by the compromise option than those in a neutral mood. When consumers are in a bad mood, however, they tend to process information in a bottom-up manner based on an assessment of individual product features. When this happens, consumers may be less likely to see the relationship among the options and the corresponding mood-management potential. Rather, they may be more sensitive to negative product features than to positive ones, and give the former more weight in their decisions (Adaval 2001). In this case, the low-end option may be assessed most negatively in terms of quality whereas the high-end option may be assessed most negatively in terms of price. Greater weight given to these negative features may lead unhappy consumers to shun the low-end and high-end options, resulting in choosing the compromise option more often than those in a neutral mood. Thus, consumers in both positive and negative moods may be inclined to choose the compromise option.

Further, this research proposes that the first possibility is more likely to occur when mood clarity is high, whereas the second possibility is more likely to occur when mood clarity is low. This is because for the mood-lifting motivation to guide consumer decision, consumers need to assess their current mood and forecast future mood after choice (Andrade 2005). Thus, when consumers have higher (lower) clarity about their current mood, they may be more (less) likely to act in accordance with a mood-lifting motivation. In the previous research demonstrating the first possibility (Lin, Yen, and Chuang 2006), participants assessed their mood before they made the choice, which may have enhanced mood clarity. In the study reported below, participants did not assess their mood until after making product choices. We expect that the relatively low mood clarity may yield a different pattern of findings as suggested by the second possibility.

Experiment

The experiment had a 3 (mood: positive vs. neutral vs. negative) x 2 (justification for choice: provided vs. not provided) between-subjects design. The latter factor was added to show a boundary condition where the predicted mood effect would diminish if people were induced to deliberate over their decisions and make easily justifiable choices.

Method. First, 194 participants were asked to write a happy, neutral, or sad experience which induced mood. Next, in a product survey, they were asked to imagine that they were going to buy a computer monitor, and were considering three options that differed only in viewable size and price—monitor A (17 in., \$119), monitor B (19 in., \$159), and monitor C (21 in., \$199). After seeing the information, participants in the justification-not-provided condition just indicated their choices, whereas participants in the justification-provided condition wrote down the reasons for choices before indicating their decisions. Next, they were asked to imagine they encountered another set of options—monitor A (19 in., \$159), monitor B (21 in., \$199), and monitor C (23 in., \$239), and then completed procedures same as those in the first scenario. These two scenarios together can rule out the possibility that participants preferred a particular product that coincided with the compromise option. In the end, participants indicated their mood.

Main Findings. For the first scenario, when not asked to provide justifications, participants were more likely to choose the compromise option when they were in a positive (50%) or negative mood (53%) than when they were in a neutral mood (24%; z -values=2.32 and 2.57, p -values<.05). In contrast, when participants explained their choices, they were similarly likely to choose the compromise option regardless of mood (44%, 40%, and 38%). Analyses regarding the second scenario provided converging evidence. When justifications were not required, choice shares of the compromise option were larger when participants were in a positive (50%) or negative (59%) mood than when they were in a neutral mood (24%; z -values=2.32 and 3.13, p -values<.05). When participants explained the reasons for choices, their choices were likely to be consistent with the decision they made in the first scenario. These findings provide initial evidence that both positive and negative moods may lead to more compromise choices than would a neutral mood under low mood clarity circumstances.

Future Research Plan. More data involving multiple product categories will be collected to validate the robustness of the findings. Whether participants assess their mood before or after the choice will be manipulated, such that a comparison between the two conditions would help further reconcile the present findings with the previous ones. Participants' mood clarity tendency will also be measured (Salovey et al. 1995). If the proposed moderation effect of mood clarity is viable, individuals' chronic differences in mood clarity would also have an impact on the mechanism through which mood influences choice.

Correlates of Cool Identity: Humor, Need for Uniqueness, Materialism, Status Concern and Brand Consciousness

Kaleel Rahman, American University in Dubai, United Arab Emirates

Helene Cherrier, American University in Dubai, United Arab Emirates

Despite some advances in understanding the meaning and origin of cool (Belk, 2006; Bird and Tapp, 2008; O'Donnell and Wardlow, 2000; Nancarrow et al. 2002), literature uncovering the meaning of cool is still in its infancy in consumer research. However, cool is a heavily used term by marketing practitioners. Advertising, web pages, shirts, music lyrics, book titles, business documents and above all people's conversations are example of places where the word cool is used. For example, a simple search in Amazon.com alone produced over 300 titles of published books which have the word cool as part of their titles, primarily with its slang meaning.

The focus of this paper is to examine the meaning of cool from a marketer's point of view. From literature, we identify possible correlates of cool identity. We conceptualize cool identity as the extent to which consumers consider themselves to be cool. One agreement among the researchers is that they consider the origin of contemporary cool to be the African American culture (Belk, 2006; Moore, 2004). It was basically an attitude adopted by African Americans as a defense mechanism against the prejudice they faced and as a form of detachment from their difficult and often insecure working conditions (Nancarrow et al., 2002). However, the meaning of cool has evolved. As Belk (2006, p.7) describes it, cool "refers to a person who is admired because she, or more often he, exhibits a nonchalant

control of emotions, a rebellious trickster demeanor, an ironic detachment from the regard of others, and a “cool” style of talking, walking, gesturing, and grooming”.

As Nancarrow and colleagues (2002) suggest, the meaning of cool has an inner layer which involves personality characteristics of individuals, as well as an outer layer involving aesthetics and lifestyle. One aspect of inner coolness is linked to irony (Pountain and Robbins, 2000). Irony refers to “a sort of humor, ridicule, or light sarcasm, which adopts a mode of speech the meaning of which is contrary to the literal sense of the words” (Webster’s, 2009). For example, one thing is said and its opposite implied, as in the comment, “Beautiful weather, isn’t it?” made when it is raining or nasty. As Pountain and Robbins (2000) posits, consumers use cool irony as a weapon in defense and important to maintain a protective cool persona. Irony is also known as sick humor and Jewish humor. Hence we propose that humor is positively related to cool identity.

Another aspect of inner coolness is related to uniqueness. Uniqueness involves a feeling that sets individuals apart from the crowd, but in a manner that is appreciated by others. Tian et al. (2001, p. 52) defined consumers’ need for uniqueness (CNFU) as “the trait of pursuing differences relative to others through the acquisition, utilization, and disposition of consumer goods for the purpose of developing and enhancing one’s self-image and social image”. CNFU is a means for satisfying NFU by using possessions creatively, making unpopular consumption choices, and avoiding buying and consuming commonly used products. According to Tian et al. (2001), all individuals use these consumption behaviors to some extent to establish a unique social image. Several authors have identified concepts of coolness related to uniqueness. Mark of distinction, statement of separateness, refusal to accept norms, anti-authoritarian (Nancarrow et. al., 2002); deviance from the mainstream (Moore, 2004); detachment (Pountain and Robbins, 2000); authenticity (Southgate, 2003). Hence we propose that need for uniqueness is positively related to cool identity

We contend that the outer layer of cool is related to several consumer behavior constructs in general and materialism, status concern, and brand consciousness in particular. As Stephens and colleagues (1975, p. 275) suggested, “the importance of outward appearance—the great importance put upon the conspicuous display of wealth as represented by clothes, flashy cars, and other status conferring material goods” play a key role in defining coolness. In writing of generational shifts in values of cool, Moore (2004, p. 72) posits that “command of fashionable clothing and grooming styles were important in establishing status. Stylishness can be linked to cool not only because stylishness is good (therefore cool in a broad sense) but also because stylishness is based on a kind of knowingness and knowingness is a key feature of cool”. As Pountain and Robbins (2002, p. 28) argue once cool was “a form of social deviance and rebellion, but that it is now losing this rebellious status and becoming the dominant ethic of late consumer capitalism”. This is consistent with several concepts used to describe coolness by different authors: Nancarrow and colleagues (2002)—dress code, flashy clothes, commodities, aesthetics of designer labels, niche brands, and consumption of performance. Southgate (2003, p. 453)—“cool is the currency of all brands”. Hence we propose that: Materialism, Status concern and Brand consciousness are positively related to cool identity

A total of 479 undergraduate students at an English medium university in UAE were asked to complete a questionnaire (in which items were randomized) as part of class exercises. The original content of this questionnaire had diverse objectives and cover more issues than those relevant for the present paper. We believe the cosmopolitan nature of students studying in UAE lends itself to undertaking this research. For example, students on average had traveled to several countries and 80% of them had traveled to a Western country. Fifty four percent were male, median age was 20 years, 59% had his/her own car, 47% had a mobile phone worth over US\$ 360.

We used sexual identity scale (Stern et. al., 1987) to develop our four-item cool identity scale: “I FEEL as though I am cool”, I LOOK as though I am cool”, I DO most things in a manner typical of someone who is cool” and “My INTERESTS are mostly those of a person who is cool” (alpha=.86).

For humor, we used three items from Carbelo-Baquero and colleagues (2006). E.g., “Other people tell me that I say funny things” (alpha=.62). For measuring uniqueness, we used highest loaded three items each on three subscales (creative choice counter-conformity; avoidance of similarity; unpopular choice counter-conformity) of need for uniqueness scale by Tian et al. (2001). E.g., “I’m often on the lookout for new products or brands that will add to my personal uniqueness” (alpha=.69, .62, .68). For materialism, we used material values short form six-item scale developed by Richins (2004). E.g., “I admire people who own expensive homes, cars, and clothes” (alpha=.71). For status concern, we used five items from Eastman and colleagues (1997). E.g., “I would buy a product just because it has status” (alpha=.79). For brand consciousness, we used four items from Shim and Gehrt (1996). E.g., “The more expensive brands are usually my choices” (alpha=.71). All items were measured on 7-point Likert scales.

In analyzing the data, we used correlation analysis in SPSS in order to gain some preliminary insight. We averaged the items under each construct to create a single item measure. Our analysis supports all of our proposed relationships. We briefly list the descriptive statistics and correlation results as follows:

- Cool identity ($M=4.53$, $SD=1.37$)
- Humor ($M=4.88$, $SD=1.16$) is positively related to cool identity ($n=477$, $r=.338$, $p<.01$)
- Creative choice counter-conformity ($M=4.52$, $SD=1.37$) is positively related to cool identity ($n=476$, $r=.326$, $p<.01$)
- Unpopular choice counter-conformity ($M=3.98$, $SD=1.33$) is positively related to cool identity ($n=477$, $r=.349$, $p<.01$)
- Avoidance of similarity ($M=3.79$, $SD=1.35$) is positively related to cool identity ($n=476$, $r=.255$, $p<.01$)
- Materialism ($M=4.36$, $SD=1.15$) is positively related to cool identity ($n=473$, $r=.386$, $p<.01$)
- Status concern ($M=4.14$, $SD=1.28$) is positively related to cool identity ($n=473$, $r=.326$, $p<.01$)
- Brand consciousness ($M=4.07$, $SD=1.31$) is positively related to cool identity ($n=475$, $r=.293$, $p<.01$)

In this paper, we have attempted to examine the meaning of coolness using possible consumer behavior constructs associated to the term. We proposed that humor, need for uniqueness, materialism, status concern and brand consciousness are positively related to coolness. Our preliminary analysis supports all our propositions. Our findings have implications for researchers and practitioners. Given the rich multicultural nature of our sample, we plan to do further analysis such as differences between religion, nationality and gender.

Social Networking Profiles & Cultural Dimensions: An Empirical Investigation

Carleen Ramlochansingh, St. John's University, USA

Ryall Carroll, St. John's University, USA

In recent years social networking has become very popular and has propelled websites like MySpace, Facebook, and LinkedIn into the mainstream. MySpace, one of the most popular of these social networking sites, was founded just six years ago and already has over 253 million user accounts worldwide (Alexa 2009). As this phenomenon grows and becomes an even larger part of people's lives, it is extremely important for marketers to understand this new medium and currently there is little research on the subject (Wallace, Walker, Lopez, and Jones 2009; Poynter 2008).

Schau and Gilly's (2003) research on motivations, intentions, and strategies for constructing personal Web spaces found that many individuals construct their digital selves referencing only the intangible concepts, things like ideas, beliefs, and values. If *culture* is defined as everything that people in a society learn in relation to values, norms, customs, traditions, and beliefs (Terpstra & Sarathy 2000), then Schau and Gilly's (2003) findings seem to indicate that individuals actually construct their digital selves referencing their culture. Therefore, this research investigates whether an individual's culture is evident in their social networking profiles.

For this study we analyzed profiles from the social networking site MySpace from three different countries with respect to three of Geert Hofstede's Five Cultural Dimensions: individuality, masculinity, and uncertainty avoidance. We reviewed 300 customized profiles by looking at the "About Me" section, where users write their personal information. The three countries under investigation were Australia, Ireland and the United States (US). These countries were chosen because of the US and Australia's similarity on the dimensions Individuality (IDV) and Masculinity (MAS), and their dissimilarity with Ireland on those dimensions, as well as the dissimilarity of the three countries on the dimension of Uncertainty Avoidance (UAI). These similarities and differences will act as our hypothesis of whether or not culture manifests itself in these profiles. If culture does play a role we should expect parallel results in terms of similarities and differences among cultural dimensions in personal profiles as we do among the countries.

The country-specific MySpace sites were used to identify the sample of 300 profiles consisting of 100 Australian, 100 Irish, and 100 US profiles with an equal number of male and female profiles for each country. Each profile page was individually printed and then specially coded on the back to indicate the country of origin. All 300 profile pages were randomized and we ensured the judges were not aware of the country coding on the back during the analysis. The "About me" written description on each profile was then evaluated on all three cultural dimensions.

An individualist (IDV) is one who exists in society only seeking their own self-interest and maybe that of their immediate family (Kale 1991). Therefore profiles were rated high on the IDV dimension if the individual primarily wrote about themselves, including but not limited to their career, hobbies, self description, and their personal likes and dislikes. Profiles were rated low on the IDV dimension if the individual wrote about themselves but also mentioned others in their profile, including but is not limited to family, friends, and/or significant others.

Distinctive Masculine (MAS) traits are assertiveness and competitiveness, and typically dominant masculine societies emphasize wealth and success (Geert-Hofstede.com). Therefore profiles were rated high on the MAS if the writing was very unemotional and the individual wrote about "liking" or "enjoying" their career, cars, and/or school but with little or no mention of or emotion towards family,

friends, and/or significant others. Whereas, profiles were rated low on the MAS dimension if the profile section the individual primarily wrote very emotionally, writing about “liking” or “loving” their family, friends, and/or significant others but with little or no mention about “liking” or “enjoying” their career, cars, and/or school.

In strong Uncertainty Avoidance (UAI) societies people attempt to predict the future in order to minimize the possibility of new, unfamiliar, unexpected, unusual circumstances (Kale 1991). Therefore if the individual wrote about their future goals and plans whether it concerned the immediate future, a month, six months and/or a year, or their long term/ life goals they were considered high on UAI. Conversely the individual was considered low on UAI if the person made no mention of any future goals and plans.

To establish reliability, a test of reproducibility was applied to the coding system (Mueller 1987). A total of 90 MySpace profile were selected randomly from the original sample by two new experimenters. Next each of the two new experimenters independently coded their random selection of 90 MySpace profiles (Mueller 1987). The results of the reproducibility test showed that the two new experimenters coded their 90 MySpace profile with an 84.2 percent similarity as the original judge.

As expected, the results showed that the US and Australia’s were not significantly different on the dimensions of Individuality and Masculinity (p ’s > .2). Surprisingly, there was also no significant difference on the dimension of Uncertainty Avoidance (UAI) (p > .2). When compared to Ireland both the US and Australia showed differences in these cultural dimensions. For Ireland, their Individuality rating was significantly lower ($M = 2.07$) than the US’s ($M = 2.44$; $t(198) = 2.918$, $p < .005$) and marginally significant to Australia’s profiles ($M = 2.33$; $t(198) = -1.779$, $p < .10$). For Ireland, their Masculinity rating was significantly higher ($M = 1.19$) than the US’s ($M = .89$; $t(198) = 2.909$, $p < .005$) and also significantly higher to Australia’s profiles ($M = .89$; $t(198) = -2.321$, $p < .5$). Lastly, for Ireland, their Uncertainty Avoidance (UAI) rating was not significantly higher ($M = 1.85$) than the US’s ($M = 1.65$; $p > .1$) but was significant to Australia’s profiles ($M = 1.61$; $t(198) = 1.973$, $p < .05$).

Since these results, for the most part, paralleled the similarities and differences among cultural dimensions in personal profiles as they do among the countries, these results confirm our expectations that culture is indeed present in individual’s personal descriptions. This research helps to build a better understanding of this growing phenomenon of social networking and we hope to build upon this knowledge base in future research.

Dhruv Grewal, Babson College, USA

Ronald Goodstein, Georgetown University, USA

While consumer research has paid significant attention to how product cues signal product quality (e.g., Bakamitsos 2006; Roggeveen, Grewal, and Gotlieb 2006; Zhang and Sood 2002), researchers have allocated fewer resources investigating how cues affect the places where consumers procure these goods. This relative lack of focus is surprising because consumer research into retail cues has a rich history (e.g., Grewal et al. 1998; Gupta and Cooper 1992; Srivastava and Lurie 2001). Yet in the past ten years, the number of publications examining how consumers react to product cues outweighs those on consumers’ reactions to retailer cues by a wide margin. The issue becomes even more important when one considers the expanding channels of retail, including the internet, kiosks, and mobile shopping to name but a few. Thus, examining how recent theories and applications in consumer behavior apply to consumers’ reactions to retailers is a timely issue. We take on that challenge by integrating research on cue-scope, congruity, and valence to test consumers’ reactions to multiple retail cues.

More specifically, our research examines how low-scope cues interact with high-scope cues to affect consumers’ evaluations. Previous research in schema-based processing suggests that the manner in which these cues interact in determining evaluations may not

be straightforward. For instance, when a stimulus is moderately incongruent with an evoked schema, consumers engage in more extensive processing of the stimulus and often form more extreme evaluations (e.g., Campbell and Goodstein 2001). In our case this suggests that when a low-scope cue is moderately incongruent with a high-scope cue, the low-scope cue may have more impact on evaluations than when it is congruent with the high-scope cue.

In addition, earlier research suggests that the valence of a high-scope cue affects when a low-scope cue is used in attitude formation (e.g., Biswas et al. 2002; Lurie and Srivastava 2005; Miyazaki, Grewal, and Goodstein 2005; Purohit and Srivastava 2001). The results of these studies, however, are equivocal with some research indicating that low-scope cues are used only when the valence of the high-scope cue is positive (Purohit and Srivastava 2001, Miyazaki et al. 2005) and other research indicating that the low-scope cue is only used when the valence of the high-scope cue is negative (Biswas et al. 2002; Lurie and Srivastava 2005). We develop and test a processing model that reconciles these conflicting findings by examining the joint impact of cue-scope, congruity, and valence in a series of related experiments. More specifically we propose and test:

H1: When a low-scope cue is congruent with an accompanying high-scope cue, it will improve evaluations when the high-scope cue is negative but have no impact on evaluations when the high-scope cue is positive.

H2: When a low-scope cue is moderately incongruent with an accompanying high-scope cue, it will improve evaluations when the high-scope cue is positive but have no impact on evaluations when the high-scope cue is negative.

Results of three experiments support these hypotheses indicating that cue congruity affects attitudes and thoughts such that a low-scope cue enhances evaluations of a retailer associated with a positive high-scope cue when the two cues are moderately incongruent. Further, the low-scope cue offsets the effects of a negative high-scope cue when the cues are congruent.

In Experiment 1 (n=320), we paired our low-scope cue (price matching guarantee, PMG) with each of the high-scope cues in order to manipulate congruity. Specifically, a price-based low-scope cue is congruent for a retailer whose reputation is based on price (cf. Srivastava and Lurie 2004), but would be somewhat incongruent for a firm whose reputation is based on service. Thus, we examined two types of reputations (congruent/moderately congruent with PMG), two levels of valence associated with the reputation (poor/excellent), and two levels of PMG (absent/present) in a 2 x 2 x 2 between-subjects design. Each participant was randomly assigned to one of the eight experimental conditions and asked to read a brief scenario describing the reputation of a retailer selling home electronics and they then either read about the retailer's PMG policy or saw nothing about a PMG. After reading the scenario participants rated their perceptions of the retailer in terms of service quality and prices. In support of our hypotheses, the results revealed a three-way interaction for both price and service perceptions.

Experiment 2 followed the same general format as Study 1. However, in this study, the new high-scope reputation cue was related to the retailer's history concerning inventory availability. Following the logic on congruity, the new low-scope cue was an in-stock guarantee (ISG). We again examine two types of congruity (congruent/moderately congruent with ISG), two levels of valence associated with the reputation (poor/excellent), and two levels of ISG (absent/present) in a 2 x 2 x 2 between-subjects design. Participants (n=93) then read a scenario which described the type and valence of the retailer's reputation and either informed them about the retailer's ISG or contained no information about an ISG. Results again supported the hypothesized three-way interaction. Finally, Experiment 3 (n=86) provides evidence as to the process accounting for the results.

In sum, by examining the joint role of cue meaning congruity and the valence of the high-scope cue, our framework provides a more comprehensive understanding of the impact of multiple cues on consumers' evaluations. This framework was supported in three independent studies that manipulated multiple instantiations of each type of cue, as well as two very different retail contexts.

Compensatory Consumption When Saying Goodbye

Pilar Rojas Gaviria, Université Libre de Bruxelles (Solvay Brussels School of Economics and Management and Centre Emile Berheim CEB), Belgium

Christian Bluemelhuber, Université Libre de Bruxelles (Solvay Brussels School of Economics and Management and Centre Emile Berheim CEB), Belgium⁸

“Guérit-on jamais des êtres qui nous quittent? [1]”

When choosing the words that best describe developed contemporary societies, specialists seem to agree on a kind of “disruptive” vocabulary. They refer to: liquid, fluid, movement, fragmentation and acceleration (e.g. Lyotard 1978; Marquard 1991; Bauman 2000; Lipovetsky and Charles 2004). These descriptors of an accelerated world capture the continual departure from familiar contexts in which post-modern citizens are embedded.

Continual departures challenge traditional reference points, such as the classic family model, life-long working community or citizenship. The ambiguity and instability of traditional reference points motivate alternative ways of organizing life, contributing to the acceleration of such phenomena as divorce, migration and switching or losing jobs.

In this fast-paced world, our research, studies compensatory consumption in the framework of consumers exposed to the loss of familiar contexts: landscapes, surroundings, and/or significant others. This study is a response to our conviction that investigating human capacity to compensate for the disappearance of familiarity in life through consumption has become an important aspect of consumer research (see for instance, Bonsu and Belk 2003; Curasi et al. 2004 or Schau et al. 2009).

The research method used for this inquiry has been inspired heavily by the bottom-up approach of *Grounded Theory* (Strauss and Corbin 1990)—starting with the data and building the theory from this foundation. This agenda is highlighted by ten case studies of people who have encountered important losses in life. After being shortly debriefed about the idea of lost under investigation, participants shared their stories about their personal loss on four occasions:

1. *A biographical written exercise*: participants were required to identify important losses that had deeply impacted on them.
2. *A lost telling exercise*: participants were recorded during an interview, in which they were asked to describe the details of the loss. Each of these personal telling exercises lasted between one and two hours, during which we interfered as little as possible with the free flow of narrative.
3. *A dialogical experience*: the two first phases enabled us to identify a number of topics common to all participants. We engaged in a dialogical experience (Thompson et al. 1989) during a second round of interviews, with the specific objective of focusing on these particular topics.
4. *Feedback exercise*: participants were invited to provide an individual feedback on the preliminary conclusions that we drew when they modified some of our interpretations and enriched the information we had.

The major results elicited from the data so far can be divided into two groups of strategies in which consumers leverage on consumption, when facing the loss of familiar contexts: *The Teddy Bear Effect* and *The Rebound Effect*.

The Teddy Bear Effect: can be defined as the coercive force that aims at preserving a past that may otherwise be forgotten, in order to ensure the development of a coherent personal narrative. Participants often bring that past closer to themselves as a reassuring strategy, when times become uncertain and challenging (Marquard 1991, p. 81).

This effect can be illustrated with the case of Bruna (32 years old), an Italian citizen who immigrated to Belgium seven years ago. She identifies living overseas as a risk of losing her Italian identity. For instance, she notices that her Italian is becoming less fluent, that she has totally lost track of Italian shops, that she does not know the “new” words used by young Italians, as she no longer watches local television.

Her personal *Teddy Bear* consists of purchasing traditional Italian food at supermarkets, which she feels is consistent with her Italian cooking background. She also travels back to Italy each time she needs to celebrate a professional success. A couple of years ago, after having bought an apartment in Belgium, the risk of losing her identity as Italian increased, she described the purchasing situation as “strange”, as she would always have thought of having her own home first in Italy.

Purchasing a house can be seen at first sight as an activity we do in order to live there later on. However, as Martin Heidegger suggests (1958), we already project ourselves dwelling in these places at the time we decide to build or buy them. Residential housing purchase decisions are material signs of our desire to stay in place. In this case, Bruna’s decision makes her realize that she was intending to remain in Belgium. Consequently, her reaction was to reinforce her personal *Teddy Bear* by buying most of her furniture in Italy and bringing it by car to Belgium.

The Rebound Effect results from the capacity of the human brain to make up and integrate concepts, and multiple alternative action plans in order to achieve future goals (Ingvar 1985). It consists of consumption-related actions performed to anticipate novelty in life and compensate for past losses. One of our participants, Caroline (28 years old), experienced a *Rebound Effect* after losing a brother in a motorcycle accident.

Her *Rebound* focuses on living a healthier and “carpe-diem” life. After her brother passed away, she became determined to overcome her anorexia, a sickness which had plagued her since she was a teenager. She describes this change in her life as a personal strategy, which obliged her to protect her own life, thus preventing her parents from losing yet another child. She now goes out for meals with friends, without having to search for an excuse for not to eat.

⁸Free translation: Do we ever heal from those who leave us?

Her “carpe-diem” *Rebound* acknowledges a new perspective on enjoying life that she and her entire family have adopted. She often consciously reinforces her hedonic consumption, for instance by going on enjoyable outings, allowing herself impulsive purchases of expensive clothes. She visits relatively expensive bars or restaurants from time to time and also bought a new car that satisfies aesthetic criteria more than utilitarian needs.

As the world continues its accelerated innovative path, consumers are exposed more and more to losses of known paths. The speed of change cannot immediately be comprehended by consumers who generally live at a slower speed. This requires “mundane” consumption experiences to compensate for the profound loss of familiarity.

High Hopes and Letdowns: The Influence of Self-Esteem on Expectations and Product Failure

Stefanie Rosen, University of South Carolina, USA

Rebecca Naylor, Ohio State University, USA

Cait Poynor, University of Pittsburgh, USA

Self-esteem, defined as how worthwhile one perceives him or herself to be, plays an important role in one’s self-concept (Swann et al. 2007). Marketing researchers have explored self-esteem in the context of consumer behavior, showing that it can affect overconsumption (Mandel and Smeesters 2008), perceptions of models (Smeesters and Mandel 2006), brand connections (Escalas and Bettman 2003), and materialism (Chaplin and Roedder-John 2007).

In our research, we explore how product expectations differ by self-esteem. Specifically, we explore the impact of self-esteem on a consumer’s expectations of product performance, particularly given other consumers’ and professionals’ ratings of the product. Our central proposition is that high and low self-esteem consumers will react differently to recommendation information because they differ in their ability to adjust their expectations. Because people with high self-esteem (HSE) are more effective at adjusting their expectations, when they have information (e.g., ratings by other consumers and/or by product experts) indicating lower quality, they adjust their expectations accordingly. However, low self-esteem (LSE) consumers are not as good at making such adjustments. As such, these consumers end up with high hopes for a low quality product. Hence we predict:

H1: Consumers with LSE will have more favorable expectations of an inferior product than consumers with HSE.

We predict hypothesis 1 will hold only in the context of an inferior product. Self-esteem does not shape consumers' expectations of products rated by others as superior because no adjustments to expectations are needed in this case—high expectations are justified for superior products.

What do these differences in expectations by self-esteem and product quality mean for evaluations of the performance of the product? From the satisfaction literature, we know consumers are upset when expectations are not met, per the expectation disconfirmation model (Oliver 1997). People with LSE are putting themselves in a position to experience negative disconfirmation because of their heightened expectations for an objectively worse product. Thus, LSE consumers are likely to judge a lower quality product even more negatively when it performs badly than will HSE consumers. By contrast, HSE people have more realistic expectations of lower quality products. Their expectations might not be met if the lower quality product does not perform, but the gap between expectations and perceived performance will be less than it is for LSE people because the expectations of HSE people are lower a priori. Formally:

H2: Consumers with LSE will have a stronger negative emotional response and will be more likely to complain about their disappointment when an inferior product fails than consumers with HSE.

We test hypothesis 1 in study 1 and hypothesis 2 in study 2. Participants in study 1 ($n=174$) completed two ostensibly unrelated tasks: indicating their level of agreement/disagreement with the 10 items of the Rosenberg (1965) self-esteem scale (Cronbach's $\alpha=.80$) and evaluating one of two shampoos. In the superior (inferior) shampoo condition, participants were told that average consumer rating of a hypothetical brand of shampoo was four (two) out of five stars and 75% (25%) of hairstylists recommended the shampoo. The order of the two tasks was counter-balanced for a 2 (shampoo quality) \times 2 (order) design. After reading the scenario, participants rated the shampoo on the following dependent variables using nine-point scales: satisfaction, overall impression, and how well they thought it worked. These items were combined into an overall product expectations index (Cronbach's $\alpha=.90$).

We conducted a 2 (shampoo quality) \times measured self-esteem ANOVA. As hypothesized, there was a significant interaction between self-esteem and shampoo quality ($F(1, 170)=6.82, p<.01$). Follow-up analyses in the superior product condition revealed that there was not a significant effect of self-esteem on product expectations ($p=.32$). In the inferior product condition, however, participants with LSE had significantly higher product expectations than participants with HSE ($F(1, 170)=8.58, p<.01$), consistent with hypothesis 1.

In study 2, participants ($n=137$) indicated their level of agreement/disagreement with the 20 items of the Heatherton and Polivy (1991) self-esteem scale (Cronbach's $\alpha=.87$) and read a scenario describing a product failure. Participants were asked to imagine that the zipper on a piece of luggage they had owned for five years had broken and that the suitcase was a brand that is considered (or not considered) very high quality. The order of the two tasks was again counter-balanced for a 2 (luggage quality: superior vs. inferior) \times 2 (order) design. After reading the scenario, participants rated their anticipated disappointment, anger, and likelihood of complaining to friends/family that the zipper had broken. Disappointment and anger were combined into an emotional response to product failure index (Cronbach's $\alpha=.70$).

We conducted two 2 (luggage quality) \times measured self-esteem ANOVAs, one predicting the emotional response to the product failure and the other predicting likelihood of negative word-of-mouth. As hypothesized, there were significant interactive effects of self-esteem and quality of luggage on both the emotional response to product failure index ($F(1, 136)=8.31, p<.01$) and likelihood of complaining to friends/family ($F(1, 136)=9.93, p<.01$). Follow-up analyses in the superior product condition revealed that participants with both HSE and LSE were equally upset ($p=.12$) and likely to complain when the superior luggage failed ($p=.09$). However, follow-up analyses in the inferior product condition showed that compared to participants with HSE, those with LSE were significantly more upset ($F(1, 136)=6.36, p=.01$) and more likely to complain ($F(1, 136)=7.51, p<.01$) when the zipper broke, supporting hypothesis 2.

Overall, we find that individuals' self-esteem shapes their expectations for products such that LSE consumers have higher expectations of lower quality products than do HSE consumers (study 1). These higher expectations influence subsequent evaluations of product performance, leading LSE consumers to feel more let down when a lower quality product does not perform well than are HSE consumers (study 2).

A Demonstration of the Influence of Advertising on Brand Choice

J. Edward Russo, Cornell University, USA
Anne-Sophie Chaxel, Cornell University, USA

Advertising influences brand choice (e.g., Mehta, Chen, & Narasimhan, 2008). This is true even for TV commercials that rely mainly on conveying a positive feeling about the brand. Although there is general agreement that such commercials can influence brand choice, there is much less agreement on how they do it. That lack of agreement may reflect the existence of several different ways that commercials succeed, each with its own process through which the viewing of the commercial influences a subsequent brand choice. The purpose of the present work is to demonstrate one such process.

That process requires two steps. First, an effective commercial must install its brand as the initial leader in a choice against a competing brand. This should be straightforward so long as the commercial for the targeted brand is superior to a commercial for the competitor. Not all viewers may see the selected commercial as superior, but it should install its brand as the initial leader for a substantial majority of them.

The second step relies on a phenomenon that occurs during the subsequent product choice. As new information is received, its evaluation tends to be biased toward supporting whichever alternative is currently leading in overall preference (Russo, Meloy and Medvec, 1998). If the superior commercial makes its brand the initial leader, then the distortion of new information during the choice process should enable it to remain in the lead and emerge as the chosen brand for a majority of consumers. Information distortion (ID) is, by now, a well established “predecision” bias (see Brownstein, 2003, for a review). It is frequently observed, difficult to eliminate (Meloy, Russo and Miller, 2006), and quite systematic, increasing linearly with the strength of preference for one option over the other (Russo et al., 1998).

In an experiment, participants were asked to imagine having to decide between two Caribbean resorts for their next vacation. They might see a commercial for each resort, possibly on their websites or on a travel-oriented TV channel. This constitutes Step 1 of our process. Then they might use the internet, books or friends to gather information on several attributes of these two resorts, such as their activities and amenities. This is Step 2.

To track the commercials’ influence on each attribute to the eventual brand choice, we used a method known as the stepwise evolution of preference (SEP; Meloy and Russo, 2004). This method requires participants to provide three responses after they have read each product attribute. The first is an evaluation of the attribute. This response is the basis of the measurement of ID. Second, participants are asked which brand they prefer at this point in the process, knowing that more information is coming. This response identifies the current leader. Finally, participants are asked for their confidence in this current leader. This third response captures the strength of their preference for the identified leader. If the superior commercial succeeds in installing its brand for a substantial majority of viewers and if ID is sufficient to preserve enough of that majority in the face of subsequent information, then the targeted brand should be chosen by a majority of participants.

A between-participant design included one experimental and one control condition. In the experimental condition, participants were shown two commercials before they saw five descriptive product attributes and made their choice of resort. A pretest showed one of the commercials (Club Zephyr) to be superior to the other (Club Helios). Neither commercial was designed to convey product information, at least explicitly. None of the five attributes favored one brand over the other (i.e., they were all written and pretested to be “neutral”). In the control group, participants saw no commercials. Their brand choice provided a baseline level of both choice proportion and ID against which the levels observed in the commercial condition could be compared.

Results confirmed our hypothesized process. First, the superior commercial did install Club Zephyr as the initial leader for a clear majority of viewers (80%). In contrast, the control group who saw the first attribute but neither commercial divided their initial preference evenly between the two resorts (50%). Second, enough of the initial effect of the commercials was preserved to enable a significant final preference for the brand with the superior commercial (76%). Third, further analysis demonstrated that the commercial for Club Zephyr resulted in a relatively large mean ID ($M=1.25$) in the evaluation of information to favor this Club. In comparison, the benchmark level of ID from the control group was only .33. We also computed the confidence in the final choice in each of the two conditions. The greater ID in the advertising condition should have led its participants to be more confident (on a scale from 50 to 100). Confirming this expectation, participants in the advertising group were reliably more confident in their final choice ($M=.83$) than those in the control group ($M=.76$). Thus, participants in the commercial condition were more convinced of their choice than participants in the no-advertising condition. This occurred despite there being little information in the advertisement condition and little directional information in any of the five attributes (which were pretested to be neutral).

These results provide one answer to the question: How might advertising influence consumer choice? We showed that a superior commercial can succeed in influencing brand choice by first installing the advertised brand as the initial leader and then letting the subsequent ID help maintain that leadership throughout a subsequent brand choice process. Thus, our findings reveal one specific process through which an advertisement can influence product choice.

Exposing Consumer Exhibitionists: The Development and Validation of the Consumer Exhibitionism Scale

Christina Saenger, Kent State University, USA

Veronica Thomas, Kent State University, USA

Jennifer Wiggins Johnson, Kent State University, USA

Robert Jewell, Kent State University, USA

Marketing researchers have long recognized phenomena wherein consumers express their self-concepts to others via their consumption activities (Belk 1988; Richins 1994; Escalas and Bettman 2005). Internet technologies, such as social networking sites and blogs, have become more prevalent, enabling consumers to make information about themselves available on a far-reaching scale. They have fundamentally altered the way consumers communicate their consumption activities to others, fostering a culture of exhibitionistic consumer behavior. Consumers are making their consumption activities more publicly available than ever before, from listing their favorite books and music to posting pictures of their lifestyles and experiences for others to see. They update others in their networks' as to their behaviors, plans, and mood through status functionalities, such as those available on Facebook, MySpace, and Twitter. Indeed, some consumers have gone beyond simply utilizing these tools to stay in touch with friends to using these technologies to express themselves to a larger audience. This need to create awareness about one's self has pervaded some individuals' lives, causing them to continually publicize who they are. The purpose of this research is to develop a scale to measure consumer exhibitionism, which we formally define as the tendency to communicate one's consumption activities for the purposes of attracting attention to one's self and informing others about one's self concept in the pursuit of personal satisfaction from making this information public. Using Churchill's (1979) method, we are in the process of refining and validating this scale for future use in consumer research.

The concept of exhibitionism stems from literature in psychology, where exhibitionism is defined as inappropriate self-exposure behavior for the purpose of self-gratification (Blair and Lanyon 1981). Applying the concept to marketing, Holbrook (2001) emphasized exhibitionism as one of the "four E's" of marketing, which focuses on the hedonic, experiential aspects of consumer behavior. Holbrook proposed that consumers use their consumption activities to shape their social images, defining the concept as "the phenomenon wherein consumers use products as signals to convey or express their actual, desired, or ideal self-concepts to others," (p.81). In Holbrook's view, all consumers are exhibitionists; however, we propose it is a tendency that consumers possess in varying amounts, warranting the development of a measurement scale. Further, we broaden Holbrook's definition by specifying two goals beyond the expression of self-concept that consumer exhibitionists seek to attain: attention and satisfaction. Consumer exhibitionism holds a symbiotic relationship with voyeuristic behavior (Holbrook 2001), implying the exhibitionist's desire to gain the attention of others. This is consistent with literature on consumption as an expression of self, where the attention of others to these consumption activities is a necessary component (Belk 1988; Richins 1994; Escalas and Bettman 2005). As a psychological construct, exhibitionistic behavior is engaged in to achieve self-gratification (Blair and Lanyon 1981), indicating that individuals seek satisfaction from exhibitionistic activities.

While consumer exhibitionism has not been previously measured in consumer research, similar constructs have been examined. While market mavens (Feick and Price 1987) and opinion leaders (Katz and Lazarsfeld 1955; Flynn, Goldsmith and Eastman 1996) use their expertise with the goal of helping others better navigate their consumption experiences, consumer exhibitionists behave with the goals of attracting attention to themselves and expressing their self-concepts, seeking personal satisfaction from the act of making information about their consumption activities publicly available. Additionally, brand evangelists "preach the brand's most loved aspects and all positive associations that come with it to people who have so far not acknowledged the wonder of it" (Matzler, Pichler, Hemetsberger 2007, 27). Though consumer exhibitionists do preach about the brands they use, this is done in effort to inform others about their consumption activities, rather than due to a sense of loyalty. Further, consumer exhibitionism is different from conspicuous consumption. While conspicuous consumption (Veblen 1899; O'Cass and McEwen 2007) is concerned with luxury goods, the communication of status, and visible consumption activity, consumer exhibitionists publicize a wide variety of public and private consumption activities that are congruent with who they are. Consumer exhibitionists are more likely to be materialistic (Richins 2004), narcissistic (Raskin and Hall 1979), have high consumer self-confidence (Bearden, Hardesty, and Rose 2001) and be extroverted.

From the literature, we initially developed a set of 27 scale items. We then conducted focus groups with 35 marketing undergraduate students in which we discussed the usage of Internet technology and interpersonal communications, and the ability of each to communicate consumption activities and self-concept related information, generating an additional 25 items for a total of 52. We presented our definition and scale items to the students from our focus groups as a member check to ensure we had accurately captured their input, and revised our items accordingly. We then presented our definition and scale items to 10 experts and colleagues for further refinement, again revising our items per their recommendations. Our current scale contains 32 items.

Our validation plan is as follows: first, we intend to administer the scale to samples from two populations, undergraduate students and MBA students, whom we deem more representative of the average consumer due to age and lifestyle differences from undergraduate students. Based on their responses, we will perform initial exploratory factor analysis and reliability analysis. Next, we will administer our refined scale to a new sample to test its internal validity. At this time, we will include scales representing the related constructs previously discussed to test nomological validity, similar constructs to test discriminant validity, and a measure of the actual behavior to test predictive validity. We will use this data to conduct confirmatory factor analysis and test the relationship between variables using structural equation modeling.

Our research contributes to the consumer behavior literature by providing a conceptual definition and measure of consumer exhibitionism. Our scale will enable researchers to investigate the effects of consumer exhibitionism on consumer behaviors of interest to marketers, such as word of mouth behavior, brand loyalty, brand choice, and online consumer behavior. This research is particularly relevant as Internet technologies that facilitate consumers' abilities to publicly express themselves become increasingly prevalent in society.

All Positive Emotions Are Not Equal: Cognitive and Motivational Differences between Pride and Surprise

Julian Saint Clair, University of Washington, USA

Abstract

Recent research has begun to explore differences between negative emotions. As for positive emotions, they have generally been lumped into a single homogeneous category when explored in relation to decision making. The study presented here is the first to demonstrate underlying cognitive and motivational differences between distinct positive emotions in the context of decision making. Due to emotional discounting, a recent effect hitherto demonstrated only with negative emotions, these effects are reversed for subjects with high need for cognition (NFC). Emotional discounting, in turn, is shown to be subject to a new boundary condition: self-esteem maintenance.

Background

Decision making is typically studied under the paradigm derived from prospect theory (Khaneman & Tversky, 1979) which seeks to measure subjective utility, likelihood estimations, and risk preference. Subjective utility is most easily understood as the value one attaches to an outcome. The paradigm often obtains these measures using gamble tasks (i.e. Isen & Geva, 1987). For example, subjects are shown a gamble as follows: "Game 3: A 50% chance to win \$10 or win nothing." To obtain subjective likelihood estimations, subjects are asked "How likely are you to win this game?" The answer takes the form of a 7-point scale anchored by "Not at all likely" and "Very likely". To obtain risk preferences and subjective utility, subjects are asked "How desirable is this game?" on a 7-point scale anchored by "Not at all desirable" and "Very desirable". The gambles take the form of win/not win and lose/not lose to separate the effects involved with loss avoidance and gain seeking—loss aversion theory shows that, for example, a \$10 loss has a stronger effect than a \$10 gain.

Predictions

The valence-only hypothesis (Johnson & Tversky, 1983) would predict that subjects in a positive mood are more likely to expect positive events to occur, and subjects in a negative mood are more likely to expect negative events to occur. This would suggest that subjects in any positive mood would report higher likelihood to win a gamble. The beyond-valence perspective (Han et al., 2007), however, is of the opinion that the important predictor of likelihood estimations is the underlying cognitive appraisal dimension of certainty. For example, a highly uncertain negative emotion (fear) should result in lower likelihood estimations than a highly certain negative emotion (anger). Indeed, Lerner and Keltner (2001) find this to be the case. To obtain a similar effect with positive emotions, we must also select two that differ on the underlying cognitive appraisal dimension of certainty. Pride and surprise are two such emotions; pride is highly certain, surprise highly uncertain (Smith & Ellsworth, 1985). Thus, taking the beyond-valence perspective, we predict that:

H1a: Subjects in the *surprise* condition will report lower likelihood to win the 50% gamble than subjects in the *control* condition.

H1b: Subjects in the *pride* condition will report higher likelihood to win the 50% gamble than subjects in the *control* condition.

Research on need for cognition (NFC) has found that those high in NFC, being more analytical thinkers, are typically less subject to emotional primes. They have in fact been shown to actively engage in cognitive discounting of negative emotion during decision making (Kuvaas & Kaufmann, 2004). The present research extends this theory by demonstrating the effect with positive emotions.

H2: The effects predicted under H1a and H1b will be moderated by NFC; the predicted effects will hold true for Low NFC subjects and reverse for High NFC subjects.

No research to date has explored boundary conditions of the emotional discounting done by high NFC subjects. Since pride is a self-focused emotion correlated with self-esteem (Tracy & Robins, 2007), it may be subject to self-esteem regulation motivations. Self-esteem maintenance theory suggests that subjects typically seek an optimal level of self-esteem (i.e., high self-esteem) (Baumeister & Jones, 1978; See Tesser, 2000 for a review). Therefore, subjects with low self-esteem who are experiencing pride may engage in less emotional discounting in an effort to bolster their self-esteem.

H3: The moderation effect of NFC in H2 of subjects in the pride condition reporting higher likelihood to win the 50% gamble will in turn be moderated by Core Self-Evaluations (CSE; a measure of self-esteem); those with low CSE will engage in less emotional discounting of pride than those with high CSE.

Also, because of the nature of the gamble propositions and the study of uncertainty, an Optimism scale is used as a control variable.

Methods

83 subjects at a large US west-coast university participated in the study for course credit. Subjects received the emotion elicitations via a relived emotion task wherein subjects are asked to recount a proud/surprise/control (grocery shopping) event in their lives (Ekman et al., 1983; Levenson, 1992; Lerner & Keltner, 2001). Subjects then received the gambles (see below for gamble descriptions) followed by the NFC scale and an Optimism scale. Subjects already completed the CSE scale prior to this study and that data was matched to the respective subjects. For the dependent variables, subjects were asked to evaluate each gamble independently on desirability and likelihood to win/lose.

- Game 1: 10% chance to win \$10 or win nothing
- Game 2: 50% chance to win \$10 or win nothing
- Game 3: 90% chance to win \$10 or win nothing
- Game 4: 10% chance to lose \$10 or lose nothing
- Game 5: 50% chance to lose \$10 or lose nothing
- Game 6: 90% chance to lose \$10 or lose nothing

Results

All hypotheses are confirmed. Repeated ANOVAs revealed no significant main effect of emotion ($p > .1$). The predicted two-way interaction of surprise with NFC was, however, significant ($p < .05$; see Equation 1). The two-way interaction of pride with NFC was not significant ($p > .1$), however, the predicted three-way interaction of pride, NFC, and CSE achieved significance ($p < .05$; see Equation 2).

Equation 1–H1a (w/ H2): $(F(4, 57) = 2.629, p < .05)$. $Y = 2.495 - 4.056(\text{Condition}) + .761(\text{Optimism}) - .639(\text{NFC}) + 1.838(\text{Condition} * \text{NFC})$. Condition 0=control, 1=surprise.

Equation 2–H1b (w/ H2/H3): $(F(5, 50) = 3.046, p < .05)$. $Y = -10.778 + 6.658(\text{Condition}) + 6.247(\text{NFC}) - .889(\text{NFC}^2) + 1.080(\text{CSE}) - .692(\text{Condition} * \text{NFC} * \text{CSE})$. Condition 0=control, 1=pride.

"From the Web to the Woods": Connecting the Online to the Offline in Consumers' Play

Daiane Scaraboto, York University, Canada

Current perspectives on play define it as "situational and reliant not simply on abstract rules but also on social networks, attitudes, or events in one's non-game life, technological abilities or limits, structural affordances or limits, local cultures, and personal understandings of leisure." (Taylor 2006, p.156). Despite several efforts directed at defining and exploring different dimensions of play (Grayson 1999; Deighton & Grayson 1995; Holbrook 1994), consumer researchers have focused mainly on the intrinsic motivations of play and the role of marketers in defining playful experiences (Kozinets et al. 2004). We have limited knowledge about other environmental and social conditions that interfere with consumers' playful activities. In this paper, I propose that two major concepts have been overlooked in their relation to play: technology and community.

The rapid expansion of technologies of information and communication promoted major social changes during the last decades (Mick & Fournier 1998). While previous studies have assessed the impact of technology in consumer agency (Kozinets et al. 2004); self-presentation (Schau & Gilly 2003), and dissatisfaction (Ward & Ostrom 2006), the interfaces between technology and play have received partial attention only. Extant theory develops in two streams: play in offline environments (Martin 2004, Holt 1995, Arnould & Price 1993), and online games studies (Mathwick & Rigdon 2004). Attempts to compare both realms have developed in cultural studies and sociology, suggesting that video games and online games serve purposes that are similar to those of offline play (e.g. Jenkins 1998, Taylor 2006). However, manifestations of nature in these two types of worlds may be essentially different. The offline environment can be perceived through all senses. It can be seen and heard, smelled, tasted, and touched. In such environments, players are subject to weather variations and their actions are usually limited to the capacities of their physical bodies. The offline world is one of potentially risky situations where there is constant need to engage all senses in order to cope with the environment (Dreyfus 2001, Tuan 1998). Cyberspace, in contrast, is perceived as "physically safe", decontextualized and aseptic (Wellman & Gulia 1999). While the efforts made so far to understand the particularities of each realm are noteworthy, we lack empirical accounts of the interfaces between the online and offline, technology and nature, in play-related activities enacted by consumers.

I complement prior research by investigating consumer practices in a playful context that involves online and offline activities: geocaching. Geocaching is an increasingly popular game played with the use of GPS devices. Frequently defined as a high-tech version of treasure hunting, it combines technology with outdoor adventure. The basic rule is that individuals hide small containers anywhere in the world and share the geographic coordinates of these caches on the Internet. Players plan a hunt by choosing from a list of caches and their locations on a public website. They download the coordinates to their GPS devices and use them to get to the place where the cache is hidden. When finding a cache, players are asked to sign the notebook, take something from the cache and leave something else to replace what they have taken. When the hunt is over, it is reported on the same website and credit is gained from each cache found. The website geocaching.com has registered over 500,000 players in more than a hundred countries and more than 837,500 active caches worldwide since 2000 (Groundspeak.com).

This investigation of geocaching is an ongoing study initiated in June 2008. I combine netnography (Kozinets 2002) with traditional ethnographic techniques to study geocachers' online and offline activities. I have conducted interviews with geocachers and participant observation in multiple online and offline sites. I gathered field notes, pictures, as well as archival data in the form of podcasts, media texts, and forum discussions.

Preliminary results indicate that the combination of multiple technologies with outdoor activities, nature, and travel attracts and brings together into geocaching individuals with diverse backgrounds, profiles, and motivations. As technology and nature are essential to the game, players need to articulate their incursions into these two apparently opposite fields. While outdoors exploration resonates with the antique "back to nature" sentiment, technology allows for control and safety within the wild and unfamiliar world of nature.

Players also switch between online and offline in order to negotiate the rules of the game, monitor competition, and integrate playful experiences into the space and time of everyday life. It is through online interaction, secured by nicknames and avatars, that players share stories about their hunts for a particular cache, reconstructing them as fantastic, collective experiences. This penetration of offline play into the online realm eventually strengthens the bonds among players and reinforces the communal aspects of play, hence suggesting a fundamental role for technology in shaping communities of play.

These preliminary themes, combined to the growing interest on the communal aspects of consumption (Muniz & O'Guinn 2001) and the increasing pervasiveness of play in current north-American society (Ackerman 1999) suggest that consumer researchers could gain much from an advanced understanding of the communal aspects of play. Although observing that "humans will find community where they will" (Muniz & Schau 2005, p. 746), consumer researchers have recently investigated communities that are mainly related to brands, branded products and the market in general (e.g. Muniz & Schau 2005, Kozinets 2002). Future studies should explore the possibility that play is the central link that brings a community together, helping us understand when and how play and consumption are co-constituted, and extending our knowledge about what sorts of side roles brands and consumption play in constituting communities of practice.

Drawing Association Rules between Purchases and In-Store Behavior: An Extension of the Market Basket Analysis

Julien Schmitt, Loughborough University, UK

Actual observation of shopping behaviors is rarely conducted in marketing research. Behavior is often inferred with a more easily measurable output: purchases. Market Basket Analysis (MBA) is one of many techniques used to study shopping behavior through purchases. It aims to identify the associations between product categories based on purchases performed in these categories. Specifically, it answers the following question: if a consumer buys an item from category A, is he more likely to buy an item from category B?

Though this technique is very popular, it has an important limitation. MBA measures associations between categories by using purchases. However, categories may be too closely related in terms of interest that consumers take in, without exhibiting strong purchase associations. To detect such associations not based on purchases, it is necessary to observe actual in-store behavior: the shoppers' paths through the store, the way they behave within product categories to observe shelves, handle products and examine them. This may reveal consumers' interests for product categories.

Using a new data collection allowing to precisely record and time-stamp shoppers' moves and gestures, we extend the classical MBA by integrating in-store physical behavior in the analysis: we draw associations not only from purchases but also from actual in-store behavior. We compare results of our new method with classical MBA results and show a significant improvement.

From purchase associations to behavioral associations

MBA was at first developed in a brick-and-mortar environment. Associations between categories were computed using panel data. Given that the MBA's practicality, it has known a rapid development. Managers consider it as a useful tool to manage cross-promotions or to develop loyalty programs. Researchers use this technique to study multi-category purchase decisions.

MBA has then been used to study cross-buying on the Internet. However, Internet data has an important difference from panel data: it is not limited to purchase behavior. Navigation data is also available, such as web-pages that are viewed, products that are examined, or specific attributes that are investigated. Research uses it to make associations between categories not only based on purchases, but also

based on navigation patterns that reveal consumers' interest for categories. More accurate associations have been computed using navigation behavior.

If such associations between behavior within one category and purchases within another exist on the Internet, they are likely to exist also in a real context. Indeed, interests for categories are considered a stronger explanation of association than purchases. Thus, we hypothesize that, in a brick-and-mortar environment, adding information about consumer behavior would lead to better associations between categories.

Research methodology

Data collection

To achieve our research objective, we developed a specially designed program. Implemented with a PDA, this program enables a very accurate data collection: Following the shopper throughout the store, the program user visualizes the store map on a screen and can locate the shopper's position by pinpointing it. This captures and time stamps the entire shopping path. When the shopper stops in front of a shelf, another screen enables the user to capture each shopper's action by clicking on different buttons. Thus, the shopping path and actions are time-stamped and automatically entered in a preformatted database.

For this study, we conducted shopper tracking in a medium-sized store specialized in beauty-care products, and we followed a total of 170 shoppers. To avoid bias, we selected shoppers on a random basis. Shoppers were not aware being followed; this allowed for an unobtrusive tracking process.

Model Development

To draw our model, we consider the variable Z_k describing the behavior adopted by the shopper in the category k . Z_k takes four different values, depending on the interest taken by the shopper at the category k . These values are:

- $Z_k="0"$: the shopper does not stop in the category k . It represents the minimum level of interest.
- $Z_k="Stop"$: the shopper stops within the category k and looks at shelves. It represents the first level of interest.
- $Z_k="Examination"$: the shopper is interested enough to handle a product from category k and investigate it. It represents the second level of interest.
- $Z_k="Purchase"$: the shopper is so interested that he decides to purchase an item. This is the maximum level of interest.

To compare performances between associations based on purchases (classical MBA) and associations based on physical behaviors (Extended MBA), we represent both these models by using Z_k .

To represent Classical MBA, we allow Z_k to take only two values: "0" or "Purchase". Thus we are able to compute the following indicator:

$$\text{Confidence}(j;i) = P(Z_i=\text{Purchase} \cap Z_j=\text{Purchase}) / P(Z_i=\text{Purchase})$$

To represent Extended MBA principle, we allow Z_k to take all its possible values: "0", "Stop", "Examination", and "Purchase". It allows the computation of two additional confidence rules:

$$\begin{aligned} \text{Confidence}_{\text{Stop}}(j;i) &= P(Z_j=\text{Purchase} \cap Z_i=\text{Stop}) / P(Z_i=\text{Stop}) \\ \text{Confidence}_{\text{Exa}}(j;i) &= P(Z_j=\text{Purchase} \cap Z_i=\text{Examination}) / P(Z_i=\text{Examination}) \end{aligned}$$

We then compare the accuracy of associations between categories issued from each of the models.

Results and discussion

Our results show that association rules are stronger when physical behaviors are taken into account simultaneously with purchases. In some cases, associations based on physical behaviors alone are stronger than associations based on purchases. This may be explained by the fact that physical behaviors represent consumers' express interests for product categories that are not taken into account by classical MBA. The better performance of the Extended MBA may also be explained by the fact that it takes into account non-buyers. Indeed, a non-negligible proportion of shoppers leaves the store without buying anything and is therefore not taken into account by classical MBA. However, non-buyers have visited the store, handled some products in different categories, which is valuable information to understand associations between categories.

Our results provide a better understanding of the influence of in-store consumer actions on cross-category decisions: some actions performed in a category may influence a purchase in another category.

For a Deeper Understanding of the Sociality that Emanates from Virtual Communities of Consumption

Alexandre Schwob, HEC Paris, France

At a time when the project of reflexive modernization (Beck, Bonss, and Lau 2003) radicalizes modern societies by disembedding the individual from even these "primordial social relations" (Knorr Cetina 2001) which are religious worldviews, previously stable and stratified social hierarchies, and social institutions, consumer researchers have stated that gatherings around specific objects or consumption activities become essential for social ties.

Thus, over the last 15 years, much effort has been dedicated to exploration of various forms and displays of common consumption interests (e.g., Belk and Costa 1998; Cova 1997; Kozinets 2001; McAlexander, Schouten, and Koenig 2002; Muniz and O'Guinn 2001; Schouten and McAlexander 1995; Thompson and Troester 2002). Some authors have strongly advocated that these consumption communities, (sub)cultures, and tribes represent a response to the erosion of traditional forms of sociality (Cova 1997; Firat and Dholakia 1997; Firat and Venkatesh 1995) in which sociality represents "the ways through which actors relate to each other to organise their practices and construe their identities" (Fiske 1998). Whereas more recently some researchers have analyzed deeply the practices of a given tribe (Hewer and Brownlie 2007), strangely enough it has to be acknowledged that very few papers published in consumer research have focused on the social construction of identities of selves in social interaction contexts (Reed 2002), or more specifically on sociality in virtual environments. An attempt to bridge these two gaps has been recently made by Schau and Gilly (2003), but the investigations of these researchers on the different aspects of sociality has not gone beyond revealing the existence of multiple social roles and the self presentations by consumers in cyberspace. I argue that the sociality emanating from Internet deserves to be better understood by considering social sites such as online discussion forums, wherein we get deeper insights into the structural elements that determine consumer identity constructions.

The sociality conveyed by consumption has mainly been conceptualized over the past decades on the individual level through extended self (Belk, 1988) and self presentation (cf. Schau and Gilly 2003), and on the collective level through social practices (Warde, 2005). As Reed (2002) I argue that, although social identity is a rarely used paradigm in consumer research, it is meaningful to conceptualize the role of relations with others and with artefacts in self-conception. I should add that this paradigm can be successfully applied to identity construction processes emanating from technology (Internet) that has a structural potential (DeSanctis and Poole 1994). Following some consumer researchers (Holt and Thompson 2004) and some structuration researchers in Information systems (Whitman and Woszczyński 2003), I chose to direct this paper on the structural focus on the role of agency in social effects. More specifically, this paper is based on traditional "social scientists methods" (Penaloza and Venkatesh 2006) in order to grasp the different ways consumers (as agents) appropriate the online discussion forums of a given virtual community, considered as consumption object and social site (Maignan and Lukas 1997; Presi and al 2006) in which sociality can be investigated. Following Schultz Kleine, Kleine, and Allen (1995), I adopt life narratives to enlighten the importance of others, and the results of personal progression in self-conception.

In order to strengthen the internal validity of the research, I have chosen to investigate forums of one particular virtual community of consumption, www.jeuxvideo.com. It concerns video game players. This website was created in 1997, and members of the community connect on the second most important French Internet forum in terms of volume of activity (measured by posts exchanged). The study proposes a hermeneutical approach applied to consumer experience of discussion forums. The research is inductive and is built upon existential-phenomenological interviews of different forumers at different times.

More specifically, I answer this main research question: "How do consumers appropriate forums of virtual communities of consumption in a sustainable way?" Relationships to forums are the focus of this research, because they constitute the most important part of consumer experience in virtual communities of consumption.

Preliminary results established from interviews of 8 regular members of the community show that, beyond the diversity of perceptions, most consumers agree on the ability of the forums to fulfill evolving needs. Nevertheless, a more precise constitutive analysis reveals elements around which consumer appropriations differ significantly. These are based on routines at the intersection between virtual and real environments, more precisely connexions to the forum, posting activity per se, and socializing from outside (but thanks to) the forums. Interrelationships between these dimensions sustain idiosyncratic knowledge projects (Zwick and Dholakia 2006) that are more or less actively sought by consumers. These knowledge projects are experienced throughout different subject positions related to different practices. Consumers build more or less salient social identities around these positions.

Two fundamental dimensions tend to influence a main "consumption logic" adopted by a given forumer: the degree to which the forum is associated to the knowledge project on a) consumption objects (here, video games) and b) other consumers. According to her/

his personal situation within these two dimensions, a forumer is more or less likely to be situated in “consumer”, “expert”, “communal”, or “social actor” logic. A given consumer can shift from a given logic to another during his/her foruming experience. Interrelationships between these “consumption logics” have now to be more deeply explained and validated with other data and possibly other methods like semiotic squares. Each of these coexisting logics seems to foster subject positions on more or less “locally grounded” and more or less “social” practices (e.g., trolls, polls, games, rankings, conflicts, hacks...) which create the culture of the forum. “Locally grounded” practices are generally deeply tied to the coexistence of different visions of forum “materiality”.

In conclusion, beyond extending knowledge on virtual communities of consumption, this research contributes to the Consumer Culture Theory (Arnould and Thompson 2005) stream of research, aiming to anchor consumer research in the sociological paradigm more deeply. As such it opens many perspectives to study the role that consumption plays in social ties.

I Shouldn't, or Should I? Distinguishing Shame and Guilt in Goal Pursuit

Rania Semaan, Baruch College CUNY, USA

Stephen Gould, Baruch College CUNY, USA

A goal is a desired outcome which enters the mind of a decision maker as a mental representation associated with affect toward which action may be directed. This research focuses on the emotional reactions to goal progress. Much of this literature has examined these relations at the level of affect. However, two equally valenced but different discrete emotional reactions to goal progress could lead to two different subsequent goal-related behaviors. In this research the focus is on two emotions that arise while evaluating oneself: Shame and Guilt. Tangney (1990) posits that even though shame and guilt might arise from the same situation, they could lead to two different actions. Shame involves negative feelings about the stable, global self; whereas, guilt involves negative feelings about a specific behavior taken by the self. Guilt has been shown to play an important role in choices and self control. However, to the best of our knowledge, there is little research to date that investigates the effect of shame on goal-related behavior.

The goal progress literature offers opposing predictions about goal-directed behavior. On the one hand, when individuals fail to accomplish their goal they are expected to experience negative emotions and negative emotions that signal an unfavorable event reinforce avoidance behaviors and therefore lower goal performance (Ilies and Judge, 2005). On the other hand, negative emotions signal a slower-than-expected progress which in turn leads people to try harder and increase their effort to accomplish their goal (Lawrence, Carver, and Scheier, 2002).

In guilt the object of concern is some specific action or failure to act. Therefore, when guilty, people feel that they did a "bad thing"; their self-concept and identity remain intact and the self remains "able". This causes a motivation for reparative action such as confessing, apologizing, and repairing.

In shame the object of concern is the entire self. When something bad happens it is experienced as a reflection of a bad self where the entire self is negatively evaluated. When experiencing shame, people feel as if they are a "bad person" with a considerable shift in self-perception. When ashamed, people want to remove themselves from the situation that has led to this experience (Tangney 1990).

Hence, we predict that when people feel guilty towards their goal progress, they would blame it on the behavior rather than the self. Therefore, they would want to repair their wrong deeds by striving harder towards their goal. Whereas when people feel ashamed towards their goal progress, they would blame it on their inability to keep on progressing towards their goal. Their self perception is changed and hence they would have an avoidance reaction and this will lead to goal violation.

However, this effect is moderated by two individual difference factors, shame proneness and guilt proneness. Each individual has the capacity to experience both shame and guilt. However some are more prone to one than the other. Only people high in shame proneness tend to blame the self when failures occur. They actively conceal their negative personal information which may lead to better performance at work. They also tend to experience self-derogation by devaluing the self (Harder, Cutler, and Rockart 1992), whereas people high in guilt proneness tend to blame the failure on the act rather than on the self. Zemack-Rugar et al. (2007) showed that only people who are high in guilt proneness tend to respond to guilt inducing situations and repeatedly link guilt with abstinence. When primed with guilt only those who were high on guilt proneness would show reduced levels of indulgence compared to those who were low on guilt proneness. Therefore, we extend their findings to predict that only those high in shame proneness and low in guilt proneness would respond to a shame inducing situation and when primed with shame they would tend to devalue the self and feel that they are unable to pursue their goal and therefore violate it.

Study 1

Method: 80 subjects participated in the study for course credit. We designed a 2 (Prime: Guilt vs. Shame) x 2 (Guilt proneness: Low vs. High) x 2 (Shame Proneness: Low vs. High) between subjects design.

First, subjects were given the shame versus guilt manipulation. They were then given the manipulation checks followed by a savings goal scenario. They were told to imagine that they have had a saving goal for the past few months. Then they were told that a friend of theirs calls and is going to a concert. Then they were asked to choose whether they would buy the package or not; where choosing to buy the package will be the goal violation. And finally subjects were given the SCAAI scale to assess the level of proneness to shame versus proneness to guilt.

Results: Results showed a significant three-way interaction between prime, guilt proneness and shame proneness ($F(1, 79)=4.2, p < 0.05$), where those who are high on shame proneness and low on guilt proneness and are primed with shame chose to violate their goal with a mean of 0.752 as opposed to 0.285 (subjects primed with shame but were low on shame proneness and high on guilt proneness). All other effects were not significant ($p > .05$). These results are consistent with the hypothesis that shame leads to avoiding your goal and in turn violating it.

Conclusion

By introducing shame, we were able to address the opposing predictions of goal failures on subsequent behavior. Moreover, we showed that even though shame is more intense and more painful than guilt (Tangney et al 1990), it doesn't necessarily lead to higher goal performance.

In subsequent studies, we aim to address the limitations of the first study. First, we will elicit shame and guilt through goal-related manipulations. Then, we aim to show that the underlying mechanism behind these effects lies in attributing the failure to oneself. Finally, we aim to explore how shame would interact with two regulatory focus orientations (promotion versus prevention; Higgins 2002). In this sense, goal failure could stem from not doing a good thing (e.g. not going to the gym) or doing a bad thing (e.g. eating unhealthy food).

Social Desirability and Indirect Questioning: New insights from the Implicit Association Test and the Balanced Inventory of Desirable Responding

Hendrik Slabbinck, Ghent University, Belgium
Patrick Van Kenhove, Ghent University, Belgium

Contrary to previous studies that treated Social Desirability Bias (SDB) as a one-dimensional construct, the two-dimensional Balanced Inventory of Desirable Responding, revealed that Indirect Questioning (IQ) is not completely free from SDB. IQ avoids egoistic response tendencies, but not moralistic response tendencies. Furthermore, by combining IQ with the Implicit Association Test (IAT) and behavioural measures, results indicated that IQ assesses individual differences of both the participant and the third-person, used as subject in IQ. The immunity to SDB of the IAT is further confirmed. The study topic was physical concern and designer clothes.

Introduction

When asking socially sensitive or delicate questions, respondents will not always reveal their true thoughts and prefer to respond in a socially correct manner. This discrepancy between someone's true and reported thoughts is called Social Desirability Bias (SDB) and can easily lead to faulty conclusions (Tourangeau & Yan, 2007). SDB is even considered one of the major sources of systematic error in social sciences research (Mick, 1996). Surprisingly, given the importance and omnipresence of SDB, only few marketing researchers have taken SDB into account in their research (Steenkamp et al., in press). Even, if SDB is considered, most researchers applied (a short form of) Marlowe and Crowne's one-dimensional scale (1964). Recent studies, however, indicated that some people are more likely to exhibit SDB in a communion-related context, associated with love, connectedness, ... whereas other people are more likely to exhibit SDB in an agency-related context, associated with power, status, These two types of SDB are referred to as moralistic (MRT) and egoistic (ERT) response tendencies (Paulhus & John, 1998). Currently, only Paulhus' Balanced Inventory of Desirable Responding (BIDR: Paulhus, 1992) is able to distinguish between MRT and ERT.

Instead of assessing SDB, different approaches exist to avoid SDB. Two such approaches are Indirect Questioning (IQ) and the Implicit Association Test (IAT: Greenwald et al., 1998).

With IQ, sensitive questions are reformulated in the third-person. As such, while respondents are uninhibitedly describing the opinion of the third-person, they are revealing their own opinion because the respondents' own opinions serve as their reference point. Despite its ability to avoid SDB and its simplicity (Fisher, 1993), the validity of IQ is still questioned because respondents could give estimates of the true answers of the third-person instead of projections of their own thoughts. So far, this question has not yet been fully answered.

The IAT, a response latency task initially developed to measure implicit attitudes, has received a remarkable level of attention to validity concerns. Several studies also concluded that the IAT is rather immune to SDB (Nosek et al., 2007). However, compared to IQ, the IAT requires a complex, time consuming administrative procedure. Moreover, the IAT only produces relative measures with arbitrary zero-points.

Research Objectives and hypotheses

The validity of IQ will be studied by combining an IQ and IAT measure of the same concept. In sum, the first goal of this research is to provide a firm answer to the question whether and under which circumstances IQ is able to avoid SDB. Second, a large collection of validity studies involving the IAT (Greenwald et al., in press), is persuasive evidence that the IAT measures something in the person. Thus, if IQ assesses individual differences of participants and not of the third-person used in IQ, we may expect that the IQ measure will correlate with the IAT measure, notwithstanding many conceptual differences between the two techniques (Sheldon et al, 2007). Finally, to test the predictive validity, IQ and IAT should predict behaviour of participants and not of the third-person.

Research Design

A pretest (n=101) revealed that questioning shopping behaviour of designer clothes was most prone to SDB. As such, participants' physical concern (PhC) was assessed in combination with their possessions of designer clothes (DC). This was done with a 3 X 2 within subjects design. PhC was assessed with a direct measure (Netemeyer, Burton & Liechtenstein, 1995), the IAT and IQ (Netemeyer et al.'s scale, rephrased in the third-person). All measures were counterbalanced. Next, SDB was assessed with the BIDR (Paulhus, 1992). Finally, several questions were asked about the amount of designer clothes participants possessed. These questions were also rephrased in the third-person to obtain an IQ measure. Reliabilities of all measures were satisfactory. Data was collected in the context of a methodological course, resulting in a large sample of 348 undergraduate students.

Results

The first major finding is that IQ is not completely free from SDB. As expected, all direct measures (PhC and DC) were significantly correlated with ERT and/or MRT. Furthermore, IQ was not correlated with ERT ($r_{\text{PhC-ERT}}=.01$, $p>.05$; $r_{\text{DC-ERT}}=-.05$; $p>.05$), but correlated significantly with MRT ($r_{\text{PhC-MRT}}=-.12$, $p<.05$; $r_{\text{DC-MRT}}=-.16$, $p<.01$).

The second major finding is that IQ is weakly, but significantly correlated with the IAT ($r=.14, p<.05$). The correlation between direct PhC and IAT is comparable ($r=.16, p<.05$). This indicates that IQ measures at least something in the person. However, analysing the relation between PhC and DC, reveals that IQ measures also something of the third-person. Indirect PhC correlated only significantly with indirect DC ($r_{\text{PhC indirect-DC direct}}=.07, p>.05$; $r_{\text{PhC indirect-DC indirect}}=.2, p<.01$), regardless whether IQ measures were controlled for ERT and MRT. The opposite was true for the direct measures ($r_{\text{PhC direct-DC direct}}=.33, p<.001$; $r_{\text{PhC direct-DC indirect}}=.10, p<.05$). The IAT measure of PhC was only correlated with direct DC ($r=.228, p<.001$) and not with indirect DC ($r=.06; p>.05$).

Discussion and follow-up research

This study clearly demonstrated the added value of the two-dimensional BIDR. The BIDR revealed that IQ only avoids ERT, but not MRT. Results further confirmed that the IAT is immune to SDB.

Correlation between IQ and IAT indicated that IQ is sensitive to individual differences. However, the lack of correlation between IQ and behavioural variables demonstrated that IQ also measures something of the third-person. Clearly, more research is needed to clarify this duality. Currently, a follow-up study is set up in which possible moderators are included. One of these is the perceived similarity between the participant and the third-person used in IQ (Fisher, 1993). If perceived similarity is low (high), participants could be motivated to differentiate (assimilate) themselves from (with) the third person, resulting in high ERT (MRT). Furthermore, this study did only assess behavioural intentions. Follow-up research will also comprise measures of actual behaviour.

The Scented Winds of Change: Conflicting Notions of Modesty and Vanity among Young Qatari and Emirati Women

Rana Sobh, Qatar University, Qatar

Russell Belk, York University, Canada

Justin Gressell, American University of Sharjah, United Arab Emirates

Individual clothing choices reflect a person's conception of social, gender, and religious identities and are means by which wearers situate themselves socially vis-a-vis established codes of behavior (Gibson 2000; LeBlanc, 2007). Muslim women's clothing is a visible form of public consumption, and has been the subject of much debate within social science literatures (for example, Abu-Odeh, 1994; El-Guindi, 1999a, 1999b; Tarlo, 2005; Ruby, 2006; Gole, 1996, 2002). Modesty in clothing for both men and women is central to Islam. Based on Islamic teachings a woman for instance should be covered in a way that does not reveal her sexuality in public. She should wear clothes that cover the body (except face and hands) and which are loose and opaque, neither revealing what is underneath nor delineating sexually attractive parts of the body (al-Qaradawi 1995:79-87). Other public consumption proscriptions include: perfume, explicit make-up, tattoos, plastic surgery, and wigs or hairpieces (Al-Albani 1994).

The requirement for modesty in women clothing has been translated into different forms and styles of body and hair coverings in different countries and also varies from person to person. A large body of work has looked at the diverse meanings and connotations of the Muslim veil and the practice of *hijab* in Muslim countries where women *decide* whether to observe modest dress, including Egypt (e.g., El-Guindi, 1999a, 1999b), Turkey (Sandikci and Ger, 2001, 2005, 2007; Secor, 2002; Gole, 2002), Mali (Shultz, 2007), Cote D'Ivoire (leBlanc, 2000), Indonesia (Jones 2003), South India (Oseall and Osealla, 2007), and London (Tarlo, 2007a, 2007b). Other work has looked at women's dress in Muslim countries where women *are expected to conform* to a black loose outer gown like the abaya or similar garments worn in Gulf countries, Iran (Balasescu, 2003, 2007), and Yemen (Moors, 2007). However, the black abaya within oil-rich Gulf countries is embedded in a different contemporary local context and is increasingly associated with status and wealth (Abaza, 2007). As a result, it has different meanings and connotations from wearing the chador in Iran, the abaya in Yemen, and purdah in South India. In

some Gulf countries like Qatar and Emirates, wearing the black *abaya* and *shayla*⁹ and in some cases the burqa or face cover is not necessarily religiously motivated. It is in some cases a social requirement that women are expected to conform to in order to remain loyal to local customs and traditional culture; it is not a legal requirement like it is in Saudi Arabia. Such loyalty is equated with national pride and dignity. Men also are required to conform to a uniform traditional white dress, the *thoub*, and head covering, the *ghatra*, in public.

Studying women clothing practices in Qatar and Emirates (UAE) is particularly interesting because of the social and economic upheaval that these countries have been undergoing and the concomitant shifts in discourses of beauty, religion and modernity in the media, advertising and other forms of local commercial imagery. The gulf region has been known to be the most conservative part of the Arab/Muslim world where traditional Arab and Muslim values are strictly adhered to and where wearing traditional clothing by both men and women is seen as an essential requirement for cultural integrity and an affirmation of citizenship. However, petrodollar-fueled economic wealth and integration into the global economy have increasingly attracted foreign investment and Westerners to the region, leading to major social changes. In many of the GCC countries, like Qatar and Emirates, the leaderships' desires for modernity and openness to the West has resulted in embracing more western values. This has caused some tensions and concerns that local values and national identities will be diluted and has led to hot debates between those advocating modernity and those emphasizing the importance of preserving local culture. New clothing styles and adornment practices are increasingly adopted by young women in the region and reflect the conflicting forces of Western values that emphasize display of women's beauty and sexuality in the public sphere and traditional values requiring modesty and promoting a virtuous public domain. This contrast is strikingly evident in shopping malls that house both abaya shops and Western style multinational clothing stores with gigantic posters of provocatively dressed Western women. The abaya itself has been gradually reinvented and has evolved from being a concealing garment that hides women's sexuality and beauty in public to an embellished fashionable, trendy haute couture garment that enhances beauty and reveals sexuality. This has created a thriving abaya fashion industry featuring local and European designers attempting to reinvent the traditional plain costume into a sophisticated and fashionable garment that denotes status and prestige and makes statements about women's affinity for fashion and modernity, all supposedly without undermining the local look.

We seek to explore how women negotiate the conflicting tensions between their desire for fashion, elegance, display of beauty, and expression of individuality in the public sphere on one hand, and their desire to be loyal to local culture and observe proper Muslim dress on the other hand. We look at dress not only as clothing but as including all bodily adornment and beauty enhancement practices (e.g., shoes, purses, watches, jewelry, sunglasses, perfumes, make-up, henna, and cosmetic surgery) that form women's looks in the public sphere. We use insights from in-depth interviews with twenty four Emirati and Qatari female students to ascertain the dynamics underlying these conflicting imperatives of modesty and vanity and to capture some of the ambivalence inherent in these performative constructions of female identity and conceptions of the self.

Preliminary findings reveal that young women resolve conflicting tensions between vanity and modesty on one hand and traditional and modern on the other, through syncreticism rather than forced choice. Thus, many choose a traditional black abaya covered with expensive Swarovski jewels. The abaya that many young women choose is also more colorful, form-revealing and gives more hints of the outfits they wear beneath. The shayla is also worn sophisticatedly high and exposes some of the hair. The traditional garment is increasingly assuming a modern fashionable appearance accessorized with jewelry, designer handbags and high heel shoes, huge and catchy sunglasses. The look is complemented with flawless make up, nails and strenuous perfumes. The abaya that used to be a unifying garment that expresses women collective religious and cultural identity has evolved into a singularly self-identifying look that is expressive of status, distinctiveness and personal identities. It is used by girls to make statements about their personal tastes and affinities to fashion. Findings also reveal that girls choose different garments, scents, and makeup in different settings. And they find ways to rationalize their own appearance choices while distinguishing it from other practices that they condemn (Bier, 1986; Greenwalt, 1986; Scott and Lyman; 1986). Rather than the dichotomous choices posed by Western authors (Lexus vs. Olive Tree; McWorld vs. Jihad), they have chosen to combine both.

⁹The black abaya is a long black loose outer garment worn by women in most gulf countries. It is intended to hide the curves of their bodies, while the shayla is a black head cloth used to cover their hair. The abaya is made of two layers of thin material to make sure it is not transparent. Some women also cover their faces with a black veil—niqab— although there is wide agreement amongst Muslim scholars that this is not a religious requirement for physical modesty in Islam but more of a norm for women in some social circles.

Consumer Pride: Emotion as a Social Phenomenon

Katherine Sredl, University of Notre Dame, USA

Consumer emotions are rarely examined from a phenomenological perspective, with few exceptions. One consumer practice that generates emotion and involves consumption is ritual (Ruth, Otnes, and Brunel 1999). According to Collins' Interaction Ritual Chain (2004), elements of sustained rituals elicit emotion in observable ways. This working paper investigates how the elements of consumption-based family rituals elicit pride. It takes an ethnographic approach, using long interviews and participant observation. The focus is on working class, middle class, and upper middle class Sunday family dinners in contemporary Zagreb, Croatia. The findings point to time, aesthetic goods, and family as elements that elicit pride. The paper presents a construct of consumer pride.

Conceptualization

Few articles in the field of consumer behavior research look specifically at pride. Using experimental research, scholars examine pride as a variable to manipulate in persuasive communications (Aaker and Williams 1998) or as a variable in consumer decision-making (Louro, Pieters, and Zeelenberg 2005; Mukhopadhyay and Johar 2007). In a related field, social psychologists note that pride emerges in social contexts and plays a central role in facilitating relationships and in maintaining social hierarchies (Leary 2007). Pride is also distinct from hubris (Tracy and Robins 2007). In spite of the growth of research in the sociology of emotions, there is little research on pride in that field (Turner and Stets 2006). Although emotions arise in ritual, interpretive consumer research on rituals tends to focus on individual practices or on social relationships (Rook 1985; Belk, Wallendorf, and Sherry 1989). Scholarship on specific group rituals, for example, family meals, tends to examine the role of ritual in creating meanings at the group and social levels (Wallendorf and Arnould 1991). Research on consumption-based rituals such as gift-giving argues that individual emotions are an important outcome of these interactions (Ruth, Otnes, and Brunel 1999; Wooten 2000).

I apply Interaction Ritual Chain (IRC), a theory for understanding the relationships between emotions, rituals, and goods, on a micro (small group) as well as a macro-social level (Collins 2004). According to Collins' Interaction Ritual Chain (2004), elements of sustained rituals such as Sunday family dinner reinforce expression of emotion and the status of symbolic goods. My question in this research is: how do consumption-based family rituals elicit pride through the use of aesthetic goods? Overall, this research project will contribute to interpretive consumer research by examining relationships between consumer rituals, aesthetic goods, and family consumption, focusing on three points that, so far, have received little attention in the literature. First, this work aims to provide a means for understanding emotions from a phenomenological perspective. Second, it develops a construct of pride, a specific emotion elicited in rituals. Third, it will consider the ways emotions elicited in ritual influence the consumption of aesthetic and luxury goods (Charters 2006).

This work examines the role of pride and aesthetic goods (i.e. tableware) in consumption-based family rituals in contemporary Zagreb, Croatia, a society that experienced the transition from state socialism as well as war in the 1990s. The mid-day Sunday meal ritual has been practiced among members of working, middle, and upper middle classes in Zagreb through pre-socialist, socialist, and post-

socialist (i.e. contemporary) eras. For decades, 2:00pm to 5.30pm on Sunday has been considered a sacred time (Belk et al.) in Zagreb, as all other activity is suspended, while generations of family members gather in the home for lunch.

Globalization has brought many changes, from new suburban shopping centers outside Zagreb, open on Sunday, to new hours for the working week. In the Yugoslav period, the work day ran from 7 a.m. to 3 p.m., providing non-working time in the daylight hours. Sunday was a non-working day. Time outside of work was for leisure and family. Now, the work day runs until 5 p.m. Supermarket chains from Austria and Italy expanded into Zagreb's suburbs and opened on Sunday. Sunday is the second most profitable day of the week for the mega-grocery stores in the suburbs ("Croatian Firms," 2009). The influence of these local and global forces on families and their social function has been significant (Ule 2004). Exploring the elements of the Sunday mid-day, such as emotions elicited, tableware used, time held, group members attending, and place held, is an opportunity better understand the role of ritual in globalization, the role of aesthetic goods in ritual, and the role of emotions in maintaining (or devaluing) rituals.

Method

Conducting depth interviews, small focus groups, and participant-observation of meals allowed this research to move beyond the traditional experimental examination of pride as solely an individual, psychobiological, or cognitive experience (McCracken 1988). In interviews, I used a semi-structured interview format to allow themes to emerge (McCracken). I inquired about informants' meal practices in their families, about their tableware inheritance and use, and about their views on family consumption and, finally, the transformation. I used the snowball method of sampling and recruiting informants who are theoretically representative; I accessed informants through key informants and through friends. A total of 39 informants participated in audio and/or video recorded interviews. Interviews were conducted in Croatian or English and yielded over 17 hours of audio, and about 560 pages of transcripts, translated into English by native Croatian speakers. I participated in 15 family meals over the course of fieldwork, which yielded 100 pages of notes and reflections. Interviews and participant observation were conducted in Zagreb, from October 2006 to July 2007.

Findings

The data analysis applies Interaction Ritual Chain (IRC), a theory developed by Randall Collins (2004), to develop a construct of pride, to understand the phenomenological experience of consumer emotions, and to consider how pride influences the consumption of goods in rituals. The findings indicate three stereotyped components of the ritual-time, aesthetic goods, and family-are integral to eliciting pride. Together, these elements create moments for experiencing pride, influence the use of aesthetic goods to elicit and communicate pride, and reinforce group hierarchies and emotional bonds. The ritual expresses pride in cultural continuity in the context of globalization. Furthermore, cultural norms affirm pride and discourage hubris. A construct of consumer pride is offered, based on the findings, with reference to social psychology scholarship on pride:

Consumer pride is an adaptive, positively valenced, self-conscious emotion, felt in the body, emergent in socially situated action, to which consumers ascribe culturally bound meaning, before, during and after interactions. Consumer pride is bolstered by acknowledgement of the self as responsible for socially valued outcomes, by display and use of goods and services, and by feedback from others. Pride is an enduring emotion, felt at the individual, group and cultural levels, that moderates consumption choices by motivating consumers to perform positive social roles through consumption, and to elicit recognition of individual achievement through consumption and social display. In sum, this working paper argues that consumers experience specific emotions (pride) in rituals. It presents a definition of consumer pride. It also argues that consumers use aesthetic goods to express pride. Future work will further explore the relationships between pride and the ritual elements and processes that elicit emotion: time, aesthetic goods, and family.

Consumer Knowledge as a Moderator of Specificity-Based Product Selection

Jason Stornelli, University of Michigan, USA

Anirban Mukhopadhyay, Hong Kong University of Science and Technology, Hong Kong, China/University of Michigan, USA

Andrew Gershoff, University of Michigan, USA

One way marketers differentiate functionally equivalent or similar offerings is by varying product claim specificity. For example, Wyeth's *Advil* brand is promoted as "the every pain reliever," but *Advil* also offers a specific migraine product. Both contain the same active ingredient (200mg solubilized ibuprofen)—but do migraine sufferers prefer *Advil Migraine* to *Advil Liqui-Gels*? Previous research has shown that consumers favor products with specific claims over those with general positioning strategies. For instance, Chernev (2007) demonstrates that "all-in-one" products offering a number of functional features are perceived as less effective compared to products with one focal feature. However, we argue that preference for specific-use alternatives may depend on the consumer's subjective category knowledge and present a study demonstrating this effect.

Prior research demonstrates that knowledge serves as an influential factor in the type and extent of information search behavior (Brucks 1985; Moorman et al. 2004), the range of choice heuristics available (Bettman, Luce, and Payne 1998), and the formation and recall of category structures (Hutchinson 1983; Alba and Hutchinson 1987). However, the relationship between objective and perceived or subjective knowledge remains unclear (Moorman et al. 2004). Subjective knowledge has been demonstrated to affect consumer choice behavior for new items with which consumers have little familiarity (Park et al. 1988), but to our knowledge, questions remain regarding the impact of subjective knowledge on familiar product categories. Together, this research suggests consumers obtain, interpret, and employ product attribute information differently depending upon both their objective and subjective knowledge, which may affect preferences for high or low product claim specificity.

We performed an experiment to examine whether perceived knowledge influences preferences for specific versus general products. The study employed a 2x2 design (*choice set*: [specific v. all-in-one products] v. [specific v. general products] x *price*: high specific v. low specific) that also measured subjects' self-reported product category knowledge. Subjects were randomly assigned to conditions with stimuli order counterbalanced.

Participants were asked to imagine they had a headache and were at a store to buy medication. They were instructed to choose between two analgesics from the same fictional brand with varied package designs. All subjects saw a specific "headache-relief" product packaged in a box featuring a glowing orange head and a "relieves your TOUGHEST headaches" tagline. Next to this, subjects saw one of two alternatives. In the all-in-one condition, an all-in-one "pain relief" product indicated for multiple uses was presented next to the specific product—these multiple uses were depicted by a glowing orange back, hand, and head on the box. Alternately, in the general condition, a "pain relief" product featuring a body with an all-encompassing orange glow was shown next to the specific product. Both alternative products claimed to relieve "your TOUGHEST pain."

Product prices were varied by condition to determine whether consumers would simply select the less-expensive alternative and to increase generalizability. In the high specific price condition, the "headache relief" medicine was priced at \$9.99 while the alternative was priced at \$7.99, and vice-versa in the low specific price condition.

After choosing an analgesic, participants' subjective knowledge of the product category was assessed using a continuous self-report measure.

Subjects reporting lower perceived knowledge selected the specific-use headache medication with approximately the same frequency when it was paired with either the general-use or all-in-one products. However, among higher-knowledge participants, choice share of the specific-use product dropped significantly when presented alongside the multiple-use item. Thus, while the majority of consumers preferred the specific-use product, a significant number of higher-knowledge individuals preferred the all-in-one item. All main effects and interactions involving price were non-significant.

These preliminary findings suggest that subjective knowledge influences consumer preference for specific-use products, but additional research is needed to untangle the causes underlying this phenomenon. One possibility is that the specific ailments listed on the all-in-one package could invoke feelings of marketplace metacognition (Wright 2002; Brown and Krishna 2004), such that higher-knowledge consumers may be making choices to counteract perceptions that marketers are encouraging redundant purchases by offering both specific and general alternatives. Alternately, metacognitive perceptions of extensive knowledge may be influencing consumers' propensity to think broadly and consider multiple usage scenarios—past research has demonstrated a broadening effect for high objective knowledge in brand recall tasks (Cowley and Mitchell 2003), but the role of subjective perceptions of knowledge remains unclear.

Alternately, subjective consumer knowledge may be influencing goal-directed purchase inferences. Recall that we gave subjects the specific goal of buying a product for headache relief. Recent research (Labroo and Kim 2009) demonstrates that consumers use increased processing effort as a signal of product instrumentality when engaged in goal-directed situations. Our findings concern the difficulty of matching an appropriate product to a salient need; this difficulty may vary depending upon the consumer's level of knowledge and the level of product claim specificity. Thus, it is possible that the higher effort required to process the all-in-one product leads higher-knowledge participants to prefer it. However, when a general-use product is included in the choice set, and/or when the consumer has a low level of knowledge, the required processing effort may be too great, leading consumers to prefer the "easier" specific product.

Follow-up studies are being considered to analyze these theoretical implications. Future experiments will manipulate the perception of knowledge by employing difficult/easy product tests for greater experimental control. We also plan to vary the level of objective

ingredient information provided to further assess the interaction with subjective knowledge perceptions and any resulting inferences regarding similarity. Subsequent tests will also focus upon the specific v. all-in-one choice set as it appears consumers are less able to infer that the general-use product is appropriate for their functional needs. Confidence, risk-perception, and resistance to persuasion will also be assessed, as these constructs are related to consumer knowledge and metacognition (Campbell and Goodstein 2001; Bearden, Hardesty, and Rose 2001; Brown and Krishna 2004).

We are hopeful this research will contribute to a fuller understanding of preference for specific versus more general products, and of inferences consumers form from their subjective and objective knowledge.

In the Mind's Eye: Embodied Simulation and Product Judgment

Aner Tal, Duke University, USA

Abstract

Spontaneous mental simulation of product interaction can have systematic effects on product judgment. Two studies demonstrate predictable effects of consumers' physical states on judgment. Physical states affect the simulated experience of products, and consequently judgment of corresponding product attributes. This notion is demonstrated for judgment of product size (study 1) and the energy provided by energy drinks (study 2). Crucially, the effects of physical states relevant to product experience on judgment are shown to depend on conditions supportive of spontaneous simulation (study 2).

Consumers' often engage in mental simulations of future consumption episodes. These simulations have been alternately named mental simulations (Escales 2004), imagery (MacInnis and Price 1987), or consumption visions (Philips 1996). Such simulations have a variety of mostly positive effects on product judgment, including improving consumers' attitude towards products (Escales & Luce 2003; Philips 1996), as well as their consumption experience (Tal, Huber and Lieb 2009).

The Spontaneous Occurrence of Simulation

Interestingly, Keller and McGill (1994) revealed that consumers may engage in imagery spontaneously and without explicit instructions. This corroborates earlier research and speculation (MacInnis and Price 1987). Various factors have been linked to personal and situational propensities to imagine product consumption, including vividness (Keller and McGill 1994; Nowlis et al. 2004), choice mode (Bolton 2003; Shiv and Huber 2000), and product type (Dhar and Werternbroch 2000). Recent work (Tal 2009) builds on this research in suggesting further conditions for the spontaneous occurrence of simulation.

Research in cognitive psychology corroborates wide-spread use of spontaneous simulation of various actions (Barsalou 2003; Jeannerod 2001). People simulate actions and interactions with objects in response to a variety of stimuli, including the observation of others' actions (Gallese and Goldman 1998), words (Tettamanti et al. 2005), and pictures of usable objects (Grafton et al. 1997; Grezes et al. 2003). Importantly, the process of spontaneous simulation is not necessarily conscious, and can consist of brain patterns simulating actions that are not accessible to awareness (Niedenthal et al. 2005).

The prevalence of spontaneous simulation suggests simulation of product interaction might occur even in the absence of explicit instructions to simulate. This makes simulations more general than it would be were it restricted to cases of deliberate imagination, which in turn raises the importance of exploring its effects on judgment.

Simulation Effects on Judgment

Spontaneous simulations are by their nature embodied, in that they involve the consumer acting with their physical body as they are at the moment of simulation (Barsalou 2003). As a consequence, simulation takes into account what actions the consumer can currently engage in. For instance, if a person cannot grasp an object from where they stand, no simulation of grasping will occur (Handy et al. 2003; Fischer and Dahl 2007).

In other words, simulations are sensitive to factors that would affect actual action. Accordingly, simulation will reflect how a product will be experienced given the consumer's current physical state. This may in turn lead to alterations in judgment corresponding to the alterations in simulated experience.

The current work explores some of these effects of spontaneous simulation on judgment. Specifically, the studies reported here show that in situations that support spontaneous simulation (studies 1-2) but not in situations that do not support it (study 2) judgment will reflect the manner in which subjective product experience should be affected by consumers' physical states.

We focus, in particular, on judgment of product size and energy. Subjectively, products provide less sustenance to people who require greater energy to act. Carrying a heavy burden necessitates more energy for action (Proffitt et al. 2003). Hence, products should be experienced as providing less sustenance (i.e., being smaller) and supplying less energy when consumers are burdened. Crucially, we project that this effect will depend on the occurrence of spontaneous simulation, and will therefore occur only in situations supporting simulation.

Study 1

Design. The study was a 2-cell repeated measures design. Participants were randomly assigned to either heavy backpack (15% of body-weight) or light backpack (5 pounds) conditions.

Procedure. Participants ($N=14$) put on the backpacks at the beginning of the study and walked a distance of approximately 30 feet before beginning so that they could feel the weight of the backpacks. They then answered questions about 21 grocery products. The questions were "how much space each product would consume to store in a pantry relative to other grocery products" (1-9 scale), and "How many days it would last for the average 4 people family" (days).

Results. The data were analyzed using a mixed-model ANOVA with product as a repeated measure. Participants carrying heavy backpacks estimated products as taking up less space (2.49 v. 3.37) and lasting less days (2.98 v. 4.89), $p<.0001$. It appears, then, that conditions supporting simulation lead burdened participants to judge products as smaller, since they would experience them as smaller (i.e., providing less sustenance) in actual experience. This alteration of subjective experience is reflected in simulation, and, consequently, judgment.

Study 2

The second study aimed to provide a conceptual replication of study 1 by demonstrating effects of physical burden on estimated energy provided by energy drinks. The hypothesis was that given that burdened participants require more energy for action, they would estimate energy drinks provide less energy. Importantly, we predicted that such a difference would emerge only when participants could see the energy drinks while answering the question. This is because visual inputs are crucial for the occurrence of spontaneous simulation (Tal 2009).

Methods. Participants ($N=72$) were randomly assigned to four groups. The design was a 2 (burden) X 2 (drink visibility) repeated measures design. Half the participants could see the drinks during the study, and half could not. Participants estimated how many hours of energy each of 6 energy drinks provided.

Results. There was a significant interaction drink-visibility X estimated-energy interaction ($p=.05$), such that participant who could see the drinks judged them to provide less energy if burdened by a heavy backpack (2.31 hours) than if not (2.85 hours, contrast $p=.05$). There was no such effect for participants who did not see the drinks.

Discussion

The studies presented here support the role of spontaneous simulation in determining consumer judgment. Specifically, the studies demonstrate that consumers' physical state can lead to predictable effects on product judgment under conditions that support spontaneous simulation. Future research should add to the generalizability of the phenomena by exploring effects brought about by different physical states and on different judgments, and further explore the process of spontaneous simulation in consumer judgment.

On Your Mind=On Your Back: How Physical Burden Works as Mental Burden

Aner Tal, Duke University, USA

The current research examines whether physical load acts in a manner that is functionally equivalent to that of mental load. Based on the reliance of both physical and mental drains on a common physical resource, we hypothesize that consumers who are under physical load will function similarly to consumers who are under mental load. This hypothesis is supported in three studies showing that physically burdened participants are willing to spend less effort in a self-control task (study 1), show greater inclination towards unhealthy but tasty foods (study 2), and display greater compromise effects (study 3).

Many tasks in consumers' day to day lives require cognitive resources (Baumeister et al. in press). For instance, some choice tasks are effortful and so require mental resources (Vohs et al. 2008). The exertion of self-control, as in the case of dieting or the renunciation of impulse-shopping, also requires cognitive resources (Baumeister et al. 2007; Vohs and Faber 2007). When sapped of mental resources, consumers may accordingly choose options that are less healthy (Shiv and Fedorikin 1999) and defer choices (Pocheptsova et al. 2007). In sum, then, cognitive resources, also termed regulatory resources, fulfill an important function in many aspects of consumer behavior.

Regulatory resources have by and large tended to be an abstract construct lacking in direct measures. However, recent research has begun to link cognitive regulatory resources to measurable physiological variables. Specifically, Baumeister and his colleagues have shown that the level of glucose in a person's blood corresponds to the level of regulatory resources she possesses at any given point (Galliot and Baumeister 2007; Galliot et al. 2007; Mascicampo and Baumeister 2008). Brain areas responsible for regulatory tasks require and consume energy, and the body's level of energy is indicated by its current level of blood-glucose. Consequently, self-regulatory tasks reduce blood-glucose levels, and, correspondingly, reduced blood-glucose levels correspond to reduced ability to successfully engage in self-control tasks.

Naturally, the level of blood-glucose in one's body is a direct reflection of physical, as well as mental, resources. Thus, it stands to reason that physical exertion, because it reduces the level of blood-glucose, would impact the level of regulatory resources consumers possess, and, consequently, impact their inclination for and capacity to successfully engage in self-control tasks.

Prior work on cognitive load and its effect on consumer behavior has, for understandable reasons, assumed that cognitive load is induced by cognitive tasks. The current work, however, explores the notion that physical exertion can function in a manner equivalent to that of cognitive load and so produce the latter's effects on consumer behavior.

Given the prevalence of physical strains in daily life (e.g., carrying heavy shopping bags), that such strain functions in a manner equivalent to cognitive load would be of considerable importance in marketing research. The studies reported here examine this notion by employing a series of tasks known to be affected by cognitive load, and examining whether physical load in the form of carrying a heavy backpack affects them in the same way as cognitive load.

General Methods

The specific manipulation used to manipulate physical exertion was wearing heavy backpacks (Proffitt et al. 2003). Half the participants in these studies wore heavy backpacks (15% of body-weight), and half the participants wear light backpacks (5 pounds). We expected participants wearing heavy backpack to display effects similar to those of cognitive load.

Study 1: Reading Articles

Participants ($N=37$) were asked how many articles they would be willing to read for a class presentation. If physical load acts as mental load, we expected high-burden participants to be less inclined to exert considerable effort, and so report a willingness to read a lower number of articles than that low-burden participants are willing to read.

Results supported the hypothesis: high-burden participants were willing to read 4.3 articles, half the number low-burden participants were willing to read (8.6). The effect was significant at the .02 level: $F(1, 35)=5.77$. In other words, physical load seems, in this case, to have acted in a manner functionally equivalent to that of mental load, reducing participants' willingness to engage in a self-control task.

Study 2: Self-Control in Food Choices

Participants ($N=73$) reported on their preference between unhealthy but attractive foods (chocolate cake, chocolate bar and ice-cream) and healthy but less tasty foods (fruit salad, granola bar, and low-fat frozen yogurt, respectively). Preference for the unhealthy but tasty option was measured on a 9-point scale. Heavy burden participants expressed stronger preference for the less healthy option (adjusted mean 6.89) than low-burden participants (3.7): $F(1, 204)=.02$.¹⁰ This provides further support that high physical load functions in a manner equivalent to high mental load, leading to projected lower performance in a self-regulatory task.

Study 3: Compromise Effect

Consumers are known to fall prey to heuristic choice-strategies such as asymmetric dominance and compromise to a greater extent under cognitive load (e.g., Drolet and Luce 2004). If physical load acts as mental load, burdened participants should choose an asymmetrically dominant option to a greater extent than non-burdened participants. To test this, participants in the current study ($N=110$) chose between three options of both MP3 players and Digital cameras. In both cases one option asymmetrically dominated another. As predicted, high-burden participants chose the compromise option to a greater extent (63.39%) than low-burden participants (49.12%): $F(1, 223)=4.76, p=.03$ (tested with mixed model with product type as a repeated measure).

Conclusion

In all three studies participants carrying a heavy physical burden displayed effects equivalent to those high mental-load participants would display: showing lower willingness to exert self-control (studies 1-2) and a greater use of heuristic choice strategies (study 3). This provides initial support for the functional equivalence of physical and mental load.

Further studies should examine whether physical load acts in a manner that is functionally equivalent to mental load in other tasks. In particular, actual, versus predicted or simulated tasks, should be employed. Further, the alternative explanation of burden acting as a simple drain on attention rather than drawing on physical resources should be ruled out. This could be achieved by using a physical drain manipulation that is unlikely to draw attentional resources, such as exercising for ten minutes prior to participation in the study.

¹⁰Since some participants in this study breezed through the study, participants who took less than one SD below the mean time to complete the study were eliminated from the sample. There was no difference in completion time between the high and low burden conditions.

Familiarity Hijack: How Morphing Faces with Celebrity Images Can Enhance Trust

Rob Tanner, University of Wisconsin-Madison, USA
Ah-reum Maeng, University of Wisconsin-Madison, USA

Social psychologists have long observed that individuals have a preference for people similar to themselves, judging them as being more attractive (Shanteau and Nagy, 1979), more persuasive (Byrne, 1971), and even being more helpful toward them (Park and Schaller, 2005). More recently, advances in technology have enabled new paradigms for researchers interested in the effects of similarity. For example, researchers specifically interested in the domain of facial similarity have used new graphical technology to morph individual's own faces into the faces of others.

In a series of studies Bailenson et al. (2009) created composite images by morphing the faces of politicians with the faces of experimental participants in a ratio of 65% politician, 35% participant. This ratio is significant as the authors demonstrate that it produces composite faces within which individuals could not perceive their own image. Put differently, participants universally believed they were viewing unaltered pictures of the politicians in question. However, while the composite images may have been identified as being those of the politicians, attitudes toward the composites reflected a different story. In fact, in a series of studies Bailenson et al. showed that individuals consistently demonstrated stronger liking for political candidates when the image of the candidate had been morphed to include 35% of the individual's own face. This effect was especially acute for individuals without a strong prior (i.e., weak partisans and independents) and occurred without any conscious awareness of the facial morphing manipulation.

This fascinating finding raises interesting theoretical questions while also opening the door to possible new methods of persuasion. From a theoretical perspective several key questions remain unanswered. In particular, it is not clear if liking for the composite faces was driven by similarity or familiarity since the two are essentially confounded when morphing an individual's own face into a composite image. From a marketing perspective the possibility that the innate persuasiveness of an agent, for example a decorative model in a print advertisement, could be enhanced by facial morphing is very intriguing. The current work was motivated by both of these issues and explores the effects of morphing the faces of public figures and celebrities into unfamiliar faces. Unlike an individual's own face, which is simultaneously both similar and familiar, the faces of public figures are familiar but not similar to the average individual. As such they provide us with a potential method of teasing apart the previously confounded effects of similarity and familiarity.

In Study 1 (N=81) participants rated the trustworthiness of two faces on a 1-10 scale. We chose to focus on trust both because from a persuasion standpoint it is a key component of source credibility, and because simple liking is a key driver of trust (Nicholson et al. 2001). Face one was a neutral male face while face two (henceforth "Bush morph") consisted of the same neutral male face morphed with 35% of the face of George Bush who we reasoned (especially since the study was carried out around the time of the election) should be highly familiar to participants. While participants rated the neutral face on the midpoint of the scale (M=5.3) they rated the Bush morph as being significantly more trustworthy (M=6.9, $t(80)=7.8$, $p<.001$). This result pertained despite 100% of subsequently debriefed participants expressing no recognition of Bush in the composite image. As such, these data support a familiarity explanation as underlying the effect of facial morphing on preference but are inconsistent with a pure similarity explanation as it is hard to imagine how a composite image featuring George Bush would make the resulting face any more similar to our subject population (undergraduate students).

While supporting a familiarity mechanism other explanations could also explain the study 1 data. In particular, a valid alternative explanation would be that individual specific meanings from the minority face in a composite image might be perceived in a morphed face even in the absence of conscious awareness of that face. While one might expect George Bush to represent lack of trust, we can certainly not rule out the possibility that subliminal perception of his identity as a president could increase perceptions of trust. Certainly, assuming that the average individual holds a positive self view, then transfer of individual meaning could potentially explain the Bailenson et al. data, all of which involved participants viewing composite images in which the minority image was their own face. Thus study 2 was designed to disentangle a pure familiarity explanation from an explanation relying on transfer of individual specific meaning.

In study 2 (N=35) participants rated the trustworthiness and athletic ability of one of two faces on a 1-10 scale. Face one was the same neutral male face from study 1 while face two (henceforth "Tiger morph") consisted of the neutral male face morphed with 35% of the face of Tiger Woods. Tiger was chosen both for his high levels of familiarity and popularity, and because he is strongly associated with athletic ability. Thus if individual specific meanings from the minority face are transferred from the morphed face we should expect to see an increase in ratings for athletic ability and trust (via liking). However, if the effects to date are driven purely by familiarity we should expect to see an effect on trust but not one on athletic ability. In fact that is exactly what we found. Consistent with study 1 participants rated the Tiger morph (M=5.33) as being more trustworthy than the neutral face (M=4.0, $t(31)=-1.9$, $p<.07$). However, they perceived no difference between the athletic ability of the Tiger morph (M=2.1) and the neutral face (M=2.4, $p>0.3$). As such these data further support a familiarity explanation as driving the effect on liking and trust and rule out an explanation based on the transfer of individual specific meaning.

Aided Information Retrieval on Content-Based Websites: Learning Faster or Learning Less?

Dimitrios Tsekouras, Erasmus University Rotterdam, the Netherlands

Benedict Dellaert, Erasmus University Rotterdam, the Netherlands

Consumers are increasingly turning to online based searches to obtain information on a wide variety of subjects. For example, in 2008, 80% of US adult internet users searched at least once for information about products, health issues, or other topics. For almost 60% of internet users, the internet constitutes the main means of searching for information (Jones & Fox 2009).

The key objective of such online information searches for consumers is to learn more about a certain topic. As a result it is very relevant to examine how knowledge formation can best be supported by various information retrieval modes that can be applied by websites. The main research question of this study therefore is how different ways of acquiring information through a given website affect consumers' learning and their intention to revisit the website. Online aids offered by websites help people save time (Peterson & Merino 2003) but the amount of learning remains unclear. Therefore these aids may be beneficial for transactional websites (i.e. when looking for a specific product) but not necessarily for content-based websites where consumers aim to acquire new knowledge.

Research on learning and education suggests a greater effectiveness of active learning practices compared to traditional passive learning techniques (McLeod 2003; Bonwell and Eison 1991). Evidence has shown that active learning practices are more effective in terms of learning outcomes and can lead to better student attitudes and improvements in students' thinking and writing (Bonwell and Eison 1991, Laws et al., 1999). The online environment structure offers an immense opportunity for applying active learning techniques through its interactive capabilities. Many studies on e-learning environments showed that e-learning is more effective than traditional teaching mainly due to the crucial role that interactivity plays in knowledge acquisition and the development of cognitive skills, leading to higher learning outcomes and evaluations of the content and structure of the learning process (Khalifa 2002). There is a difference between e-learning and information search on the internet. E-learning constitutes a structured environment with a specific focus and content which is mainly led by the instructor. Online information search comprises a goal oriented task which is led by an individual's need to solve a recognized problem. Past research so far has been focusing on the importance of knowledge formation modes in teaching environments and the beneficial effects of active learning techniques. We expect that this differential effect between active and passive modes also applies in the case of online information retrieval from a website. Therefore, we propose that the use of different information provision modes (aided or unaided search) can influence the retrieval effectiveness of the visitors on a website.

Since learning leads to goal achievement we also propose that it is a key driver of website evaluation and loyalty. Based on goal setting theories, goal achievement leads to higher degrees of satisfaction and attitude towards the medium (Locke & Latham 1990). Consequently, learning plays an important role in the formation of a positive attitude towards content-based websites as well as on the intention of repeated visits. Previous studies have focused on process-oriented learning and the acquisition of skills that could lead to a state of lock-in due to cognitive barriers (Haubl & Murray 2002) but have largely neglected the role of content-oriented learning (Mittal & Sawhney 2001). In this study, we provide an additional complementary explanation of website loyalty by highlighting the importance of content learning in the context of a content-based website.

Finally, we hypothesize that there is an asymmetric effect of aided versus unaided knowledge formation on mode loyalty. Website visitors who are engaged in unaided (active) search modes are expected to be more willing to remain loyal to their initial search mode because they invested cognitive effort in their initial search task and they are expected to be more reluctant to abandon this investment compared to searchers in the aided (passive) knowledge formation mode where no substantial cognitive effort was endowed. This difference can be attributed to the sunk cost experienced by the visitors of the website (Arkes & Blumer 1985). In addition, differences in mode loyalty could be explained by the increased perceived feeling of control as well as enjoyment that the active search mode offers to the visitors (Dellaert & Dabholkar 2009).

Based on an experimental study using a website for health information, we explore how different ways of acquiring information through a given informational website have a different effect on the intention to revisit the website. We manipulated the ways of acquiring information from a website in aided (passively distributed recommendations) and unaided (actively sought information). Based on process and evaluation data from 190 respondents, we find support for our expectation that active information seeking behavior leads to higher retention effects through the greater learning and positive evaluations towards the website and the search experience. We show that the effect of active knowledge formation on website loyalty is fully mediated by its effect on content learning outcomes. Finally, the hypothesized asymmetric effect of active knowledge formation mode of acquiring the information compared is also confirmed, with a higher lock-in state towards the unaided than to the aided information retrieval mode.

From a consumer behavior perspective, it is insightful to investigate how different knowledge formation modes can lead to differences in terms of learning and loyalty. From an online information provider perspective, it is important to understand the ways that several features of a website can lead to repeated visits over time. There is a trade-off between speed of retrieval and learning. Therefore, it really depends on the objective of the visitors, which type of information retrieval mode will lead to the greatest revisit intention.

A Research of the Spillover Effect of Gift Promotion—Its Forming and Fluctuation

Chung-Hui Tseng, Tamkang University, Taiwan

Recently, gift promotion is taken as an important issue for firms. Because the gift is free, consumers tend to discount gift's value. Does this discounting evaluation spill to other products belonging to the same category of the gift so that these products also be devaluated by consumers? The research was going to investigate whether the discounting perception toward gift would spill to other product categories with the same brand of the gift, or spill to the same product category with other brands. In this study, we defined the phenomenon as a "spillover effect of gift promotion".

Reviewing relevant literature, spillover effect was discussed in the field of brand extension or brand alliance; however, little discussions about spillover effect of gift promotion were found. Therefore, it is necessary to deeply investigate the forming and fluctuation of spillover effect of gift promotion. In brief, this research consists of two studies. Study one focuses on the forming of spillover effect of gift promotion. Assimilation and contract effect (Herr, Sherman and Fazio, 1983) was taken as the main theory to infer the formation of spillover effect of gift promotion. Study two further examined its fluctuating factors, including an antecedent factor—promotion depth of gift promotion, two consequent factors—perceived value of spillover effect on the same product with other brand and on the same brand with other product category, and two moderating factors—brand awareness and involvement of gift. Anchoring and adjustment theory (Tversky and Kahneman, 1974; Lola, 1982; Yadav, 1994) was taken as the theory to infer the influence of promotion depth on perceived value of spillover effect.

Experiment design was adopted in the two studies. Subjects were college students by convenient sampling. Subjects of the two studies were different. Study one adopted a 2 (gift promotion: present/absent) groups between-subject design. 50 valid questionnaires were gathered. Study two used a 2 (promotion depth of gift promotion: high/low) x 2 (brand awareness of gift: high/low)=4 groups between-subject design. 324 valid questionnaires were analyzed. Besides, involvement of gift were measured and picked out two parts of sample—high and low score of involvement—to test hypotheses.

In the two studies, measurement of perceived value of spillover effect was as below. For example, the gift in the gift promotion was Adidas running shoes, and we would like to measure perceived value of spillover effect on Puma running shoes. In the first step, subjects were asked to answer this question "before" reading an ads of gift promotion: "If you have a budget to buy a pair of running shoes, how much money ($NT\$X$) would you like to pay it?" Following, "after" subjects reading an ads of gift promotion, they were asked to answer another question: "if you have a budget to buy a pair of running shoes, how much money ($NT\$Y$) would you like to pay a pair of "Puma" running shoes?" Then, the perceived value of spillover effect on Puma running shoes were $(Y-X)/X$. If the score was negative, spillover effect did appear. This is the measurement method of perceived value of spillover effect on the same product with other brand. And, same method was used to measure perceived value of spillover effect on the same brand with other product category of gift.

After statistical analysis, study one found that when gift promotion presented, it had negative effect on relative products with the gift according to significant result of a t-test. In other word, gift promotion caused negative score of spillover effect on relative product with the gift. This study found out the formation of spillover effect of gift promotion.

Following, study two further found that the spillover effect of gift promotion would show up on other products with the same brand of the gift as well as on the same product category with other brand. In addition, based on results of two three-way ANOVAs, as deeper the promotion depth was, the stronger the spillover effect of gift promotion was. Furthermore, brand awareness of gift did play a moderating role on the spillover effect. That is, under high brand awareness of gift, the difference between spillover effect caused by high and low promotion depth of gift promotion was smaller than the difference under low brand awareness. Finally, involvement of gift also did play a moderating role on the spillover effect. That is, under high involvement of gift, the difference between spillover effect caused by high and low promotion depth of gift promotion was smaller than the difference under low involvement.

Research contributions comprised three points. First, this research discussed background theory of spillover effect of gift promotion and offered a reasonable inference for the phenomenon of spillover effect of gift promotion. Second, finding of this research including two studies make gift promotion research much richer. Moreover, this research, based on experimental results, also offered significant managerial implications for managers.

Extended Service Encounters and Customer Emotion Management

Gulnur Tumbat, San Francisco State University, USA

The aim of this study is to understand customers' full emotional involvement in service encounters and reveal the emotional nature of their ongoing self-presentation in extended service encounters. This paper presents an exploratory study into customer emotion management in extended service encounters and argues that customers' co-production of the service experience may also include active monitoring and management of their emotions. Such emotion control and resultant display affect the service outcome not only for those customers themselves but also for service providers and other patrons present. Thus, it is important for service marketers to understand and manage their customers' participation in the service experience also through their emotion management in order to provide satisfactory outcomes.

Commercial Construction of Extraordinary Experiences

Gulnur Tumbat, San Francisco State University, USA

The urge for extraordinary experiences is a dominant theme in modern social thought. Although we came to learn a lot about such experiences from various phenomenological accounts that stand in opposition to mundane daily lives, we know very little about how such experiences are strategically constructed and marketed to consumers. In other words, we have a pretty good understanding of such experiences from the consumers' perspective but production side lack such focus with few exceptions and therefore needs more attention. The aim of this research is thus to tackle this particular gap. This research addresses the following questions: How do extraordinary experiences in the marketplace are promoted? What are the strategies used by marketers? How do consumers expectations are shaped by marketers' representations?

Exploring the Influence of Spirituality: A New Perspective on Senior Consumers' Behavior

Gaëlle Ulvoas-Moal, ESC BRETAGNE Brest, France

Abstract

The interest in spirituality in consumer behaviour is growing. Previous research suggests that consumers' behaviour is influenced by their level of spiritual development and commitment, and that it can be spiritually motivated. This paper explores the influence of spirituality on the consumer behaviour of older adults, as they reach spiritual maturity or undergo intensive spiritual growth toward the end of their life. Responding to a call for conceptual clarification, we define spirituality and differentiate it from religion and religiosity. Spiritual development is explained and the spiritual needs of older adults are described. Research propositions on the influence of spirituality on the consumer behaviour of older adults are presented.

Although spirituality has been a central concept in psychology and sociology for the past ten years, little research has explored its influence on consumer behaviour. The paucity of available research results lies in part from a lack of consensus regarding the definition of spirituality and some confusion between the concepts of spirituality, religion and religiosity (Zinnbauer et Pargament, 2005, McGinn, 1993). Therefore, our study aims at establishing a clear conceptual framework for the study of the influence of spirituality on consumer behaviour, involving a definition of the concept, an explanation of the differences with religion and religiosity and a description of spiritual development.

As the chronological and sequential theory of spiritual development (Fowler, 1981) identifies the last part of life as favourable to increased spiritual development and the achievement of spiritual maturity, thus leading to the display of more salient spiritual characteristics, our second objective is to understand the spirituality of older adults and to identify their spiritual needs.

Our overall objective, therefore, is to draw from the extant literature a research agenda to examine the influence of spirituality on the behaviour of senior consumers. In order to do so, we undertook an extensive inter-disciplinary literature review in the fields of psychology, sociology, psychiatry, gerontology and consumer behaviour, over the last three decades.

Conceptual framework for the study of spirituality in consumer behaviour:

The identification of the characteristics of spirituality (Ulvoas, 2009) leads to the following definition of the concept: "Spirituality is the construction of the meaning of one's life. It appeals to one's ability for transcendence¹¹ and its objects are the inner self, alterity¹² and the sacred¹³." Spirituality involves a spiritual identity, which can be religious or non religious, and a level of spiritual commitment. Religion, as "a unified system of beliefs and practices related to the sacred" (Delener, 1990), is the most common form of spirituality. It has two dimensions: religious identity (the tradition within which the members of a specific religious group practice their religion, for example Christianity) and religiosity, which is one's level of religious commitment.

The spirituality of older adults:

The spirituality of older adults stems from their cognitive maturity and their ability for gerotranscendence, which Tornstam (1994, 1999) describes as a "shift from a rational and materialist perspective to an increasingly cosmic and transcendent one". Spiritual development is a mechanism which enables older adults to cope with the losses associated with old age (in physical and intellectual capabilities, in body image, of the usual place of residence) and to defend themselves against age related aggressions such as ageism (Mattes, 2005; McFadden, 1996).

Their increasing consciousness of their own mortality can generate strong anxiety (Urien, 2008), which spiritual growth can help reduce, as it involves finding the meaning of one's life and death and a reflection on after life (Ita, 1995). Spiritual needs of older adults involve: restoring personal dignity and transcending the losses and handicaps of old age; reducing death anxiety, accepting to die and preparing for dying; finding the global meaning of one's life, believing in the continuity of life and caring about future generations; establishing positive relationships with others, reducing guilt and reconciling; and establishing an intimate relationship with the sacred (McKinley, 2001; Fry, 2000).

Influences of spirituality on consumer behaviour:

The literature review in the field of consumer behaviour reveals four general types of influence of spirituality. First, spiritual identity and related spiritual values influence the formation of attitude, and erect consumption limits and taboos; the stronger the level of spiritual commitment, the stronger this influence (Homer and Kahle, 1988; Mokhlis, 2006). Spiritual values shape consumption ethics while prescribing the rejection of non compatible consumption behaviours such as the illicit purchase of products, and the adoption of those in line with spiritual values such as purchasing from fair trade distribution channels, or religious prescriptions such as the consumption of Halal food for religious Muslims (Shaw and al., 2005; Mokhlis, 2006). Research propositions directly derived from this, which can be shared by all consumers no matter their age, would be that:

P1a: Spiritually committed consumers, including seniors, have a favourable attitude toward the consumption of products and services in line with their spiritual values.

P1b: Spiritually committed consumers, including seniors, have an unfavourable attitude toward the consumption of products and services opposed to their spiritual values.

Second, spiritual development modifies consumers' identity, which leads to a shift in the orientation of their consumption, from ego satisfaction in early stages of spiritual development to an increasing sensitivity to the impact of their consumption on others in later stages (Ball et al., 2001; Hampton et al., 2002). Hence, as senior consumers have been identified as either spiritually mature or intensively spiritually developing, a research proposition could be stated as follows:

P2a: Spiritually mature senior consumers are more aware of the impact of their consumption on their environment and try to use it to create a positive impact.

P2b: Spiritually developing senior consumers use consumption to fuel their spiritual growth.

Third, a market offering can be entrusted with a spiritual value which contributes to the overall consumption value as perceived by the consumer (Holbrook, 1999).

P3: Senior consumers perceive a market offering including a significant spiritual value as superior to a market offering which includes none.

Finally, spiritual needs generate spiritual motives for consumption (Skousgaard, 2006), which can be intrinsic and aimed at satisfying the spiritual values of the consumer, and extrinsic and aimed at enhancing the comfort level and social prestige of their beholder. Both motivations can coexist (Weaver and Agle, 2002). We formulate our two final propositions as:

P4a: Intrinsically spiritually motivated consumption of seniors is geared at satisfying spiritual needs.

P4b: Extrinsically motivated consumption of seniors is geared at increasing their comfort level and enhancing the way their environment perceives them.

¹¹Transcendence corresponds to "an individual's capability to step out of his/her immediate perception of time and space and to see life from a wider, more detached angle" (Piedmont, 1999).

¹²Alterity should be understood in a broad sense and includes other human beings, nature and the universe. It is the interconnection of these objects that enables the holistic perspective on life and provides its meaning (Ulvoas, 2009).

¹³The sacred is "a perception of either a divine being or a sense of ultimate reality or truth" (Larson et al., 1998): God, gods, a divine being, the supreme energy, the wholeness of life.

Conclusion and further research

This paper provides a conceptual framework for the study of the influence of spirituality on consumer behaviour. It identifies seniors as consumers with salient spiritual characteristics, including spiritual maturity or intensive spiritual growth, and potentially strong spiritual motivations for consumption. Further research is necessary to examine our research propositions. Given the importance of these growing demographics in most developed economies and the size of certain age-related sectors, including tourism, a better understanding of the influence of spirituality on consumption would appear essential and long overdue.

Older Adults' Use of New Media

Iris Vermeir, University College Ghent & Ghent University, Belgium
Neal Van Loock, University College Ghent, Belgium

The study of older adults' use of technology has mainly focused on barriers like learning new skills, sensory or cognitive abilities that keep older adults from adopting technological innovations. However, research has shown that some older adults are looking for creative and challenging offers and are active, innovative customers (Szmigin & Carrigan, 2001). The purpose of this research is to investigate which variables determine negative or positive intentions to use new media like the internet and digital TV. The central question

is: what are the underlying factors causing different levels of utilization of new technologies? We want to extend previous research on older adults' use of new media technology by combining cognitive, motivational, individual differences and social factors. We use the technology acceptance model (TAM) (Davis, 1986) as a basic framework to test our hypotheses. TAM includes both cognitive factors and motivational factors to investigate technology acceptance and has been successfully used in a wide spectrum of studies (Venkatesh & Davis, 2000). Two important aspects of TAM are perceived ease of use and perceived usefulness which in turn influence –through intentions- acceptance and use of the new technology. Despite vast support for the TAM, additional external variables could influence technology acceptance (Venkatesh, 2000). For example, the impact of user characteristics like individual variables (personality) on perceived ease of use and usefulness as the main factors that influence the behavioral intention to use the system and on behavioral intention as well, is not adequately regarded yet. Previous research already suggested that individual differences are significant factors in explaining both, technology acceptance and user behavior (Arning & Ziefle, 2006)

We extended the TAM in several ways. We included individual differences (risk aversion, innovativeness) and social influences (internalization, identification and compliance) as key determinants that influence new technology's use. Moreover, we investigated the acceptance of new technologies by older adults. Practitioners and researchers need a better understanding of why older people resist or embrace new technologies. Insights in older adults' motivations to accept new technologies could help attune communications to this elderly segment, ultimately leading to higher acceptance of new, helpful technologies. In addition, encouraging older consumers to use the Internet could be valuable for firms, as the sheer number of older consumers gradually increases and they tend to have greater wealth and spending power.

Several hypotheses are postulated. Following Arning and Ziefle (2006), we argue that especially for older adults, ease of use is an important determinant of perceived usefulness of new technologies. We also expect that a higher level of internalization (i.e. the process by which, when one perceives that an important referent thinks one should use a system, one incorporates the referent's belief into one's own belief structure, Malholtra & Galletta, 1999), identification (occurs when system users adopt attitudes and behaviors to achieve a *satisfying, self-defining relationship* with another person or group, Malholtra & Galletta, 1999) and innovativeness are positively related to perception of usefulness, ease of use and use of new technologies. We expect that compliance (occurs when the user adopts particular behaviors to obtain rewards or avoid punishments, Malholtra & Galletta, 1999) and risk aversion are negatively related to perception of usefulness, ease of use and the use of new technologies.

Survey data were collected through self-administered anonymous questionnaires filled in by 179 older adults. Structural equation modeling was performed to analyze the relationships proposed in the hypotheses. Two full structural measurement models (internet/digital TV) were estimated with each scale items used as an indicator of its associated latent variable. The final measurement models had good fit. Next, two structural models were estimated. Results showed adequate model fit for both models. We found no large differences for determinants of intentions to use internet and digital TV. Results show that positive intentions to use both new media are determined by ease of use, identification, compliance and innovativeness. Compliance positively influenced the perceived usefulness and the intention to use internet and digital TV. Ease of use of internet was negatively influenced by compliance. Internalization directly influenced intentions to use digital TV but not Internet. Internalization had an indirect influence on internet use through ease of use and usefulness. Risk aversion did not directly influence use of new media. However, older adults who had higher risk aversion had a lower ease of use perception of internet, indirectly influencing their intention to use the internet. Perception of usefulness did not influence use of new media. Older adults do not need to perceive new media as useful in order to use it. Usefulness was influenced by perceptions of ease of use. Usefulness was also influenced by compliance, internalization and identification (for internet).

In sum, our study not only confirms the importance of perceived ease of use in the basic TAM, but also demonstrates that, in the context of new media use (1) other beliefs (i.e. internalization, identification, and compliance) and (2) individual characteristics (innovativeness, risk aversion) can significantly influence consumer intentions and perceptions of usefulness and ease of use.

Consumers Prefer Television Ads with Dance; Researching the Effects of Dance on Consumer Behavior

Carla Walter, Missouri Southern State University, USA
Loay Altamimi, University of Savoie, France

Prior to 1990, music was considered incidental to the advertising message and its effects on consumer behavior. Importantly, consumer researchers found that music was much more than incidental (Scott 1990). That breakthrough path was facilitated by other researchers examining advertising effects on consumers using theoretical frameworks that borrowed from a variety of disciplines (see McCracken 1986, Scott 1994, Mick and Buhl 1992, McQuarrie and Mick 1999, and Joy and Sherry 2003 for examples). With both this historical yet continual pressing of the frontiers of consumer research as a means of inspiration, this research had multiple purposes. The first was to explore consumers and their relationship with advertisements using dance in them. The second was to evaluate if there were international differences between preferences, and beyond that, what gender preferences existed if any. Finally the research was set to explore what effects an ad with dance in it would have on consumer behavior with respect to the product being advertised. One hundred and one respondents were surveyed in the United States and France in two separate phases to facilitate the research. The two surveys were available to respondents in two versions (English and French) and both were conducted via the internet, using proprietary web-based software (*Sphinx Plus2-Edition Lexica-V5* and *SphinxOnline* <http://www.sphinxonline.com> was also utilized in the survey design as well as monitoring data collection and the results analysis). In comparison to traditional methods of survey data collection, web surveys are considered to be a faster and a less expensive way to collect data from a global audience (Schmidt, 1997; Wyatt, 2000; Roztocki and Lahri, 2003; Wright, 2005). Also and more importantly for this study, using the web makes it possible to deliver almost any kind of content (including videos) and to introduce new types of interactivity into the survey process (Baulac, Bolden and Moscarola, 2000; Conrad, Couper and Tourangeau, 2003), such as play/stop video, show/hide or jump to certain elements and questions depending on the respondent's answer.

In the first phase we tested a survey method for examining connections between dance in television advertising, culture, and consumption. The survey incorporated a variety of questions to gather data (i.e., television viewing, search behavior and preference for ads with dance in them online and on television, and demographic information) and utilized open-ended questions based on five interpretive dance premises (Sklar 2001). The assumption was that dance is used in advertising because it communicates nonverbally cultural information and in turn may connect this information to consumption. The three product advertisements using dance in the foreground were Nike, Isenbeck Beer, and MasterCard. The respondents were presented with hyperlinks to the three different television ads to view and rate their preference for. Next they were asked to describe the types of people, dance, and culture presented in their respective preferred ad, and the connection they saw between the type of dance used and the product advertised. The findings suggest that dance in the television ads used in this research communicated information as argued. The findings in phase one make a significant contribution to the literature in demonstrating that dance in television ads influences consumers and their relationship with culture and consumption (Walter et al, accepted, *Consumer Culture Theory 4*, 2009).

In the second round, the same respondents were surveyed again, building on results from the first round. Data from phase two suggests that 67% of respondents preferred ads with dance in them, and the highly significant preference was integral to the advertisement. The main reasons for the enthusiasm for the ads were that dance provided entertainment (65%), a favorable distraction (12%), and hedonic feelings (11%). Preference for all ads was further correlated with respondent's memories of past events. Mainly these centered on a) socialization in educational institutions from childhood through university; b) respondents being reminded of someone else, such as a friend or relative while watching the dance; and c) a social event such as a wedding or party. Two other findings were additionally noteworthy: nearly half of the respondents indicated "Yes", the dance in the ad would influence their desire to buy the product; and just over half stated the opposite. In anticipation of the polarized answers, respondents were queried open endedly on the survey as to their reasons for a "No" or "Yes" response. Respondents who thought the ad would influence their buying indicated they liked the dancing for each of the ads. For the Isenbeck Beer and MasterCard commercial, their view of the dance as humorous was important to the respondents. For Nike and Isenbeck Beer, they also felt the dance made the product interesting. However, for all three of the ads, respondents had "other" reasons for believing the dance would make them buy the product. For those respondents who indicated the dance did not encourage them to buy the product, this was highly significant based on the ad choice. Reasons centered around dislike of credit cards for the MasterCard advertisement. The notion that the advertisement has nothing to do with the product was important for each of the three ads. However again, "other" was given as a large percentage reason for not buying the product for Nike and Isenbeck Beer.

In summary, this exploratory research builds upon dance, advertising, and consumer theories and contributes to the literature in three ways. First, dance may enter the consumer research realms as a viable aspect of television ads, and perhaps ads in hypermedia generally, proving important for understanding consumer behavior in terms of preference or non preference for a product for a variety of cognitive and affective reasons. Secondly, the research method is one that can be adapted to other advertisements that use dance in them, or not, and used for extending the research for example, as in exploring the neurobiological effects on consumers watching dance in advertising. Third, consumer researchers are now sensitized to the use of dance in television advertising, broadening the resources available to evaluate consumers and their behaviors. However, in addition to the neurobiological research agenda, an expanded analysis of consumers' reasons for ad preference with dance in advertisements and measures of the degree to which this preference in different cultures exists can influence consumer behavior is needed. To accomplish this, our research stream includes utilization of in-depth interviews and ethnographic research approaches in addition to the survey methods articulated here.

Pioneering (Dis)advantage and Later Entrant (Dis)advantage: The Role of Consumer Goals in Pioneer and Later Entrant Brand Advantages

Tor Arne Wanebo, Norwegian University of Life Sciences, Norway
Even J. Lanseng, Norwegian School of Management, Norway

A widely held assumption in consumer research is that there can be only one pioneer brand in a product category and that this pioneer has advantages (i.e. market share and profits) over later entrants. However, most of the brands in a product category are late entrants. This paper investigates whether a late entrant can overcome the pioneer's advantage and achieve one for itself by becoming included in a goal-derived category. The assumption made here is that a favorable position in a goal-derived category simultaneously shields the late entrant from a typicality judgment that would favor the more typical pioneer and places the late entrant closer to a favorable evaluative judgment (i.e. an ideal category member) than the pioneer. Results from two experimental studies suggest that a late entrant strategy capitalizing on consumer's goal-derived categorization is superior to a strategy of adding new and unique attributes in a taxonomic product category. This is true for both the late entrant and for a pioneer that tries to re-position itself when challenged by the later entrant.

The Dynamics of Goal Revision: Updating the Discrepancy-Reducing Model of Self-Regulation

Chen Wang, University of British Columbia, Canada
Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China

Existing research on goal-directed behaviors has largely focused on the process in which people strive for a static goal (Austin and Vancouver 1996; Carver and Scheier 1981; Locke and Latham 1990). However, relatively little attention has been directed toward the dynamic process of goal setting. As Fishbach and colleagues have demonstrated (Fishbach and Dhar 2005; Fishbach, Dhar, and Zhang 2006), goals are not always static. Rather, people frequently revise their goals upward or downward based on the goal-performance discrepancy.

This research examines the dynamics of goal revision by updating the discrepancy-reducing model of self-regulation (Carver and Scheier 1981, 1998). Based on cybernetic control theory (Miller, Galanter, and Pribram 1960), Carver and Scheier's classic model of self-regulation suggests that people continuously monitor the discrepancy between their current state and a desired standard, and that goal-directed behaviors are aimed at reducing such discrepancies.

One limitation of this model is that it treats the goal as a static standard. In this research, we propose instead that the goal is a dynamic function, specifically, an S-shaped function of the goal-performance discrepancy. Based on this proposition, we incorporate an additional element—"Goal Calibrator"—into Carver and Scheier's model. In our revised model, the goal-performance discrepancy serves not only as an input to the system, as suggested by the original model, but also as the input to the goal calibrator. This goal calibrator is directed by an S-shaped function, generating the updated goal for further monitoring. Further, the S-shaped function features the common properties of *proportionality* and *diminishing sensitivity* for both self-set goals and assigned goals, while exhibiting *failure aversion* for self-set goals and *satisficing* for assigned goals.

A series of four experiments provide empirical support for our theorizing. Study 1 provides initial evidence for our hypothesized goal revision for self-set goals. In the context of saving money, we used a one-factor between-subjects design (discrepancy valence: positive vs. negative). The goal-performance discrepancy was manipulated by giving hypothetical feedback. Participants were asked to imagine setting up a financial goal of saving as much money as possible for each of five consecutive months. They were asked to write down their desired saving amount for the first month. Then they were presented with a hypothetical performance outcome (e.g., you saved 15% more vs. less than your goal). Based on the feedback, participants were asked to set up their financial goal for the next month, and the next feedback was presented after that. These procedures were repeated for five iterations. The performance outcomes for each month were random integers between 15% and 19%, always either positive or negative based on feedback condition. A 2 (discrepancy valence) x 5 (month) mixed ANOVA yielded a significant interaction ($F(4,116)=2.57, p<.05$). The pattern was consistent with our prediction. Positive discrepancy resulted in continuous upward goal revision—savings targets for each month were higher than in the previous month. In contrast, negative discrepancy led to the maintenance of the original goal—savings target stayed flat from month to month. This experiment demonstrated (a) the existence of goal revision for self-set goals, and (b) the property of *failure aversion*.

Study 2 replicated the effects in another context, and further investigated the effort exertion under different discrepancy valence. We used a similar design as study 1, but in the context of working out with the goal of burning as many calories as possible on the treadmill for five consecutive days. Consistent with our hypotheses, a 2 (discrepancy valence) x 5 (day) mixed ANOVA yielded a significant interaction ($F(4,40)=6.45, p<.001$), such that those with positive discrepancy indicated the same amount of effort in each trial, whereas those with negative discrepancy indicated increasingly more effort to strive for the goal.

Study 3 further tested the characteristics of the S-shaped function by examining the interaction between the valence and the magnitude of the discrepancy. Specifically, as to self-set goals, we expected *proportionality* and *diminishing sensitivity* for discrepancies with the same valence but differential magnitudes, and *failure aversion* for discrepancies with the same magnitude but opposite valences. We used a 2 (discrepancy magnitude: small vs. large) x 2 (discrepancy valence: positive vs. negative) factorial design. Participants were presented a scenario in which they held a goal of burning 200 calories on the treadmill. The goal-performance discrepancy was manipulated by giving hypothetical outcomes (i.e., burning 10 vs. 110 calories more vs. less). Participants were then asked to establish the calorie goal for the next day based on their current performance. As predicted, a 2x2 ANOVA yielded a significant interaction ($F(1,62)=64.64, p<.001$). Consistent with our hypothesized *proportionality*, large discrepancies resulted in greater goal revision than small discrepancies of the same valence. Further, discrepancies had a smaller marginal impact when they were more distant from the origin point, referring to *diminishing sensitivity*. Moreover, positive discrepancies led to larger goal revision than negative discrepancies of the same magnitude, as the predicted *failure aversion*.

Study 4 tested the unique property of *satisficing* for assigned goals. In this study, we utilized a computerized anagram task to establish assigned goals. A similar design as study 1 was used. Participants were first asked to freely set up a goal for the first anagram (i.e., "to find ___% of the possible solutions"). Manipulated feedback was presented after participants submitted their answers (i.e., 5% more vs. less than your goal). Since the anagram tasks were cognitively intensive, only three iterations were implemented. A 2 (discrepancy valence) x 3 (iteration) mixed ANOVA yielded a significant interaction ($F(2,39)=10.317, p<.001$). As predicted, those with positive discrepancies initially maintained the original goal, but revised the goal upward as they kept receiving positive feedback. By contrast, those with negative discrepancies revised the goal downward based on the negative feedback. These effects demonstrated the property of *satisficing* for assigned goals.

In sum, the studies reported above provide empirical support for a revised discrepancy-reducing model of self-regulation. This work contributes to the classic discrepancy-reducing model, and therefore the larger goal revision literature.

Social Marketing in Action: Increasing Recycling in a Large Organization

Todd Weaver, Georgia State University, USA

Topic

In recent years, environmental sustainability has become a matter of great concern, prompting individuals, communities, and organizations to take up the difficult task of identifying and reducing their environmental impact. By employing Action Research methodology to intervene in a specific problem situation over time, my research will address the important question of whether grassroots social marketing efforts can successfully increase pro-environmental behavior in a large organization.

Theoretical Frameworks

The majority of research on pro-environmental behavior has employed two related theories: Ajzen's theory of planned behavior (1991) and Schwartz's model of altruistic behavior (1977). Researchers have used these models to examine pro-environmental behavior descriptively by demonstrating the relationship between attitudes, norms and/or intentions and behavior (e.g., Tonglet, Phillips and Bates 2004; Guagnano, Stern and Deitz 1995). However, relatively little research has attempted to identify the processes by which pro-environmental behaviors can be initiated and increased over time. By using Action Research to investigate these behavioral models in a specific context, I hope to gain insight into the behavioral antecedents of pro-environmental behavior as well as the social marketing techniques that can influence these antecedent conditions.

Methodology

Action Research involves a collaboration between the researcher and an organization or community that leads to immediate and ongoing improvements in a problem situation (Susman and Evered 1978). Action Research is particularly appropriate for contributions to transformative consumer research (Ozanne and Saatcioglu 2008), which has been championed by the Association for Consumer Research (Mick 2006). Although there are a variety of Action Research approaches, I am employing Susman and Evered's cycle (1978), which includes the following five steps: diagnosing, action planning, action taking, evaluating, and specifying learning.

The context of this research is a large, southeastern university that is lagging behind other local universities in terms of sustainability efforts. In order to make the scope of this project manageable, I am restricting my focus to recycling, since recycling is a tangible and visible aspect of sustainability that is easily understood by most people. The first step of the Action Research process involves engaging with the community to gain a shared understanding of the problematic situation. I employed a variety of ethnographic methods in this diagnosing stage, including semi-structured interviews with informants that spanned the three focal categories of students, faculty, and staff; an on-line, qualitative survey of the same groups; observations of recycling behavior on campus; and secondary research that included academic journals, publications of the university, and publications of recycling-oriented organizations, such as the Association for the Advancement of Sustainability in Higher Education (AASHE). These sources revealed three important themes that will guide the subsequent steps of the Action Research project.

Initial Findings

The first theme that emerged from my research is that recycling has not been an institutional focus at this university. Unlike many colleges today, there is no person or department tasked with improving sustainability. Although several groups are undertaking a variety of independent efforts to increase recycling, the overall effectiveness of these efforts seems to be limited by their ad-hoc, uncoordinated approach. Different constituencies hear different messages concerning recycling, see different types of recycling bins in different places, and are not sure that recycling bins will be available in a given space or building. This lack of focus has likely suppressed important precursors for recycling, such as social norms and ascriptions of responsibility in Schwartz's (1977) model.

The second theme that emerged is that there is a general lack of awareness of the recycling services available on campus. Community members are not sure which materials can be recycled on campus, nor are they confident that materials placed in bins are actually recycled. If awareness were higher, it would be reasonable to expect that recycling would increase at the university even absent any other changes in current practice. For example, in Ajzen's (1991) model, the lack of awareness would have a detrimental effect on perceived behavioral control over recycling.

Finally, the third theme that emerged from my research is that many students, faculty and staff members do not regard recycling as an important norm. Just as the university's administration has not emphasized recycling and other sustainability initiatives, it seems that many campus constituents do not feel that recycling is a priority. Again, this finding relates to the behavioral antecedents identified in the Schwartz (1977) and Ajzen (1991) models. For example, according to Schwartz (1977), the internalization of social norms regarding

recycling would be an important antecedent of recycling behavior. Together, these themes provide an explanation of the low level of recycling at this university, but they also suggest ways in which recycling might be increased via social marketing efforts.

Current Status and Expected Contributions

Currently I am engaging with campus groups in the action planning stage, in which we will use our shared understanding of the problematic situation to develop social marketing campaigns aimed at increasing recycling at the university. These efforts will focus on creating the behavioral antecedents identified by Ajzen (1991) and Schwartz (1977). Furthermore, longitudinal measures of these antecedents will provide evidence of their relationship to recycling behavior. Once complete, I anticipate that this research will not only increase recycling in the focal organization, but it will also provide important insights into the process by which recycling behavior can be initiated and increased over time.

The Influence of Intrinsic and Extrinsic Messages and Benefits on Motivations to Donate

Jennifer Wiggins Johnson, Kent State University, USA

Pamela Grimm, Kent State University, USA

Bret Ellis, Kent State University, USA

It is a common practice for nonprofit organizations to send marketing communications to potential donors that have either intrinsically or extrinsically focused messages. Communications with intrinsically focused messages may emphasize the organization's need, the positive outcomes that the donation will have for the organization and its constituents, and the satisfaction that the donor will feel from having helped the organization. Extrinsically focused messages may emphasize the extrinsic rewards or benefits that the donor will receive in exchange for his or her donation, such as invitations to special events, tangible rewards, or social recognition. The purpose of this research was to determine whether *message focus*, either intrinsic or extrinsic, had an impact on donors' motivation to donate.

Research on motivation has repeatedly found that extrinsic rewards can decrease an individual's intrinsic motivation to engage in a behavior (Deci and Ryan 1985; Harackiewicz, Manderlink, and Sansone 1984; Harackiewicz and Sansone 2000; Lepper, Greene, and Nisbett 1973). This overjustification effect suggests that when individuals experience both intrinsic and extrinsic rewards for a behavior, the behavior is overjustified and the individual attributes the behavior to the extrinsic reward (Deci and Ryan 1985). This results in a drop in intrinsic motivation after the receipt of the rewards. Non-marketing messages have been found to reverse the effects of extrinsic rewards on intrinsic motivations by making intrinsic motivations more salient (Fazio 1981). We believe that the benefits stressed in marketing communications, either intrinsic or extrinsic, will have an impact on motivations to donate that may mitigate the effects of offering a reward for the donation.

An experiment was used to investigate this phenomenon. Three groups of undergraduate students, at three different locations, received different communications messages asking them to participate in a food drive. Messages were delivered verbally by their instructor and through a series of three e-mail messages. One group received intrinsically focused messages, one group received extrinsically focused messages and the third group acted as a control and received no messages, only basic information about the food drive. The intrinsically focused messages emphasized the help that the students would provide for families in need, and the extrinsically focused messages emphasized a promised reward of a pizza party to the students if they reach a predetermined goal for the food drive. While only the extrinsic messages condition emphasized the pizza party, all of the groups were promised and received a pizza party at the conclusion of the food drive if they met a set goal.

Under the cover of a research project on donations being conducted by a friend of the instructor, participants' intrinsic and extrinsic motivations to participate in the food drive were measured three times: once prior to the receipt of any messages, once after the message manipulation, and once after the pizza party. Motivations were measured using two multi-item scales measured on a 1-7 scale with endpoints "strongly agree" and "strongly disagree." Students received extra credit for participating in the research.

A total of 142 students participated in the study: 60 in the intrinsic condition; 54 in the extrinsic condition and 26 in the control group. The items designed to measure motivation were factor analyzed across all three groups. Four items for intrinsic motivation and four items for extrinsic motivation were retained. Factor loadings for the items ranged from .73 to .94, and $\alpha=.94$ for the intrinsic motivation items and $\alpha=.88$ for the extrinsic motivation items. The four items for each factor were summed resulting in a mean range of 4 to 28. Manipulation

checks indicated that the instructor for the control group had communicated additional messages, compromising the results. Therefore, the control group was dropped from further analysis.

A repeated measures analysis of intrinsic and extrinsic motivation was conducted using message condition as a between subjects factor. We expected to observe an increase in intrinsic motivation from t_1 to t_2 for the group that received intrinsic messages, and not for the group that received extrinsic messages, and the opposite effect for extrinsic motivation. If the overjustification effect occurred, we further expected the intrinsic motivation of both groups to drop from t_2 to t_3 , after the receipt of the reward. Our results for the intrinsic messages group were slightly different but theoretically consistent. From t_1 to t_2 , the intrinsic messages group did not change their intrinsic motivation, but their extrinsic motivation decreased significantly. From t_2 to t_3 , after the reward was administered, the intrinsic messages group's extrinsic motivation increased significantly, consistent with the overjustification effect. However, this increase returned their level of extrinsic motivation to approximately what it was at t_1 , suggesting that there may have been some mitigating effect of the messages.

The results for the extrinsic messages group, however, were less clear. From t_1 to t_2 , the extrinsic messages group did not significantly change their extrinsic motivation, but their intrinsic motivation increased significantly. The most plausible explanations for this counter-intuitive result was the crash of the economy that took place while the experiment was in progress. The changing economic circumstances, combined with publicity regarding the needs of local food banks in the area, may have influenced the results. It should also be noted that both groups exhibited a very high level of intrinsic motivation to start, suggesting that the results may also reflect a ceiling effect. After the receipt of the reward, however, they experienced the drop in intrinsic motivation associated with the overjustification effect, which again returned them to approximately the same level of intrinsic motivation that they began with at t_1 . This again suggests that the messages may have in some way mitigated the overjustification effect, but not in the intended manner.

In order to overcome these limitations, a second study has been planned and will be conducted in May. The second study involves university alumni donations. A single instructor will be responsible for the intrinsic and extrinsic message group, mitigating possible instructor effects. The second study should provide additional insights into the effects of message framing on intrinsic and extrinsic motivations to donate.

Real Men Don't Eat Quiche: Discrepancy Between Automatic and Deliberate Gender-Expressive Choices in Men

Jim Wilkie, Northwestern University, USA

David Gal, Northwestern University, USA

Consumers often purchase products to signal desired identities to their self and others (e.g. Belk 1988; Wernerfelt 1990; Berger & Heath 2007). This paper examined how gender identity considerations affect product choice. What occurs when men and women must choose between a personally appealing, gender-incongruent item and a less appealing, gender-congruent item? Are there gender differences in why certain products are chosen?

Much research has displayed that men and women are faced with pressures to conform to standards set forth by gender norms (e.g. Crocker et al. 1998). Building on research showing that individuals often regulate their impulses in accordance with norms and expectations when they have sufficient cognitive resources to do so (Shiv, Fedorikhin & Nowlis 2005), we posit that individuals will similarly regulate their choices of gender-expressive items. That is, we posit that the availability of cognitive resources will increase the likelihood that individuals choose gender-congruent items that conflict with their automatic preferences.

It is further proposed that men might be more motivated than women to regulate their choices of gender expressive items. This is based on research which has suggested that women and men might face different motivations to conform to gender norms. For instance, women might be more motivated to conform to gender norms when occupying traditional male roles, such as management leadership positions, due to devaluation of women that exhibit "masculine" traits in such roles (Eagly et al. 1992), while men, on the other hand, might be more motivated to conform to gender norms in attempts to maintain their gender identity, due to heightened psychological consequences of gender role deviation for men relative to women (e.g. O'Heron & Orlofsky 1990). Our propositions were supported in three experiments.

Experiment 1: Food Choices

Experiment 1 tested the hypothesis that resource availability would affect choice patterns for products which could be used to signal one's gender identity. Specifically, Experiment 1 examined how gender associations of food items affect the choices of men and women.

Participants made 16 choices from pairs of food items descriptively listed on a menu. For each pair of items provided, subjects chose the food option they most preferred. Each pair consisted of a masculine dish and a feminine dish. The gender of the dish was manipulated through ingredients (e.g. a masculine dish might contain bacon whereas a feminine dish might contain red wine sauce) and food

descriptions (e.g. a masculine dish might be described as “hearty” whereas a feminine dish might be described as “luscious”). All subjects were asked to assume that the nutritional content for each item within a pair were roughly equivalent. Participants were randomly assigned to complete this task under high or low cognitive resource availability.

Consistent with our predictions, an ANOVA revealed a significant interaction between gender and cognitive load on menu item choice, $F(1,162)=6.14$, $p < .05$, and that male (but not female) choices were significantly different between cognitive load conditions $F(1,160)=13.51$, $p < .01$. Males in the high load condition ($M=.559$, $SD=.24$) chose significantly more (less) feminine (masculine) dishes than males in the low load condition ($M=.379$, $SD=.19$), $F(1,160)=13.51$, $p < .001$, $d=.83$. In contrast, females in the high ($M=.641$, $SD=.21$) and low ($M=.630$, $SD=.18$) load conditions did not differ in their choices $F(1,160) = .05$, $p=.82$, $d=.06$.

Experiment 2: Product Shape

The purpose of experiment 2 was to provide convergent evidence for the role of cognitive resources in gender choice in a different domain.

Building on recent perceptual research which displayed that certain geometric shapes connote affective meaning (e.g. Aronoff 2006), it was hypothesized that angular objects better portray masculine concepts (e.g. aggression) whereas rounded objects better portray feminine concepts (e.g. warmth). Participants were shown a series of two products side by side from twelve different product categories (e.g. beds) and asked to choose the item that they most preferred between the two. For each pair of items there was one option with predominantly rounded features and another option with predominantly angled features (pretests confirmed that the rounded items appeared more feminine and the angular items more masculine). Participants were randomly assigned to complete this task under high or low cognitive load.

Consistent with our proposition that men would be more likely to regulate their choices given sufficient cognitive resources, an ANOVA revealed a significant interaction between gender and cognitive load on product choice, $F(1,273)=4.226$, $p < .05$, and that male (but not female) choices were significantly different between cognitive load conditions, $F(1,271)=5.85$, $p < .05$. Males in the high load condition ($M=.477$, $SD=.18$) chose significantly more (less) rounded (angled) products than males in the low load condition ($M=.400$, $SD=.16$), $F(1,273)=7.72$, $p < .01$, $d=.45$. In contrast, females in the high ($M=.511$, $SD=.17$) and low ($M=.514$, $SD=.14$) load conditions did not significantly differ in their choices, $F(1,273)=.11$, $p=.74$, $d=.02$.

Experiment 3: Resource Depletion

The third experiment was developed to provide evidence that the previous results were due to greater gender identity concerns for men (relative to women). It was posited that men would show greater signs of depletion following choices made from a mixed gender choice set (relative to an all-masculine choice set) whereas women would show no difference in depletion between a mixed choice set and all-feminine choice set.

Participants completed two choice tasks similar to experiments 1 and 2 (i.e. food and shape choice tasks) before completing an anagram task designed to measure ego depletion (Baumeister, Bratslavsky, Muraven, and Tice 1998- Experiment 2).

Consistent with our hypothesis that males, but not females, would be particularly depleted by choosing between masculine and feminine options, the interaction between choice sets and gender was significant, $F(1,150)=4.08$, $p < .05$. Planned contrasts for this interaction indicated that males who received mixed gender choice sets ($M=5.04$, $SD=3.86$) solved significantly fewer anagrams than males who received masculine choice sets ($M=7.45$, $SD=3.68$), $F(1,150)=5.66$, $p < .05$, $d=.64$. Further, there was no difference in the number of anagrams solved for females who received mixed gender choice sets ($M=6.73$, $SD=3.96$) and females who received feminine choice sets ($M=6.52$, $SD=3.68$), $F(1,150)=.02$, $p=.90$, $d=.05$.

Examining a Four-Component Model of Consumer Identification Experiences

Chelsea Willness, Brock University, Canada
 Katherine White, University of Calgary, Canada
 James Agarwal, University of Calgary, Canada

Conceptualization

An emergent theme in the marketing literature is that companies should endeavor to develop long-lasting, deep, and meaningful relationships with their customers (De Wulf et al. 2001; Palmatier et al. 2006). One way these relationships might be cultivated is through the development of a strong sense of identification with the organization (Bhattacharya and Sen 2003). We conceptualize consumer-to-company identification (C-C identification; Bhattacharya and Sen 2003) as when the individual feels a sense of connection with the organization, and these beliefs become self-referential or self-defining in nature (e.g., Ahearne et al. 2005).

We propose that consumer identification experiences are often more complex than existing theories can account for. Thus, we test an expanded model of C-C identification and examine the consequences of differing C-C identification experiences. To do so, we draw on theories of social identity (Tajfel and Turner 1979) and organizational identity (Kreiner and Ashforth 2004) to explicate and test an expanded model of consumer identification with organizations. We extend emerging research on C-C identification by proposing that consumer identification is not a uni-dimensional construct. We make a contribution to the marketing literature by highlighting four distinct identification experiences—identification, disidentification, ambivalent identification, and neutral identification—as they arise in the consumer context. Further, we demonstrate the nomological validity of the expanded model by showing that it predicts company evaluations, perceptions of trustworthiness, in-role behaviors, and extra-role behaviors.

Our proposed two-dimensional model holds that consumers can experience either low or high identification *and* either low or high disidentification, resulting in four consumer identification experiences. Identification (high identification/low disidentification) occurs when the individual feels a sense of connection with the organization and beliefs about the company become self-defining in nature (Dutton et al. 1994). Disidentification (low identification/high disidentification) occurs when the individual actively separates his/her identity from the organization and experiences a negative relational categorization of the self and the organization (Elsbach and Bhattacharya 2001). Ambivalent identification (high identification/high disidentification) toward organizations occurs when an individual simultaneously identifies and disidentifies with an organization (Elsbach 1999). Neutral identification (low identification/low disidentification) involves being low in both identification and disidentification with regard to an organization (Elsbach 1999).

Method

Using a market research company, 9000 people were mailed a letter inviting them to participate (8606 were received after accounting for post office returns). In total, 794 people responded (9.23%) with $N=420$ complete responses ($Age: M=47.67, SD=11.98$). There was no evidence of non-response bias (Armstrong and Overton 1977).

Participants were asked to think of a company that they had patronized in the past, and then completed scale measures to assess the different identification experiences (identification, disidentification, neutral identification, and ambivalent identification; α s=.88, .94, .86, and .88, respectively; adapted from Kreiner and Ashforth, 2004). Respondents also completed measures of company evaluations (White and Dahl 2006; $\alpha=.97$), trust (e.g., Ganesan 1994; $\alpha=.93$), and in-role ($\alpha=.92$) and extra-role ($\alpha=.92$) behaviors (adapted from Zeithaml et al. 1996). We tested for common method variance (Lindell and Whitney 2001), which was nonsignificant.

Major Findings

We performed confirmatory factor analysis (CFA) to estimate the overall measurement model. Adequate reliability (e.g., $CR>.70$; $AVE>.50$), convergent validity (e.g., loadings $>.60$), and discriminant validity (e.g., $\sqrt{AVE}>r$) were exhibited. Our proposed four-factor model consisted of 4 items to measure each identification dimension, which demonstrated good fit to the data based on the standard criteria of fit indices (Hu and Bentler 1999). We tested four alternative models, none of which reached acceptable levels of fit compared to our proposed model.

Correlation analysis (controlling for demographics) revealed that each identification experience was related to consumer outcomes in predicted ways (all $p<.01$): Identification was significantly positively correlated with evaluations of the company ($r=.478$), trust ($r=.492$), in-role behaviors ($r=.362$), and extra-role behaviors ($r=.573$). Disidentification was strongly negatively correlated with evaluations of the company ($r=-.828$), trust ($r=-.777$), in-role behaviors ($r=-.786$), and extra-role behaviors ($r=-.746$). Ambivalent identification was weakly to moderately negatively correlated with evaluations of the company ($r=-.319$), trust ($r=-.373$), in-role behaviors ($r=-.195$), and extra-role behaviors ($r=-.295$). Neutral identification was weakly negatively correlated with evaluations of the company ($r=-.277$), trust ($r=-.311$), in-role behaviors ($r=-.263$), and extra-role behaviors ($r=-.320$). Regression analyses also supported predictions.

Conclusions

This research reveals the complexity of consumers' identification experiences with the companies they patronize. An expanded four-factor model of C-C identification provides superior fit to the data compared to alternative models, revealing that consumers can experience four distinct organizational identification patterns—identification, disidentification, ambivalent identification, and neutral identification. This finding has important implications for both researchers and practitioners. From a theoretical standpoint, the results show that different forms of organizational identification can and do arise even under conditions where the individual is not a formal group member. From a practical perspective, this research delineates the full range of consumer identification experiences and enables enhanced insight into how customers develop relationships with the companies they patronize. Elucidating the complexity of consumer identification experiences, then, is a step toward further understanding positive consumer-company relationships and resilient consumer loyalty.

Our findings show that identification is associated with the most favorable consumer outcomes, whereas disidentification is associated with the least favorable consumer outcomes. Both neutral and ambivalent identification were related to consumer outcomes in predicted ways—more negative evaluations, perceptions of trust, in-role behaviors, and extra-role behaviors were reported as feelings of neutrality and ambivalence toward the company increased. Ambivalent identification is more strongly related to disidentification than identification and negatively related to consumer outcomes, indicating that it has largely negative consequences. Marketers need to ensure, even with a loyal consumer base that highly identifies with the company, that nothing negative occurs to simultaneously activate feelings of disidentification. The ambivalent consumer also represents an untapped and accessible market that has the potential to be positively swayed to more strongly identify with the company. The current research is an important first step towards elucidating the multi-faceted nature of consumer identification.

The Defensive Trust Effect: Consumers' Defensive Use of Belief in a Just World to Cope with Consumption Threat

Andrew Wilson, St. Mary's College of California, USA
Peter Darke, Schulich School of Business, York University, Canada

Consumers cope with many stressful situations: poor service, difficult decisions, and misleading persuasion attempts. Existing evidence suggests that consumers react with distrust towards marketers to avoid being wronged. Campbell and Kirmani (2000) show that consumers respond to salesperson flattery by attending to potential ulterior motives, and lowering trust when such motives are plausible. Darke and Ritchie (2007) show that consumers respond to being misled by an advertiser with generalized suspicion towards all advertisers.

This research examines whether some consumers respond in exactly the opposite way—by displaying increased trust. Our research uses Cognitive Experiential Self Theory (CEST; Epstein & Pacini, 1999) and the notion of secondary control (Rothbaum, Weisz, & Snyder, 1982) to suggest that some consumers respond to threats by evoking basic beliefs about the world, leading to increased trust of the marketer, and reassurance of positive outcomes. This coping strategy is herein termed *defensive trust coping (DTC)*.

CEST posits that humans adapt through the development of two systems, termed *rational* and *experiential*. These systems serve multiple goals, including accuracy (maximizing pleasure and minimizing pain) and defense (protecting self-esteem). Individuals hold basic beliefs about the nature of the world, such as the extent to which the world is meaningful vs. chaotic. We use Lerner's (1980) Belief in a Just World (BJW) as a proxy. BJW predicts certain behaviors, especially blaming victims (Rubin & Peplau, 1975). Attributing a victim's fate to his or her own failing reduces the perceived threat to BJW holders. Such coping strategies fit with secondary control (Rothbaum et al., 1982), where individuals adjust their beliefs or perceptions to reduce threat.

Given a choice between differentiable alternatives, threat is greater post-choice. Consumers experience anticipated regret following choice (Brehm, 1956). Moreover, primary control is reduced post-choice because the control exercised through the act of choosing has been lost to the past. Thus, we predict that consumers enlist basic beliefs to a greater extent post-choice than pre-choice.

In study 1, 84 undergraduates were randomly assigned to a between-participants design with choice stage as the experimental factor. Participants imagined themselves interacting with a salesperson while shopping for a digital camera they needed right away. The salesperson presented two alternatives, and recommended one over the other. Product specifications were provided in a comparison matrix, based on the local market.

Marketing agent *trust* was operationalized by adapting Delgado-Ballester's (2004) seven-item benevolence scale (Likert-type; 7 point; $\alpha=.92$). BJW was measured using the seven item *personal belief in a just world* scale (Dalbert, 1999; also 7-point Likert-type; $\alpha=.84$). Pre-choice participants ($n=84$) responded to the trust scale, and then chose. Post-choice participants ($n=86$) first chose, and then responded to the trust scale. Then all participants completed the BJW scale and other items.

A median split was performed on BJW ($Md=5.00$). A 2 (choice stage: pre vs. post) \times 2 (BJW: high vs. low) ANOVA on trust revealed no main effects (all $p's > .2$), but a significant interaction between choice stage and BJW groups ($F(1, 80)=4.891, p < .05$). A complex contrast was calculated by assigning weights of zero to both pre-choice conditions, one to the post-choice/high-BJW condition, and negative one to the post-choice/low-BJW condition (Rosenthal and Rosnow 1984), which was significant ($F\psi(1, 80)=5.33, p < .05$). This was interpreted as support for our theorizing that high-BJW consumers respond to post-choice threat by becoming more trusting whereas low-BJW participants responded in accordance with the more rational view that greater uncertainty should engender greater distrust (Slovic et al. 1991).

Study 2 considers conditions under which the level of pre-choice threat rivals that of post-choice by making the choice more conflicted. Consumers experience pre-decisional conflict in the absence of a clear reason to choose one alternative over the other (Shafir, Simonson, & Tversky, 1993). 195 undergraduates were randomly assigned to a single factor (pre-choice vs. post-choice) between-participants design. As before, participants imagined an interaction with a salesperson, and responded to the same scales. The product comparison matrix was changed such that the alternatives were non-differentiable. Both cameras were priced at \$275.

A 2 (choice stage: pre-choice) \times 2 (BJW: high vs. low) ANOVA of the trust variable revealed a main effect of BJW, $F(1, 192)=11.13, p < .001$; supporting our view that consumers would enlist DTC in the pre-choice stage when the choice involved decision conflict.

Study 3 extended the findings in three important ways: 1) tested whether DTC operates by preconscious processing, by including a manipulation of cognitive load, 2) establish more causal evidence for the role of DTC by manipulating BJW, and 3) investigate whether an obvious, salient ulterior motive on the part of the salesperson represent a boundary condition for the effect. Load was manipulated by a procedure based on Campbell and Kirmani (2000). BJW was manipulated by a memory task in which participants were asked to write a short essay about a time when they received a deserved positive outcome. Ulterior motive was manipulated by varying the recommendation of the salesperson. She recommended the less (more) expensive alternative in the low (high) ulterior motive condition.

242 undergraduate were assigned to 2 (BJW prime) \times 2 (load) \times 2 (ulterior motive) between participants design. BJW was also a measured factor. Some lower order effects were found, all of which were qualified by a marginal 4-way interaction ($F(1, 223)=3.373, p=.068$). The analysis was split on the ulterior motive factor, which found no effects in the high ulterior motive conditions (all $F's < 1$, all $p's > .2$)—evidence for the boundary condition. In the low ulterior motive conditions, the analysis revealed a 3-way interaction between BJW prime, BJW scores, and load ($F(1, 111)=5.883, p < .05$). Complex contrast suggests that the BJW-primed, high-BJW-score, high load cell ($M=4.81$) differed from all others ($M's$ range from 3.46 to 4.32; $F\psi(1, 111)=12.24, p < .001$), suggesting that these three factors combined to create elevated trust judgments.

When Does Greenwashing Work? Consumer Perceptions of Corporate Parent and Corporate Societal Marketing Firm Affiliation

Andrew Wilson, St. Mary's College of California, USA

Stacey Robinson, Florida State University, USA

Peter Darke, Schulich School of Business, York University, Canada

This research investigates how the affiliation between a socially responsible marketer firm (corporate societal marketing-CSM) and corporate parent affects consumer perceptions and attitudes. It examines the effects of affiliation when the association is perceived as hidden and subsequently in violation of social norms of openness. The study explores whether any effects impact the parent company and its brands; findings suggest corporate parent affiliation does not automatically lead to negative evaluation of niche marketer brands. However, the openness of the affiliation impacts the positivity or negativity of effect flowing back to the parent company and its affiliated brands.

Corporate societal marketing (CSM) is an increasingly popular brand building technique (Drumwright and Murphy 2001; Hoeffler and Keller 2002). One factor seemingly driving this is an upward trend in consumer expectations of firm social responsibility. A 2004 report found 86% of Americans are likely to switch brands, assuming equivalent price and quality, to one supporting a cause (Cone 2004).

Acquisitions of successful CSM-based firms, serving socially concerned consumers, by conglomerate parent firms is another apparent trend. There are many such examples, recent notable acquisitions include: Green & Black's, a small organic chocolate maker, acquired by Cadbury Schweppes; Coca-Cola acquired premium juice maker Odwalla; Colgate-Palmolive purchased Tom's of Maine, producer of socially-responsible items, and Burt's Bees, an all-natural cosmetic firm, was purchased by chemical giant Clorox Company.

In each case, the parent firm acquired a CSM-based firm built largely on the basis of its corporate societal marketing activities and continued operation of the CSM-based brand(s) more or less unchanged. The apparent strategy of leaving the small organization in place and continuing to market a CSM-oriented brand, assumes consumers will continue to value both brands despite affiliation. This study examines consumer perceptions of the parent firm's brands following acquisition of a CSM-based firm and seeks to appraise consumer evaluations of the parent firm brand(s) when the affiliation between it and the CSM-based firm is known.

Perhaps the acquisition of a CSM-based firm and subsequent operation as independent subsidiaries can be viewed as a persuasion tactic (Friestad and Wright 1994). This work extends investigations of the effectiveness of CSM as a brand building strategy as firm affiliation effects appear unstudied. The study of these effects is important given the trend toward increased consumer expectations of social commitment from marketers and actual acquisitions of CSM-based brands (Harrison 2006).

Additionally, this work considers consumers may infer motives for the CSM-based firm acquisition; such inferences may lead to generalized distrust for the parent firm's products given the circumstances surrounding the acquisition (Campbell 1999; Darke and Ritchie 2007). This work examines the factors that determine whether consumers infer sincere or ulterior motives. Finally, acquisition activity may have effects which spillover to related and unrelated products within the brand portfolio (Roehm and Tybout 2006); this is examined by varying the degree of similarity between brands based upon the consumer's brand schema.

Method & Results

For Study 1, participants reviewed a website of a CSM-based personal products company containing details about its environmental and community activities. Participants were asked about the extent to which the firm was environmentally concerned and engaged in the community. This scale was meant to facilitate brand/firm involvement and evoke attitude commitment towards the brand. Participants read a news article containing an earnings announcement on the parent firm and brief story about an incident resulting in environmental damage. 167 adults were randomly assigned to a between-participants experimental design with disclosure as the experimental factor. Disclosure was manipulated by varying the text of the CSM firm's website. In the disclosure condition, the website mentioned the relationship to the parent firm; the no-disclosure condition did not. Beliefs about the effectiveness of the parent firm's flagship brand were measured. An ANOVA on the effectiveness of the parent firm's product revealed those exposed to the disclosure condition believed the brand was less effective ($M=5.11$) than did controls ($M=5.41$; $F(1, 165)=3.516, p=.063$). It seems when participants learned of the affiliation between the firms, they became suspicious of the parent firm's motives. Such suspicion may generalize to evaluations of the firm's brands.

Study 2 sought to clarify the conditions under which the effects demonstrated in study 1 would be observed and whether the previous study's effects would generalize to other brands in the parent firm's portfolio. The past environment record of the parent firm (track-record) and the level of friendliness/hostility of the transaction in which the CSM-based brand becomes affiliated with the parent are two factors of interest.

Measures of attitude towards the parent brands overlapping CSM-based firm brands (toothpaste) included a functionally related (oral rinse), semantically related (dishwashing liquid), and dissimilar brand (cat food).

270 participants were randomly assigned to a 3 (disclosure: none, open, hidden) X 2 (track record: bad, good) X 2 (hostility of acquisition: hostile, friendly) factorial design. The procedure was identical to study 1, except the news story allowed for manipulation of additional variables. Disclosure, track record and acquisition were manipulated by varying the text of the story. An ANOVA of brand beliefs related to the effectiveness of the parent firm's flagship brand (toothpaste) revealed a significant 3-way interaction ($F(1, 253)=5.828, p<.05$). Follow up contrasts revealed under a friendly acquisition, with a bad track record, hidden disclosure led to *increased* evaluations ($M=5.83$) as compared with controls ($M=5.15$; $p<.05$). No such effects were observed when the parent had a good track record (all $p's>.2$). This is consistent with our theorizing when the parent has a bad track record (and thus is motivated to take action to improve) consumers would infer a sincere motive when the acquisition is friendly, as it is reasonable to assume the CSM-based firm has verified the sincerity of corporate parent through their cooperation with the acquisition.

In the hostile acquisition conditions, a different pattern emerged. Hidden disclosure led to *decreased* evaluations ($M=5.26$) compared with controls ($M=5.89$; $p<.05$). There are no differences under the good track record condition, it seems consumers infer an impression management (or other insincere) motive for the affiliation with the CSM-firm.

To test our hypothesis on the effects generalizing to related brands, a series of ANOVAs with attitude toward each brand as the dependent variable was conducted, revealing a similar 3-way interaction for the overlapping (toothpaste; $F(1, 253)=4.249$, $p<.05$) and semantically related brand (dishwashing liquid; $F(1, 253)=2.537$, $p=.081$), but not for the functionally related ($F<1$) or dissimilar brand ($F<1$).

Naturally Occurring Brands: A New Perspective on Place Marketing

Christine Wright-Isak, Florida Gulf Coast University, USA

This work investigates the intersection of two powerful concepts in marketing research, which have rarely been thought to intersect: brand and community.

Theoretical antecedents:

- *Place Marketing*: Kotler, Heider and Rein (1992) take a primarily macro view of places and their reasons for and tactics used to market themselves. Their focus might be said to take place from the vantage point of the "self-interested place" for it emphasizes economic causes and consequences in which marketing is called on to attract tourists, corporations and industries, or workers on the basis of functional place attributes like tropical climate, low taxes and good schools. Although imagery is acknowledged to be a factor useful in place marketing, they approach it tactically such that accidental benefits of historic or cultural heritage and amenities are communicated to enhance imagery or overcome negative perceptions. Intended audiences include corporations who will be employers and investors in local infrastructure, tourists and conventioners who will add to local revenue streams, government bodies who can provide aid or residents who constitute a workforce that can be used as an asset.
- *Brand Communities*: O'Guinn and Muniz (1997) focus on communities in marketing but not on the place dimension. They borrowed the sociological concept of community to unpack the underlying symbolic phenomena affecting consumer loyalty to brands. Their work describes episodic community with a very limited number of commitment dimensions. Schouten studied Harley Davidson riders and the community that emerged offers the outlaw spirit of this brand as a benefit. More recently, Holt (2003) applied the idea of belonging to a brand's value set to understanding socio-cultural significance of brand meanings. All of these used the term community to refer to communion of hearts and minds and not geographically. However, O'Guinn and Belk did unite that idea with physical place in their study of Heritage Village (1989).
- *Sociology of Communities*: Sociologists and other consumer researchers have viewed place phenomena as patterned social interactions of individuals that give rise to consistent sets of expectations about how daily life in a given place will occur—culminating in particular characterizations of such places. At one end of a continuum of community studies we find ethnographies of American place like *The Social Order of the Slum* in Chicago (Suttles, 1968) or *Small Town in Mass Society* (Vidich and Bensman 1958). In-between the city and the town have been studies of suburbia like the *Levittowners* (Gans 1967). More episodic but nevertheless place centered is the emergence of norms and periodic social structure centered on consumption in a swap meet studied by Russell Belk, John Sherry and Melanie Wallendorf, (1988) or a flea market (Sherry 1990). At the other end we find Perin (1977) specifically examining the intersection of macro level geographic community and micro level behaviors among neighbors in *Everything in its Place: Social Order and Land Use in America*.

Theoretical Synthesis

The intellectual convergence of these perspectives depends on acknowledging that the idea of a symbol that is so central to the concept of brand is a phenomenon of meaning creation. Scholars often view symbols as *existing manifestations of the outcomes of a process of social investment of meaning* in a tangible figure or item. Marketers conceive of brands as *intentionally created clusters of meaning* signified with a mark that can be used to signal consumers about that cluster of meanings. Both perspectives tend to under-acknowledge

the continuing interaction of expectation and actual experience associated with a symbol or a brand by consumers. We assert that the “consumer” or the “follower” of a brand has an equal role with its purveyor in determining its significance.

We reason that the three main forms of small town, suburb or city each have a distinct constellation of meanings which makes them symbols. If these three symbols are used by consumers to anticipate what kind of residential community life will take place within them and if these anticipations affect how they choose where to live, then the community forms are potentially “naturally occurring brands.” Whereas Kotler et. al. delineated how particular places might purposefully manipulate their features and images as brands (e.g. Chicago, Sarasota), the three archetypal forms of community are not deliberately marketed. Thus the term “naturally occurring.” The nature of their significance in consumer decisions adds the term “brands.” But for our reasoning to stand, we need to know whether consumers do in fact share a common understanding of the meaning of these types and whether the constellation of meanings is transmitted to subsequent generations within the culture.

This Research consists of two studies conducted 20 years apart. The first is a previously unpublished study comparing small town community to the other two forms to ascertain the role of community stereotype in residence selection. The findings raised interest in the theoretical intersection of place and community and brand as concepts. The second is recent research into whether the relevant images and meanings of town, suburb and city consist of holds true among today’s Millennials. Also incorporated into the second study are some measures designed to indicate how such understanding might be transmitted to new generations.

STUDY I: 1985 The study used a three year ethnography, and a set of 6-hour in-depth interviews with 20 newcomers to study the small town form of community. The immediate 50 mile radius around the town in central NJ contained numerous instances of all three types of place-community.

- Findings: a community selection process that perpetuates the typology. Newcomers to a region selected new homes from an array of communities that they characterized using the town-suburbia-city constellation of images and meanings. In choosing a “small town life” they desired the specific social contract of small town neighboring norms they intended to fulfill themselves.
- Identification of the community as a small town by using a commonly understood set of visual cues to the three types of community. In response to unstructured questions respondents explicitly associated images of all three types of community with distinct and separate sets of expectations neighbors would have toward one another.
- Moreover, many had never lived in a small town before, so experience was not how they learned the meaning of this type. Many indicated their understanding arose from portrayals in American literature, cinema and television.

STUDY II: 2009—Investigating the Millennial Generation understanding of the set of community “brands.” If community types are “naturally occurring brands” we can expect that each new generation becomes socialized to the meanings associated with them.

- *The broad hypothesis* is that Millennials, being at one or more generations away from the respondents in the original study, and inhabiting a very different social and technological world than 1985 consumers, will *not* assign the same brand labels or meanings to the three types of community in response to visual cues.
- *A second broad hypothesis* is that in addition to interpersonal or familial socialization processes cultural transmission of the constellation of images and meanings associated with each type of community may also occur via television and literature.
- *The research design:* Used survey methodology to investigate how Americans understand these three types of community. Approximately 200 surveys were fielded using both verbal and nonverbal stimuli. 130 were completed with college students up to age 25, another 70 were completed with non-student adults over the age of 35.
- *Study II is limited by region and by number of respondents*, but provides a basis for a larger follow-up study across generations and regions of the U.S.A.

FINDINGS: Analysis indicates the typology is understood by Millennials in the same way as older generations. They link unlabeled pictures of each type of place-community with the “brand” label linked by the older sample consistent with the patterns found by Study I. Briefly:

- *Small towns*—Main Street stores and homes, close-knit, supportive but controlling
- *Suburbia*—cul de sac arrangement of houses, “ticky-tacky,” good for kids but conformist
- *Cities*—anonymous, fast and noisy, sophisticated and socially “open” but ruthlessly competitive

Regarding extrafamilial cultural transmission of “brand” meaning, there was considerable overlap in the viewing of the same TV shows, and reading the same books. TV Land network in particular has enabled Millennials to view the same shows (like “Mayberry RFD” or “Ozzie and Harriet” or “Family Ties” as older generations.

Trading between Effort and Money: Consumer Participation and Service Pricing

Lan Xia, Bentley University, USA
Rajneesh Suri, Drexel University, USA

Research in co-production suggests that businesses can treat consumers as partial employees and boost productivity. While some consumers are motivated to do the work by the higher perceived control and convenience, co-production does require consumer effort (i.e., non-monetary input). Little research has examined the process how consumers trade off their effort (i.e., work) with price. In this research we examine factors influencing consumers' tradeoff between work and money. Using 4 experiments, we showed that for the same work, consumers want to save more but pay less. Further, this main effect is moderated by both consumer and service characteristics.

Conditions Under Which "Trivial" Attributes Become Important in Consumer Judgment

Na Xiao, Queen's University, Canada
Peter Dacin, Queen's University, Canada
Laurence Ashworth, Queen's University, Canada

We examine conditions under which attributes that have little or no impact on the performance of a product, known as "trivial attributes", nevertheless have an important impact on product evaluation. Existing work on trivial attributes has shown that they can positively affect product evaluation when they serve to distinguish the product from other comparable options (Carpenter et al., 1994) and when they help justify a particular choice (Brown and Carpenter, 2000; Schlosser and Shavitt, 2002). In a similar vein, attributes that are trivial because the meaning of the attribute is ambiguous or unknown can also positively impact product evaluation, primarily due to conditions, such as a positive brand reputation (Broniarczyk and Gershoff, 2003) or expectations that marketers will adhere to conversational norms, that cause consumers to draw positive inferences about the meaning of the attribute. Inferences based on trivial attributes have also been shown to lower product evaluations when they lower perceptions of the ability of the product to perform its core functions (Meyvis and Janiszewski, 2002).

In short, trivial attributes appear to impact product evaluations for two broad reasons: first, due to the inferences that consumers make based on those attributes; and second, when trivial attributes help consumers make or justify a choice. We suggest that the impact of trivial attributes in the latter case can be attributed more broadly to the ability of the attribute to fulfill contextually activated goals that are not directly related to the performance of the product. In choice contexts, such goals relate primarily to the ease of making a decision (see Bettman et al. 2008 for a discussion of choice goals). However, we argue that different contexts are likely to activate a broad array of different goals that can, under certain circumstances, render a trivial attribute meaningful.

We propose that contextual goals are most likely to cause trivial attributes to become influential when these goals are anxiety-provoking; that is, when they are important, unfulfilled, and their achievement is uncertain (Lazarus 1991). As individuals seek to reduce their anxiety, we expect them to pay special attention to any product information that does, or could, aid in the fulfillment of the anxiety-causing goal. In short, attributes that would ordinarily be ignored may take on special meaning when consumers are in a state of anxiety caused by contextual goals unrelated to the core functions of the product. Finally, we further predicted that this effect should be moderated by consumer self-confidence. Consumers who are particularly confident in their ability to fulfill their goals should be less likely to rely on trivial attributes to help achieve additional contextual goals. We tested this in Study 2.

These hypotheses were investigated in two experiments. We used the same experimental paradigm in both: participants chose between three different bottles of red wine. Four attributes were provided for each brand. Three of those were pretested to be non-trivial: price, vintage, and alcohol content. The fourth was pretested to be trivial and included information on whether or not the label displayed the "picking time" of the grapes. Only one brand was said to include picking time information (participants were simply told whether the label included picking time information or not—they were not given specific picking times). Importantly, the brand was counterbalanced across participants, as was the order in which the attributes were presented.

Anxiety was manipulated in both experiments by varying aspects of the choice context designed to inspire impression management concerns. In the low anxiety condition, participants were told that they were choosing a wine to take to an informal party. In the high anxiety condition, the wine was for their future father-in-law. Manipulation checks across experiments showed anxiety levels did indeed vary across these situations.

Study 1: Ninety-seven students participated in a 2-level (anxiety: high, low) between subjects design. We measured how much participants thought about each attribute as they made their decision (along a 5-point scale). Participants also indicated how important each attribute was to their decision by dividing 100 points across the four attributes. Results indicated that participants thought more intensely about the trivial attribute ($M_s=3.44$ vs. 2.67 ; $F(1, 95)=7.98, p<.05$) and that the trivial attribute was more important to their decision (M_s

=12.31 vs. 21.87; $F(1, 95)=18.81, p<.01$) when anxiety levels were high. Differences in the actual brand chosen, however, failed to reach significance.

Study 2: Ninety-two students participated in a study identical to Study 1 except that we also measured differences in individuals' confidence in their abilities as they pertained to the product at hand (adapted from Bearden et al.'s self-confidence measure; 2001). We predicted that individuals high in self-confidence would be less likely to rely on the trivial attribute as a means to reduce goal-related anxiety. Results replicated findings from Study 1: there was a significant main effect of the anxiety manipulation on perceived importance of the trivial attribute ($F(1, 88)=3.84, p<.059$). This effect was further replicated on the overall evaluation of brand—consumers evaluated the brand with the higher level of the trivial attribute (counterbalanced across brands) more positively when anxiety was high ($F(1, 88)=7.36, p=.01$). Although the predicted interaction did not reach significance in either case, the direction of means did suggest that the effect was primarily driven by consumers low in self-confidence ($ps=.057$ and $.045$ vs. $ps>.50$ and $.08$ for high self-confidence). It is important to note that high self-confidence participants did not experience less anxiety as a result of the manipulation. In other words, the effects of self-confidence were not caused through a reduction in anxiety, but rather perceptions of consumers' ability to fulfill their goals.

To summarize, existing work on trivial attributes has highlighted a number of ways in which such attributes can influence product evaluation. Our research contributes to this literature by demonstrating that the role of trivial attributes is importantly influenced by contextually activated goals—goals that are not related to the core functions of a product but nevertheless can exert an important influence on the way in which consumers interpret the products' attributes. More generally, this suggests that the specific goals activated in any particular product evaluation context are likely to exert an important influence on how each attribute is interpreted and its influence on overall product evaluation and choice.

Washing Away Your (Good or Bad) Luck: Superstition, Embodiment, and Gambling Behavior

Alison Jing Xu, University of Illinois at Urbana-Champaign, USA

Rami Zwick, University of California at Riverside, USA

Norbert Schwarz, University of Michigan, USA

Observations of superstitious behavior suggest that gamblers and athletes change their physical appearance after a streak of bad luck, but avoid doing so after a streak of good luck. We test the metaphorical link between changes in physical status and changes in luck in a gambling situation, using hand washing as a manipulation of physical status. Participants who encountered a winning streak bet less in a subsequent round after having than after not having washed their hands. Conversely, participants who encountered a losing streak bet more in a subsequent round after having than after not having washed their hands.

The Effect of Product Familiarity on Price Discount Framing

Ya-Chung Sun, Vanung University, Taiwan

Chiung-Chiao Chang, Vanung University, Taiwan

Shih-Chieh Chuang, National Chung Cheng University, Taiwan

Yin-Hui Cheng, National Taichung University, Taiwan

Consumer knowledge of prices plays an important role in price management since it not only determines how prices are perceived and valued but also influences consumers' purchase decisions (Binkely and Bejnarowicz, 2003; Monroe, 1973, 1992; Simon, 1989; Turley and Cabaniss, 1995). Consumer response to price stimuli may involve cognitive processes such as attention, comprehension, retention and recall, as well as behavioral processes such as the formation of purchase intentions and actual purchase behaviors (Olson and Jacoby 1977).

Product Familiarity

Familiarity has been the focus of recent empirical studies in consumer research that examine information acquisition (Bettman and Park 1980), reactions to advertising (Anderson and Jolson 1980; Edell and Mitchell 1978; Marks and Olson 1981), and the choice of decision rules by consumers (Park 1976).

Familiarity is defined as the number of product-related experiences that have been accumulated by a consumer (Abla and Hutchinson 1987). A consumer's familiarity with a product or brand plays a critical role in his/her information processing and brand evaluation (Abla and Hutchinson 1987; Fazio 1986; Johnson & Russo 1984).

Price Discount Framing

Monroe, Grewal and Compeau (1991, p. 13) noted that "research on the issue of reference price must consider the extent that individuals have different degrees of familiarity with the product category and with the different prices charged for various product alternatives." Similarly, Zeithaml (1988) argued that the price-quality relationship is influenced by consumer price awareness and the ability to detect quality variation in a product class.

Consumers who are more knowledgeable about product and price may make different decisions than consumers who are less knowledgeable. Specifically, those who are knowledgeable should be less willing to pay prices that do not reflect the quality of the product compared to those who lack that knowledge (Rao and Sieben, 1992). Hence, this study examined how consumers with different levels of product familiarity generate different perceptual savings under varied price discount framing presentation forms. As advanced in the previous section, the following hypotheses are offered:

H1: For low-price products, the less familiar consumers are with a product, the higher the likelihood that they will perceive the price reduction when the price reduction is framed in percentage terms instead of dollars.

Study 1 demonstrates that under the low-price product condition, consumers that are more familiar with the product perceive no significant difference in the price reduction whether they are presented in dollar terms or in percentage terms. Furthermore, consumers that are less familiar with the product perceive a more significant difference in the price reduction when it is presented in percentage terms than when it is presented in dollar terms.

Manipulation of Familiarity

The notebook computer was the stimuli. Three indicators were used to measure familiarity, one for the product and the others for the two attributes presented in each product category (Sheng, Parker, & Nakamoto, 2005).

Procedure

The experiment was conducted in a classroom setting. Paper and pencil method was adopted in this study. In the beginning of the experiment, the notebook was adopted to measure the product familiarity of the 166 participants'.

For the notebook computer situation, two price discount scenarios (A and B) with different price discount presentation forms (dollar versus percentage) were used to measure the participants' perceptions of the price discount promotions respectively.

A. Imagine that you had received a direct mail advertisement from your credit card company, offering a NTD 6,250 discount on the purchase of a brand A, AMD Mobile Sempron 3400+ notebook computer regularly priced at NTD 25,000. What degree of perceptual saving does this product bring?

B. Imagine that you had received a direct mail advertisement from your credit card company, offering a 25% discount on the purchase of a brand A, AMD Mobile Sempron 3400+ notebook computer regularly priced at NTD 25,000. What degree of perceptual saving does this product bring?

Results

Measurement of product familiarity

In this experiment, three indicators were used to measure the participants' familiarity with a notebook computer. The median score (=4) was adopted to set the level of high and low familiarity. Under the notebook computer condition, 115 among the 166 participants were in the high familiarity group, while 51 were in the low familiarity group.

Perceived significance of saving

A two-way factorial ANOVA was employed to test the participants' perceptions of the savings. The main effect of the framing price promotion message on the low price notebook computer condition was significant ($F(1,162)=4.301, p<.05$). The participants perceived a price reduction presented in percentage terms ($M=4.47$) as more significant than the same a price reduction presented in dollar terms ($M=3.37$). There was an interaction effect between product familiarity and presentation form on the participants' perceptions of the price promotions ($F(1,162)=8.768, p<.05$).

Under the low-price computer condition, consumers who were more familiar with the product perceived no significant price reduction, whether it was presented in dollar terms ($M=4.58$) or in percentage terms ($M=4.36$) $t(113)=0.77, p>.1$. On the other hand, consumers with a lower level of product familiarity with the product perceived a more significant price reduction when it was presented in percentage terms ($M=4.00$) compared to being presented in dollar terms ($M=2.77$) $t(49)=-3.38, p<.001$. These results support H1.

General Discussion

Study 1 demonstrated that under the low-price product condition, those consumers that were more familiar with the product perceived no significant difference in the price reduction whether it was presented in dollar terms or in percentage terms. More importantly, consumers that were less familiar with the product perceived a more significant difference in the price reduction when it was presented in percentage terms compared to being presented in dollar terms. These results supported H1.

Our results show that for the low-price product category conditions, consumers that are less familiar with the product perceived that there was a more significant difference in price reduction when it was presented in percentage terms than presented in dollar terms. Marketers often target their communication efforts to audiences with varying levels of product category familiarity. When forming intentions to purchase, consumers with a high level of product familiarity access and process the different price discount framings. On the other hand, consumers with a low product familiarity rely on fewer but salient price cues to make product judgments and purchase intentions. Hence, marketers must tailor their promotion strategies to affect different familiarity groups

Best Before/Consume More-A Consumer Cultural Exploration into Freshness and Regulations of Contemporary Food Consumption

Carl Yngfalk, Stockholm University, Sweden

Freshness remains a largely unexamined product attribute within consumer research. "Best before dates" printed on products influences food acceptance and has an impact on consumption through subjects' perceptions of freshness and disposal tendencies thereof. This research analyzes this issue by problematizing the relation between discourse constituting subjects' perceptions of freshness in perishable products and subjects' tendencies to dispose these objects. Further, this research should be of interest to both producers and retailers of the food industry as well as regulators.

Introduction and method

Consumer preferences and purchase decisions concerning perishable food products are highly influenced by characteristics concerning price and freshness (International Food Information Council (IFIC) Foundation 2007; Lennernäs et al. 1997; Nordic Council of Ministers 2001). Whilst being a highly individual and perceived characteristic, a most evident source of information intervening with peoples' perceptions of freshness is the "best before" date. Within the European Union, the best-before date label (e.g. best before 01-01-09) is by far the most used and vital source of package information concerning freshness and it is required by federal law to be present on all food products on the market. In Sweden, where this research is conducted, this has been the issue since 1972, creating a peculiar and interesting research environment.

The best before date, communicating freshness, remains a largely unexamined product attribute. In the domains of food science there has been much research conducted on the date label's effects on food quality and nutrition content. In our field—the Journal of Consumer Research community—outside the domains of food science, some scholars, with Brian Wansink as vanguard, have briefly touched upon the psychological and economic impact of freshness dating and expiration dates (Kerley et al. 2008; Wansink and Wright 2006). Shortly put, these scholars have rather briefly illustrated (in controlled environments) that the date label bias human senses by producing stigma and, thus, directly influences consumer perception (Wansink and Wright 2006). In a recent JCR article, also, Sen and Block (2009) problematize the issue concerning the freshness date and describe subjects' willingness to consume products past their freshness dates and how this willingness changes with ownership; in their study, consumers are more likely to consume products out-of-date when they own the products compared to other situations (Sen and Block 2009). While research of this kind focuses largely on the behavioral aspects of the consumer subject concerning their relation to the product attribute, the understanding of discourse intervening with and shaping our perception of freshness in the first place remains quite unclear.

Besides the article by Sen and Block and the brief efforts by Wansink *et al* to problematize the date label's influence on consumer culture there are no efforts made to explore freshness and its impact on food consumption in a larger, social perspective and as powerful control mechanism—organizer of, not only consumption but also production.

Conceptualization and aim

Reasonably, consumers prefer fresh over less fresh food. This research problematizes the relation between discourse constituting subjects' perceptions of freshness in perishable products and subjects' tendencies to dispose these objects. Traditionally, consumer research and marketing have focused largely on product acquisition and value creation processes, as contradictory to peoples' disposal tendencies. It is argued here that by analyzing food product disposal practices among not only consumers, but among *different* actor groups on the market (such as consumers, producers, retailers), a better understanding is gained of socio-cultural, institutional instruments that

channel and 'direct' discourse and which, thus, operate as mechanisms of bringing power relations into being. This should be of interest to both producers and regulators.

Through deep interviews with consumers, executive representatives from leading actors in food production, chief state-regulators of food labeling, and retail merchants, this research seeks to further deepen our understanding of how regulative forces in consumer culture and control mechanisms in the supply chain, reach out and intervene with individual subjects' food disposal tendencies.

Further, this research takes as a starting point the discursive power model presented by Denegri-Knott, Zwick, and Schroeder (2006). This model highlights forces which produce discourses and practices and seek to define "normal" consumer behavior in "certain consumption contexts" (Denegri-Knott et al. 2006; see also Thompson 2004). Concerning food freshness one interesting and important question to ask is through which discourses subjects' perception of freshness is constituted and why.

By exploring different subjects' perceptions of freshness and the best before dates, and drawing on high level theoretization of desire (Baudrillard 1998; Deleuze et al. 1988; Deleuze and Guattari 2004; Deleuze 2006), as well as power (e.g. Foucault et al. 1998), *the aim is to illuminate the relation between flows of institutional forces (in a constituting, productive sense, seen from the collective level) and the subjects and objects these adhere to. The aim is also to bring other actor groups into consumer research than merely the consumer while conducting consumer research.*

Scents and Semantics: Do Fragrance Names Influence Consumer Perceptions of Scented Products?

Lauren Yourshaw, University of Pennsylvania, USA

Take a moment and think about the type of products you use or consume throughout your typical day. Now, think about how many of those products are scented. Scent is an integral attribute of numerous consumer products and is used to differentiate products both across and within product categories. The importance of fragrance attributes in the marketing of consumer products is clearly evident by the ever increasing variety of scents being offered. Take for example the laundry detergent category where Tide®, the market leading detergent brand, offers consumers over 15 different scents just for liquid detergent including Mountain Spring, Tropical Clean, Vanilla & Lavender, Soft Ocean Mist and Glacier just to name a few. With all of these fragrance variants inhabiting the marketplace, how do consumers make their choices?

Very little work in consumer research *has focused on how consumers process olfactory attributes that are specific to products. Of the research that has been done with scents in the consumer domain, the main focus has been on how ambient scents (i.e. scents in the environment and do not emanate from a product) influence consumer decision making. Findings from these studies demonstrate that ambient odors can affect both variety seeking and information search (Mitchell, Kahn, and Knasko 1995) as well as overall product judgments (Bosmans, 2006). Moreover, ambient scents can also enhance consumers' ability to recall brands (Morrin and Ratneshwar, 2003). But whether fragrance attributes inherent to a product affect product judgments has received limited attention; therefore, the broad goal of this research is to better understand the factors that shape the perception of olfactory product attributes.*

Previous research in consumer behavior has shown that verbal labels are one factor that plays a role in the processing of sensory information and manipulating these labels can influence consumer evaluations. *Framing of attribute information in either positive or*

negative terms has been shown to affect taste evaluations (Levin and Gaeth, 1988) and more recent work by Hoegg and Alba (2007), demonstrates that verbal labels (brand names) can influence taste discrimination. Miller and Kahn (2005) also show that manipulating the typicality and specificity of color and flavor names affects hedonic ratings and ultimately consumer choice decisions. Although verbal labels have been shown to affect the perception of various sensory attributes (i.e. color, flavor etc.) no research has investigated the effect that verbal names of olfactory attributes have on consumer product evaluations.

Work in psychology, however has illustrated the general malleability of odor perception and shows that indeed, semantic framing of a scent can strongly shape a person's perception. The same odor stimuli labeled with a positively or negatively valenced label evokes different hedonic ratings (Herz and von Clef, 2001). For example, the scent of pine needles is rated more pleasant when it is labeled "Christmas tree" compared to when it is presented again to the same subject but labeled "spray disinfectant". Based on this work and findings in consumer research, it is reasonable to hypothesize that the perception of a scented product can be influenced by semantic framing. The work presented here seeks to investigate the effect that changing the descriptiveness of the label given to a scented product has on the overall evaluation of the product.

To test this, a study was conducted in which participants evaluated six different commercially available scented candles. The stimuli were prepared by placing shavings from each candle into 2 ounce plastic cups which were then covered with a lid. Participants were randomly assigned to one of two descriptive label conditions: concrete label condition (e.g. rose) or abstract label condition (e.g. soft floral). Each subject evaluated three candles whose primary odor characteristics were familiar to participants (cinnamon, rose, and powder) as well as three candles whose primary odor characteristics were unfamiliar (citronella, jasmine, and honeysuckle). Pretests were conducted to determine scent familiarity. After smelling each candle, participants made various hedonic evaluations as well as willingness purchase ratings.

Results of the study indicate that verbal labels do influence overall product judgments; however the effect is moderated by odor familiarity. For familiar scents, participants' hedonic ratings were significantly higher when the scent was labeled with an abstract name as compared to a concrete name. However, when the characteristics of the odor were unfamiliar, hedonic ratings were reversed such that odors were evaluated more positively when labeled with a concrete name as compared to an abstract name. A similar pattern of results was also seen with willingness to purchase measures.

In summary, the results from this work demonstrate that scent perceptions are in fact malleable. Whether or not the changes in hedonic judgment are a result of changes in the actual perception of the sensory information needs further investigations. In subsequent studies, we will attempt to understand the mechanisms that underlie these changes in scent evaluations.

Cross Physical Sense: How Weight Influences Consumer Stress and Importance Rating

Meng Zhang, Chinese University of Hong Kong, Hong Kong, China
Xiuping Li, National University of Singapore, Singapore

Weight is an integral part of consumer sensory perception, and a central attribute in product design. For example, to make laptops feel less heavy, colors like white or silver are often used. The location of cookie images on a package could be used to influence how consumers perceive the weight of cookies, which in turn, influence their evaluations of the package (Deng and Kahn 2009).

However, prior consumer research on weight concept has been largely focused on how sensory experience in the other domains influences judgment of weight. In this research, we propose that consumers' physical experience of carrying heavy objects (e.g., carrying a bag of groceries) can influence judgments "irrelevant" to the weight perception. Further, we propose that the experience of carrying heavy weight might influence judgments across domains by two routes (1) activating a physiological state shared by the physical sense of heavy; (2) activating the associated semantic concepts that linked to the weight concept. These two routes, in turn, determine whether these effects are reciprocal: When there is a shared physiological state, the effects are more likely to be bi-directional than when only semantic links are shared.

Specifically, in this study, we investigate how carrying weight influences the judgment of stress and importance. We choose to work on these two kinds of judgments based on the following justifications. First, in daily language, there is ample evidence that we often use sensory experience of weight to describe and understand the emotional experience of stress (heavy steps; my sprits sunk) and the abstract concept of importance (heavily weighted). These may reflect a co-activation of these constructs in our mind. Second, judgments of stress and importance might be differentially linked to "heavy" via one of the above-mentioned routes: Stress, as a basic emotion, is associated with physiological reactions; importance, on the other hand, is primarily a semantic construct. Therefore, these two concepts are good

candidates to help us test our theorizing. We predict that for judgments shared a physiological base (i.e., “heavy” and “stress”),¹⁴ the effects are more likely to be reciprocal, however, for the condition when one judgment is physiological (i.e., “heavy”), but the other is an abstract concept (i.e., “important”), the effects are more likely to be uni-directional (from “heavy” to “importance”). This is because that prior research has found that it is relatively earlier for a physical experience to have effects on an associated abstract concept than the other way around (Boroditsky 2000).

Two experiments were conducted to test our predictions. Experiment 1 provided the first investigation of our hypotheses whereas experiment 2 (on going) further examined the underlying mechanism. Two hundred and fifty-two participants participated in experiment 1. It had a 4 (*Prime*: Heavy, Stress, Importance, Control, between subjects) x 3 (*Target*: Heavy judgment, Stress judgment and Importance judgment, within subjects) mixed design. Upon arrival, participants were told to take part in two unrelated tasks. For the first task, participants in the heavy perception condition were asked to carry a shopping bag with three bottles of water (1.8L each).¹⁵ In the stress condition, participants were asked to recall and briefly describe an event that they felt very stressed, whereas in the importance condition, participants were asked to recall a very important decision they made. In the control condition, participants only completed the second task.

After the first task, participants were given a questionnaire set composed of three tasks: weight estimation, stress levels and important rating (the order was counterbalanced). In weight estimation task, participants estimated the weight of a package (2-item: on a 9-point scale and actual weight estimation in grams). For task related to stress judgment, they were asked to indicate how stressful thinking about class presentation made them feel (on a 9-point scale; 3-item: not at all/very stressful, worried, pressured). For importance judgment, participants needed to rate the importance of a new course on general education (on a 9-point scale; 3-item: not at all/very important, critical, crucial)

The items on stress ($\alpha=.87$) and importance ($\alpha=.91$) were averaged. ANOVAs for repeated measures were performed using the averaged ratings on stress and on importance, and subjective weight judgments as dependent variables. The results supported our hypotheses. Data revealed a main effect of judgment types, qualified by the two-way interaction ($ps < .001$). A closer examination of data showed that carrying a heavy bag, as compared to control condition, had an effect on all judgments in the second questionnaire: participants reported a higher weight estimation ($M = 6.11$; 1134.92 g; $M_{\text{control}} = 5.30$; 603.49g), felt more stressful towards an event ($M = 6.70$; $M_{\text{control}} = 6.13$) and rated a new subject more important ($M = 6.07$; $M_{\text{control}} = 5.13$; $ps < .001$). Recalling a stressful event, as compared to control, had significant effects on weight judgment ($M = 6.05$; 776.30; $M_{\text{control}} = 5.30$; 603.49) and stress feelings ($M = 6.82$; $M_{\text{control}} = 6.13$; $ps < .001$), but not on importance ($M = 5.20$; $M_{\text{control}} = 5.13$; $p > .1$). Finally, importance prime only had effects within the same domain of importance rating ($M = 5.84$; $M_{\text{control}} = 5.12$, $p < .01$), but no effects on the other two domains (weight judgment: $M = 5.37$; 621g ; $M_{\text{control}} = 5.30$; 603g; Stress feeling: $M = 6.42$; $M_{\text{control}} = 6.12$, $p > .1$). In other words, these results showed that (1) all the concepts had significant influences within their own domain, consistent with the predictions of priming literature; (2) as we expected, physical sense of carrying heavy objects led people to feel more stressful, and regarded a subject as more important; (c) The link between “heavy” and “stress” were reciprocal, whereas between “heavy” and “importance” was more uni-directional.

In the second experiment (on going), we examined the underlying mechanisms of the asymmetric findings further. If, as we argue, the bi-directional effects depend on whether a physiological state is shared between two domains, then inducing participants with a “physical focus” vs. “thinking focus” should moderate the effects. Specifically, instructing participants to focus on their “physical experience” when doing the task should strengthen the effects between heavy and stress in both directions; however, instructing participants to focus on their “thoughts” should strengthen the effects of “heavy” on “importance”. No other effects were predicted. Our on-going experiment 2 had provided some initial support to these predictions.

Counteractive Construal in Consumer Goal Pursuit

Ying Zhang, University of Texas at Austin, USA

Szu-Chi Huang, University of Texas at Austin, USA

Susan Broniarczyk, University of Texas at Austin, USA

The present research explores a self-control operation, namely counteractive construal, that helps consumers resolve the conflicts between an important goal and a short-term temptation by altering the construal of the temptation. We propose that when experiencing a self-control conflict, consumers intentionally construe temptation as more damaging to the attainment of a long-term goal, and use these

¹⁴They might also share some semantic links.

¹⁵A pilot test shows that participants would regard this bag as heavy.

distorted construals to help resolve the conflict in favor of the goals. Four studies in two self-regulatory domains (dieting goal and academic goal) provided converging evidence for the counteractive construal hypothesis. We found that people who were experiencing self-control conflict expected tempting food items to contain more calories, or expected parties to take more time away from studying, and were consequently less interested in consuming these temptations.

Consumers often face temptations in the pursuit of important long-term goals. Because the pursuit of such temptations potentially undermines the attainment of the goal, the presence of both the goal and temptation constitutes a self-control dilemma, which requires individuals to engage in self-control effort in order to maintain their goal pursuit (Aspinwall and Taylor 1997; Fishbach, Friedman, and Kruglanski 2003; Trope and Fishbach 2000). In this research, we propose a self-control mechanism, namely counteractive construal, that consumers employ to help them resist the temptation. Specifically, we propose that whenever consumers experience a conflict between a long-term goal and a short-term temptation, they augment the extent to which the temptation may undermine the goal attainment, thus are more likely to resist the temptation and resolve the self-control conflict in favor of the long-term goal.

Despite consumers' wish to perceive the world in an accurate and objective way, prior research has demonstrated that individuals' motivational states have a profound influence in shaping their perceptions and judgments (Baumeister and Newman 1994; Kunda 1990). Because one's perceptions and judgments are heavily influenced by their motivational states, it is possible that one's motivation to maintain their goal pursuit would potentially alter the construal and assessment of the options in this conflict (Fishbach, Shah, and Kruglanski 2004). In other words, one may help resolve the self-control conflict by augmenting the perceived cost of pursuing the temptation, such that it poses a greater threat to the attainment of the more important goal and would therefore be avoided.

Since we conceptualize counteractive construal as a self-control response designed to help individuals maintain their goal pursuit when facing a dilemma, we expect it to occur only when consumers experience the conflict between a long-term goal and a short-term temptation. The strength of the counteractive operation, accordingly, should depend on the intensity of the conflict: when the conflict is minimal, such as when the goal is unimportant, or the temptation is inaccessible, counteractive construal is unlikely to occur. Based on prior findings in the substitutability between self-control and external control, we further hypothesize that whenever there are externally imposed controls, counteractive construal becomes unnecessary because the external controls would be sufficient to ensure that the long-term goal would not be undermined by the temptation (Kruglanski et al. 2002; Tesser, Martin, and Cornell 1996). Because of the instrumental nature of counteractive construal, we further expect that it should only occur when self-control is effective in helping avoid the temptations. In situations where self-control is of no value in fending off the temptation, we expect no counteractive alterations in the construal of the temptation.

Three studies tested the present predictions. Across all studies, consumers faced a dilemma between succumbing to an immediately gratifying temptation and maintaining their goal pursuit, and we measured their perceptions of the tempting targets to test the counteractive construal hypothesis.

Study 1 and 2 tested whether consumers with (vs. without) an accessible dieting goal would construe tempting food items (cookies and drinks) to contain more calories, depending on whether they expected to have an opportunity to consume the tempting items or not. In study 1, we used a goal strength x temptation availability (available vs. unavailable) two factor design, where the temptation availability was manipulated as a between-subject factor and the strength of the dieting goal was measured as an individual difference factor. The dependent variable was the estimated calorie content in a piece of chocolate-chip cookie. We found that for participants who were told that they would have an option to take one cookie at the end of the study, the strength of their dieting goal positively predicted the amount of calories they perceived the cookie to contain. In contrast, for those who were not offered the option to take a cookie, there was no such relation.

Study 2 directly manipulated the accessibility of the dieting goal for participants and tested their construal of a tempting drink depending on whether they anticipated to have the option to consume the drink or not. We employed a 2 (dieting goal prime: yes vs. no) x 2 (temptation availability: available vs. unavailable) between-subject design. We manipulated the accessibility of participants' dieting goal by changing the settings of the small experiment room with three large posters depicting fit females or natural sceneries. The dependent variable was the estimated calorie content in a cup of sweetened soda. The results confirmed our hypothesis. For participants whose dieting goal was made accessible, they construed the soda to contain more calories when they expected it to be available for consumption than when they did not expect it to be available. However, when participants' dieting goal was not made accessible, the perceived amount of calories in the soda did not differ between those who expected to have an option to consume and those who did not.

Study 3 tested the hypothesis in a different context and included another dependent variable: participants' behavior intentions toward the temptation. We asked undergraduate participants to estimate the duration of a party when shown a flyer that invited them to a party either before or after they reported their desired GPA. We predicted that students who read the party invitation after reporting their desired GPA, in comparison to those who read the flyer before reporting their desired GPA, would experience a self-control conflict and expect the party to be longer, and in turn show lower interest in attending the party. The results showed the predicted goal strength x self-control conflict interaction. When participants viewed the party flyer after answering the school-related questions, their desired GPA positively predicted the anticipated duration of the party. Such relation was not found among participants who viewed the party flyer before answering school related questions. In addition, for participants who experienced the self-control conflict between the academic goal and the tempting party, the estimated duration negatively predicted their intention to attend the party, whereas there was no such relation among participants who did not experience the self-control conflict.

In order to accomplish important long-term goals, consumers need to resist temptations, which are immediately gratifying yet costly to the goal attainment. The present research documented counteractive construal as a self-control mechanism that helps people resolve the conflict between a short-term temptation and a long-term goal. By perceptually increasing the cost of pursuing the temptation when experiencing such dilemma, consumers become more likely to avoid the temptation and maintain their goal pursuit.

Fashion Systems and Historical Culture in the Development of Chinese Global Branding

Wu Zhiyan, University of Exeter, UK

Janet Borgerson, University of Exeter, UK

Jonathan Schroeder, University of Exeter, UK

Global market trends move toward increasing global cultural convergence and, at the same time, a need for local cultural differentiation. To address these contradictory forces, the research investigates processes and practices of marketers and consumers in three related cases: Jay Chou (a well-known Chinese music artist); the Beijing Olympics opening ceremony; and Shanghai Tang (a global fashion brand). The studies reveal strategic processes and mechanisms involved in the creation of a series of texts and codes from Chinese cultural resources. The theoretical and practical significance of studying historical culture, fashion systems and integrating current branding theories in a more holistic manner contributes a new approach to apparent contradictions that clearly must be dealt with simultaneously.

Methodology: multi-sited ethnography studies and ECM Data collection

Multi-sited ethnography is suited for interdisciplinary cultural studies on global and local areas and expresses the diffusion and circulation of cultural meanings, objects and identities in different time and space (Marcus 1998). Interviewing global consumers and marketers in different locations and observing consumption environments and consumers' consumption behaviours, as well as websites and other media resources, reveal the possibility and process of understanding, and engaging, Chinese global branding strategy. An extended case method, a mode of "logical analysis on the data interpretation of field observation, interviews, primary source materials, archived texts" (Holt 2002, p. 73), is employed to illuminate recent global brand culture initiatives from China.

Historical Culture in Branding

From a cultural branding perspective, retro activities and aesthetic fashions, including reproduction (Pearman 1999), retro-servicing (Alexander 1999), retro-styling (Brown 1999), retro retail stores (Maclaran and Stevens 1998), and heritage marketing hybrids, recognize the past's use in brand development. In other words, historical culture is employed to develop brands. Indeed, the presentation of historical culture, or the past, in marketing has been investigated for several decades. Some researchers contend that the prevalence of retroactivities is motivated by consumers' nostalgic desire (e.g. Lowenthal 1985; Belk 1991; Borgerson and Schroeder 2003; Holak and Havlena 1992; Stern 1992; Holbrook 1993; Holbrook and Schindler 1996, 2003).

Others claim that marketing the past is a way of secularizing the sacred historical, cultural, and religious elements and beliefs to enhance marketing activities (e.g. Belk, Wallendorf and Sherry 1989; O'Guinn and Belk 1989). As Eckhardt and Bengtsson suggest in the Chinese case, it may be valuable to engage the past as a strategic brand-signifying practice (2007). Moreover, they demonstrate Chinese branding's emergence in imperial China, marking a long history of attention to these processes.

Brand Development Culture and Fashion Systems

Schroeder and Salzer-Mörling discuss the roles that history and culture play in understanding the cultural codes of branding, expanding recognition of research that taps into what they call brand culture (2006). They write, "If brands exist as cultural, ideological, and political objects, then brand researchers require tools developed to understand culture, politics, and ideology..." (2006, p. 1). Thus, we understand the importance of social, cultural, and historical resources in undertaking branding, marketing, and consumer research.

For purposes of this research, a fashion transformation process model (Cholachatpinyo et al., 2002) allows us to recognize fashion as a system that influences global brand development, engaging fashion branding processes from macro-subjective (economic values/assumptions that legitimize particular activity); macro-objective (marketplace and economic activities); micro-objective (interaction between individual and variety of fashion objects); and micro-subjective perspectives (psychological phenomena of individual and of the interaction among individuals).

Symbolic production and consumption

Arnould and Thompson (2005) indicate that studies of symbolic production and consumption mainly “draw from semiotic and literary critical theories to analyze the symbolic meanings, cultural ideals, and ideological inducements encoded in popular culture texts and the rhetorical tactics that are used to make these ideological appeals compelling”. Studies on symbolic consumption mainly focus on the critical arguments about “sign domination” and “sign experimentation.” Derivation of sign meaning draws from “sign domination,” relying on the social structure and “sign experimentation,” focusing on consumers’ agency. The notion of symbolic production and consumption in brand culture is grounded in the assumption that non-linguistic sign systems, including aspects of advertising or traditional rituals, are structured like language by means of codes or conventions, yet may demonstrate both aspects of sign derivation.

Global Brand Culture

Cayla and Arnould (2009) adopt a cultural approach to branding in the global marketplace based on different attempts to develop an informed historical and cultural “analysis of brands” (p. 13). Global myths might be targeted to build international brands. Put simply, global brands arouse a global myth and “the global myth of the independent, self-actualizing, decision-making consumer is simultaneously a participant in and citizen of a modernizing world” (p. 102). Holt (2004) posits that a cultural branding approach can “identify the most valuable type of myth for the brand to perform at a particular historical juncture, and then provide specific direction to creative partners on how to compose the myth” (p. 218).

Moreover, Cayla and Eckhardt (2008) evoke the modernity of Asian branding. They found that Asian brand managers highlight universal practices of globalization that simulate “a generic, hyper-urban, and multicultural experience... infused with diverse cultural referents, and therefore contribute to the creation of an imagined Asia as urban, modern and multicultural” (p. 216). For example, Singapore-based fashion brand 77th Street, and Hong Kong-based fashion brand Giordano resolutely emphasize and demonstrate the modernity and fashionableness of Asian brands and its brand development.

Brand culture goes further than recognizing the roles that culture, in various guises, can play for brands and in branding processes. Rather, brands and branding participate in processes of co-creating culture (Schroeder 2009). This research offers a framework to better understand global and local brands’ development, exploring consumption and management discourses related to historical culture and fashion in the Chinese context. The findings also address the lack of privileged positions for contemporary Chinese brands in competition with more prominent global brands.
